Preface

1. Conventions

A note on the typographical conventions that have been used in this text:

This is the normal font type used for ordinary text.

```
This monospaced font is used to describe program code.

This monospaced font is used to describe screen output,
differentiated from code if required.
```

This See Also:
is a tip used for cross-referencing material either within the documentation, or externally.

This Note:
is a note used for revealing a point of interest or special feature

Special formatting is used to highlight `functions()` and their *`parameters`* above the rest of the text.

Important keywords are *emphasized* using bolding (or strong character typing) and text that is

Important
very important and must be noticed

is displayed in a traditional red warning color

Chapter 1. Overview

Abstract

A quick overview on Virtuoso providing answers to simple questions that may already be in mind.

1.1. What is Virtuoso?

OpenLink Virtuoso is the first CROSS PLATFORM Universal Server to implement Web, File, and Database server functionality alongside Native XML Storage, and Universal Data Access Middleware, as a single server solution. It includes support for key Internet, Web, and Data Access standards such as: XML, XPATH, XSLT, SOAP, WSDL, UDDI, WebDAV, SMTP, SQL-92, ODBC, JDBC, and OLE-DB. Virtuoso currently supports the following Operating systems - Windows 95/98/NT/2000, Linux (Intel, Alpha, Mips, PPC), Solaris, AIX, HP-UX, Unixware, IRIX, Digital UNIX, DYNIX/PTX, FreeBSD, SCO, MacOS X.

Virtuoso is a revolutionary, next generation, high-performance virtual database engine for the Distributed Computing Age. It is a core universal data access technology set to accelerate our advances into the emerging Information Age.

Virtuoso provides transparent access to your existing data sources, which are typically databases from different database vendors.

Through a single connection, Virtuoso will simultaneously connect your ODBC, JDBC, UDBC, OLE-DB client applications and services to data within Oracle, Microsoft SQL Server, DB/2, Informix, Progress, CA-Ingres and other ODBC compliant database engines. All your databases are treated as single logical unit.

The diagram below depicts how applications that are built in conformance with industry standards (such as ODBC, JDBC, UDBC, and OLE-DB) only need to make a single connection via Virtuoso's Virtual Database Engine and end up with concurrent and real-time access to data within different database types.

Further still, Virtuoso exposes all of its functionality to Web Services. This means that your existing infrastructure can be used support Web Services directly without any hint of replacement.

1.2. Why Do I Need Virtuoso?

You need Virtuoso because Knowledge is power or competitive advantage (depending on how you choose to exploit it). All Knowledge comes from Information. Information is produced from Data.

The Internet is reducing the cost of accessing Information, thereby increasing the appetite and rates at which Information is produced and consumed. Unfortunately data required for the production of Information simply does not reside within one database engine within your organization.

Whether you know it or not it is highly probable that the quest for critical information within your organization actually requires traversing several data sources served by numerous database engines from different database vendors.

Virtuoso simply reduces the cost of bringing together data from different data sources with the view to accelerating the production of information by your Query Tools, Web & Internet Application Development Environments, Traditional Application Development Tools, and Desktop Productivity Tools.

Virtuoso enables you to compete effectively in the Information Age.

One of the biggest challenges facing the uptake of XML is the availability of key XML Data itself. Virtuoso simplifies the process of creating XML data from existing HTML, syndicated XML, and SQL databases. Virtuoso enables real-time creation of Dynamic XML documents (DTD or XML Schema based) from homogeneous or heterogeneous SQL Databases "on the fly".

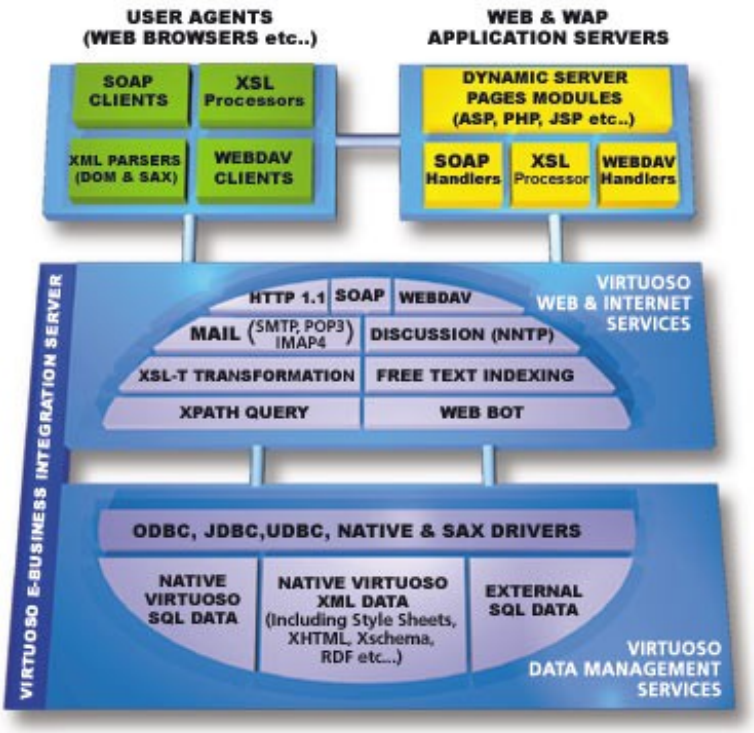
By implementing a number of protocols in a single server solution, Virtuoso provides you with a unifying foundation upon which next generation eBusiness solutions can be developed and deployed. Virtuoso reduces the cost of bringing together data from different data sources and leverages this into increased effectiveness of your Query Tools, Web & Internet Application Development Environments, Traditional Application Development Tools, and Desktop Productivity Tools. Virtuoso enables you compete effectively in the Information Age.

OpenLink Software is an acclaimed technology innovator and leading vendor of High-Performance & CROSS PLATFORM eBusiness solutions that adhere to a broad range of industry standards that include: ODBC, JDBC, OLE DB, SQL, WebDAV, HTTP, XML, SOAP, UDDI, WSDL, SMTP, NNTP, POP3, LDAP amongst others.

Our product & services portfolio includes a suite of High-Performance Universal Data Access Drivers for ODBC, OLE DB and JDBC, Internet Data Integration Servers, Virtual and Federated Database Engines, Embeddable SQL-Database Engines, Application Servers, Enterprise Portal Servers and professional services expertise capable of handling the most demanding eBusiness application development, deployment, and integration challenges.

1.3. Key Features of Virtuoso

Figure 1.1. OpenLink Virtuoso Product Architecture



1.3.1. XML Document Storage & Creation

Virtuoso enables you to develop eBusiness solutions that use *XML* as a common data access foundation layer that provides transparent access to structured and unstructured data. XML Data documents can be created internally, or imported from around the Web and then stored in Virtuoso. You can also create dynamic XML documents by transforming SQL to XML on the fly, leveraging data that resides within homogeneous and/or heterogeneous database(s). *XPATH 2.0* query language support enables you to query entire XML Documents using and industry standard query language. The Virtuoso Server provides some basic support for the *XQuery 1.0* XML Query Language specification. There is *XML Schema* support for extending Virtuoso Data types used by SOAP Services.

1.3.2. Web Page Hosting

Virtuoso has an integrated HTTP web server, for static HTML pages, or dynamic content using Virtuoso Server Pages (*VSP*) . Hosting and execution of *PHP4* scripts is supported via Virtuoso Server Extensions Interface (VSEI) for Zend.

1.3.3. Web Services Creation & Hosting

Enables the creation of *SOAP* compliant Web Services from SQL Stored Procedures, these procedures may be native to Virtuoso or resident in third party databases that support ODBC or JDBC. Virtuoso automatically generates *WSDL* files for the Stored Procedures that it exposes as Web Services. As a *UDDI* server (registry) all of your Web Services can be stored for access across the internet or within an intranet. It can also synchronize data with other UDDI servers.

1.3.4. WebDAV Compliant Web Store

WebDAV support enables Virtuoso to act as the Web Content Store for all of your eBusiness data, this includes Text, Graphics and Multimedia files. WebDAV support also enables Virtuoso to play the familiar roles of a FILE & WEB SERVER, hosting entire Web sites within a single database file, or across multiple database files.

1.3.5. Content Replication & Synchronization

Virtuoso's sophisticated data replication and synchronization engine enables the automated distribution and updating of SQL and Web Content across distributed Virtuoso servers.

1.3.6. Transparent Access To Heterogeneous Data

Virtuoso's Virtual Database Engine enables you to produce Dynamic Web Content from any major database management system. This enables dynamic, real-time HTML and XML generation from any number of different database engines concurrently.

1.3.7. Mail Delivery & Retrieval Services

Virtuoso can act as an *SMTP* , *POP3* , and *IMAP4* proxy to any email client. This enables the development and deployment of sophisticated database driven email solutions.

1.3.8. NNTP Aggregation & Serving

Virtuoso supports the Network News Transfer Protocol used by Internet newsgroup forums. *NNTP* servers manage the global network of collected newsgroup postings and represent a vast repository of targeted information archives. As an NNTP aggregator, Virtuoso enables integration of multiple news forums around the world. All news content in Virtuoso is dynamically indexed to provide keyword searches, enabling rapid transformation of disparate text data into information. Virtuoso also acts as an NNTP server, enabling creation of new Internet and Intranet News Forums to leverage the global knowledgebase into eBusiness Intelligence.

1.4. Virtuoso FAQ

We have received various inquiries on high-end metadata stores. We will here go through some salient questions. The requested features include:

- Scaling to trillions of triples
- Running on clusters of commodity servers
- Running in federated environments, possibly over wide-area networks
- Built-in inference
- Transactions
- Security
- Support for extra triple level metadata, such as security attributes

Questions:

1.4.1. What is the storage cost per triple?

This depends on the index scheme. If indexed 2 ways, assuming that the graph will always be stated in queries, this is 31 bytes.

With 4 indices, supporting queries where the graph can be left unspecified (i.e., triples from any graph will be considered in query evaluation), this is 39 bytes. The numbers are measured with the LUBM validation data set of 121K triples, with no full-text index on literals.

With 4 indices and a full text index on all literals, the Billion Triples Challenge data set, 1115M triples, is about 120 GB of database pages. The database file size is larger due to space in reserve and other factors. 120 GB is the number to use when assessing RAM-to-disk ratio, i.e., how much RAM the system ought to have in order to provide good response. This data set is a heterogeneous collection including social network data, conversations harvested from the Web, DBpedia, Freebase, etc., with relatively numerous and long text literals.

The numbers do not involve any database page stream compression such as gzip. Using such compression does not save in terms of RAM because cached pages must be kept uncompressed but will cut the disk usage to about half.

1.4.2. What is the cost to insert a triple (for the insertion itself, as well as for updating any indices)?

The more triples are inserted at a time, the faster this goes. Also, the more concurrent triple insertions are going on, the better the throughput. When loading data such as the US Census, a cluster of 2 commodity servers can insert up to 100,000 triples per second.

A single 4-core machine can load 1 billion triples of LUBM data at an average rate of 36K triples per second. This is limited by disk.

1.4.3. What is the cost to delete a triple (for the deletion itself, as well as for updating any indices)?

The delete cost is similar to insert cost.

1.4.4. What is the cost to search on a given property?

If we are looking for equality matches, a single 2GHz core can do about 250,000 single triple random lookups per second as long as disk reads are not involved. If each triple requires a disk seek the number is naturally lower.

Parallelism depends on the query. With a query like counting all x and y such that x knows y and y knows x, we get up to 3.4 million single-triple lookups-per-second on a cluster of 2 8-core Xeon servers. With complex nested sub-queries the parallelism may be less.

Lookups involving ranges of values, such as ranges of geographical coordinates or dates use an index, since quads are indexed in a manner that collates in the natural order of the data type.

1.4.5. What data types are supported?

Virtuoso supports all RDF data types, including language-tagged and XML schema typed strings as native data types. Thus there is no overhead converting between RDF data types and types supported by the underlying DBMS.

1.4.6. What inferencing is supported?

Subclass, subproperty, identity by inverse-functional properties, and owl:sameAs are processed at run time if an inference context option is specified in the query.

There is a general-purpose transitivity feature that can be used for a wide variety of graph algorithms. For example:

```
SELECT ?friend
WHERE
  {
    <alice> foaf:knows ?friend option (transitive)
```

```
}
```

would return all the people directly or indirectly known by <alice>.

1.4.7. Is the inferencing dynamic, or is an extra step required before inferencing can be used?

The mentioned types of inferencing are enabled by a switch in the query and are done at run-time, with no step for materialization of entailed triples needed. The pattern:

```
{?s a <type>}
```

would iterate over all the RDFS subclasses of <type> and look for subjects with this type.

The pattern:

```
{<thing> a ?class}
```

will, if the match of ?class has superclasses, also return the superclasses even though the superclass membership is not physically stored for each superclass.

Of course, one can always materialize entailed triples by running SPARQL/SPARUL statements to explicitly add any implied information.

If two subjects have the same inverse functional property with the same value, they will be considered the same. For example, if two people have the same email address, they will be considered the same.

If two subjects are declared to be owl:sameAs, either directly or through a chain of x owl:sameAs y, y owl:sameAs z, and so on, they will be considered the same.

These features can be individually enabled and disabled. They all have some run time cost, hence they are optional. The advantage is that no preprocessing of the data itself is needed before querying, and the data does not get bigger. This is important, especially if the database is very large and queries touch only small parts of it. In such cases, materializing implied triples can be very costly. See discussion at E Pluribus Unum

1.4.8. Do you support full-text search?

Virtuoso has an optional full-text index on RDF literals. Searching for text matches using the SPARQL regex feature is very inefficient in the best of cases. This is why Virtuoso offers a special *bif:contains* predicate similar to the SQL *contains* predicate of many relational databases. This supports a full-text query language with proximity, and/or/and-not, wildcards, etc.

While the full-text index is a general-purpose SQL feature in Virtuoso, there is extra RDF-specific intelligence built into it. One can, for example, specify which properties are indexed, and within which graphs this applies.

1.4.9. What programming interfaces are supported? Do you support standard SPARQL protocol?

Virtuoso supports the standard SPARQL protocol.

Virtuoso offers drivers for the Jena, Sesame, and Redland frameworks. These allow using Virtuoso's store and SPARQL implementation as the back end of Jena, Sesame, or Redland applications. Virtuoso will then do the query optimization and execution. Jena and Sesame drivers come standard; contact us about Redland.

Virtuoso SPARQL can be used through any SQL call level interface (CLI) supported by Virtuoso (i.e., ODBC, JDBC, OLE-DB, ADO.NET, XMLA). All have suitable extensions for RDF specific data types such as IRIs and typed literals. In this way, one can write, for example, PHP web pages with SPARQL queries embedded, just using the SQL tools. Prefixing a SQL query with the keyword "sparql" will invoke SPARQL instead of SQL, through any SQL client API.

1.4.10. How can data be partitioned across multiple servers?

Virtuoso Cluster partitions each index of all tables containing RDF data separately. The partitioning is by hash. The result is that the data is evenly distributed over the selected number of servers. Immediately consecutive triples are generally in the same partition, since the low bits of IDs do not enter in into the partition hash. This means that key compression works well.

Since RDF tables are in the end just SQL tables, SQL can be used for specifying a non-standard partitioning scheme. For example, one could dedicate one set of servers for one index, and another set for another index. Special cases might justify doing this.

With very large deployments, using a degree of application-specific data structures may be advisable. See "Does Virtuoso support property tables".

1.4.11. How many triples can a single server handle?

With free-form data and text indexing enabled, 500M triples per 16G RAM can be a ballpark guideline. If the triples are very short and repetitive, like the LUBM test data, then 16G per one billion triples is a possibility. Much depends on the expected query load. If queries are simple lookups, then less memory per billion triples is needed. If queries will be complex (analytics, join sequences, and aggregations all over the data set), then relatively more RAM is necessary for good performance.

The count of quads has little impact on performance as long as the working set fits in memory. If the working set is in memory, there may be 15-20% difference between a million and a billion triples. If the database must frequently go to disk, this degrades performance since one can easily do 2000 random accesses in memory in the time it takes to do one random access from disk. But working-set characteristics depend entirely on the application.

Whether the quads in a store all belong to one graph or any number of graphs makes no difference. There are Virtuoso instances in regular online use with hundreds of millions of triples, such as DBpedia and the Neurocommons databases.

1.4.12. What is the performance impact of going from the billion to the trillion triples?

Performance dynamics change when going from a single server to a cluster. If each partition is around a billion triples in size, then the single triple lookup takes the same time, but there is cluster interconnect latency added to the mix.

On the other hand, queries that touch multiple partitions or multiple triples in a partition will do this in parallel and usually with a single message per partition. Thus throughput is higher.

In general terms, operations on a single triple at a time from a single thread are penalized and operations on hundreds or more triples at a time win. Multiuser throughput is generally better due to more cores and more memory, and latency is absorbed by having large numbers of concurrent requests.

See a sample of SPARQL scalability .

1.4.13. Do you support additional metadata for triples, such as time-stamps, security tags etc?

Since quads (triple plus graph) are stored in a regular SQL table with special data types, changing the table layout to add a column is possible. This column would not however be visible to SPARQL without some extra tuning. For coarse grain provenance and security information, we recommend doing this at the graph level, where triples that belong together are tagged with the same provenance or security are in the same graph. The graph can then have the relevant metadata as its properties.

If tagging at the single triple level is needed, this will most often not be needed for all triples. Hence altering the table for all triples may not be the best choice. Making a special table that has the graph, subject, predicate and object of the tagged triple as a key and the tag data as a dependent part may be more efficient. Also, this table could be more easily accessed from SPARQL.

Using the RDF reification vocabulary is not recommended as a first choice but is possible without any alterations.

Alterations of this nature are possible but we recommend contacting us for specifics. We can provide consultancy on the best way to do this for each application. Altering the storage layout without some extra support from us is not recommended.

1.4.14. Should we use RDF for our large metadata store? What are the alternatives?

If the application has high heterogeneity of schema and frequent need for adaptation, then RDF is recommended. The alternative is making a relational database.

Making a custom non-RDF object-attribute-value representation on Virtuoso or some other RDBMS is possible but not recommended.

The reason for this is that this would miss many of the optimizations made specifically for RDF, use of the SPARQL language, inference, compatibility with diverse browsers and front end tools, etc. Not to mention interoperability and joinability with the body of linked data. Even if the application is strictly private, using entity names and ontologies from the open world can still have advantages.

If some customization to the quad (triple plus graph layout) is needed, we can provide consultancy on how to do this while staying within the general RDF framework and retaining all the interoperability benefits.

1.4.15. How multithreaded is Virtuoso?

All server and client components are multithreaded, using pthreads on Unix/Linux, Windows native on Windows. Multithread/multicore scalability is good; see BSBM

In the case of Virtuoso Cluster, in order to have the maximum number of threads on a single query, we recommend that each server on the cluster be running one Virtuoso process per 1.2 cores.

1.4.16. Can multiple servers run off a single shared disk database?

This might be possible with some customization but this is not our preferred way. Instead, we can store selected indices in duplicate or more copies inside a clustered database. In this way, all servers can have their own disk. Each key of each index will belong to one partition but each partition will have more than one physical copy, each on a different server. The cluster query logic will perform the load balancing. On the update side, the cluster will automatically do a distributed transaction with two phase commit to keep the duplicates in sync.

1.4.17. Can Virtuoso run on a SAN?

Yes. Unlike Oracle RAC, for example, Virtuoso Cluster does not require a SAN. Each server has its own database files and is solely responsible for these. In this way, having shared disk among all servers is not required. Running on a SAN may still be desirable for administration reasons. If using a SAN, the connection to the SAN should be high performance, such as Infiniband.

1.4.18. How does Virtuoso join across partitions?

Partitioning is entirely transparent to the application. Virtuoso has a highly optimized message-flow between cluster nodes that combines operations into large batches and evaluates conditions close to the data. See a sample of RDF scaling.

1.4.19. Does Virtuoso support federated triple stores? If there are multiple SPARQL end points, can Virtuoso be used to do queries joining between these?

This is a planned extension. The logic for optimizing message flow between multiple end-points on a wide-area network is similar to the logic for message-optimization on a cluster. This will allow submitting a query with a list of end-points. The query will then consider triples from each of the end points, as if the content of all the end points were in a single store.

End-point meta information, such as voiD descriptions of the graphs in the end-points, may be used to avoid sending queries to end points that are known not to have a certain type of data.

1.4.20. How many servers can a cluster contain?

There is no fixed limit. If you have a large cluster installed, you can try Virtuoso there. Having an even point-to-point latency is desirable.

1.4.21. How do I reconfigure a cluster, adding and removing machines, etc?

We are working on a system whereby servers can be added and removed from a cluster during operation and no repartitioning of the data is needed.

In the first release, the number of server processes that make up the cluster is set when creating the database. These processes with their database files can then be moved between machines but this requires stopping the cluster and updating configuration files.

1.4.22. How will Virtuoso handle regional clusters?

Performance of a cluster depends on the latency and bandwidth of the interconnect. At least dual 1Gbit ethernet is recommended for each node. Thus a cluster should be on a single local or system area network.

If regional copies are needed, we would replicate between clusters by asynchronous log shipping. This requires some custom engineering.

When a transaction is committed at one site, it is logged and sent to the subscribing sites if they are online. If there is no connection, the subscribing sites will get the data from the log. This scheme now works between single Virtuoso servers, and needs some custom development to be adapted to clusters.

If replicating all the data of one site to another site is not possible, then application logic should be involved. Also, if consolidated queries should be made against large, geographically-separated clusters, then it is best to query them separately and merge the results in the application. All depends on the application level rules on where data resides.

1.4.23. Is there a mechanism for terminating long running queries?

Virtuoso SPARQL and SQL offer an "anytime" option that will return partial results after a configurable timeout.

In this way, queries will return in a predictable time and indicate whether the results are complete or not, as well as give a summary of resource utilization.

This is especially useful for publishing a SPARQL endpoint where a single long running query could impact the performance of the whole system. This timeout significantly reduces the risk of denial of service.

This is also more user-friendly than simply timing-out a query after a set period and returning an error. With the anytime option, the user gets a feel for what data may exist, including whether any data exists at all. This feature works with arbitrarily complex queries, including aggregation, GROUP BY, ORDER BY, transitivity, etc.

Since the Virtuoso SPARQL endpoint supports open authentication (OAuth), the authentication can be used for setting timeouts, so as to give different service to different users.

It is also possible to set a timeout that will simply abort a query or an update transaction if it fails to terminate in a set time.

Disconnecting the client from the server will also terminate any processing on behalf of that client, regardless of timeout settings.

The SQL client call-level interfaces (ODBC, JDBC, OLE-DB, ADO.NET, XMLA) each support a cancel call that can terminate a long running query from the application, without needing to disconnect.

1.4.24. Can the user be asynchronously notified when a long running query terminates?

There is no off-the-shelf API for this but making an adaptation of the SPARQL endpoint that could proceed after the client disconnected and, for example, could send results by email is trivial. Since SOAP and REST Web services can be programmed directly in Virtuoso's stored procedure language, implementing and exposing this type of application logic is easy.

1.4.25. How many concurrent queries can Virtuoso handle?

There is no set limit. As with any DBMS, response times get longer if there is severe congestion.

For example, having 2 or 3 concurrent queries per core is a good performance point which will keep all parts of the system busy. Having more than this is possible but will not increase overall throughput.

With a cluster, each server has both HTTP and SQL listeners, so clients can be evenly spread across all nodes. In a heavy traffic Web application, it is best to have a load balancer in front of the HTTP endpoints to divide the connections among the servers and to keep some cap on the number of concurrently running requests, enforcing a maximum request-rate per client IP address, etc.

1.4.26. What is the relative performance of SPARQL queries vs native relational queries?

This is application dependent. In Virtuoso, SPARQL and SQL share the same query execution engine, query optimizer, and cost model. If data is highly regular (i.e., a good fit for relational representation), and if queries typically access most of the row, then SQL will be more efficient. If queries are unpredictable, data is ragged, schema changes frequent, or inference is needed, then RDF will do relatively better.

The recent Berlin SPARQL Benchmark shows some figures comparing Virtuoso SQL and SPARQL and SPARQL in front of relational representation. However, the test workload is heavily biased in favor of relational. See also BSBM: MySQL vs Virtuoso.

With the TPC-H workload, relationally stored data, and SPARQL mapped to SQL, we find that with about half the queries there is no significant cost to SPARQL. With some queries there is additional overhead because the mapping does not produce a SQL query identical to that specified in the benchmark.

1.4.27. Does Virtuoso Support Property Tables?

For large applications, we would recommend RDF whenever there is significant variability of schema, but would still use an application-specific, relational style representation for those parts of the data that are regular in format. This is possible without loss of flexibility for the variable-schema part. However, this will introduce relational-style restrictions on the regular data; for example, a person could only have a single date-of-birth by design. In many cases, such restrictions are quite acceptable. Querying will still take place in SPARQL, and the representation will be transparent.

A relational table where the primary key is the RDF subject and where columns represent single-valued properties is usually called a property table. These can be defined in a manner similar to defining RDF mappings of relational tables.

1.4.28. What performance metrics does Virtuoso offer?

There is an extensive array of performance metrics. This includes:

- Cluster status summary with thread counts, CPU utilization, interconnect traffic, clean and dirty cache pages, virtual memory swapping warning, etc. This is either a cluster total or a total with breakdown per cluster node.
- Disk access, lock contention, general concurrency, and access count per index
- Statistics on memory usage for disk caching index-by-index, cache replacement statistics, disk random and sequential read times
- Count of random, sequential index access, disk access, lock contention, cluster interconnect traffic per query/client
- Detailed query-execution plans are available through the `explain` function

1.4.29. What support do you provide for concurrent/multithreaded operation? Is your interface thread-safe?

All client interfaces and server-side processes are multithreaded. As usual, each thread of an application should use a different connection to the database.

1.4.30. What level of ACID properties is supported?

Virtuoso supports all 4 isolation levels from dirty read to serializable, for both relational and RDF data.

The recommended default isolation is read-committed, which offers a clean historical read of data that has uncommitted updates. This mode is similar to the Oracle default isolation and guarantees that no uncommitted data is seen, and that no read will block waiting for a lock held by another client.

There is transaction logging and roll forward recovery, with two phase commit used in Virtuoso Cluster if an update transaction modifies more than one server.

For RDF workloads which typically are not transactional and have large bulk loads, we recommend running in a "row autocommit" mode without transaction logging. This virtually eliminates log contention but still guarantees consistent results of multithreaded bulk loads.

Setting this up requires some consultancy and custom development but is well worthwhile for large projects.

1.4.31. Do you provide the ability to atomically add a set of triples, where either all are added or none are added?

Yes. Doing this with millions of triples per transaction may run out of rollback space. Also, there is risk of deadlock if multiple such inserts run at the same time. For good concurrency, the inserts should be of moderate size. As usual, deadlocks are resolved by aborting one of the conflicting transactions.

1.4.32. Do you provide the ability to add a set of triples, respecting the isolation property (so concurrent accessors either see none of the triple values, or all of them)?

Yes. The reading client should specify serializable isolation and the inserting client should perform the insert as a transaction, no row autocommit mode.

1.4.33. What is the time to start a database, create/open a graph?

Starting a Virtuoso server process takes a few seconds. Making a new graph takes no time beyond the time to insert the triples into it. Once the server process(es) are running, all the data is online.

With high-traffic applications, reaching cruising speed may sometimes take a long time, specially if the load is random-access intensive. Filling gigabytes of RAM with cached disk pages takes a long time if done a page at a time. To alleviate this, Virtuoso pre-reads 2MB-sized extents instead of single pages if there is repeated access to the same extent within a short time. Thus cache warm-up times are shortened.

1.4.34. What sort of security features are built into Virtuoso?

For SQL, we have the standard role-based security and an Oracle-style row-level security (policy) feature.

For SPARQL, users may have read or update roles at the level of the quad store.

With RDF, a graph may be owned by a user. The user may specify read and write privileges on the graph. These are then enforced for SPARUL (the SPARQL update language) and SPARQL.

When an RDF graph is based on relationally stored data in Virtuoso or another RDBMS through Virtuoso's SQL federation feature (i.e., if the graph is an Linked Data View of underlying SQL data), then all relational security controls apply.

Further, due to the dual-nature of Virtuoso, sophisticated ontology-based security models are feasible. Such models are not currently used by default, but they are achievable with our consultancy.

1.5. Tips and Tricks

1.5.1. How Can I convert triples with geo properties to geometries to use spartial query?

Assuming a Named Graph with the following triples:

```
...
<http://linkedgeodata.org/triplify/node454640663> <http://www.w3.org/1999/02/22-rdf-syntax-ns#type> <http

```

```
...
```

In order to convert these triples (with geo properties) to geometries to use spartial query, you need to run the `DB.DBA.RDF_GEO_FILL ()` function to populate the special RDF_GEO table with the point information as detailed at Creating Geometries From RDF Data documentation section.

Then the geo-spatail information will be available and can be queried.

Note: RDF_GEO and associated indexes are created when the database is first created and thus just needs to be populated with the geometry data in the RDF triples, which is what the `DB.DBA.RDF_GEO_FILL ()` function does.

1.5.2. How Can I execute SPARQL queries containing '$' character using ISQL?

Assuming a SPARQL query should filter on the length of labels:

```
SELECT ?label
FROM <http://mygraph.com>
WHERE
  {
    ?s ?p ?label
    FILTER(regex(str(?label), "^.{1,256}$") )
  }
```

ISQL uses '*$* ' character as a prefix for macro names of its preprocessor. When '*$* ' character is used in SPARQL query to be executed in ISQL, the character should be replaced with '*$$* ' notation or an escape char + numeric code:

```
SQL> SPARQL
SELECT ?label
FROM <http://mygraph.com>
WHERE
  {
    ?s ?p ?label
    FILTER(REGEX(str(?label), "^.{1,256}$$") )
  }
```

Note also that the FILTER written in this way, finds *?label-s* with length less than 256.

To achieve fast results, *REGEX* should be replaced with the *bif:length* function:

```
SQL> SPARQL
SELECT ?label
FROM <http://mygraph.com>
WHERE
  {
```

```
    ?s ?p ?label
    FILTER (bif:length(str(?label))<= 256)
  }
```

In this way the SPARQL query execution can work much faster if the interoperability is not required and *?label-s* are numerous.

1.5.3. How can I find on which table deadlocks occur?

One possible way to find on which table deadlocks occur is to execute the following statement:

```
SELECT TOP 10 *
FROM SYS_L_STAT
ORDER BY deadlocks DESC
```

1.5.4. How Can I configure parameters to avoid out of memory error?

In order to avoid out of memory error, you should make sure the values for the paramaters *NumberOfBuffers* and *MaxCheckpointRemap* are not set with the same values.

For example, the following configuration will cause an error out of memory:

```
# virtuoso.ini

...
[Parameters]
NumberOfBuffers = 246837
MaxDirtyBuffers = 18517
MaxCheckpointRemap = 246837
...
```

Changing the value of the parameter *MaxCheckpointRemap* with let's say 1/4 of the DB size will resolve the issue.

1.5.5. What are "Generate RDB2RDF triggers" and "Enable Data Syncs with Physical Quad Store" Linked Data Views options?

These Linked Data Views options basically persist the triples in the transient View Graph in the Native Quad Store. The Data Sync is how you keep the transient views in sync with the persisted triples.

Without this capability you cannot exploit faceted browsing without severe performance overhead when using Linked Data based conceptual views over ODBC or JDBC accessible data sources.

Note: Using these options when the RFViews have already been created is not currently possible via the Conductor UI. Instead you should be able to add them manually from isql:

1. Drop the Linked Data View graph and Quad Map.
2. Create it again with the RDB2RDF Triggers options enabled.

See Also:
RDB2RDF Triggers

1.5.6. How to Manage Date Range SPARQL queries?

The following examples demonstrate how to manage date range in a SPARQL query:

Example with date range

```
SELECT ?s ?date
FROM <http://dbpedia.org>
WHERE
  {
    ?s ?p ?date . FILTER ( ?date >= "19450101"^^xsd:date && ?date <= "19451231"^^xsd:date )
  }
LIMIT 100
```

Example with bif:contains

Suppose there is the following query using bif:contains for date:

If ?date is of type xsd:date or xsd:dateTime and of valid syntax then bif:contains(?date, '"1945*"') will not found it, because it will be parsed at load/create and stored as SQL DATE value.

So if data are all accurate and typed properly then the filter is:

```
(?date >= xsd:date("1945-01-01") && ?date < xsd:date("1946-01-01"))
```

i.e. the query should be:

```
SELECT DISTINCT ?s ?date
FROM <http://dbpedia.org>
WHERE
  {
    ?s ?p ?date . FILTER( ?date >= xsd:date("1945-01-01") && ?date < xsd:date("1946-01-01")  && (str(?p)
  }
LIMIT 10
```

If data falls, then the free-text will be OK for tiny examples but not for "big" cases because *bif:contains(?date, '"1945*"')* would require that less than 200 words in the table begins with 1945. Still, some data can be of accurate type and syntax so range comparison should be used for them and results aggregated via UNION.

If dates mention timezones then the application can chose the beginning and the end of the year in some timezones other than the default.

1.5.7. How can I see which quad storages exist and in which quad storage a graph resides?

Let's take for example a created Linked Data View from relational data in Virtuoso . The RDF output therefor should have two graphs which reside in a quad storage named for ex.:

```
http://example.com/rdfv_demo/quad_storage/default
```

Also the RDF is accessible over the SPARQL endpoint with the following query:

```
define input:storage <http://example.com/rdfv_demo/quad_storage/default>
SELECT *
WHERE
  {
    ?s ?p ?o
  }
```

Now one could ask is there a way to define internally (once) that the quad storage should be included in queries to the SPARQL endpoint? So that the user does not have to define the *input:storage* explicitly in each query, like this:

```
http://example.com/sparql?query=select * where { ?s ?p ?o }&default-graph-uri=NULL&named-graph-uri=NULL
```

All metadata about all RDF storages are kept in "system" graph <http://www.openlinksw.com/schemas/virtrdf#> (namespace prefix *virtrdf:*). Subjects of type *virtrdf:QuadStorage* are RDF storages. There are three of them by default:

```
SQL> SPARQL SELECT * FROM virtrdf: WHERE { ?s a virtrdf:QuadStorage };
s
VARCHAR
_______________________________________________________________________________

http://www.openlinksw.com/schemas/virtrdf#DefaultQuadStorage
http://www.openlinksw.com/schemas/virtrdf#DefaultServiceStorage
http://www.openlinksw.com/schemas/virtrdf#SyncToQuads

3 Rows. -- 3 msec.
```

- *virtrdf:DefaultQuadStorage*

is what's in use if no input:storage specified.
- *virtrdf:DefaultServiceStorage*

  will be used for SPARQL federation.
- *virtrdf:SyncToQuads*

  is to keep the list of Linked Data Views that are translated into RDB2RDF triggers.

There are two ways of using the Linked Data View from above in SPARQL endpoint without *define input:storage* :

1. Create Linked Data View right in

   virtrdf:DefaultQuadStorage

   or add the view in other storage and then copy it from there to

   virtrdf:DefaultQuadStorage

   .

   - In any of these two variants, use:

     ```
     SPARQL ALTER QUAD STORAGE virtrdf:DefaultQuadStorage . . .
     ```
2. Use

   SYS_SPARQL_HOST

   table as described here and set

   SH_DEFINES

   so it contains your favorite

   define input:storage

   .

1.5.8. Can I drop and re-create the DefaultQuadStorage?

Currently system metadata consist of three "levels":

1. *QuadMapFormats*

   are used to describe transformations of individual SQL values (or types of SQL values),
2. *QuadMaps*

   refers to

   QuadMapFormats

   (via

   QuadMapValues

) and describe some "minimal" independent RDB2RDF transformations,
3. *QuadStorages*

   organizes

   QuadMaps

.

QuadStorages contains only "symlinks" to maps, if you drop a storage you don't drop all mappings inside. If you drop the *DefaultQuadStorage* or some other built-in thing, it can be safely recovered by `DB.DBA.RDF_AUDIT_METADATA` , with first parameter set to 1. This will keep your own data intact. However we recommend to write a script that declares all your formats, Linked Data Views and storages, to be able to reproduce the configuration after any failures.

1.5.9. How to display only some information from RDF graph?

Virtuoso supports graph-level security, as described here but not subject-level or predicate-level. When exposing data that needs protected access, triples should be confined to private name graphs which are protected by ACLs using WebID.

Note, how you can use WebID to protect Virtuoso SPARQL endpoints .

See Also:
RDF Graphs Security

1.5.10. Is it possible to have the SPARQL endpoint on a different port than the Conductor?

Virtuoso Web Server has the capability to create extra listeners using the Conductor interface .

1. At install time you have your HTTP Server port in your virtuoso.ini set to 8890, which you want to keep in your local network as this contains ALL the endpoints that you have registered in Virtuoso. So as long as you do not open this port in your firewall, you can only get at it from the local machine.
2. Next you should create a new vhost entry using the EXTERNAL name of your machine and use port 80 (or a higher port if you do not want to run as root) for ex.:

```
Interface: 0.0.0.0
Port: 8080
Http Host:  my.example.com
```

3. Next you add a "New directory to this line", click on "Type" radio button and choose "Sparql access point" from the drop-down list and press Next button. Set "Path" to /sparql and press the "Save Changes" button to store.
4. At this point you have created: http://my.example.com:8080/sparql which functions exactly the same as your internal http://example.com/sparql. You can now open your firewall and allow outside machines to connect to port 8080 so people can use your SPARQL endpoint without access to any other endpoint on your Virtuoso installation.
5. You should probably also change your virtuoso.ini so:

```
[URIQA]
DefaultHost = my.example.com:8080
```

6. If you use port 80, you do not have to add :80 at the end of this setting, although it should not make any difference.
7. You can now add other directories / endpoints to the new

   my.example.com

   interface you just created e.g. a nice / directory that points to a index.html which describes your site etc.

Internet Domains

1.5.11. How to enable the Virtuoso Entity Framework 3.5 ADO.Net Provider in Visual Studio 2010?

The Virtuoso Entity Framework 3.5 ADO.Net Provider is current only list as a Visible control in the Visual Studio 2008 IDE as the current installers only create the necessary registry entries for Visual Studio 2008. To make it visible in the Visual Studio 2010's IDE the following registry settings need to be manually updated and manual addtions to some of the VS 2010 XML configuration files:

1. Export following registry keys to .reg files and using a text editor, such as Wordpad, edit the Visual Studio version numbers from 8.0 or 9.0 to 10.0:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\VisualStudio\8.0\DataProviders\{EE00F82B-C5A4-4073-8FF1-33F8
- and -
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\VisualStudio\8.0\DataSources\{90FBCAF2-8F42-47CD-BF1A-88FF41
```

2. Once edited, save and double click them to create the new registry entries under:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\VisualStudio\10.0....
```

3. In addition, locate the file C:\WINDOWS\Microsoft.NET\Framework\v2.0.50727\CONFIG\machine.config, locate the node, then locate the

   <add name="VirtuosoClient3? Data Provider" ...

   node within it:

```
<add name="VirtuosoClient3 Data Provider" invariant="OpenLink.Data.Virtuoso"
    description=".NET Framework Data Provider for Virtuoso" type="OpenLink.Data.Virtuoso.VirtuosoC
```

and copy is to the equivalent C:\WINDOWS\Microsoft.NET\Frameworks\v4.0.30128\CONFIG\machine.config location.

Visual Studio 2010 will then have the necessary information to locate and load the Virtuoso ADO.Net provider in its IDE.

The registry should typically contain the following entries for Visual Studio 2010 as a result:

```
Windows Registry Editor Version 5.00

[HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\Microsoft\VisualStudio\10.0\DataProviders\{0886A2BB-03D0-4E00-8A

```

The next Virtuoso releases, 6.3+ will support this new Visual Studio 2010 release out of the box.

1.5.12. How Can I Control the normalization of UNICODE3 accented chars in free-text index?

The normalization of UNICODE3 accented chars in free-text index can be controlled by setting up the configuration parameter *XAnyNormalization* in the virtuoso.ini config file, section [I18N]. This parameter controls whether accented UNICODE characters should be converted to their non-accented base variants at the very beginning of free-text indexing or parsing a free-text query string. The parameter's value is an integer that is bitmask with only 2 bits in use atm:

1. 0: the default behavior, do not normalize anything, so "Jose" and "José" are two distinct words.
2. 2: Any combined char is converted to its (smallest known) base. So "é" will lose its accent and become plain old ASCII "e".
3. 3: This is equl to 1|2 and when set then performs both conversions. As a result, pair of base char and combinig char loses its second char and chars with accents will lose accents.

If the parameter is required at all, the needed value is probably 3. So the fragment of virtuoso.ini is:

```
[I18N]
XAnyNormalization=3
```

In some seldom case the value of 1 can be appropriate. The parameter should be set once before creating the database. If changed on the existing database, all free-text indexes that may contain non-ASCII data should be re-created. On a typical system, the parameter affects all text columns, XML columns, RDF literals and queries.

Strictly speaking, it affects not all of them but only items that use default "x-any" language or language derived from x-any such as "en" and "en-US" but if you haven't tried writing new C plugins for custom languages you should not look so deep.

As an example, with *XAnyNormalization=3* once can get the following:

```
SQL>SPARQL

INSERT IN <http://InternationalNSMs/>
   { <s> <sp> "Índio João Macapá Júnior Tôrres Luís Araújo José" ;
     <ru> "&#1054;&#1085; &#1076;&#1086;&#1073;&#1072;&#1074;&#1080;&#1083; &#1082;&#1072;&#1088;&#1090;&

INSERT INTO <http://InternationalNSMs/>, 2 (or less) triples -- done

SQL> DB.DBA.RDF_OBJ_FT_RULE_ADD (null, null, 'InternationalNSMs.wb');

Done. -- 0 msec.

SQL>vt_inc_index_db_dba_rdf_obj();

s  sp  Índio João Macapá Júnior Tôrres Luís Araújo José

1 Rows. -- 1 msec.

SQL> SPARQL
SELECT *
FROM <http://InternationalNSMs/>
WHERE
  {
    ?s ?p ?o . ?o bif:contains "'&#1087;&#1086;&#1089;&#1090;&#1072;&#1074;&#1080;&#1083; &#1072;&#1082;&

s  ru  &#1054;&#1085; &#1076;&#1086;&#1073;&#1072;&#1074;&#1080;&#1083; &#1082;&#1072;&#1088;&#1090;&#108
```

There was also request for function that normalizes characters in strings as free-text engine will do with XAnyNormalization=3 , the function will be provided as a separate patch and depends on this specific patch.

Virtuoso Configuration File

1.5.13. How Can I define graph with virt:rdf_sponger option set to "on"?

Suppose we have the following scenario:

1. Create Virtuoso user using Conductor for ex. with name "john" and pwd 1.
2. Create for the user a RDF Sink folder for ex. with name "MySinkFolder" from type "RDF Upload Folder" or use the

   rdf_sink

   folder created automatically for your user.
3. In the properties page of the RDF sink folder add in the WebDAV section this property

   virt:rdf_graph

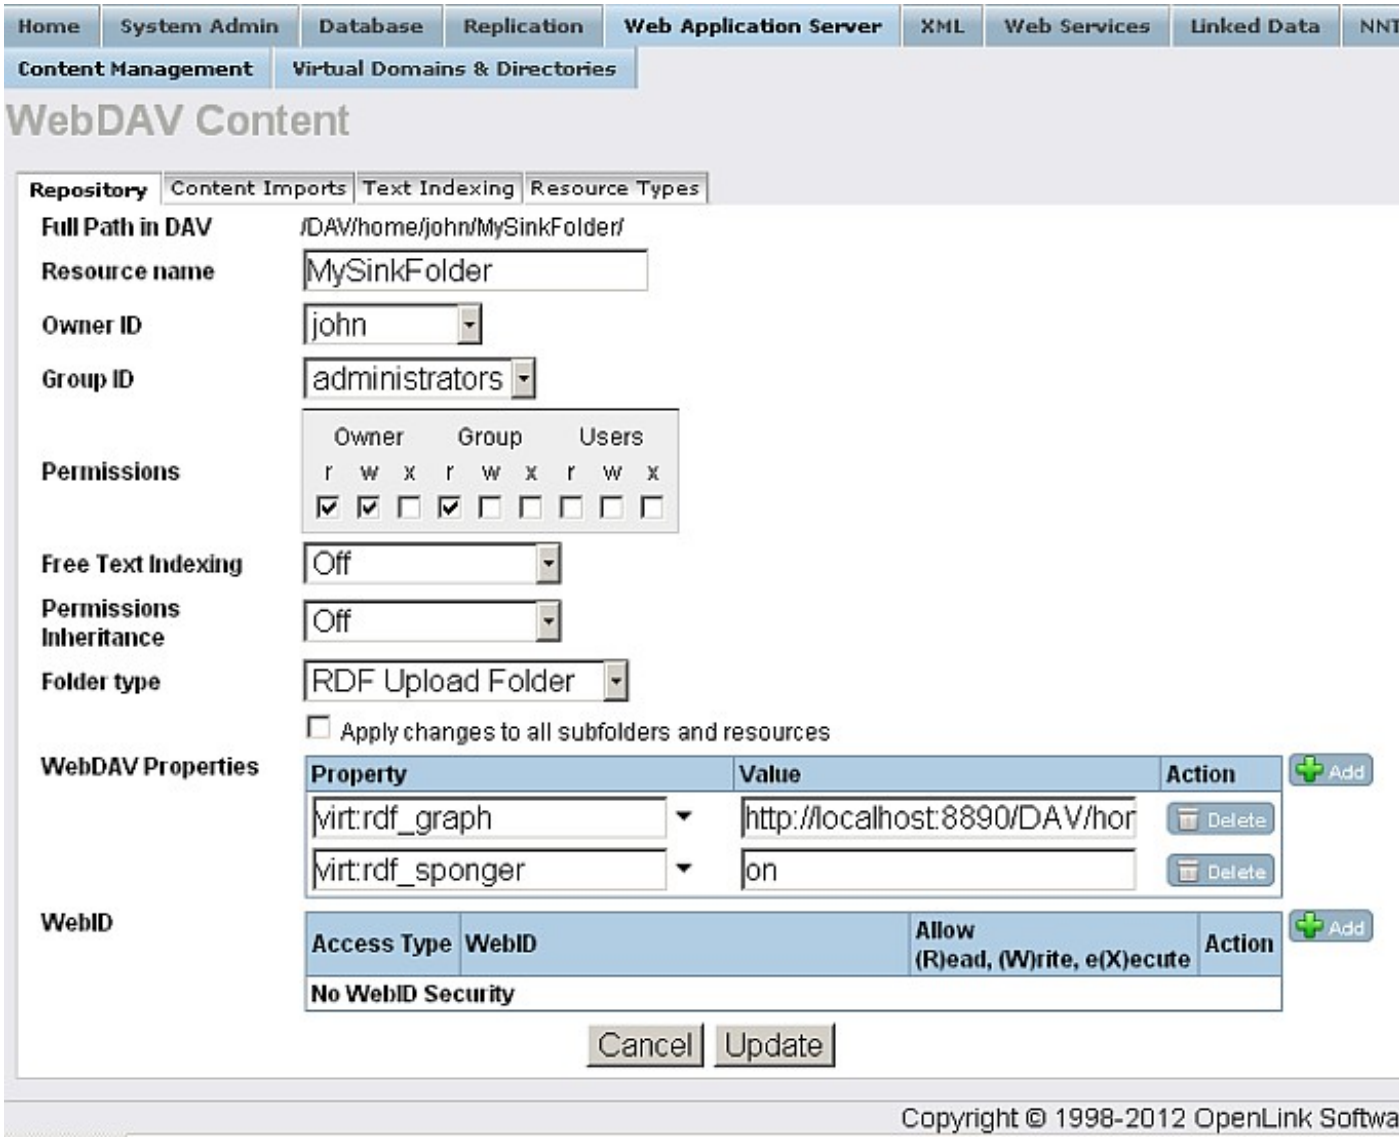
   with value:

   ```
   http://host:port/DAV/home/<user-name>/<rdf-sink-folder>/
   ```

```
-- So in our example it should be:
http://example.com/DAV/home/john/MySinkFolder/
```

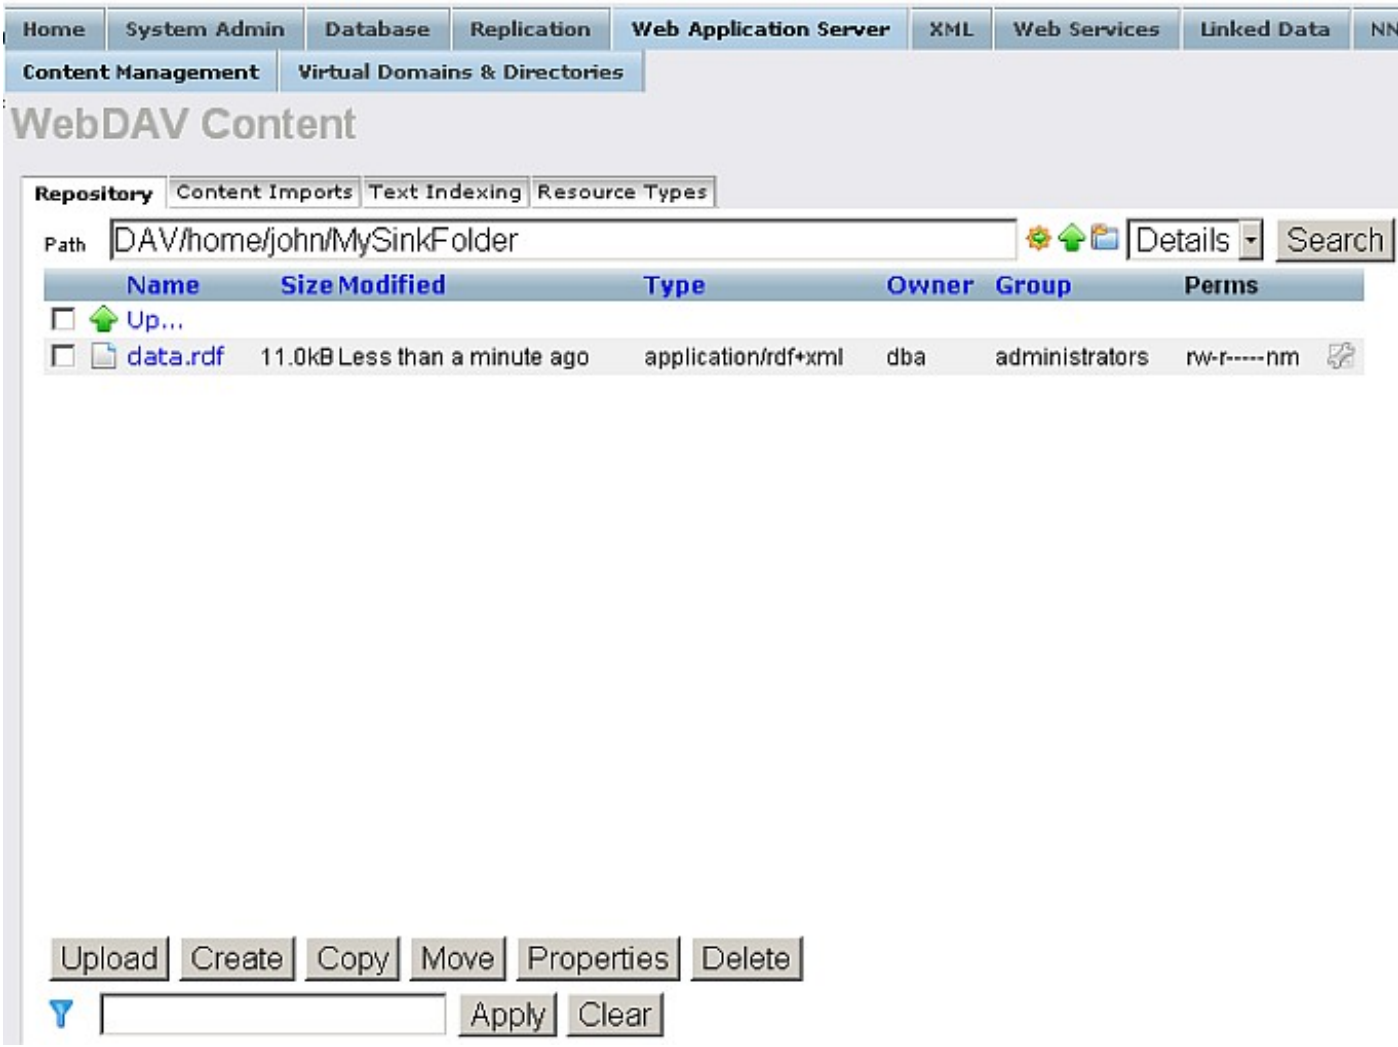
4. Add another property virt:rdf_sponger with value "on".

Figure 1.2.



5. Upload RDF files to the RDF Sink folder "MySinkFolder", for ex. upload file with name "data.rdf":

Figure 1.3.



6. As result the RDF data should be stored in graph depending on your folder name etc.:

```
http:///local.virt/DAV/home/<user-name>/<rdf-sink-folder>/<resource>

-- So in our example it will be:
http:///local.virt/DAV/home/john/MySinkFolder/data.rdf
```

   a. Go to http://host:port/sparql ;
   b. Execute simple query to view the graph triples:

```
SELECT  *
FROM <http://local.virt/DAV/home/john/MySinkFolder/data.rdf>
WHERE
  {
    ?s ?p ?o
  }
```

Figure 1.4.

Virtuoso SPARQL Query Editor
About | Namespace Prefixes | Infer
Default Data Set Name (Graph IRI)
Query Text
SELECT *
FROM <http://local.virt/DAV/home/john/MySinkFolder/data.rdf>
WHERE
{
?s ?p ?o
}
Sponging:
Use only local data (including data retrieved before), but do not retrieve more
Results Format:
HTML
(The CXML output is disabled, see details)
Execution timeout:
0
milliseconds (values less than 1000 are ignored)
Options:
Strict checking of void variables
(The result can only be sent back to browser, not saved on the server, see details)

7. In order to define any graph you want with the options from above, you should execute:

```
SQL> DAV_PROP_SET ('/DAV/home/<user-name>/<rdf-sink-folder>/',  'virt:rdf_graph', iri, <user-name>

-- So in our example it should be:
SQL> DAV_PROP_SET ('/DAV/home/john/MySinkFolder/',  'virt:rdf_graph', 'http://mydata.com', 'john',
```

   - Note: calling this function uses the given IRI as the graph IRI when sponging stuff put in <your-rdf-sink-folder>.

8. Finally you should execute the following command to get the RDF data from the new graph:

```
SQL> SELECT DAV_PROP_GET ('/DAV/home/<user-name>/<your-rdf-sink-folder>/', 'virt:rdf_graph',<user-

-- So in our example it should be:
SQL> SELECT DAV_PROP_GET ('/DAV/home/john/MySinkFolder/', 'virt:rdf_graph','john', '1');

Query result:
DAV_PROP_GET
http://example.com/DAV/home/john/MySinkFolder/

No. of rows in result: 1
```

1.5.14. How do I use SPARUL to change a selection of property values from URI References to Literals?

Assume a given graph where triples are comprised of property values that are mixed across URI References and Typed Literals as exemplified by the results of the query below:

```
SELECT DISTINCT ?sa ?oa
```

```
FROM <http://ucb.com/nbeabase>
WHERE
  {
    ?sa a <http://ucb.com/nbeabase/resource/Batch> .
    ?sa <http://ucb.com/nbeabase/resource/chemAbsNo> ?oa . FILTER regex(?oa, '-','i')
  }
```

You can use the following SPARUL pattern to harmonize the property values across relevant triples in a specific graph, as shown below:

```
SQL> SPARQL
INSERT INTO GRAPH <http://ucb.com/nbeabase>
  {
    ?sa <http://ucb.com/nbeabase/resource/sampleId> `str (?oa)`
  }
WHERE
  {
    ?sa <http://ucb.com/nbeabase/resource/chemAbsNo> ?oa . FILTER regex(?oa, '-','i')
  }
```

1.5.15. How is a Checkpoint performed against a Virtuoso Clustered Server?

The cluster cl_exec() function is used to perform a checkpoint across all node of a Virtuoso cluster as follows:

```
SQL>cl_exec ('checkpoint');
```

This typically needs to be run after loading RDF datasets into a Virtuoso cluster to prevent lose of data when the cluster is restarted.

1.5.16. How can I use CONSTRUCT with PreparedStatements?

Assume a given query which uses pragma *output:format '_JAVA_'* with CONSTRUCT:

```
SPARQL DEFINE output:format '_JAVA_'
   CONSTRUCT { ?s ?p ?o }
WHERE
  {
    ?s ?p ?o .
    FILTER (?s = iri(?::0))
  }
LIMIT 1
```

In order to work correctly, the query should be modified to:

```
SPARQL DEFINE output:format '_JAVA_'
   CONSTRUCT { `iri(?::0)` ?p ?o }
WHERE
  {
    `iri(?::0)` ?p ?o
  }
LIMIT 1
```

Equivalent variant of the query is also:

```
SPARQL DEFINE output:format '_JAVA_'
  CONSTRUCT { ?s ?p ?o }
WHERE
  {
    ?s ?p ?o .
    FILTER (?s = iri(?::0))
  }
LIMIT 1
```

1.5.17. How can perform SPARQL Updates without transactional log size getting exceed?

Since SPARUL updates are generally not meant to be transactional, it is best to run these in:

```
SQL> log_enable (2);
```

mode, which commits every operation as it is done. This prevents one from running out of rollback space. Also for bulk updates, transaction logging can be turned off. If so, one should do a manual checkpoint after the operation to ensure persistence across server restart since there is no roll forward log.

Alternatively, the "*TransactionAfterImageLimit* " parameter can be set in the virtuoso.ini config file to a higher value than its 50MB default:

```
#virtuoso.ini
...
[Parameters]
...
TransactionAfterImageLimit = N bytes default 50000000
...
```

1.5.18. How can I write custom crawler using PL?

The following code is an example of loading data via crawler with special function to generate link for downloading:

```
create procedure EUROPEANA_STORE (
  in _host varchar,
  in _url varchar,
  in _root varchar,
  inout _content varchar,
  in _s_etag varchar,
  in _c_type varchar,
  in store_flag int := 1,
  in udata any := null,
  in lev int := 0)
{
   declare url varchar;
   declare xt, xp any;
   declare old_mode int;
   xt := xtree_doc (_content, 2);
   xp := xpath_eval ('//table//tr/td/a[@href]/text()', xt, 0);
   commit work;
   old_mode := log_enable (3,1);
   foreach (any u in xp) do
     {
       u := cast (u as varchar);
       url := sprintf ('http://semanticweb.cs.vu.nl/europeana/api/export_graph?graph=%U&mimetype=default&
       dbg_printf ('%s', u);
         {
           declare continue handler for sqlstate '*' {
             dbg_printf ('ERROR: %s', __SQL_MESSAGE);
           };
           SPARQL LOAD ?:url into GRAPH ?:u;
         }
     }
   log_enable (old_mode, 1);
   return WS.WS.LOCAL_STORE (_host, _url, _root, _content, _s_etag, _c_type, store_flag, 0);
}
```

Set Up the Content Crawler to Gather RDF

1.5.19. How Can I Get an exact mapping for a date?

Assume a given attempts to get an exact mapping for the literal "1950" using *bif:contains* :

```
SPARQL
SELECT DISTINCT ?s ?o
FROM <http://dbpedia.org>
WHERE
  {
    ?s ?p ?o .
   FILTER( bif:contains (?o, '"1950"')
           && isLiteral(?o)
           && ( str(?p) ! = rdfs:label  || str(?p) !=  foaf:name
           && ( ?o='1950')
         )
  }
```

As an integer 1950 or date 1950-01-01 are not texts, they are not in free-text index and thus invisible for CONTAINS free-text predicate.

A possible way to make them visible that way is to introduce an additional RDF predicate that will contain objects of the triples in question, converted to strings via str() function.

Thus better results will be approached: if searches about dates are frequent then a new predicate can have date/datetime values extracted from texts, eliminating the need for bif:contains.

Therefor, the query from above should be changed to:

```
SPARQL
SELECT DISTINCT ?s ?o
FROM <http://dbpedia.org>
WHERE
  {
    ?s ?p ?o .
    FILTER (  isLiteral(?o)
              && (  str(?p) != str(rdfs:label) || str(?p) !=  foaf:name )
              && str(?o) in ("1950", "1950-01-01"))
  }
```

1.5.20. How Can I Get certificate attributes using SPARQL?

The SPARQL query should use the *cert:hex* and *cert:decimal* in order to get to the values, so for ex:

```
PREFIX cert: <http://www.w3.org/ns/auth/cert#>
PREFIX rsa: <http://www.w3.org/ns/auth/rsa#>

SELECT ?webid
FROM <http://webid.myxwiki.org/xwiki/bin/view/XWiki/homepw4>
WHERE
  {
    [] cert:identity ?webid ;
             rsa:modulus ?m ;
     rsa:public_exponent ?e .
     ?m cert:hex "b520f38479f5803a7ab33233155eeef8ad4e1f575b603f7780f3f60ceab1\n34618fbe117539109c015c5f9
     ?e cert:decimal "65537"^^xsd:string
  }
```

1.5.21. How can I make Multi Thread Virtuoso connection using JDBC?

See details here .

1.5.22. How Do I Perform Bulk Loading of RDF Source Files into one or more Graph IRIs?

See details here .

1.5.23. How to exploit RDF Schema and OWL Inference Rules with minimal effort?

When you install Virtuoso, it's reasoner and highly scalable inference capabilities may not be obvious. Typical cases involve using *rdfs:subClassOf* predicates in queries and wondering why reasoning hasn't occurred in line with the semantics defined in RDF Schema.

The experience applies when using more sophisticated predicates from OWL such as *owl:equivalentProperty* , *owl:equivalentClass* , *owl:sameAs* , *owl:SymmetricalProperty* , *owl:inverseOf* etc ...

Virtuoso implemented inference rules processing in a loosely coupled manner that allow users to conditionally apply inference context (via rules) to SPARQL queries. Typically, you have to create these rules following steps outlined here .

This tips and tricks note provides a shortcut for setting up and exploring RDF Schema and OWL reasoning once you've installed the Virtuoso Faceted Browser VAD package .

Virtuoso Faceted Web Service

1.5.24. How can I dump arbitrary query result as N-Triples?

Assume the following arbitrary query:

```
SPARQL define output:format "NT"
CONSTRUCT { ?s a ?t }
FROM virtrdf:
WHERE { ?s a ?t };
```

For iteration over result-set of an arbitrary query, use `exec_next()` in a loop that begins with `exec()` with cursor output variable as an argument and ends with `exec_close()` after it is out of data.

1.5.25. How do I bind named graph parameter in prepared statement?

Assume the following SPARQL query:

```
CONSTRUCT
  {
    ?s ?p ?o
  }
FROM ?context
WHERE
  {
    ?s ?p ?o
  }
```

To bind the named graph context of the query from above, the best solution due to performance implications, is to change the syntax of the query as:

```
CONSTRUCT
  {
    ?s ?p ?o
  }
WHERE
  {
    graph `iri(??)` { ?s ?p ?o }
  }
```

Note: In case of using "FROM clause", it needs a constant in order to check at the compile time whether the IRI refers to a graph or a graph group:

- Assume "FROM clause" is used as for ex:

```
CONSTRUCT
  {
    ?s ?p ?o
  }
FROM `iri(??)`
WHERE
  {
    ?s ?p ?o
  }
```

- In this case can be made security checks at the compile time (i.e., once) and not waste time at the run time.

- Assume "FROM clause" is used as for ex:

```
CONSTRUCT
  {
    ?s ?p ?o
  }
FROM iri(??)
WHERE
  {
    ?s ?p ?o
  }
```

  - In this case a compile-time check, a run-time check or 50/50 mix of them can be performed, depending on the security policies.
- FROM without constant would mean that security rules, if they present in the storage, are used at the run time, for every triple that matches every triple pattern in the default graph. This issue can be reproduced if FROM is not specified at all: if security differs from default then the effect is noticeably bad.

1.5.26. How can I insert binary data to Virtuoso RDF storage in plain queries and with parameter binding via ADO.NET calls?

The following example shows different methods for insert binary data to Virtuoso RDF storage in plain queries and with parameter binding via ADO.NET calls:

```
# Test_Bin.cs

using System;
using System.Runtime.InteropServices;
using System.Text;
using System.Data;
using OpenLink.Data.Virtuoso;

#if ODBC_CLIENT
namespace OpenLink.Data.VirtuosoOdbcClient
#elif CLIENT
namespace OpenLink.Data.VirtuosoClient
#else
namespace OpenLink.Data.VirtuosoTest
#endif
{
    class Test_Bin
    {
        [STAThread]
        static void Main(string[] args)
        {
            IDataReader myread = null;
            IDbConnection c;

            c = new VirtuosoConnection("HOST=localhost:1111;UID=dba;PWD=dba;");

            IDbCommand cmd = c.CreateCommand();
            int ros;

            try
            {
                c.Open();

                cmd.CommandText = "sparql clear graph <ado.bin>";
                cmd.ExecuteNonQuery();
```

```
//insert binary as base64Binary
                cmd.CommandText = "sparql insert into graph <ado.bin> { <res1> <attr> \"GpM7\"^^<http://w
                cmd.ExecuteNonQuery();

//insert binary as hexBinary
                cmd.CommandText = "sparql insert into graph <ado.bin> { <res2> <attr> \"0FB7\"^^<http://w
                cmd.ExecuteNonQuery();

//prepare for insert with parameter binding
                cmd.CommandText = "sparql define output:format '_JAVA_' insert into graph <ado.bin> { `ir

//bind parameters for insert binary as base64Binary
                IDbDataParameter param = cmd.CreateParameter();
                param.ParameterName = "p1";
                param.DbType = DbType.AnsiString;
                param.Value = "res3";
                cmd.Parameters.Add(param);

                param = cmd.CreateParameter();
                param.ParameterName = "p2";
                param.DbType = DbType.Int32;
                param.Value = 4;
                cmd.Parameters.Add(param);

                param = cmd.CreateParameter();
                param.ParameterName = "p3";
                param.DbType = DbType.AnsiString;
                param.Value = "GpM7";
                cmd.Parameters.Add(param);

                param = cmd.CreateParameter();
                param.ParameterName = "p4";
                param.DbType = DbType.AnsiString;
                param.Value = "http://www.w3.org/2001/XMLSchema#base64Binary";
                cmd.Parameters.Add(param);

                cmd.ExecuteNonQuery();

                cmd.Parameters.Clear();

//bind parameters for insert binary as hexBinary
                param = cmd.CreateParameter();
                param.ParameterName = "p1";
                param.DbType = DbType.AnsiString;
                param.Value = "res4";
                cmd.Parameters.Add(param);

                param = cmd.CreateParameter();
                param.ParameterName = "p2";
                param.DbType = DbType.Int32;
                param.Value = 4;
                cmd.Parameters.Add(param);

                param = cmd.CreateParameter();
                param.ParameterName = "p3";
                param.DbType = DbType.AnsiString;
                param.Value = "0FB7";
                cmd.Parameters.Add(param);

                param = cmd.CreateParameter();
                param.ParameterName = "p4";
                param.DbType = DbType.AnsiString;
                param.Value = "http://www.w3.org/2001/XMLSchema#hexBinary";
                cmd.Parameters.Add(param);

                cmd.ExecuteNonQuery();

                cmd.Parameters.Clear();

//bind parameters for insert binary as byte[]
                param = cmd.CreateParameter();
                param.ParameterName = "p1";
```

```
                    param.DbType = DbType.AnsiString;
                    param.Value = "res5";
                    cmd.Parameters.Add(param);

                    param = cmd.CreateParameter();
                    param.ParameterName = "p2";
                    param.DbType = DbType.Int32;
                    param.Value = 3;
                    cmd.Parameters.Add(param);

                    param = cmd.CreateParameter();
                    param.ParameterName = "p3";
                    param.DbType = DbType.Binary;
                    byte[] bin_val = {0x01, 0x02, 0x03, 0x04, 0x05};
                    param.Value = bin_val;
                    cmd.Parameters.Add(param);

                    param = cmd.CreateParameter();
                    param.ParameterName = "p4";
                    param.DbType = DbType.AnsiString;
                    param.Value = System.DBNull.Value;
                    cmd.Parameters.Add(param);

                    cmd.ExecuteNonQuery();

                    cmd.Parameters.Clear();

    //execute select and check the results
                    cmd.CommandText = "sparql SELECT ?s ?o FROM <ado.bin> WHERE {?s ?p ?o}"; ;
                    myread = cmd.ExecuteReader();
                    int r = 0;

                    while (myread.Read())
                    {
                        Console.WriteLine("=== ROW === "+r);
                        for (int i = 0; i < myread.FieldCount; i++)
                        {
                            string s;
                            if (myread.IsDBNull(i))
                                Console.Write("N/A|\n");
                            else
                            {
                                object o = myread.GetValue(i);
                                Type t = myread.GetFieldType(i);

                                s = myread.GetString(i);
                                Console.Write(s + "[");
                                if (o is SqlExtendedString)
                                {
                                    SqlExtendedString se = (SqlExtendedString)o;
                                    Console.Write("IriType=" + se.IriType + ";StrType=" + se.StrType + ";Valu
                                    Console.Write(";ObjectType=" + o.GetType() + "]|\n");
                                }
                                else if (o is SqlRdfBox)
                                {
                                    SqlRdfBox se = (SqlRdfBox)o;
                                    Console.Write("Lang=" + se.StrLang + ";Type=" + se.StrType + ";Value=" +
                                    Console.Write(";ObjectType=" + o.GetType() + "]|\n");
                                    object v = se.Value;
                                    if (v is System.Byte[])
                                    {
                                        byte[] vb = (byte[])v;
                                        for (int z = 0; z < vb.Length; z++)
                                        {
                                            Console.WriteLine(""+z+"="+vb[z]);
                                        }
                                    }
                                }
                                else
                                    Console.Write(o.GetType() + "]|\n");
                            }
                        }
                        r++;
```

```
                }
            }
            catch (Exception e)
            {
                Console.WriteLine("{0} Exception caught.", e);
            }
            finally
            {
                //                if (myread != null)
                //                  myread.Close();

                if (c.State == ConnectionState.Open)
                    c.Close();

            }

        }
    }
}
```

Output log for example is in the log.txt:

```
# log.txt
=== ROW === 0
res1[IriType=IRI;StrType=IRI;Value=res1;ObjectType=OpenLink.Data.Virtuoso.SqlExtendedString]|

1.5.27. How can I insert RDF data from Visual Studio to Virtuoso?

The following example shows how to insert RDF Data from Visual Studio to Virtuoso:

```
using System;
using System.Runtime.InteropServices;
using System.Text;
using System.Data;
using OpenLink.Data.Virtuoso;

#if ODBC_CLIENT
namespace OpenLink.Data.VirtuosoOdbcClient
#elif CLIENT
namespace OpenLink.Data.VirtuosoClient
#else
namespace OpenLink.Data.VirtuosoTest
#endif
{
    class Test_Insert
    {
        [STAThread]
        static void Main(string[] args)
        {
            IDataReader myread = null;
            IDbConnection c;

            c = new VirtuosoConnection("HOST=localhost:1111;UID=dba;PWD=dba;Charset=UTF-8");

            IDbCommand cmd = c.CreateCommand();
            int ros;

            try
            {
```

```
                    c.Open();

                    cmd.CommandText = "sparql clear graph <ado.net>";
                    cmd.ExecuteNonQuery();

                    cmd.CommandText = "sparql insert into graph <ado.net> { <a> <P01> \"131\"^^<http://www.w3
                    cmd.ExecuteNonQuery();

                    cmd.CommandText = "sparql insert into graph <ado.net> { <a> <P02> \"1234\"^^<http://www.w
                    cmd.ExecuteNonQuery();

                    cmd.CommandText = "sparql insert into graph <ado.net> { <a> <P03> \"12345.12\"^^<http://w
                    cmd.ExecuteNonQuery();

                    cmd.CommandText = "sparql insert into graph <ado.net> { <a> <P04> \"123456.12\"^^<http://
                    cmd.ExecuteNonQuery();

                    cmd.CommandText = "sparql insert into graph <ado.net> { <a> <P05> \"123456.12\"^^<http://
                    cmd.ExecuteNonQuery();

                    cmd.CommandText = "sparql insert into graph <ado.net> { <a> <P06> \"01020304\"^^<http://w
                    cmd.ExecuteNonQuery();

                    cmd.CommandText = "sparql insert into graph <ado.net> { <a> <P07> \"01.20.1980T04:51:13\"
                    cmd.ExecuteNonQuery();

                    cmd.CommandText = "sparql insert into graph <ado.net> { <a> <P08> \"01.20.1980\"^^<http:/
                    cmd.ExecuteNonQuery();

                    cmd.CommandText = "sparql insert into graph <ado.net> { <a> <P09> \"01:20:19\"^^<http://w
                    cmd.ExecuteNonQuery();

                    cmd.CommandText = "sparql insert into graph <ado.net> { <a> <P10> \"test\" }";
                    cmd.ExecuteNonQuery();

                    cmd.CommandText = "sparql define output:format '_JAVA_' insert into graph <ado.net> { <b>

    //add Object URI
                    add_triple(cmd, "S01", 1, "test1", null);

                    add_triple(cmd, "S08", 3, (float)12345.12, null);
                    add_triple(cmd, "S09", 3, 123456.12, null);
                    add_triple(cmd, "S10", 3, new DateTime(2001, 02, 23, 13, 44, 51, 234), null);
                    add_triple(cmd, "S11", 3, new DateTime(2001, 02, 24), null);
                    add_triple(cmd, "S12", 3, new TimeSpan(19, 41, 23), null);

                    add_triple(cmd, "S13", 4, "GpM7", "http://www.w3.org/2001/XMLSchema#base64Binary");
                    add_triple(cmd, "S14", 4, "0FB7", "http://www.w3.org/2001/XMLSchema#hexBinary");
                    byte[] bin_val = { 0x01, 0x02, 0x03, 0x04, 0x05 };
                    add_triple(cmd, "S15", 3, bin_val, null);

                }
                catch (Exception e)
                {
                    Console.WriteLine("{0} Exception caught.", e);
                }
                finally
                {
```

```
                if (c.State == ConnectionState.Open)
                    c.Close();

            }

        }

        static void add_triple(IDbCommand cmd, string sub, int ptype, object val, string val_add)
        {
                cmd.Parameters.Clear();

                IDbDataParameter param = cmd.CreateParameter();
                param.ParameterName = "p1";
                param.DbType = DbType.AnsiString;
                param.Value = sub;
                cmd.Parameters.Add(param);

                param = cmd.CreateParameter();
                param.ParameterName = "p2";
                param.DbType = DbType.Int32;
                param.Value = ptype;
                cmd.Parameters.Add(param);

                param = cmd.CreateParameter();
                param.ParameterName = "p3";
                if (val != null && val.GetType() == typeof (System.String))
                    param.DbType = DbType.AnsiString;
                param.Value = val;
                cmd.Parameters.Add(param);

                param = cmd.CreateParameter();
                param.ParameterName = "p4";
                param.DbType = DbType.AnsiString;
                param.Value = val_add;
                cmd.Parameters.Add(param);

                cmd.ExecuteNonQuery();
        }

    }
}
```

RDF Insert Methods in Virtuoso

1.5.28. How does default describe mode work?

The default describe mode works only if subject has a type/class. To get any anonymous subject described CBD mode should be used:

```
$ curl -i -L -H "Accept: application/rdf+xml" http://lod.openlinksw.com/describe/?url=http%3A%2F%2Fwww.mp
HTTP/1.1 303 See Other
Date: Mon, 21 Mar 2011 14:24:36 GMT
Server: Virtuoso/06.02.3129 (Linux) x86_64-generic-linux-glibc25-64  VDB
Content-Type: text/html; charset=UTF-8
Accept-Ranges: bytes
TCN: choice
Vary: negotiate,accept,Accept-Encoding
Location: http://lod.openlinksw.com/sparql?query=%20DESCRIBE%20%3Chttp%3A%2F%2Fwww.mpii.de%2Fyago%2Fresou
2Frdf%2Bxml
Content-Length: 0

HTTP/1.1 200 OK
Date: Mon, 21 Mar 2011 14:24:37 GMT

...
```

1.5.29. What should I do if the Virtuoso Server is not responding to HTTP requests?

Assume the Virtuoso server is not responding to HTTP requests although SQL connection is working. In order to determine what activity is being performed that might account for this:

1. Check the status:

```
SQL> status('');
REPORT
VARCHAR
_______________________________________________________________________________

OpenLink Virtuoso VDB Server
Version 06.02.3129-pthreads for Linux as of Mar 16 2011
Registered to Uriburner (Personal Edition, unlimited connections)
Started on: 2011/03/17 10:49 GMT+60

Database Status:
  File size 0, 37598208 pages, 7313125 free.
  1000000 buffers, 993399 used, 76771 dirty 0 wired down, repl age 25548714 0 w. io 0 w/crsr.
  Disk Usage: 2642884 reads avg 4 msec, 30% r 0% w last  1389 s, 1557572 writes,
    15331 read ahead, batch = 79.  Autocompact 308508 in 219226 out, 28% saved.
Gate:  71130 2nd in reads, 0 gate write waits, 0 in while read 0 busy scrap.
Log = virtuoso.trx, 14922248 bytes
VDB: 0 exec 0 fetch 0 transact 0 error
1757362 pages have been changed since last backup (in checkpoint state)
Current backup timestamp: 0x0000-0x00-0x00
Last backup date: unknown
Clients: 5 connects, max 2 concurrent
RPC: 116 calls, -1 pending, 1 max until now, 0 queued, 2 burst reads (1%), 0 second brk=9521074176
Checkpoint Remap 331113 pages, 0 mapped back. 1180 s atomic time.
    DB master 37598208 total 7313125 free 331113 remap 40593 mapped back
   temp  569856 total 569851 free

Lock Status: 52 deadlocks of which 0 2r1w, 86078 waits,
   Currently 1 threads running 0 threads waiting 0 threads in vdb.
Pending:

25 Rows. -- 1274 msec.
SQL>
```

2. Connect with the PL debugger and see what is running currently using the info threads call:

```
$ isql 1111 dba <password> -D
DEBUG> info threads
```

3. This should return the current code being executed by the Sever.
4. Run `txn_killall()` to kill any pending transactions which may enable the server to start responding to HTTP requests again:

```
SQL> txn_killall();

Done. -- 866 msec.
```

1.5.30. What CXML params are supported for the SPARQL URL pattern?

The following options are supported for CXML link behavior in the SPARQL URL Pattern:

1. Local faceted navigation links:

```
# CXML_redir_for_subjs=&CXML_redir_for_hrefs=&:

http://lod.openlinksw.com/sparql?default-graph-uri=&should-sponge=&query=SELECT+DISTINCT+%3Fcafe+%
```

2. External Resource Links:

```
# CXML_redir_for_subjs=&CXML_redir_for_hrefs=121:

http://lod.openlinksw.com/sparql?default-graph-uri=&should-sponge=&query=SELECT+DISTINCT+%3Fcafe+%
```

3. External faceted navigation links:

```
# CXML_redir_for_subjs=&CXML_redir_for_hrefs=LOCAL_PIVOT:

http://lod.openlinksw.com/sparql?default-graph-uri=&should-sponge=&query=SELECT+DISTINCT+%3Fcafe+%
```

4. External description resource(TTL):

```
# CXML_redir_for_subjs=&CXML_redir_for_hrefs=LOCAL_TTL:

http://lod.openlinksw.com/sparql?default-graph-uri=&should-sponge=&query=SELECT+DISTINCT+%3Fcafe+%
```

5. External description resource(CXML):

```
# CXML_redir_for_subjs=&CXML_redir_for_hrefs=LOCAL_CXML:

http://lod.openlinksw.com/sparql?default-graph-uri=&should-sponge=&query=SELECT+DISTINCT+%3Fcafe+%
```

1.5.31. How can I replicate all graphs?

To replicate all graphs (except the system graph http://www.openlinksw.com/schemas/virtrdf#), one should use http://www.openlinksw.com/schemas/virtrdf#rdf_repl_all as graph IRI:

```
SQL> DB.DBA.RDF_RDF_REPL_GRAPH_INS ('http://www.openlinksw.com/schemas/virtrdf#rdf_repl_all');
```

1.5.32. What is best method to get a random sample of all triples for a subset of all the resources of a SPARQL endpoint?

The best method to get a random sample of all triples for a subset of all the resources of a SPARQL endpoint, is decimation in its original style:

```
SELECT ?s ?p ?o
FROM <some-graph>
WHERE
  {
    ?s ?p ?o .
    FILTER ( 1 > bif:rnd (10, ?s, ?p, ?o) )
  }
```

By tweaking first argument of *bif:rnd()* and the left side of the inequality you can tweak decimation ratio from 1/10 to the desired value. What's important is to know that the SQL optimizer has a right to execute *bif:rnd (10)* only once at the beginning of the query, so we had to pass additional three arguments that can be known only when a table row is fetched so *bif:rnd (10, ?s, ?p, ?o)* is calculated for every row and thus any given row is either returned or ignored independently from others.

However, *bif:rnd (10, ?s, ?p, ?o)* contains a subtle inefficiency. In RDF store, graph nodes are stored as numeric IRI IDs and literal objects can be stored in a separate table. The call of an SQL function needs arguments of traditional SQL datatypes, so the query processor will extract the text of IRI for each node and the full value for each literal object. That is significant waste of time. The workaround is:

```
SPARQL
SELECT ?s ?p ?o
FROM <some-graph>
WHERE
  {
    ?s ?p ?o .
    FILTER ( 1>  <SHORT_OR_LONG::bif:rnd>  (10, ?s, ?p, ?o))
  }
```

This tells the SPARQL front-end to omit redundant conversions of values.

1.5.33. How can I replicate all graphs?

To replicate all graphs (except the system graph http://www.openlinksw.com/schemas/virtrdf#), one should use http://www.openlinksw.com/schemas/virtrdf#rdf_repl_all as graph IRI:

```
SQL> DB.DBA.RDF_RDF_REPL_GRAPH_INS ('http://www.openlinksw.com/schemas/virtrdf#rdf_repl_all');
```

1.5.34. How can I use SPARQL to make Meshups?

The following example demonstrates how to use SPARQL in order to make Meshups:

```
PREFIX dbo: <http://dbpedia.org/ontology/>
PREFIX rtb: <http://www.openlinksw.com/schemas/oat/rdftabs#>

CONSTRUCT
  {
    ?museum geo:geometry ?museumgeo ;
             rtb:useMarker 'star' ;
             foaf:name ?musname;
             rdfs:comment ?muscomment.
    ?edu geo:geometry ?edugeo ;
          rtb:useMarker 'book' ;
          foaf:name ?eduname;
          rdfs:comment ?educomment.
    ?wh geo:geometry ?whgeo;
            rtb:useMarker '03';
            foaf:name ?whname;
            rdfs:comment ?whcomment.
  }
WHERE
  {
    {
      ?museum a dbo:Museum;
              geo:geometry ?museumgeo;
              foaf:name ?musname;
              rdfs:comment ?muscomment.
      filter (lang(?musname)='en' && lang(?muscomment)='en')
    }
    UNION
    {
      ?edu a dbo:University;
           geo:geometry ?edugeo;
           foaf:name ?eduname;
           rdfs:comment ?educomment.
      filter (lang(?eduname)='en' && lang(?educomment)='en')
    }
    UNION
    {
      ?wh a dbo:WorldHeritageSite;
            geo:geometry ?whgeo;
            rdfs:label ?whname;
            rdfs:comment ?whcomment.
      filter (lang(?whname)='en' && lang(?whcomment)='en')
    }
  }
```

1.5.35. How can I use the net_meter utility before starting the ingestion to a cluster?

The net_meter utility is a SQL procedure that runs a network test procedure on every host of the cluster. The network test procedure sends a message to every other host of the cluster and waits for the replies from each host. After the last reply is received the action is repeated. This results in a symmetrical load of the network, all points acting as both clients and servers to all other points.

```
net_meter (
  in n_threads int,
  in n_batches int,
  in bytes int,
  in ops_per_batch int)
```

The parameters have the following meaning:

- *n_threads*

  : The number of network test instances started on each host. A value of 4 on a cluster of 4 hosts would result in a total of 16 network test procedures spread over 4 processes.
- *n_batches*

  : The number of message exchanges done by each network test procedure. A message exchange consists of sending one request to every other host of the cluster and of waiting for all to have replied.
- *bytes*

  : The number of bytes sent to each host in each message exchange. The reply from each host has the same number of bytes.
- *ops_per_batch*

  : This causes each message batch to contain several operations. In practice this is a multiplier on the number of bytes.

Example

Assume anuser has run 2 sets of tests on a cluster:

The first one was 1 thread, 1000 batches, 1000 bytes per exchange, 1 operation per batch:

```
SQL> net_meter (1, 1000, 1000, 1);

round_trips     MBps
REAL            REAL

_______________________________________

1245.393315542000254  2.489418401123078

1 Rows. -- 39345 msec.
```

resulted in a measured throughput of 2.5 MBps

The second one was 1 thread, 5000 batches, 10000 bytes per exchange, 1 operation per batch:

```
SQL> net_meter (1, 5000, 10000, 1);

round_trips     MBps
REAL            REAL

_______________________________________________

15915.291672080031181  305.017186586494738

1 Rows. -- 15394 msec.
```

resulted in a measured throughput of 305 MBps.

This indicates that the user's network is slow when sending multiple short messages.

When using the ingestion you should check the:

```
status('cluster');
```

command a few times and check the XX KB/s amount which should be around or above the 2500 mark.

1.5.36. How can I use the LOAD command to import RDF data?

SPARQL INSERT can be done using the LOAD command:

```
SPARQL INSERT INTO <..> { .... } [[FROM ...] { ... }]
```

```
SPARQL LOAD <x> [INTO <y>]

-- <ResourceURL> will be the Graph IRI of the loaded data:
SPARQL LOAD <ResourceURL>
```

Examples

Load from Resource URL

In order to load data from resource URL for ex: http://www.w3.org/People/Berners-Lee/card#i , execute from isql the following command:

```
SQL> SPARQL LOAD <http://www.w3.org/People/Berners-Lee/card#i>;
callret-0
VARCHAR
_______________________________________________________________________________

Load <http://www.w3.org/People/Berners-Lee/card#i> into graph <http://www.w3.org/People/Berners-Lee/card#

1 Rows. -- 703 msec.
SQL>
```

Load from file

1. Create DAV collection which is visible to public, for ex: http://example.com/DAV/tmp
2. Upload to the DAV collection a file for ex. with name listall.rq and with the following content:

```
SPARQL
PREFIX rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
PREFIX rdfs: <http://www.w3.org/2000/01/rdf-schema#>
PREFIX sioc: <http://rdfs.org/sioc/ns#>
SELECT ?x ?p ?o
FROM <http://mygraph.com>
WHERE
  {
    ?x rdf:type sioc:User .
    ?x ?p ?o.
    ?x sioc:id ?id .
    FILTER REGEX(str(?id), "^King")
  }
ORDER BY ?x
```

3. Execute from ISQL the following command:

```
SQL>SPARQL LOAD bif:concat ("http://", bif:registry_get("URIQADefaultHost"), "/DAV/tmp/listall.rq"
callret-0
VARCHAR
_______________________________________________________________________________

Load <http://example.com/DAV/tmp/listall.rq> into graph <http://myNewGraph.com> -- done

1 Rows. -- 321 msec.
```

Directly LOAD triples using ISQL

```
SQL>SPARQL INSERT INTO graph <http://mygraph.com>
{
  <http://myopenlink.net/dataspace/Kingsley#this>
  <http://www.w3.org/1999/02/22-rdf-syntax-ns#type>
  <http://rdfs.org/sioc/ns#User> .

  <http://myopenlink.net/dataspace/Kingsley#this>
  <http://rdfs.org/sioc/ns#id>
  <Kingsley> .

  <http://myopenlink.net/dataspace/Caroline#this>
  <http://www.w3.org/1999/02/22-rdf-syntax-ns#type>
  <http://rdfs.org/sioc/ns#User> .

  <http://myopenlink.net/dataspace/Caroline#this>
```

```
  <http://rdfs.org/sioc/ns#id>
  <Caroline> .
};
```

1.5.37. How can I delete graphs using stored procedure?

The following script demonstrates the use of custom stored procedures for deleting graph(s). It first creates a table *GRAPHS_TO_DELETE* , into which the names of the graphs to be deleted should be inserted, as follows:

```
use MYUSR;

create procedure GRAPHS_TO_DELETE_SP (in gd_iris any)
{
  declare gd_iri iri_id;
  declare dp, row any;
  result_names (gd_iri);
  dp := dpipe (0, '__I2IDN');
  foreach (varchar iri in GD_IRIS) do
    {
      dpipe_input (dp, iri);
    }
  while (0 <> (row := dpipe_next (dp, 0)))
    {
      result (row[0]);
    }
}
;

drop view GRAPHS_TO_DELETE_VIEW;
create procedure view GRAPHS_TO_DELETE_VIEW as MYUSR.DBA.GRAPHS_TO_DELETE_SP (gd_iris) (gd_iri any);

create procedure DELETE_GRAPHS (in g_iris any)
{
  declare g_iids any;
  if (not isvector (g_iris) and g_iris is not null)
    signal ('22023', '.....', 'The input argument must be an array of strings or null');
  if (not length (g_iris))
    return 0;
  delete from DB.DBA.RDF_QUAD where G in (select * from GRAPHS_TO_DELETE_VIEW where gd_iris = g_iris) opt
  return row_count ();
}
;
```

Finally call the procedure DELETE_GRAPHS to perform the deletion of the specified graphs. Note it does not return a result set and can be called as follows:

```
SQL> select MYUSR.DBA.DELETE_GRAPHS (vector ('g1', 'g2', 'g3'));
```

This will return the number of triples removed from the specified graphs.

Note: the procedure only applies to the cluster so to get IRI IDs via partitioned pipe (DAQ). It is not usable on single.

1.5.38. How can I use SPARUL to add missing triples to a Named Graph?

What?

Use of SPARUL to add missing triples to a Named Graph. For example, an ontology/vocabulary extension.

Why?

A lot of ontologies and vocabularies started life prior to emergence of the Linked Data meme. As a result, many do not include rdfs:isDefinedBy relations (via triples) that associate Classes and Properties in an ontology with the ontology itself, using de-referencable URIs. The downside of this pattern is that Linked Data's follow-your-nose pattern isn't exploitable when viewing these ontologies e.g., when using contemporary Linked Data aware browsers.

How?

If SPARUL privileges are assigned to SPARQL or other accounts associated with SPARQL Endpoint. Or via WebID? protected SPARQL endpoint with SPARUL is granted to SPARQL or specific accounts or WebIDs in a group.

```
INSERT INTO <LocalNamedGraphIRI>
  { ?s rdfs:DefinedBy <LocalOntologyEntityURI>.
    ?o rdfs:isDefinedBy <http://www.w3.org/ns/auth/acl>. }
FROM <ExtSourceNamedGraphIRI>
WHERE
  {
    ?s a ?o
  }
```

Example

1. Load Quad Named Graph via Sponger based query:

```
DEFINE get:soft "replace"
SELECT DISTINCT *
FROM <http://www.w3.org/ns/auth/acl#>
WHERE
  {
    ?s ?p ?o
  }
```

2. Added Triples via SPARUL to Ontology Named Graph:

```
INSERT INTO <http://www.w3.org/ns/auth/acl#>
  {  ?s rdfs:DefinedBy <http://www.w3.org/ns/auth/acl>.
     ?o rdfs:DefinedBy <http://www.w3.org/ns/auth/acl>. }
FROM <http://www.w3.org/ns/auth/acl#>
WHERE
  {
    ?s a ?o
  }
```

3. Via Conductor or Command-line iSQL courtesy of SPASQL execute the following statements:

    a. Remove an existing graph:

```
SPARQL
CLEAR GRAPH <http://www.w3.org/ns/auth/acl/> ;

SPARQL
CLEAR GRAPH <http://www.w3.org/ns/auth/acl> ;

SPARQL
CLEAR GRAPH <http://www.w3.org/ns/auth/acl#> ;
```

    b. Load a new graph:

```
SPARQL
LOAD <http://www.w3.org/ns/auth/acl> ;
```

    c. Add missing rdfs:isDefinedBy triples via SPARUL:

```
SPARQL
INSERT INTO <http://www.w3.org/ns/auth/acl>
  {  ?s rdfs:DefinedBy <http://www.w3.org/ns/auth/acl>.
     ?o rdfs:DefinedBy <http://www.w3.org/ns/auth/acl>. }
FROM <http://www.w3.org/ns/auth/acl>
WHERE
  {
    ?s a ?o
  } ;
```

4. Verification: Access the following url:

http://<cname>/describe/?uri=http://www.w3.org/ns/auth/acl

Virtuoso Sponger ???

1.5.39. How can I use the SPARQL IF operator for SPARQL-BI endpoint?

Assume a SPARQL query is to be executed against the Virtuoso DBpedia SPARQL endpoint (http://dbpedia.org/sparql) to retrieve the decimal longitude of the "NJ Devils' hometown" with cardinal direction, which determines whether the decimal is positive (in the case of East) or negative (in the case of West).

Virtuoso supports SPARQL-BI, an extended SPARQL 1.0 implementation from before SPARQL 1.1 was ratified, thus the "IF" operator is not currently supported, but an equivalent `bif:either` built-in SQL function does exist enabling an equivalent query to be executed:

```
PREFIX rdfs: <http://www.w3.org/2000/01/rdf-schema#>
PREFIX dbo: <http://dbpedia.org/ontology/>
PREFIX dbp: <http://dbpedia.org/property/>
SELECT ?team ( (bif:either( ?ew = 'W', -1, 1)) * (?d + (((?m * 60) + ?s) / 3600.0)) as ?v)
  {
    ?team a dbo:HockeyTeam . ?team rdfs:label 'New Jersey Devils'@en .
    ?team dbp:city ?cityname . ?city rdfs:label ?cityname .
    ?city dbp:longd ?d; dbp:longm ?m; dbp:longs ?s; dbp:longew ?ew .
  }
```

Figure 1.6. SPARQL IF operator for SPARQL-BI endpoint

Supported SPARQL-BI "define" pragmas

SPARQL-BI ???

1.5.40. How can I handle checkpoint condition?

In general, to control checkpoint in order to bypass client timeouts during long checkpoints when inserting triples into the Virtuoso server, one must disable automatic checkpoint by:

```
SQL> checkpoint_interval (0);
```

and also to make sure the AutoCheckpointLogSize is off. Then can be performed checkpoint whenever the client wants using the 'checkpoint' command.

However the need of cache check is not needed unless instance shows regular errors. By default the cache check is disabled.

Virtuoso offers a new option in the Virtuoso ini file to enable the check of page maps: *PageMapCheck* , 1/0 default 0:

```
-- Virtuoso.ini

...
[Parameters]
...
PageMapCheck  = 0
...
```

Also customer can add *CheckpointSyncMode = 0* in order to disable sync during checkpoint to speed the operations.

1.5.41. How can I incorporate Content Negotiation into RDF bulk loaders?

The examples from below demonstrate how to incorporate Content Negotiation into RDF bulk loaders:

- Using the `DB.DBA.RDF_LOAD_RDFXML` function:

```
DB.DBA.RDF_LOAD_RDFXML (http_get ('http://purl.org/ontology/mo/', null, 'GET', 'Accept: applicatio
```

- Using the `DB.DBA.TTLP` function: The call to http client should be modified to ask for appropriate content type as for ex:

```
DB.DBA.TTLP (http_get ('http://purl.org/ontology/mo/', null, 'GET', 'Accept: text/n3', null, null,
```

1.5.42. Virtuoso Linked Data Deployment In 3 Simple Steps?

Injecting Linked Data into the Web has been a major pain point for those who seek personal, service, or organization-specific variants of DBpedia. Basically, the sequence goes something like this:

1. You encounter DBpedia or the LOD Cloud Pictorial.
2. You look around (typically following your nose from link to link).
3. You attempt to publish your own stuff.
4. You get stuck.

The problems typically take the following form:

1. Functionality confusion about the complementary Name and Address functionality of a single URI abstraction.
2. Terminology confusion due to conflation and over-loading of terms such as Resource, URL, Representation, Document, etc.
3. Inability to find robust tools with which to generate Linked Data from existing data sources such as relational databases, CSV files, XML, Web Services, etc.

To start addressing these problems, here is a simple guide for generating and publishing Linked Data using Virtuoso.

Step 1 - RDF Data Generation

Existing RDF data can be added to the Virtuoso RDF Quad Store via a variety of built-in data loader utilities.

Many options allow you to easily and quickly generate RDF data from other data sources:

- Install the Sponger Bookmarklet for the URIBurner service. Bind this to your own SPARQL-compliant backend RDF database (in this scenario, your local Virtuoso instance), and then perform Network Resource Fetch of some HTTP-accessible resources.
- Convert relational DBMS data to RDF using the Virtuoso Linked Data Views Wizard.
- Starting with CSV files, you can:
    - Place them at an HTTP-accessible location, and use the Virtuoso Sponger to convert them to RDF or;
    - Use the CVS import feature to import their content into Virtuoso's relational data engine; then use the built-in Linked Data Views Wizard as with other RDBMS data.
- Starting from XML files, you can:
    - Use Virtuoso's inbuilt XSLT-Processor for manual XML to RDF/XML transformation or;
    - Leverage the Sponger Cartridge for GRDDL, if there is a transformation service associated with your XML data source, or;
    - Let the Sponger analyze the XML data source and make a best-effort transformation to RDF.

Step 2 - Linked Data Deployment

Install the Faceted Browser VAD package (fct_dav.vad) which delivers the following:

1. Faceted Browser Engine UI
2. Dynamic Hypermedia Resource Generator:
    - delivers descriptor resources for every entity (data object) in the Native or Virtual Quad Stores
    - supports a broad array of output formats, including HTML+RDFa, RDF/XML, N3/Turtle, NTriples, RDF-JSON, OData+Atom, and OData+JSON.

Step 3 - Linked Data Consumption & Exploitation

Three simple steps allow you, your enterprise, and your customers to consume and exploit your newly deployed Linked Data --

1. Load a page like this in your browser: http://<cname>[:<port>]/describe/?uri=<entity-uri>
    - <cname>[:<port>] gets replaced by the host and port of your Virtuoso instance
    - <entity-uri> gets replaced by the URI you want to see described -- for instance, the URI of one of the resources you let the Sponger handle.
2. Follow the links presented in the descriptor page.
3. If you ever see a blank page with a hyperlink subject name in the About: section at the top of the page, simply add the parameter "&sp=1" to the URL in the browser's Address box, and hit [ENTER]. This will result in an "on the fly" resource retrieval, transformation, and descriptor page generation.
4. Use the navigator controls to page up and down the data associated with the "in scope" resource descriptor.

1.5.43. What are the differences between create, drop, clear and delete Graph?

In Virtuoso it does not matter whether *CREATE GRAPH* and *DROP GRAPH* are called or not. Their purpose is to provide compatibility with the original SPARUL that was designed for Jena. Some Jena triple stores require explicit creation of each graph (like CREATE TABLE in SQL), they report errors if one tries to create a graph twice and so on.

For Virtuoso, a new graph is not an important system event, it has single quad store shared by all graphs. When a graph is made by *CREATE GRAPH* , its name is placed in an auxiliary table that is used solely to signal appropriate errors on CREATE graph that is CREATE-d already or on DROP of a missing graph; this table is not used in any way in SPARQL or other subsystems. In a perfect world, smart development tools will query that table to give hints to a programmer regarding available graphs, but the reality is not so perfect.

What's more important is a difference between *DELETE FROM g { ?s ?p ?o } FROM g WHERE { ?s ?p ?o }* and *CLEAR GRAPH g* , as both will delete all triples from the specified graph <g> with equal speed, but *CLEAR GRAPH* will also delete free-text index data about occurrences of literals in this specific graph. So *CLEAR GRAPH* will make the database slightly more compact and the text search slightly faster. (Naturally, *DROP GRAPH* makes *CLEAR GRAPH* inside, not just *DELETE FROM ...*)

RDF Insert Methods in Virtuoso

1.5.44. How can I perform search for predicate values?

What?

Creation of a stored procedure that enables users to find properties based on their string based token patterns.

Why?

When working with datasets from disparate datasources in a common named graph, there are times when you seek to scope sparql or spasql queries to specific property IRI/URI patterns without embarking upon inefficient regex heuristics.

What?

Make a stored procedure for querying against the main quad store table (rdf_quad). Surface the procedure as a magic predicate using "bif:" prefix. To find all the properties whose predicates start with "http://www.openlinksw.com/", a Virtuoso/PL procedure can be used as listed below:

```
SQL> create procedure PREDICATES_OF_IRI_PATH (
  in path varchar,
  in dump_iri_ids integer := 0)
{
  declare PRED_IRI varchar;
  declare PRED_IRI_ID IRI_ID;
  declare path_head_len integer;

  if (dump_iri_ids)
    result_names (PRED_IRI_ID);
  else
```

```
  result_names (PRED_IRI);

for ( SELECT RP_NAME, RP_ID
      FROM RDF_PREFIX
      WHERE (RP_NAME >= path) AND (RP_NAME < path || chr(255)) ) do
  {
    declare fourbytes varchar;
    fourbytes := '----';
    fourbytes[0] := bit_shift (RP_ID, -24);
    fourbytes[1] := bit_and (bit_shift (RP_ID, -16), 255);
    fourbytes[2] := bit_and (bit_shift (RP_ID, -8), 255);
    fourbytes[3] := bit_and (RP_ID, 255);

    for ( SELECT RI_NAME, RI_ID from RDF_IRI
          WHERE (RI_NAME >= fourbytes) AND (RI_NAME < fourbytes || chr(255)) ) do
      {
        if (exists (SELECT TOP 1 1 FROM RDF_QUAD WHERE P=RI_ID))
          result (case when (dump_iri_ids) then RI_ID else RP_NAME || subseq (RI_NAME, 4) end);
      }
  }

for ( path_head_len := length (path)-1; path_head_len >= 0; path_head_len := path_head_len - 1)
  {
    for ( SELECT RP_NAME, RP_ID from RDF_PREFIX
          WHERE RP_NAME = subseq (path, 0, path_head_len) ) do
      {
        declare fourbytes varchar;
        fourbytes := '----';
        fourbytes[0] := bit_shift (RP_ID, -24);
        fourbytes[1] := bit_and (bit_shift (RP_ID, -16), 255);
        fourbytes[2] := bit_and (bit_shift (RP_ID, -8), 255);
        fourbytes[3] := bit_and (RP_ID, 255);

        for ( SELECT RI_NAME, RI_ID from RDF_IRI
              WHERE (RI_NAME >= fourbytes || subseq (path, path_head_len))
              AND (RI_NAME < fourbytes || subseq (path, path_head_len) || chr(255)) ) do
          {
            if (exists (SELECT TOP 1 1 FROM RDF_QUAD WHERE P=RI_ID))
              result (case when (dump_iri_ids) then RI_ID else RP_NAME || subseq (RI_NAME, 4) end);
          }
      }
  }
}
;

Done. -- 16 msec.
```

Example Usage

1. Execute:

```
set echo on;
```

2. Collect all predicates that start with:

```
-- http://www.openlinksw.com/
SQL>PREDICATES_OF_IRI_PATH ('http://www.openlinksw.com/', 1);

```

If you want to use the procedure's output inside SPARQL queries, it can be wrapped by a procedure view and it in turn can be used in an Linked Data View but it is redundant for most applications.

For typical "almost static" data, it is more practical to write a procedure that will store all found predicates in some dedicated "dictionary" graph and then use the graph as usual.

1.5.45. How can I use INSERT via CONSTRUCT Statements?

You can write an ordinary CONSTRUCT statement, ensure that it generates the triples intended to be added, and then replace the leading CONSTRUCT keyword with the INSERT INTO phrase.

Example:

1. Assume new triples need to be added for the equivalentClass:

```
CONSTRUCT
  {
    ?s <http://www.w3.org/2002/07/owl#equivalentClass> `iri (bif:replace(?o,'http://schema.rdfs.or
   }
FROM <http://www.openlinksw.com/schemas/rdfs>
WHERE
  {
    ?s <http://www.w3.org/2002/07/owl#equivalentClass> ?o
```

```
        };
```

2. Execute the CONSTRUCT query from the htp://cname/sparql SPARQL endpoint.
3. View the generated triples to ensure they are correct.
4. Replace CONSTRUCT with INSERT INTO:

```
SPARQL INSERT INTO <http://www.openlinksw.com/schemas/rdfs>
  {
    ?s <http://www.w3.org/2002/07/owl#equivalentClass> `iri (bif:replace(?o,'http://schema.rdfs.or
   }
FROM <http://www.openlinksw.com/schemas/rdfs>
WHERE
  {
    ?s <http://www.w3.org/2002/07/owl#equivalentClass> ?o
  } ;
```

1.5.46. How to clear graphs which are related to empty graphs?

The following example demonstrates how to remove graphs which are related to empty graphs:

```
PREFIX nrl:<http://www.semanticdesktop.org/ontologies/2007/08/15/nrl#>
SELECT ( bif:exec(bif:sprintf("SPARQL CLEAR GRAPH<%s>", str(?mg))))
WHERE
  {
    ?mg nrl:coreGraphMetadataFor ?g .
    FILTER(?g in ( <urn:nepomuk:local:8a9e692a> )) .
    FILTER ( !bif:exists((SELECT (1) WHERE { GRAPH ?g { ?s ?p ?o . } . })) ) .
  }
```

1.5.47. How can I use sub-queries to enable literal values based joins?

What?

Use of subqueries to enable literal values based joins.

Why?

Sophisticated access to literal values via subqueries provides powerful mechanism for enhancing sparql graph patterns via dynamic literal value generation.

How?

Use select list variables from subqueries to produce literal object values in sparql graph patterns.

Example

Assume in the following query, where should be used a sub-query to replace ?app:

```
SELECT DISTINCT ?r
WHERE
  {
    graph ?g
      {
        ?r nie:url ?url .
      }  .
      ?g nao:maintainedBy ?app .
      ?app nao:identifier "nepomukindexer" .
  }
```

If it is not sure that ?app is the only, for e.g., the triple ?app nao:identifier "nepomukindexer" can appear in more than one graph, then the query should be changed to:

```
SELECT DISTINCT ?r
WHERE
  {
    graph ?g
      {
        ?r nie:url ?url .
```

```
        }  .
        ?g nao:maintainedBy ?app .
        FILTER (?app = (SELECT ?a WHERE { ?a nao:identifier "nepomukindexer" }))
}
```

or even shorter:

```
SELECT DISTINCT ?r
WHERE
  {
   graph ?g
     {
       ?r nie:url ?url .
     }  .
   ?g nao:maintainedBy `(SELECT ?a WHERE { ?a nao:identifier "nepomukindexer" })` .
 }
```

1.5.48. How can I execute query with labels preference order?

The way to prefer one label to the other can be done as follows:

- Have a procedure which returns preference order:

```
create procedure lbl_order (in p any)
{
  declare r int;
  r := vector (
  'http://www.w3.org/2000/01/rdf-schema#label',
  'http://xmlns.com/foaf/0.1/name',
  'http://purl.org/dc/elements/1.1/title',
  'http://purl.org/dc/terms/title',
  'http://xmlns.com/foaf/0.1/nick',
  'http://usefulinc.com/ns/doap#name',
  'http://rdf.data-vocabulary.org/name',
  'http://www.w3.org/2002/12/cal/ical#summary',
  'http://aims.fao.org/aos/geopolitical.owl#nameListEN',
  'http://s.opencalais.com/1/pred/name',
  'http://www.crunchbase.com/source_description',
  'http://dbpedia.org/property/name',
  'http://www.geonames.org/ontology#name',
  'http://purl.org/ontology/bibo/shortTitle',
  'http://www.w3.org/1999/02/22-rdf-syntax-ns#value',
  'http://xmlns.com/foaf/0.1/accountName',
  'http://www.w3.org/2004/02/skos/core#prefLabel',
  'http://rdf.freebase.com/ns/type.object.name',
  'http://s.opencalais.com/1/pred/name',
  'http://www.w3.org/2008/05/skos#prefLabel',
  'http://www.w3.org/2002/12/cal/icaltzd#summary',
  'http://rdf.data-vocabulary.org/name',
  'http://rdf.freebase.com/ns/common.topic.alias',
  'http://opengraphprotocol.org/schema/title',
  'http://rdf.alchemyapi.com/rdf/v1/s/aapi-schema.rdf#Name',
  'http://poolparty.punkt.at/demozone/ont#title'
   );
  if (isiri_id (p))
    p := id_to_iri (p);
  r := position (p, r);
  if (r = 0)
    return 100;
  return r;
}
;
```

- Execute the following query:

```
SPARQL
DEFINE input:inference "facets"
SELECT ?o
WHERE
  {
    <http://uriburner.com/about/id/entity/http/www.linkedin.com/in/kidehen#CV_mfrTl4s6Jy> virtrdf:
       ?p ?o .
```

```
  }
ORDER BY (sql:lbl_order (?p));
```

- Or execute the following query using sql:

```
SELECT __ro2sq (O), lbl_order (P)
FROM RDF_QUAD table option (with ''facets'')
WHERE G = __i2id (?)
  AND S = __i2id (?)
  AND P = __i2id (''http://www.openlinksw.com/schemas/virtrdf#label'', 0)
ORDER BY 2
```

1.5.49. How can I get object datatype?

To get object datatype should be used the internal Virtuoso/PL function `DB.DBA.RDF_DATATYPE_OF_OBJ` , visible in SPARQL as sql:RDF_DATATYPE_OF_OBJ.

Suppose the following scenario:

```
# Explicit typecast (insert)
SQL> sparql insert into <test_datatype> { <a> <string> "string 1"^^xsd:string . };
callret-0
VARCHAR
_______________________________________________________________________________

Insert into <test_datatype>, 1 (or less) triples -- done

1 Rows. -- 94 msec.

#Not explicit typecast (insert)
SQL> sparql insert into <test_datatype> { <a> <string> "string 2". };
callret-0
VARCHAR
_______________________________________________________________________________

Insert into <test_datatype>, 1 (or less) triples -- done

1 Rows. -- 16 msec.

SQL> SPARQL
SELECT ?o (iri(sql:RDF_DATATYPE_OF_OBJ(?o, 'untyped!')))
FROM <test_datatype> { <a> <string> ?o} ;
o                      callret-1
VARCHAR                VARCHAR
_______________________________________________________________________________

string 1               http://www.w3.org/2001/XMLSchema#string
string 2               untyped!

2 Rows. -- 16 msec.
SQL>
```

1.5.50. How Can I Backup and Restore individual table(s) and individual index(s)?

See more details here .

1.5.51. What bif:contains free-text options can I use?

Virtuoso supports the following free-text options for bif:contains:

1. *OFFBAND*

   : See description for this free-text option in this section .

   - Note: it is useful only if data comers via an Linked Data View and the source relational table uses this trick;
2. *SCORE*

: This free-text option is calculated as described in this section :

```
SQL>SPARQL
SELECT ?s1 as ?c1, ?sc, ?rank
WHERE
  {
    {
      {
        SELECT ?s1, (?sc * 3e-1) as ?sc, ?o1,
          (sql:rnk_scale (<LONG::IRI_RANK> (?s1))) as ?rank
        WHERE
          {
            ?s1 ?s1textp ?o1 .
            ?o1 bif:contains  '"CNET"'  option (score ?sc)  .
          }
        ORDER BY DESC (?sc * 3e-1 + sql:rnk_scale (<LONG::IRI_RANK> (?s1)))
        LIMIT 20
        OFFSET 0
      }
    }
  };

c1                                                sc      rank
_____________________________________________________________________
http://www.mixx.com/stories/45003360/justi...   3           5.881291583872891e-14
http://www.mixx.com/stories/45099313/bing_...   2.7     5.881291583872891e-14
http://dbpedia.org/resource/CBS_Interactive       1.5     5.881291583872891e-14
http://dbpedia.org/resource/CBS_Interactive       1.5     5.881291583872891e-14

4 Rows. -- 1 msec.
```

3. *SCORE_LIMIT*

: This free-text option works as it is in plain SQL free-text. See more details :

```
SQL> SPARQL
SELECT ?s ?sc
WHERE
  {
    ?s ?p ?o .
    ?o bif:contains "tree" OPTION (score ?sc , score_limit 20)
  };

s                                                                   sc
VARCHAR                                                             INTEGER
_____________________________________________________________________________

http://www.openlinksw.com/virtrdf-data-formats#default              24

7 Rows. -- 2 msec.
```

1.5.52. What SPARQL Endpoint Protection Methods can I use?

Virtuoso supports the following SPARQL Endpoint protection methods:

1. Secure SPARQL Endpoint Guide using WebID Protocol
2. Secure SPARQL Endpoint Guide via OAuth
3. Secure SPARQL Endpoint Guide via SQL Accounts -- usage path digest authentication

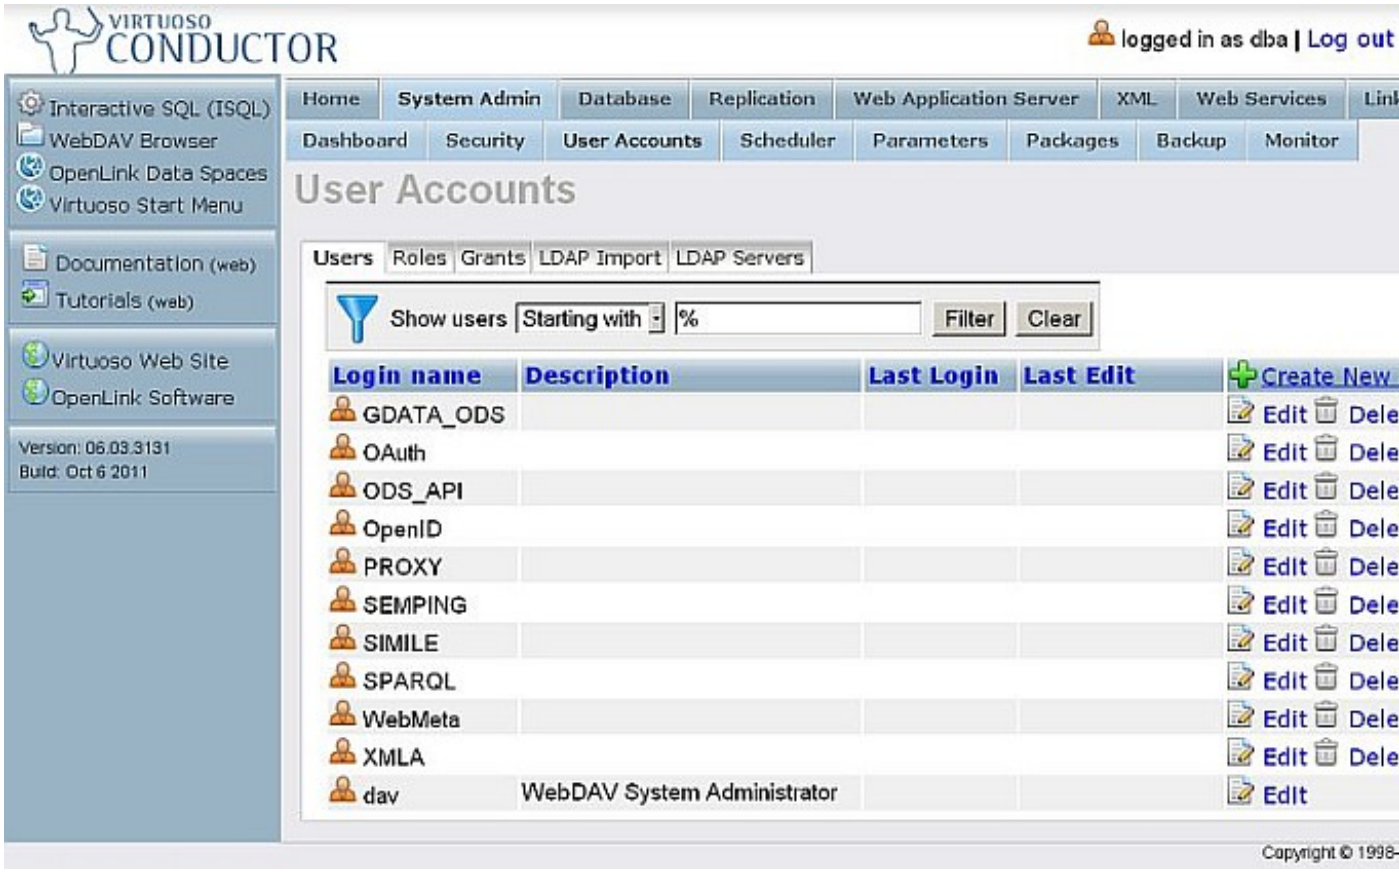
1.5.53. How do I assign SPARQL role to SQL user?

This section a sample scenario how to assign SPARQL (for ex. SPARQL_SELECT) role to Virtuoso SQL user:

1. Go to http://cname/conductor .

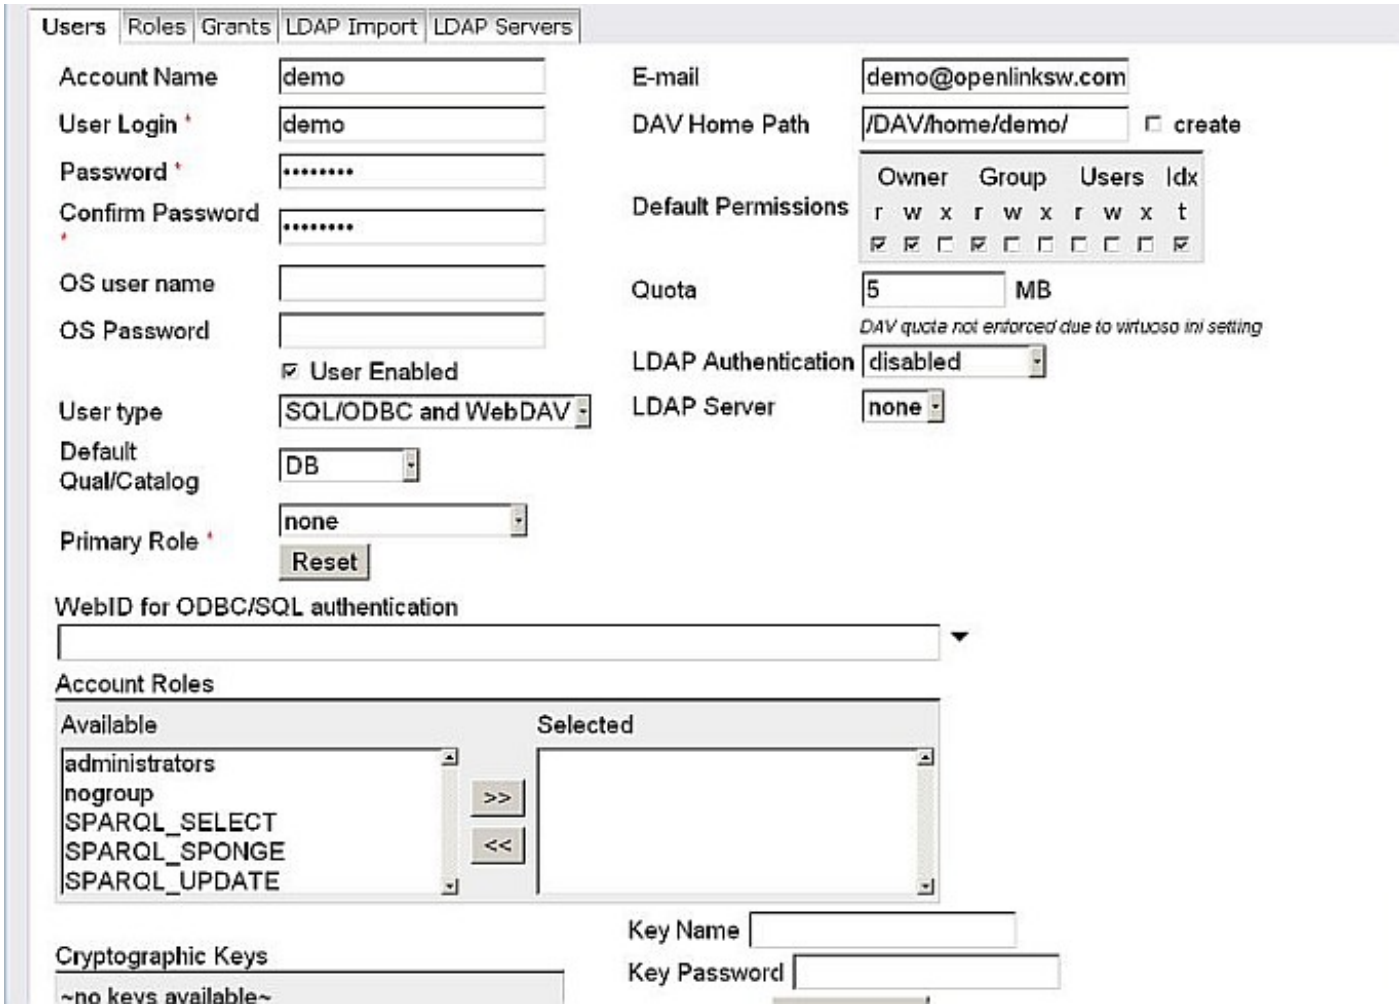
2. Enter dba credentials.
3. Go to System Admin -> User Accounts:

Figure 1.7. Assign SPARQL Role to SQL User



4. Click "Edit" for a given user from the very last right column:

Figure 1.8. Assign SPARQL Role to SQL User

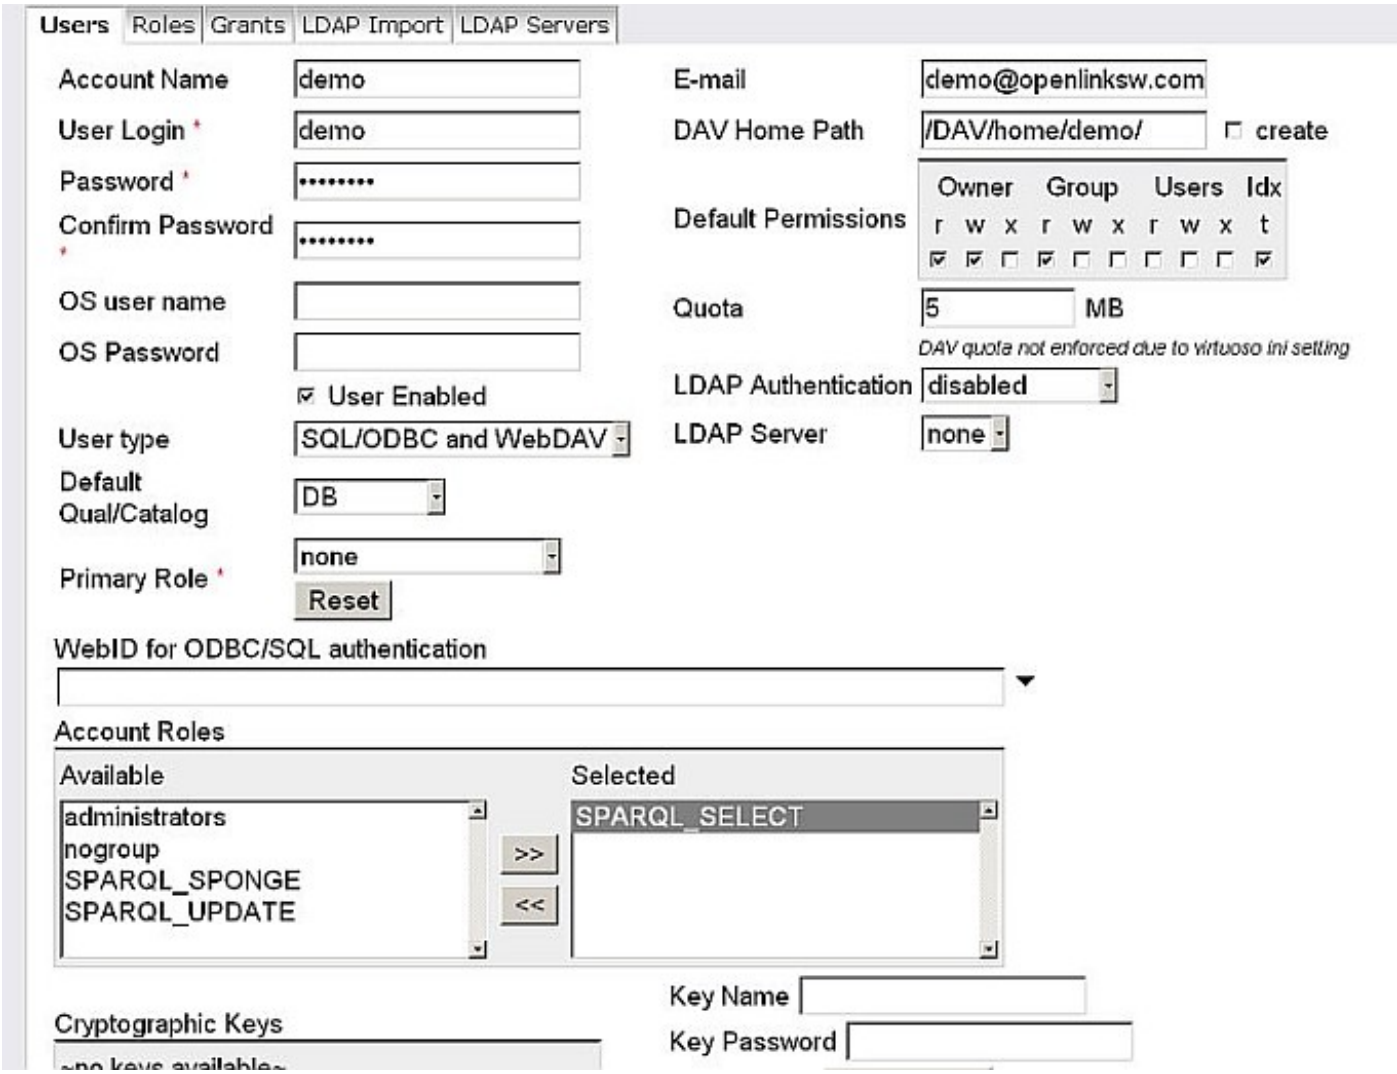


5. From "Accounts Roles" drop-down list select a SPARQL Role, for ex.

   SPARQL_SELECT

   and click the ">>" button:

   Figure 1.9. Assign SPARQL Role to SQL User



6. Click "Save".

1.5.54. How Do I Gecode Data?

What?

Automatic geocoding of data in quad store.

Why?

Enable exploitation of SPARQL-GEO for geospatial oriented queries.

How?

To gecode data one should call the `rdf_geo_fill` API from Conductor or iSQL:

```
SQL> rdf_geo_fill ();

Done. -- 282 msec.
```

SPARQL-GEO sample queries

- All Educational Institutions within 10km of Oxford, UK :

```
SELECT DISTINCT ?thing AS ?uri ?thingLabel AS ?name ?date AS ?established ?lat ?long WHERE
  {
    <http://dbpedia.org/resource/Oxford> geo:geometry ?sourcegeo .
    ?resource geo:geometry ?matchgeo .
```

```
    ?resource geo:lat ?lat .
    ?resource geo:long ?long .
    FILTER ( bif:st_intersects ( ?matchgeo, ?sourcegeo, 5 ) ) .
    ?thing ?somelink ?resource .
    ?thing <http://dbpedia.org/property/established> ?date .
    ?thing rdfs:label ?thingLabel .
    FILTER ( lang ( ?thingLabel ) = "en" )
  }
```

- Things within close proximity of London:

```
SELECT DISTINCT ?resource ?label ?location WHERE
  {
    <http://dbpedia.org/resource/London> geo:geometry ?sourcegeo .
    ?resource geo:geometry ?location ; rdfs:label ?label .
    FILTER ( bif:st_intersects ( ?location, ?sourcegeo, 20 ) ) .
    FILTER ( lang ( ?label ) = "en" )
  }
```

1.5.55. How Can I Delete a Specific Triple Across Graphs?

Suppose the following situation:

- There is a specific triple somewhere in a massive dataset in a Virtuoso DBMS.
- There are too many possible named graphs associated with the pattern so

  SPARQL DELETE

  (which requires

  FROM

  i.e., Named Graph scoping) isn't adequate

What is the solution?

Using SQL you can execute the following:

```
SQL> SPARQL
DELETE FROM rdf_quad
WHERE s = iri_to_id ('http://linkeddata.uriburner.com/about/id/entity/http/twitter.com/kidehen')
  AND o = iri_to_id ('http://purl.org/ontology/bibo/Document')
  AND p = iri_to_id ('http://www.w3.org/1999/02/22-rdf-syntax-ns#type');
```

1.5.56. How Do I Use NOT EXISTS in SPARQL Query?

Virtuoso supports "NOT EXISTS" SPARQL 1.1 feature. For example:

```
SQL> SPARQL
SELECT COUNT(*)
WHERE
  {
    ?s ?p "Novosibirsk"  FILTER NOT EXISTS { ?s ?p "&#1053;&#1086;&#1074;&#1086;&#1089;&#1080;&#1073;&#10
  }

callret-0
```

```
INTEGER
313
No. of rows in result: 1
```

This query is equivalent to the following query:

```
SQL> SPARQL
SELECT COUNT(*)
WHERE
  {
    { ?s ?p "Novosibirsk" } MINUS { ?s ?p "&#1053;&#1086;&#1074;&#1086;&#1089;&#1080;&#1073;&#1080;&#1088

callret-0
INTEGER
 313
No. of rows in result: 1
```

1.5.57. How Do I Use MINUS in SPARQL Query?

Virtuoso supports "MINUS" SPARQL 1.1 feature. For example:

```
SQL> SPARQL
SELECT COUNT(*)
WHERE
  {
    { ?s ?p "Novosibirsk" } MINUS { ?s ?p "&#1053;&#1086;&#1074;&#1086;&#1089;&#1080;&#1073;&#1080;&#1088

callret-0
INTEGER
 313
No. of rows in result: 1
```

This query is equivalent to the following query:

```
SQL> SPARQL
SELECT COUNT(*)
WHERE
  {
    ?s ?p "Novosibirsk"  FILTER NOT EXISTS { ?s ?p "&#1053;&#1086;&#1074;&#1086;&#1089;&#1080;&#1073;&#10
  }

callret-0
INTEGER
313
No. of rows in result: 1
```

1.5.58. How Do I Use Transitive SPARQL Query Options and Exploit Inference Rules?

This section contains subClassOf oriented subsumption examples and examples for Transitive Options e.g., Scope the reasoning to layers in the hierarchy.

Transitive query options examples usage

- Transitivity with sameAs and graph
- Transitive Closure via Graph Path Expressions: TBox
- Transitive Closure via Graph Path Expressions: ABox
- Inference Rule using transitive properties from SKOS vocabulary

subClassOf examples usage

- Processing Large Hierarchies in SPARQL
- Example for TBox Subsumption
- Example for Receptors
- Inference Rule using transitive properties from SKOS vocabulary

1.5.59. What is the difference between the functions SAMPLE, GROUP_CONCAT and GROUP_DIGEST?

This section demonstrates the differences between the functions `SAMPLE` , `GROUP_CONCAT` and `GROUP_DIGEST` .

Assume the following query that should get all ?assets as a list with delimiters:

```
SPARQL SELECT ?view ?path (sql:GROUP_CONCAT (?asset, ' ')) as ?asset_list
FROM <http://mygraph.com>
WHERE
 {
   ?view <viewPath> ?path ;
     <viewContent> ?asset ;
     <viewType>  'phyview'.
 }
;
```

This method is not universal, because conversion to strings will eliminate the difference between strings and IRIs and there should be some delimiter that never appears in values of ?asset. In addition, the query may fail with "row too long" error if values of ?asset are lengthy and/or numerous enough. It is also possible the query not work completely free from duplicates if more than one list is desired. E.g.:

```
SPARQL
SELECT ?view (sql:GROUP_CONCAT (?path, ' ')) as ?path_list
  (sql:GROUP_CONCAT (?asset, ' ')) as ?asset_list
FROM <http://mygraph.com>
WHERE
  {
    ?view <viewPath> ?path ;
      <viewContent> ?asset ;
      <viewType> 'phyview' .
  }
```

will not contain duplicates in lists only if either ?path or ?asset is unique for every found ?view; but if it's so unique then there's no need in the corresponding sql:GROUP_CONCAT().

If there are many values per property but it's enough to return any single value and ignore the rest then use sql:`SAMPLE ()` function instead of sql:`GROUP_CONCAT ()` .

If there are many values per property and it's better to show more than one value but "row too long" error happens, then the sql:`GROUP_DIGEST ()` function can be used:

```
SPARQL
SELECT ?view (sql:GROUP_DIGEST (?path, ' ', 1000, 1)) as ?path_list
  (sql:GROUP_DIGEST (?asset, ' ', 1000, 1)) as ?asset_list
FROM <http://mygraph.com>
WHERE
  {
    ?view <viewPath> ?path ;
      <viewContent> ?asset ;
      <viewType> 'phyview' .
  }
```

1.5.60. How Do I use CONSTRUCT with objects which are value of aggregate function?

The following section demonstrates usage example of CONSTRUCT Query with object which is a value of the aggregate function COUNT:

1. Assume following SPARQL SELECT Query:

```
SELECT DISTINCT ?category COUNT(?category) AS ?count
WHERE
  {
    ?s<http://purl.org/dc/terms/subject> ?category
    FILTER(?s =<http://dbpedia.org/resource/Higgs_boson> || ?s =<http://dbpedia.org/resource/Gluon
  }
```

2. To present it as CONSTRUCT Query, one should put "SELECT DISTINCT" into the CONSTRUCT's WHERE clause as a subquery. So for example it could be:

```
CONSTRUCT
  {
    ?category a<http://www.w3.org/2004/02/skos/core#Concept> .
    ?category<http://www.turnguard.com/virtuoso/aggregates#count>  ?count
  }
WHERE
  {
    {
      SELECT DISTINCT ?category COUNT(?category) AS ?count
      WHERE
        {
          ?s <http://purl.org/dc/terms/subject> ?category
          FILTER(?s =<http://dbpedia.org/resource/Higgs_boson> || ?s =<http://dbpedia.org/resource
        }
    }
  }
```

1.5.61. How Do I Clean Up Errant Data using SPARQL Update Language?

What?

Cleaning up errant data using SPARQL Update Language.

Why?

All data endeavors involve varying degrees of prospective and retrospective error correction.

How?

Given a triple in a Virtuoso Quad store that contains an errant URI e.g. one that accidentally contains spaces, here is a SPARQL example that showcases how to delete said triple using a built-in function:

```
DELETE FROM <your_graph>
  {
    `iri("http://isbsg.clearbluewater.com.au/wsf/datasets/378/Capers Jones_107_12122011081257")`
     a <http://isbsg.org/ontology/data/Dataset>
  };
```

1.5.62. How to Use SPARQL to add missing isDefinedBy relations to an Ontology?

What?

Using SPARQL to add missing isDefinedBy relations to an Ontology.

Why?

isDefinedBy relations make Ontologies (TBox) more navigable using follow-your-nose pattern. This also makes ABox instance data more discoverable.

How?

Use SPARQL to generate relations that associate Classes and Properties the Ontology that describes them.

Example Using the Ontology for vCards

In this example we will use:

- Ontology Document URL: http://www.w3.org/2006/vcard/ns ;
- Ontology URI: http://www.w3.org/2006/vcard/ns# ;
- A local Named Graph IRI to host SPARQL Update (SPARUL) the new relations.

```
## Uncomment line below if using Virtuoso and executing SPARQL via iSQL
## or via an ODBC, JDBC, ADO.NET connection

## SPARQL

## Uncomment line (a SPARQL pragma) below if using Virtuoso and there
## isn't a local Named Graph holding triples retrieved from the Ontology URL

## DEFINE get:soft "add"

INSERT INTO <urn:data:qos:vcard>
  { ?s rdfs:isDefinedBy <http://www.w3.org/2006/vcard/ns#> }
FROM <http://www.w3.org/2006/vcard/ns>
WHERE
  {
    ?s a ?o
  }
```

Example Using the Recorded Media Ontology

In this example we will use:

- Ontology Document URL: http://www.w3.org/ns/ma-ont ;
- Ontology URI: http://www.w3.org/ns/ma-ont# ;
- A local Named Graph IRI to host SPARQL Update (SPARUL) the new relations.

```
SPARQL
INSERT INTO <urn:data:qos:ma-ont>
  { ?s rdfs:isDefinedBy <http://www.w3.org/ns/ma-ont#> }
FROM <http://www.w3.org/ns/ma-ont>
WHERE
  {
    ?s a ?o
  }
```

1.5.63. How Can I execute load of sql dump from jdbc?

LOAD" is not a Virtuoso SQL command, it's an ISQL one. The ISQL checks the command to be executed, whether it's of special "isql"-ish syntax or not, it executes commands it understand and send the rest to the server, unchanged.

There's no way to mimic ISQL's behavior right on the server, without ISQL. However some files can be loaded via the `DB.DBA.VAD_LOAD_SQL_FILE` function.

1.5.64. How Can I Use MODIFY to update triples?

The following queries are equivalent:

```
MODIFY <http://test.com/>
DELETE {?s ?p ?o}
INSERT {?s_new ?p ?o}
FROM <http://test.com/>
WHERE
{
  {
    SELECT iri(bif:replace(str(?s),"http://test.com/link","http://test.com/extra/link" ) )
      AS ?s_new ?s ?p ?o
    WHERE
      {
        ?s ?p ?o FILTER (regex (str(?s), "http://test.com/link"))
      }
  }
}

MODIFY <http://test.com/>
DELETE {?s ?p ?o}
INSERT {`iri(?s_new)` ?p ?o}
FROM <http://test.com/>
WHERE
  {
```

```
    {
      SELECT bif:replace(str(?s),"http://test.com/link","http://test.com/extra/link" )
        AS ?s_new ?s ?p ?o
      WHERE
        {
          ?s ?p ?o FILTER (regex (str(?s), "http://test.com/link"))
        }
    }
  }

MODIFY <http://test.com/>
DELETE {?s ?p ?o}
INSERT
  { `iri(bif:replace(str(?s),"http://test.com/link","http://test.com/extra/link" ))`  ?p ?o }
FROM <http://test.com/>
WHERE
  {
    {
      ?s ?p ?o FILTER (regex (str(?s), "http://test.com/link"))
    }
  }
}
```

1.5.65. How Can I execute INSERT/DELETE (SPARUL) statements against a WebID? protected SPARQL endpoint?

View our sample scenario .

1.5.66. How can I make HTTP Logging and Recording in Virtuoso?

HTTP Logging

Virtuoso can keep http log with all the requests that are made to the HTTP endpoint. Here are the steps:

1. Edit your virtuoso.ini and add the following setting:

   ```
   [HTTPServer]
   HTTPLogFile                = logs/http15022012.log
   ```
2. Restart Virtuoso.
3. Virtuoso will now maintain a http log in the logs subdirectory, with one line per request as in:

   ```
   180.76.5.87 - - [15/Feb/2012:21:50:44 +0100] "GET /data/Wilton_power_stations.json HTTP/1.0" 200 8
     "Mozilla/5.0 (compatible; Baiduspider/2.0; +http://www.baidu.com/search/spider.html)"
   180.76.5.87 - - [15/Feb/2012:21:50:45 +0100] "POST /sparql HTTP/1.0" 200 3012 "" ""
   ```
4. The first request after midnight will open a new logfile, to make sure the logfile does not keep growing. Old logfiles can be gzipped or removed by hand to conserve disk space.

The HTTP log files that Virtuoso produces can be processed by programs like Webalizer or AWstats to accurately measure site usage.

HTTP Logging Format

Virtuoso supports HTTP Logging format string like Apache Module mod_log_config . That string can be set in the "HTTPLogFormat" INI file param which works in conjunction with the "HTTPLogFile" INI file param. For example:

```
...
[HTTPServer]
...
HTTPLogFormat = %h %u %t "%r" %s %b "%{Referer}i" "%{User-agent}i" "%{NetId}e"
```

In this example we have %{User-Agent}i which means to log the HTTP header for user-agent. In similar way can log other input headers, "e" modifier is for environment variable NetId in this case.

Note that not all escapes from Apache Module mod_log_config are supported.

HTTP Recording

Virtuoso can also record the complete HTTP request for both GET and POST requests, including all incoming headers, POST parameters etc. This is a very useful tool for debugging, but it will cost performance and disk space, so it should not be left on for long periods of time. Each request will be written to a separate file.

Note : Some filesystem types like ext2 and earlier versions of ext3 on Linux cannot handle huge amounts of files in a single directory without slowing down the whole system.

Example of a GET request

```
GET /sparql?query=DESCRIBE%20%3CnodeID%3A%2F%2Fb15481%3E&output=text%2Fcxml     HTTP/1.1
Host: example.com
Connection: Keep-alive
Accept: */*
From: googlebot(at)googlebot.com
User-Agent: Mozilla/5.0 (compatible; Googlebot/2.1; +http://www.google.com/bot.html)
Accept-Encoding: gzip,deflate
```

Example of a POST request

```
POST /ods_services/Http/usersGetInfo HTTP/1.1
User-Agent: Opera/9.80 (Macintosh; Intel Mac OS X 10.5.8; U; en) Presto/2.9.168 Version/11.51
Host: example.com
Accept: text/html, application/xml;q=0.9, application/xhtml+xml, image/png, image/webp, image/jpeg, image
  image/x-xbitmap, */*;q=0.1
Accept-Language: en,en-US;q=0.9,ja;q=0.8,fr;q=0.7,de;q=0.6,es;q=0.5,it;q=0.4,pt;q=0.3,pt-
  PT;q=0.2,nl;q=0.1,sv;q=0.1,nb;q=0.1,da;q=0.1,fi;q=0.1,ru;q=0.1,pl;q=0.1,zh-CN;q=0.1,zh-TW;q=0.1,ko;q=0.
Accept-Encoding: gzip, deflate
Referer: https://example.com/ods/
Cookie: interface=js; oatSecurityCookie=0123456878794576; sid=b3fae40reb78bc4bababab3cb2a70fb111
Connection: Keep-Alive
Content-Length: 77
Content-Type: application/x-www-form-urlencoded
Authorization: Basic bnQacPPuhhxs
Content-Transfer-Encoding: binary
```

Example Enabling recording

1. Go to the directory where the database is started from:

   ```
   mkdir sys_http_recording
   chmod 777 sys_http_recording
   ```
2. Edit virtuoso.ini and set:

   ```
   [HTTPServer]
   EnableRequestTrap          = 1
   ```
3. Next connect with isql to your database and run the following commands:

   ```
   registry_set ('__save_http_history_on_disk', '1');
   registry_set ('__save_http_history', '/');
   ```
4. Finally restart Virtuoso.
5. As result at this point every HTTP GET and POST request will be logged with all the parameters, headers and settings.

Example Disabling recording

1. To temporary disable the recordings, edit virtuoso.ini and set:

   ```
   [HTTPServer]
   EnableRequestTrap          = 0
   ```
2. Next you should remove the two registry items:

   ```
   registry_remove ('__save_http_history_on_disk');
   registry_remove ('__save_http_history');
   ```
3. Finally restart Virtuoso.

1.5.67. Quad Store Data Loading via Virtuoso's In-built Content Crawler?

This section covers the use of Virtuoso's in-built content crawler as a mechanism for scheduled of one-off data loading operations for its native quad store.

Why is this important?

Transforming external data sources into Linked Data "on the fly" (e.g., via the 'Sponger') is sufficient for many use cases, but there are times when the volume or sheer nature of a data source makes batch-loading necessary. For example, Freebase offers RDF representations of its data, but it doesn't publish RDF dumps; even if it did, such dumps would usually be outdated by the time they were loaded. Thus, a scheduled crawl of that resource collection offers a viable alternative.

How to Set Up the Content Crawler for Linked Data generation and import

The Virtuoso Conductor can be used to set up various Content Crawler Jobs:

- Setting up a Content Crawler Job to Import Linked Data into the Virtuoso Quad Store
- Setting up a Content Crawler Job to Retrieve Sitemaps (when the source includes RDFa)
- Setting up a Content Crawler Job to Retrieve Semantic Sitemaps (a variation of the standard sitemap)
- Setting up a Content Crawler Job to Retrieve Content from Specific Directories
- Setting up a Content Crawler Job to Retrieve Content from ATOM feed
- Setting up a Content Crawler Job to Retrieve Content from SPARQL endpoint

1.5.68. What is the ShortenLongURIs Virtuoso configuration parameter?

The ShortenLongURIs parameter is a Virtuoso configuration setting to shorten extremely long URIs in datasets when loading with the RDF Bulk Loader.

Some RDF datasets have long URIs that exceed the Virtuoso internal maximum size of 1900 bytes and thus need to be shortened to avoid errors like:

```
"SR133: Can not set NULL to not nullable column 'DB.DBA.RDF_QUAD.S' (or .O, or .P)"
```

which has been seen loading some of the DBpedia 3.7 datasets, for example.

The Virtuoso ShortenLongURIs parameter needs to be set in the [SPARQL] section of the Virtuoso configuration file (virtuoso.ini by default) and restart the Virtuoso Server.

```
[SPARQL]
.
.
.
ShortenLongURIs = 1
.
.
.
```

Note : This parameter is only in the Virtuoso 06.03.3131+ commercial builds, at the time of writing it is not included in the open source 6.1.4 archives but will be in the next 6.1.5 release. A patch to enable this feature is however available from the Virtuso patches page on source forge , which can be applied to a 6.1.4 archive from source forge and the Virtuoso server binary rebuilt.

1.5.69. How Can I send SOAP requests to Virtuoso SPARQL Endpoint?

This section presents sample scenario how to execute SPARQL query in SOAP request over Virtuoso SPARQL Endpoint.

1. Assume the following sample SOAP request containing simple SPARQL query:

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/" xmlns:xsd="http://www.
   <soapenv:Body>
      <query-request xmlns="http://www.w3.org/2005/09/sparql-protocol-types/#">
         <query xmlns="">SELECT DISTINCT ?z FROM virtrdf: {?x ?y ?z .} LIMIT 10</query>
      </query-request>
   </soapenv:Body>
```

```
</soapenv:Envelope>
```

2. Save locally the content from above for ex. to file with name "soap.xml".
3. To pass the SOAP request to a Virtuoso SPARQL Endpoint, execute the following curl command:

```
$ curl -d@soap.xml -H "Content-Type:text/xml" -H "SOAPAction: ''" http://example.com/sparql
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
  <soapenv:Body>
    <query-result xmlns="http://www.w3.org/2005/09/sparql-protocol-types/#">
      <sparql xmlns="http://www.w3.org/2005/sparql-results#" xmlns:xsi="http://www.w3.org/2001/XML
        <head>
         <variable name="z"/>
        </head>
        <results distinct="false" ordered="true">
          <result>
            <binding name="z">
             <uri>http://www.openlinksw.com/schemas/virtrdf#QuadMapFormat</uri>
            </binding>
          </result>
          <result>
            <binding name="z">
             <uri>http://www.openlinksw.com/schemas/virtrdf#QuadStorage</uri>
            </binding>
          </result>
          <result>
            <binding name="z">
             <uri>http://www.openlinksw.com/schemas/virtrdf#array-of-QuadMapFormat</uri>
            </binding>
          </result>
          <result>
            <binding name="z">
             <uri>http://www.openlinksw.com/schemas/virtrdf#QuadMap</uri>
            </binding>
          </result>
          <result>
            <binding name="z">
             <uri>http://www.openlinksw.com/schemas/virtrdf#QuadMapValue</uri>
            </binding>
          </result>
          <result>
            <binding name="z">
             <uri>http://www.openlinksw.com/schemas/virtrdf#array-of-QuadMapColumn</uri>
            </binding>
          </result>
          <result>
            <binding name="z">
             <uri>http://www.openlinksw.com/schemas/virtrdf#QuadMapColumn</uri>
            </binding>
          </result>
          <result>
            <binding name="z">
             <uri>http://www.openlinksw.com/schemas/virtrdf#array-of-QuadMapATable</uri>
            </binding>
          </result>
          <result>
            <binding name="z">
             <uri>http://www.openlinksw.com/schemas/virtrdf#QuadMapATable</uri>
            </binding>
          </result>
          <result>
            <binding name="z">
             <uri>http://www.openlinksw.com/schemas/virtrdf#QuadMapFText</uri>
            </binding>
          </result>
        </results>
      </sparql>
    </query-result>
  </soapenv:Body>
</soapenv:Envelope>
```

1.5.70. How Can I Delete Triples containing blank nodes?

Please see details and sample scenario here .

1.5.71. How Can I Get a full explain plan for a simple SPARQL query?

Please see details and sample scenario here .

1.5.72. How Can I Use Expressions inside CONSTRUCT, INSERT and DELETE {...} Templates?

Please examples here .

1.5.73. How to optimize bif:dateadd in SPARQL query using selective index-friendly filter?

What?

Index-friendly filter for Date range (bif:dateadd) optimization within SPARQL query.

Why?

Achieve fast results and better performance.

How?

Assume the following SPARQL query:

```
SELECT ?wiki,
       ?dbp,
       bif:datediff('second',  xsd:DateTime(?extracted), now()) AS ?secondsAgo
 FROM <http://nl.dbpedia.org>
WHERE
  {
    ?wiki foaf:primaryTopic ?dbp .
    ?dbp dcterms:modified ?extracted .
    FILTER ( bif:datediff('minute', now(), xsd:DateTime(?extracted)) <= 10 )
  }
ORDER BY DESC(?extracted)
LIMIT 30
```

Let's take a look at the calculation of:

```
FILTER ( bif:datediff('minute', now(),  xsd:DateTime(?extracted)) <= 10 ) .
```

For each "is modified" triple we:

1. Convert ?extracted to xsd:dateTime;
2. Calculate datediff;
3. Make a comparison and know whether we hit or miss 10 minutes interval

Written so, this will lead to a potentially long loop, because even if the optimizer will realize that the filter is selective, it can't discover why is it so selective.

Now let's change the filter to:

```
FILTER ( ?extracted > bif:dateadd('minute', -10, now())) .
```

`now()` can be calculated once at the very beginning of the query execution because it does not depend on any rows in a given table. Then `bif:dateadd` has all arguments known and thus the whole `bif:dateadd('minute', -10, now())` can be calculated only once and produce some value. Therefor `FILTER ( ?extracted > some_known_value )` can be represented as a single search step: look at index and get triples with known P, known G, O greater than the given one and any S. That's pretty fast and predictable step, good for both optimizer and the runtime.

We can rephrase the query to filter index-friendly:

```
SELECT ?wiki,
       ?dbp,
        bif:datediff('second',  xsd:DateTime(?extracted) ,
        now()) AS ?secondsAgo
 FROM <http://nl.dbpedia.org>
WHERE
  {
    ?wiki foaf:primaryTopic ?dbp .
    ?dbp dcterms:modified ?extracted .
     FILTER ( ?extracted > bif:dateadd('minute', -10, now()))
  }
ORDER BY DESC (?extracted)
LIMIT 30
```

In this case the presence or the absence of the order by does not matter too much, because the query is way more straightforward: selective index-friendly filter first, and the selection could be ordered naturally via hot index used by the filter.

Note also that if you know the datatype of an object literal, there's no need to write a cast like xsd:dateTime --- it can make an expression index-unfriendly even if it will always return the argument unchanged on your specific data.

1. View the SPARQL Query Definition via SPARQL Protocol URL
2. View the SPARQL Query Results via SPARQL Protocol URL

1.5.74. How can I Determine the data usage across a Virtuoso instance?

What?

How to determine the data usage across a Virtuoso instance.

Why?

There are times when a variety of DBMS activities (e.g., automated content crawling) can lead to increase in database size, without the instance operator being fully aware of such activities and their consequences.

How?

Run the following statement:

```
        SELECT TOP 20 * FROM sys_index_space_stats ORDER BY iss_pages DESC;

Query result:
ISS_KEY_TABLE ISS_KEY_NAME ISS_KEY_ID            ISS_NROWS       ISS_ROW_BYTES ISS_BLOB_PAGES ISS_ROW_PAG
 WS.WS.SYS_DAV_RES         WS.WS.SYS_DAV_RE..    492   630627      437635794     501049         57521
 DB.DBA.RDF_QUAD           DB.DBA.RDF_QUAD       487   25134153  321502272     0                    49779
 DB.DBA.RDF_QUAD           RDF_QUAD_POGS         489   14749814  307163163     0                    47191
 WS.WS.SYS_DAV_RES....     DB.DBA.RDF_OBJ        501   1139934   160445830     10748          21478
 WS.WS.SYS_DAV_RES         WS.WS.SYS_DAV_RE..    729   432       307124        28840          97
 DB.DBA.RDF_IRI            DB.DBA.RDF_IRI        485   4378779   138542078     0                    22479
 DB.DBA.RDF_IRI            DB_DBA_RDF_IRI_UN..   486   4259557   139496730     0                    20187
......
```

1.5.75. How to discover the capabilities of a SPARQL endpoint to enhancing SPARQL-FED usage from Virtuoso instances?

What?

How to discover the capabilities of a SPARQL endpoint en route to enhancing SPARQL-FED usage from Virtuoso instances.

Why?

There are features supported in Virtuoso SPARQL that aren't supported by other SPARQL engines. There are also a lot of Virtuoso instances behind bubbles in the LOD cloud. Net effect, a Virtuoso instance operator is faced with varied behavior when attempting to use SPARQL-FED functionality.

How?

Run this command to load metadata (or lack thereof) from an external SPARQL endpoint:

```
SPARQL LOAD SERVICE <{sparql-endpoint-iri> DATA
```

Example

1. Run:

```
Query result:
ANY
 Load service <http://lod.openlinksw.com/sparql> data -- done.
 Trying to query <http://lod.openlinksw.com/sparql> as SPARQL web service endpoint, POST mode...
```

2. Check the retrieved data:

```
SPARQL
SELECT *
  FROM virtrdf:
 WHERE
     {
       <http://lod.openlinksw.com/sparql> ?p ?o
     }
 LIMIT 10

Query result:
p                                                                o
ANY                                                              ANY
http://www.openlinksw.com/schemas/virtrdf#isEndpointOfService      http://lod.openlinksw.com/sparq
http://www.openlinksw.com/schemas/virtrdf#dialect                000037ff
```

1.5.76. How to split a urlencoded ";-" separated list of urls in a SPARQL query?

1. Assume the following string: "http://example.org/test1;http://example.org/test2".
2. In order to split the given string into two values i.e. http://example.org/test1 and http://example.org/test2 , one should use `split_and_decode()` which returns an array. Thus the `aref()` also needs to be used for loading the elements.
3. Example:

```
SELECT bif:aref (bif:split_and_decode('http%3A%2F%2Fexample.org%2Ftest1%3Bhttp%3A%2F%2Fexample.org
{ ?S ?P ?O }
LIMIT 1
```

- View the SPARQL Query Definition via SPARQL Protocol URL
- View the SPARQL Query Results via SPARQL Protocol URL

1.5.77. How to Update Large SPARQL Data avoiding due to database checkpoint abortion?

Assume while performing large SPARQL update, for example of triples around 80 millions in total, one gets the following error which aborts the update:

```
"Transaction aborted due to a database checkpoint or database-wide
atomic operation. Please retry transaction" .
```

The error means that the SPARQL update has possibly encountered a database checkpoint during the load. Thus one should check the CheckpointInterval in the INI file and possible increase its value:

```
;
;  Server parameters
;
[Parameters]
...
CheckpointInterval       = 60
...
```

Note: The RDF Bulk loader can be used for loading large datasets, and it will handle the checkpoint matter automatically.

1.5.78. How to Manage SSL Protocols and Ciphers used with Virtuoso?

What?

As of Virtuoso 7.2, SSL protocol and cipher support is now configurable for connections from all HTTP, ODBC, JDBC, ADO.NET, and OLE-DB clients.

Why?

Default binding to OpenSSL can expose Virtuoso instances to version- and cipher-specific SSL vulnerabilities (e.g., recent Poodle exploit). Being able to scope Virtuoso's use of SSL to one or more specific versions provides instance administrators better protection against a moving target.

How?

Basic SSL Protocol Configuration

Basic configuration is through the `SSL_Protocols` values in the `[Parameters]` and `[HTTP]` sections of the Virtuoso INI file. These are comma+space-separated (", ") value lists. Including a protocol name explicitly enables it; preceding the protocol name with an exclamation point ("`!` ") explicitly disables it.

Basic SSL Protocol Configuration

Table 1.1. Supported SSL Protocols and INI keyword values List

SSL/TLS Version	Value for INI file	Notes
SSLv2	-	Permanently disabled.
SSLv3	`SSLv3`	Disabled by default. To our knowledge, only required by IE6/Windows XP clients.
TLSv1	`TLSv1`	Enabled by default.
TLSv1.1	`TLSv1.1`	Enabled by default, supported if available in local `openssl` library.
TLSv1.2	`TLSv1.2`	Enabled by default, supported if available in local `openssl` library.

Advanced SSL Cipher List Configuration

The `SSL_Cipher_List` values in the `[Parameters]` and `[HTTP]` stanzas of the Virtuoso INI file may also be adjusted, to disable particular ciphers when there are security reports about some new attack that breaks them. These are colon-separated ("`:` ") value lists.

Including a protocol name or groupname explicitly enables it; preceding the protocol name with an exclamation point ("`!` ") explicitly disables it. You can review the ciphers supported by your local `OpenSSL` library with the command:

```
openssl ciphers -v ALL
```

For instance, we recommend explicitly forbidding anonymous cipher suites (i.e., ones that do not use certificates, and are therefore susceptible to man-in-the-middle attacks) using `!aNULL` .

We also recommend including `@STRENGTH` at the end of the list, so that `OpenSSL` will prioritize the enabled ciphers by key length, regardless of the list order.

Recommended Settings

The sample settings below provide a reasonable tradeoff of security versus flexibility. As shown, we have enabled `SSLv3` on the HTTPS ports for IE6 users, but left this disabled on the SQL data port.

```
[Parameters]
SSL_Protocols   = TLSv1, TLSv1.1, TLSv1.2
SSL_Cipher_List = HIGH:!aNULL:!eNULL:!RC4:!DES:!MD5:!PSK:!SRP:!KRB5:!SSLv2:!EXP:!MEDIUM:!LOW:!DES-CBC-SHA

[HTTP]
SSL_Protocols   = SSLv3, TLSv1, TLSv1.1, TLSv1.2
SSL_Cipher_List = HIGH:!aNULL:!eNULL:!RC4:!DES:!MD5:!PSK:!SRP:!KRB5:!SSLv2:!EXP:!MEDIUM:!LOW:!DES-CBC-SHA
```

Chapter 2. Installation Guide

Abstract

This chapter applies exclusively to the various commercial releases of Virtuoso. If you are working with the open source version, please refer to the instructions on the web site where you obtained it.

This chapter describes how to install OpenLink Virtuoso VDBMS. It contains both a quick start install guide and full walk through install guides for major platforms.

Virtuoso has been designed from the ground-up to be easy to implement.

The installation generally runs without problems, run the setup program or script and follow the on screen instruction prompts. You will be asked some questions, if in any doubt please follow the instructions in this guide in order to install and configure your Virtuoso components correctly.

Once installed, each instance of Virtuoso is controlled by an INI (initialization) file. This file links the Virtuoso Server process with an actual database file or device. For example, the demo instance of Virtuoso on all platforms is controlled by the demo.ini file that is found in the demo directory along with the demo.db and related files. There is a one-to-one relationship between server processes and database files.

The INI file is a text file consisting of keys and key values. You will set several of these values during installation. At any time thereafter, their values can be changed by editing the INI file with a standard text editor.

The details of the INI file sections, keys, and the meanings of the key values are described in the Configuring Server Startup Files section.

2.1. Virtuoso on All platforms Commmon Specifics

2.1.1. Installation Requirements

A typical installation will require a minimum of 400Mb of hard disk space to install the code, samples, documentation and sample database. The database will need additional space for data inserted, backups, logs and reports, web pages, etc.

The size of the database .db file will not reduce when data is removed. The spare space will however be reclaimed for later use.

2.1.2. Operational Requirements

The Virtuoso database requires a minimum of 64Mb of system memory for each instance to operate in. Each connection will take between 70kb and 130kb of memory.

The memory usage is affected by the following parameters in the Virtuoso configuration file .

ServerThreads

ServerThreadSize

MainThreadSize

FutureThreadSize

NumberOfBuffers

See the following Parameter section for more details.

2.1.3. Operating System Support

Virtuoso runs on the following operating systems:

Windows

Linux

Unix: AIX, HP-UX, Solaris, etc.

Mac OS X

2.1.4. Limits

The below table lists the most important parameters and limits for a database or a Virtuoso server instance. For space consumption of individual data types, see Space Consumption .

Table 2.1. Limits

Limit Description	Value
Identifier length	100
User name and password length	100
SQLstmt and proc text	100K+
varchar length	Constrained by max row length when stored into non-LOB column, 10MB inside procedure code.
Numeric precision	Max 40 digits
LOB column length	2GB
row length	4086
Columns per row	200
Database size	32TB for data, 32TB for temp data
Page size	8K
File size	64 bit file offsets on supporting OS's
Files per database	unlimited
Table size	Up to database size
Tables per database	64K keys, a table takes 1 key for primary key, 1 key per index and 1 key for each obsolete primary key layout resulting from adding or dropping columns.
Indexes per table	Unlimited, subject to global cap on keys.
Row in sorting/distinct temp	4078b, as in tables
Locks per transaction	Depends on memory, 16b per row lock, 60b per page with at least one row lock.
Changes per transaction	Depends on memory, ini parameter allows cap on rollback before image.
Virtual memory>	Depends on OS, 64 bit pointers on 64 bit platforms
Threads	Depends on OS, ini files specifies cap for pool for SQL client and web server worker thread pools.
Max connections	Depends on OS fdset size, at least 2048, license can set a limit
Memory per connection	22K plus up to 100 cached SQL statement compilations

2.2. Virtuoso for Windows

2.2.1. Before You Start

To ensure a smooth installation, please review the following checklist before you start the setup program.

Have you downloaded the software?

If you have not already done so, please download your copy of OpenLink Virtuoso from the OpenLink web site. The URL is http://www.openlinksw.com . When you visit the site, select "Download & Evaluation".

1. Select product "OpenLink Virtuoso: Personal Edition "
2. From "Product Category" choose "Universal Server"
3. From "Product" choose "Virtuoso Universal Server"
4. Select "Database Version"
5. From "server OS" select "Windows" and click "Next"
6. Select a release and click "Next"
7. You will be prompt to login in not already.
8. Click "Next"
9. Download the desired component. For example, click the HTTP link for "Multi-Threaded Universal Server (Commercial Edition) for OpenLink Virtuoso 4.x"

Do you have the License file?

The server will need a license file, and this is automatically delivered by email as part of the download process. It is therefore important to supply a valid email address. The installer will prompt for the license file location.

Reinstalling Virtuoso?

If you are reinstalling Virtuoso, you must first shutdown any additional database servers you have configured on non default ports. The databases on port 1111 and 1112 will automatically be stopped during the install process. On Windows NT/2000/XP, go to the services applet in the Control Panel. There you can stop services that appear with names of the form "OpenLink Virtuoso DBMS Server [instance name]".

On Windows NT/2000/XP you can also shut them down with the following commands in the Virtuoso\bin directory:

```
virtuoso-odbc-t.exe +service stop
virtuoso-odbc-t.exe +instance myinstance +service stop
virtuoso-odbc-t.exe +instance anotherinstance +service stop
```

Note:

There is an alternative executable available for Virtuoso called: virtuoso-odbc-f.exe, which you may have installed. This version is designed for versions of Windows that offer no native threading support such as Windows 98, and offers no advantages over virtuoso-odbc-t.exe for Windows NT/2000/XP.

You can list the services with their status using:

```
virtuoso +service list
```

Allocation of TCP/IP ports

The Default database have the following port allocations:

Table 2.2. Port Usage

Port	Used by
1111	Default Virtuoso Server port
8889	Default Virtuoso Visual Server Administration Interface HTTP port

By default, the Virtuoso DBMS listens on port 1111. This port number is not selectable at install time. If the port is currently in use by another server then after the installation completes you will need to change the port number in the Local Virtuoso ODBC DSN that is created during the installation process, and also in the following file:

```
C:\Program Files\OpenLink Software\Virtuoso 5.0\bin\virtuoso.ini
```

To check if a port is in use on NT, you can use the following command, and review the output:

```
netstat -an | more
```

Do you already have an ODBC Data Source Name (DSN) that works?

The Virtual Database aspects of the Virtuoso for ODBC assumes that you already have an ODBC driver on your machine from a database vendor, OpenLink Software, or from another 3rd party vendor. It is a useful sanity-check to ensure that you have an ODBC System Data Source Name (DSN) on your machine, and that it successfully connects to your database, and that it retrieve data. Any ODBC compliant tool can be used to test that your ODBC Data Source Name (DSN) works, such as the sample application we provide - C++ Demo32, and that it is sufficiently robust to operate with Virtuoso. Virtuoso is ODBC Driver Independent and certified to work with any drivers that are ODBC level 1 or higher.

2.2.2. Getting To Know Your Virtuoso Components

Virtuoso is made up of several components, these components fall into two distinct categories: Client Components and Server Components.

Client Components Package

These are the components typically used to communicate with a local or remote Virtuoso server, this includes:

Virtuoso Drivers for ODBC

Virtuoso Drivers for JDBC

ISQL Utility

ISQLO Utility

Documentation

Samples

Server Components

These are the components that service Virtuoso clients, these include:

Virtuoso Virtual Database Servers for: ODBC based interfaces - the files "virtuoso-odbc-f" (for Virtuoso Lite) and "virtuoso-odbc-t" (For Virtuoso Enterprise Edition).

Virtuoso HTTP Server.

Virtuoso System Manager to configure the database through the HTTP interface.

2.2.3. Installation Steps

Prepare to Install

If you are upgrading an existing Virtuoso installation and want to preserve your existing data and configuration files:

1. Shut down your Virtuoso instance as normal.
2. Right-click on the existing `Virtuoso.app` (exact name may vary), and select `Show Package Contents`.
3. Drill down to `Contents` -< `virtuoso` -< `database`.
4. Check the size of the `virtuoso.trx` file, found in the `database` folder alongside the `virtuoso.db` and `virtuoso.ini` files.

    - If zero bytes, proceed to step 6.
    - If larger than zero bytes, start the instance from the command line with the extra argument, " +checkpoint-only ", and recheck `.trx` file size -- expecting zero bytes.
    - If larger `.trx` files persist, contact Technical Support .

5. Make a backup of your existing Virtuoso Database and Configuration files (defaults are `virtuoso.db` and `virtuoso.ini`) prior to performing the steps that follow. *Note* : Virtuoso's online backup feature , if enabled, should have already generated a backup-set.
6. Use the Add/Remove Programs utility to uninstall any previously installed Virtuoso components. Data and configuration files will be left behind by this process.

Download the Virtuoso Installer Program

1. Download the Virtuoso 7.2 installer archive (wavpz2zz.msi) from the download site .

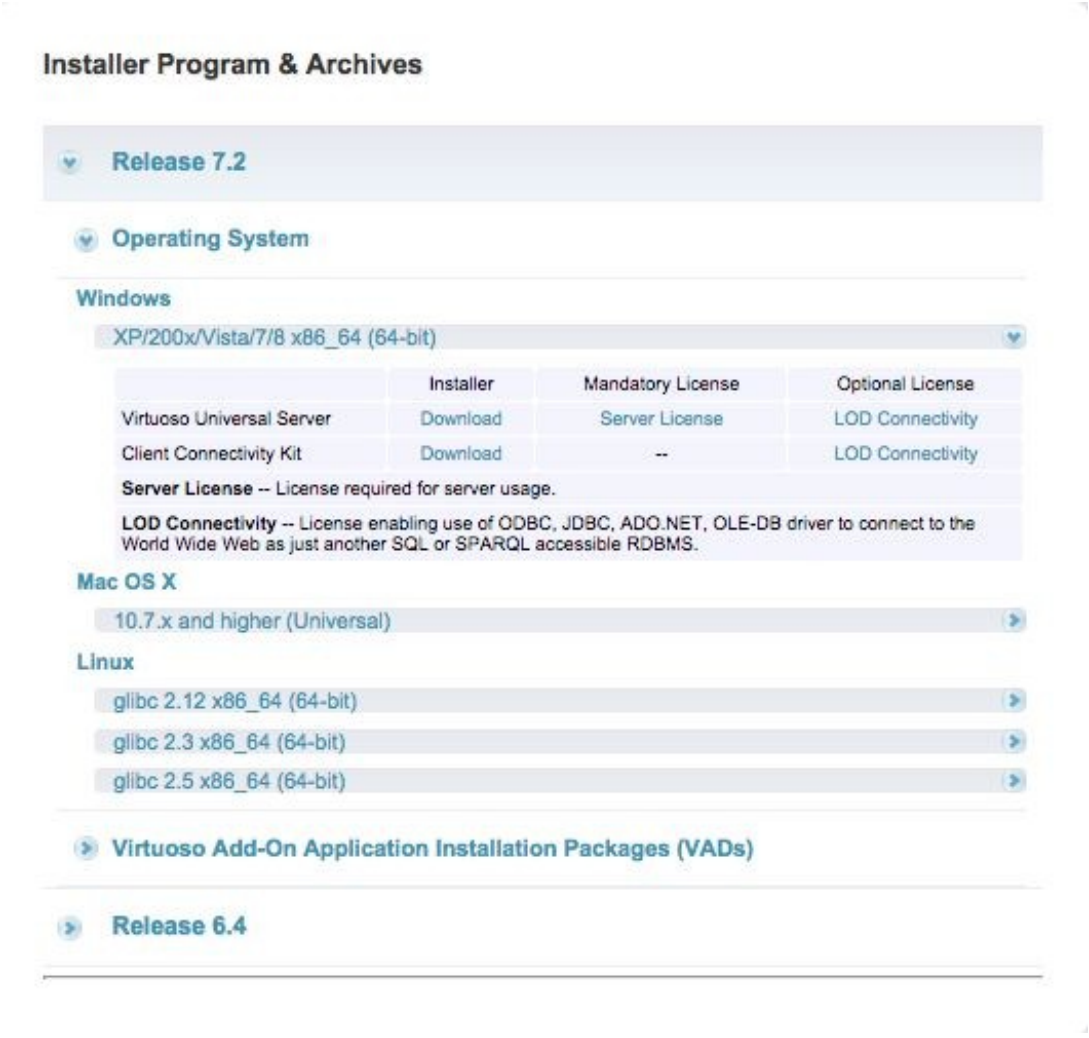
   Note

   : Virtuoso 7.x is 64-bit only, and requires Vista or Windows Server 2003, or later.

Obtain a License File

1. If you haven't already obtained a suitable Virtuoso 7.x license file, return to the download site , and click the link for *Free Eval License* (15 day duration, requires only your email address) or *Free Pilot License* (30 day duration, requires some additional personal and business information).

   Figure 2.1. Installing the Virtuoso Universal Server on Windows -- Obtain a License File



2. Fill out the relevant form, and download the license file when presented.

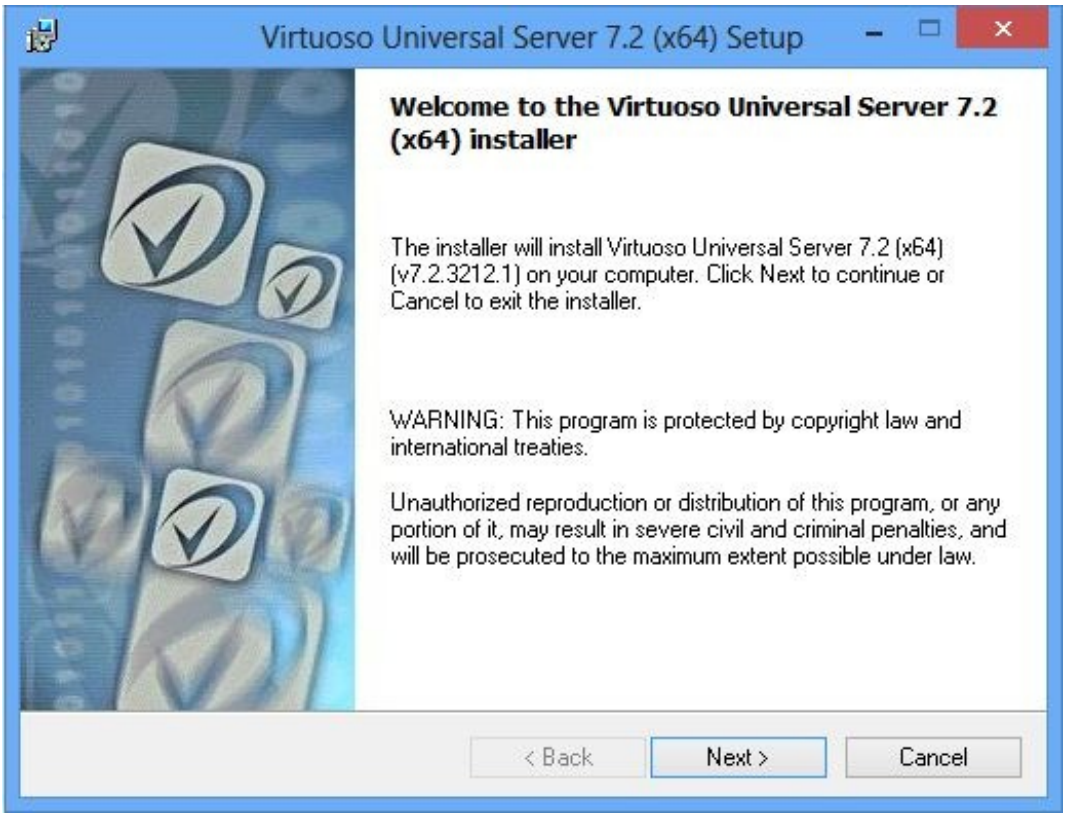
   Note

   : the file must be named `virtuoso.lic` for use. Some browsers may rename the file during download; you can simply rename the file on your machine.

Run the Virtuoso Installer

1. Double-click the installer archive, `wavpz2zz.msi` , to start the process with the Installer Program Introduction.

   Figure 2.2. Installing the Virtuoso Universal Server on Windows -- Run the Virtuoso Installer

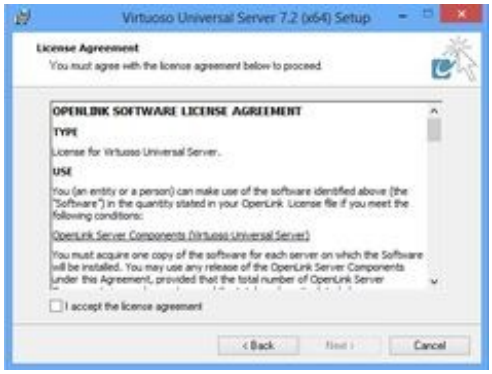
   


2. Click

   Next

   , and you'll be presented with the License Agreement:

   Figure 2.3. Installing the Virtuoso Universal Server on Windows -- License Agreement

3. Tick the box for

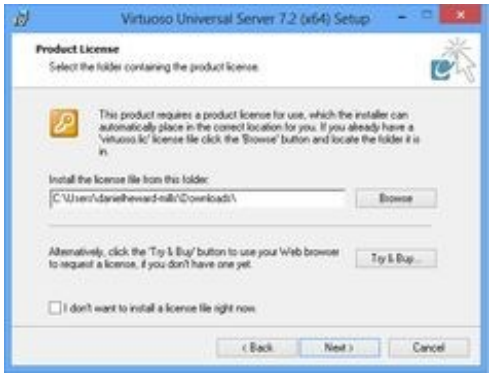
   I accept

   , and click

   Next

. You'll be asked to locate your license file:

Figure 2.4. Installing the Virtuoso Universal Server on Windows -- License Agreement Accept



4. Use the

   Browse

   button to locate the license file you obtained earlier, or click the

   Try and Buy

   button to obtain a new one now, or tick the box for

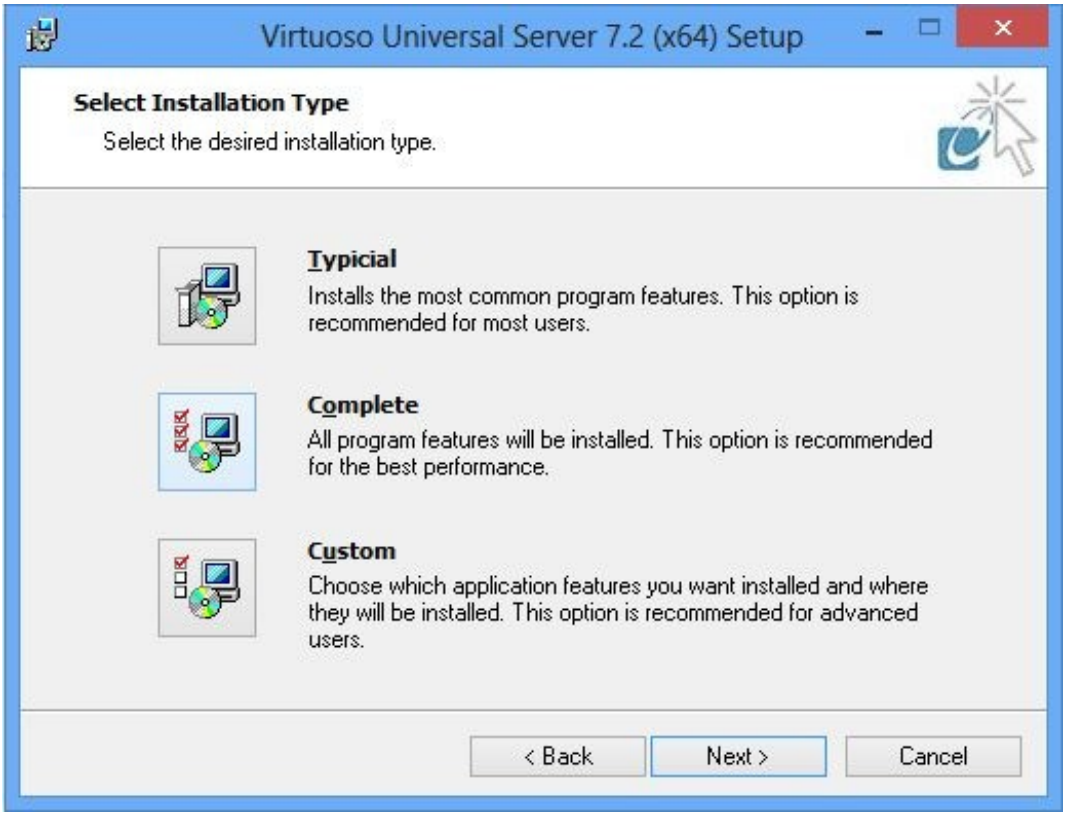
   I don't want to install a license file now

   . Then, click

   Next

   . You'll be prompted to select an Installation Type:

Figure 2.5. Installing the Virtuoso Universal Server on Windows -- Choose Installation Type



5. Select the desired option:

   - *Typical*

     -- installs to the default filesystem location, may not include all components
   - *Complete*

     -- installs to the default filesystem location, includes all components
   - *Custom*

     -- to install to any filesystem location, and select which components will be installed

6. Click

   Next

   , and if you chose

   Typical

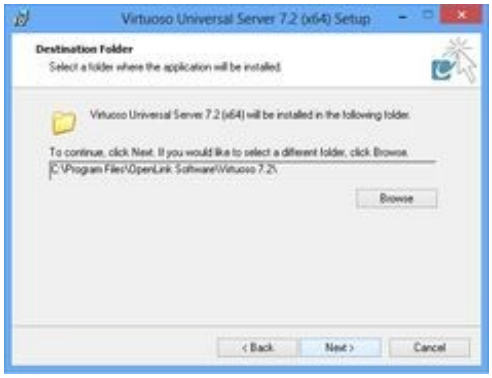
   or

   Complete

   , skip this and the next step; if you chose

   Custom, you'll be prompted to choose a destination folder:

Figure 2.6. Installing the Virtuoso Universal Server on Windows -- Choose Destination Folder



7. Click

   Next

   , and if you chose

   Custom

   , you'll be prompted for Feature Selection:

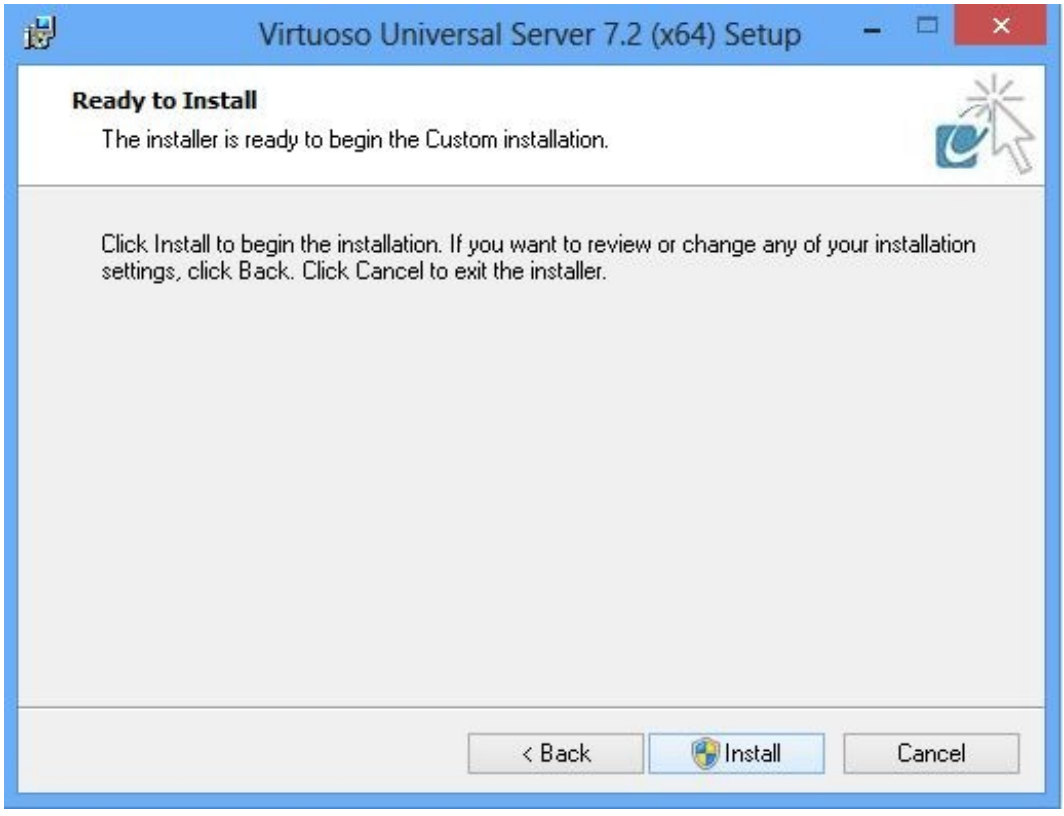
   Figure 2.7. Installing the Virtuoso Universal Server on Windows -- Feature Selection

8. Click

   Next

   , and the installer will indicate it's ready to begin:

   Figure 2.8. Installing the Virtuoso Universal Server on Windows -- Read to install



9. Click install, and wait for notification of completion.

Start the Virtuoso Service Manager, and Locate it in the Task Bar

1. Launch the Virtuoso Service Manager from your

   Start

   menu.

   Figure 2.9. Installing the Virtuoso Universal Server on Windows -- Launch the Virtuoso Service Manager.

2. Look for an icon to appear in the Task Bar at the bottom right of your screen.

   Figure 2.10. Installing the Virtuoso Universal Server on Windows -- Look for an icon

Start and Administer your Virtuoso Instance

1. Right-click on the Virtuoso Service Manager icon in the Task Bar, and click on

   OpenLink Virtuoso Server - Start

   :

   Figure 2.11. Installing the Virtuoso Universal Server on Windows -- Start your Virtuoso Instance

2. Open the

   Virtuoso Conductor

   , Virtuoso's HTTP-based administration tool, by loading this URL in your Web Browser: http://example.com/conductor .

   Figure 2.12. Installing the Virtuoso Universal Server on Windows -- Virtuoso Conductor

3. Use the Conductor to configure your Virtuoso instance for future use. For example, it is

   strongly

   advised that you change the default passwords for the

   dba

   and

   dav

   super-user accounts (drill down to

   System Admin

-<

User Accounts

).

Optional - Restore your old Data and Configuration Files

If you preserved existing data and configuration files at the start of this process, now is the time to bring them back into play.

1. If you used Virtuoso's online backup feature, the documentation will walk you through the restoration process.
2. If you simply copied the INI and DB files elsewhere, and if they were Virtuoso 7.x files, you can just stop the current Virtuoso instance, and replace the newly created INI and DB with the old ones. For best results, we do advise that you compare the content of the old INI with the new, and add any new settings from the new to the old, adjust as may be appropriate to your deployment.
3. If you simply copied the INI and DB files elsewhere, and if they were Virtuoso 6.x or older files, there are some extra steps that must be taken.

2.2.4. Post Installation

Post-Installation Sanity Check

A quick way to check that the database is running, is to point a browser to the http port. The following example URLs will show the System Manager for the default, and the demo Virtuoso databases:

```
http://example.com
http://example.com:8890
```

Troubleshooting DB Startup Failures

Install failure

Check the .log file in your Virtuoso installation db location, for ex:

```
C:\Program Files\OpenLink Software\Virtuoso 7.2\db\virtuoso.log
```

which is for the database and log files etc. in order to review the installed files binaries and databases (defaults) for issues if install fails.

.lck existance

Check .log in case of .lck issue

Delete the .lck file and repeat the steps from above.

.trx incompatiblity issue

Check .log in case of .trx incompatiblity issue

oplmgr issue

See Troubleshooting License Problems

2.2.5. Starting Your Virtuoso Server

Due to subtle differences between the Windows 95 family (including Windows 98 and Windows ME) and the Windows NT family (including Windows 2000, Windows XP, Vista, Windows 7, Windows 2000 Server, Windows Server 2003, and Windows Server 2008), specific instructions for starting and stopping your Virtuoso server are supplied for each Windows family.

Windows NT family

You can start your Virtuoso server in one of two ways, automatically or manually, the default mode configured by your installer is Automatic.

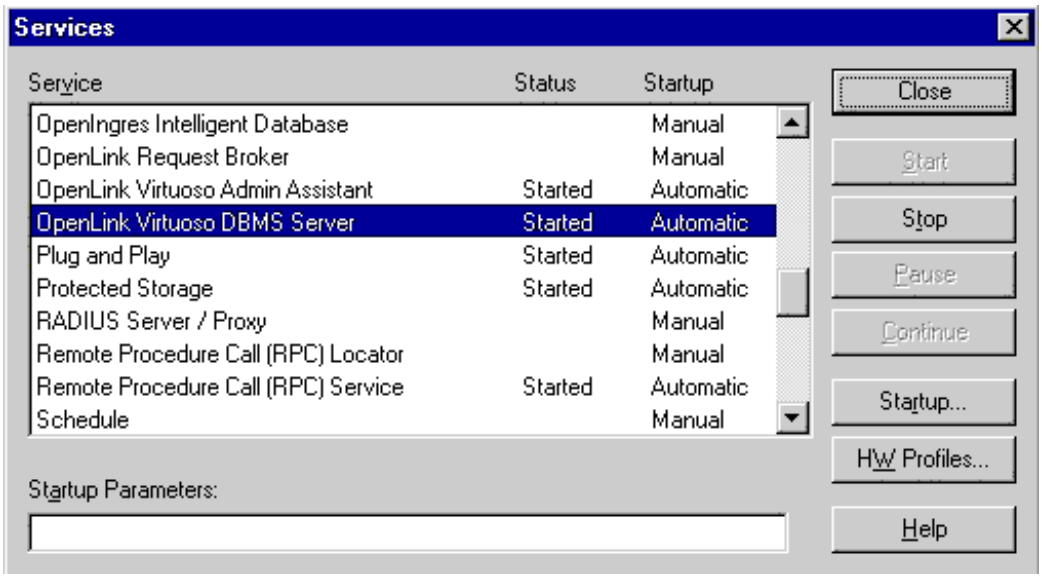
Automatic Startup

Your Virtuoso servers (default and demonstration databases) are configured at installation time as "Automatic Startup" services. Thus, rebooting your machine after installation is all that is required in order for your Virtuoso servers to be ready to start receiving connections from client applications. The service is actually started during the installation, however some files may be locked, so a reboot is required to complete the install.

Manual Startup

You can manually start your Virtuoso server in one of two ways, either via the "services" control panel applet or from within a DOS shell. When doing this via the "Services" control panel Applet you need to simply open up your control panel and click on the "services" applet. This will present you with a screen similar to the one below:

Figure 2.13. Services Applet



Click the "Start" or "Stop" button in order to start or stop a highlighted Virtuoso Server.

To start your Virtuoso servers manually using DOS command prompts, start a DOS shell and then enter the following command:

```
virtuoso-odbc-f +service start
```

Windows 95 family

You can start your Virtuoso server under Windows 95/98 in one of two ways, automatically or manually, the default mode configured by your installer is Automatic.

Automatic Startup

Your Virtuoso servers (default and demonstration databases) are configured at installation time as "Automatic Startup" services. Thus, rebooting your machine after installation is all that is required in order for your Virtuoso servers to be ready to start receiving connections from client applications.

If Virtuoso does not start automatically on Windows 95/98 after installation you will need to add the following line to the system's "autoexec.bat" file (assuming you have installed Virtuoso using the installers default installation folder):

```
C:\Program Files\OpenLink\Virtuoso\bin\virtuoso-odbc-f +service start
```

Manual Startup

You can start your Virtuoso servers manually by entering the following commands at the DOS command line prompt:

```
virtuoso-odbc-f +service start
virtuoso-odbc-f +instance demo +service start
```

Note:
If you encounter a "Program Not Found" error this is because your Virtuoso installation's "bin" sub-directory is not part of your PATH environment variable.

2.2.6. Creating and Deleting Virtuoso Services

At sometime you may need to have multiple Virtuoso server processes running on your Windows servers or simply need to add or delete existing Virtuoso servers that have been registered with the "Services" control panel applet. You do this by executing the following commands:

Adding new Virtuoso Server service: virtuoso-odbc-f +service create -I <your chosen service name>

Deleting an existing Virtuoso service: virtuoso-odbc-f +service delete -I <service that you are deleting>

Starting a new Virtuoso service manually: virtuoso-odbc-f +service start -I <service name>

Showing a list of existing Virtuoso services: virtuoso-odbc-f +service list

Note:
This functionality is only available on Windows NT/2000/XP.

Ensure that the services applet from the control panel is closed while issuing the above commands to prevent locking.

2.2.7. Configuring Virtuoso Client Components

The Virtuoso client components set consists of the following:

Virtuoso Driver for ODBC
Virtuoso Driver for JDBC
Native Virtuoso Interactive SQL Query (ISQL)
ODBC based Interactive SQL Query Utility (ISQLO)
The sections that follow address the configuration and utilization of each one of these client components separately.

Virtuoso Driver for ODBC

The Virtuoso Driver for ODBC conforms to both the ODBC 1.x,2.x,and 3.x versions of the ODBC specification, it implements Core, Level 1, Level 2, and Extensions functionality. This driver enables you to communicate with local or remote Virtuoso servers across any combination of platforms supported by Virtuoso.

At installation time two ODBC data source names (DSN's) are created with default values by the Virtuoso installer, the first DSN named "Local Virtuoso" provides a link to a local default Virtuoso database server instance, while the other named "Local Virtuoso Demo" provides a link to a local Virtuoso server for the Virtuoso demonstration database.

See Also:
the Data Access Interfaces chapter for more detailed information regarding the Virtuoso ODBC Driver setup

Virtuoso Drivers for JDBC

The Virtuoso Drivers for JDBC are available in "jar" file formats for the JDBC 1.x, JDBC 2.x and JDBC 3.x JDBC specifications. These are Type 4 Drivers implying that utilization is simply a case of adding the relevant "jar" file to your CLASSPATH and then providing an appropriate JDBC URL format in order to establish a JDBC session with a local or remote Virtuoso server. It is important to note that when you make a JDBC connection to a Virtuoso Server, you do also have access to Native and External Virtuoso tables. Thus, you actually have a type 4 JDBC Driver for any number of different database types that have been linked into Virtuoso.

See Also:
The JDBC Driver section in the Access Interfaces chapter.

Native Virtuoso Interactive SQL Query (ISQL)

To assist you with the use of Virtuoso an interactive SQL interpreter utility called "ISQL" is bundled with all Virtuoso installations. This utility allows you to enter and execute SQL statements from a command line prompt against a local or remote Virtuoso server.

The command line format for executing this utility is:

```
isql [<hostname>][:<port#>]
```

The steps that follow guide you through the process of using ISQL to verify your Virtuoso installation:

1. Open up a DOS shell
2. Move into the "bin" sub-directory of your Virtuoso installation
3. Type the following command: isql

   This will connect you to the default Virtuoso server at port "1111", if you want to connect to your demonstration Virtuoso database (which listens at port 1112 by default) then enter: isql 1112
4. At the ISQL command line prompt type in the following command:

   ```
   tables ;
   ```

   This will produce a list of tables in the current Virtuoso database, you can also enter other SQL statements e.g.:

   ```
   select * from Customers
   ```

   This will produce a listing of records in the "Customers" table.
5. If you are not able to perform these task that it implies that your Virtuoso database server is not running or that it has not been installed properly.

ODBC based Interactive SQL Query Utility (ISQLO)

In addition to a Native ISQL utility, your Virtuoso installation includes an ODBC based version of "ISQL" called "ISQLO", this enable you to connect to ODBC DSN's rather than Virtuoso only. To use this program perform the following steps:

1. Open up a DOS shell
2. Move into the "bin" sub-directory of your Virtuoso installation
3. Type the following command :

   ```
   isqlo <enter a valid ODBC Data Source Name>
   ```

   Note:
   If your DSN contains spaces you will need to enclose it within double quotes when passing it as a parameter to ISQLO
4. Enter any valid SQL at the ISQLO command line prompt.
5. You can also use this utility from within the Virtuoso Conductor

2.2.8. Default passwords

See the following Quick Start chapter for very important information about changing the default passwords .

2.3. Installing the Virtuoso Universal Server on Unix-like OS (AIX, HP-UX, Linux, Solaris, etc.)

2.3.1. Installation

Once the required tar file has been downloaded from the web or ftp site and placed in a designated installation directory the

installation process is ready to commence.

- Choose or create a suitable user account to own your Virtuoso installation.
- Un-tar the file to obtain the install script and archive file using a command like this, where XX specifies the OS identifier (e.g., l3 = Linux glibc23 x86, l9 = Linux glibc25 x86_64, sv = Solaris 2.10 x86_64, etc.):

```
tar -xvf XXvpz2zz.tar
```

- If a license file exists, place this in the same directory as the installation files, and it will automatically be applied during installation. If upgrading an existing Virtuoso instance, be sure to take a backup of your database file and shut down the existing instance before proceeding.
- Run the install script using the following command:

```
$ sh ./install.sh

- Extracting Virtuoso Universal Server vX.Y

- Creating default environment settings

- Creating default database settings
Installing new virtuoso.ini in $VIRTUOSO_HOME/database
Installing new php.ini in $VIRTUOSO_HOME/database
Creating symlink to $VIRTUOSO_HOME/bin/virtuoso-iodbc-t

- Registering ODBC drivers

- Registering .NET provider for Mono

- Installing VAD packages in database (this can take some time)

- Checking where license should be stored

- Starting OpenLink License Manager

- Checking for initial Virtuoso license

- Starting Virtuoso server instance

- Finalizing installation

This concludes the first part of the installation.

Please start a browser manually and open the following URL to finalize
the installation process:

     http://<hostname>:8890/install/

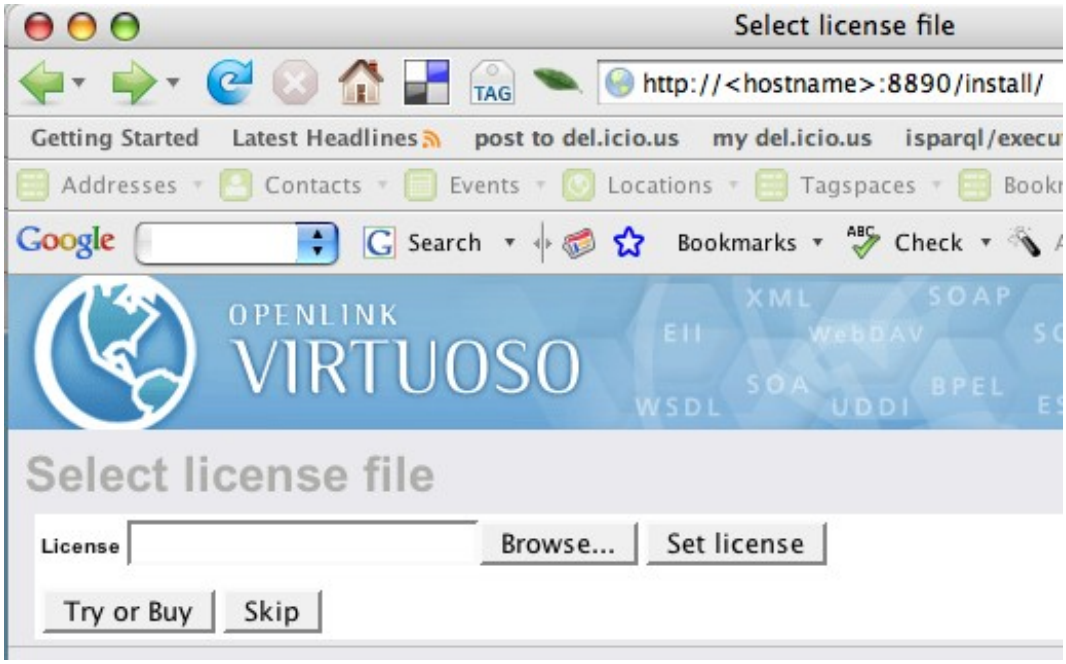
Installation completed
$
```

- Proceed to the Configuration section below.

2.3.2. Configuration

- Once the URL above has been loaded into a browser, you can select a license file for use with the installation; if a license file is already in place, you can "Skip" this task with the obvious button:

Figure 2.14. License file

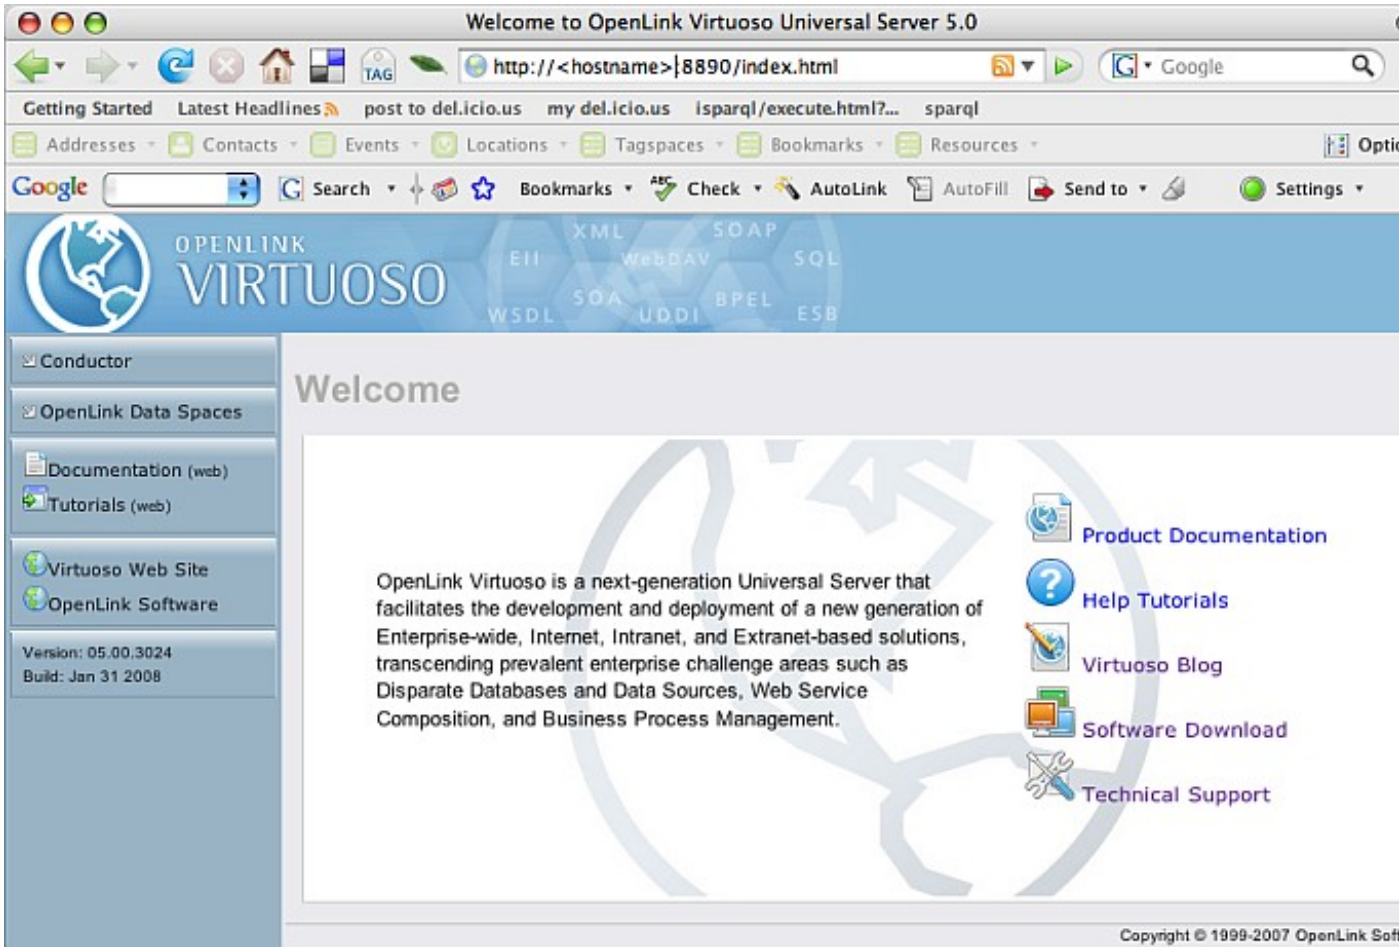


- It is strongly advised that the standard "dba" and "dav" user account password be changed using the post installation page provided:

Figure 2.15. DAV/DBA authentication Setting page

- The post installation page is now complete and the Virtuoso Welcome page is presented:

Figure 2.16. Post installation page



- The installation is now ready for use.

2.3.3. Demo Database

Installation steps .

2.4. Virtuoso for Mac OS X

2.4.1. Before You Install

Before installing the Virtuoso software for Mac OS X you must ensure that you have the correct package from the OpenLink Web Site.

2.4.2. Virtuoso Drag and Drop Installer for Mac OS X

Note : Virtuoso 7 and its Drag-and-Drop Installer for Mac OS X require Lion (10.7.x), Mountain Lion (10.8.x), Mavericks (10.9.x), or later. Virtuoso 6 remains available for deployment on Leopard (10.5.x) or Snow Leopard (10.6.x).

1. Download and double-click on the Virtuoso installer disk image,

   mwvp2zzz.dmg

   , to start the installation.

   Figure 2.17. Mac OS X installer: Start installation

2. Drag the Virtuoso application icon to your Applications folder (recommended) or any preferred location on your Mac.

Figure 2.18. Mac OS X installer: Drag Virtuoso Application

3. Double-click the Virtuoso application (e.g., Virtuoso 7.1.app) to launch the Virtuoso Application Manager Menu Extra, which will display as a V symbol in the menu bar.

Figure 2.19. Mac OS X installer: Drag Virtuoso Application

4. Select

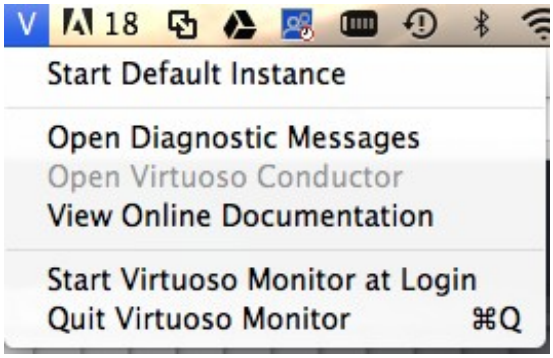
   Start Default Instance

   from the

   V

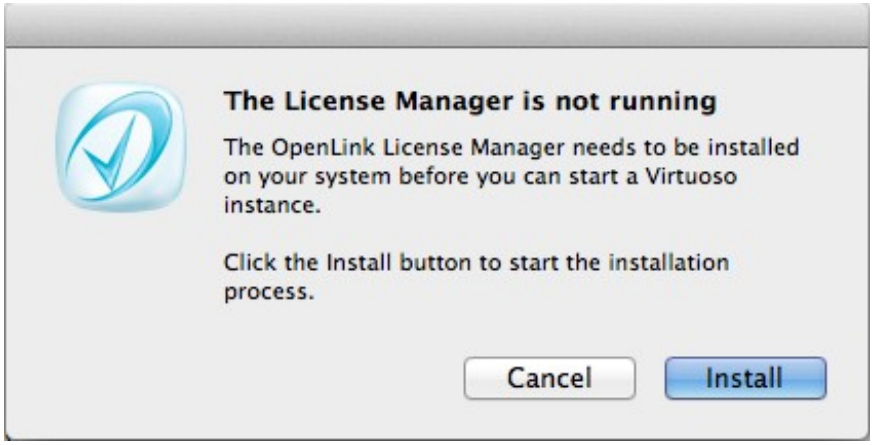
   menu.

Figure 2.20. Mac OS X installer: Drag Virtuoso Application



5. If this is a first time installation of OpenLink components, a dialog will be prompt you to install the OpenLink License Manager.

Figure 2.21. Mac OS X installer: Drag Virtuoso Application

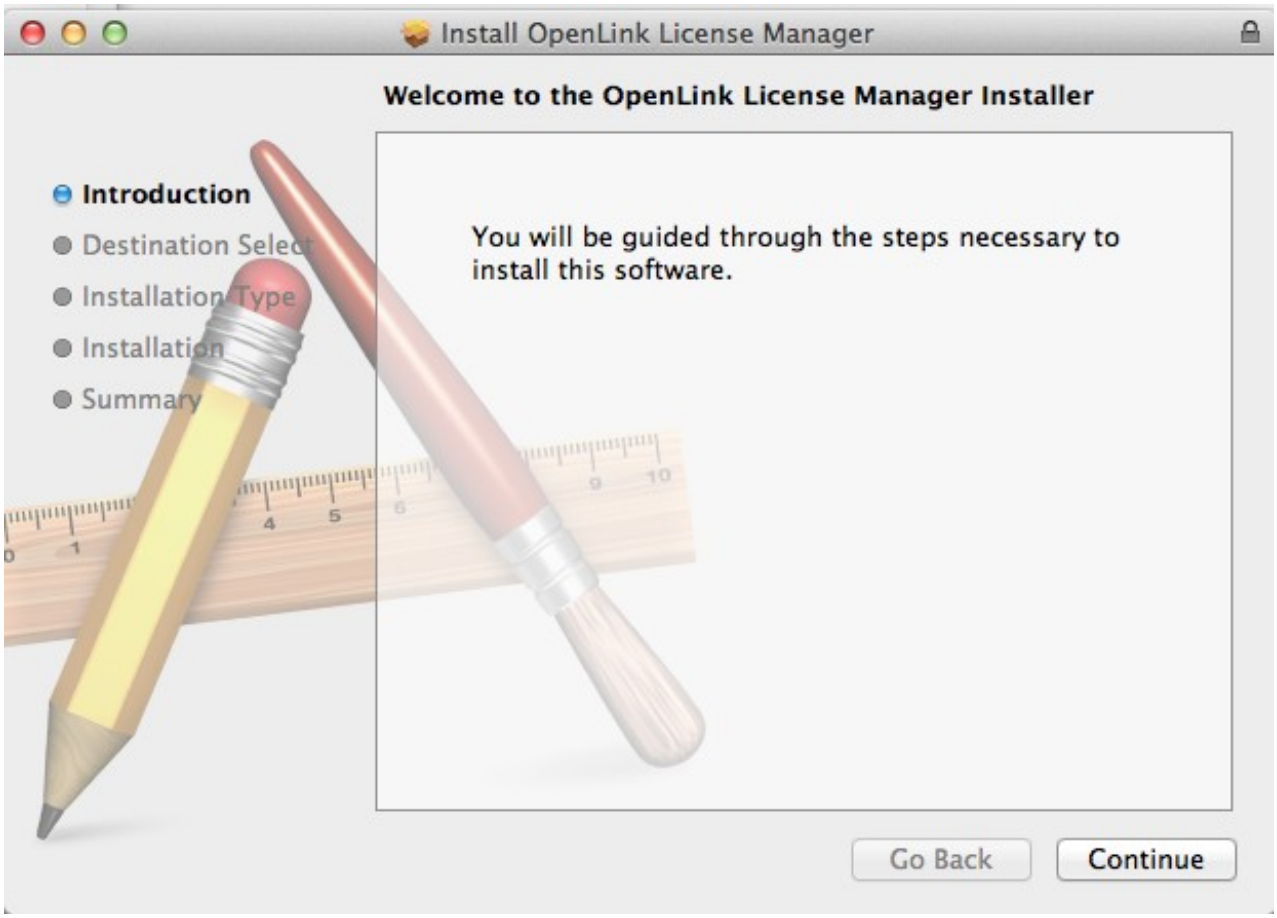


a. Click the

Continue

button to start the installation.

Figure 2.22. Mac OS X installer: Drag Virtuoso Application



b. Select the disk the installation should be performed on.

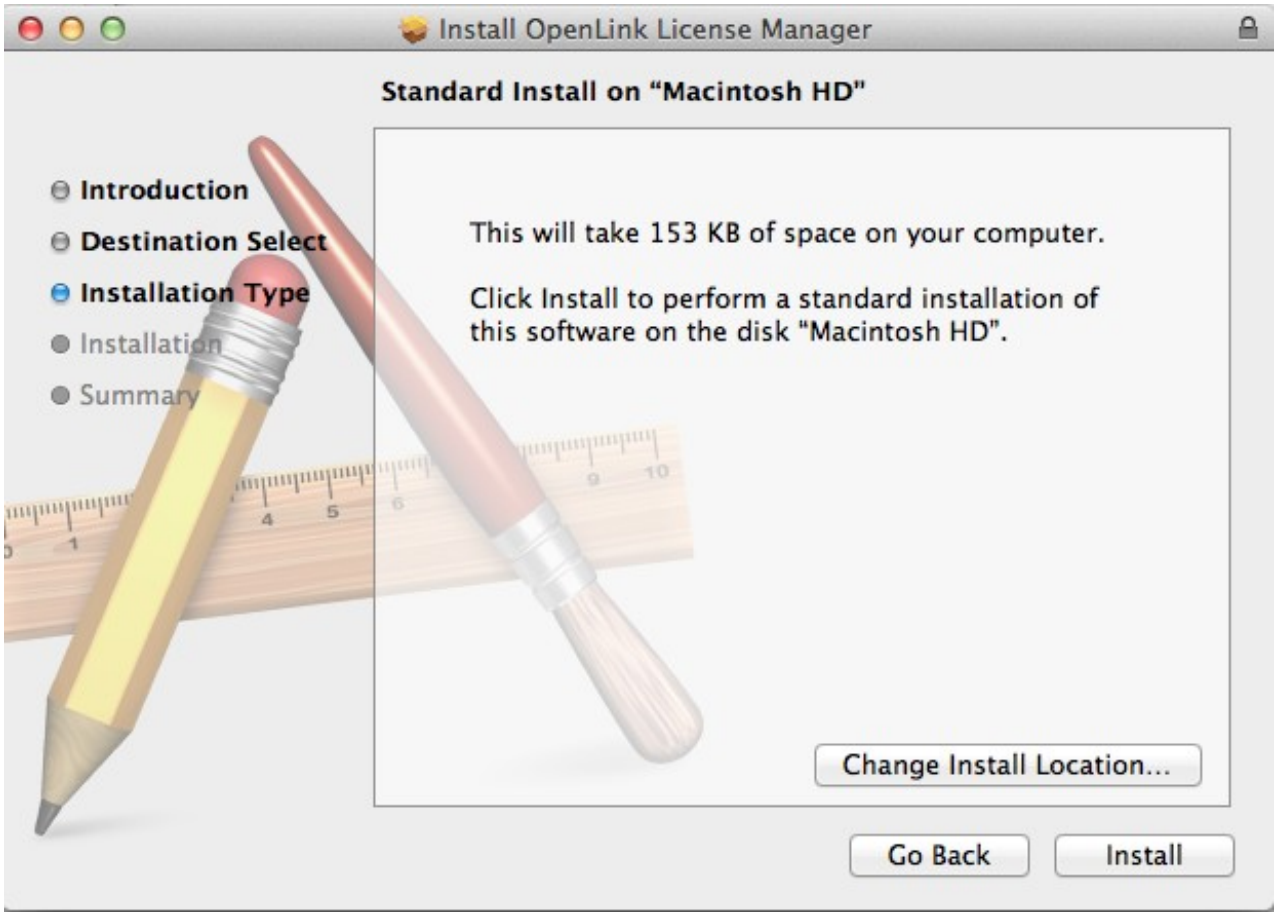
Figure 2.23. Mac OS X installer: Drag Virtuoso Application

c. Click

Install

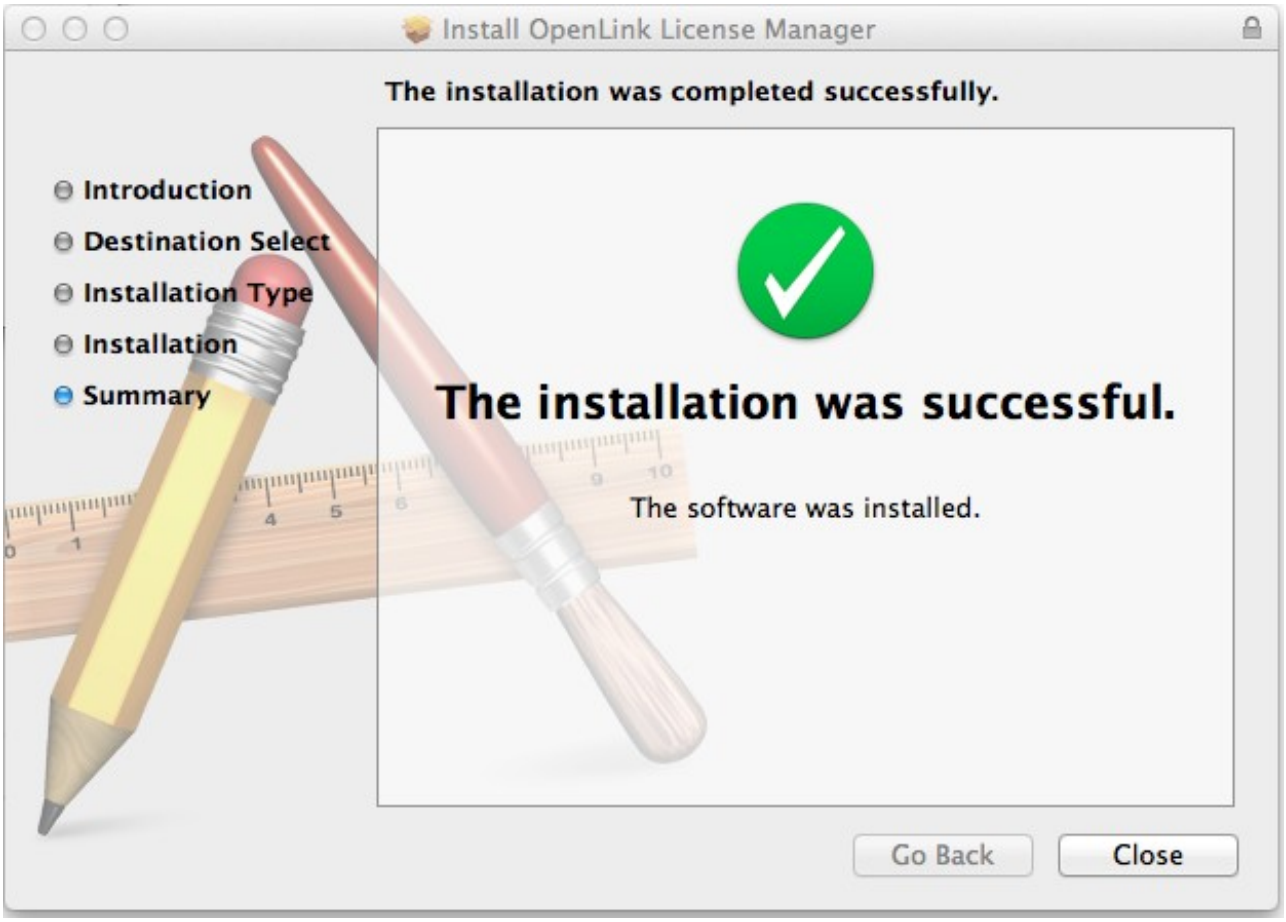
to commence the installation of the License Manager components.

Figure 2.24. Mac OS X installer: Drag Virtuoso Application



d. The following dialog will be displayed to confirm successful installation of the License Manager, which will be automatically started and ready for use upon installation.

Figure 2.25. Mac OS X installer: Drag Virtuoso Application



6. If a license file is not already in place, you will be prompted to locate an available license file or to purchase one for installation. Click the Install button to install the license file of your choice.

Figure 2.26. Mac OS X installer: Drag Virtuoso Application

   a. Navigate to the location of the license file to be installed, and click the

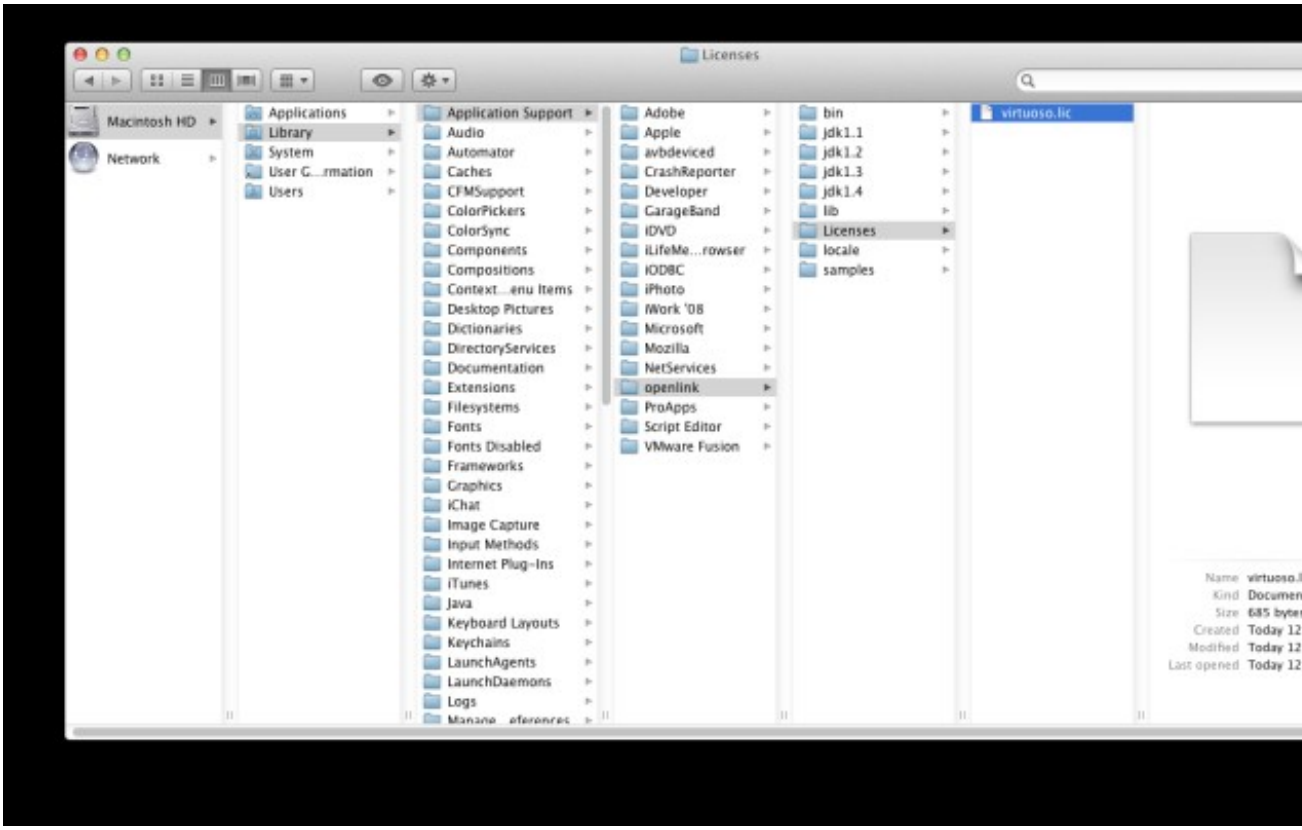
   Open

   button. The installer will move it into the

   /Library/Application Support/openlink/Licenses/

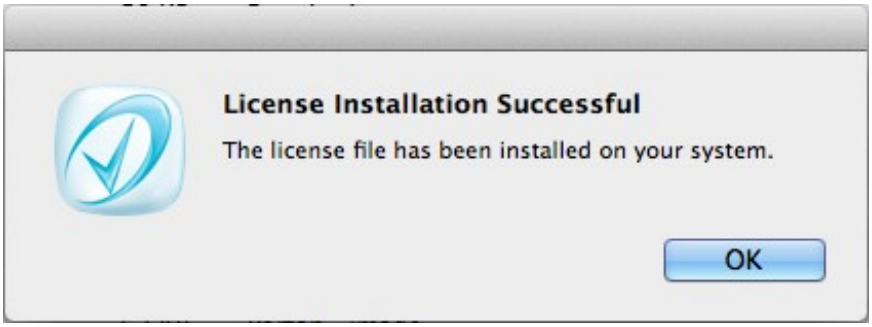
   folder.

Figure 2.27. Mac OS X installer: Drag Virtuoso Application



b. A dialog confirming the successful installation of the license file will be displayed.

Figure 2.28. Mac OS X installer: Drag Virtuoso Application

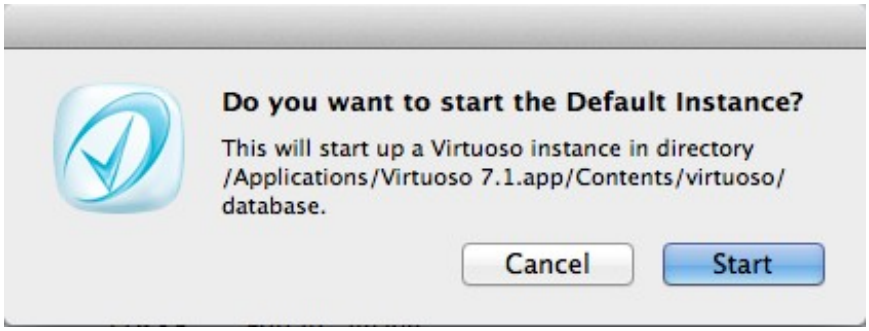


7. The Default database instance can now be started by clicking the

   Start

   button.

Figure 2.29. Mac OS X installer: Drag Virtuoso Application



8. The Virtuoso server is now ready for use, and the browser-based Virtuoso Conductor administration interface may be accessed by selecting

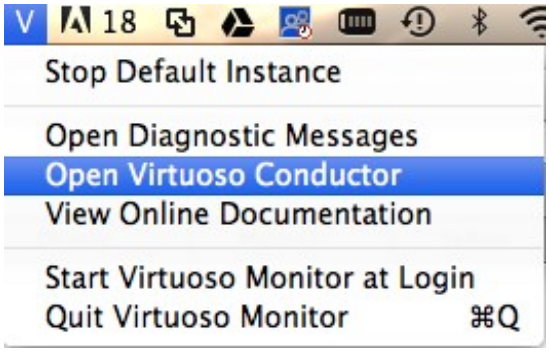
   Open Virtuoso Conductor

   from the

   V

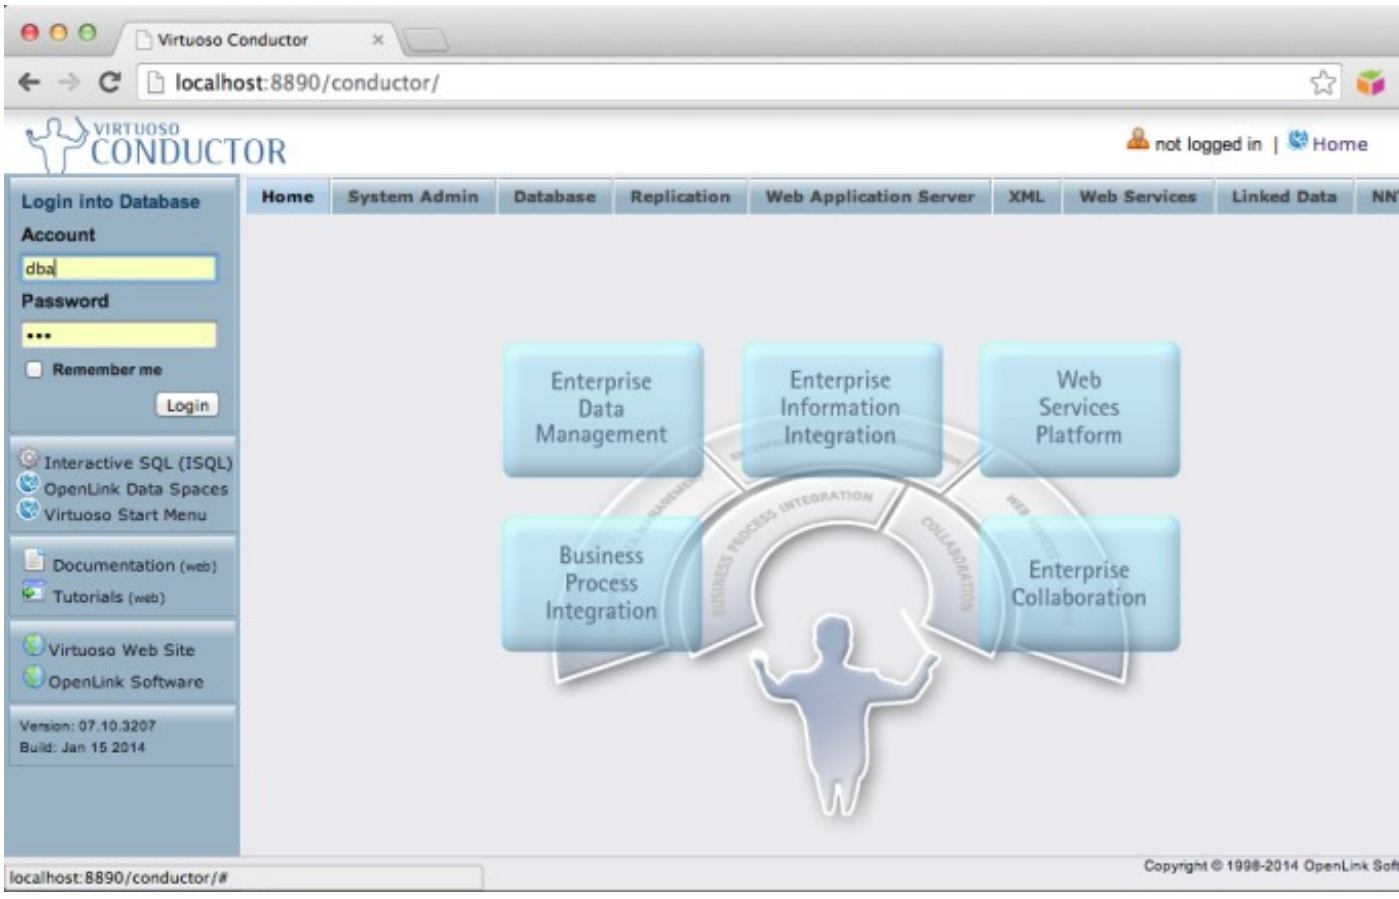
   menu.

Figure 2.30. Mac OS X installer: Drag Virtuoso Application



9. The Virtuoso Conductor may also be accessed by manually loading the URL <http://example.com/conductor> (or <http://full-hostname.example.com:8890/conductor> from a remote host) into any web browser.

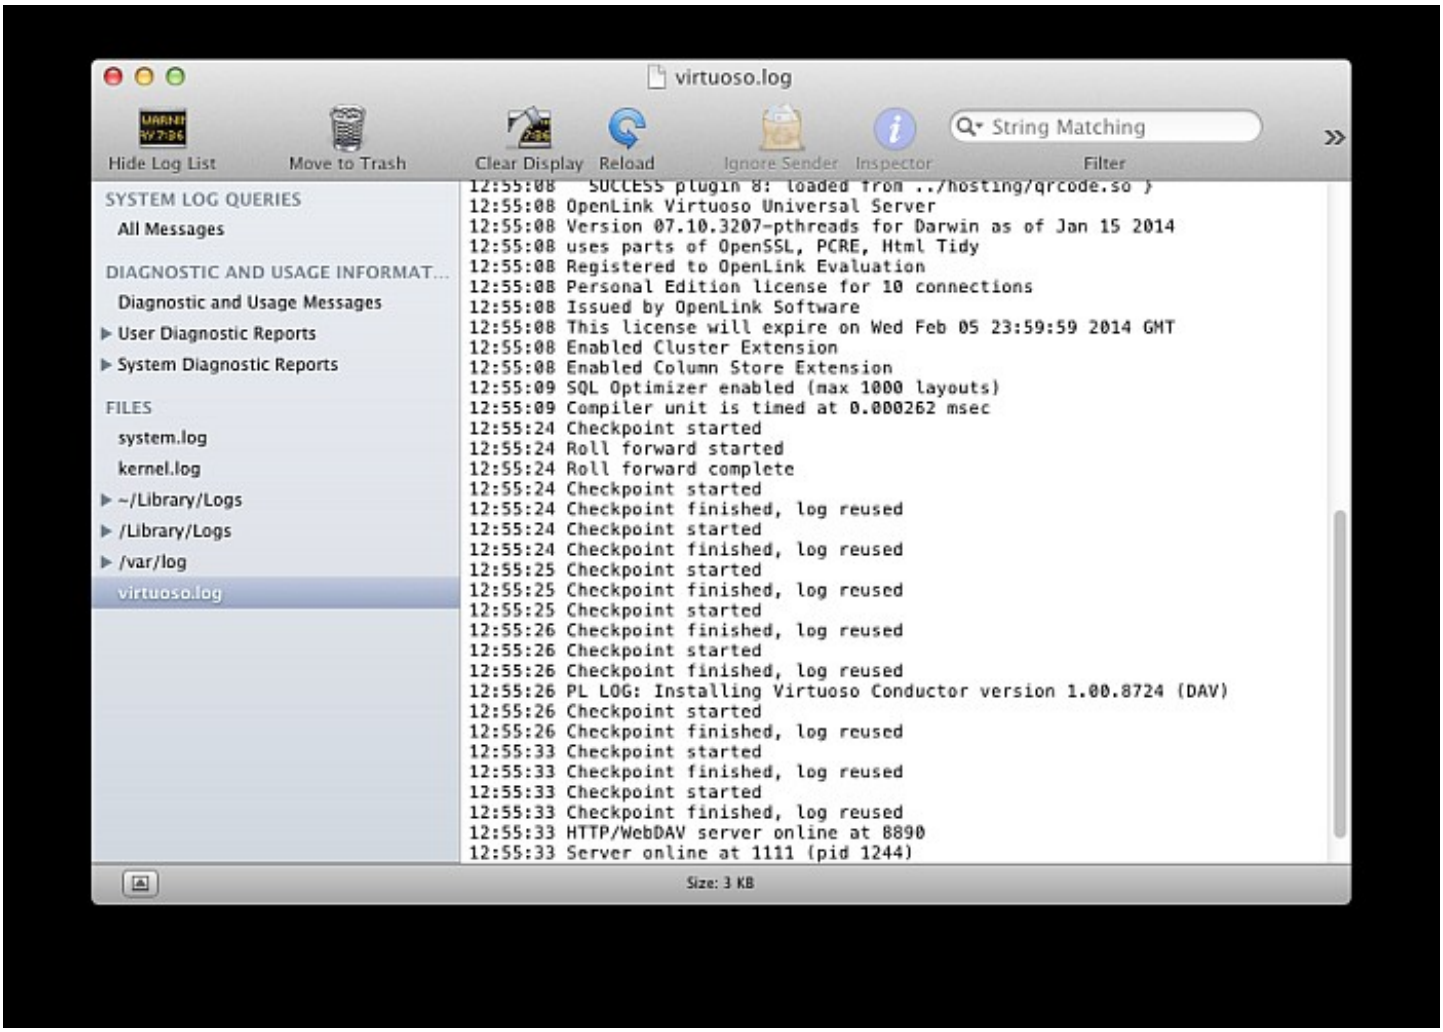
Figure 2.31. Mac OS X installer: Drag Virtuoso Application



Troubleshooting

Many issues may be quickly diagnosed and resolved by reviewing Virtuoso's `.log` file, typically located alongside the active `.db` file.

Figure 2.32. Mac OS X installer: Troubleshooting



The default instance log file may be opened in Mac OS X's Console.app by:

- selecting

  Open Diagnostic Messages

  from the

  V

  menu
- right-clicking on the

  Virtuoso 7.1.app

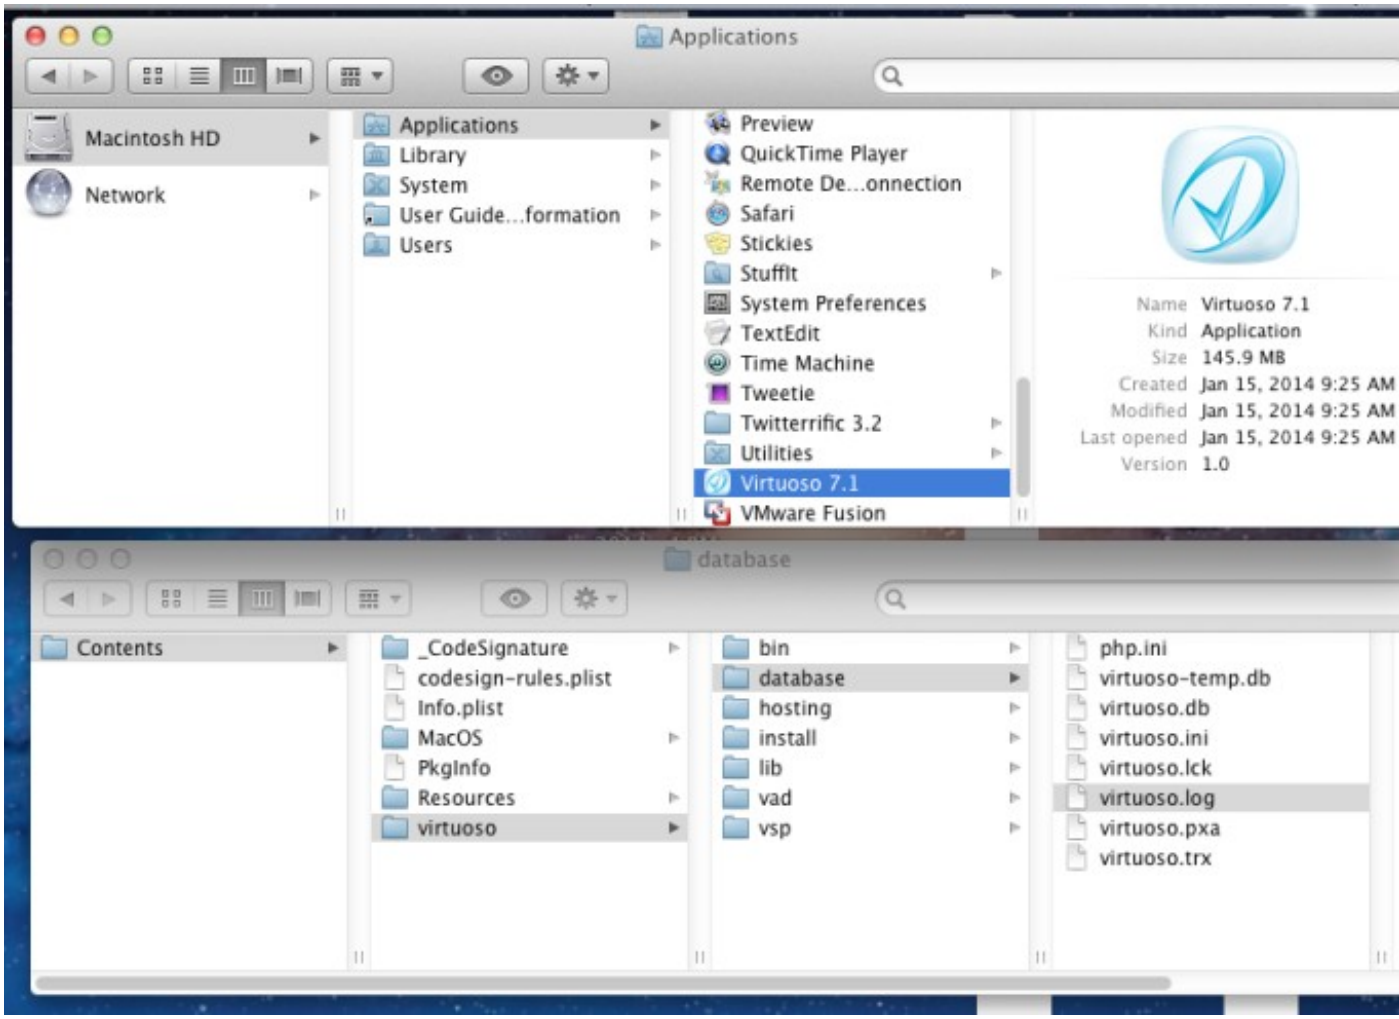
  icon, select

  View Package Contents

  , and then drilling down to

Contents -> virtuoso -> database -> virtuoso.log

Figure 2.33. Mac OS X installer: Troubleshooting



- executing the following command in

  Terminal.app

  :

```
open /Applications/Virtuoso\ 7.1.app/Contents/virtuoso/database/virtuoso.log
```

Missing license file

Make sure that the license file, always named `virtuoso.lic` is in the correct location, as described above -- `/Library/Application Support/openlink/Licenses/.`

Restarting the License Manager may be necessary. Rebooting should always result in a running License Manager, but you can also use the *Terminal.app* :

```
cd /Library/Application\ Support/openlink/bin
./oplmgr -fd /Library/Application\ Support/openlink/Licenses
```

Expired license file

Acquire a non-expired license file, by purchase or conversation with Technical Support or your Account Manager, and replace the expired file with the non-expired, as documented .

Cannot contact the License Manager

Rebooting should always result in a running License Manager. You can use *Terminal.app* to check whether it's running:

```
ps -ef | grep oplmgr | grep -v grep
```

If no process is listed, these two commands should get it running:

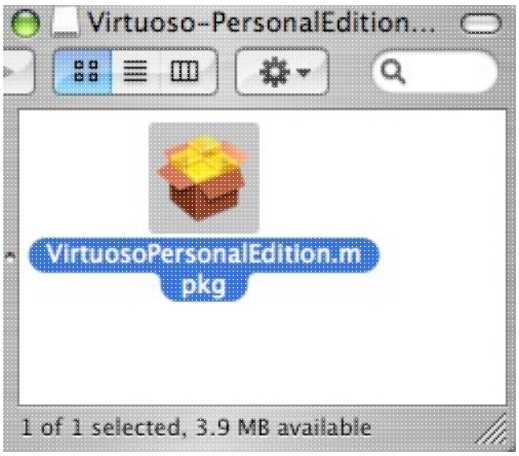
```
cd /Library/Application\ Support/openlink/bin
./oplmgr -fd ../Licenses
```

If the process is listed, there are many possible causes, including firewall or other networking issues. Please allow our Support Team to assist you in diagnosis and resolution.

2.4.3. Installing Virtuoso 6 or earlier

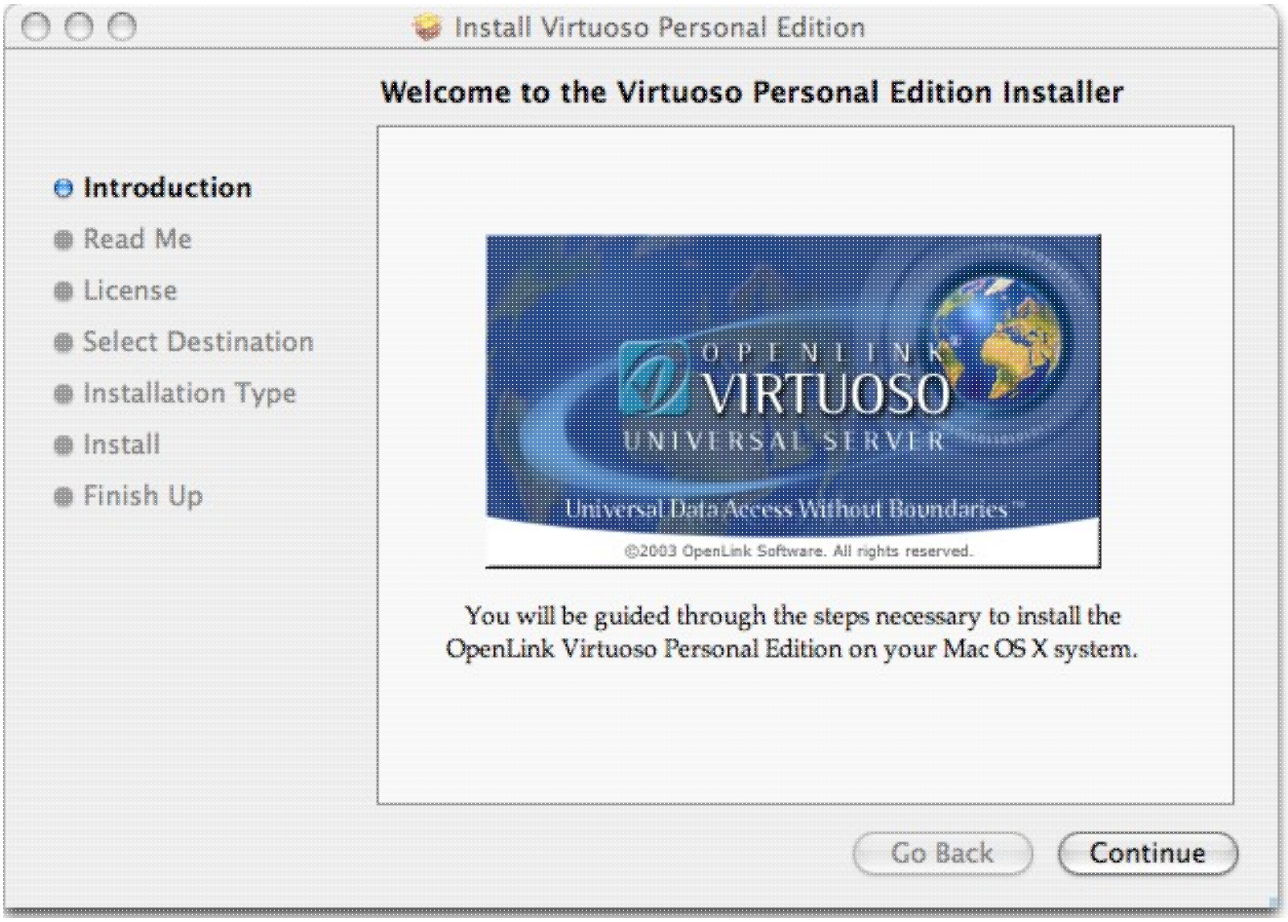
Open the Virtuoso Personal Edition Disk Image file ntvpz2zz.dmg by either double clicking on the DMG file in the Finder windows or using the "open" command from a Terminal window, to mount the Disk Image containing the VirtuosoPersonalEdition.mpkg installer.

Figure 2.34. Mounting the Disk Image



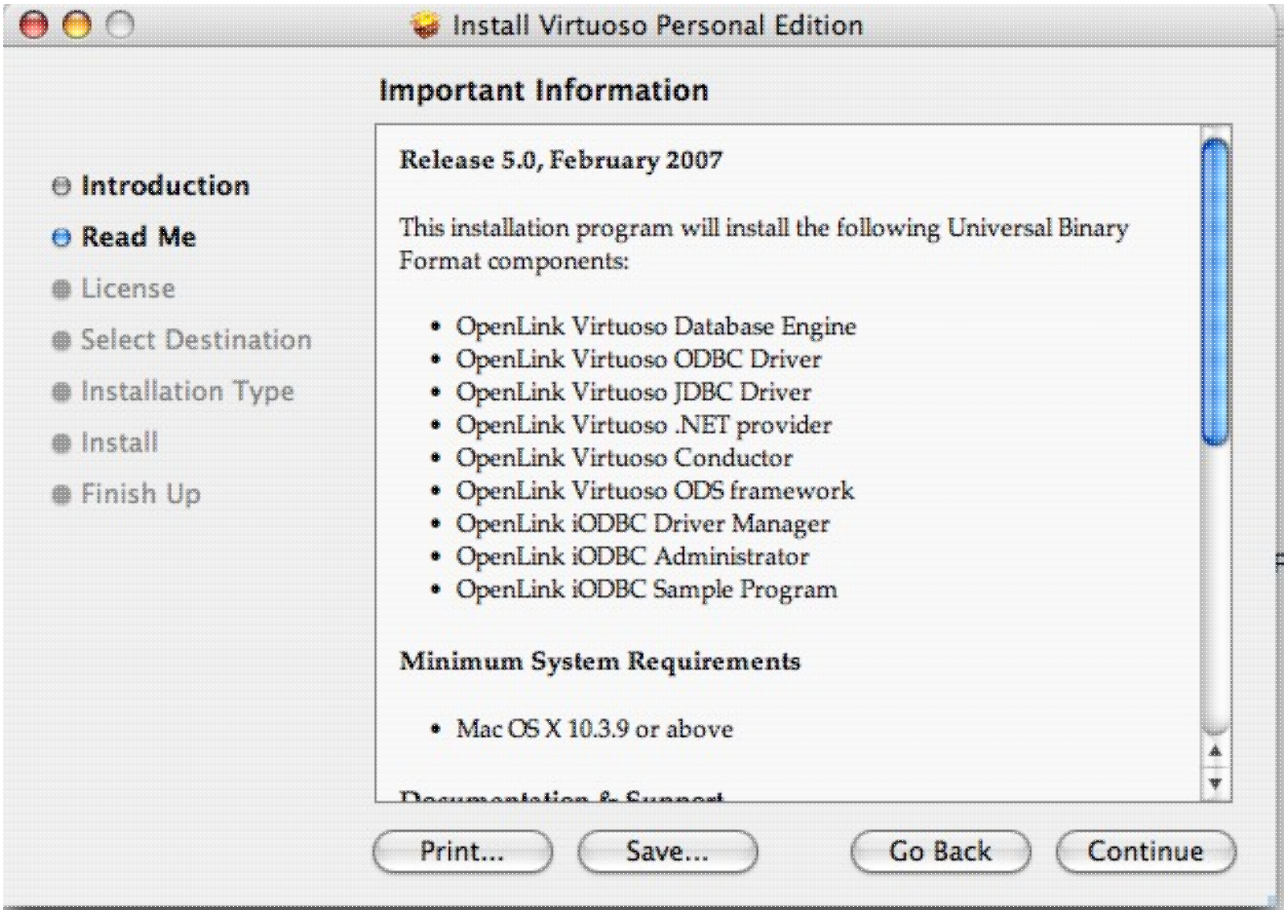
The installer will load the Introduction page.

Figure 2.35. Installer Introduction Page



Review the Readme page for any important information concerning the product installation.

Figure 2.36. Important Information

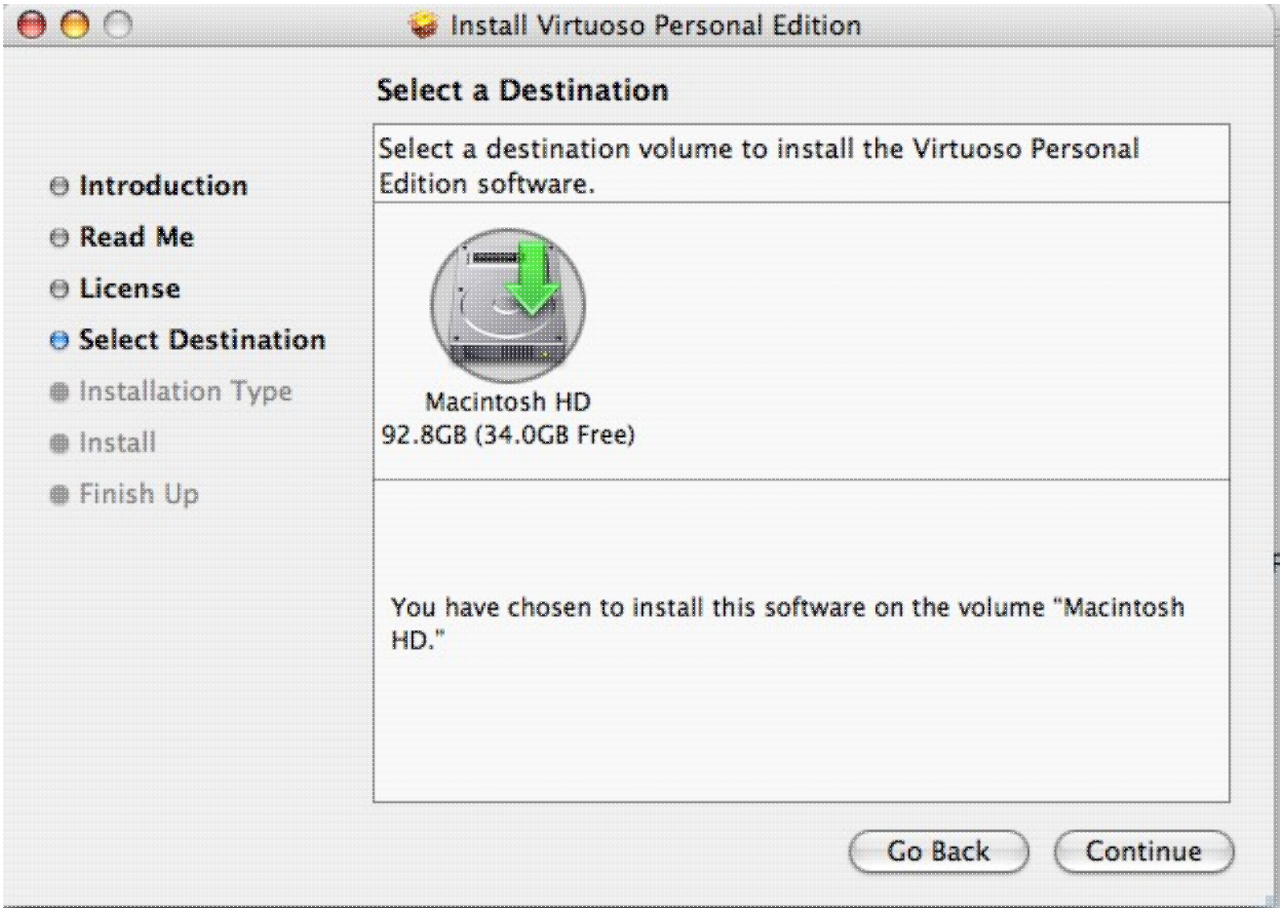


Read the license agreement and "agree" to the terms.

Figure 2.37. Software License Agreement

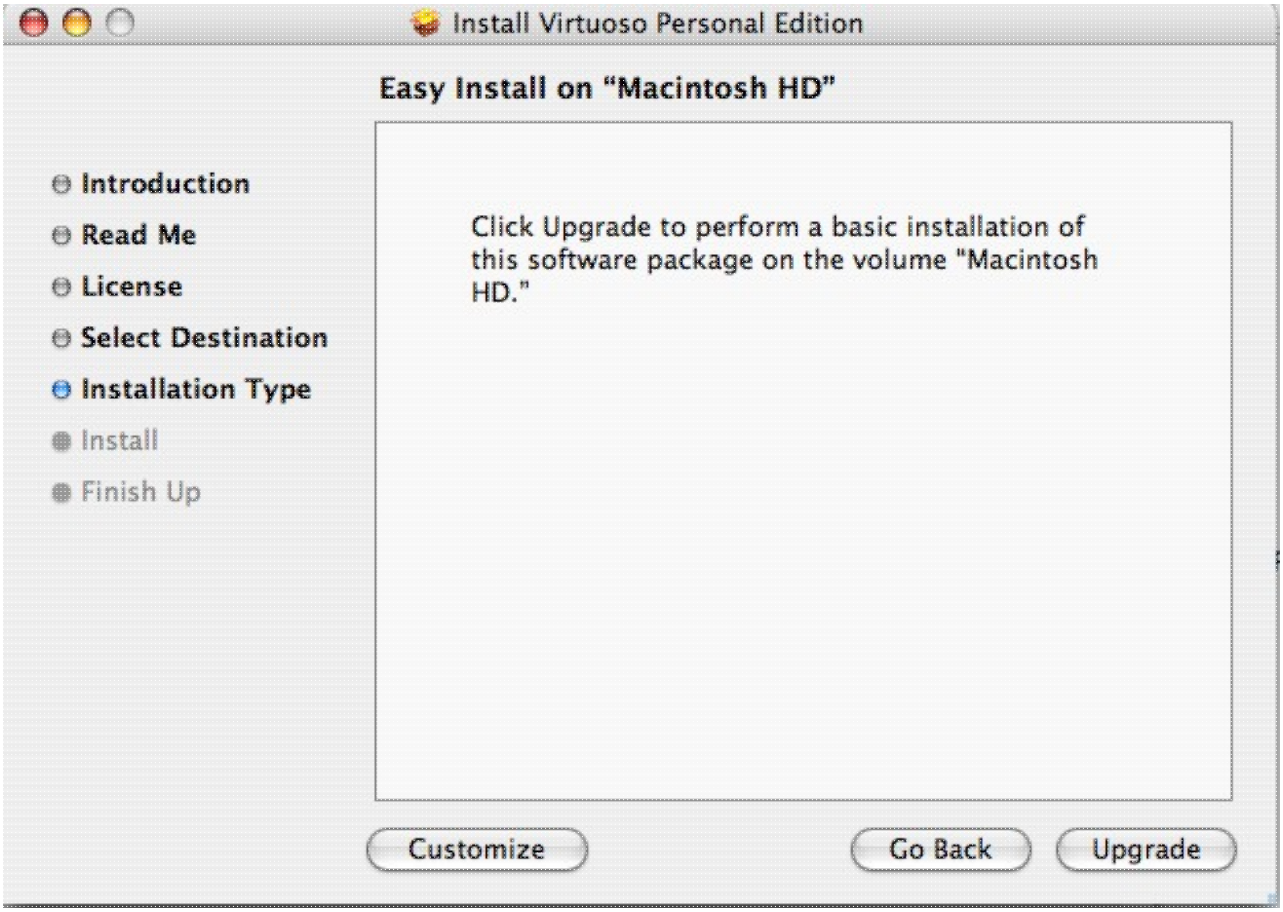
Select the Destination volume the software is to be installed on.

Figure 2.38. Select Destination



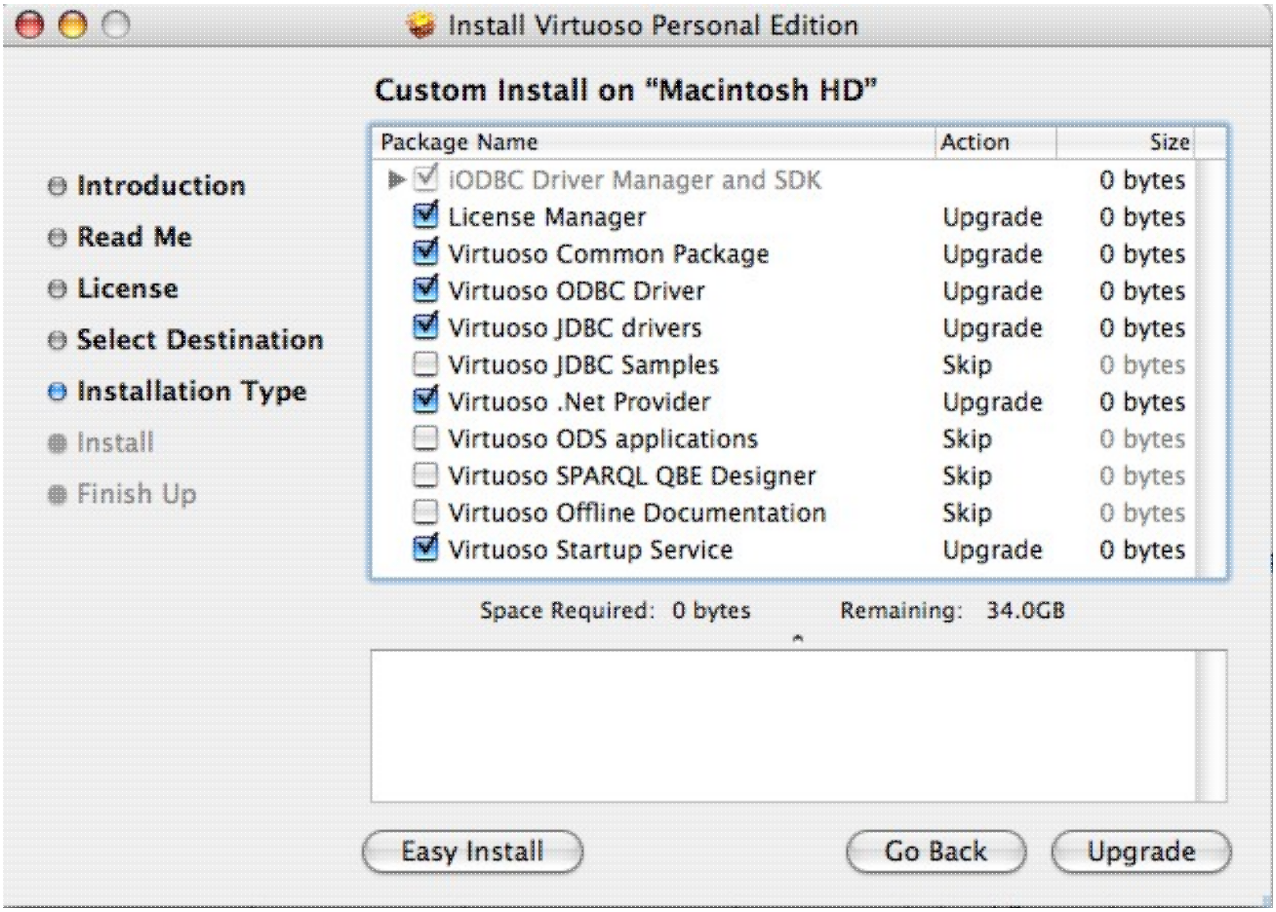
Choose to perform and Easy(default) installation or click on the "customize" button to perform a Custom installation.

Figure 2.39. Selecting the Type of Installation



If the "Custom" option was selected in the previous step then select the packages to be installed.

Figure 2.40. Customizing the Installation

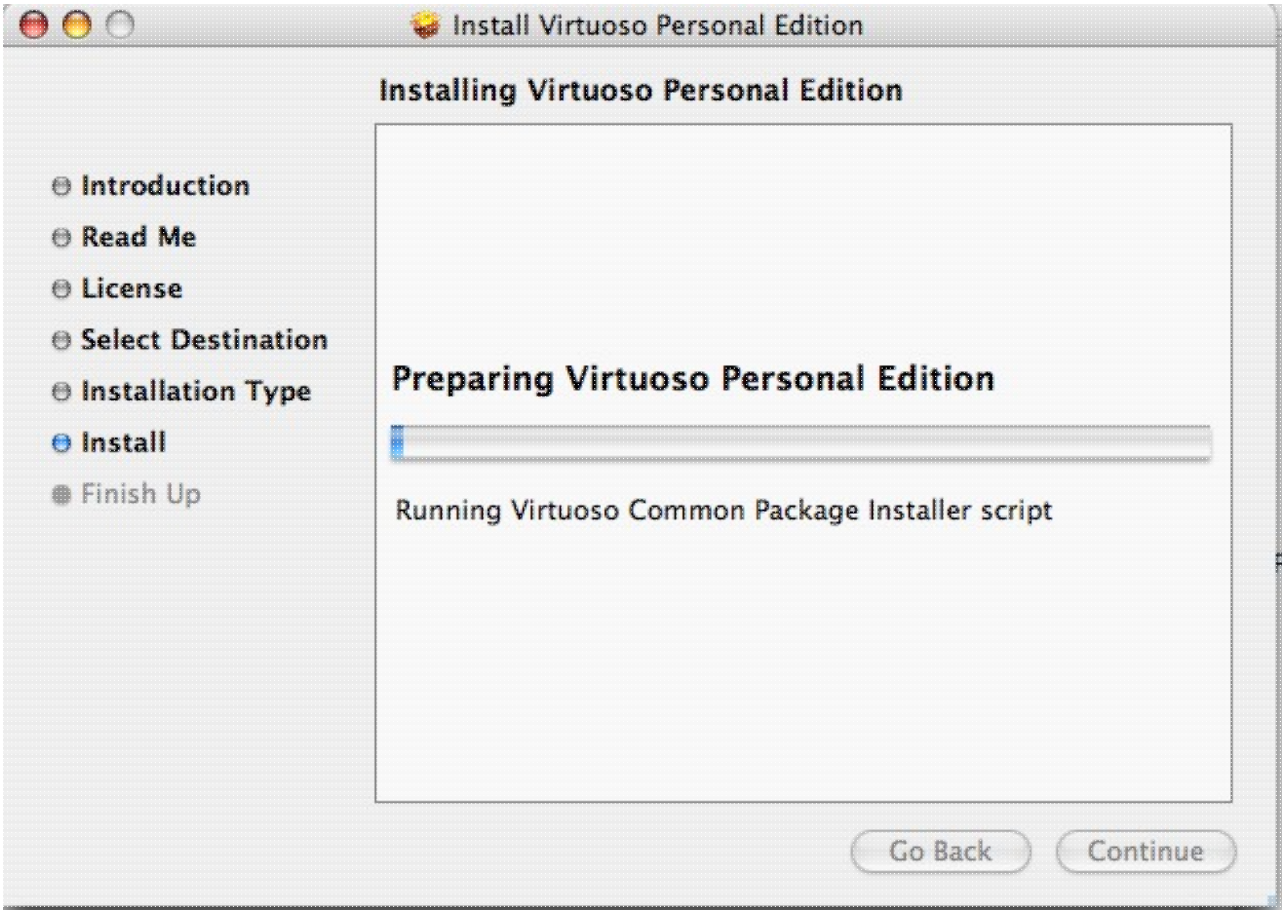


The software must be install by a user with Administrative privileges on the machine.

Figure 2.41. Identifying yourself as Administrator

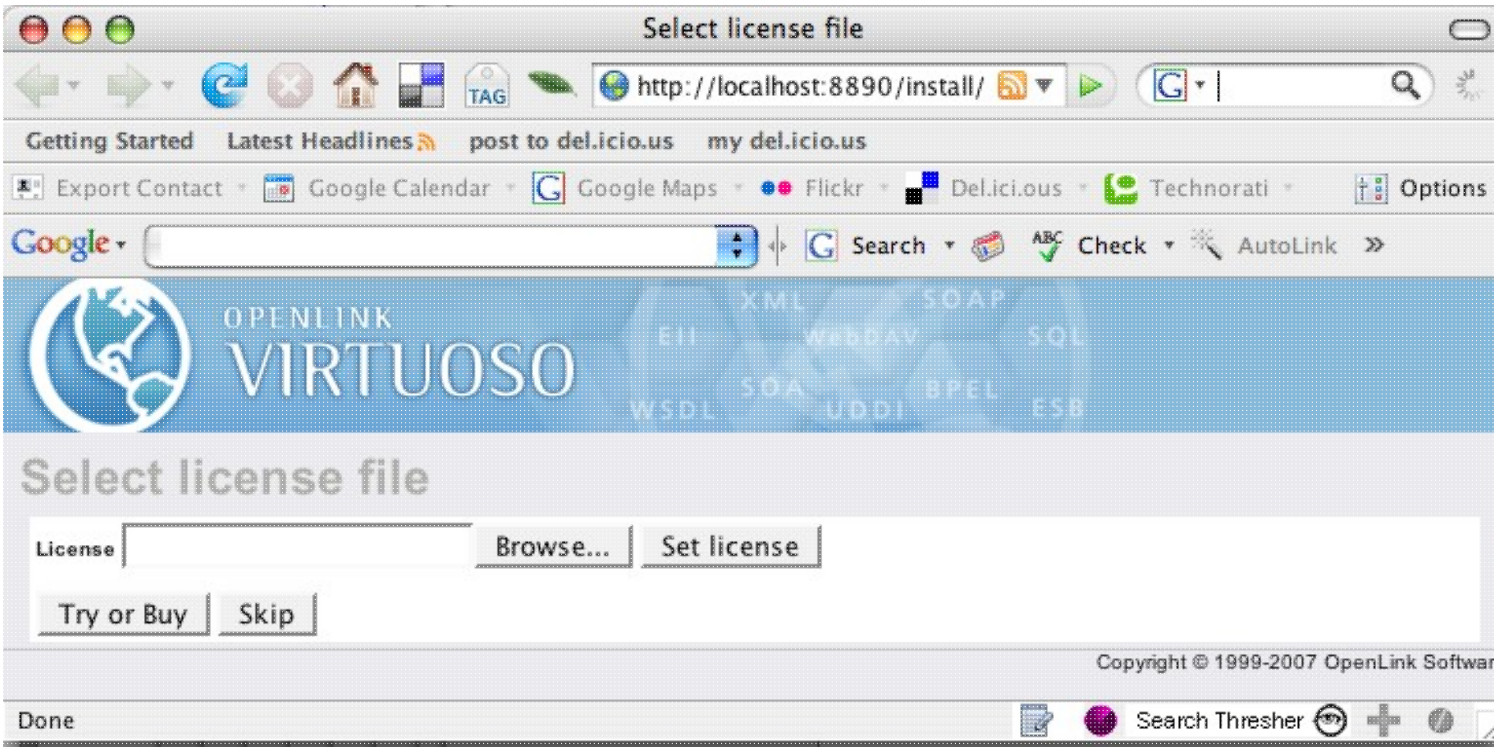
The software components will be installed the status of which is indicated by the progress bar.

Figure 2.42. Preparing ...



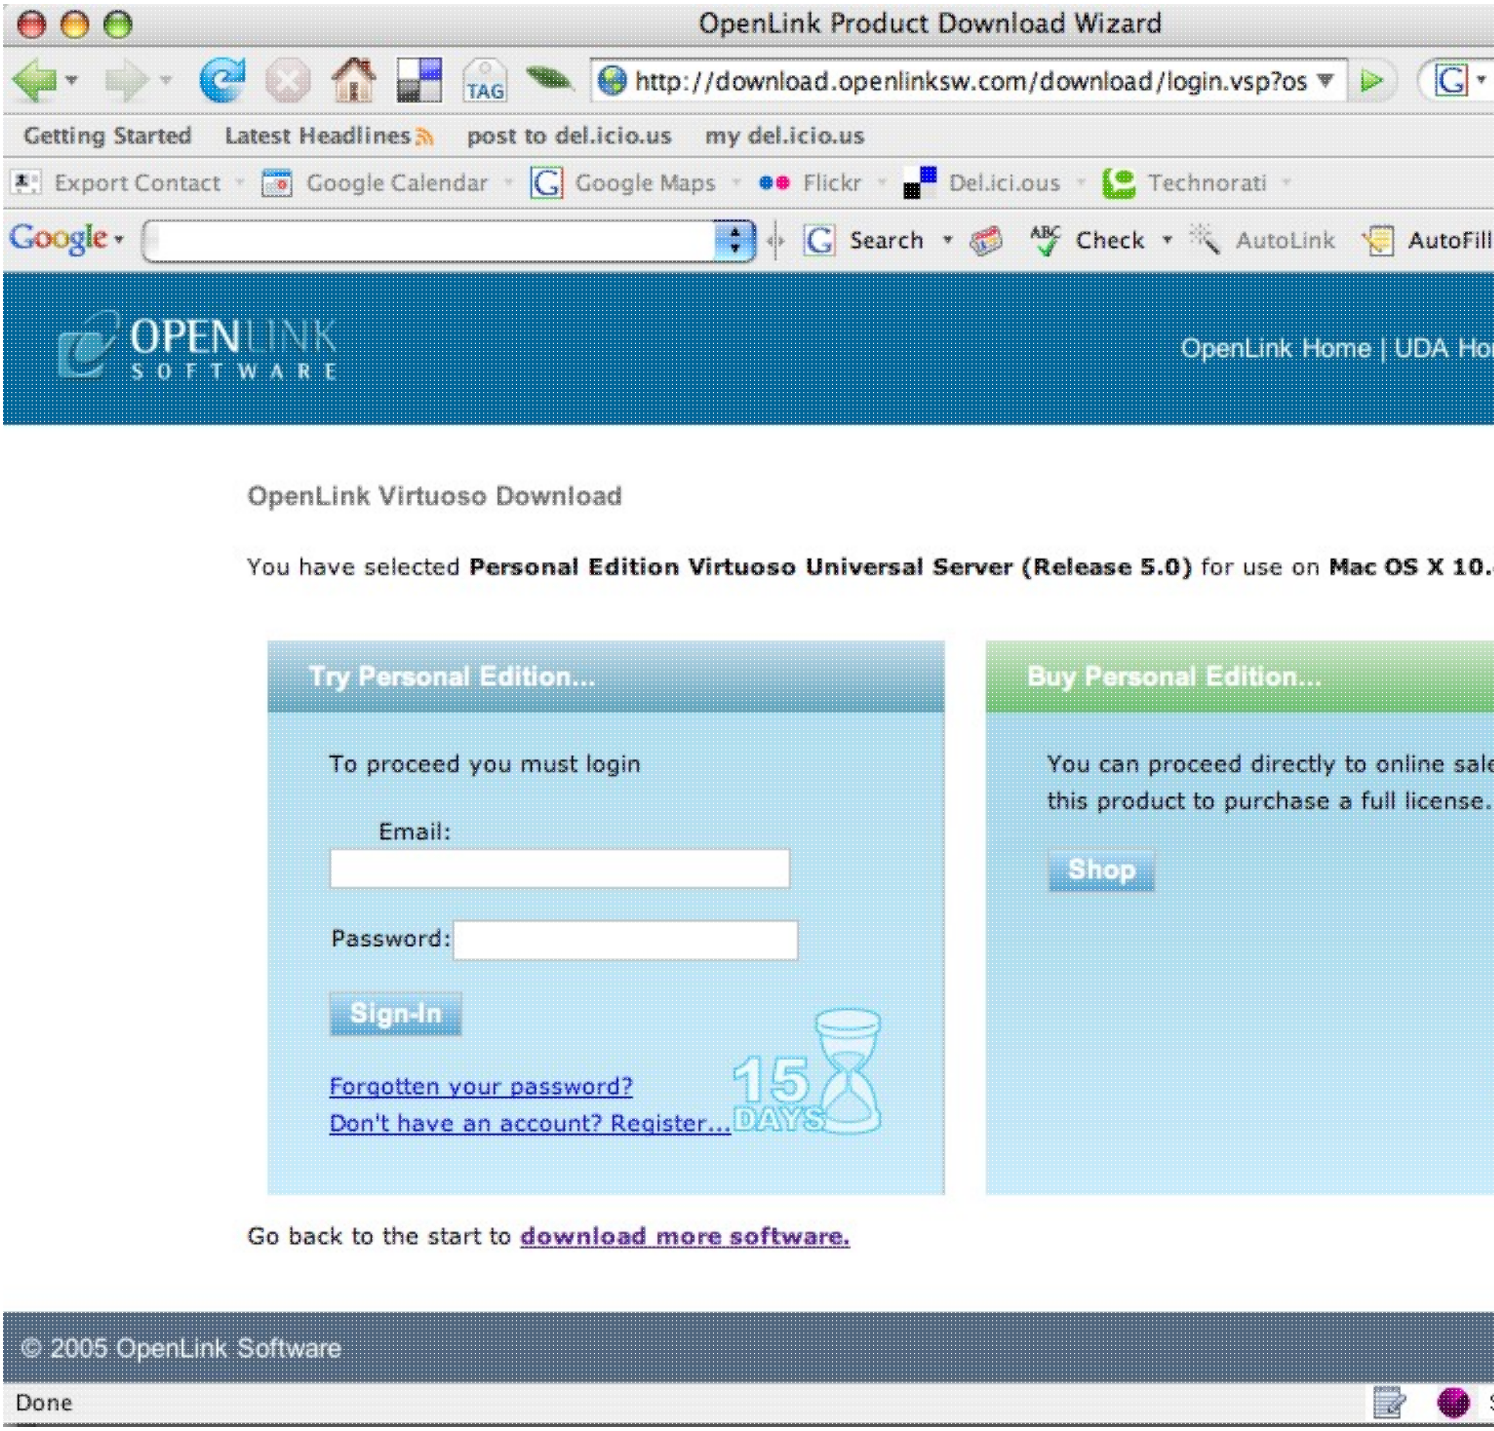
The Virtuoso Server is started at the end of this process. A Web page is loaded to enable you to obtain a trial or full license from the OpenLink online shop:

Figure 2.43. Admin Assistant



Choose to obtain a Trial license for an evaluation or enter the shop site to purchase a full license.

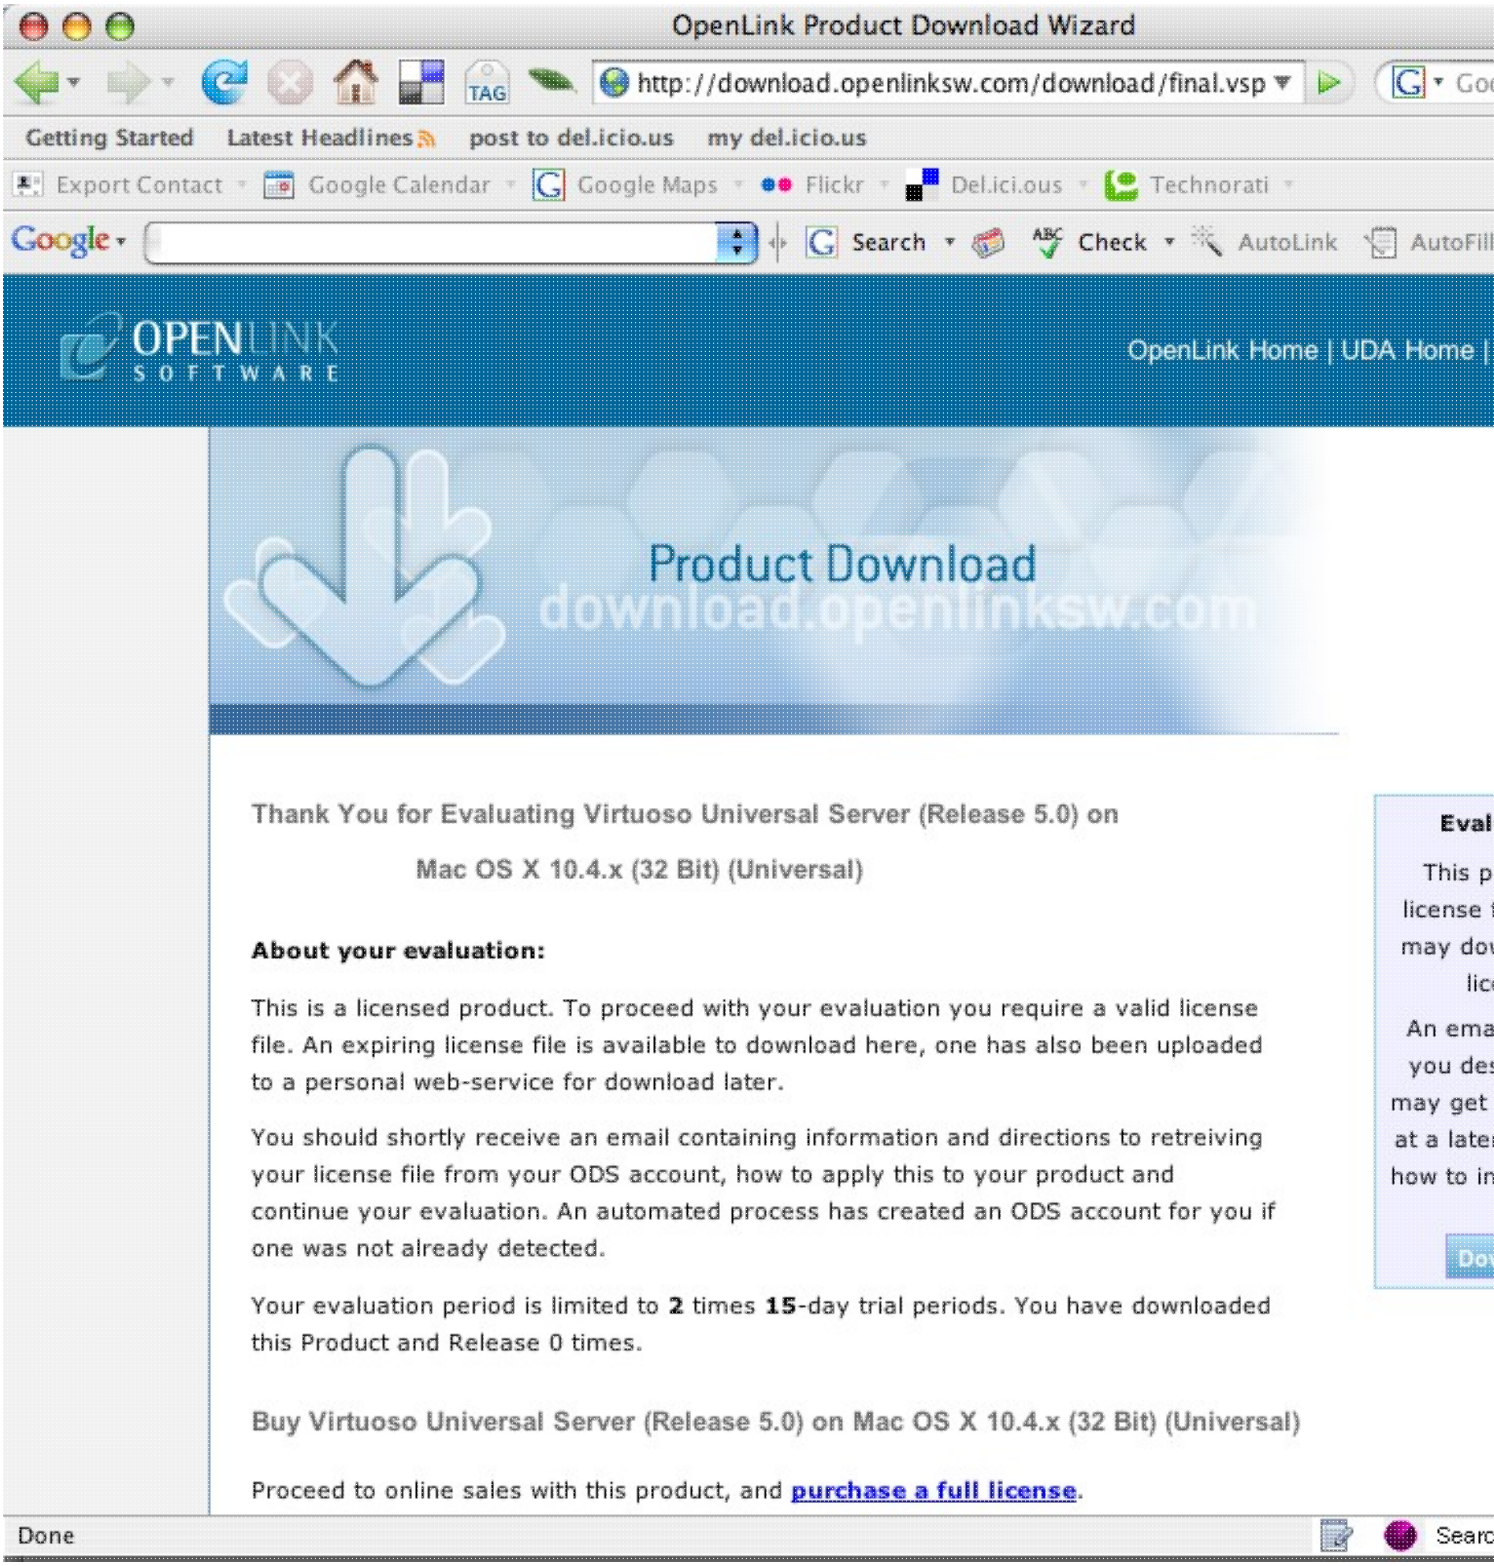
Figure 2.44. The Trial license page



Click on the "Download License" button on the right to obtain the license file immediately. An e-mail will also be sent to your registered email address. This email contains the details of the Virtuoso license and the location of an OpenLink Data Spaces account where you can obtain an additional demo license at a later date.

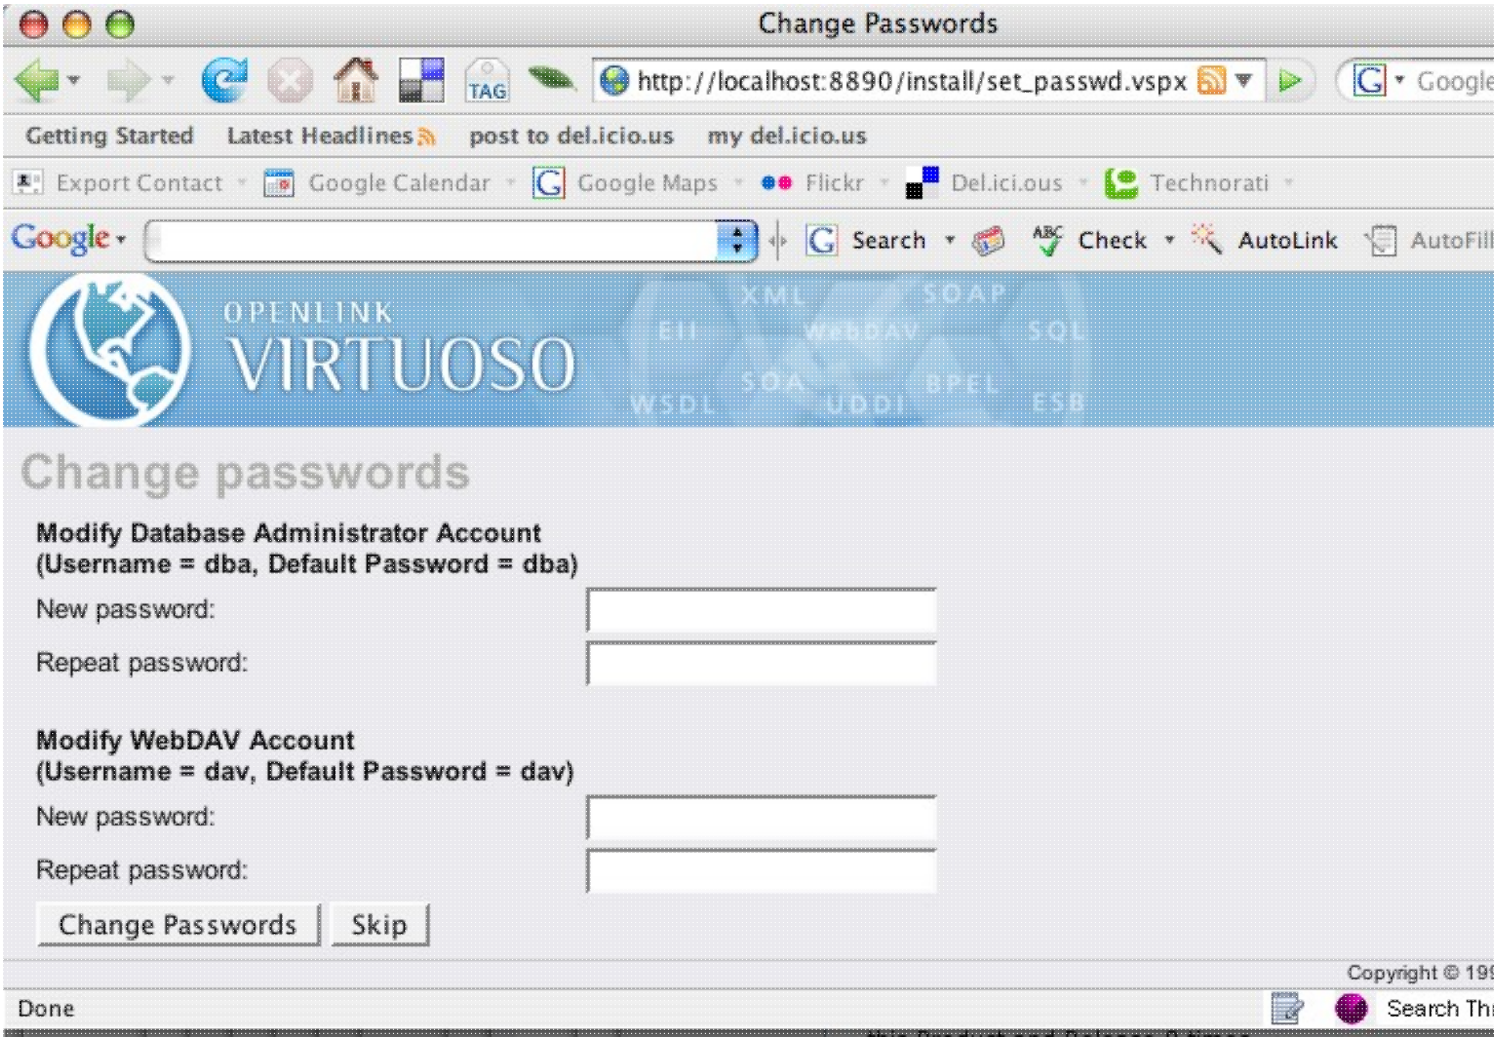
Once a license file is available on your Mac, use the "Browse" button to locate it. Then, use the "Set License" button to initialize the Virtuoso server with it:

Figure 2.45. Download license



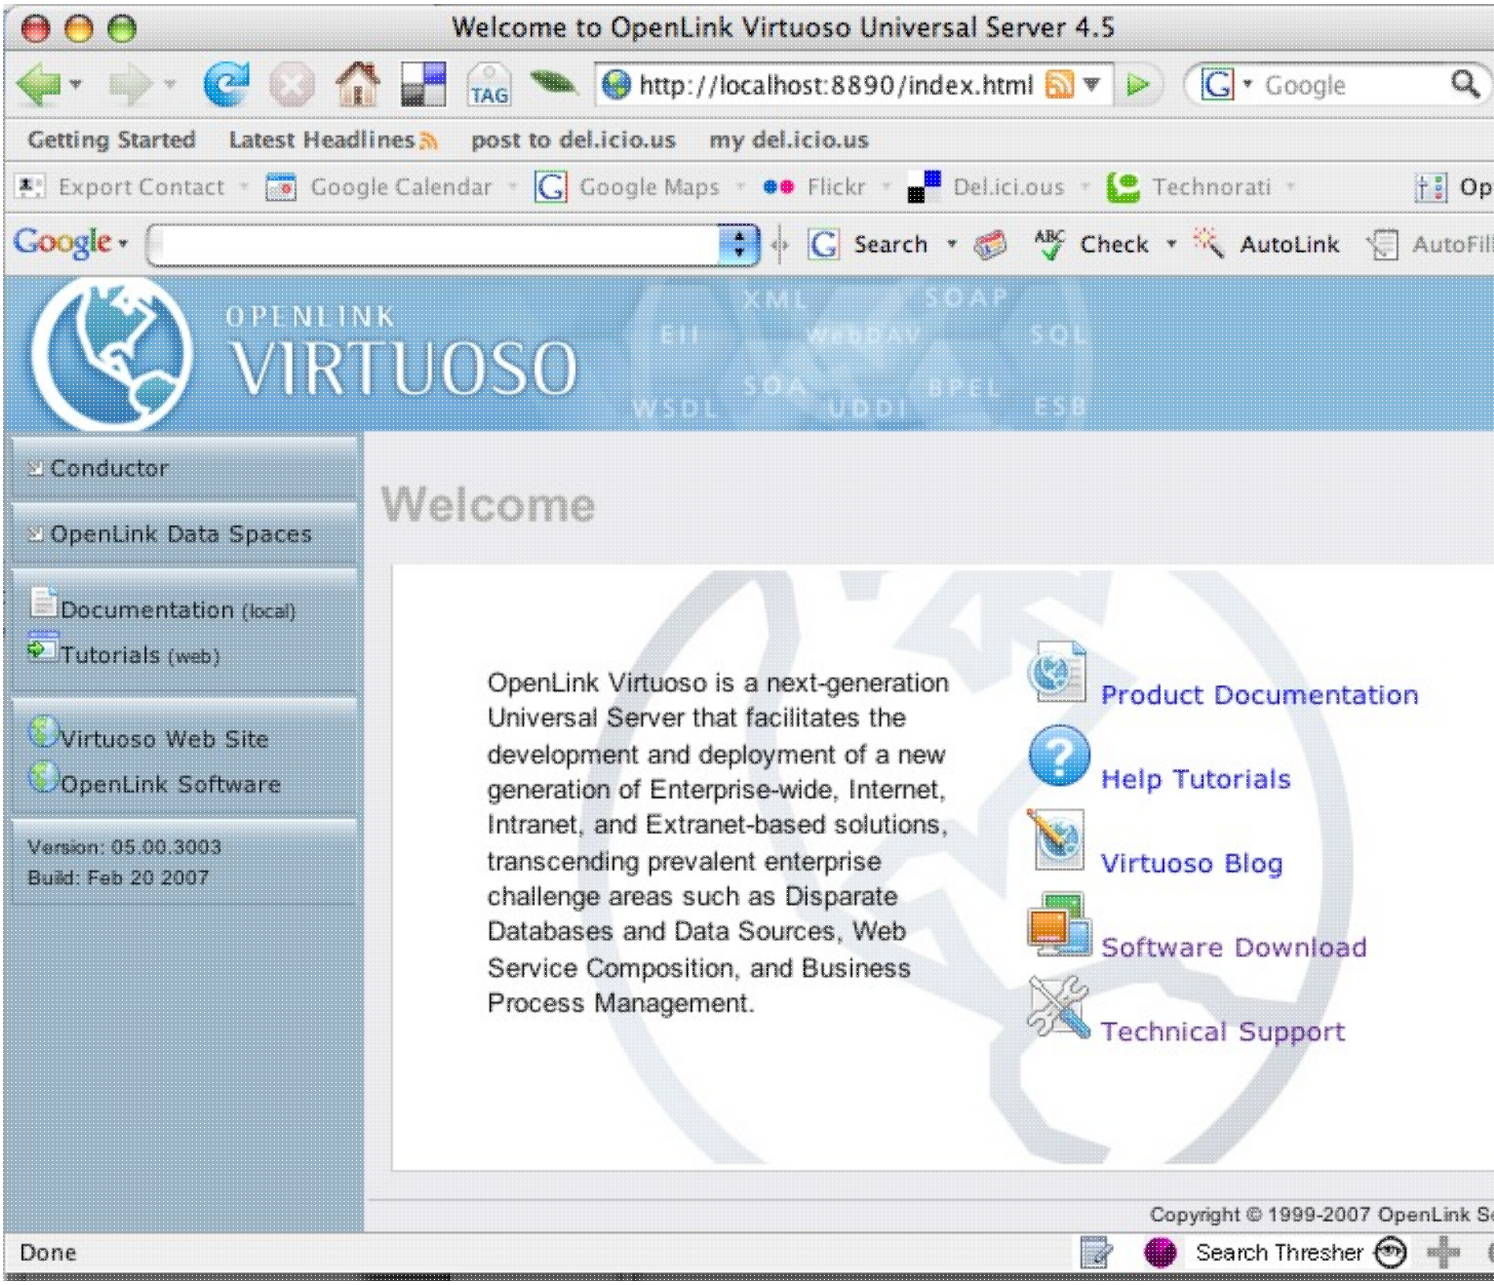
Change the "dba" and "dav" user passwords from their default of "dba" and "dav" to a value of your choice:

Figure 2.46. Change passwords



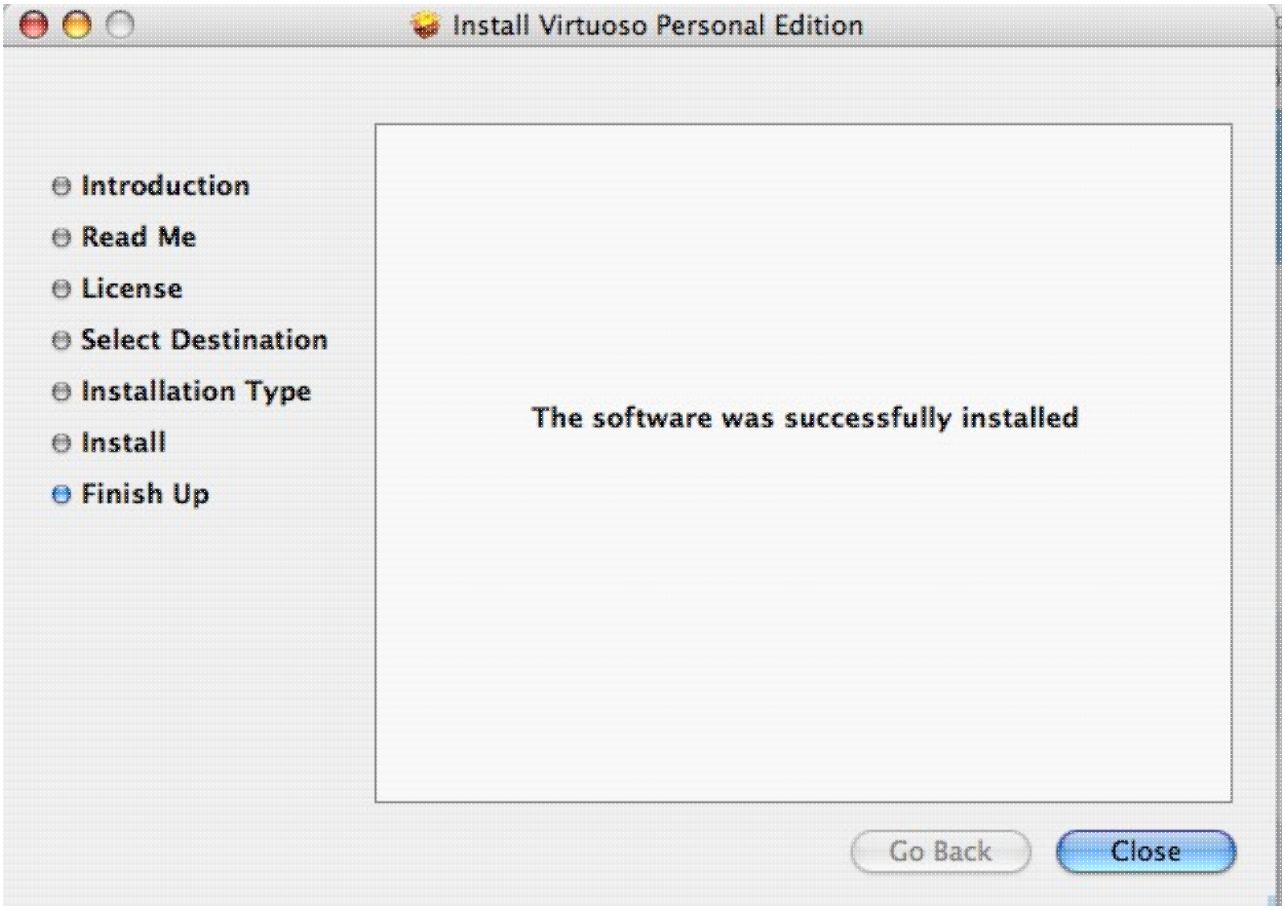
The Virtuoso Server Welcome page will now be displayed. The server is online. This Web based page can be used for general configuration and usage of the Virtuoso Server:

Figure 2.47. Welcome



The Installation is now complete.

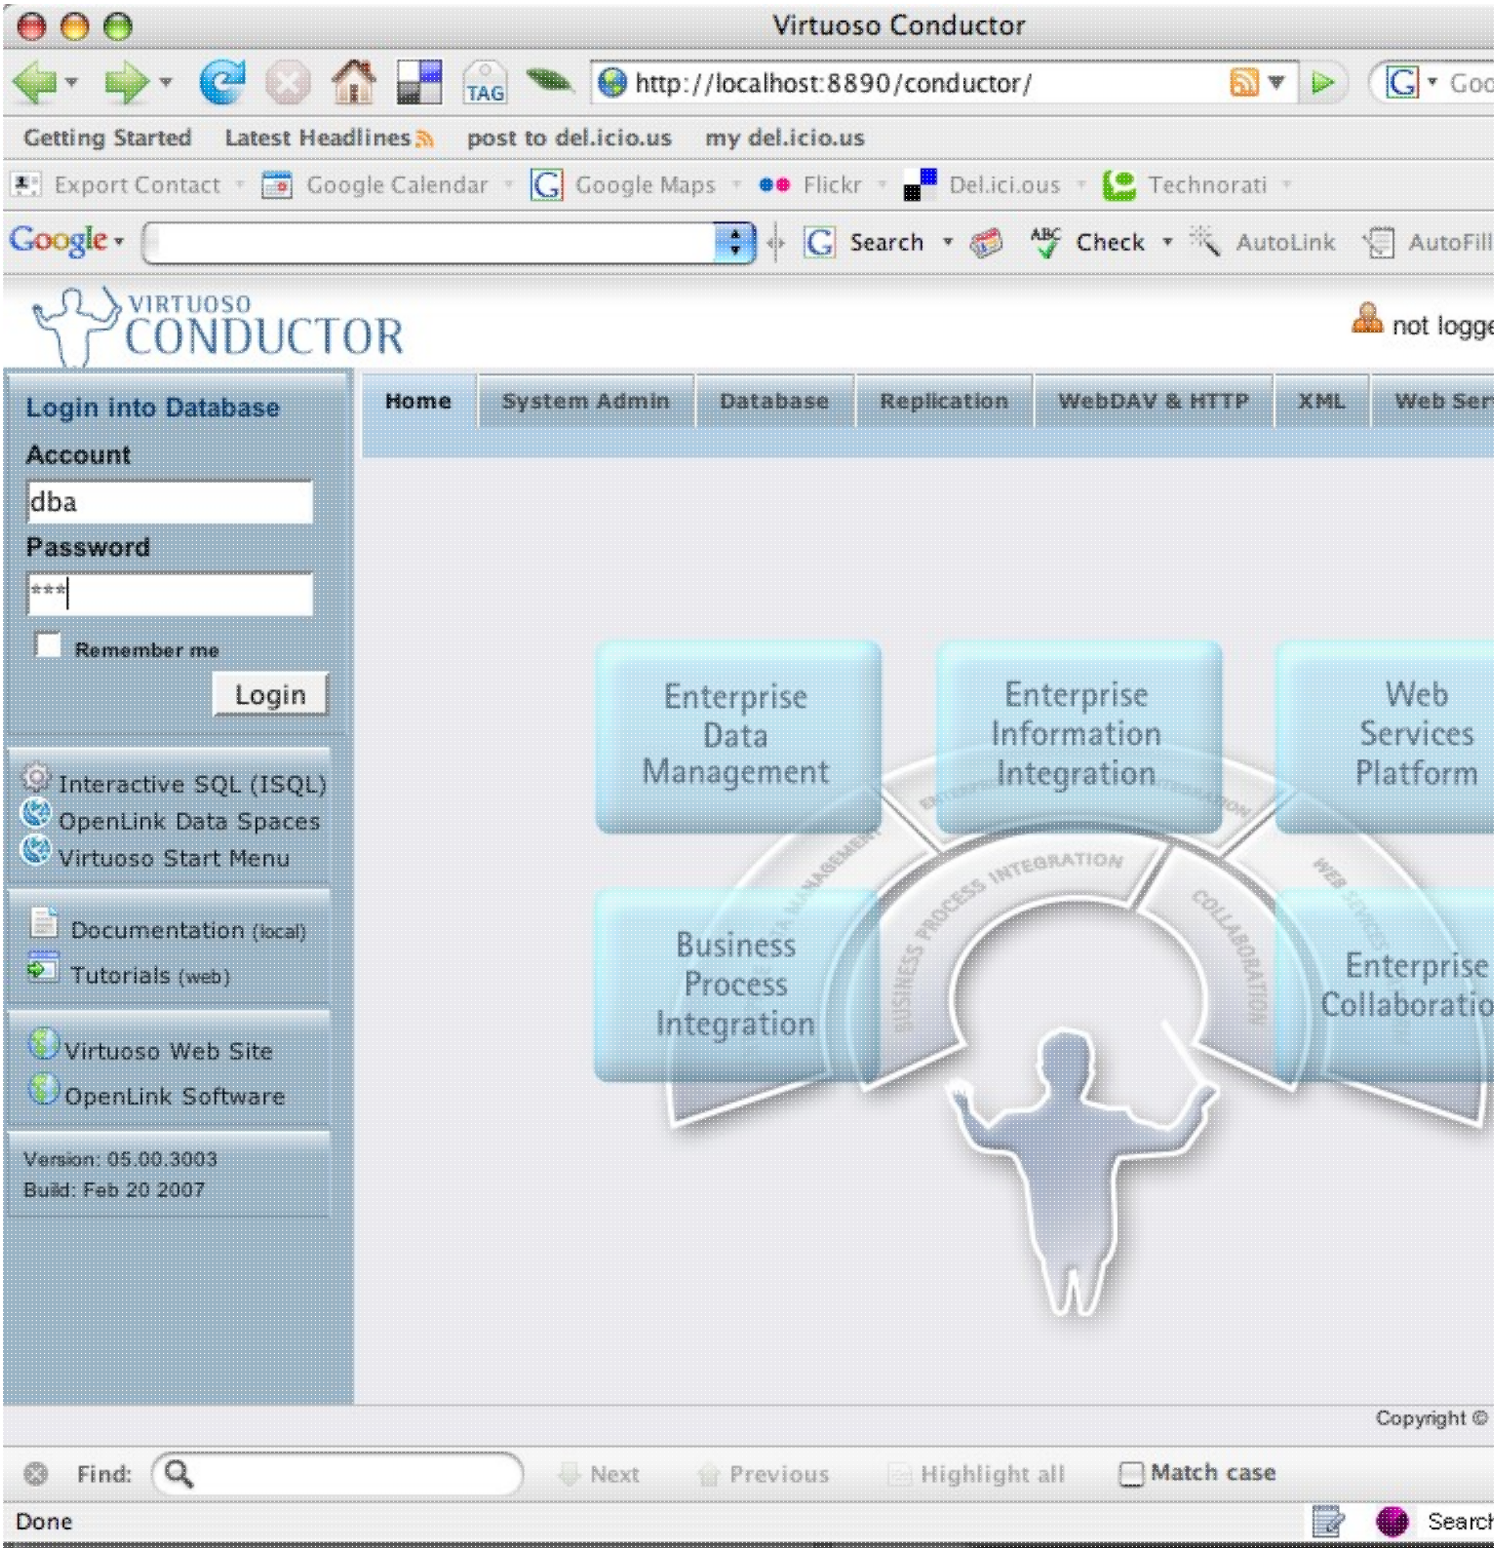
Figure 2.48. Installation complete



2.4.4. Configuration

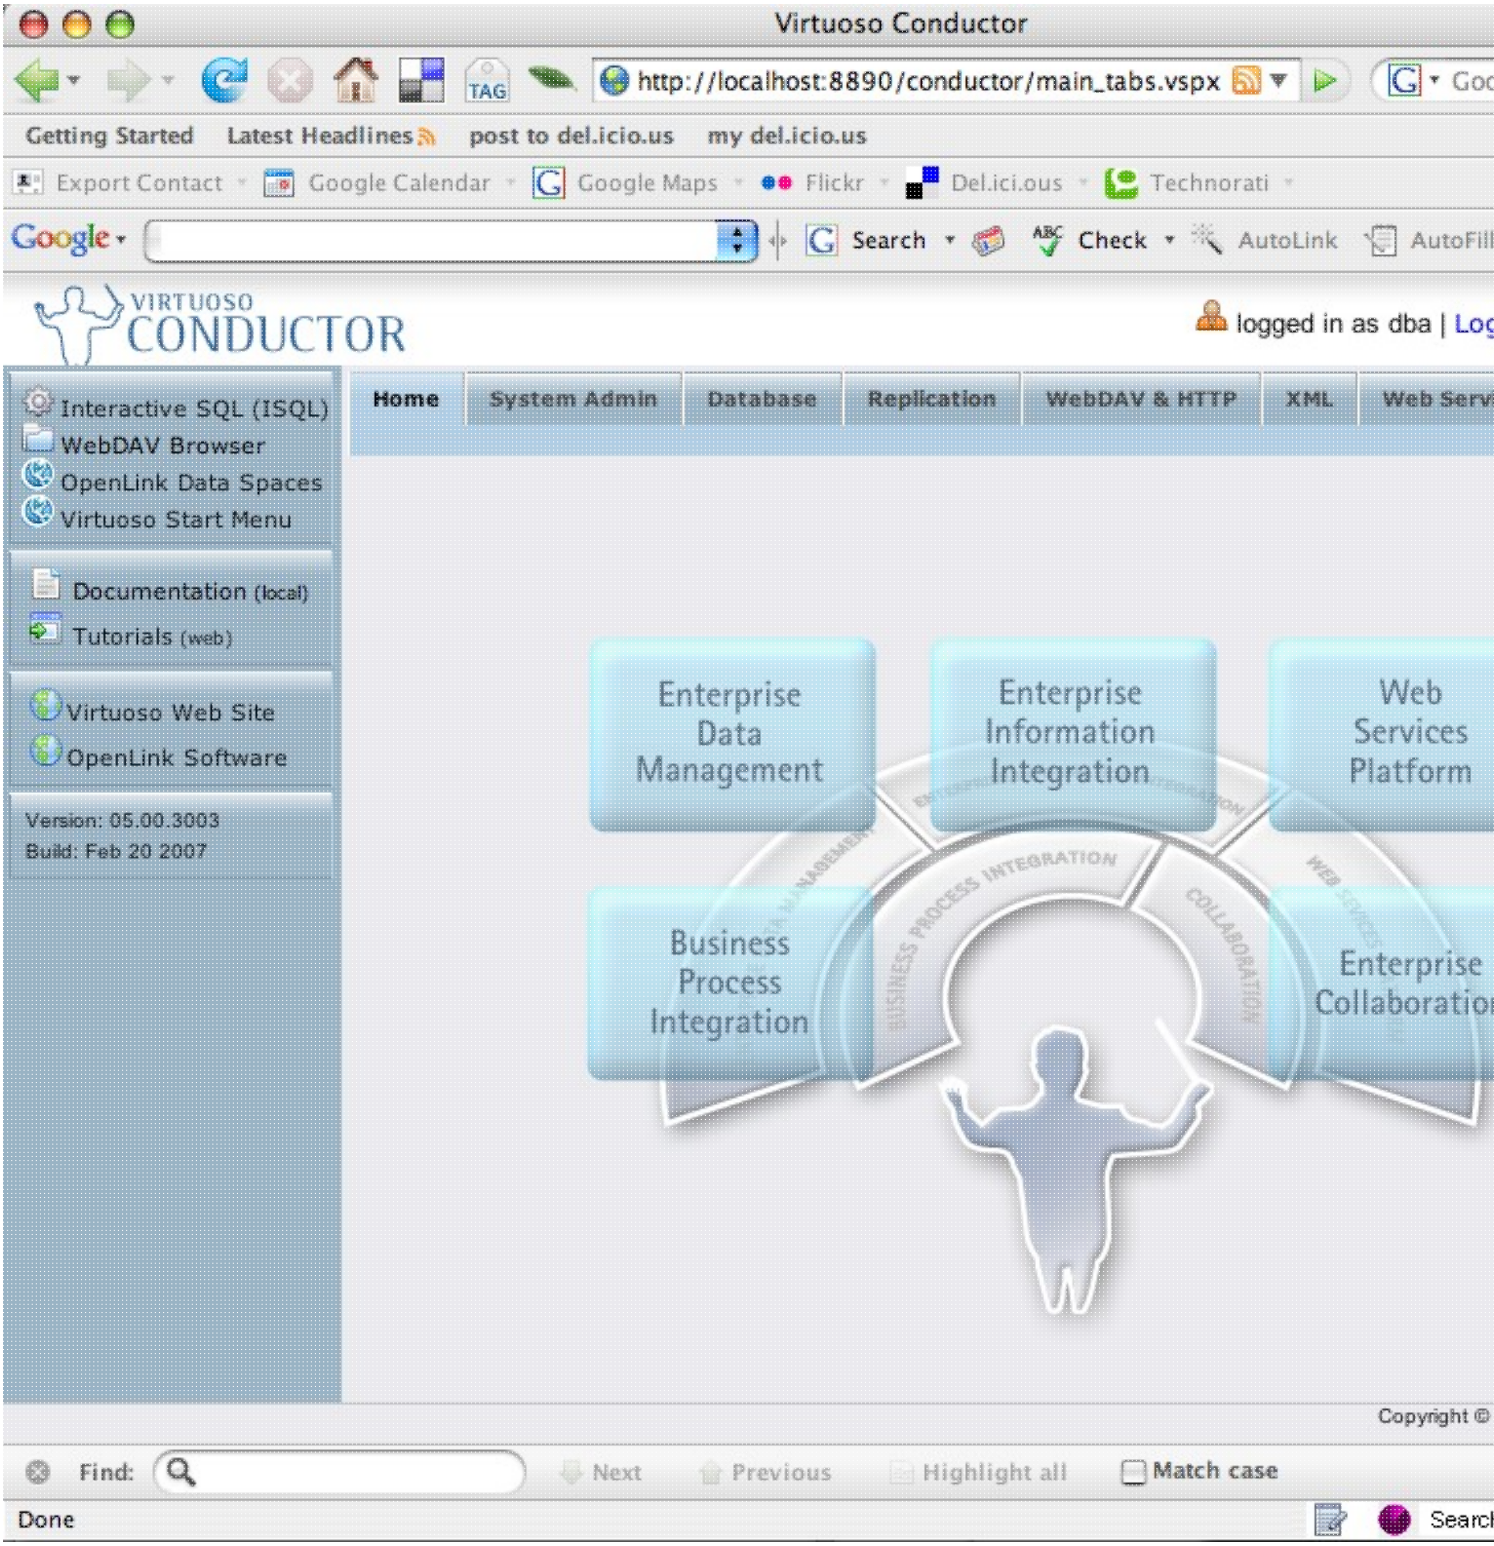
Click on the "Conductor" link in the left frame of the Welcome page to load the Virtuoso Conductor which is the Administration interface for the installation. Enter the "dba" username and password to login.

Figure 2.49. Configuration



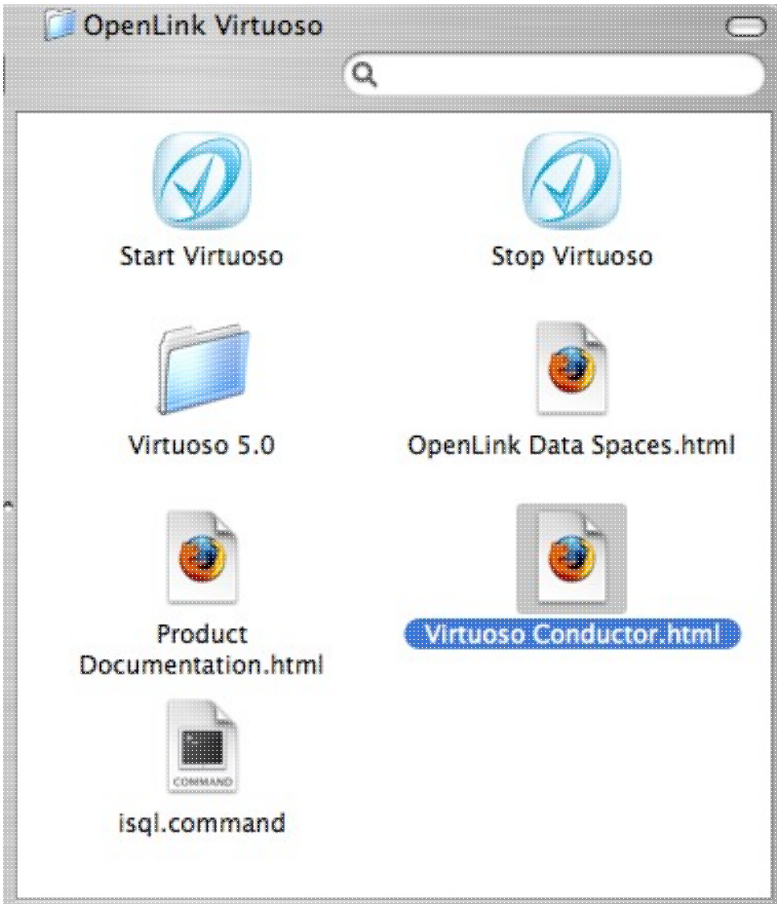
Once logged into the conductor click on any of the "Tabs" along the top to Administer the various features of the Virtuoso Universal Server installation.

Figure 2.50. Various features using Conductor Tabs



Apple scripts for starting and stopping your Virtuoso Universal Server installation are located in the "/Application/OpenLink Virtuoso" folder of the machine.

Figure 2.51. Location of apple scripts



2.4.5. Post Installation

Post-Installation Sanity Check

A quick way to check that the database is running, is to point a browser to the http port. The following example URLs will show the System Manager for the default, and the demo Virtuoso databases:

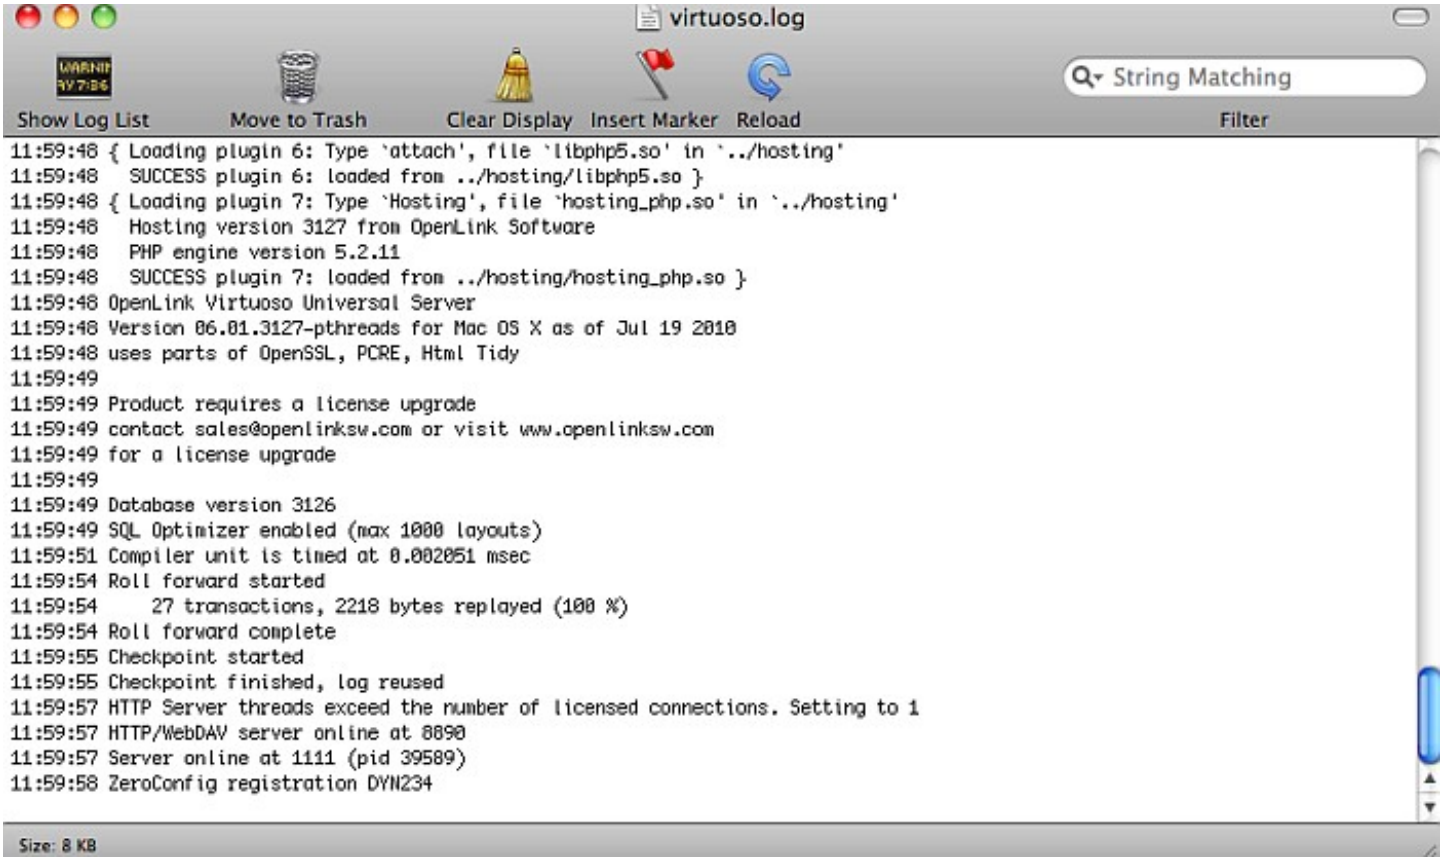
```
http://example.com
http://example.com
http://a_virtuoso_server.org:8890
```

Troubleshooting DB Startup Failures

Install failure

Check the .log file in oplmgr (License Manager) location: `/Library/Application Support/openlink/bin/` , which is for the database and log files etc. in order to review the installed files binaries and databases (defaults) for issues if install fails.

Figure 2.52. The .log file



.lck existance

Check .log in case of .lck issue

Delete the .lck file and repeat the steps from above.

.trx incompatiblity issue

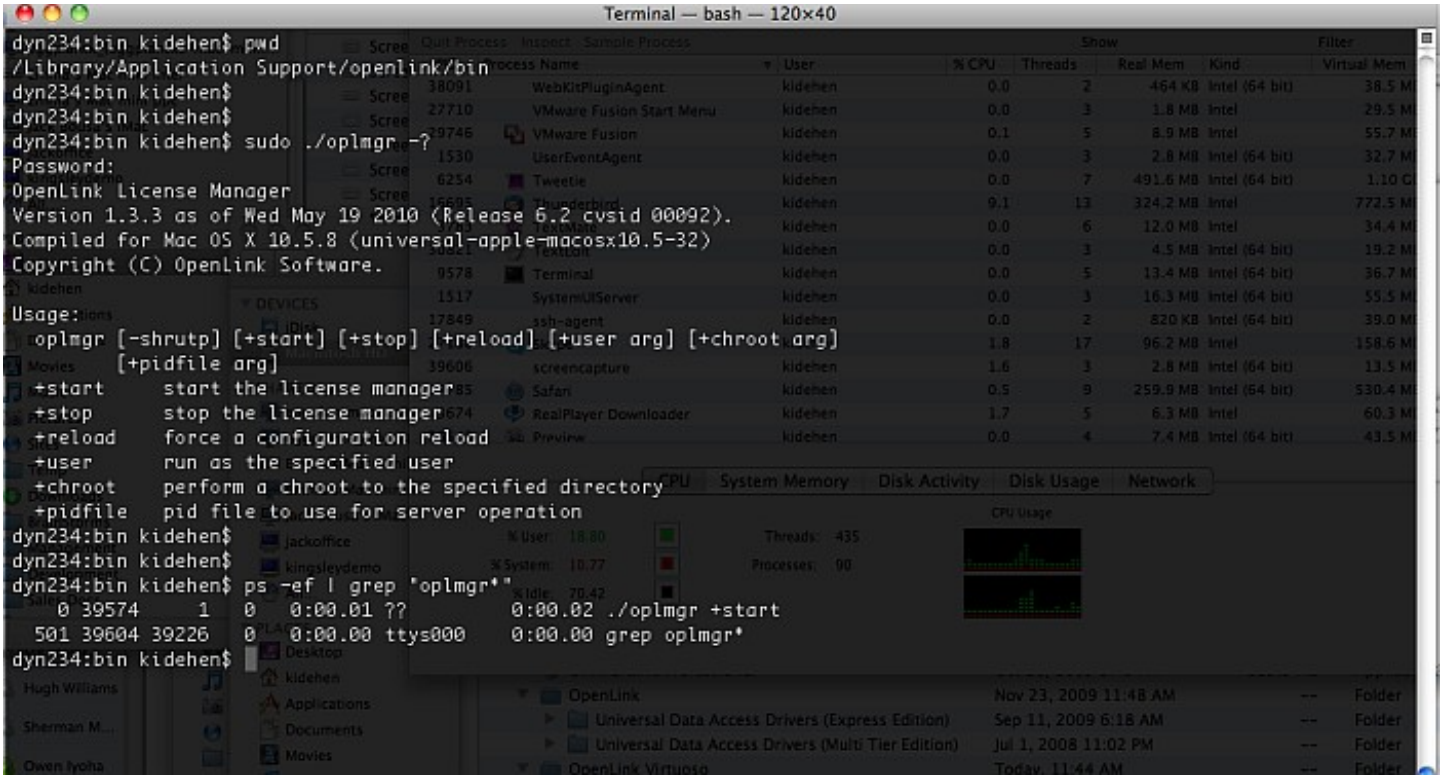
Check .log in case of .trx incompatiblity issue

oplmgr issue

To stop, start, or reload (which updates licenses) use the following commands:

```
/Library/Application Support/openlink/bin/oplmgr +start | +stop | +reload
```

Figure 2.53. The .log file



See Also:
OpenLink License Management

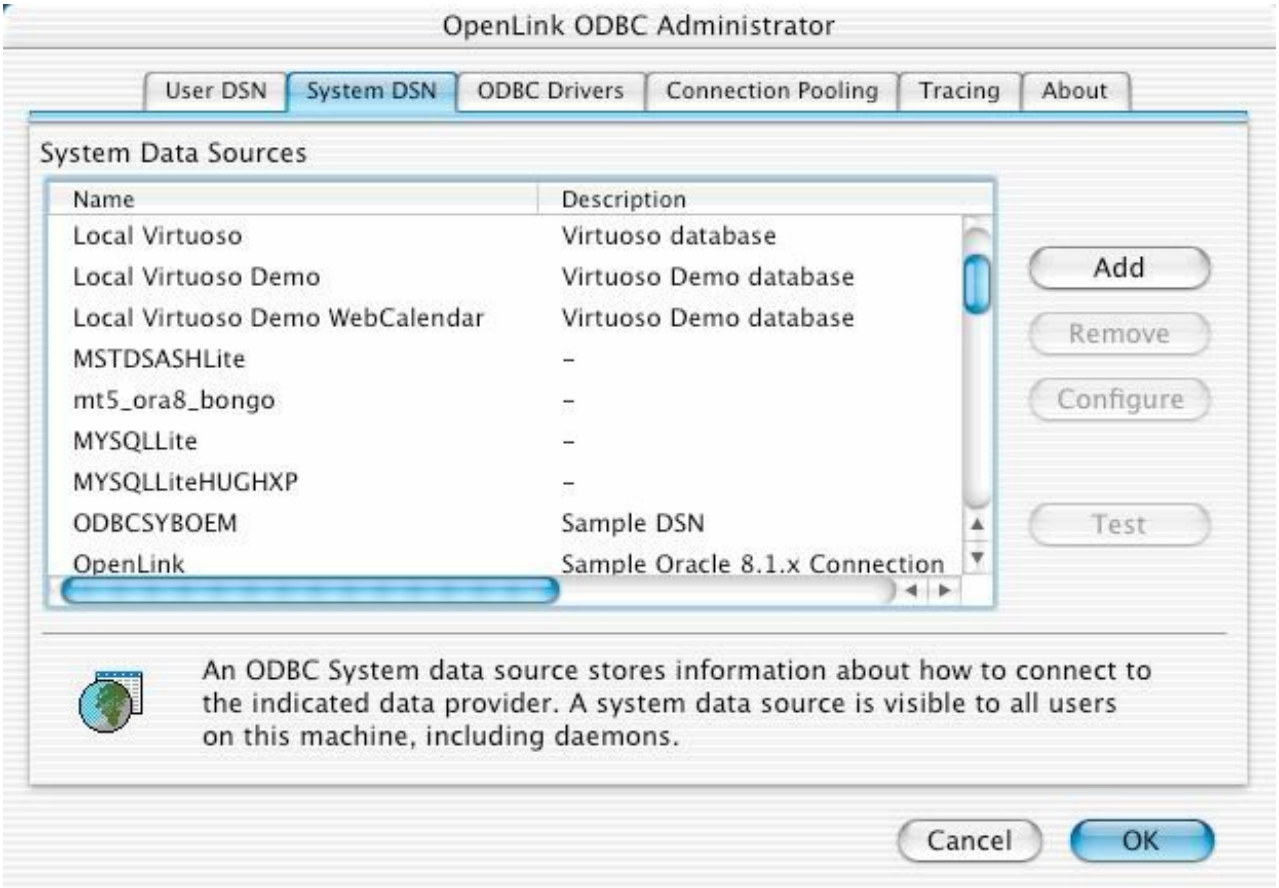
2.4.6. Configuring an ODBC Data Source

Launch the iODBC Administrator, assuming that you have the iODBC Administrator installed.

On some Mac OS X systems installed on an HFS partition, the icons may not be displayed correctly or at all, due to a Mac OS X bug. In such cases a simple reboot of your system should correct this.

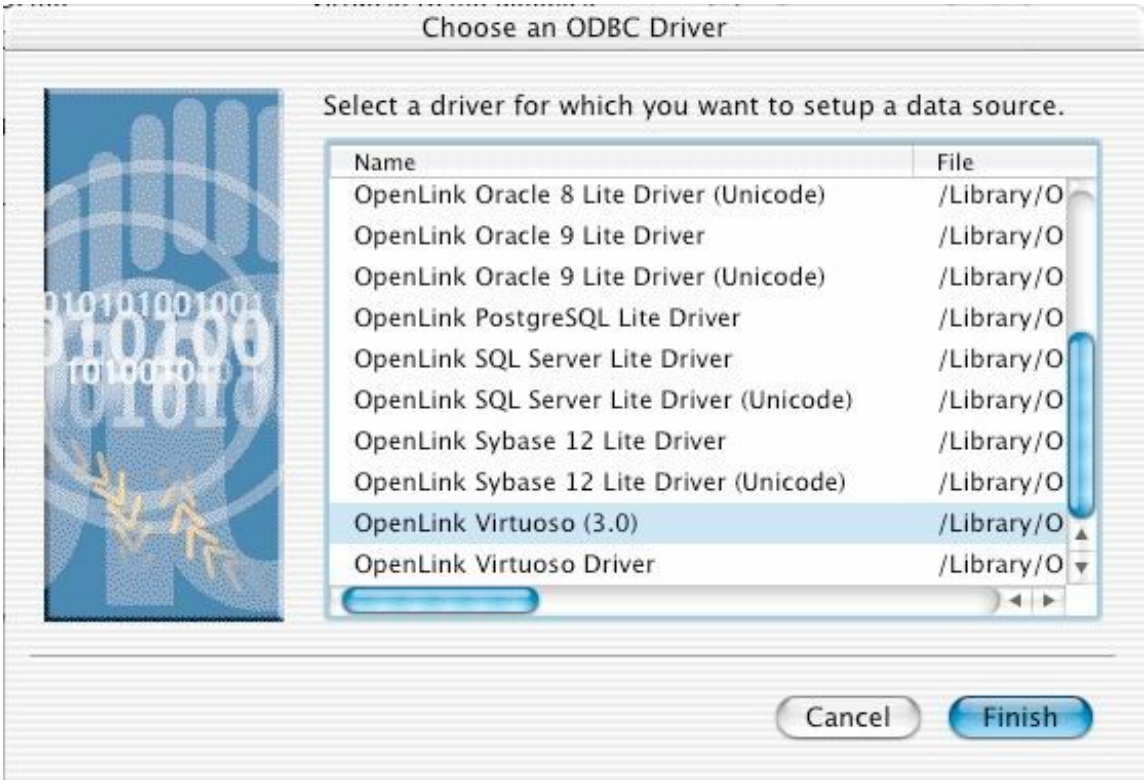
Once the iODBC Administrator window has appeared you can press the *Add* button on the either the *User DSN* or the *System DSN* panel to add a new Data Source entry.

Figure 2.54. ODBC Administrator



Choose the driver that you wish to create a Data Source for, in this case the Virtuoso Driver (3.0).

Figure 2.55. ODBC Administrator - Choose Virtuoso Driver

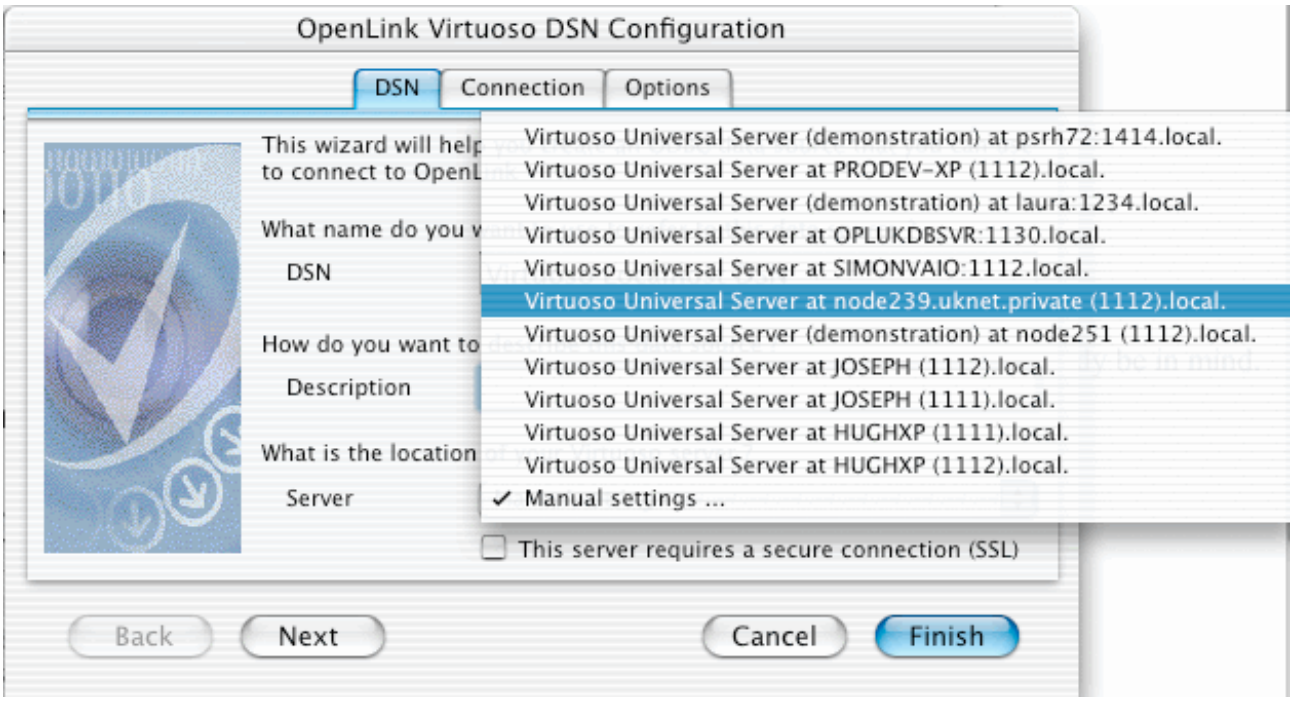


Provide all required details in the fields provided by the setup panel.

Figure 2.56. ODBC Administrator - Configure Virtuoso DSN

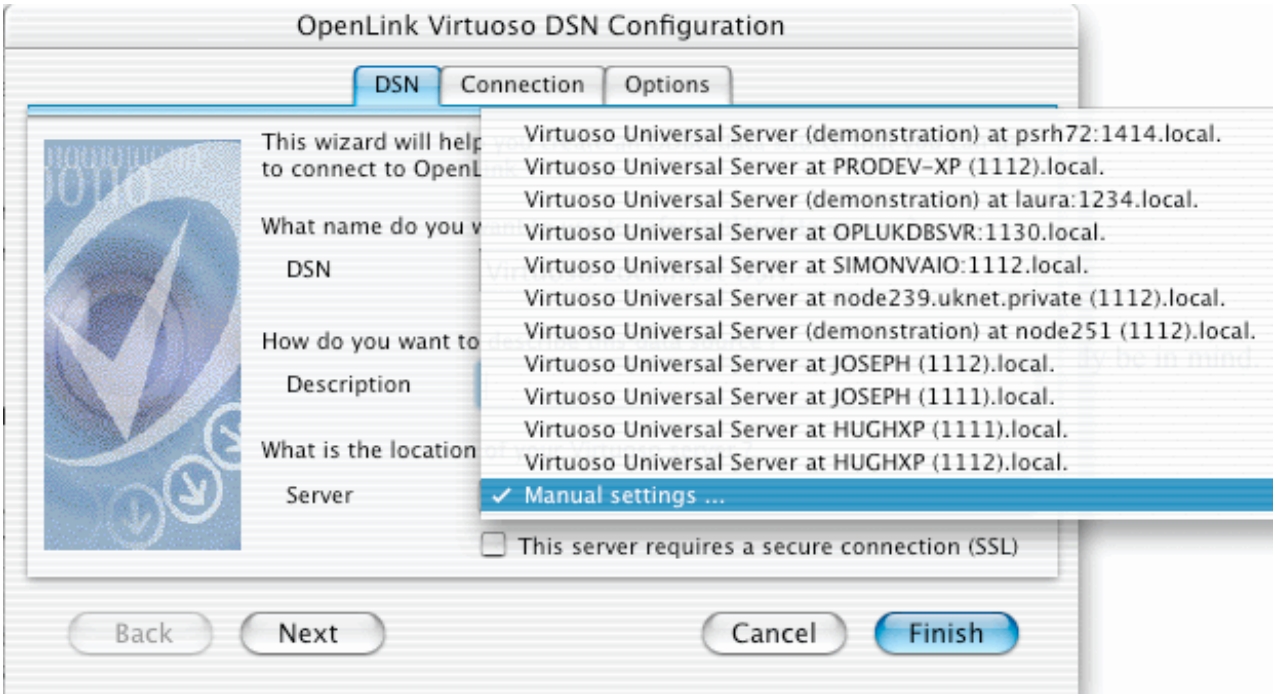
The server can be picked from the list of Zero Configuration Datasources that is discovered.

Figure 2.57. Pick Zero Config



Alternatively a manual selection can be made for the server.

Figure 2.58. Pick manual mode



In this case enter the hostname (or IP) and port number.

Figure 2.59. Manual Server Entry

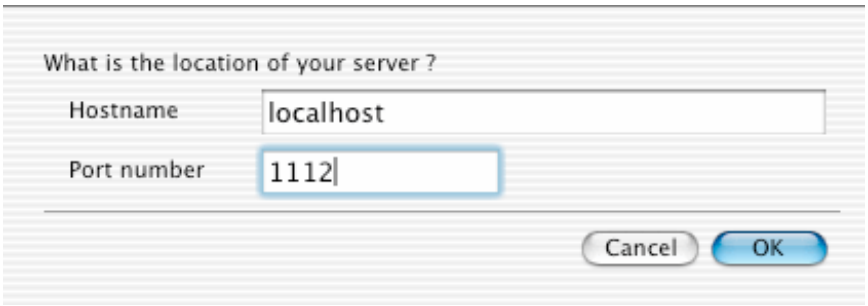


Figure 2.60. ODBC Administrator - Configure Virtuoso DSN

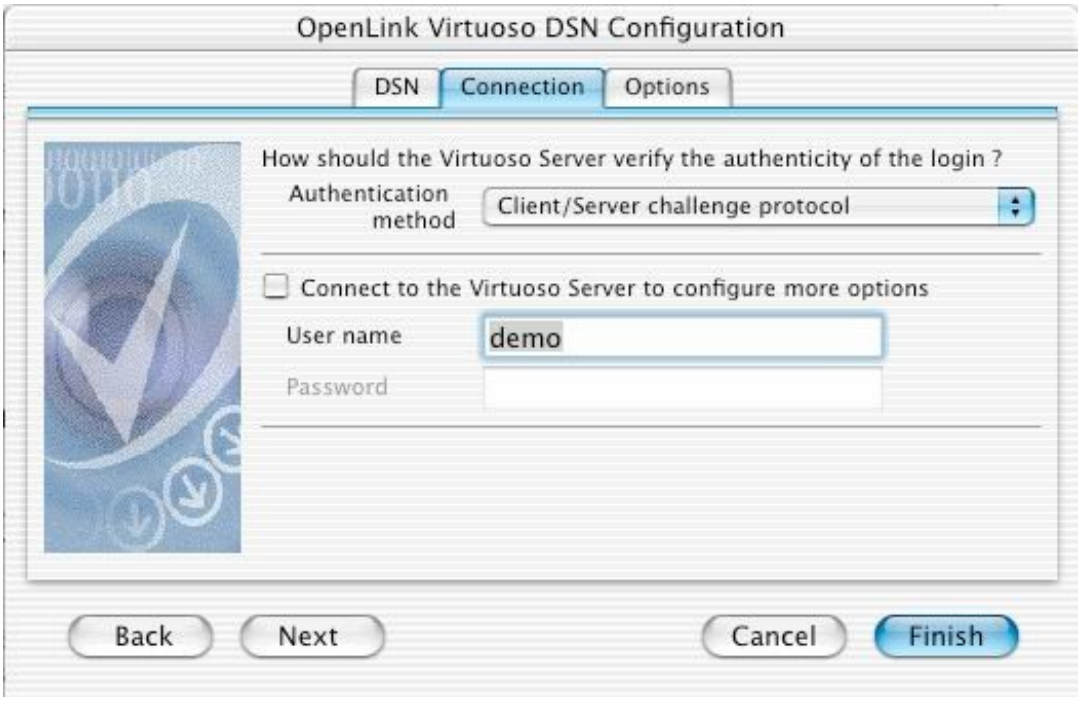

Figure 2.61. ODBC Administrator - Configure Virtuoso DSN

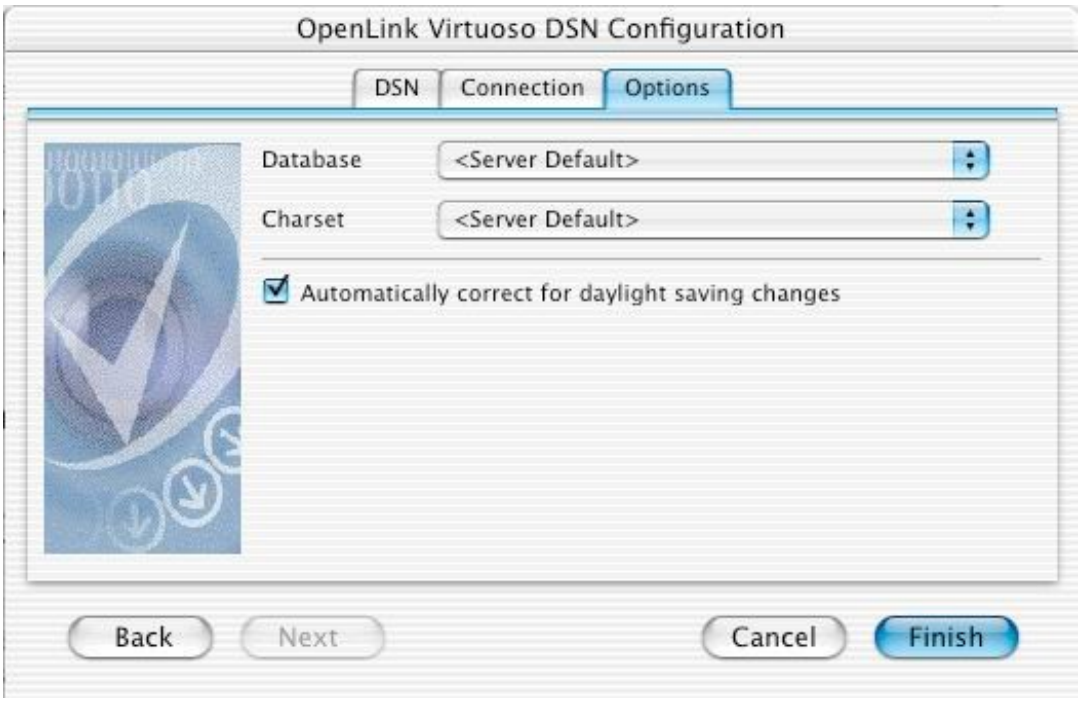


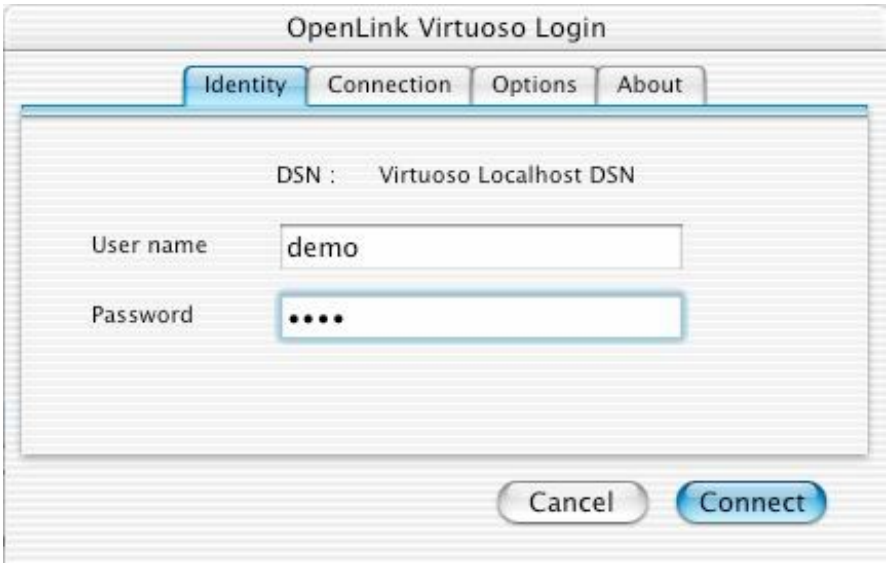
Press the *Finish* button to save the Data Source information.

2.4.7. Testing an ODBC Data Source

Select the Data Source from the DSN list, and press the *Test* button.

You will be prompted for a username and password to establish a connection with the Data Source.

Figure 2.62. Login - Identity Tab



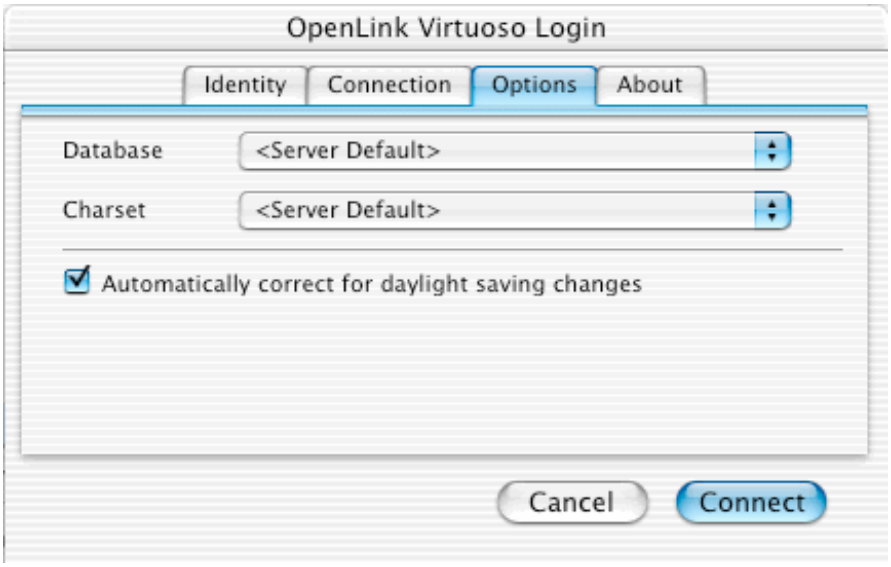
The login dialogue also allows you to alter the configuration if required.

Under the Connection Tab are the fields for the remote server, and the authentication method. Typically the defaults are used.

Figure 2.63. Login - Connection Tab

The Options page has Database, Charset and daylight savings configuration. Typically the defaults are used.

Figure 2.64. Login - Options Tab

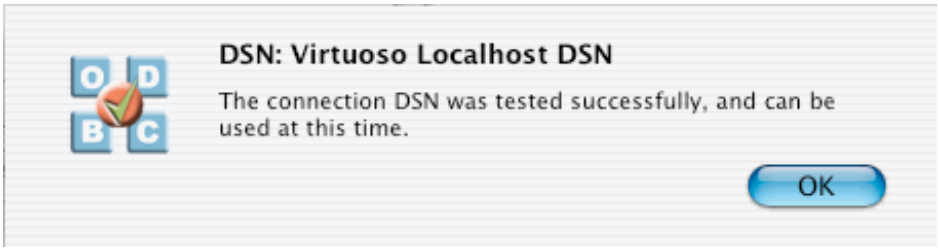


The About page shows the software details.

Figure 2.65. Login - About

The result of the test is shown in a popup window.

Figure 2.66. Test Result



2.4.8. Default passwords

See the following Quick Start chapter for very important information about changing the default passwords .

2.4.9. Demo Database

Installation steps .

2.5. OpenLink License Management

2.5.1. License Files

License Activation

Mac OS X

1. Launch `Terminal.app (/Applications/Utilities/)`
2. Execute the command `cd "/Library/Application Support/openlink/bin/"`
3. Execute the command `oplmgr +stop`
4. Retrieve your new Virtuoso license file from an email or ODS Briefcase .
5. Replace the old license file with the new license file. (You may delete the old file, or safely retain it in this location by changing the `.lic` file extension to `.lic-old` .)
6. Execute the command `oplmgr +start`

Windows

1. Launch the

   Services

Control Panel (may be in the

Administrative Tools

sub-folder).
2. Locate and select the

   OpenLink License Manager service

   .
3. Click the

   Stop

   icon.
4. Retrieve your new Virtuoso license file from an email or ODS Briefcase .
5. Replace the old license file with the new license file. (You may delete the old file, or safely retain it in this location by changing the `.lic` file extension to `.lic-old` .)
6. Go back to the

   Services

   Control Panel.
7. Locate and select the

   OpenLink License Manager

   service.
8. Click the

   Start

   icon.

Unix-like OS (AIX, HP-UX, Linux, Solaris, etc.)

1. Open a Unix terminal.
2. `cd` into the root of your Virtuoso installation.
3. Use one of the following commands to set Virtuoso-related environment variables. (Note that they do, and must, begin with dot-space-dot-slash.)

   - `. ./virtuoso-enterprise.sh` - bash, bsh, ksh, and related shells
   - `. ./virtuoso-enterprise.csh` - csh, tcsh, and related shells
4. Execute the command: oplmgr +stop
5. Retrieve your new Virtuoso license file from an email or ODS Briefcase . Use binary-mode ftp to transfer the new license to the Unix box, if required.
6. Place the new license in the bin sub-directory of the Virtuoso installation.
7. Set and export an `OPL_LICENSE_DIR` environment variable that passes the path to the directory that contains your Virtuoso license file, e.g

   - `export OPL_LICENSE_DIR="/opt/virtuoso/bin/"`
   - `OPL_LICENSE_DIR="/opt/virtuoso/bin/" ; export OPL_LICENSE_DIR`
8. Execute the command: `oplmgr +start`

Retrieve OpenLink Licenses from Your ODS Briefcase

OpenLink's registered users receive an automatic OpenLink Data Spaces (ODS) account on the My OpenLink home page. This account allows registered users to experience and explore OpenLink's Virtuoso Universal Cilent applications.It also provides a convenient storage mechanism for OpenLink commercial and evaluation license keys.

This page shows you how to access licenses that reside in your ODS Briefcase . A second 15 Day evaluation license is

automatically copied to the Briefcase, when you download our software and receive your first 15 Day key. You may access the Briefcase by clicking on the link that appears in the email that contains the first license. Alternatively, you may identify the ODS url by logging into the OpenLink site.

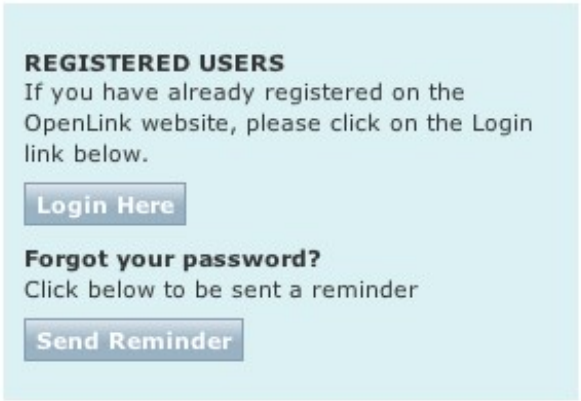
The following instructions will allow you to access your ODS Briefcase via the OpenLink Web site.

1. Click the Login link that appears on the OpenLink Web page.

Figure 2.67. ODS Briefcase

2. Click the "Login Here" button that appears in the Registered Users box.

Figure 2.68. ODS Briefcase

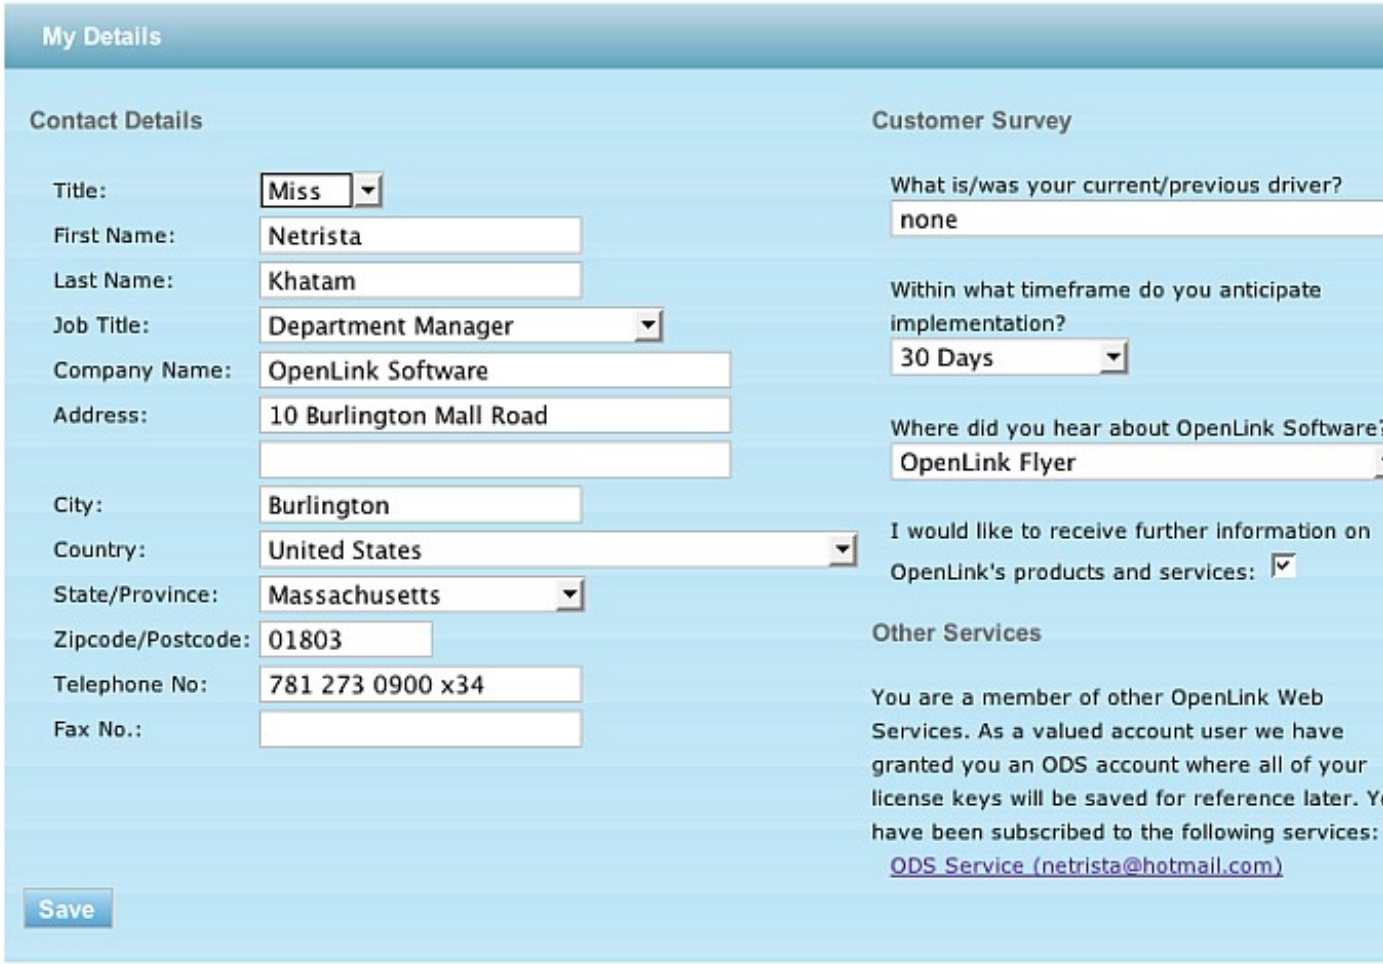


3. Click the "Check my profile" link that appears in the Welcome box.

Figure 2.69. ODS Briefcase

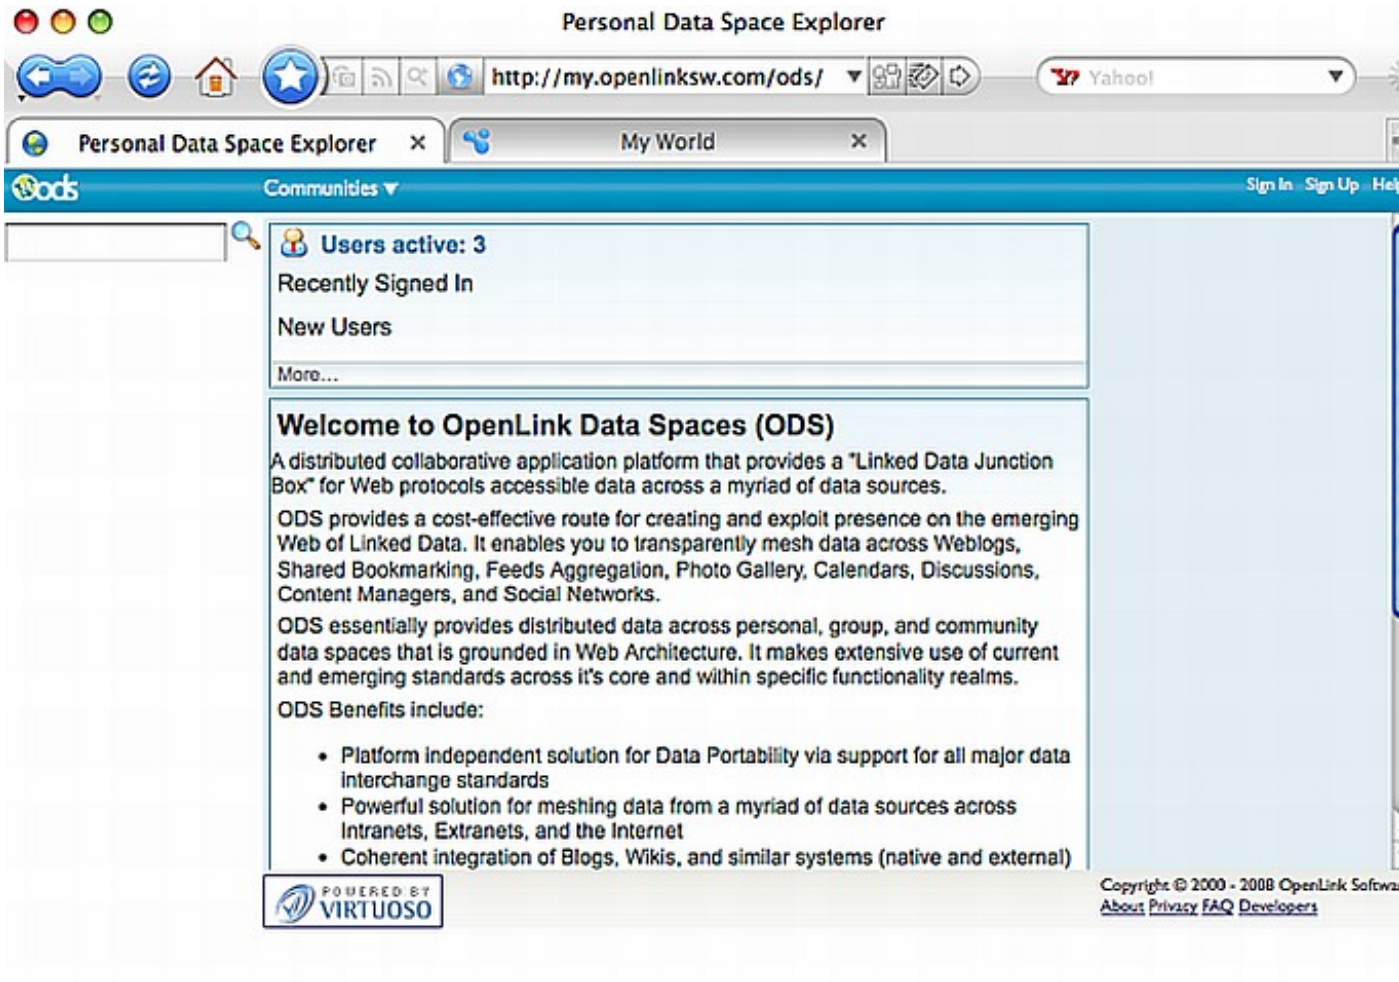
4. Click the ODS Service URL that appears in the lower right hand corner of the My Details dialog.

Figure 2.70. ODS Briefcase



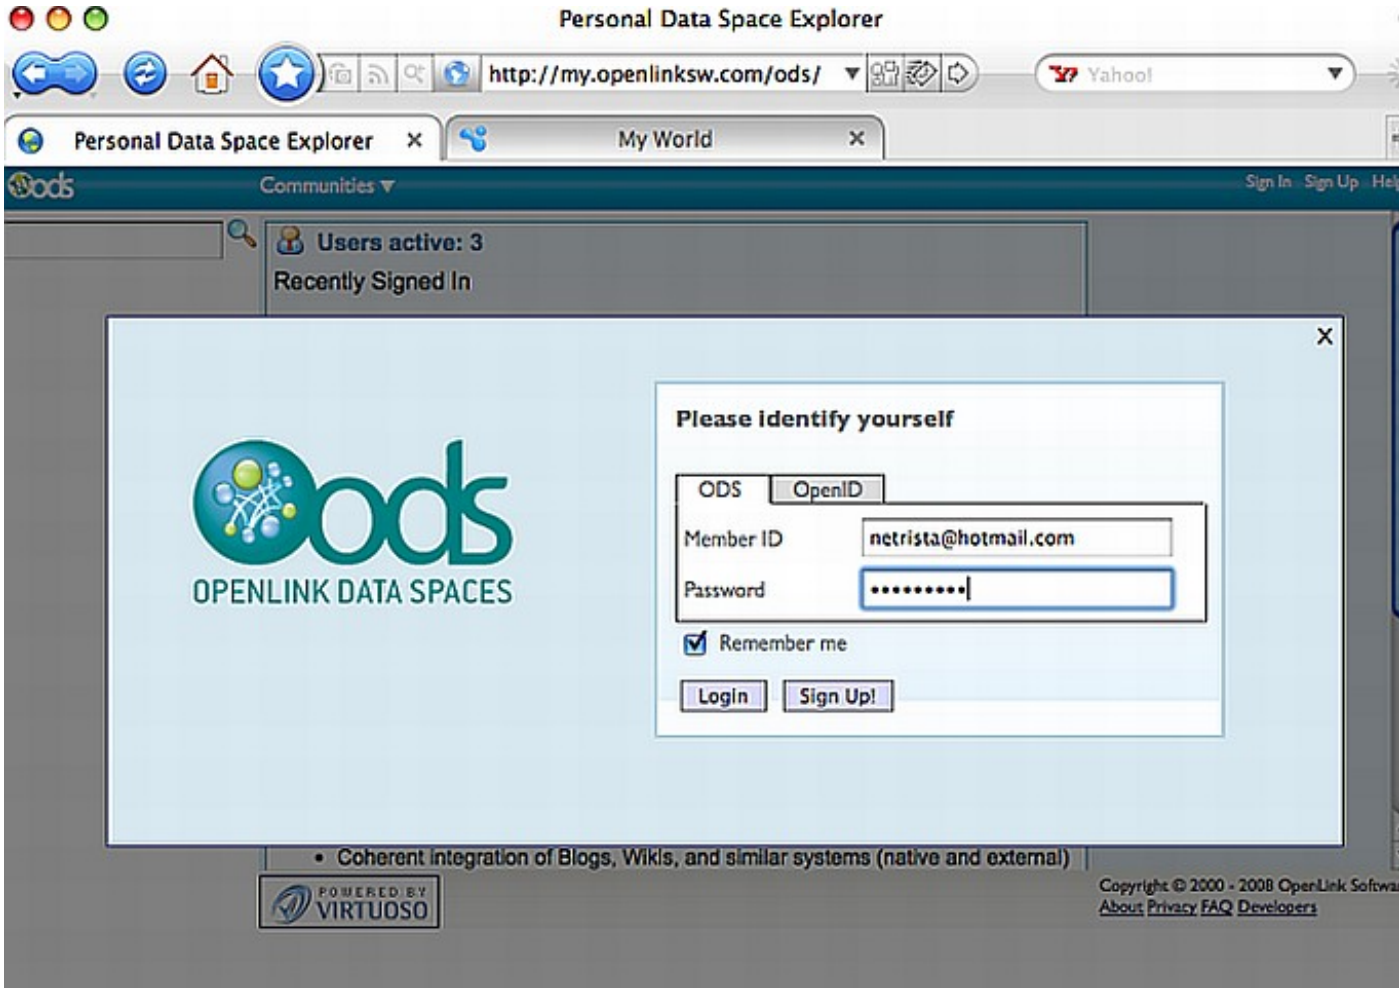
5. Allow the My OpenLink Web page to load in a Web browser.

Figure 2.71. ODS Briefcase



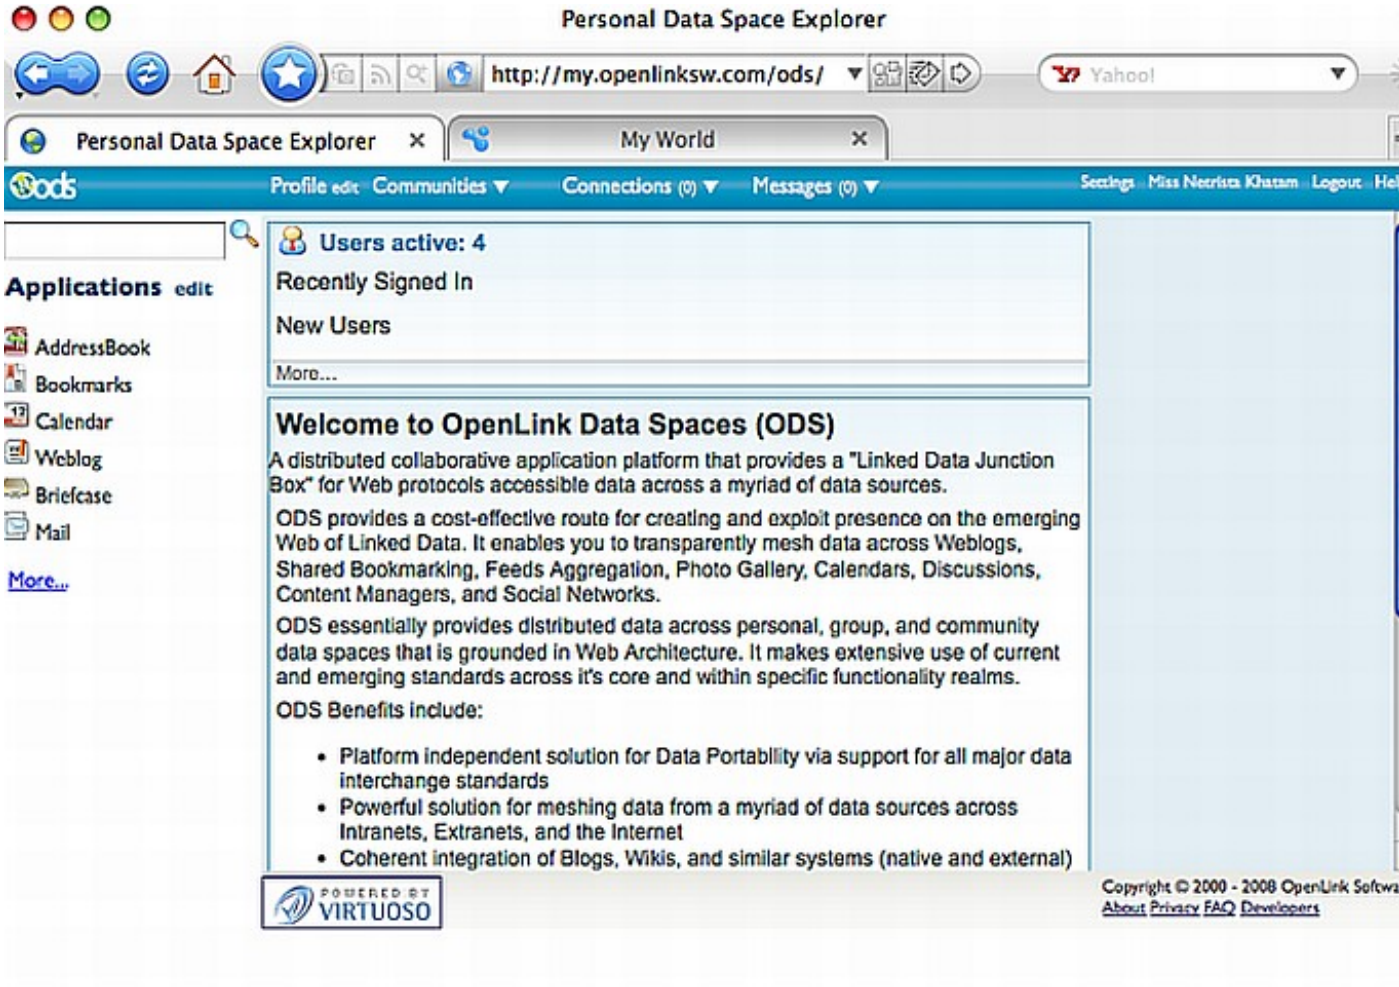
6. Login to your OpenLink Data Space using your OpenLink login.

Figure 2.72. ODS Briefcase



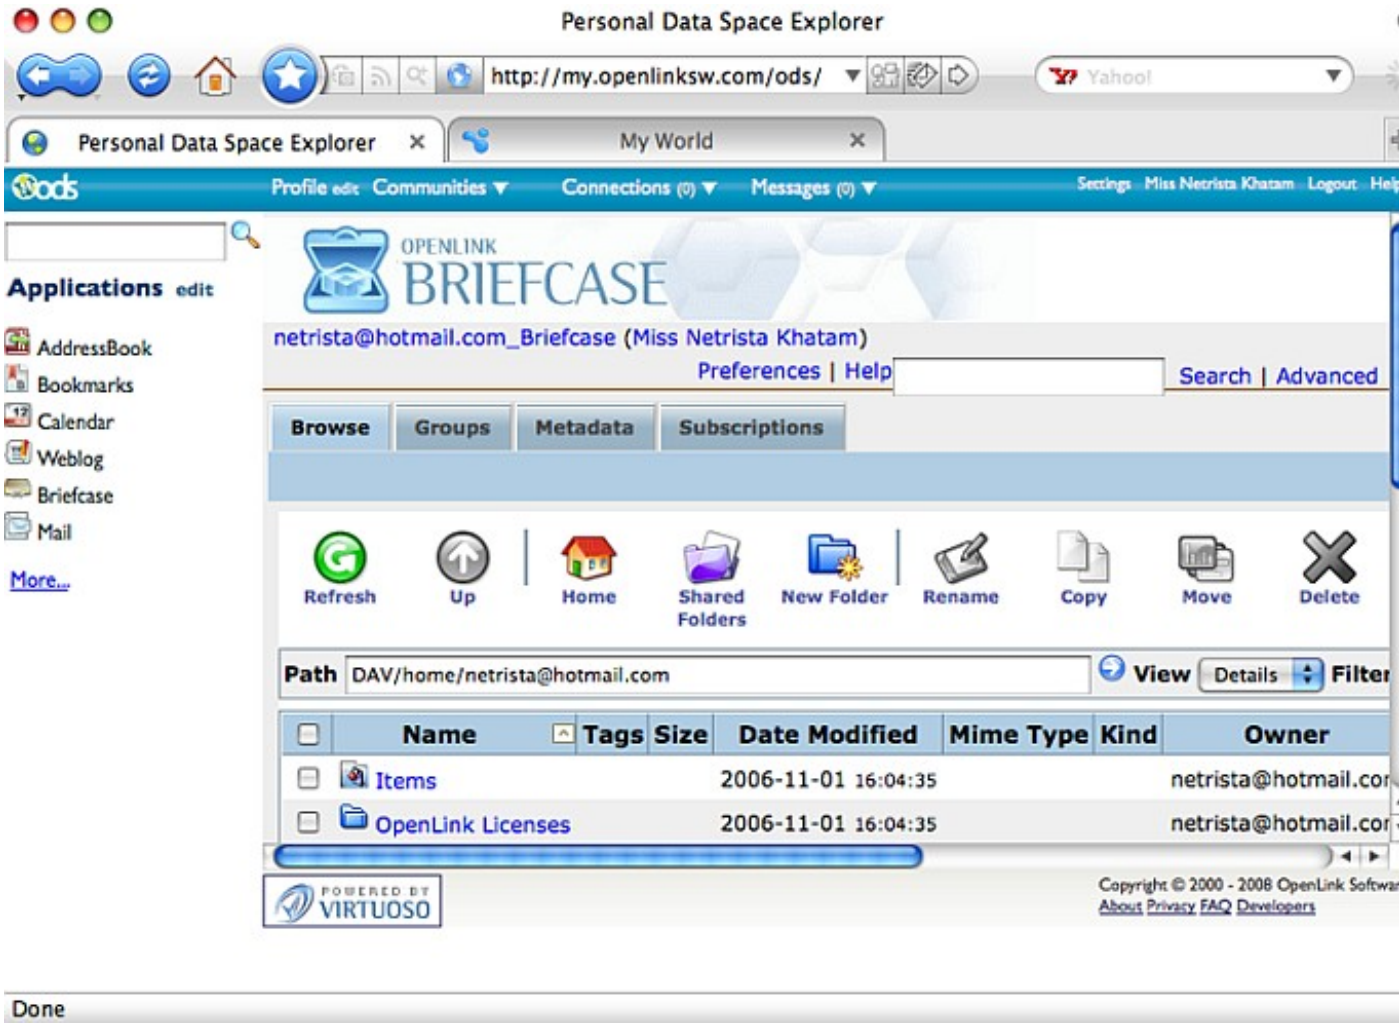
7. Click the Briefcase link that appears in the ODS menu bar at the top of the page.

Figure 2.73. ODS Briefcase



8. Your license will appear as a Resource Item under the Briefcase Summary.

Figure 2.74. ODS Briefcase



Click the license link to download your license. Provide your OpenLink username and password if prompted for a DAV login.

License Preservation

Users may choose to preserve the existing license file when applying a new license file. This facilitates a rollback to the original file, if the replacement file is problematic.

Mac OS X

- Use StuffIt or a similar utility to store the file in a compressed archive.
- Rename the file, e.g., from `virtuoso.lic` to `virtuoso.lic-old`

Windows

Use WinZip or a similar utility to copy your license file to a .zip archive.

Unix-like OS (AIX, HP-UX, Linux, Solaris, etc.)

Use tar or gzip to copy your license file into an archive. For example: `tar cvzf virtuoso-lic.tgz virtuoso.lic`

License Removal

Users may choose to remove expired or deprecated license files altogether to ensure the uptake of a new license file.

Mac OS X

1. Shutdown your OpenLink License Manager
2. Click the Search icon.

3. Type your license name into the search box. For example: virtuoso.lic
4. Drag the license from the search results onto the trash icon.
5. Expand the Finder menu.
6. Click Empty Trash.

Windows

1. Launch the

   Services

   Control Panel (may be in the

   Administrative Tools

   sub-folder).
2. Locate and select the

   OpenLink Virtuoso

   service.
3. Click the

   Stop

   icon.
4. Locate and select the

   OpenLink License Manager

   service.
5. Click the

   Stop

   icon.
6. Launch the Windows Search utility, from the Start menu.
7. Search for all files with the name `virtuoso.lic`..
8. Drag all found licenses to the Recycle Bin.
9. Empty the Recycle Bin

Unix-like OS (AIX, HP-UX, Linux, Solaris, etc.)

1. Login to the Unix or Linux operating system.
2. Use the find command to locate relevant license files, and check their permissions and ownership.

```
bash-2.03$ find / -name virtuoso.lic -exec ls -l {} \;
-rw-r--r--   1 virtuoso other        645 Mar 11 08:06 /usr/virtuoso/bin/virtuoso.lic
bash-2.03$
```

3. Use the rm command to remove the license file(s).

```
bash-2.03$ rm /usr/virtuoso/bin/virtuoso.lic
```

4. If the file permissions and ownership require, you can use sudo -

```
bash-2.03$ sudo rm /usr/virtuoso/bin/virtuoso.lic
Password:
bash-2.03$ ls /usr/virtuoso/bin/virtuoso.lic
bash-2.03$
```

   - or su to the appropriate user or group -

```
bash-2.03$ su virtuoso
Password:
```

```
bash-2.03$ rm /usr/virtuoso/bin/virtuoso.lic
bash-2.03$ ls /usr/virtuoso/bin/virtuoso.lic
bash-2.03$
```

2.5.2. License Manager

Monitor License Consumption

OpenLink's License Manager technology provides a sophisticated and easy to use License statistics and monitoring facility. This page introduces you to that facility and provides alternative techniques for versions of the software that do not contain it.

1. Launch the Virtuoso Web interface.
2. Click the

   Conductor

   link.
3. Login with your Virtuoso dba account.
4. Click the

   System Admin

   tab.
5. Locate the

   License

   section to review the terms of your Virtuoso license.
6. Locate the

   Clients

   section to review open connections that consume Virtuoso license points.

Start the License Manager Process

Mac OS X

1. Launch `Terminal.app (/Applications/Utilities/)`
2. Execute the command `cd "/Library/Application Support/openlink/bin/"`
3. Execute the command `oplmgr +start`

Windows

1. Launch the

   Services

   Control Panel (may be in the

   Administrative Tools

   sub-folder).
2. Locate and select the

   OpenLink Virtuoso

   service.
3. Click the

   Start

icon.

Unix-like OS (AIX, HP-UX, Linux, Solaris, etc.)

1. Open a Unix terminal.
2. `cd` into the root of your Virtuoso installation.
3. Use one of the following commands to set Virtuoso-related environment variables. (Note that they do, and must, begin with dot-space-dot-slash.)
   - `. ./virtuoso-enterprise.sh` > - bash, bsh, ksh, and related shells
   - `. ./virtuoso-enterprise.csh` - csh, tcsh, and related shells
4. Execute the command: `oplmgr +start`

Note : OpenLink recommends that you create an `/etc/init.d/` script that sets the environment and runs `oplmgr +start` at boot time.

Stop the License Manager Process

Mac OS X

1. Launch `Terminal.app (/Applications/Utilities/)`
2. Execute the command `cd "/Library/Application Support/openlink/bin/"`
3. Execute the command `oplmgr +stop`

Windows

1. Launch the

   Services

   Control Panel (may be in the

   Administrative Tools

   sub-folder).
2. Locate and select the

   OpenLink License Manager service

   .
3. Click the

   Stop

   icon.

Unix-like OS (AIX, HP-UX, Linux, Solaris, etc.)

1. Open a Unix terminal.
2. `cd` into the root of your Virtuoso installation.
3. Use one of the following commands to set Virtuoso-related environment variables. (Note that they do, and must, begin with dot-space-dot-slash.)
   - `. ./virtuoso-enterprise.sh` - bash, bsh, ksh, and related shells
   - `. ./virtuoso-enterprise.csh` - csh, tcsh, and related shells
4. Execute the command: oplmgr +stop

Reinitialize the License Manager Process

Mac OS X

1. Launch `Terminal.app (/Applications/Utilities/)`
2. Execute the command `cd "/Library/Application Support/openlink/bin/"`
3. Execute the command `oplmgr +reload`

Windows

1. Launch the

   Services

   Control Panel (may be in the

   Administrative Tools

   sub-folder).
2. Locate and select the

   OpenLink License Manager service

   .
3. Click the

   Restart

   icon.

Unix-like OS (AIX, HP-UX, Linux, Solaris, etc.)

1. Open a Unix terminal.
2. `cd` into the root of your Virtuoso installation.
3. Use one of the following commands to set Virtuoso-related environment variables. (Note that they do, and must, begin with dot-space-dot-slash.)

   - `. ./virtuoso-enterprise.sh` - bash, bsh, ksh, and related shells
   - `. ./virtuoso-enterprise.csh` - csh, tcsh, and related shells
4. Execute the command: oplmgr +reload

Additional Usage Notes

The license manager takes several command-line arguments, as revealed by its "usage" output (produced by any unrecognized argument) --

```
bash$ oplmgr --help
OpenLink License Manager
Version 1.2.2 as of Thu Feb 15 2007 (Release 6.0 cvsid 00084).
Compiled for Linux 2.4.20-46.9.legacysmp (i686-generic-linux-glibc23-32)
Copyright (C) OpenLink Software.

Usage:
oplmgr [-shrutp] [+start] [+stop] [+reload] [+user arg] [+chroot arg]
[+pidfile arg]
+start     start the license manager
+stop      stop the license manager
+reload    force a configuration reload
+user      run as the specified user
+chroot    perform a chroot to the specified directory
+pidfile   pid file to use for server operation
```

2.5.3. Debugging License Problems

Virtuoso license problems are easy to debug. The following information provides a conceptual framework and troubleshooting tips suitable for all licensing problems.

Identifying License Problems

License problems occur when users attempt to apply them to products or when they hit a ceiling associated with concurrent usage. Most license errors are explicit and include text that states that a license is invalid, expired, or exceeded. Problems associated with performance or stability problems that do not produce license related errors are not likely to be caused by licenses. There is no scenario in which use of an evaluation key would contribute to limited functionality. OpenLink's products are fully functional regardless of the license key applied. The license key simply dictates the length of time for which a product may be used.

Source of License Problems

Licenses problems appear under the following circumstances:

- A license file is ftp'd in ASCII.
- The license covers a different OpenLink product.
- The license covers a different OpenLink release.
- A machine has more physical Processor cores than allotted for by the license.
- The license can not be found.
- The wrong license is being found.
- You did not perform the appropriate steps to register the license.
- The License Manager process needs to be restarted.
- The license is inadequate for your level of concurrent activity

Troubleshooting License Problems

Use the following tips to resolve your licensing tips or supply OpenLink Technical Services with your findings:

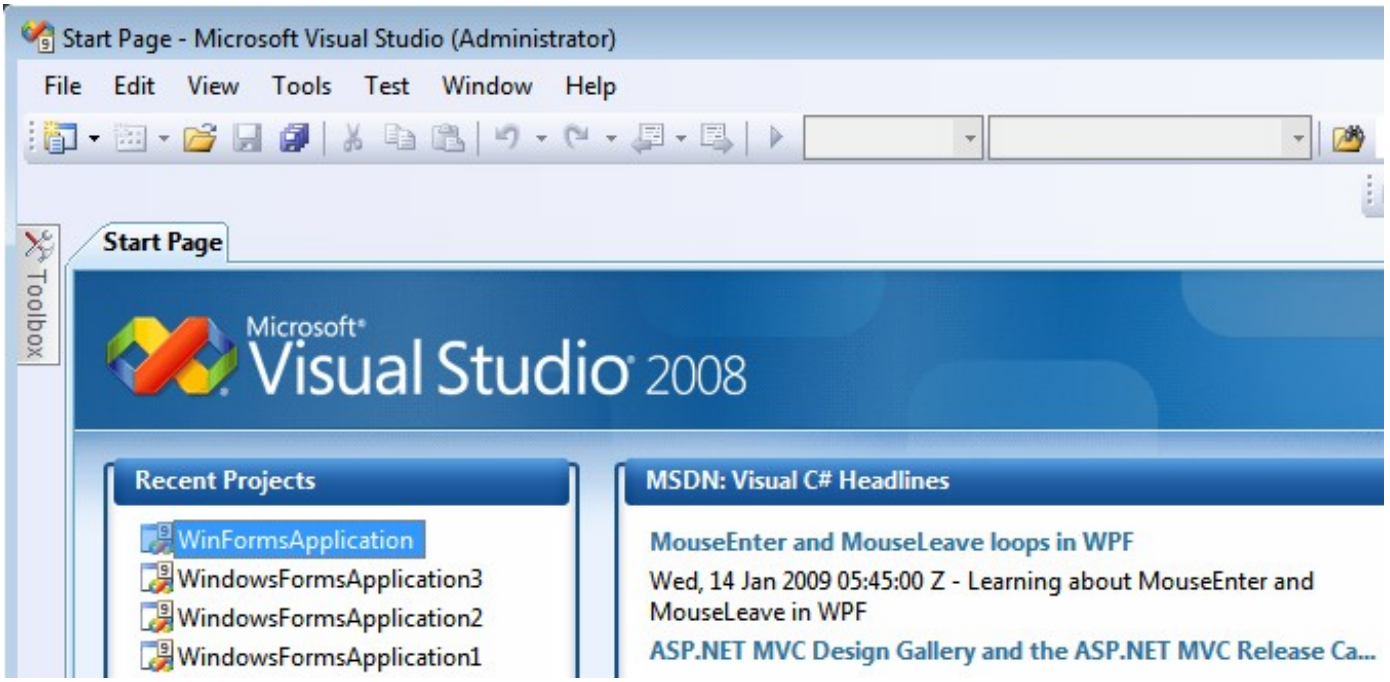
- FTP all licenses (virtuoso.lic) in binary mode.
- Review the terms of the email that contained the license.
- Ensure that the license that you have received is for Virtuoso Universal Server and not a data access provider or driver.
- Compare the Virtuoso version on your machine with the version covered by the license key.
- Identify the number of physical Processor cores on the box that hosts the license and ensure those cores are covered by the license key.
- Use OpenLink's licensing guidelines to ensure that the license is placed in the appropriate location on the target machine.
- Use the host machine's search utilities to ensure that expired or deprecated license files are removed from the host machine and deleted from the trash.
- Use OpenLink's licensing guidelines to ensure that you have performed the license application procedure using the correct steps in the appropriate order.
- Use the host monitoring utilities to ensure that applicable processes have been restarted as detailed in OpenLink's licensing guidelines.

2.6. Virtuoso ADO.Net Data Grid Form Application

This section details the steps required to create a simple Visual Studio 2008 Windows Form application with associated DataGridView control for displaying data in selected tables from a Virtuoso database.

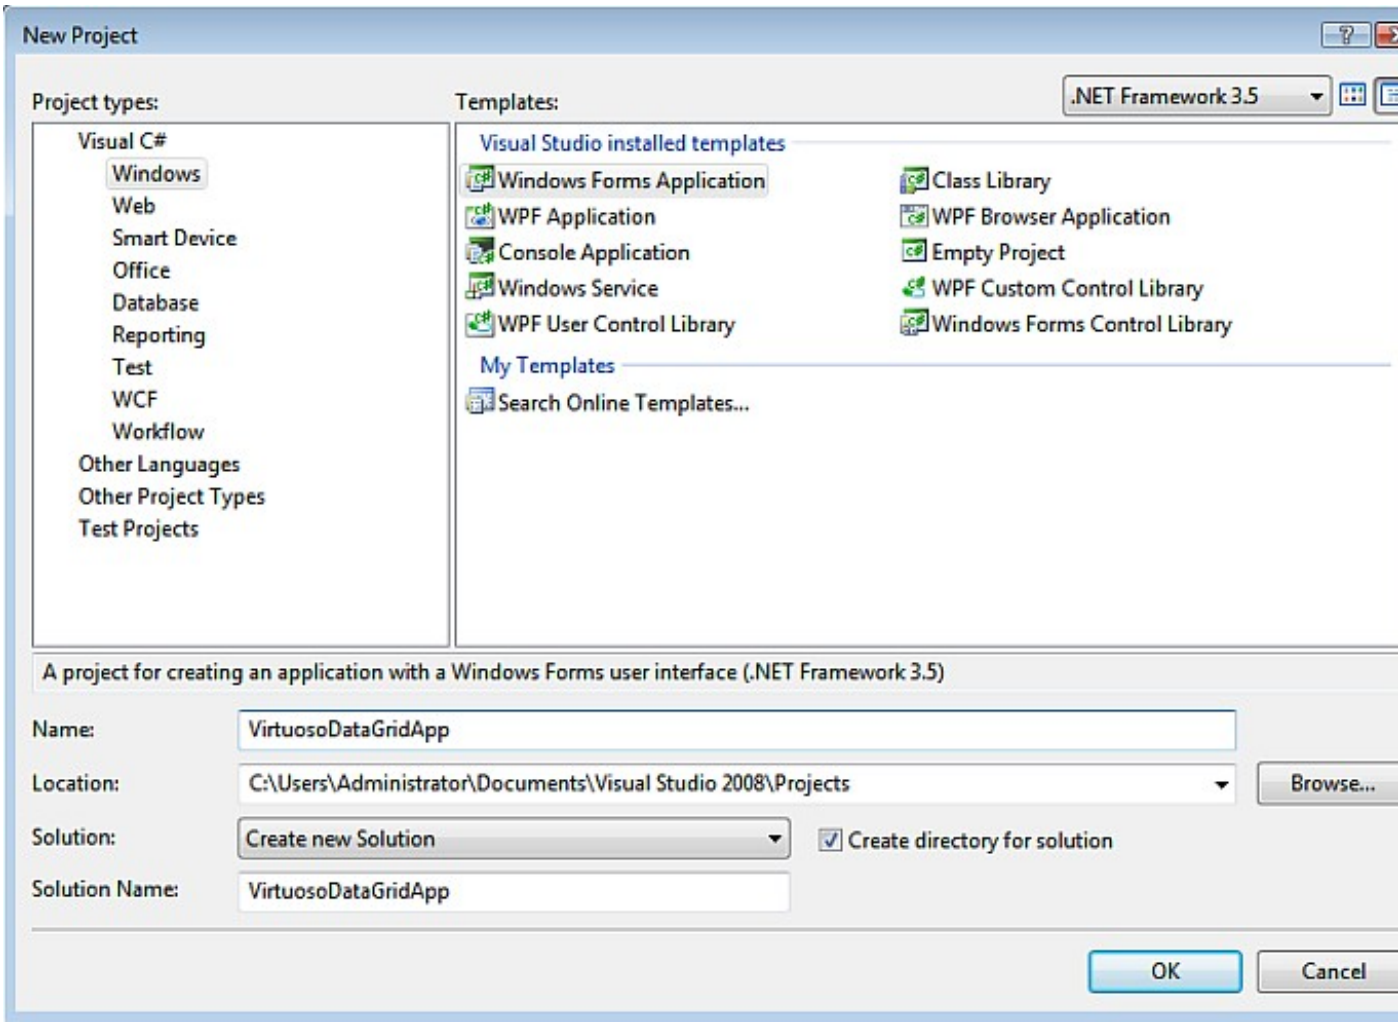
1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 2.75. Visual Studio



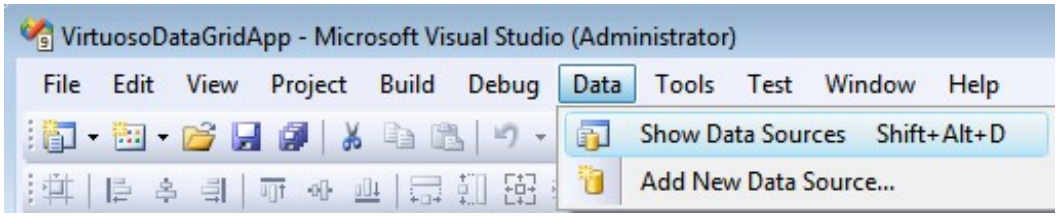
2. Create a Web Application project by going to the File menu in Visual Studio and choosing New Project.
3. When the New Project window appears, choose either Visual Basic or Visual C# as the programming language.
4. Within the language category, click on Windows and select Windows Form Application from the right-hand panel.
5. Choose a name for the project, for example VirtuosoDataGridApp, and click OK.

Figure 2.76. name for the project



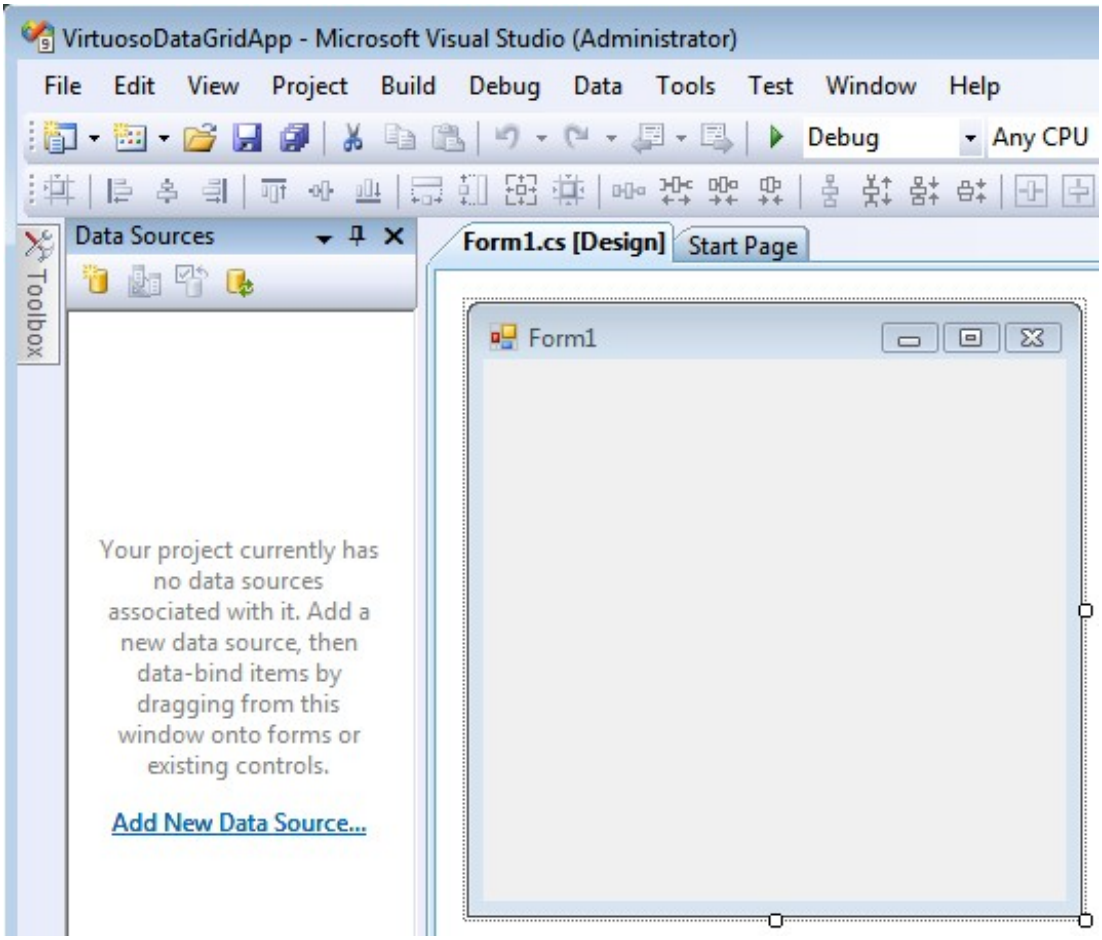
6. From the Data, menu select the Show Data Sources menu item to display a list of available Data sources.

Figure 2.77. Show Data Sources



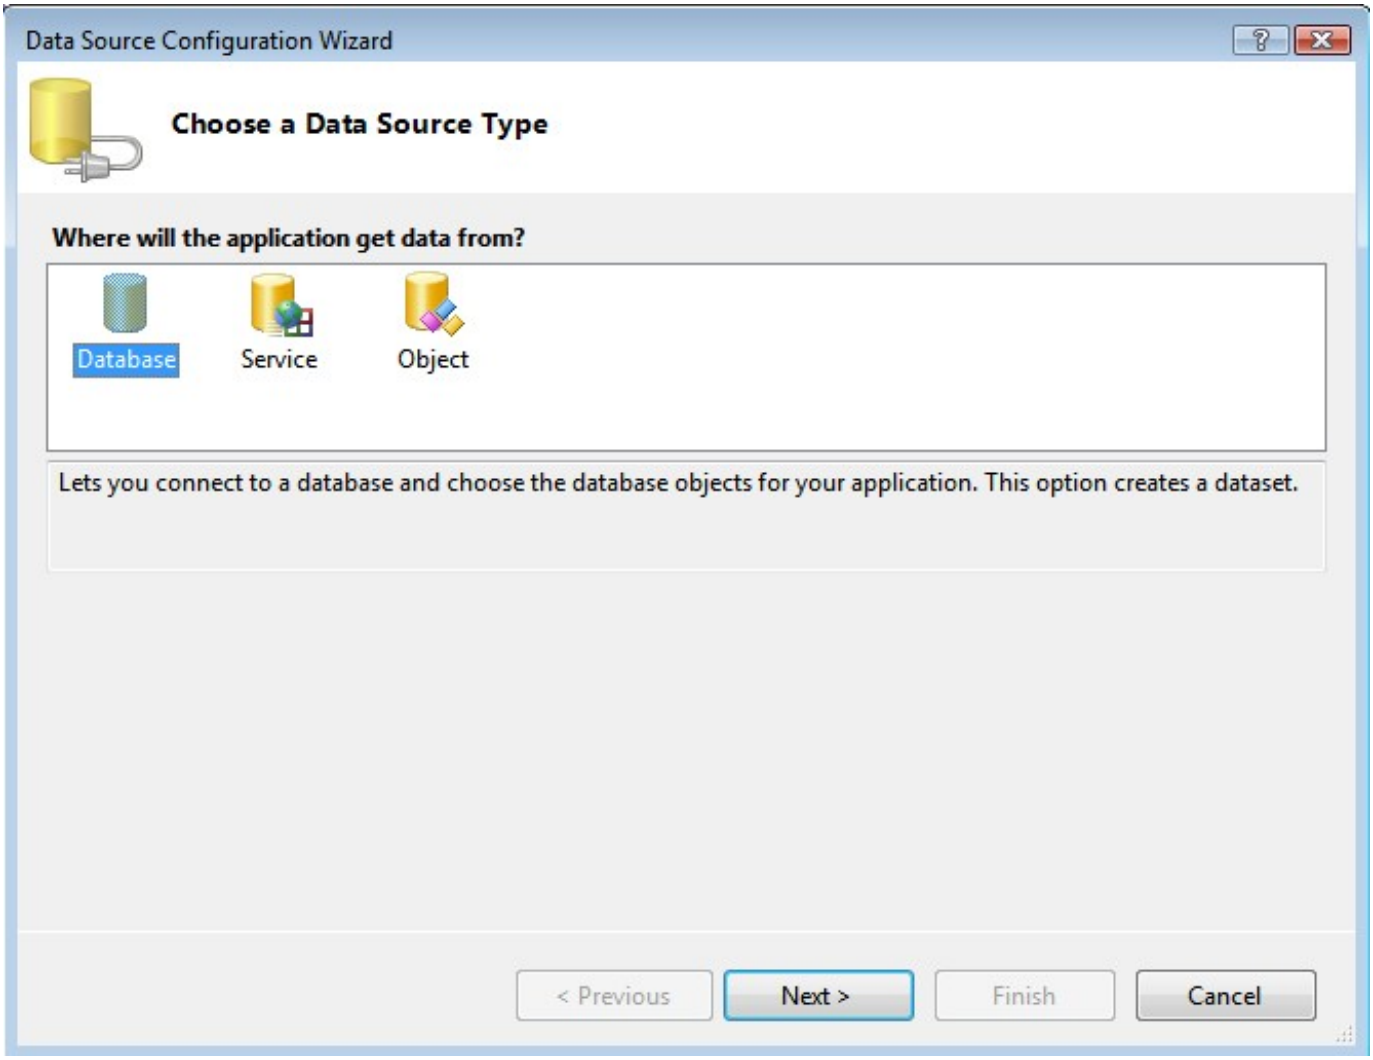
7. Click on the Add New Data Source link to add a new data source.

Figure 2.78. Add New Data Source



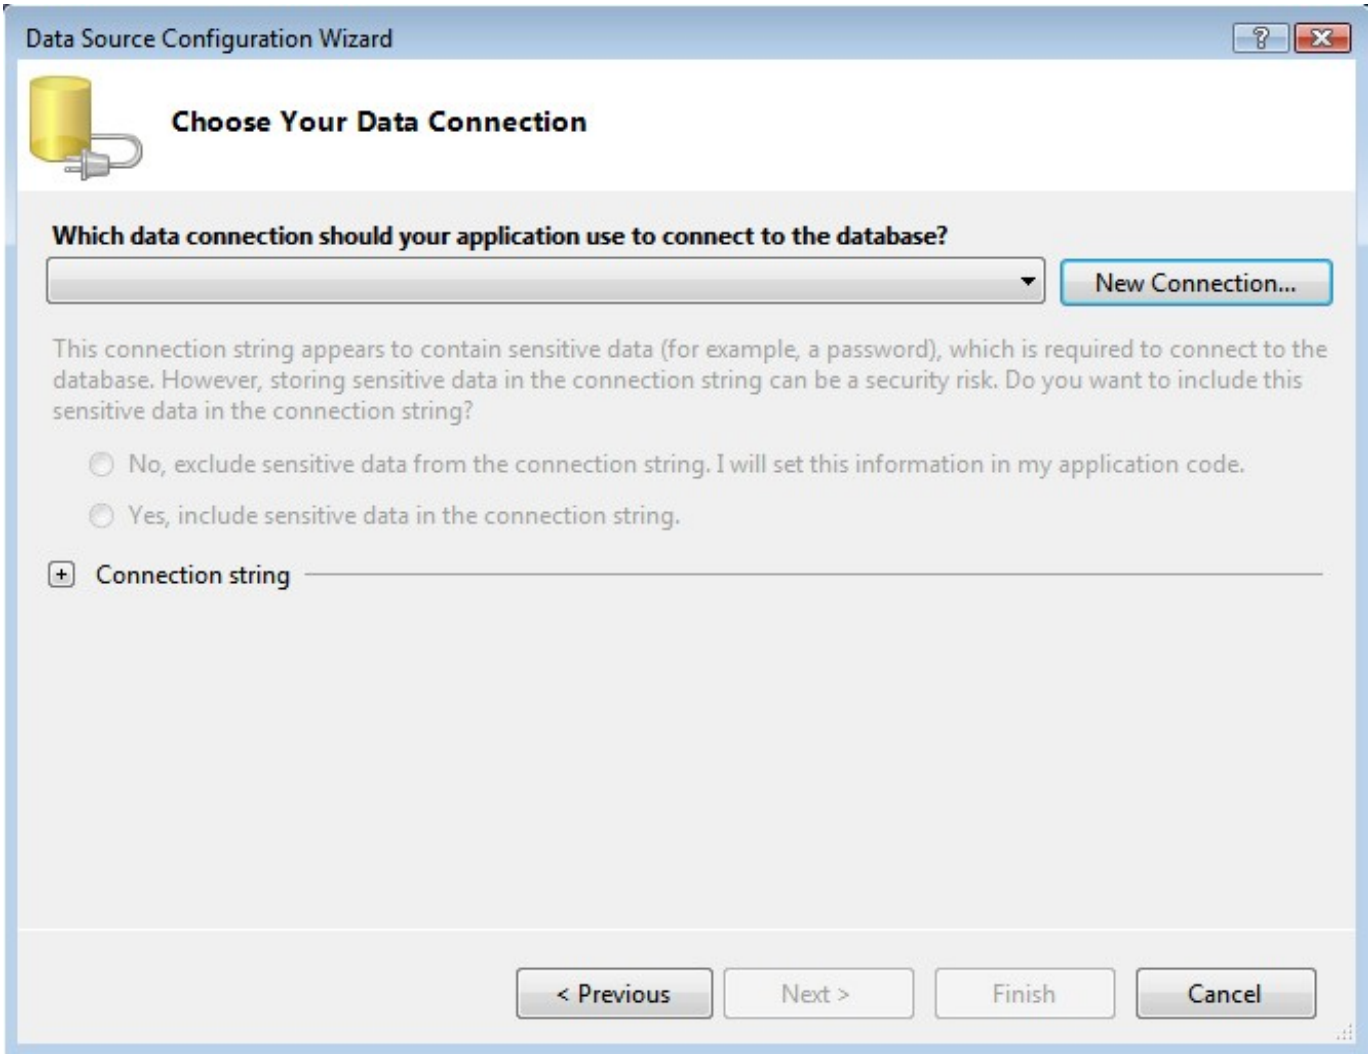
8. In the Data Source Configuration Wizard dialog Choose Data Source Type page, select the Database data source type and click Next.

Figure 2.79. Data Source Configuration Wizard



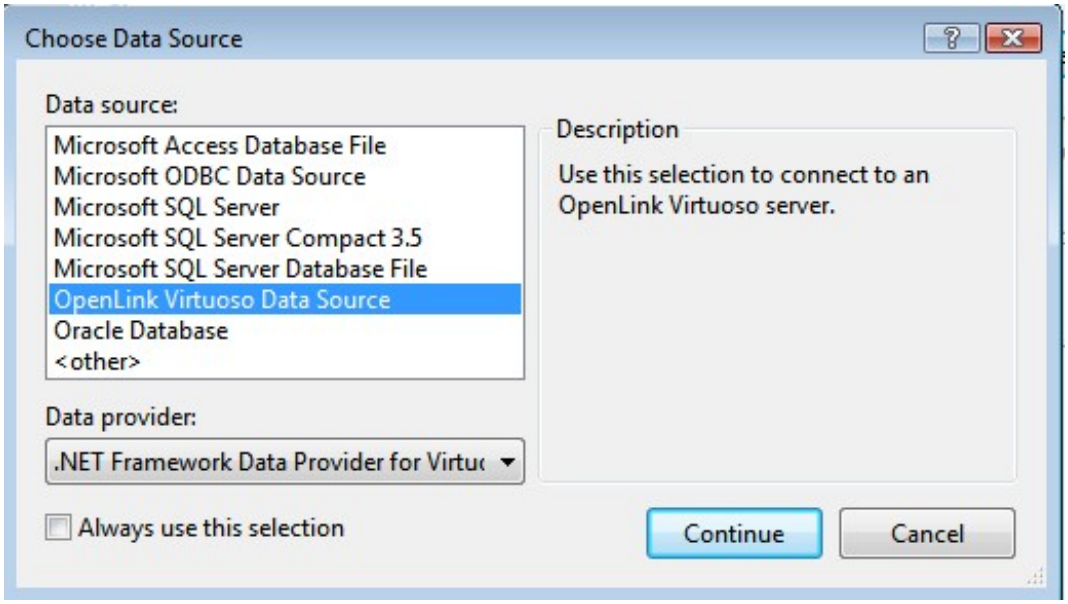
9. In the Data Source Configuration Wizard dialog Choose your Data Connection page, select the New Connection button.

Figure 2.80. Data Connection page



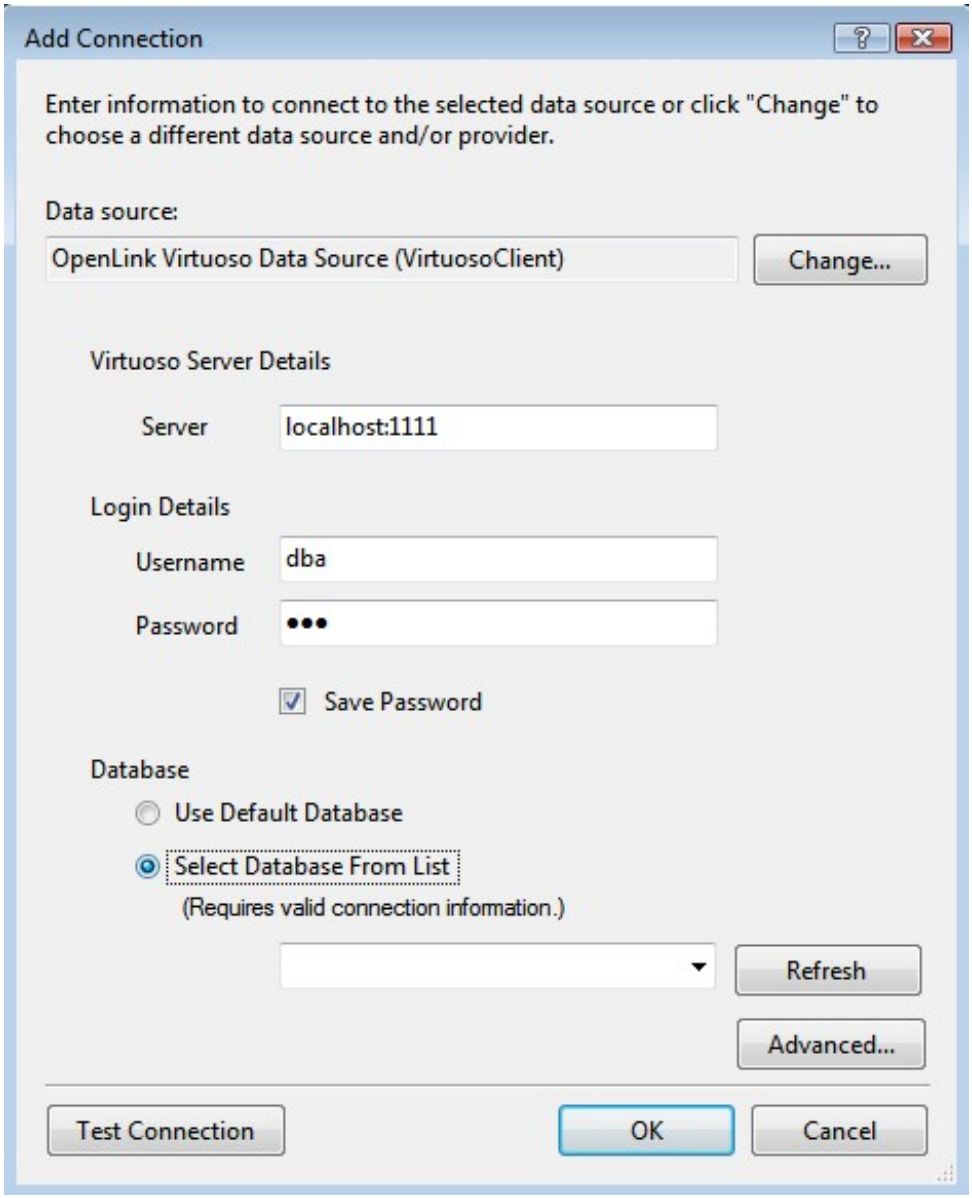
10. In the Choose Data Source dialog, select OpenLink Virtuoso Data Source from the list and click Continue.

Figure 2.81. OpenLink Virtuoso Data Source



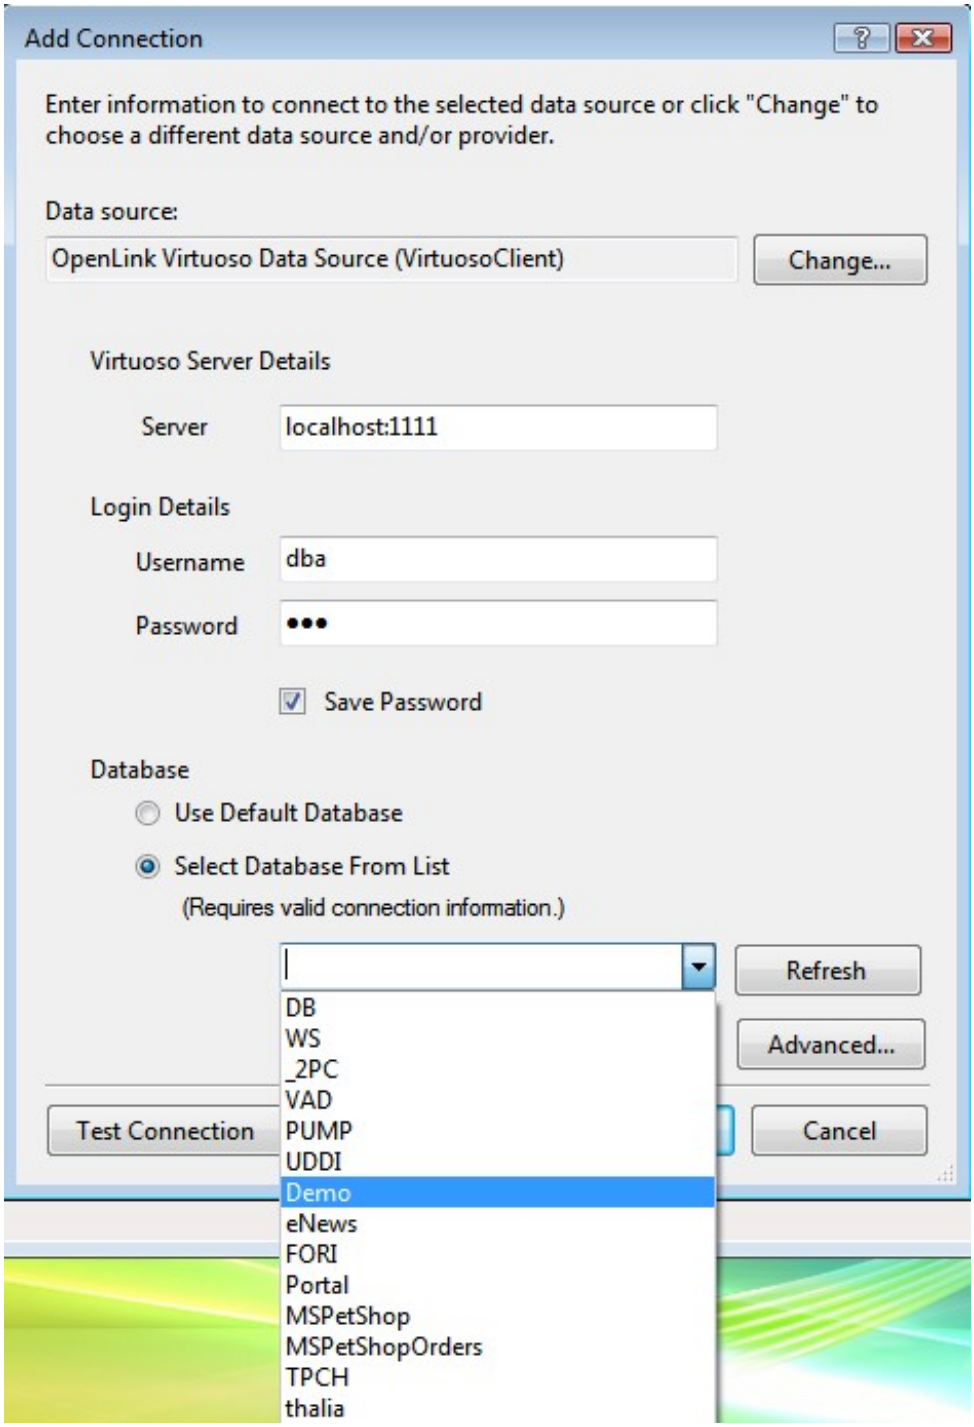
11. In the Add Connection dialog, specify the hostname, portno, username, and password for the target Virtuoso Server and check the Save Password check box.

Figure 2.82. Add Connection dialog



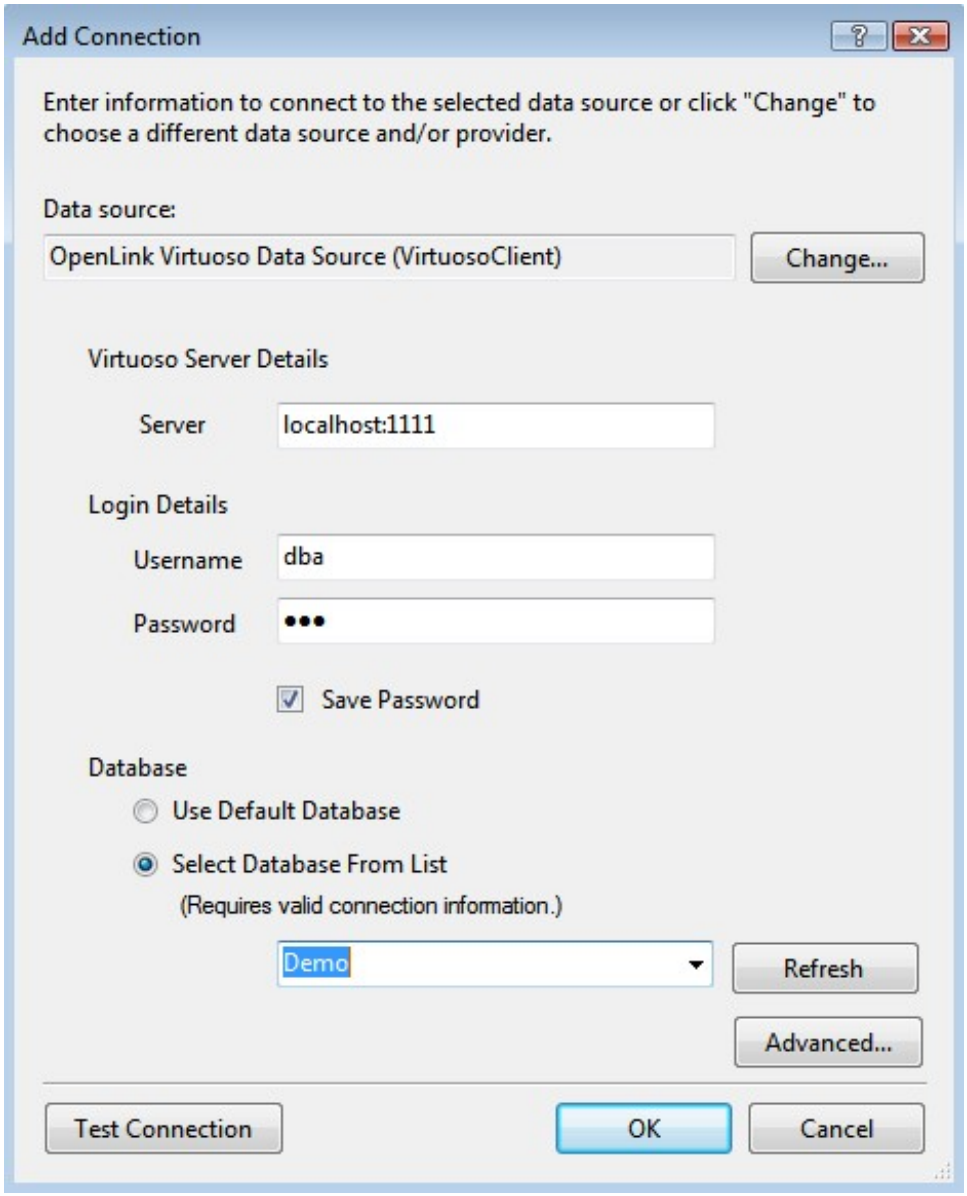
12. Select the Select Database From List radio button and choose School from the drop down list of available databases.

Figure 2.83. Select Database From List



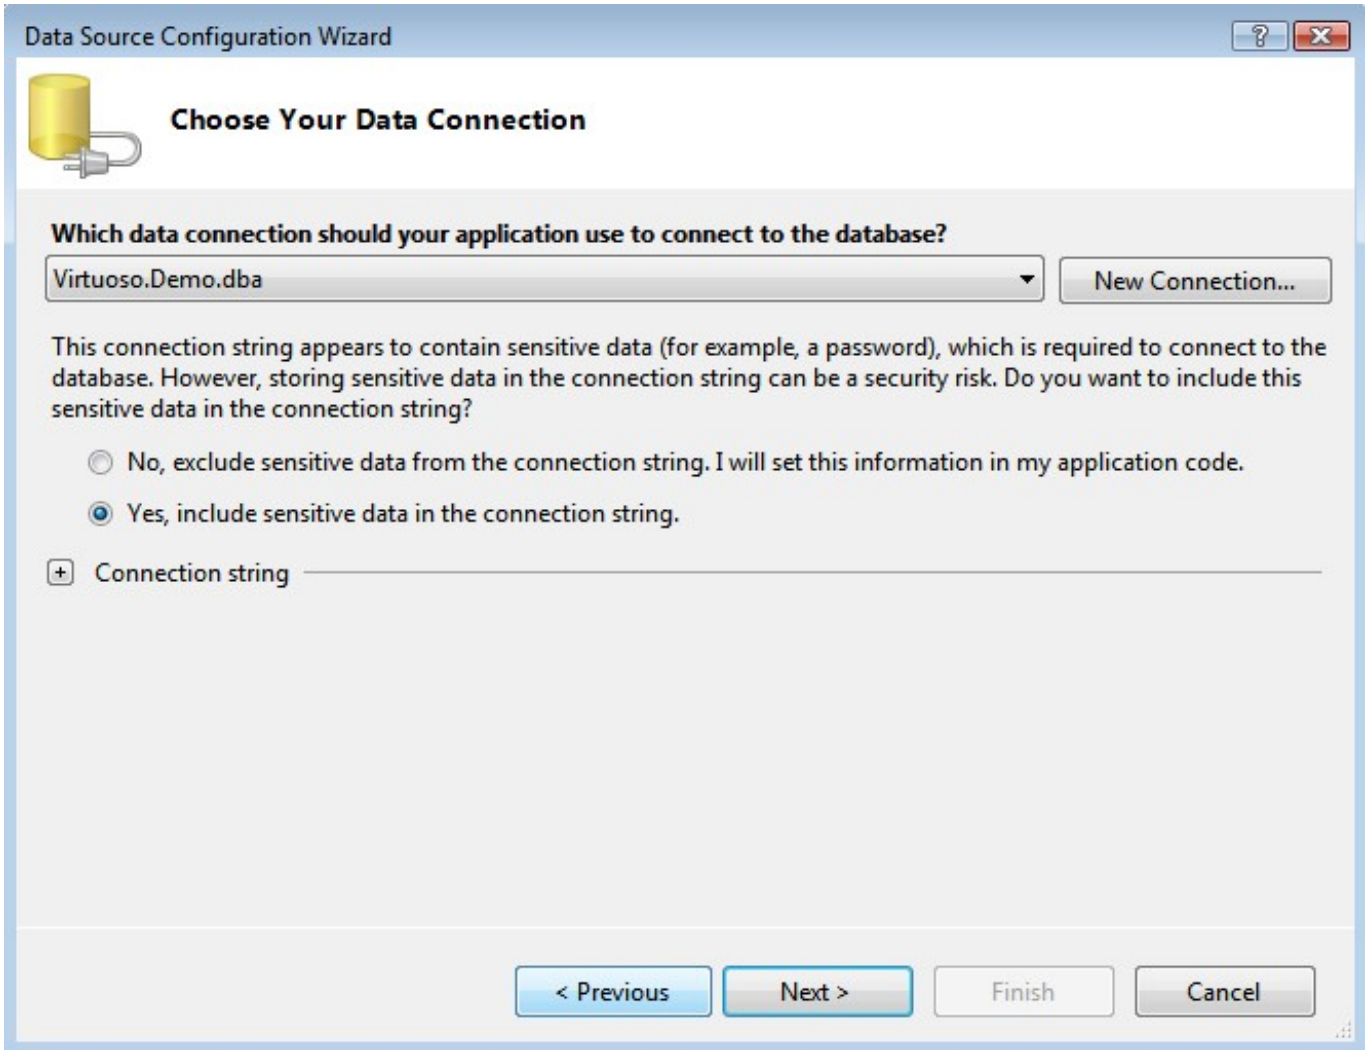
13. Click the Test Connection button to verify the connection is successful and then click OK to add the connection.

Figure 2.84. Test Connection



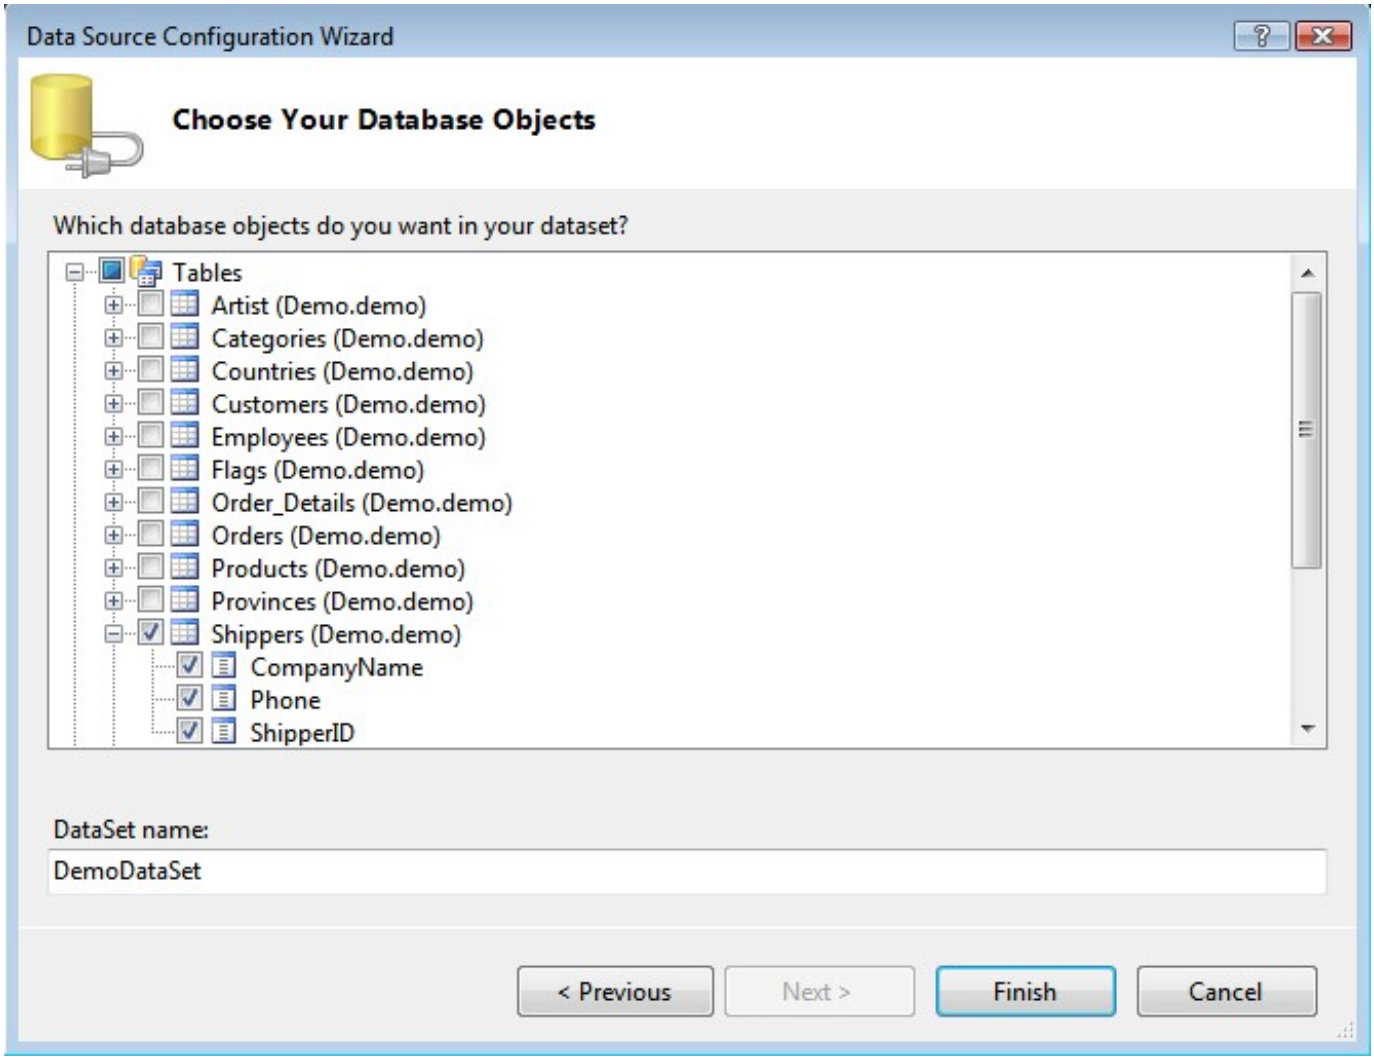
14. Select the Yes, include sensitive data in the connect string radio button and click Next to continue.

Figure 2.85. connect string



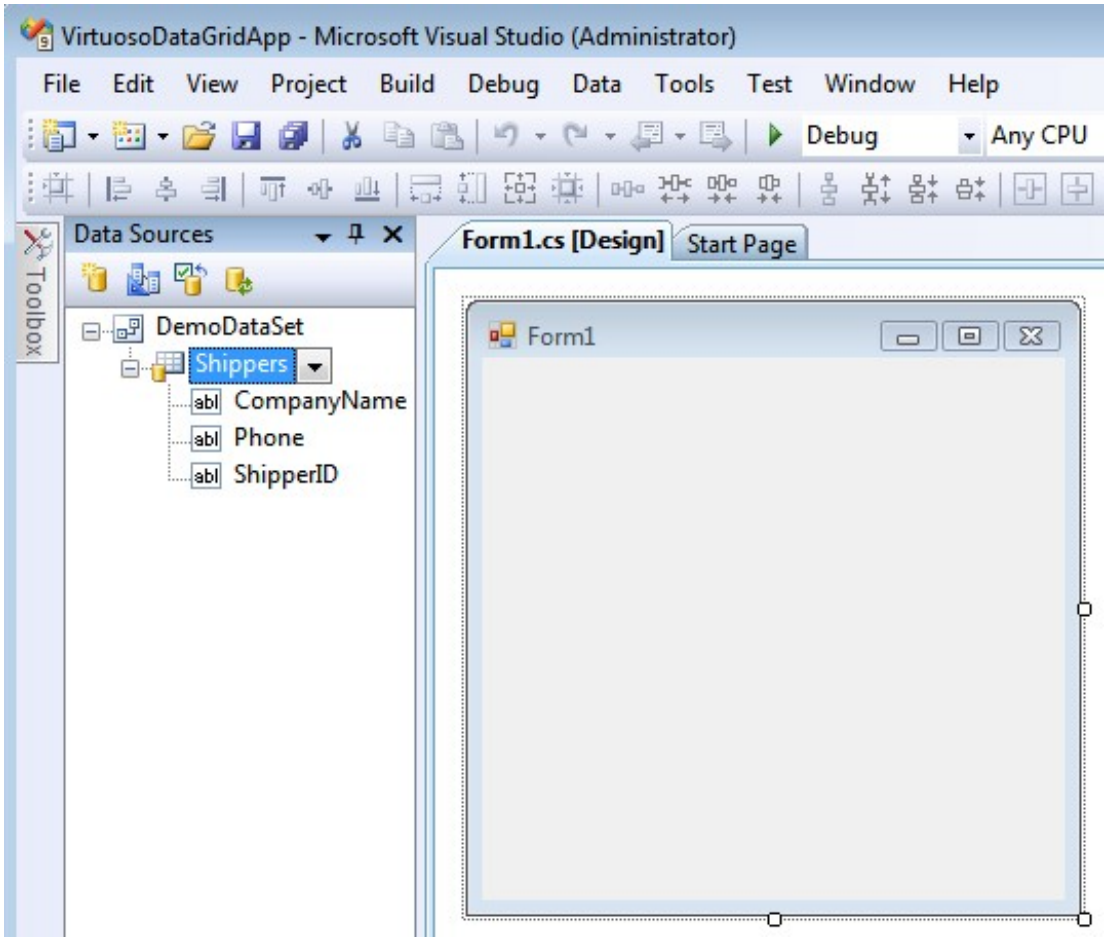
15. In the Choose your Database Objects dialog select the table and columns to be queried, the shippers table is used in this example.

Figure 2.86. Choose your Database Objects



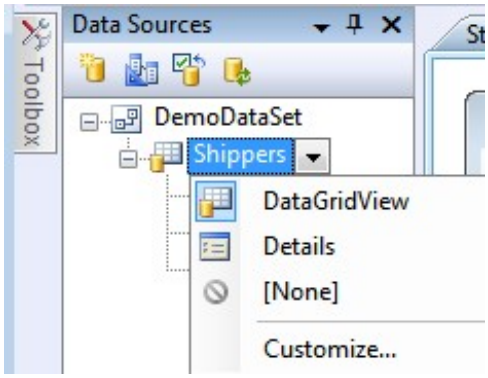
16. A DataSet for the shippers database object is created

Figure 2.87. shippers database



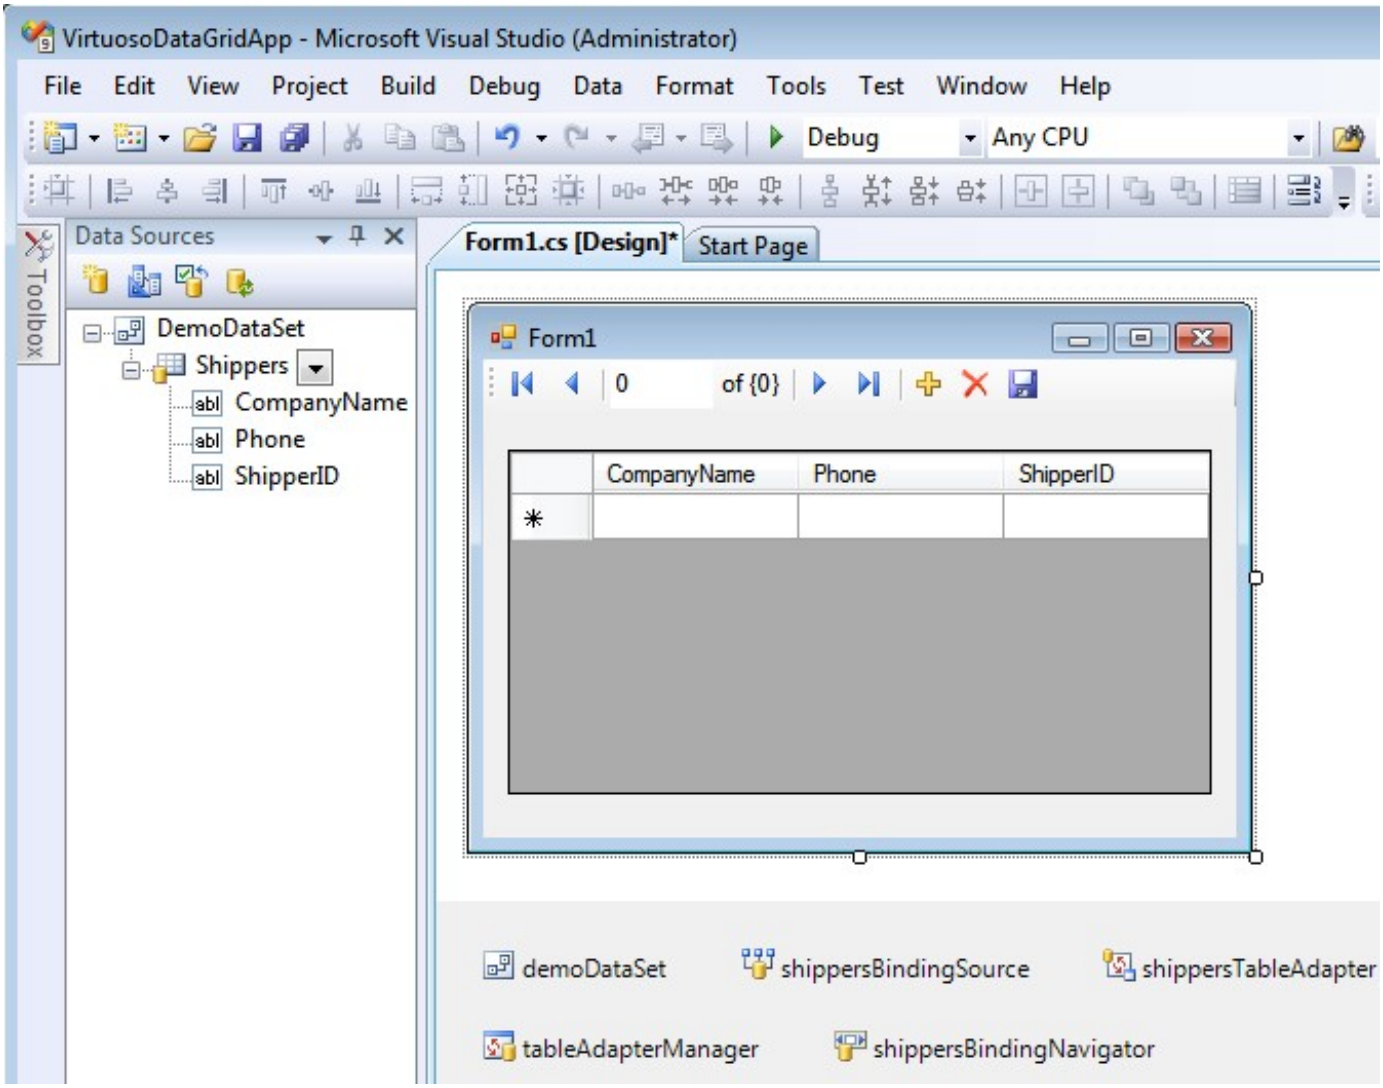
17. From the drop down list box next to the Shippers table ensure the DataGridView item is selected

Figure 2.88. DataGridView



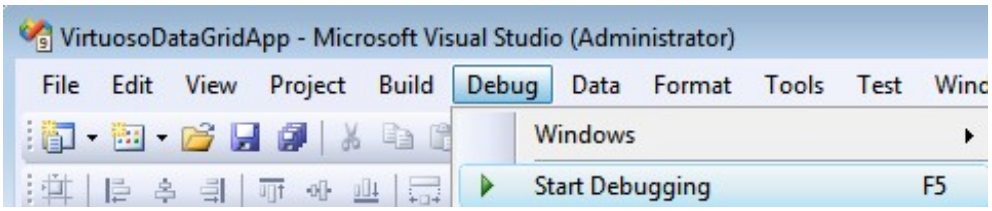
18. Drag the Shippers DataSet item onto the Form to create a scrollable and editable association of the Shippers table object with the Data Grid View automatically.

Figure 2.89. Drag



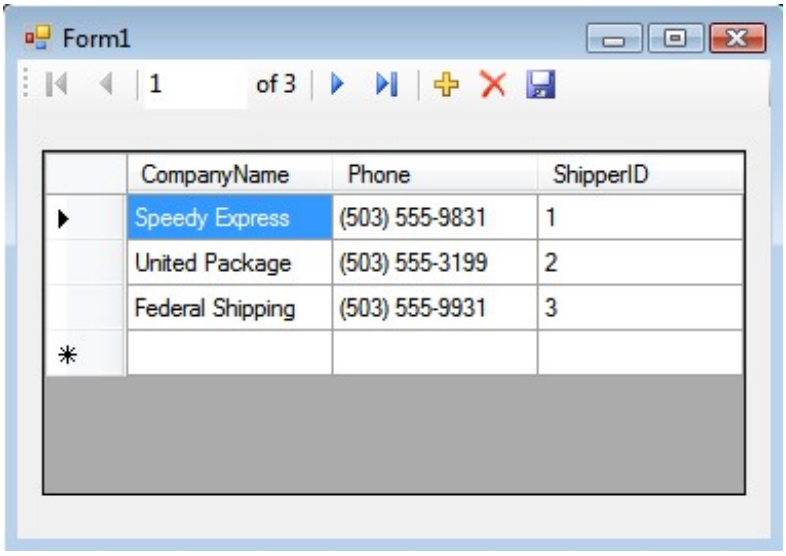
19. From the Debug Menu select the Start Debugging menu item to run the application.

Figure 2.90. Debug



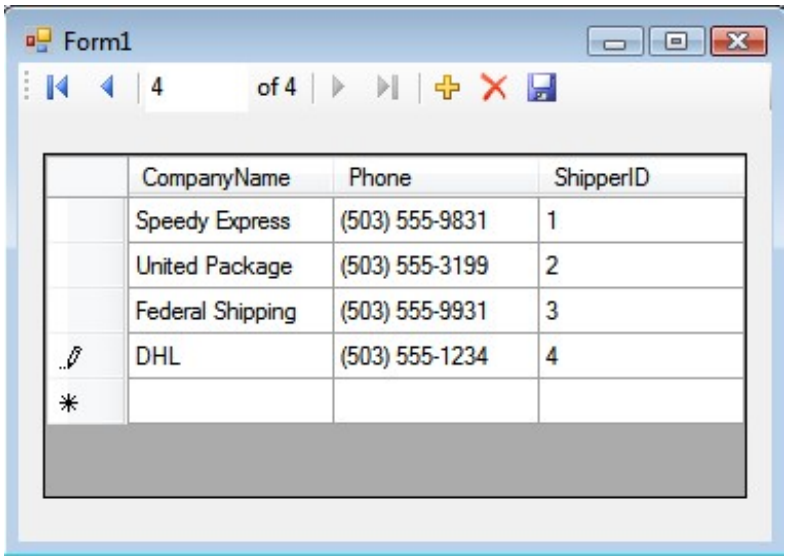
20. The data in the Shippers table will be displayed in the DataGrid application created.

Figure 2.91. DataGrid



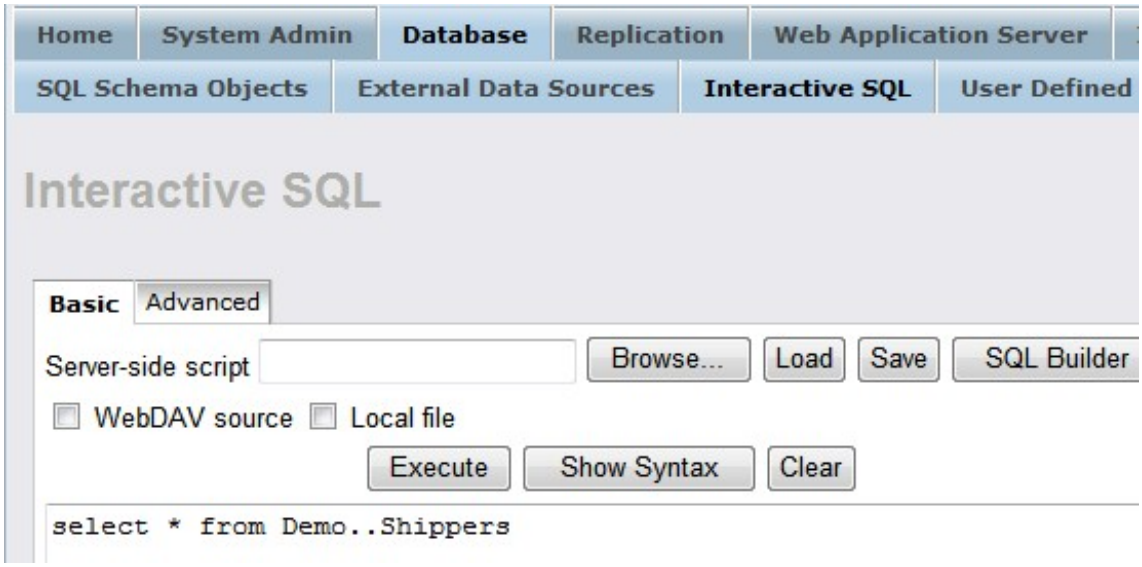
21. A new row can be inserted (updated or deleted) as indicated for the new DHL record inserted below and the save button clicked to save the change to the database.

Figure 2.92. new row



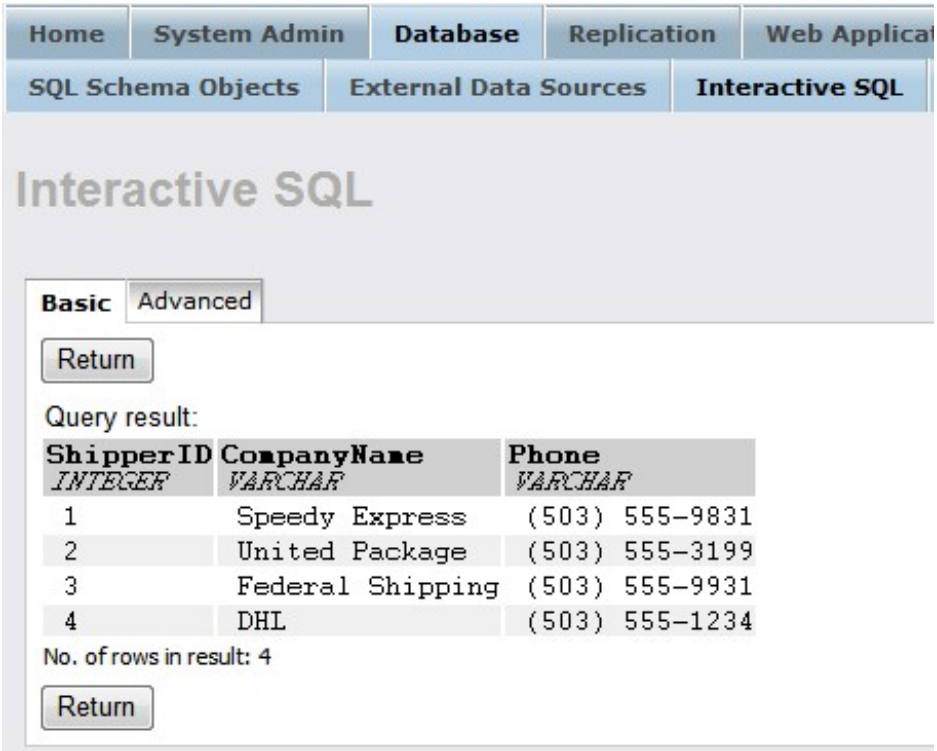
22. The Virtuoso Interactive SQL tab of the Conductor can be used to run the query select * from Demo..Shippers.

Figure 2.93. Interactive SQL tab



23. To verify the change has been successfully made in the database.

Figure 2.94. verify



The task is now complete.

2.7. Using Visual Studio 2008 to Build an Entity Frameworks based Windows Form Application

Virtuoso Entity Framework School DB Windows Form Application. This section demonstrates how Visual Studio 2008 can be used to generate mapping files for an Entity Data Model (EDM), based on a 1:1 mapping to tables in the School database. This will be done by creating a Windows Forms application in Visual Studio, create queries that access data in the School model, bind the query results to display controls to show the results of the queries, and then make updates to objects and persist the changes to the database.

2.7.1. Pre-requisites

In order to create an Entity Framework Application in your own environment you will need:

1. Microsoft Visual Studio 2008 SP1, the ADO.NET Entity Framework runtime and associated tools are included in Visual Studio 2008 SP1.
2. A running Virtuoso Universal Server instance.

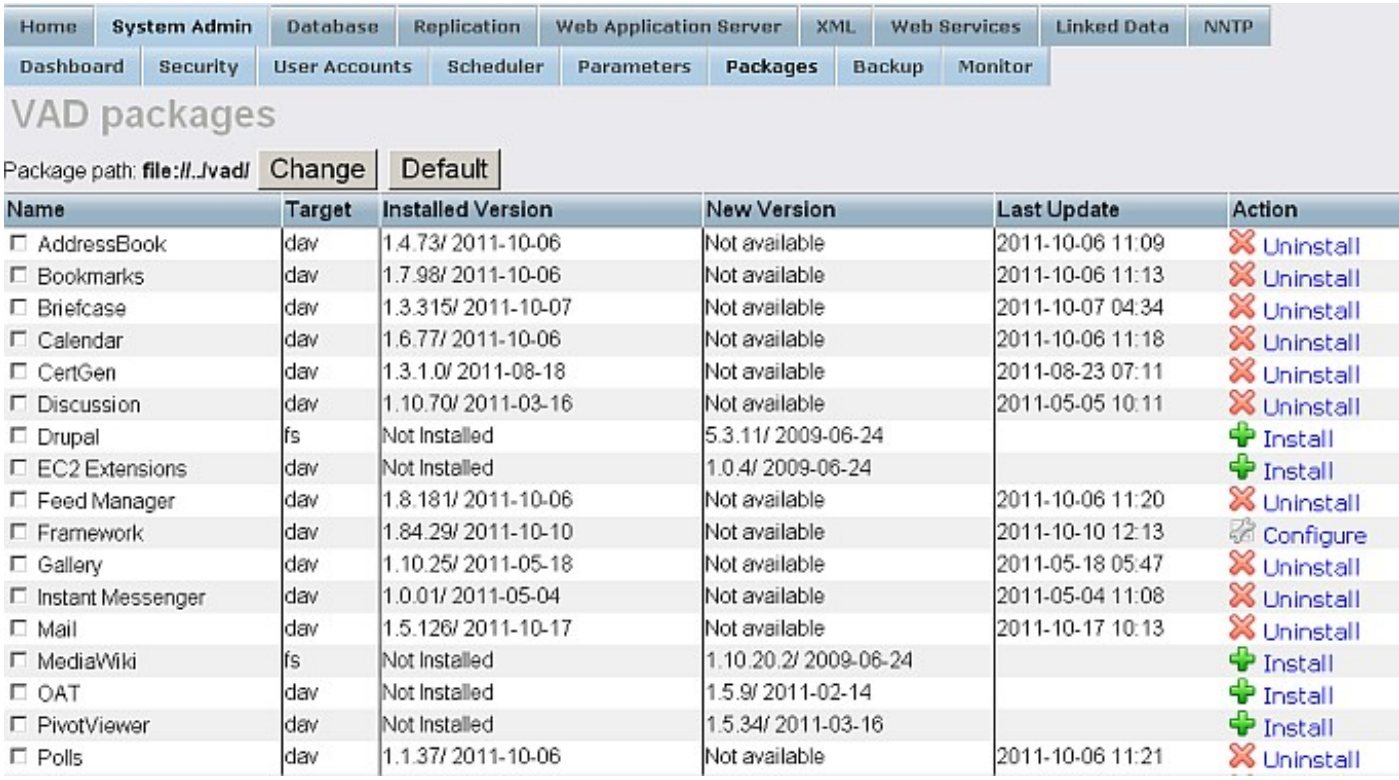
2.7.2. Create the School database and schema

1. Download the Schools Database VAD (schools_db_dav.vad) package.
2. Navigate to the

   System Admin -> Packages

   tab of the Virtuoso Conductor.

   Figure 2.95. Conductor Packages



3. Scroll down to the

   Install Package

   section of the tab, use the

   Upload Package

   option

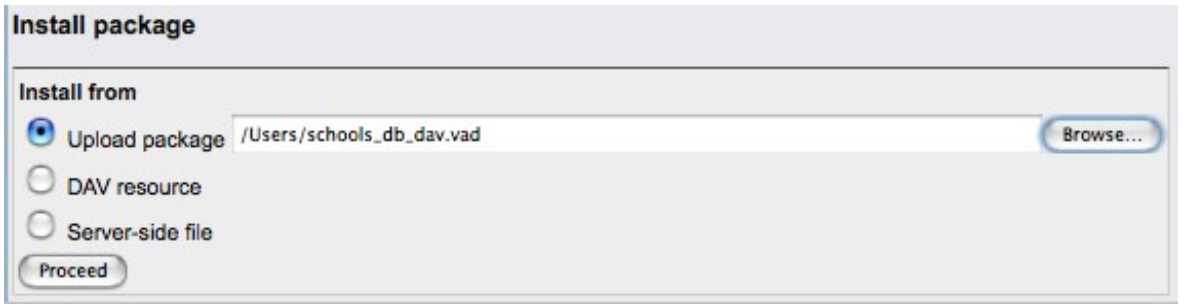
   Browse

   button to locate the schools_db_dav.vad package and click

   proceed

   .

Figure 2.96. Install package

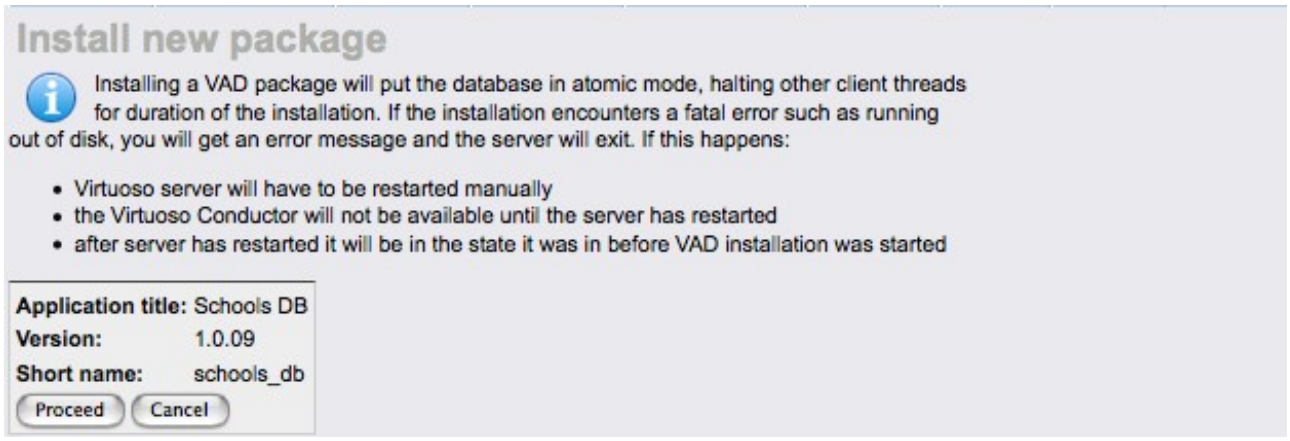


4. Click the

   Proceed

   button to begin the installation process.

   Figure 2.97. Install package.



5. Once complete return to the

   Packages

   tab and scroll down to confirm the *schools_db* package is listed as installed.

   Figure 2.98. Install package

Create the Course Manager application using Visual Studio

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 2.99. Visual Studio 2008 SP1 IDE

2. On the

   File menu

   click

   New Project

   .
3. Choose either

   Visual Basic

   or

   Visual C#

   in the

   Project Types

   pane.
4. Select

   Windows Forms Application

   in the

   Templates

   pane.
5. Enter

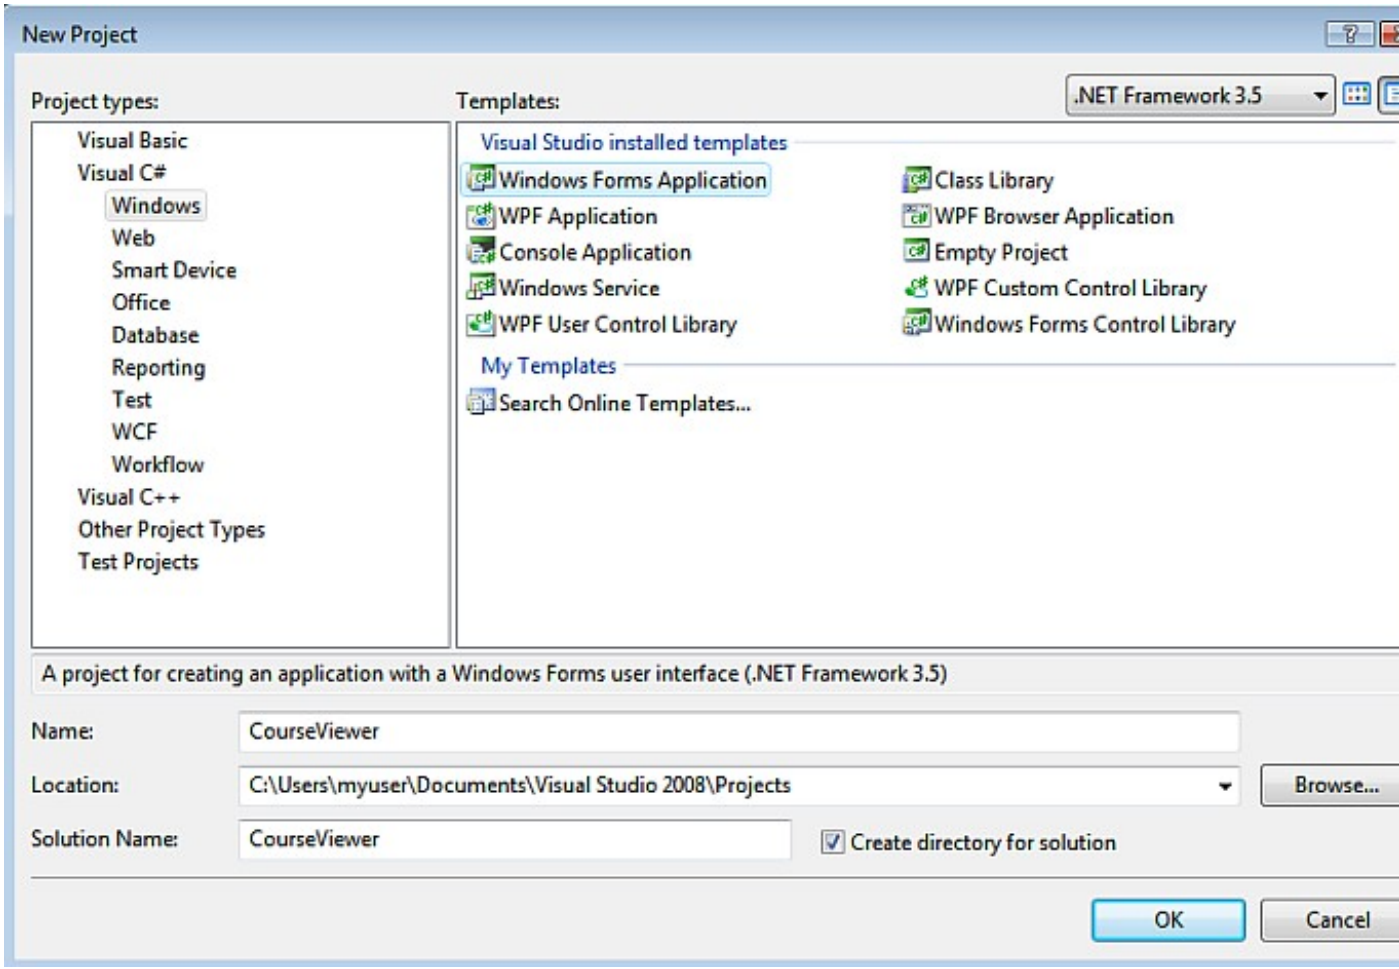
   CourseManager

   for the project name, and then click

   OK

   .

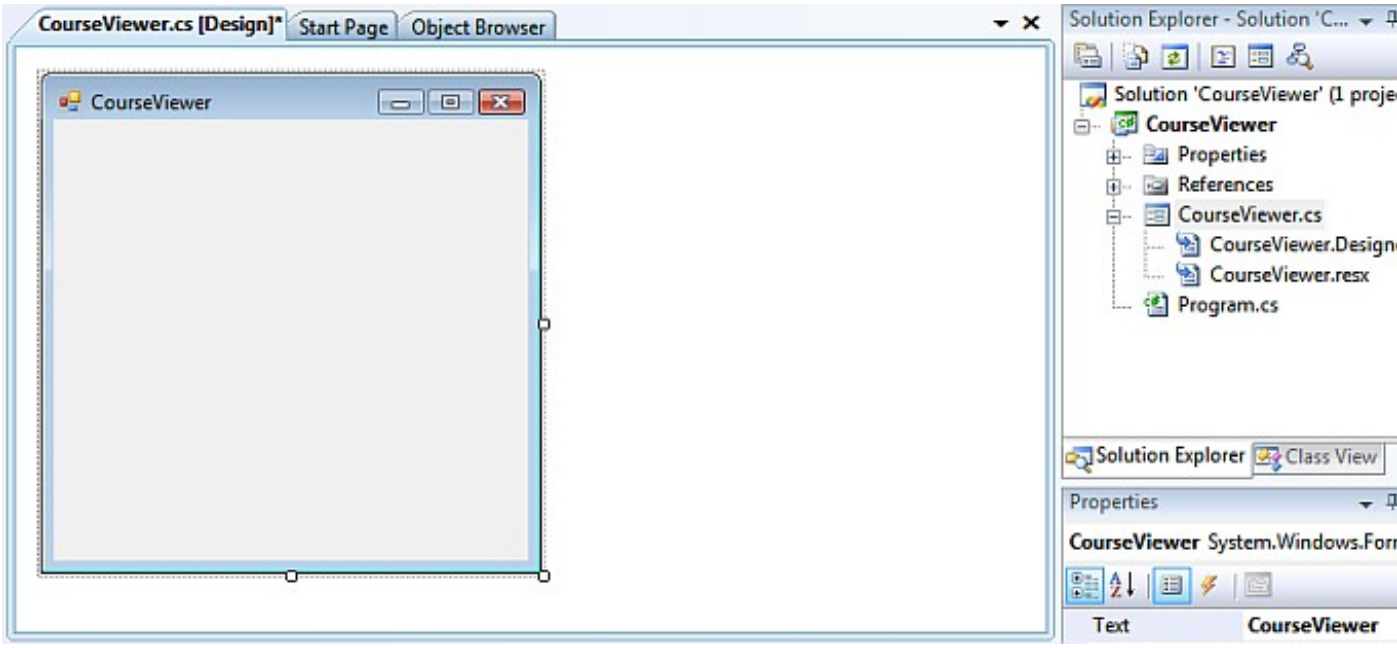
Figure 2.100. Create project



Create the Course Viewer form

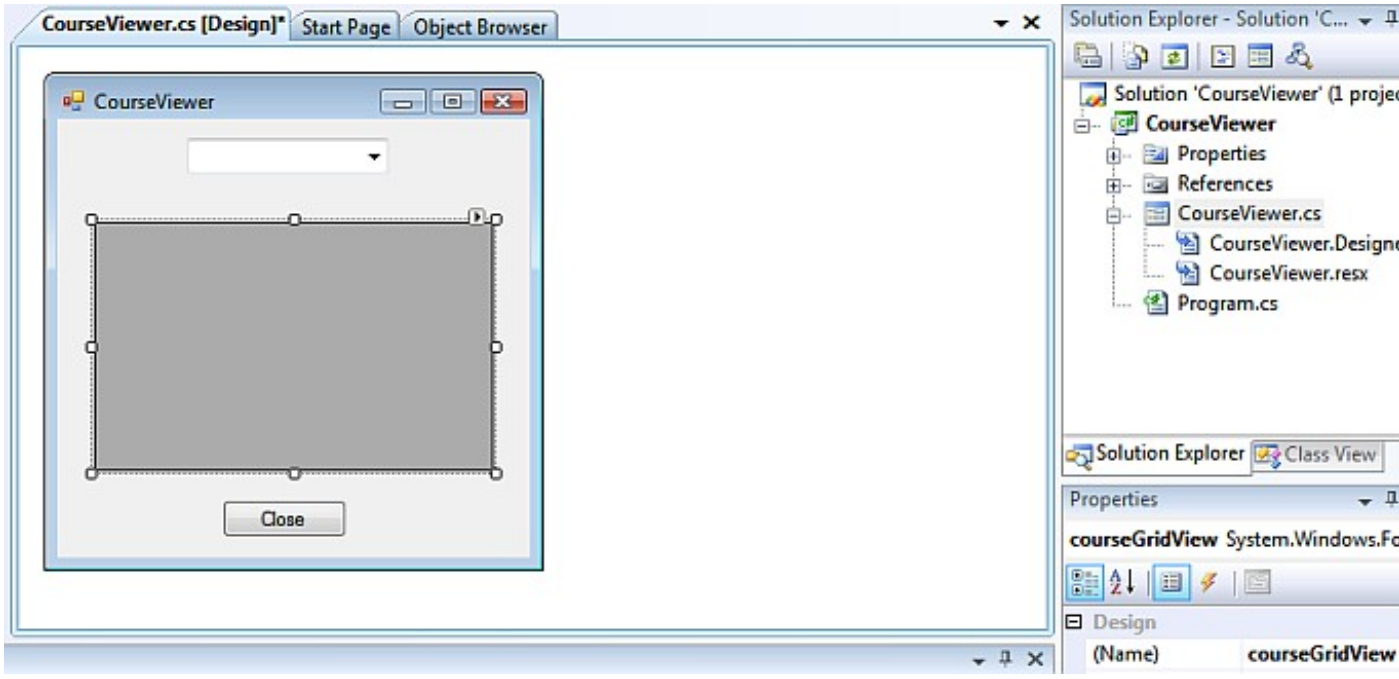
1. In the *CourseManager* project, select the default form (Form1).
2. In the *File Properties* pane, change the File Name to *CourseViewer.vb* or *CourseViewer.cs* .
3. In *Solution Explorer* , double-click *CourseViewer.vb* or *CourseViewer.cs* to open the form.

Figure 2.101. CourseViewer.vb



4. In the *Toolbox* , expand *Common Controls* , drag the *ComboBox* control to the form, and change the name of the control to *departmentList* .
5. In the *Toolbox* , drag the *Button* control to the form, change the *Name* of the control to *closeForm* , and change the *Text value* to *Close* .
6. In the *Toolbox* , expand *Data* , drag the *DataGridView* control to the form, and change the *Name* of the control to *courseGridView* .

Figure 2.102. DataGridView



7. Double-click the *closeForm* button control. This opens the code page for the form and creates the closeForm_Click event handler method.
8. In the *closeForm_Click* event handler method, type the following code that closes the form:

```
Visual Basic

' Close the form.
Me.Close()

C#

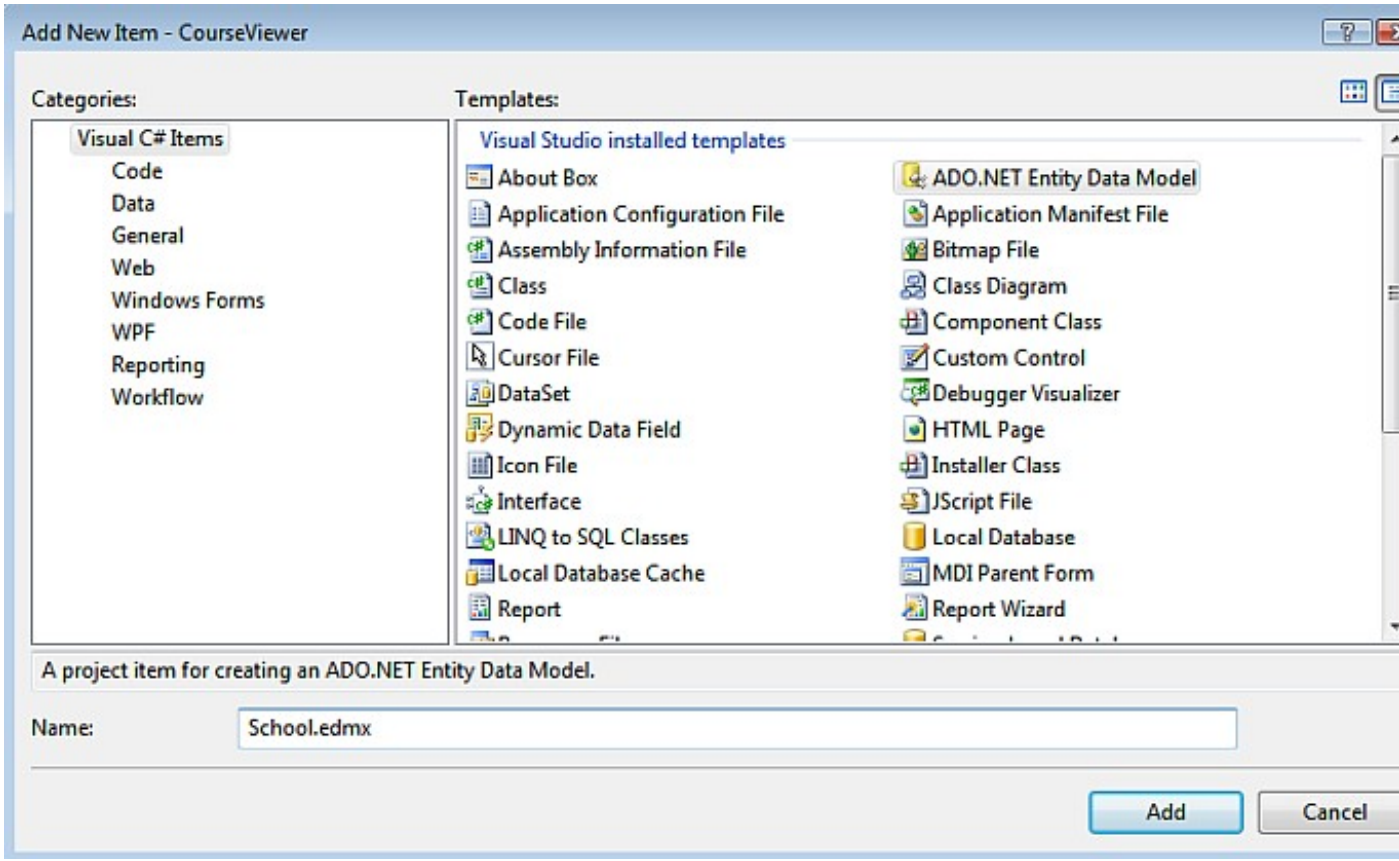
// Close the form.
this.Close();
```

2.7.3. Generating the School Entity Data Mode

Add the ADO.NET Entity Data Model item template

1. Select the CourseManager project in Solution Explorer, right-click, point to Add, and then click New Item.
2. Select ADO.NET Entity Data Model in the Templates pane.
3. Type School.edmx for the model name and click Add. The opening page of the Entity Data Model Wizard is displayed.

Figure 2.103. School.edmx



Generate the EDM

1. Select

   Generate from database

   in the

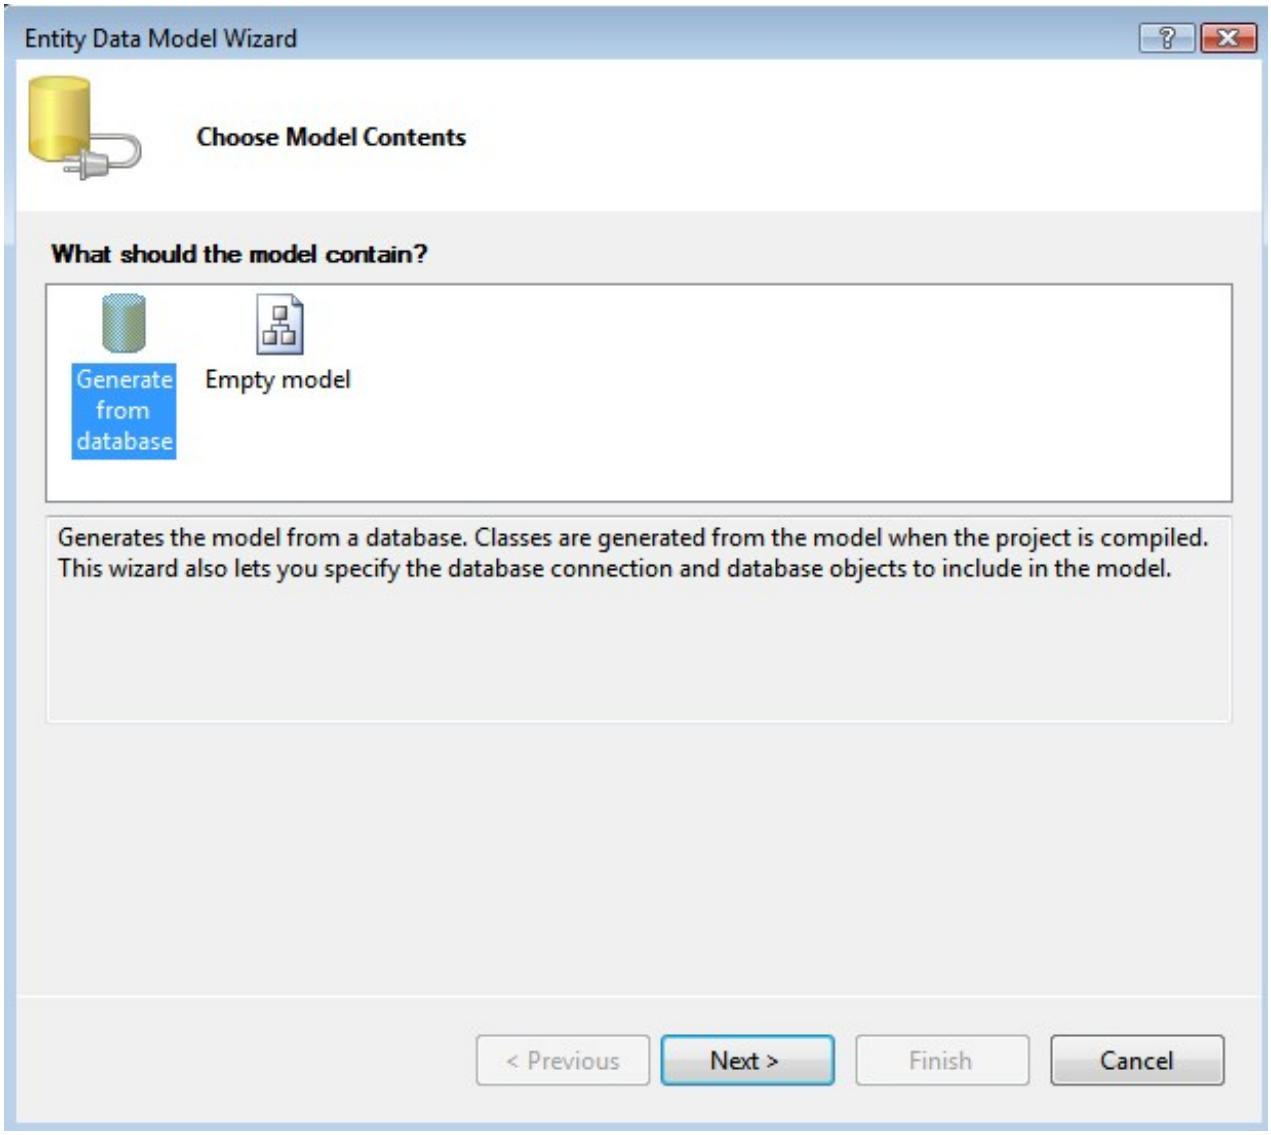
   Choose Model Contents dialog box

   . Then click

   Next

   .

   Figure 2.104. Model Contents

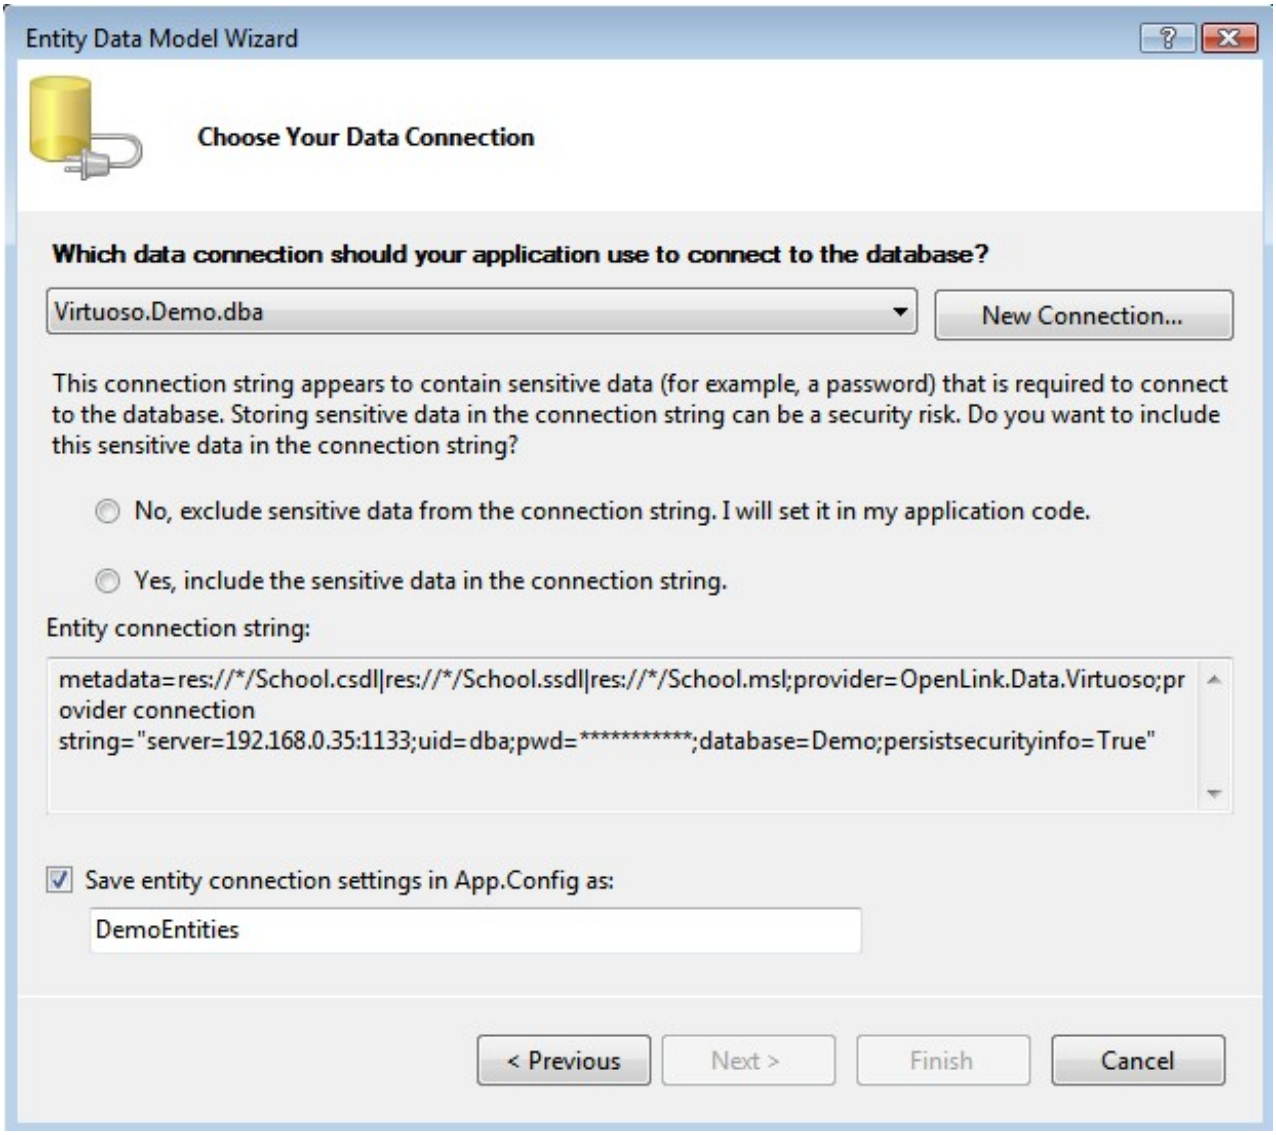


2. Click the

   New Connection

   button.

Figure 2.105. New Connection



3. Choose the OpenLink

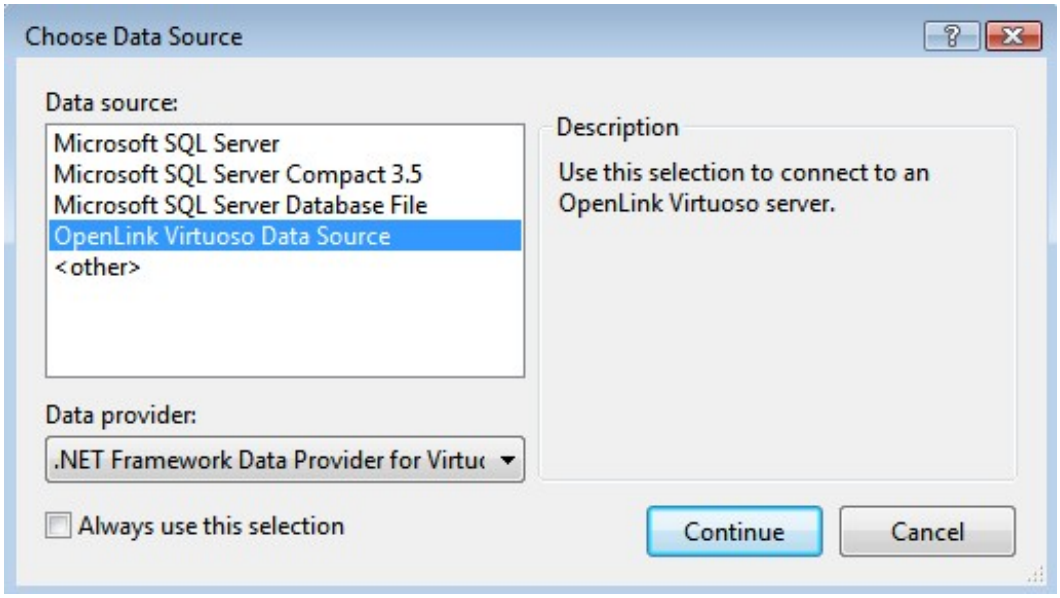
   Virtuoso Data Source

   and click

   Continue

   .

   Figure 2.106. Virtuoso Data Source



4. In the

   Connection Properties

   dialog specify the

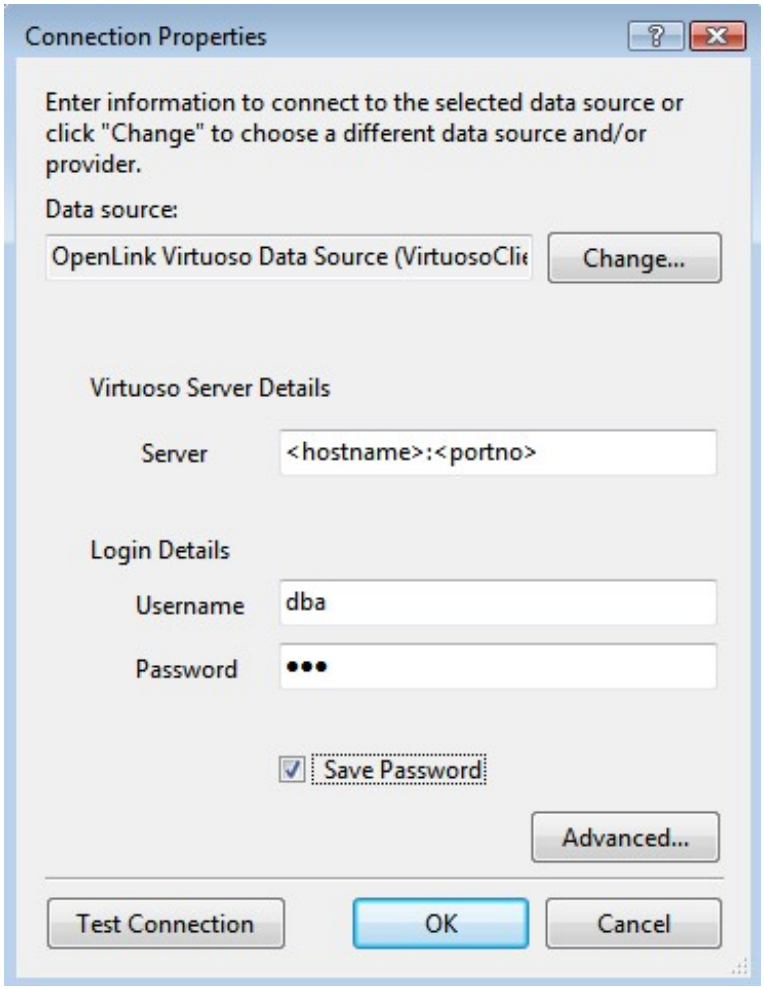
   hostname, portno, username and password

   for the target Virtuoso Server and click the

   Advanced

   button.

   Figure 2.107. Connection Properties



5. In the

   Advanced Properties

   dialog set the

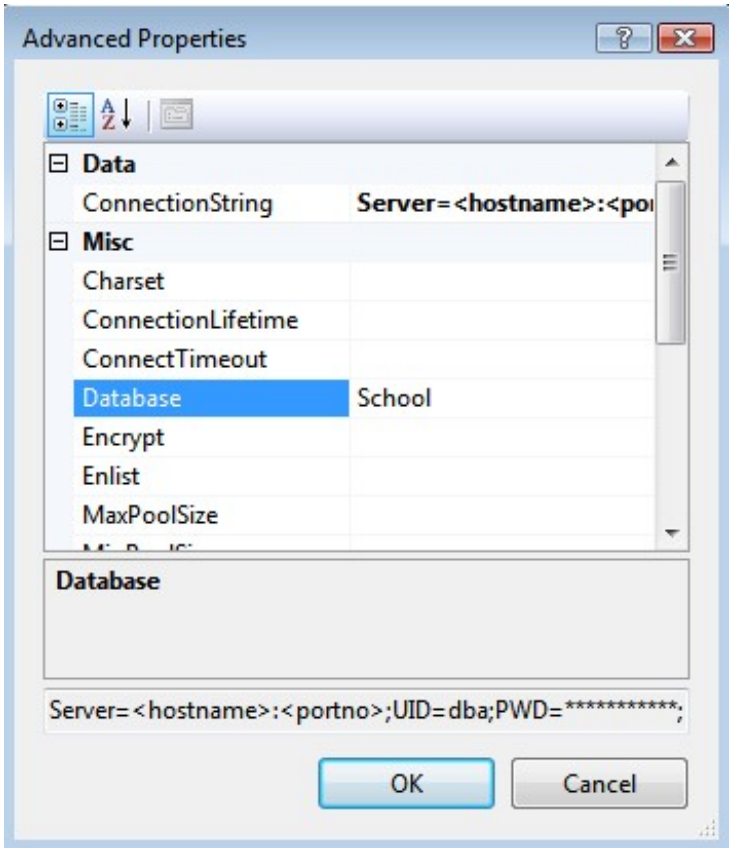
   Database parameter

   to

   School

   and click OK.

Figure 2.108. Advanced Properties

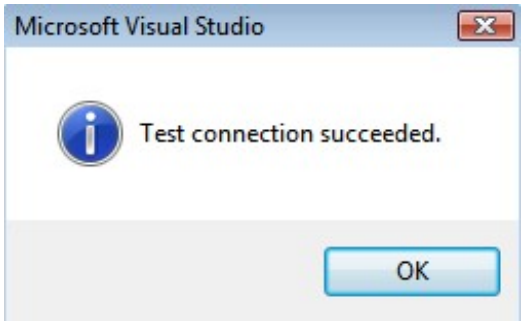


6. Press the

   Test Connection

   dialog to verify the database is accessible.

   Figure 2.109. Test Connection



7. Set the

   entity connect string name

   to

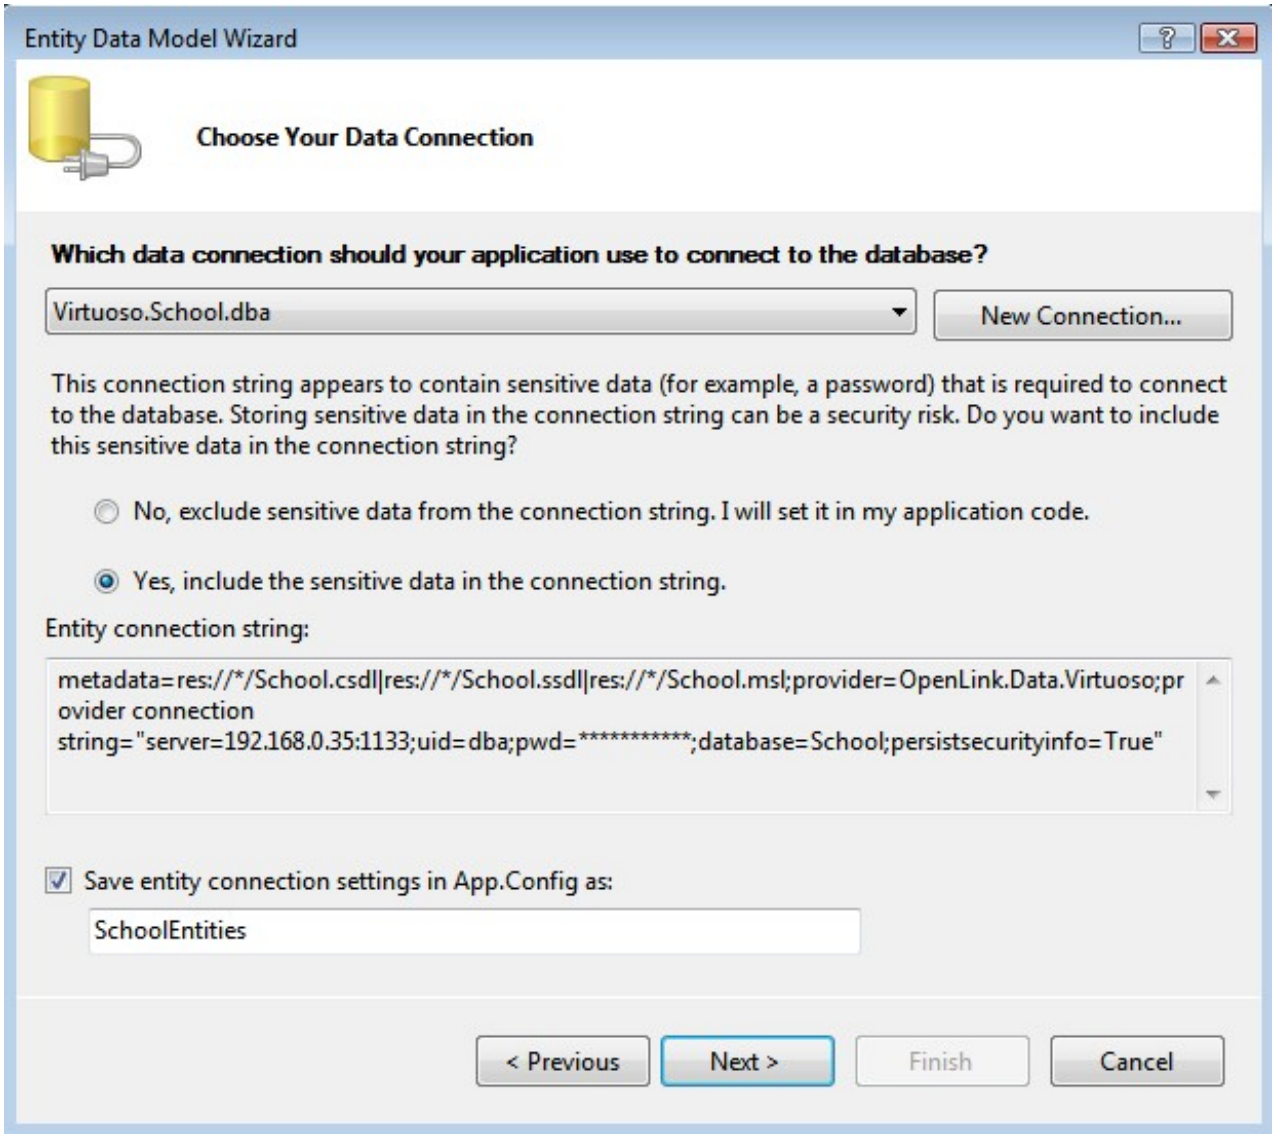
   SchoolEntities

   and click

   Next

   .

   Figure 2.110. entity connect string name



8. In the

   Choose your Database Objects

   page select the

   Tables

   check box to select all table in the

   School database

   for addition to the EDM, set the

   Model Namespace

   to

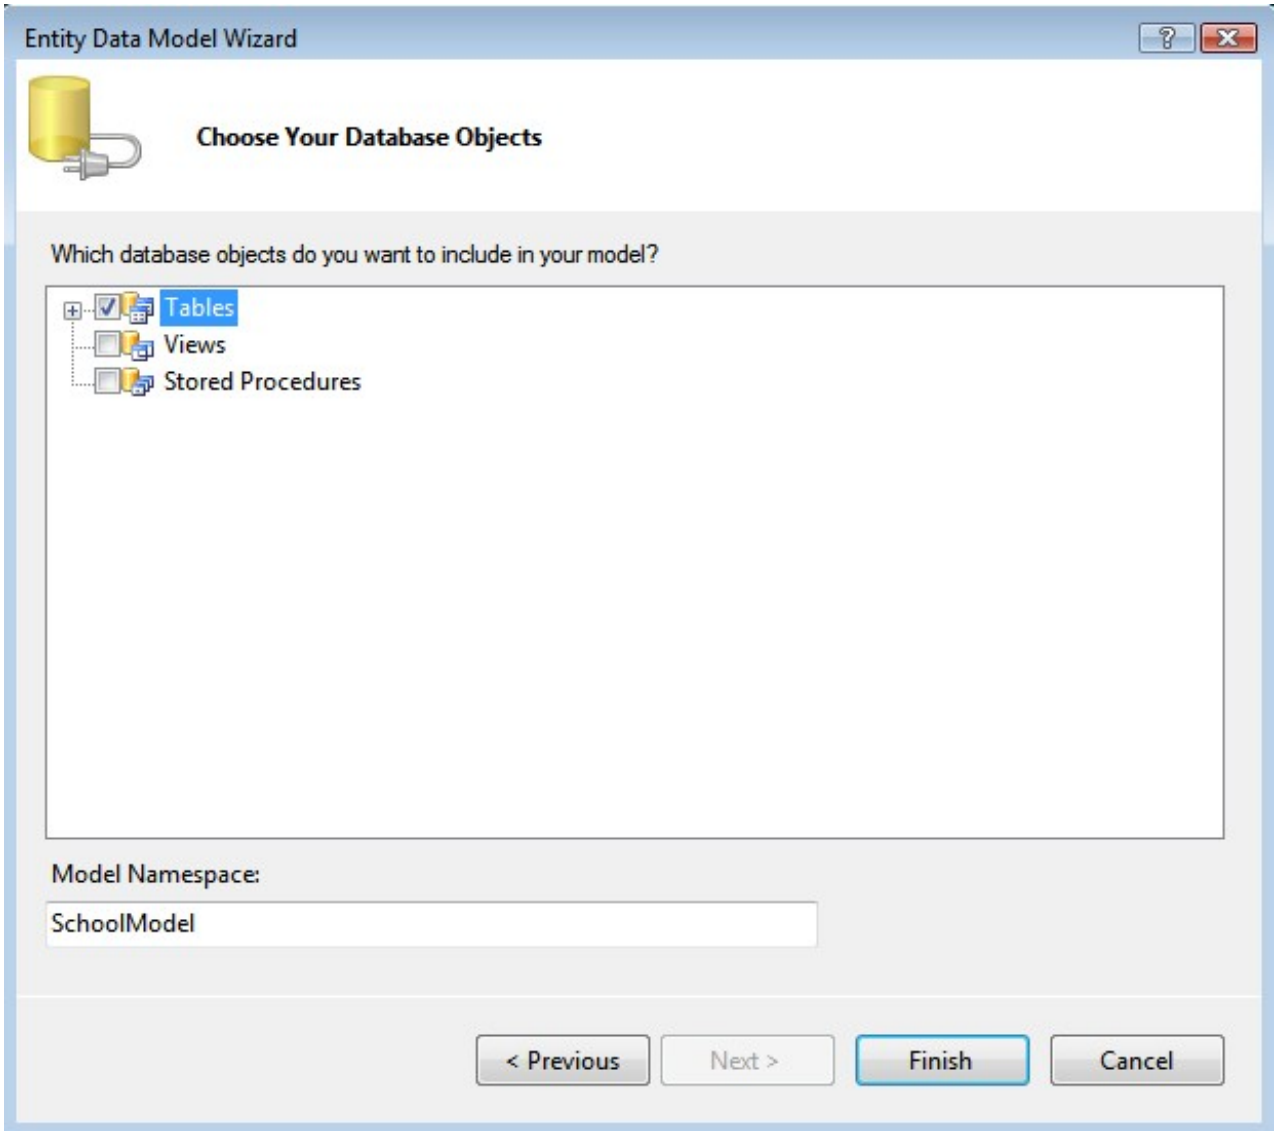
   SchoolModel

   and click

   Finish

   .

Figure 2.111. Database Objects



View the EDM in the ADO.NET Entity Data Model Designer

1. In the

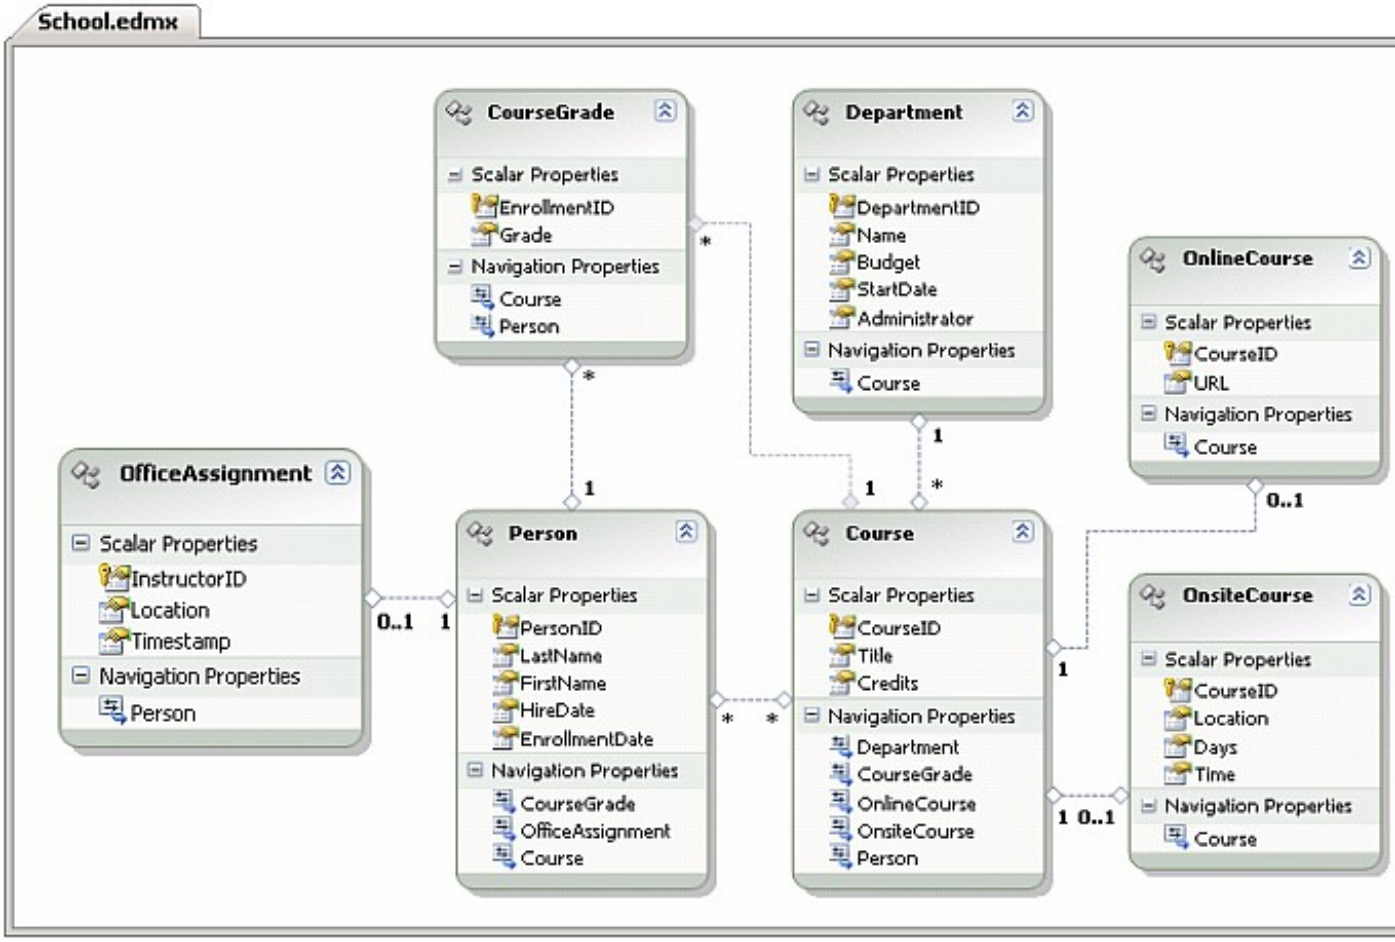
   Solution Explorer

   , double-click the

   School.edmx

   file. This displays the School model in the ADO.NET Entity Data Model Designer window.

   Figure 2.112. Solution Explorer



2. From the

   View

   menu, select

   Other Windows

   , and then click

   Model Browser

   to display the

   Entity Model Browser

   window.
3. Expand the

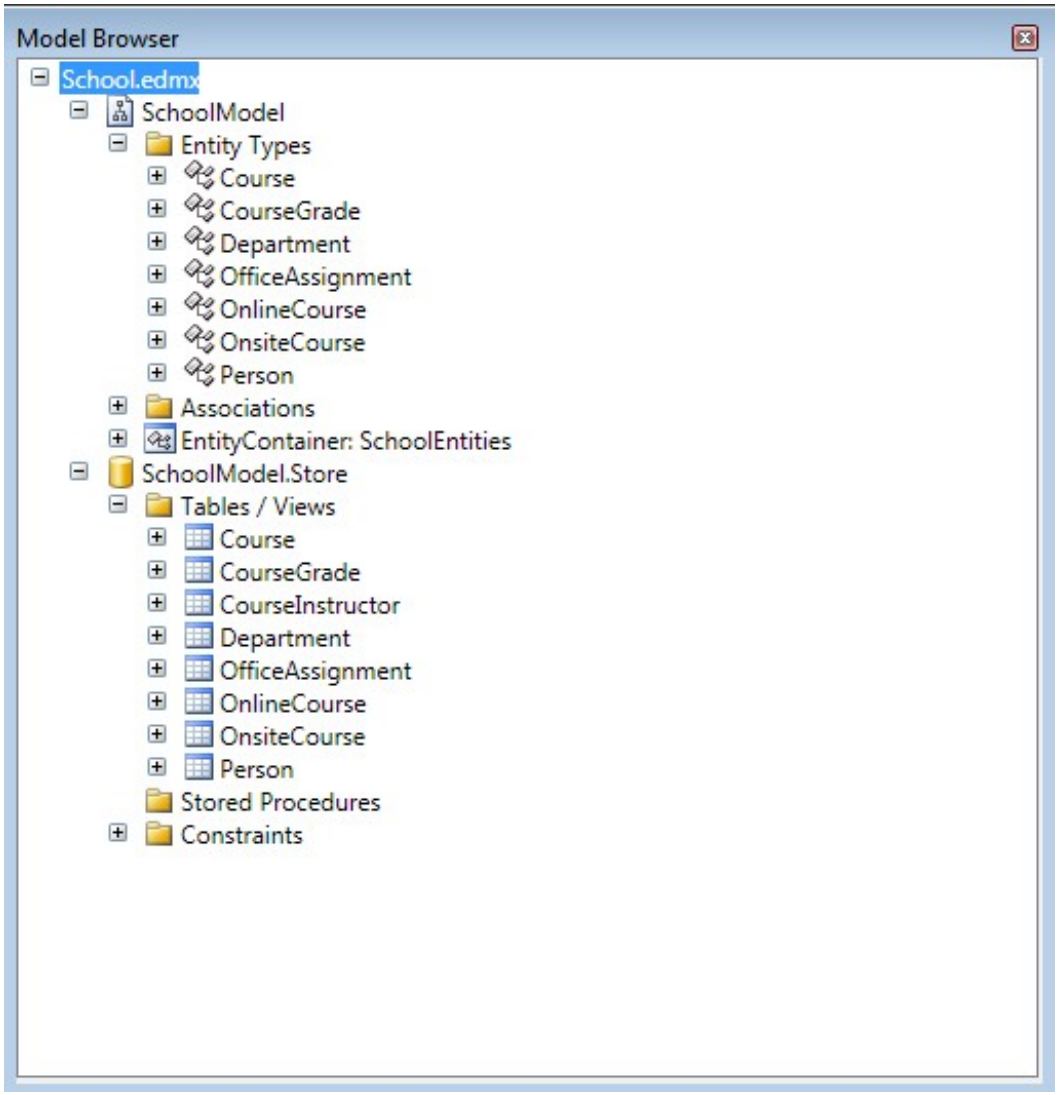
   SchoolModel

   and

   SchoolModel.Store

   nodes to view conceptual and store definitions, respectively.

   Figure 2.113. SchoolModel



4. From the

   View menu

   , select

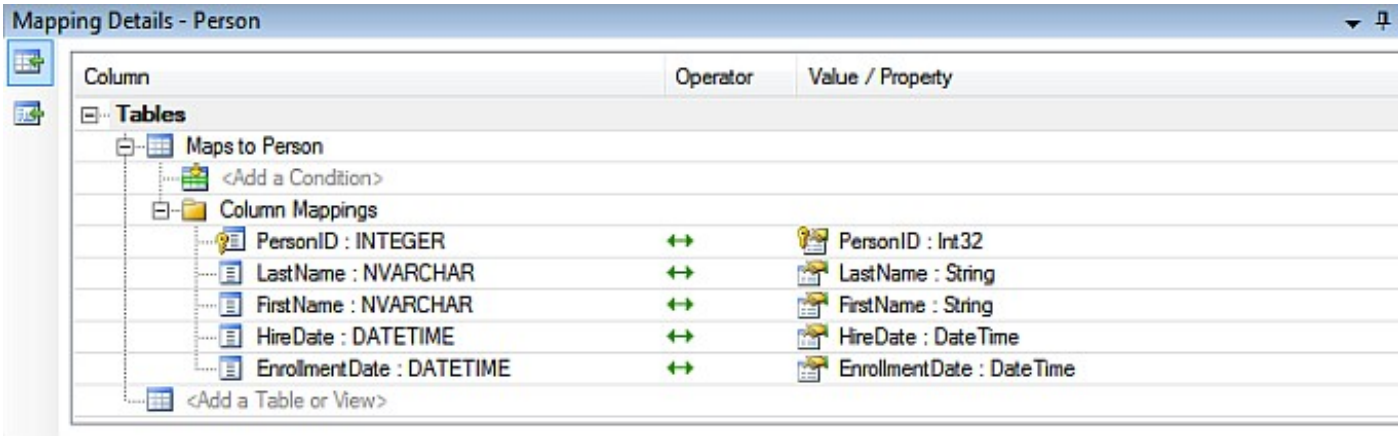
   Other Windows

   , click

   Mapping Details

   , and then click an entity (Person for example) or association in the Entity Designer.
5. This displays the Entity Mapping Details window with information about the object-relational mapping for the selected object.

Figure 2.114. View menu



2.7.4. Querying Entities and Associations

This section creates strongly-typed queries against the CLR objects that represent entities and associations in the School model, and bind display controls to the object collections returned from these queries.

Query the departments in the School database

1. At the beginning of the code file for the

   CourseViewer

   form, add the following

   using

   (C#) or

   Imports

   (Visual Basic) statements to reference the model created from the School database and the entity namespace.

   ```
   Visual Basic

   Imports System.Data.Objects
   Imports System.Data.Objects.DataClasses

   C#

   using System.Data.Objects;
   using System.Data.Objects.DataClasses;
   ```

2. At the top of the partial class definition for the

   CourseViewer

   form, add the following code that creates an

   ObjectContext

   instance.

   ```
   Visual Basic

   ' Create an ObjectContext instance based on SchoolEntity.
   Private schoolContext As SchoolEntities

   C#

   // Create an ObjectContext instance based on SchoolEntity.
   ```

```
private SchoolEntities schoolContext;
```

3. In the

   CourseViewer

   form designer, double-click the

   CourseViewer

   form. This opens the code page for the form and creates the

   courseViewer _Load

   event handler method.
4. In the

   courseViewer _Load

   event handler method, copy and paste the following code that defines the

   DataGridView

   , executes a query that returns a collection of departments (ordered by

   Name

   ), and binds the collection of

   Department

   objects to the departmentList control.

```
Visual Basic

' Initialize the ObjectContext.
schoolContext = New SchoolEntities()

' Define a query that returns all Department objects and related
' Course objects, ordered by name.
Dim departmentQuery As ObjectQuery(Of Department) = _
    schoolContext.Department.Include("Course").OrderBy("it.Name")

Try
    ' Bind the ComboBox control to the query, which is
    ' executed during data binding.
    Me.departmentList.DisplayMember = "Name"
    Me.departmentList.DataSource = departmentQuery
Catch ex As Exception
    MessageBox.Show(ex.Message)
End Try

C#

// Initialize the ObjectContext.
schoolContext = new SchoolEntities();

// Define a query that returns all Department objects and related
// Course objects, ordered by name.
ObjectQuery<Department> departmentQuery =
    schoolContext.Department.Include("Course").OrderBy("it.Name");

try
{
    // Bind the ComboBox control to the query, which is
    // executed during data binding.
    this.departmentList.DisplayMember = "Name";
    this.departmentList.DataSource = departmentQuery;
```

```
}
catch (Exception ex)
{
    MessageBox.Show(ex.Message);
}
```

Display courses for the selected department

1. In the

   CourseViewer

   form designer, double-click the

   departmentList

   control. This creates the

   departmentList_SelectedIndexChanged

   event handler method.
2. Paste the following code that loads the courses that are related to the selected department.

```
Visual Basic

Try
    ' Get the object for the selected department.
    Dim department As Department = _
        CType(Me.departmentList.SelectedItem, Department)

    ' Bind the grid view to the collection of Course objects
    ' that are related to the selected Department object.
    courseGridView.DataSource = department.Course

    ' Hide the columns that are bound to the navigation properties on Course.
    courseGridView.Columns("Department").Visible = False
    courseGridView.Columns("CourseGrade").Visible = False
    courseGridView.Columns("OnlineCourse").Visible = False
    courseGridView.Columns("OnsiteCourse").Visible = False
    courseGridView.Columns("Person").Visible = False

    courseGridView.AutoResizeColumns(DataGridViewAutoSizeColumnsMode.AllCells)
Catch ex As Exception
    MessageBox.Show(ex.Message)
End Try

C#

try
{
    // Get the object for the selected department.
    Department department =
        (Department)this.departmentList.SelectedItem;

    // Bind the grid view to the collection of Course objects
    // that are related to the selected Department object.
    courseGridView.DataSource = department.Course;

    // Hide the columns that are bound to the navigation properties on Course.
    courseGridView.Columns["Department"].Visible = false;
    courseGridView.Columns["CourseGrade"].Visible = false;
    courseGridView.Columns["OnlineCourse"].Visible = false;
    courseGridView.Columns["OnsiteCourse"].Visible = false;
    courseGridView.Columns["Person"].Visible = false;

    courseGridView.AutoResizeColumns(DataGridViewAutoSizeColumnsMode.AllCells);
}
catch (Exception ex)
{
    MessageBox.Show(ex.Message);
```

```
}
```

2.7.5. Inserting and Updating Data

In this section the changes made to Course objects bound are saved to the DataGridView control to the database and also run the completed Course Manager application.

Save changes made to objects

1. In the

   Toolbox

   , expand

   Common Controls

   , drag the

   Button

   control to the

   CourseViewer

   form designer, change the

   name

   of the control to

   saveChanges

   , and change the

   Text

   value to

   Update

   .
2. In the

   CourseViewer

   form designer, double-click the

   saveChanges

   control. This creates the

   saveChanges_Click

   event handler method.
3. Paste the following code that saves object changes to the database.

```
Visual Basic

Try
    ' Save object changes to the database, display a message,
    ' and refresh the form.
```

```
        schoolContext.SaveChanges()
        MessageBox.Show("Changes saved to the database.")
        Me.Refresh()
    Catch ex As Exception
        MessageBox.Show(ex.Message)
    End Try

    C#

    try
    {
        // Save object changes to the database, display a message,
        // and refresh the form.
        schoolContext.SaveChanges();
        MessageBox.Show("Changes saved to the database.");
        this.Refresh();
    }
    catch (Exception ex)
    {
        MessageBox.Show(ex.Message);
    }
```

4. In the

   closeForm_Click

   event handler method, type the following code. This code disposes of the object context before the form is closed.

```
    Visual Basic

       ' Dispose the object context.
        schoolContext.Dispose()

    C#

        // Dispose the object context.
        schoolContext.Dispose();
```

Build and run the Class Scheduling application

1. From the

   Debug

   menu, select

   Start Debugging

   or

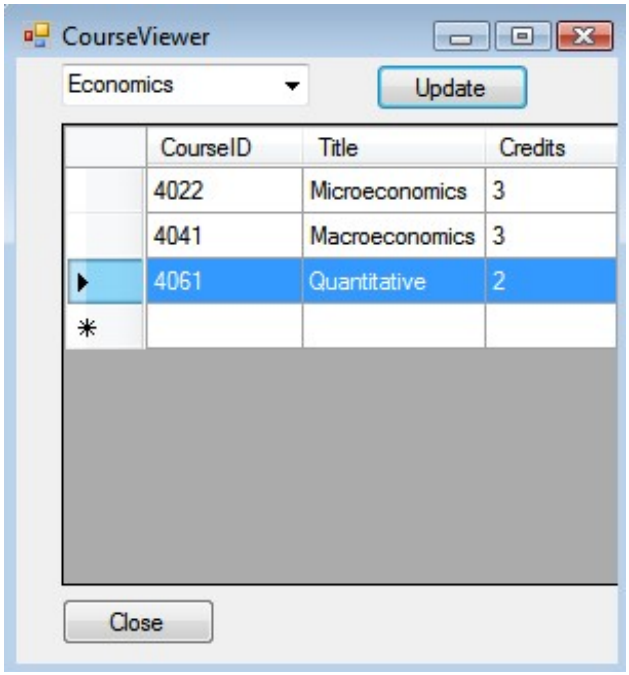
   Start Without Debugging

   , to build and run the application.
2. When the form loads, select a department from the

   ComboBox

   control to display the courses that belong to that department.

   Figure 2.115. ComboBox



3. In the

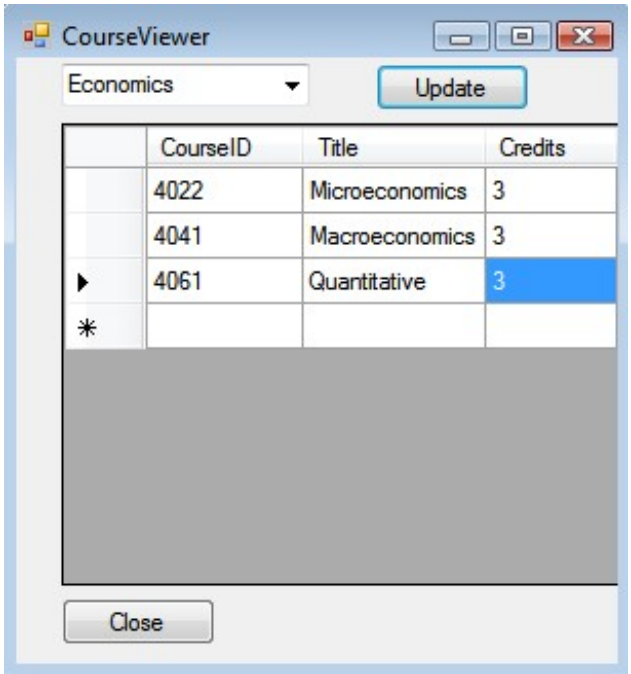
   DataGridView

   , update course information or add a new course and then click

   Update

   to save changes to the database and displays a message box that declares the number of saved changes.

   Figure 2.116. DataGridView



The process is now complete

2.8. Using Visual Studio 2008 to Build an ADO.NET Data Services based Application

Using Microsoft ADO.Net Data Services with Virtuoso

2.8.1. Introduction

The goal of Microsoft ADO.NET Data Services is to enable applications to expose data as a data service that can be consumed by web clients within corporate networks and across the internet. A data service is reachable via regular HTTP requests, using standard HTTP verbs such as GET, POST, PUT and DELETE to perform CRUD operations against the service. The payload format used by the service is controllable by the application, but all options are simple, open formats such as JSON and Atom/APP.

The use of web-friendly technologies make ADO.NET Data Services ideal as a data back-end for AJAX-style applications, Rich Interactive Applications and other applications that need to operate against data that is stored across the web.

2.8.2. Getting Started: Creating Data Services

Pre-requisites

In order to create a data service using ADO.NET Data Services in your own environment you will need Microsoft Visual Studio 2008 SP1. The ADO.NET Entity Framework runtime and associated tools are included in Visual Studio 2008 SP1.

Selecting a Data Source

The ADO.NET Data Service server framework is comprised of two halves. The top-half is the runtime itself; this part is "fixed", and it implements URI translation, the Atom/JSON wire formats, the interaction protocol, etc. This is what makes an ADO.NET Data Service look like an ADO.NET Data Service. The bottom half is the data-access layer and is pluggable. Communication between layers happens in terms of the IQueryable interface plus a set of conventions to map CLR graphs into the URI/payload patterns of ADO.NET Data Services.

The first step in creating an ADO.NET Data Service is to determine the data source that is to be exposed as a set of REST-based endpoints (ie. select or create a data access layer). For relational data stored in Microsoft SQL Server or other 3rd Party databases, ADO.NET Data Services currently enables easily exposing a conceptual model created using the ADO.NET Entity Framework (EF). For all other data sources (XML section, web service, application logic layer, etc) or to use additional database access technologies (ex. LINQ to SQL), a mechanism is provided which enables any data source, as per the plug-in model described above, to be exposed as an ADO.NET Data Service.

To create a data service which exposes a relational database through an Entity Framework conceptual model see "Creating a Data Service using the ADO.NET Entity Framework". To create a data service which exposes another data source see "Creating a Data Service from any Data Source".

2.8.3. Creating a Data Service using the ADO.NET Entity Framework

ADO.NET Data Services are a specialized form of Windows Communication Foundation services, and thus can be hosted in various environments. The below example will create an ADO.NET Data Service which is hosted inside an ASP.NET site. In order to create a data service, you must first create a web project; you will then need to establish a connection with the database that will be exposed by the service, and then create the data service itself within the web application. Below is a step-by-step description of this process.

The following steps can be used for creating a Data Service using the Virtuoso ADO.Net Provider for accessing the sample Northwind Demo database:

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 2.117. Visual Studio 2008 SP1 IDE.

2. Create a

   Web Application

   project by going to the

   File

   menu in Visual Studio and choosing

   New Project

   .
3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as the programming language.
4. Within the language category click on

   Web

   , and select

   ASP.NET Web Application

   from the right-hand panel.
5. Choose a name for the project, for example

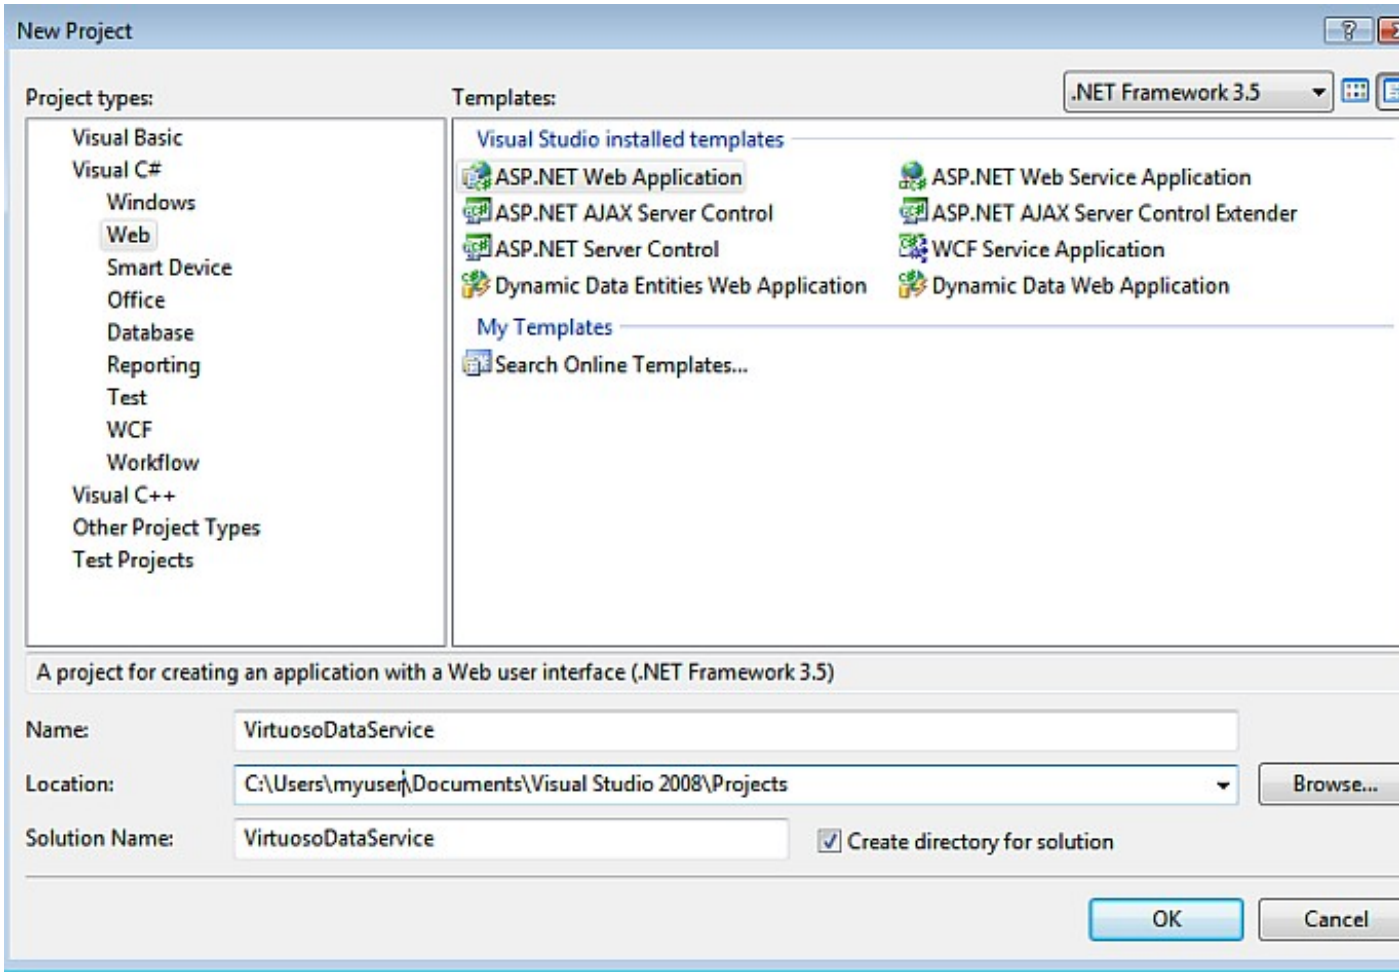
   VirtuosoDataService

   , and click

   OK

   .

   Figure 2.118. Name project

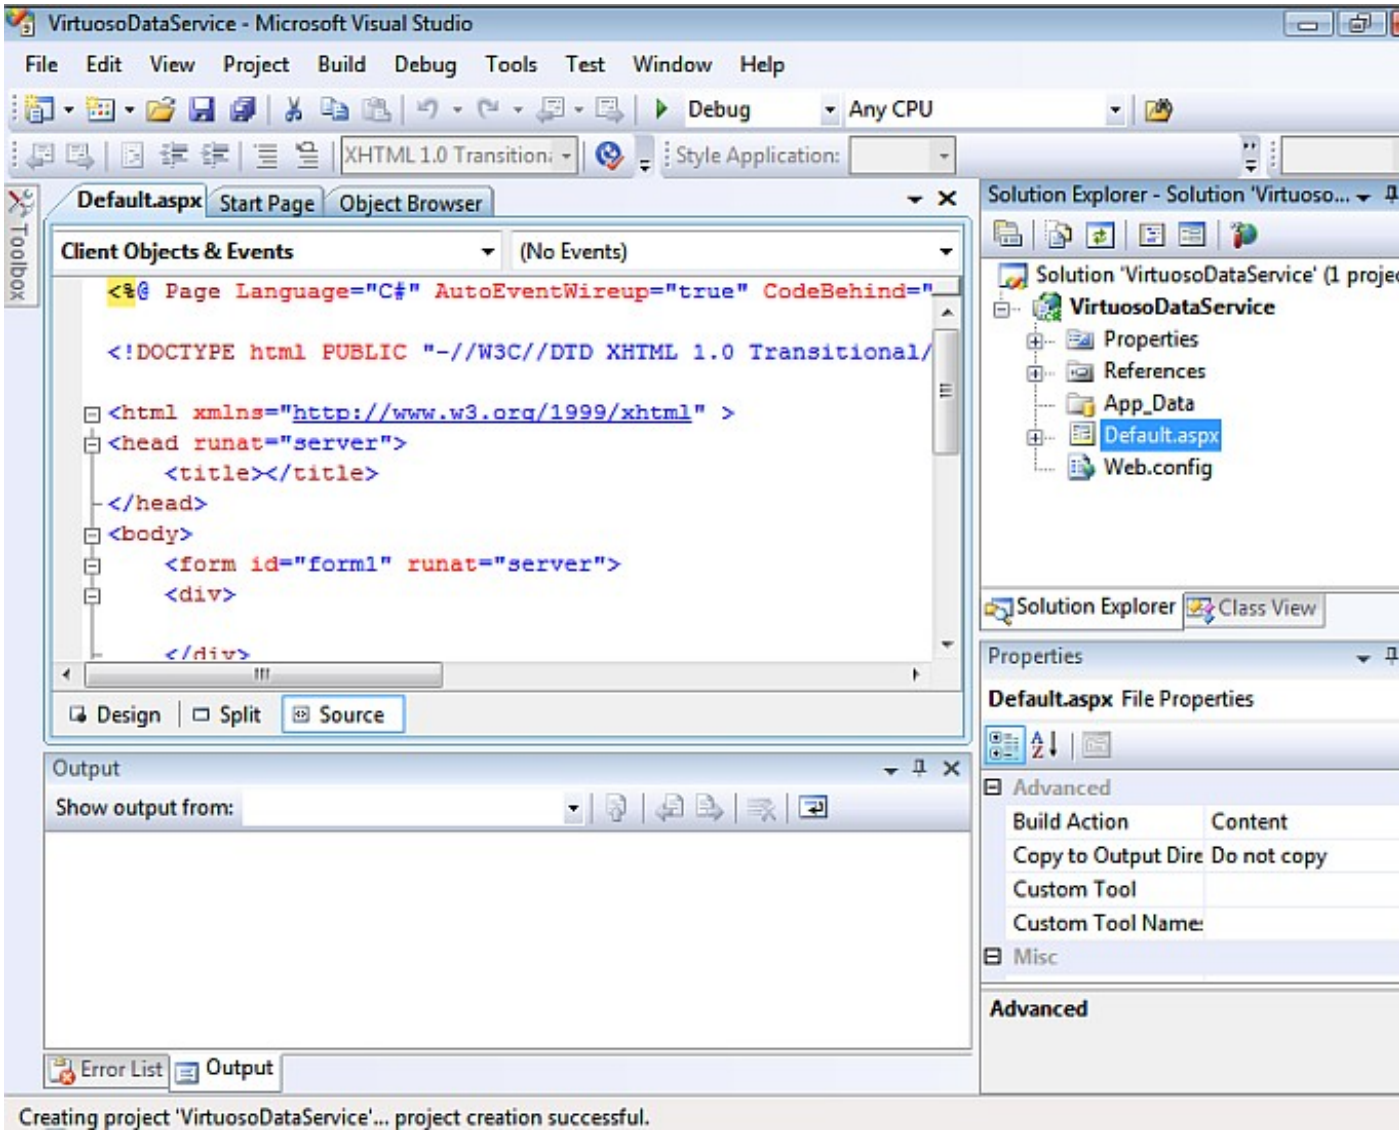


6. This will create a new project called

   VirtuosoDataService

   .

Figure 2.119. Create project



7. Right click on the

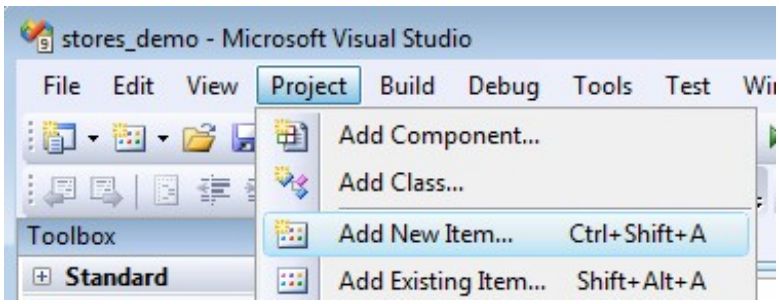
   VirtuosoDataService

   project name of the Solution Explorer pane, then select the

   Add -> New Item

   menu options.

   Figure 2.120. New Item



8. The

   Add

New Item dialog will appear, choose the

ADO.NET Entity Data Model

template, give it the name

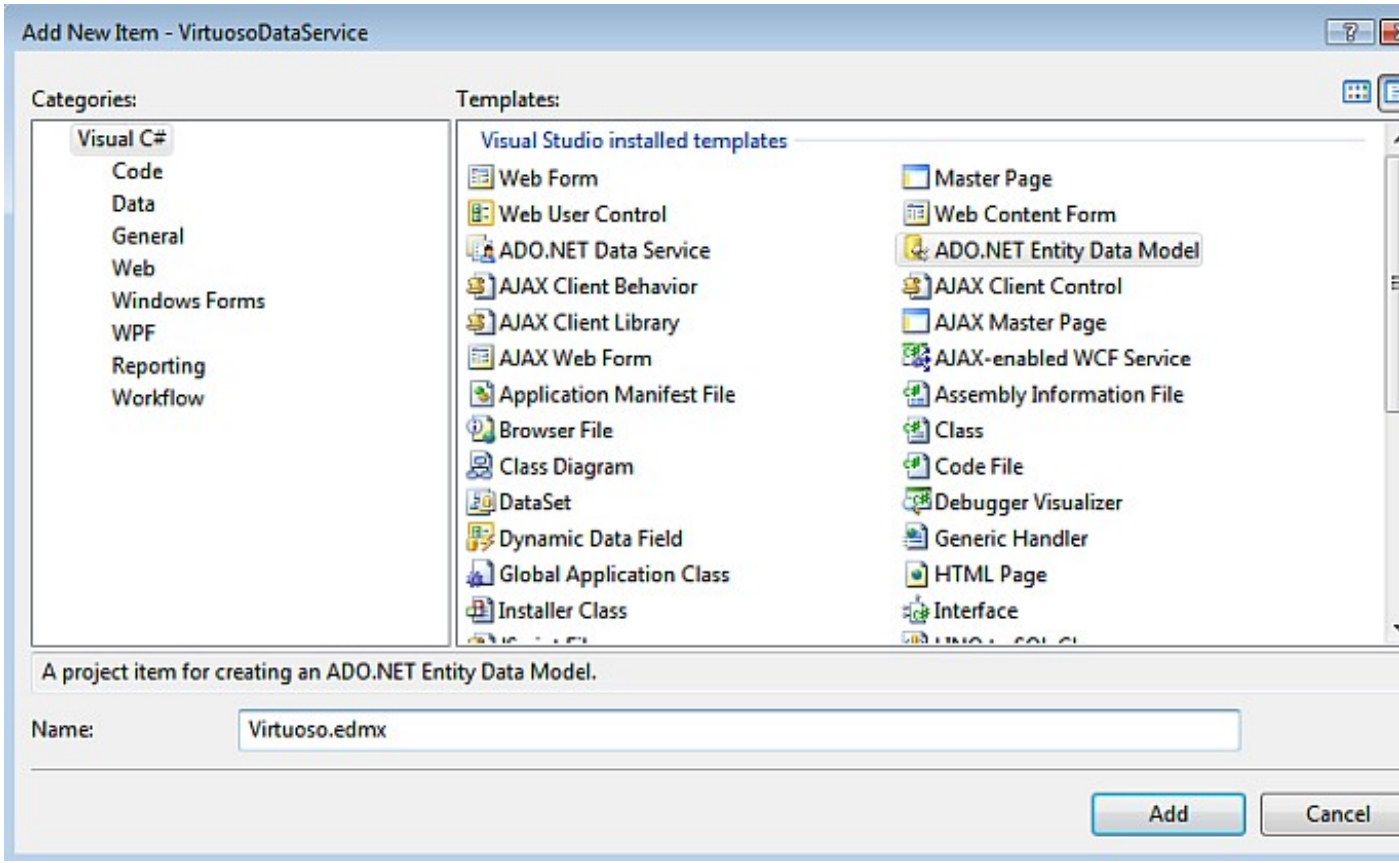
Virtuoso.edmx

and click

Add

to start the creation of the ADO.Net Entity Data Model.

Figure 2.121. Entity Model



9. In the

Entity Data Model Wizard

dialog

Choose Model Contents

page select the

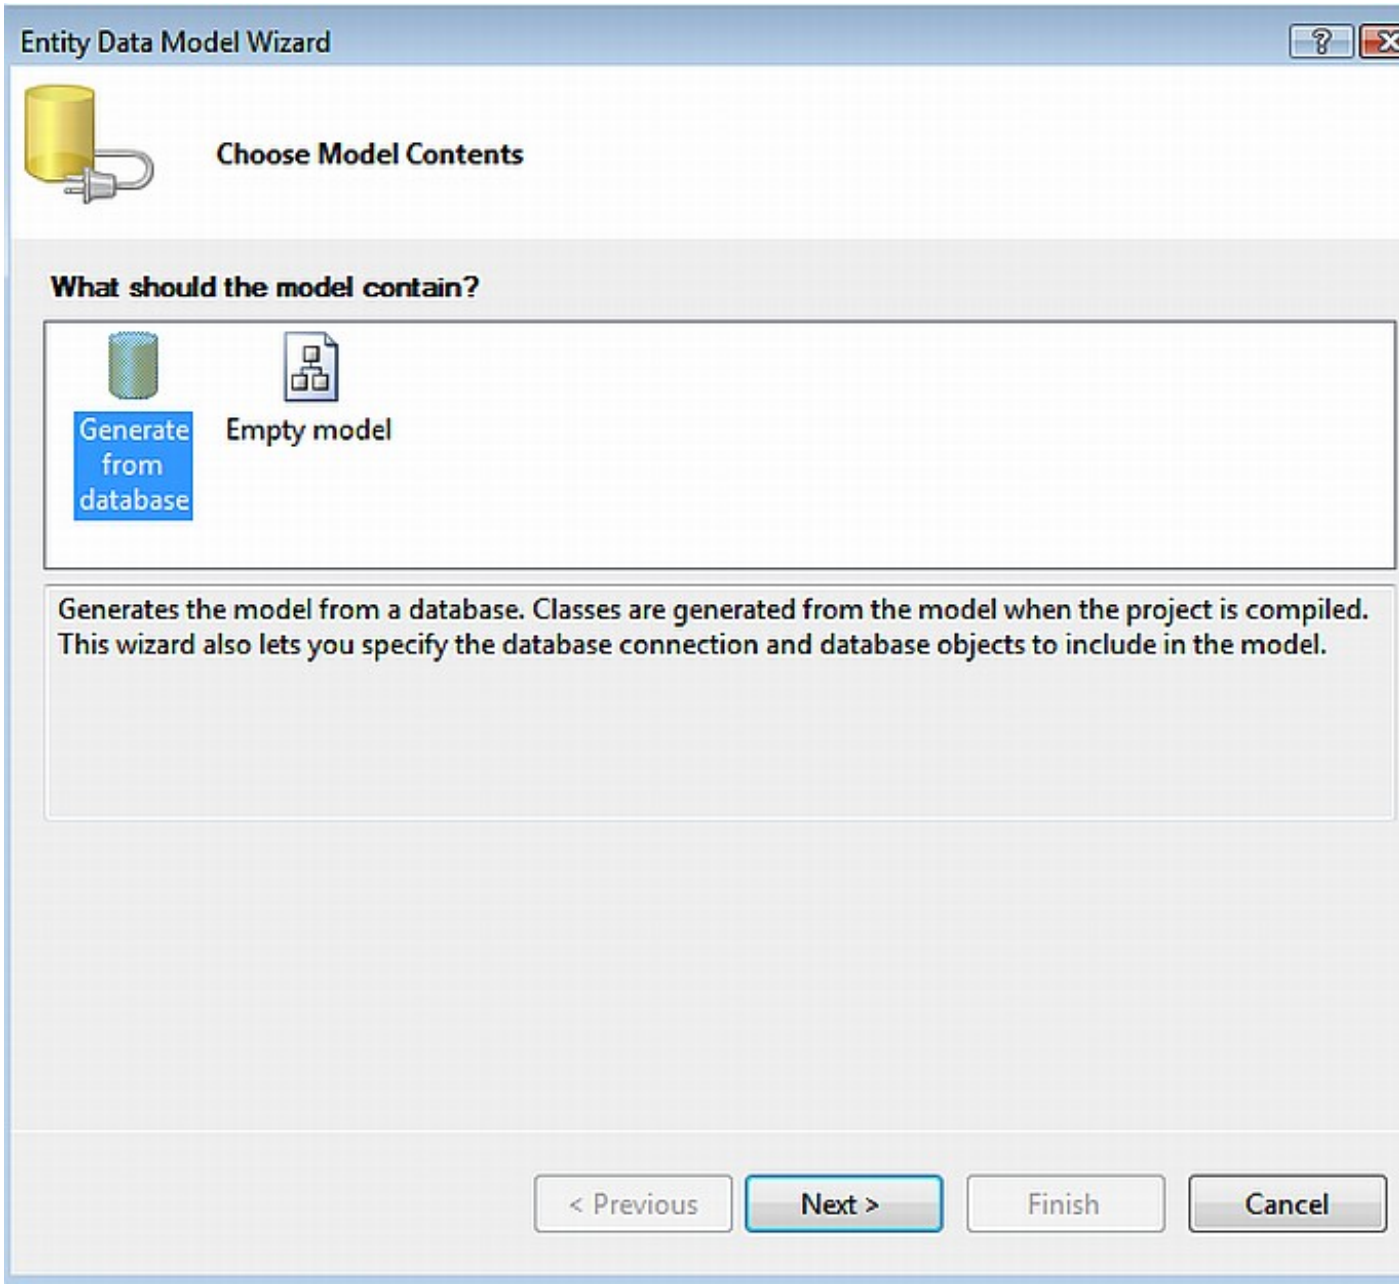
Generate from Database

model type and click

Next

.

Figure 2.122. Model Contents



10. In the

    Entity Data Model Wizard

    dialog

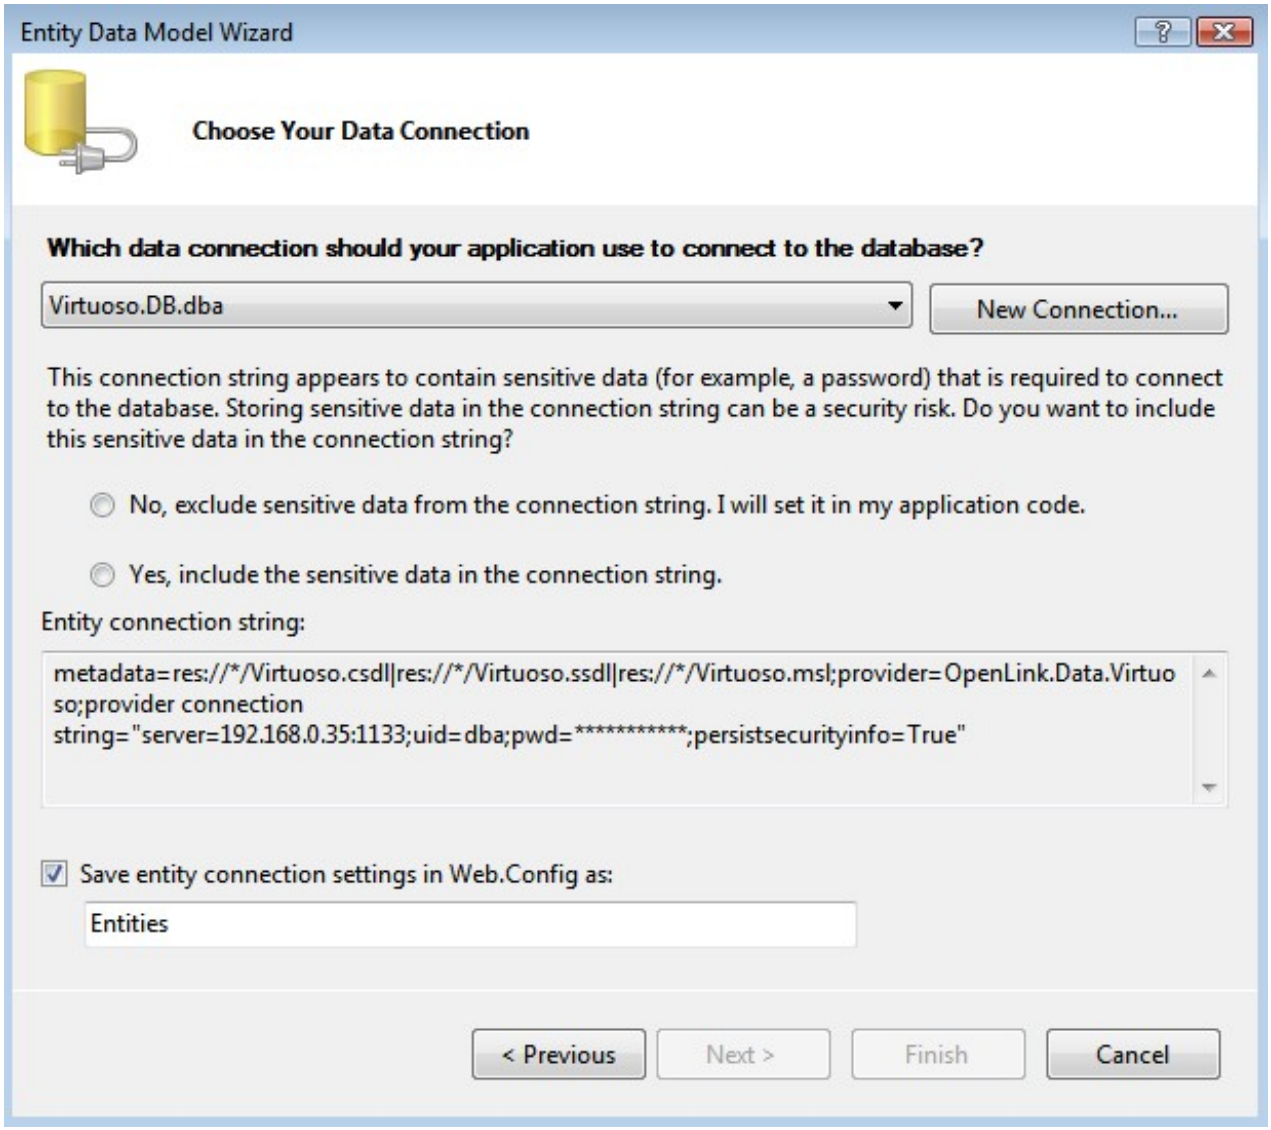
    Choose your Data Connection

    page select the

    New Connection

    button

Figure 2.123. Data Connection



11. In the

    Choose Data Source

    dialog, select the OpenLink

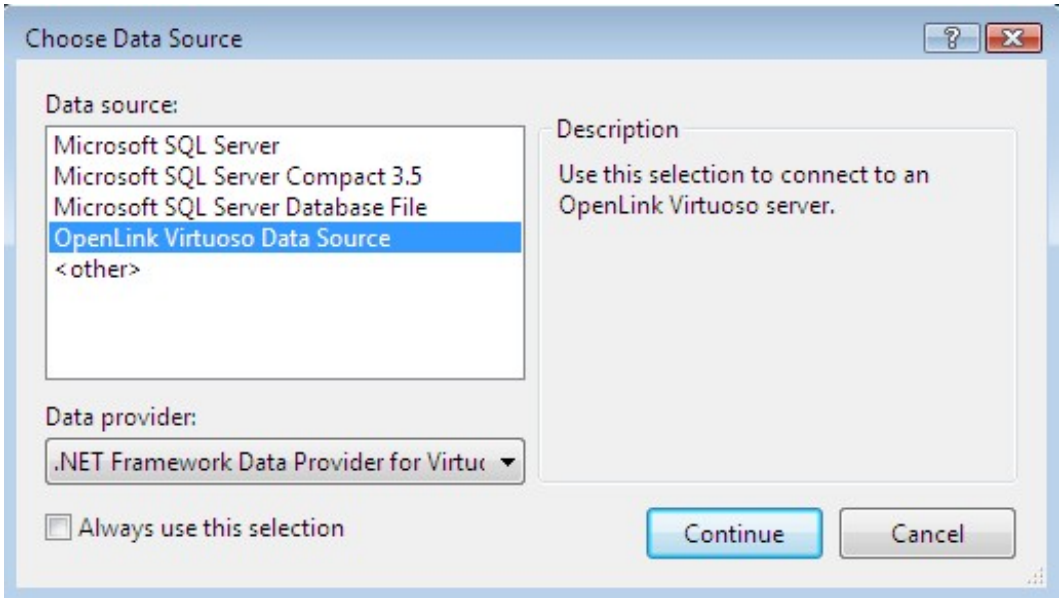
    Virtuoso Data Source

    from the list displayed and click

    Continue

    .

Figure 2.124. Data Source



12. In the

    Add Connection

    dialog, specify the

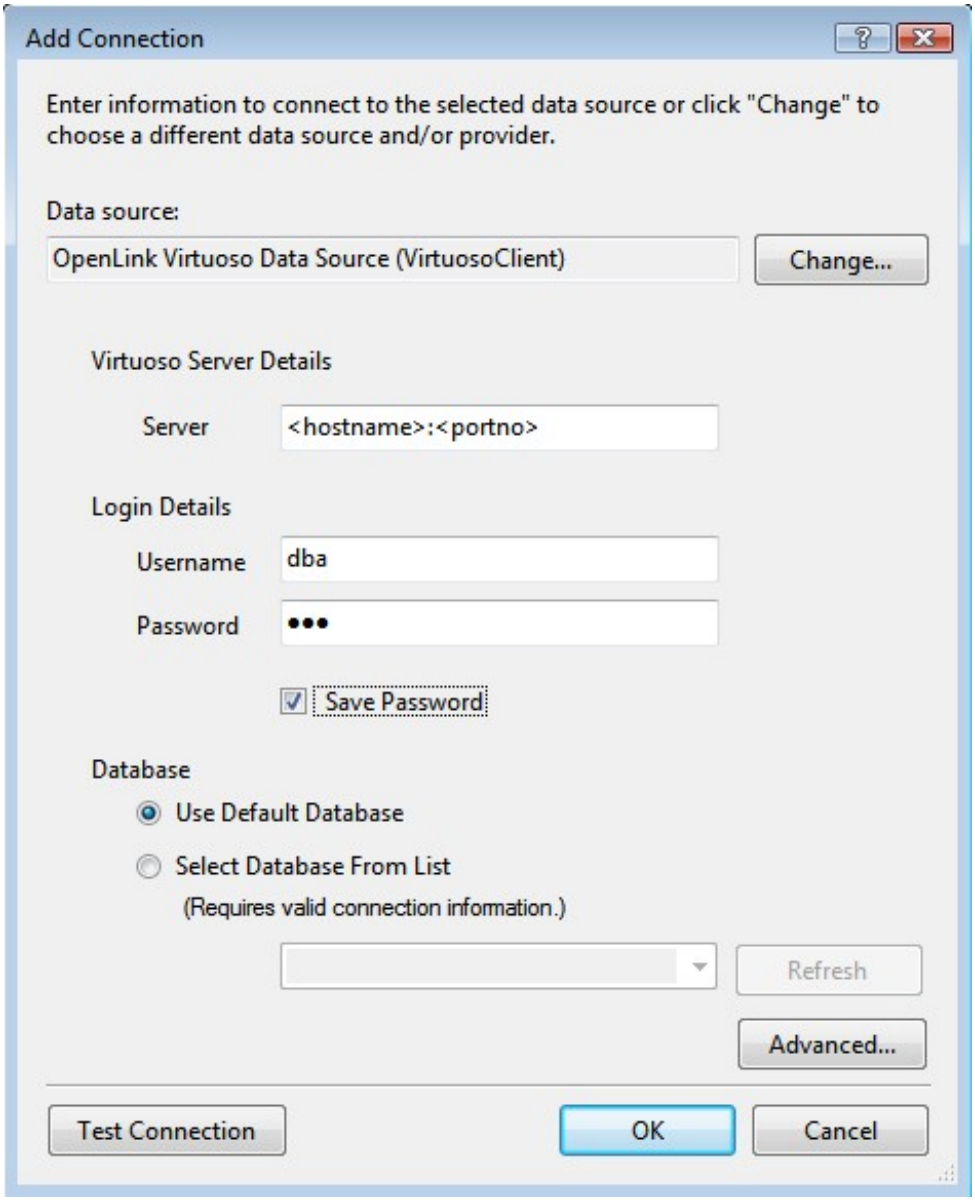
    hostname, portno, username and password

    for the target Virtuoso Server and check the

    Save Password

    check box.

    Figure 2.125. Connection Properties



13. Select the

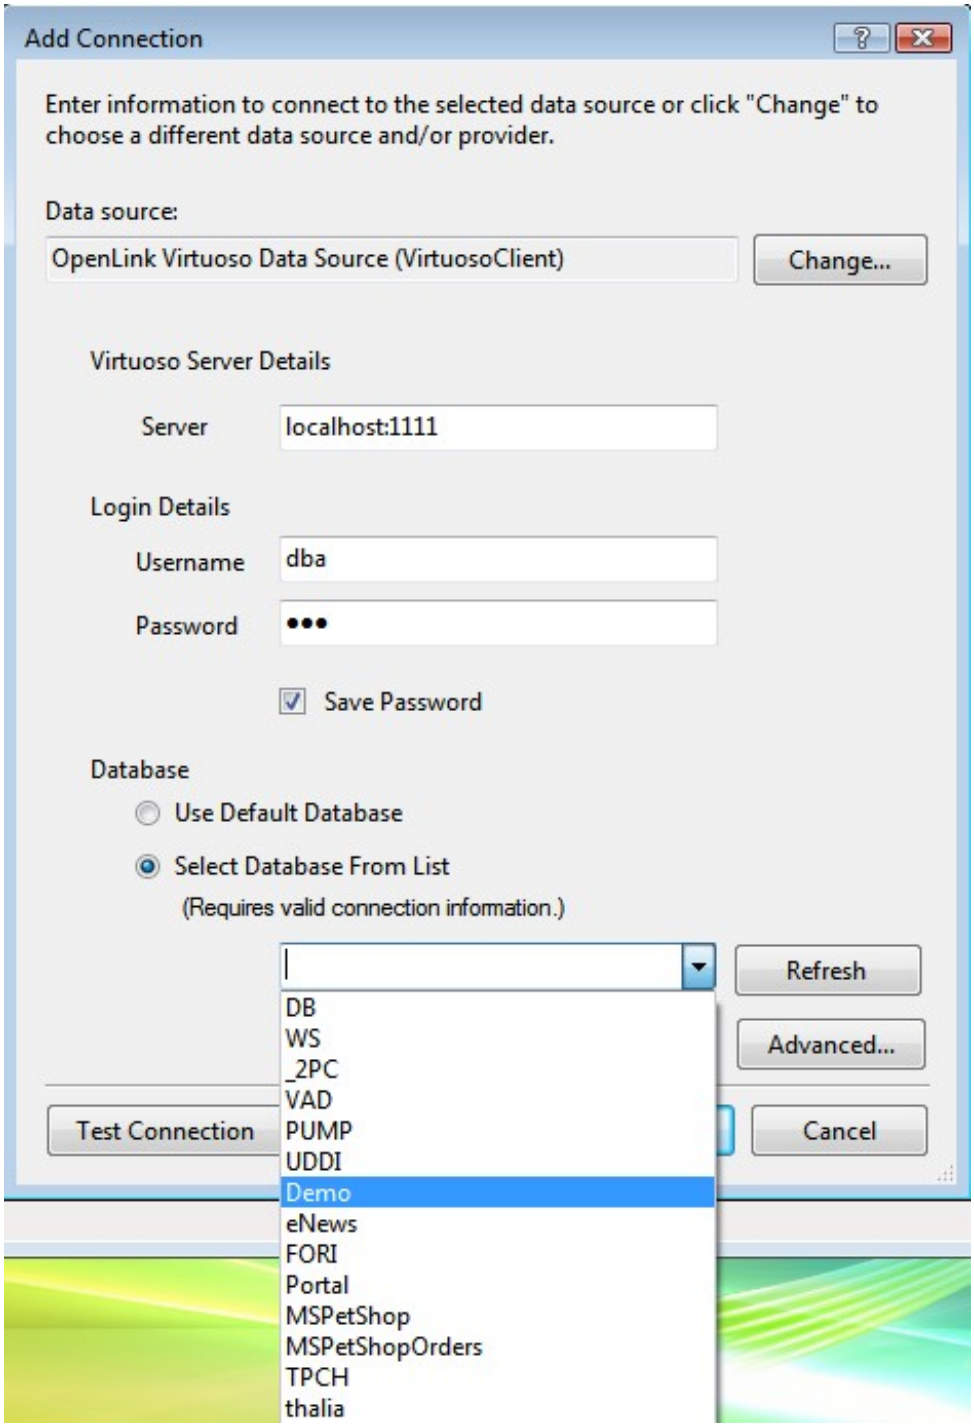
    Select Database From List

    radio button and choose

    Demo

    from the drop down list, assuming the Virtuoso Demo Database is installed.

Figure 2.126. Advanced Properties

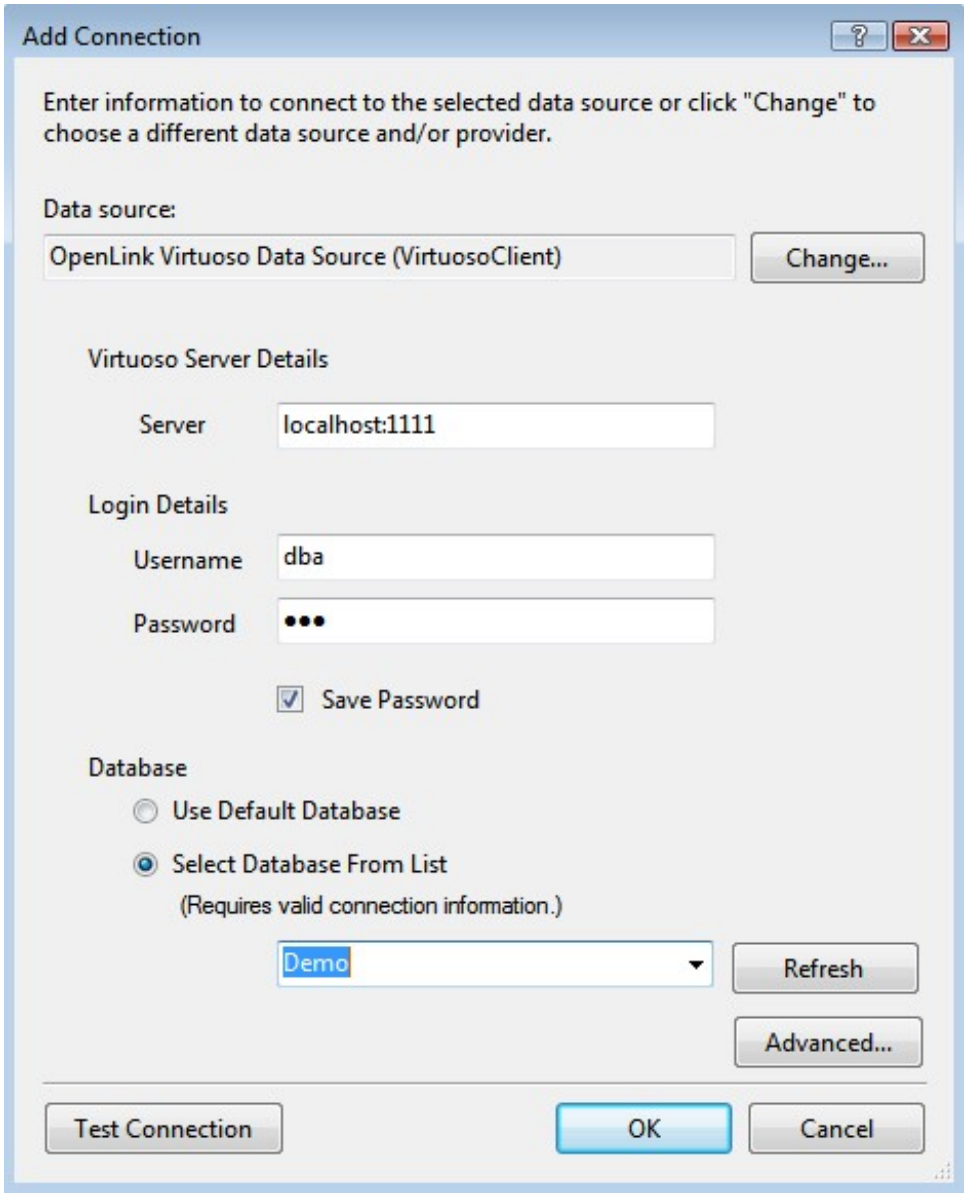


14. Click the

    Test Connection

    button to verify the connection is successful and then click OK to add the connection.

    Figure 2.127. Test Connection



15. Set the

    entity connect string

    name to

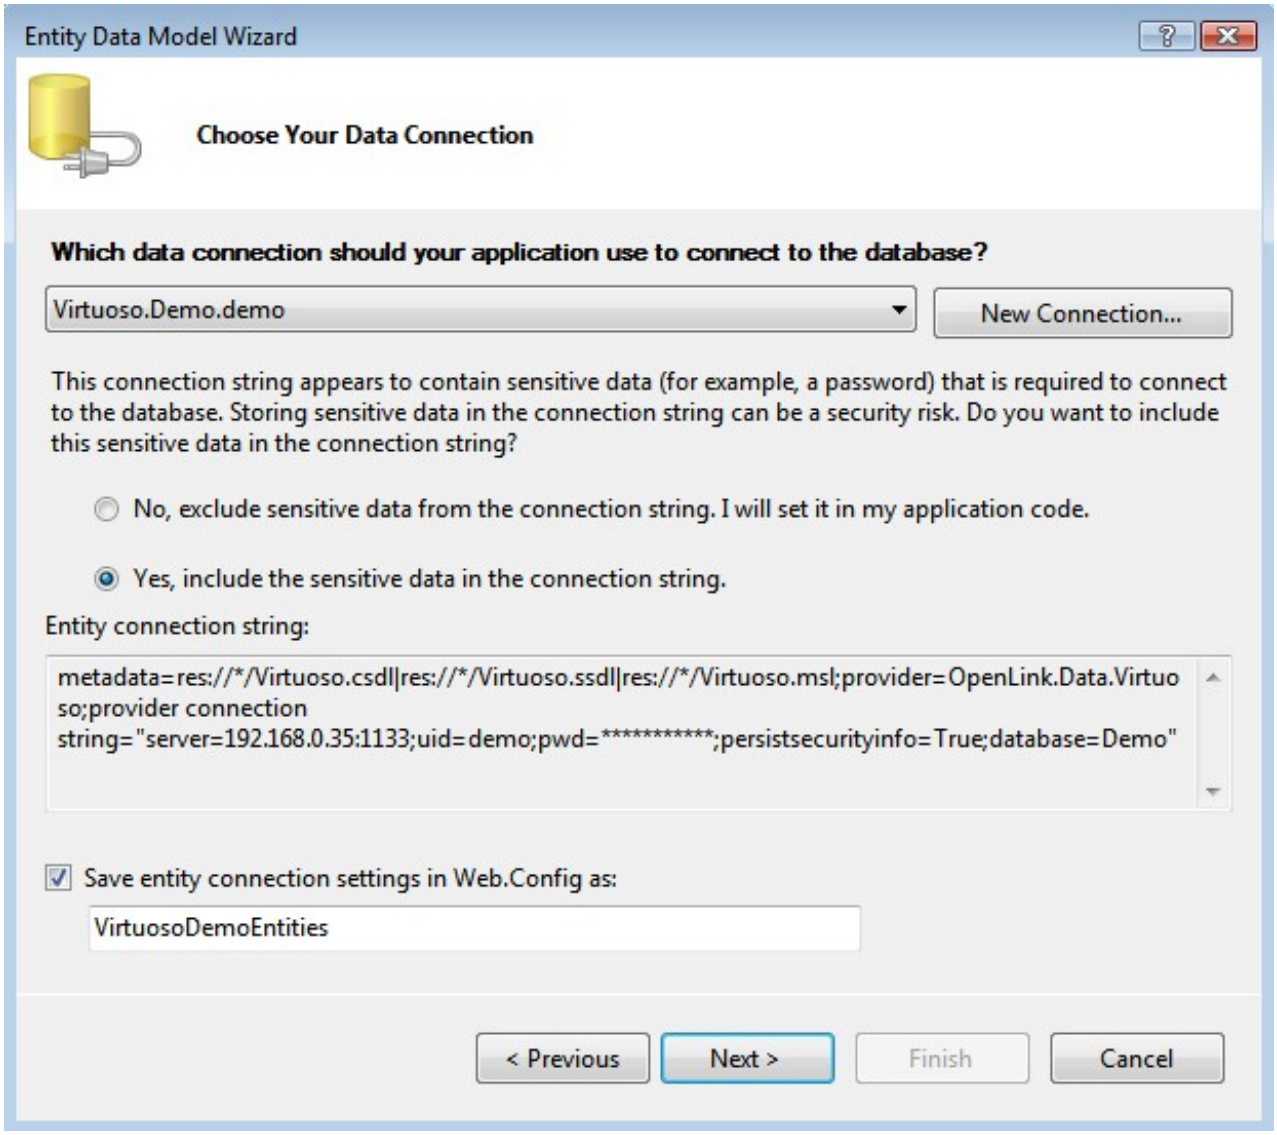
    VirtuosoDemoEntities

    (note this name as it is required in step 17 below) and click

    Next

    .

    Figure 2.128. entity connect string



16. In the

    Choose your Database Objects

    page select the

    Tables

    check box to select all tables in the Demo database for addition to the Entity Data Model, set the

    Model Namespace

    to

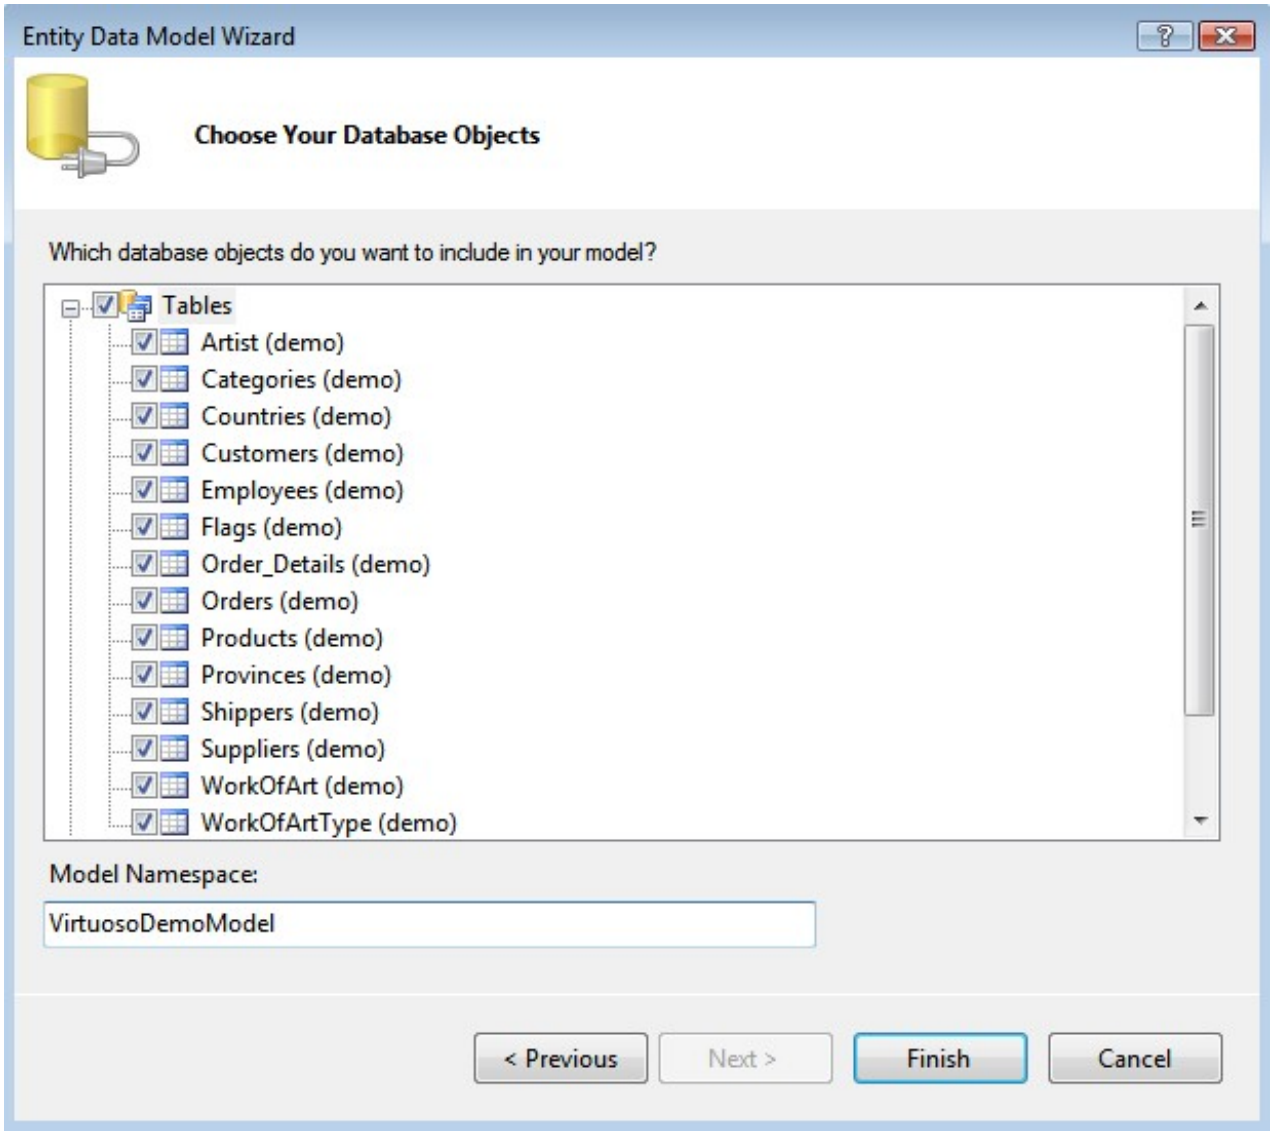
    VirtuosoDemoModel

    and click

    Finish

    .

Figure 2.129. Database Objects

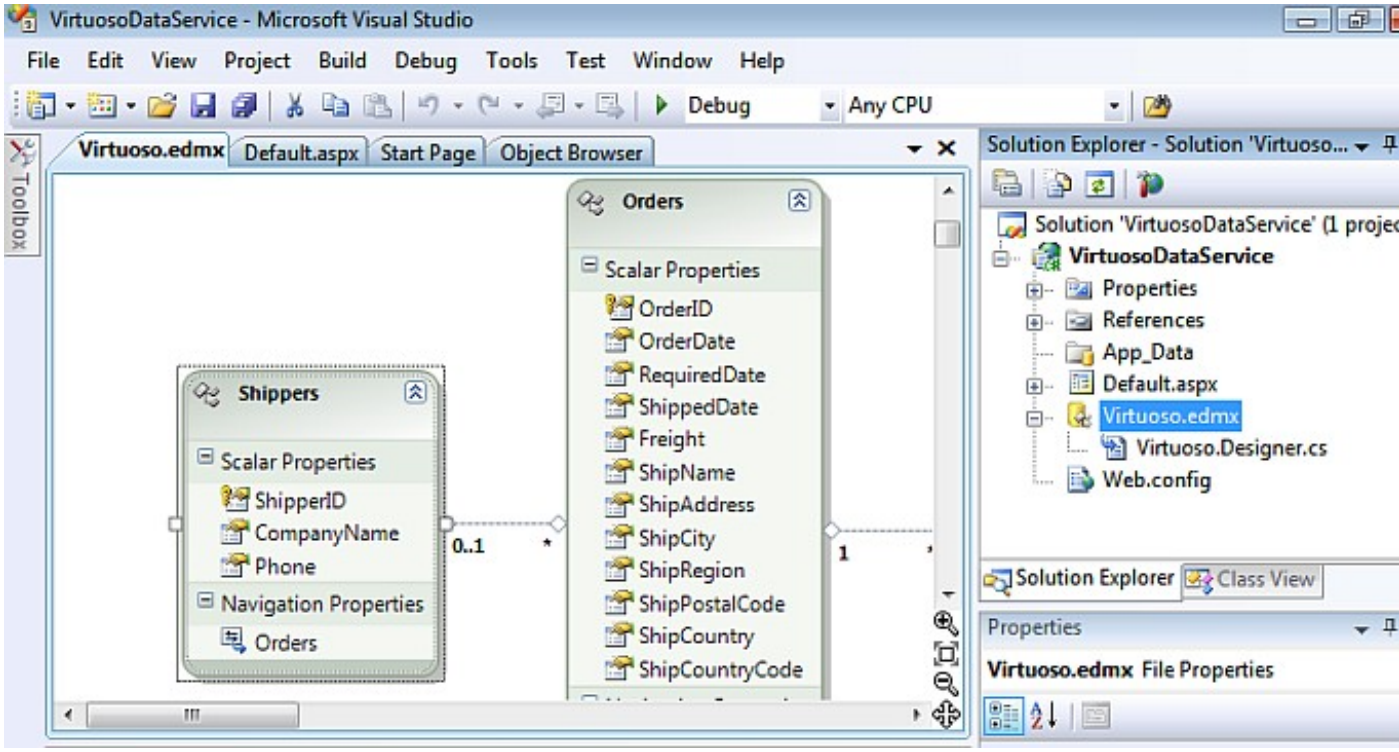


17. The

    Virtuoso.edmx

    EDM will be created with the tables and relationships displayed in the Visual Studio IDE

    Figure 2.130. Virtuoso.edmx



18. Right click on the

    VirtuosoDataService

    project name of the

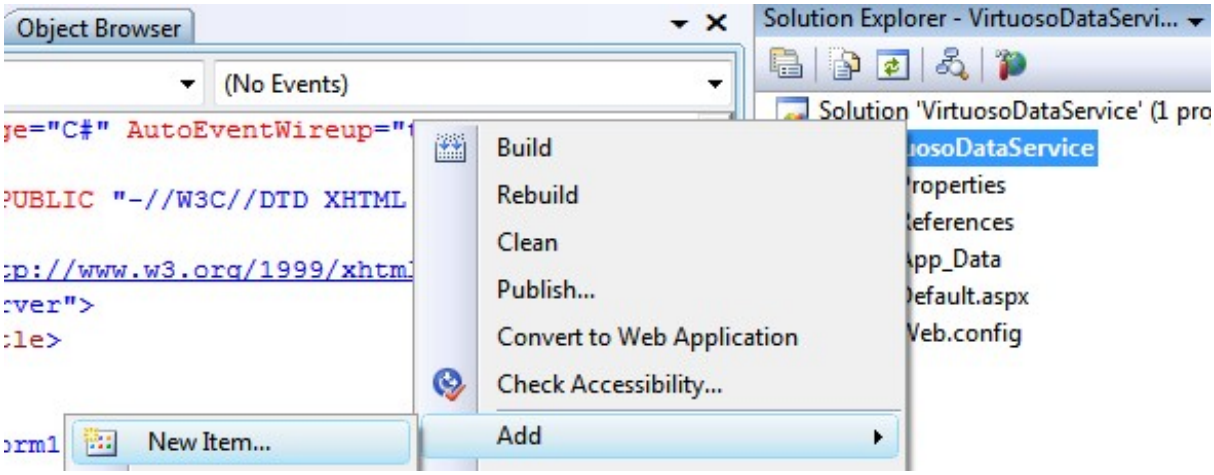
    Solution Explorer pane

    , then select the

    Add -> New Item

    menu options.

Figure 2.131. New Item



19. The

    Add New Item

    dialog will appear, choose the

ADO.NET Data Service

template, give it the name

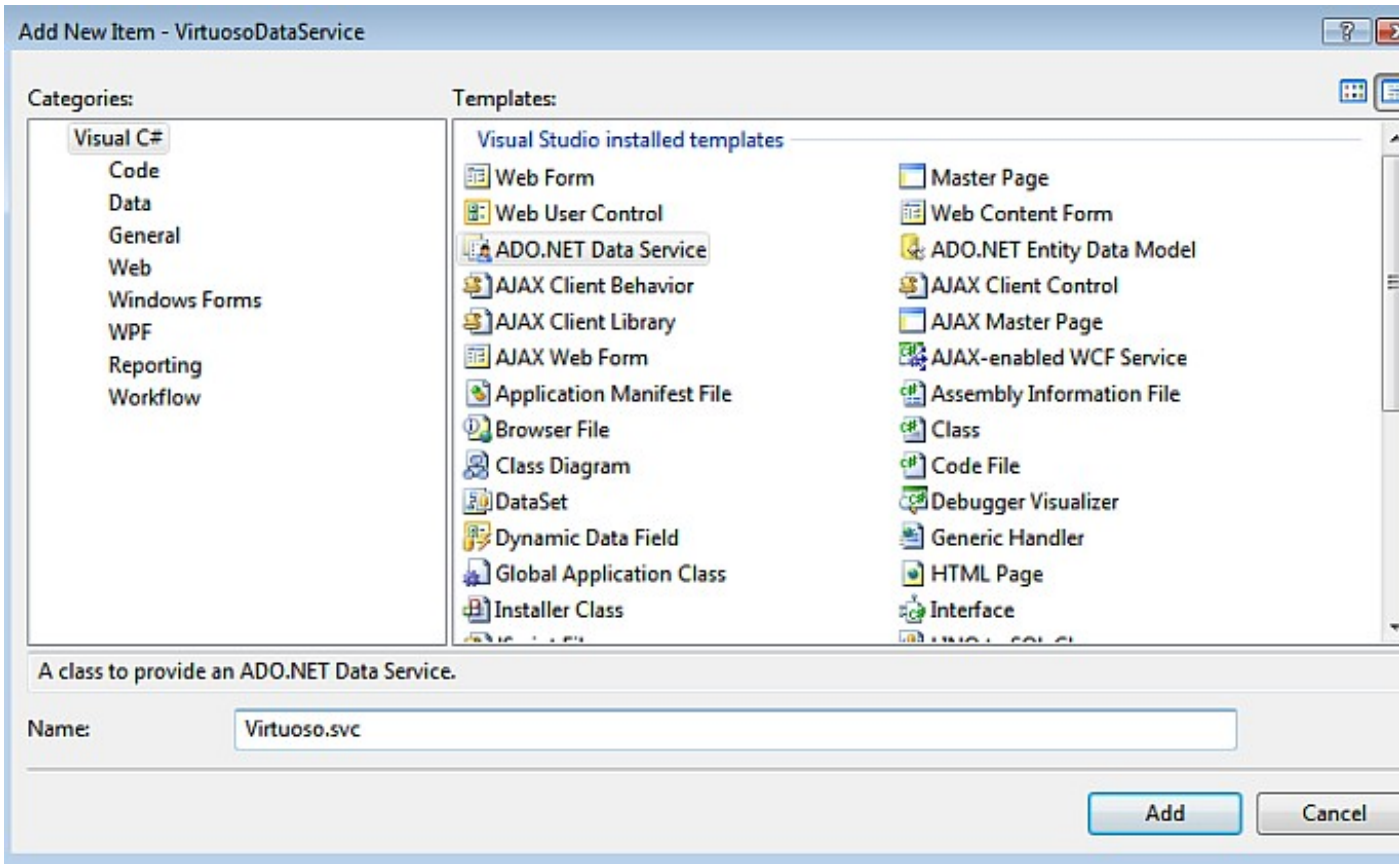
Virtuoso.svc

and click

Add

to create the ADO.Net Data Service.

Figure 2.132. ADO.NET Data Service



20. In the

Virtuoso.svc.cs

Data Service file created add the data source class name of

VirtuosoDemoEntities

(note this is the name set in step 12) as the

DataService

name and enable the access to the Data Service by adding the entry

config.SetEntitySetAccessRule("", EntitySetRights.All);*

in the

InitializeService

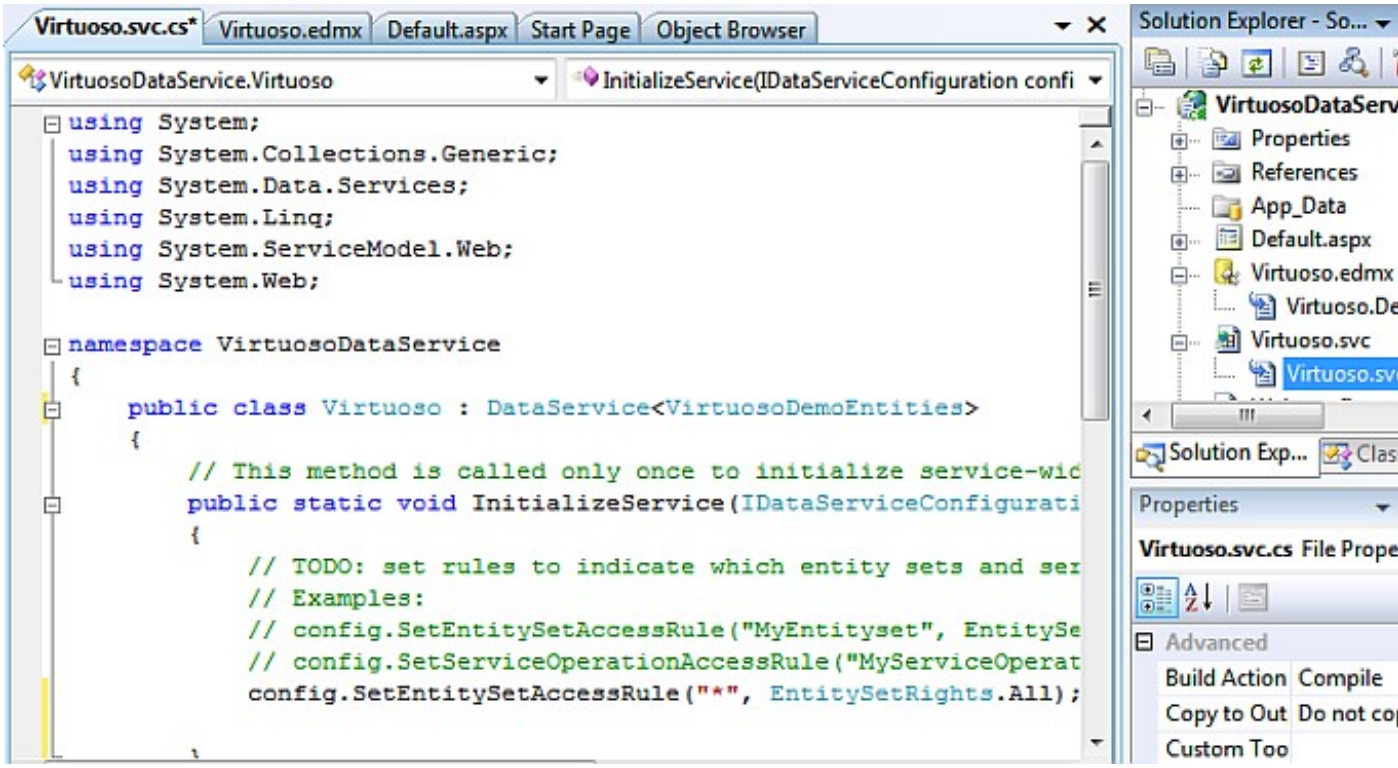
method.

```
// C#

using System;
using System.Web;
using System.Collections.Generic;
using System.ServiceModel.Web;
using System.Linq;
using System.Data.Services;

namespace SimpleDataService
{
    public class Northwind : DataService<VirtuosoDemoEntities>
    {
        public static void InitializeService(IDataServiceConfiguration  config)
        {
            config.SetEntitySetAccessRule("*", EntitySetRights.All);
        }
    }
}
```

Figure 2.133. Data Service

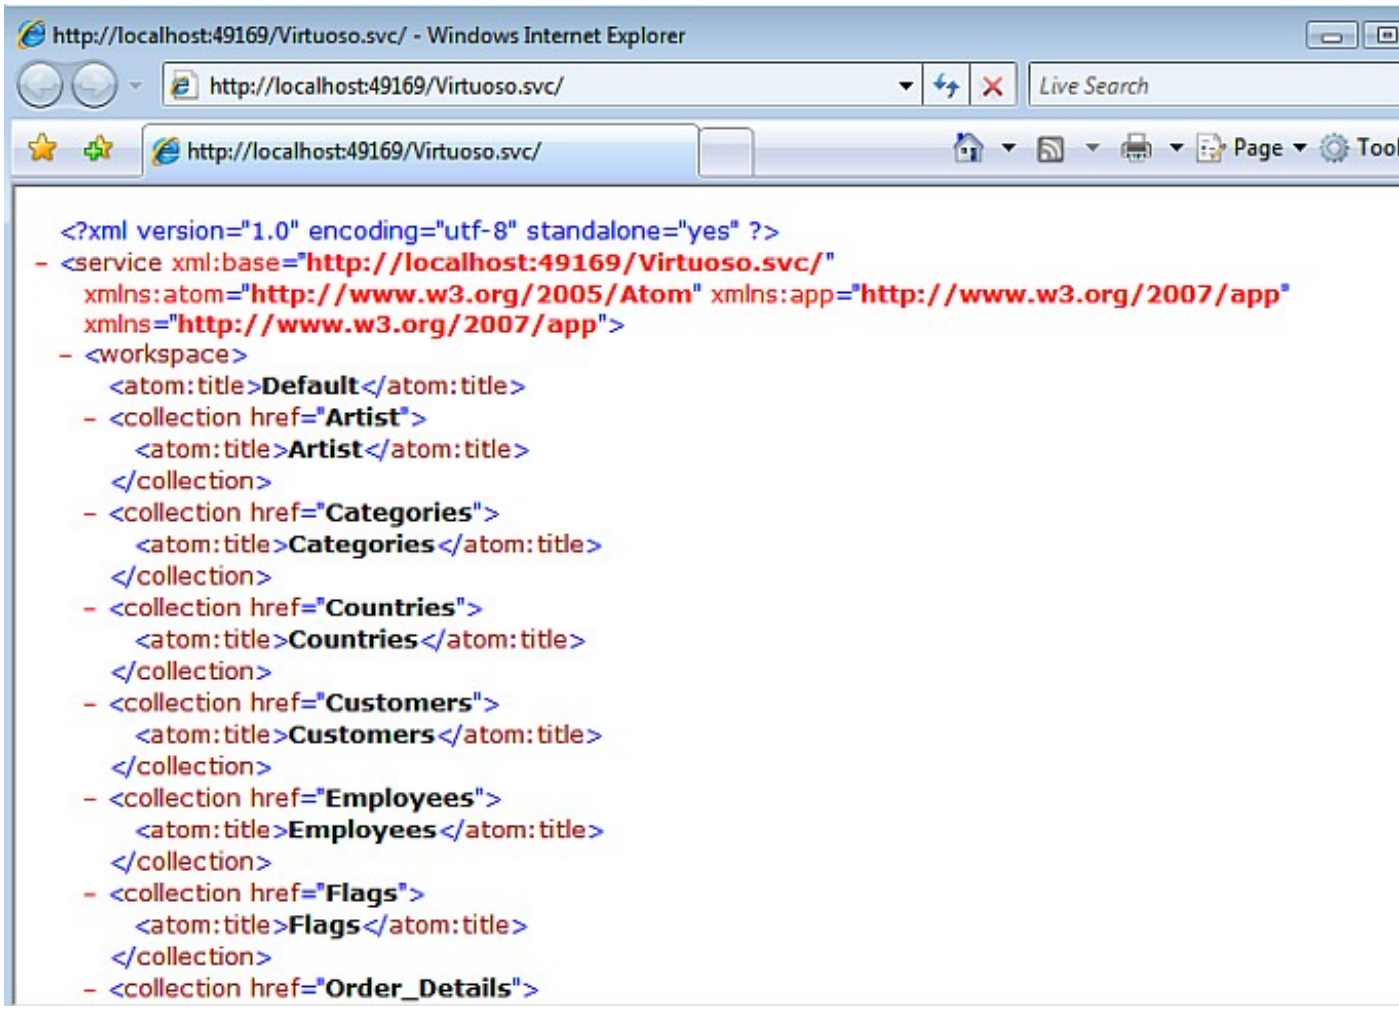


21. To test the Data Service, simply hit

    Ctrl+F5

    within Visual Studio, which will start the development web server, run the Data Services server inside and load a Web browser page displaying the list of available tables/entities of the Demo database.

Figure 2.134. test the Data Service



22. To access a specific entity instance like the

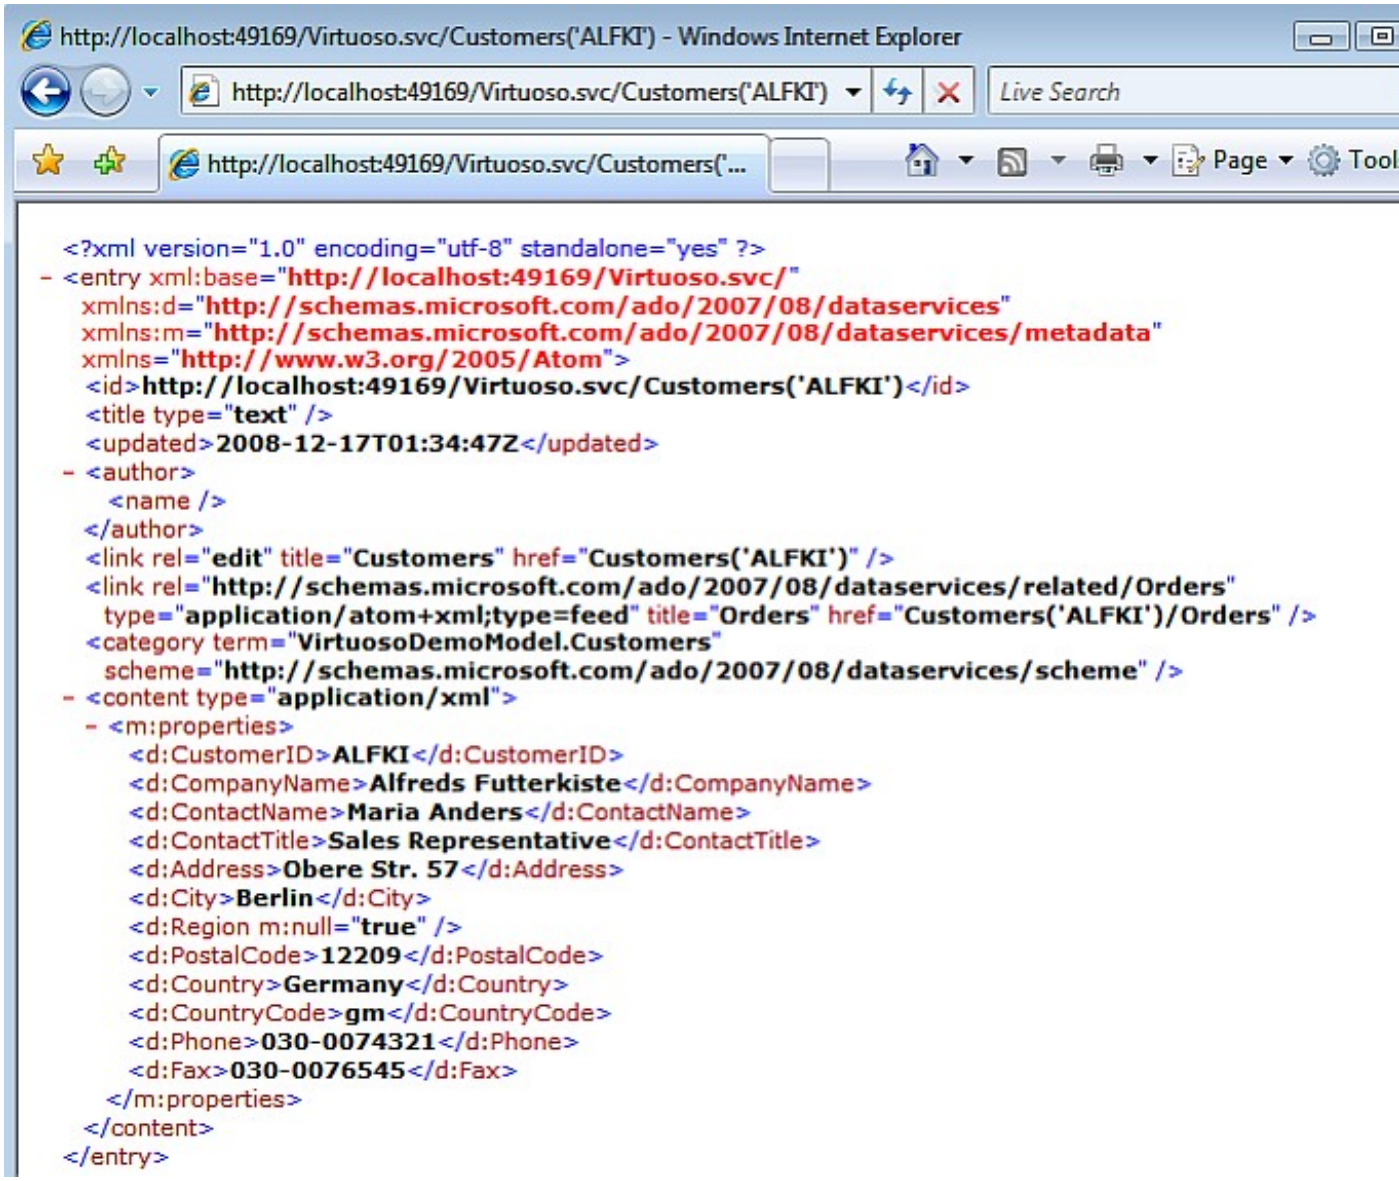
    Customers

    table

    ALFKI

    record, this would be specified as http://host/vdir/Virtuoso.svc/Customers('ALFKI') .

    Figure 2.135. Access a specific entity instance



NOTES

1. *Important*

   - To view

   Atom

   (the default format returned by an ADO.NET Data Service) in Internet Explorer, you must first ensure that

   Feed Reading View

   is turned

   off

   . This can be done on the

   Content tab

   of

Tools in Internet Options

.

2. If a Data Services entity instance URI page fails to load you can turn

   Verbose

   errors on by adding

   config.UseVerboseErrors = true;

   in the

   virtuoso.svc.cs InitializeService

   method to obtain more detailed information from the server as to why the page failed to load:

```
public static void InitializeService(IDataServiceConfiguration config)
{
config.UseVerboseErrors = true;
config.SetEntitySetAccessRule("*", EntitySetRights.All);
}
```

2.9. Windows Form Application for accessing Virtuoso RDF data via SPASQL using the Virtuoso ADO.Net Provider

This section will guide you through creating a simple application that allows you to access RDF data in a Virtuoso database as an Entity DataSet and explore that RDF data in an intuitive way by clicking on dereferenceable IRIs .

2.9.1. Pre-requisites

1. Microsoft Visual Studio 2008
2. The Virtuoso ADO.Net provider for .Net 3.5 and the Entity Framework.
3. The example assumes that you have a local Virtuoso server with the Northwind demo database installed. If the demo database is not already installed then download the demo database VAD package (demo_dav.vad) and install it. The VAD package will create a new database in Virtuoso called demo containing the familiar Northwind tables. It will also creates Linked Data Views of the Northwind tables. In the example we assume the database is accessible on a hostname of "demo.openlinksw.com" on the default port 80, where an actually live instance of the Virtuoso Demo database is hosted. Users would use the appropriate hostname and port number of their Virtuoso installation to create the sample application, and would be would be example.com for a default installation or whatever the URIQA DefaultHost Virtuoso configuration parameter is set to when the demo database VAD package is installed.

2.9.2. Creating the Application

Step 1 - Create a view of the RDF data.

We want to be able to access the RDF data in Visual Studio and the easiest way to do this is to create a view of the data that we are interested in and bind that view to a DataSet. This can be considered as using server side SPARQL . Virtuoso supports an extension to standard SQL that allows execution of SPARQL. If a SQL query begins with the keyword SPARQL then the rest of the query is interpreted by as SPARQL. If a SPARQL query is used as the definition of a view then that view can be manipulated using SQL like any other view. In this way the result set from a SPARQL query can be easily accessed from Visual Studio using ADO.Net and the Entity Framework.

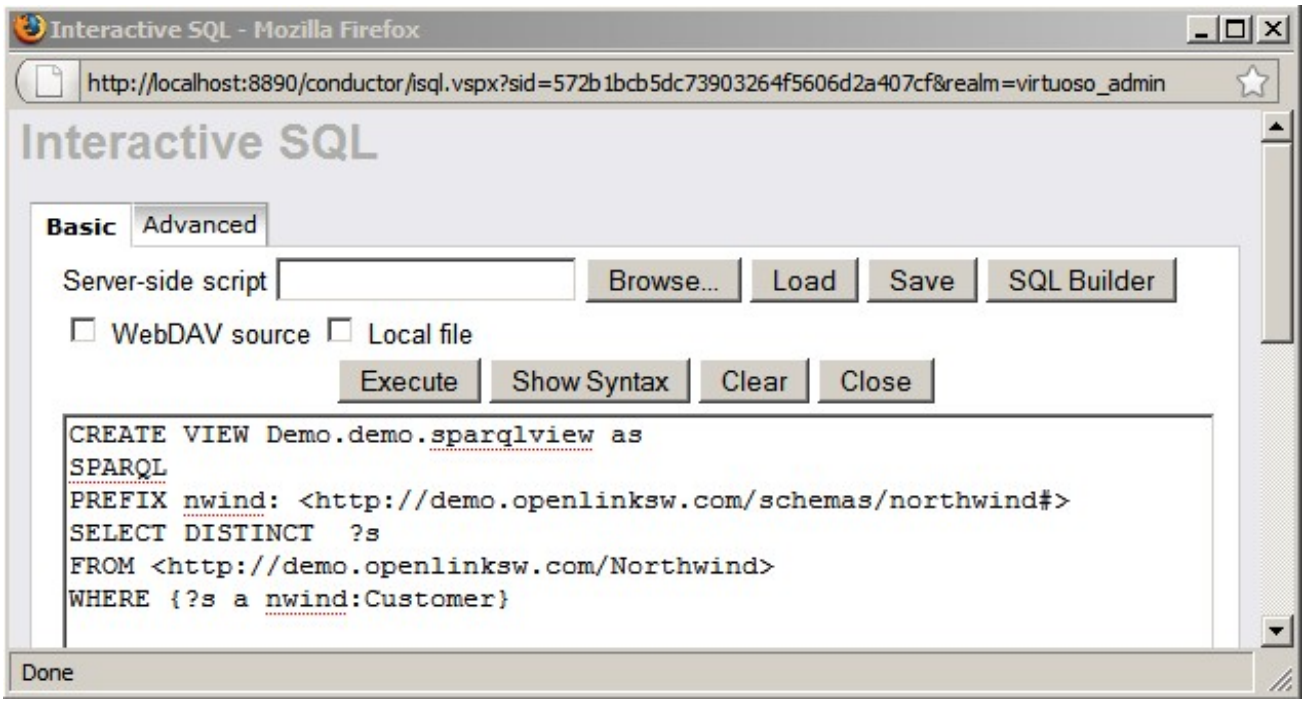
To create a view of the customers in the Northwind first open the Virtuoso Conductor and log in as dba. Then open iSQL from the menu on the left and execute the following statement.

```
CREATE VIEW Demo.demo.sparqlview as
```

```
SPARQL
PREFIX nwind: <http://demo.openlinksw.com/schemas/northwind#>
SELECT DISTINCT  ?s
FROM <http://demo.openlinksw.com/Northwind>
WHERE {?s a nwind:Customer}
```

Note: If the view is added to the Visual Studio project as user "demo" (or any other than "dba'), then it must be ensured that the "SPARQL_SELECT" and "SPARQL_SPONGE" roles are assigned to this user, which can be done via the Virtuoso Conductor in the "System Admin" -> "User Accounts" tab.

Figure 2.136. SPARQL_SPONGE



Step 2 - Create a simple grid form in Visual Studio

1. Open

   Visual Studio

   and create a new

   Windows Forms Application

   called RDFDemo.
2. In the

   Form Designer

   drag a

   DataGridView

   on to the form.
3. Click the

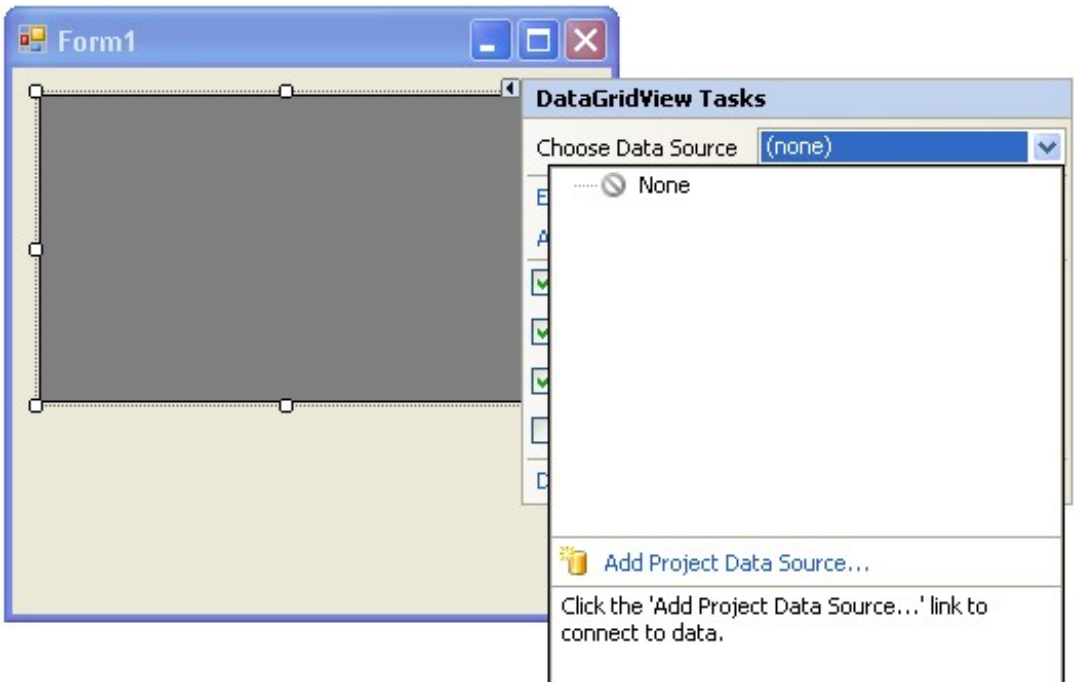
   Choose Data Source

   drop down and select

   Add Project Data Source

.

Figure 2.137. Data Source



4. In the

   Data Source Configuration Wizard

   choose Database and then set up a connection to the demo database on your local Virtuoso server.
5. On the

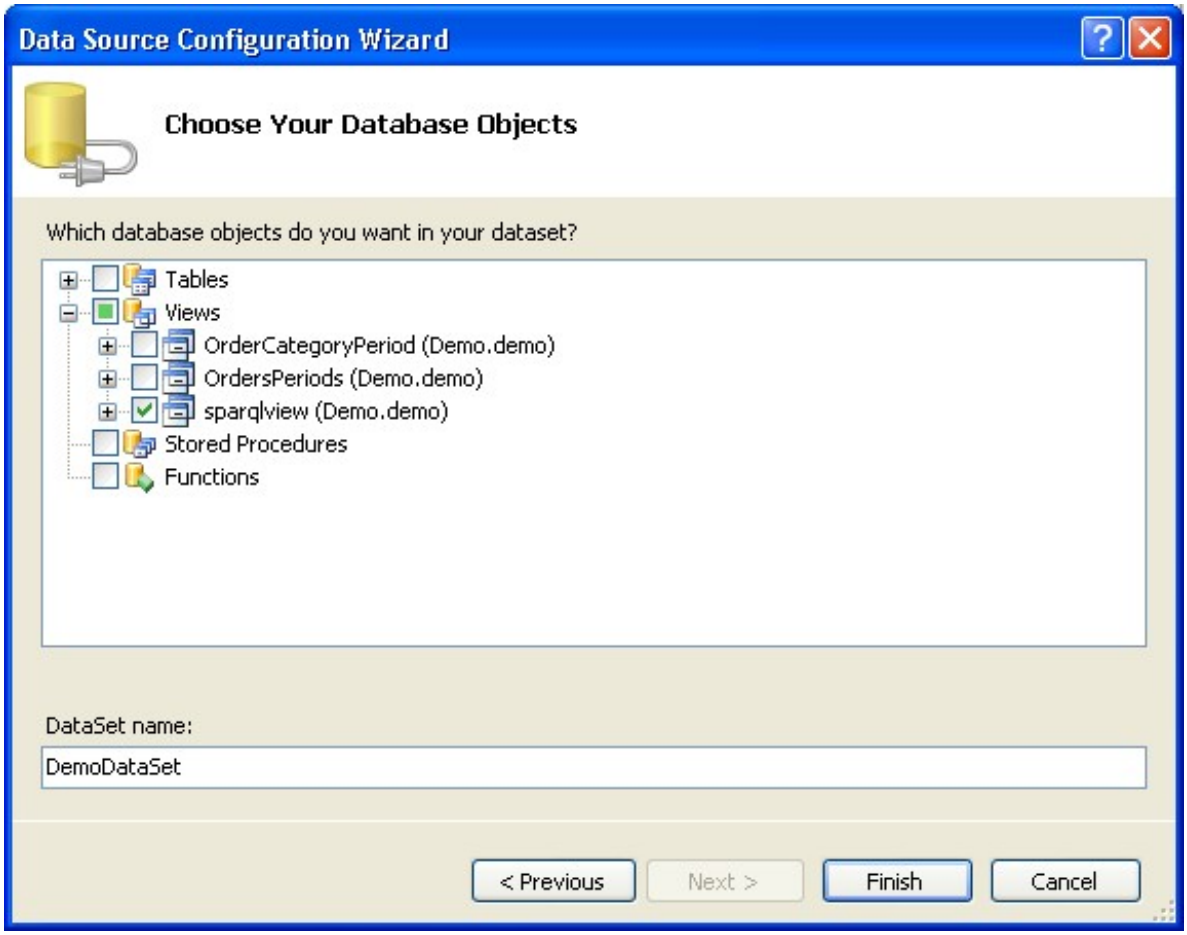
   Choose Your Data Objects

   page expand the

   Views

   and select sparqlview.

Figure 2.138. Data Source Configuration Wizard



6. Click

   Finish

   .
7. In the

   Form Designer

   select dataGridView1 and change the

   AutoSizeColumnsMode

   to AllCellsExceptHeader.
8. Select the

   DefaultCellStyle

   and click on the ellipsis. This will open the

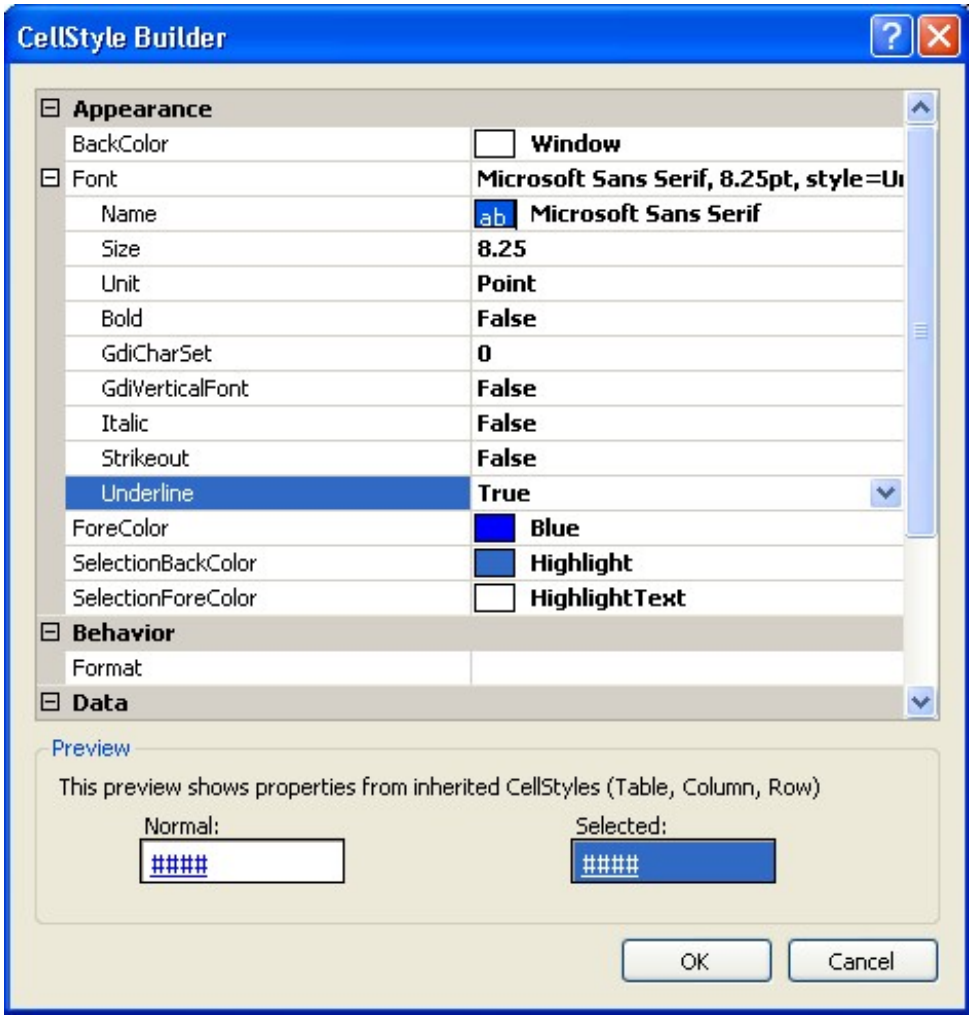
   CellStyleBuilder

   . Change the

   ForeColor

   to Blue.

   Figure 2.139. CellStyleBuilder



9. Expand

   Font

   and change

   Underline

   to True. Click

   OK

   .

Step 3 - Change the mapping of the DataSet.

In the Solution Explorer you will now have a DataSet called DemoDataSet.xsd. If you double click on this it opens the DataSet Designer. Select the column called s in the sparqlview table and in the Properties pane change the DataType from System.String to System.Object.

The data returned by a SPARQL query can either be an IRI or a literal value. In order to distinguish between the two the Virtuoso ADO.Net provider defines an additional data type, SQLExtendedString. By setting the column type to System.Object we can cast the fetched data back to SQLExtendedString and find out if an individual value is an IRI or a literal and handle it appropriately.

Step 4 - Create the on_click event handler for the cells in the DataGridView.

Return to the *Form Designer* and double click on the cell of the *DataGridView* . This creates the *dataGridView1_CellContentClick* method in Form1.cs. This is the method that handles clicking on IRI objects in the grid.

Paste in the following block of code into the body of the *dataGridView1_CellContentClick* method.

```
int column = e.ColumnIndex;
 object o = dataGridView1.Rows[e.RowIndex].Cells[e.ColumnIndex].Value;
 Type t = dataGridView1.Rows[e.RowIndex].Cells[e.ColumnIndex].ValueType;

 if (o is SqlExtendedString)
 {
     SqlExtendedString se = (SqlExtendedString) o;
     ExtendedStringHandler seHandler = new ExtendedStringHandler(se, this.sparqlviewTableAdapter.Connecti
     seHandler.displayData();
 }
 else if (o is SqlRdfBox)
 {
     //doesn't do anything at the moment
 }
```

As we are using the SQLExtendedString extension from the Virtuoso ADO.Net provider you will also need to add

```
using OpenLink.Data.Virtuoso;
```

at the top of the file.

Step 5 - Create a class to handle exploring the RDF data.

- Add a new C# class to the project called ExtendedStringHandler, by Right clicking on RDFDemo in the

  Solution Explorer

  and

  Add

  a

  Class

  .
- Add the following using statements to the top of the file

  ```
  using OpenLink.Data.Virtuoso;
  using System.Data;
  using System.Windows.Forms;
  using System.Drawing;
  using System.Data.Mapping;
  using System.Data.Common;
  ```
- Paste the following block of code into the class definition.

  ```
  StringBuilder DescribeCommand;
  VirtuosoConnection ParentConnection;
  List<Label> labelList = new List<Label>();
  List<TextBox> textBoxList = new List<TextBox>();
  DescribeDataSet describeDataSet = new DescribeDataSet();
  Boolean isIRI = false;

  public ExtendedStringHandler(SqlExtendedString iri, VirtuosoConnection parentConnection)
   {
       ParentConnection = parentConnection;
       if (iri.IriType == SqlExtendedStringType.IRI)
       {
           isIRI = true;
           DescribeCommand = new StringBuilder("sparql select * from <http://demo.openlinksw.com/Nor
       }
   }

   public string describeCommandText
   {
  ```

```
    get
    {
        return DescribeCommand.ToString();
    }
}

public void getDescribeData()
{
     VirtuosoCommand myCommand = new VirtuosoCommand(this.describeCommandText, this.ParentConnect
    VirtuosoDataAdapter myAdapter = new VirtuosoDataAdapter();
    myAdapter.SelectCommand = myCommand;
    myAdapter.Fill(describeDataSet.DataTable1);
}

public void displayData()
{
    if (isIRI)
    {
        getDescribeData();
        Form describeForm = new Form();
        describeForm.AutoScroll = true;
        describeForm.Width = 840;

        Label label1 = new Label();
        label1.AutoSize = true;
        label1.Font = new Font(label1.Font.FontFamily, label1.Font.Size + 3.0F, label1.Font.Style
        describeForm.Controls.Add(label1);

        DataTable table1 = describeDataSet.Tables[0];
        if (table1.Rows.Count == 0)
            label1.Text = "No Details Available";
        else
        {
            foreach (DataRow row in table1.Rows)
                if (row[0].ToString() == "http://www.w3.org/1999/02/22-rdf-syntax-ns#type")
                {
                    StringBuilder title = new StringBuilder(row[1].ToString() + " details");
                    label1.Text = title.ToString();
                    break;
                }

            foreach (DataRow row in table1.Rows)
            {
                Label propertyLabel = new Label();
                TextBox valueBox = new TextBox();
                valueBox.Width = 400;

                object property = row[0];
                object value = row[1];

                if (value is SqlExtendedString)
                {
                    valueBox.ForeColor = Color.Blue;
                    valueBox.Font = new Font(valueBox.Font.FontFamily, valueBox.Font.Size, valueB
                }
                propertyLabel.Text = row[0].ToString();
                propertyLabel.AutoEllipsis = true;
                propertyLabel.AutoSize = false;
                propertyLabel.Width = propertyLabel.PreferredWidth > 380 ? 380 : propertyLabel.Pr

                Binding bind = new Binding("Text", row[1], "");
                valueBox.DataBindings.Add(bind);

                labelList.Add(propertyLabel);
                textBoxList.Add(valueBox);
            }

            for (int i = 0; i < table1.Rows.Count; i++)
            {
                textBoxList[i].Click += new EventHandler(this.iri_Click);
                labelList[i].Location = new Point(10, i * 20 + 50);
                textBoxList[i].Location = new Point(400, i * 20 + 50);
                describeForm.Controls.Add(labelList[i]);
```

```
                    describeForm.Controls.Add(textBoxList[i]);
                }

                describeForm.Height = labelList.Count * 20 + 100 > 500 ? 500 : labelList.Count * 20 +
            }
            describeForm.ShowDialog();
        }
        else
        {
            Form blankForm = new Form();
            Label label1 = new Label();
            label1.Text = "Blank Node";
            label1.Font = new Font(label1.Font.FontFamily, label1.Font.Size + 3.0F, label1.Font.Style
            blankForm.ShowDialog();
        }
    }

    public void iri_Click(object sender, EventArgs e)
    {
        int boxNum = 0;

        for (int i = 0; i < textBoxList.Count; i++)
        {
            if (sender == textBoxList[i])
            {
                boxNum = i;
                break;
            }
        }

       Object o = describeDataSet.DataTable1.Rows[boxNum][1];
        if (o is SqlExtendedString)
        {
            SqlExtendedString se = (SqlExtendedString)o;
            ExtendedStringHandler seHandler = new ExtendedStringHandler(se, ParentConnection);
            seHandler.displayData();
        }
        else if (o is SqlRdfBox)
        {
           //doesn't do anything at the moment
       }
    }
```

The ExtendedStringHandler class creates a new SPARQL query based on the IRI that was clicked. This query is executed against Virtuoso using the ADO.Net connection in the same way that any SQL statement would be executed across an ADO.Net connection. This can be considered as Client Side SPARQL. The result set from the query describes the selected object and is returned as an ADO.Net DataAdapter. The DataAdapter is used to fill a DataTable which is displayed on a new form. We now need to add the new DataSet to the project and define the DataTable that will hold the query results.

Step 6 - Add a new DataSet to hold the query results.

1. Right click RDFDemo in the

   Solution Explorer

   and add a new

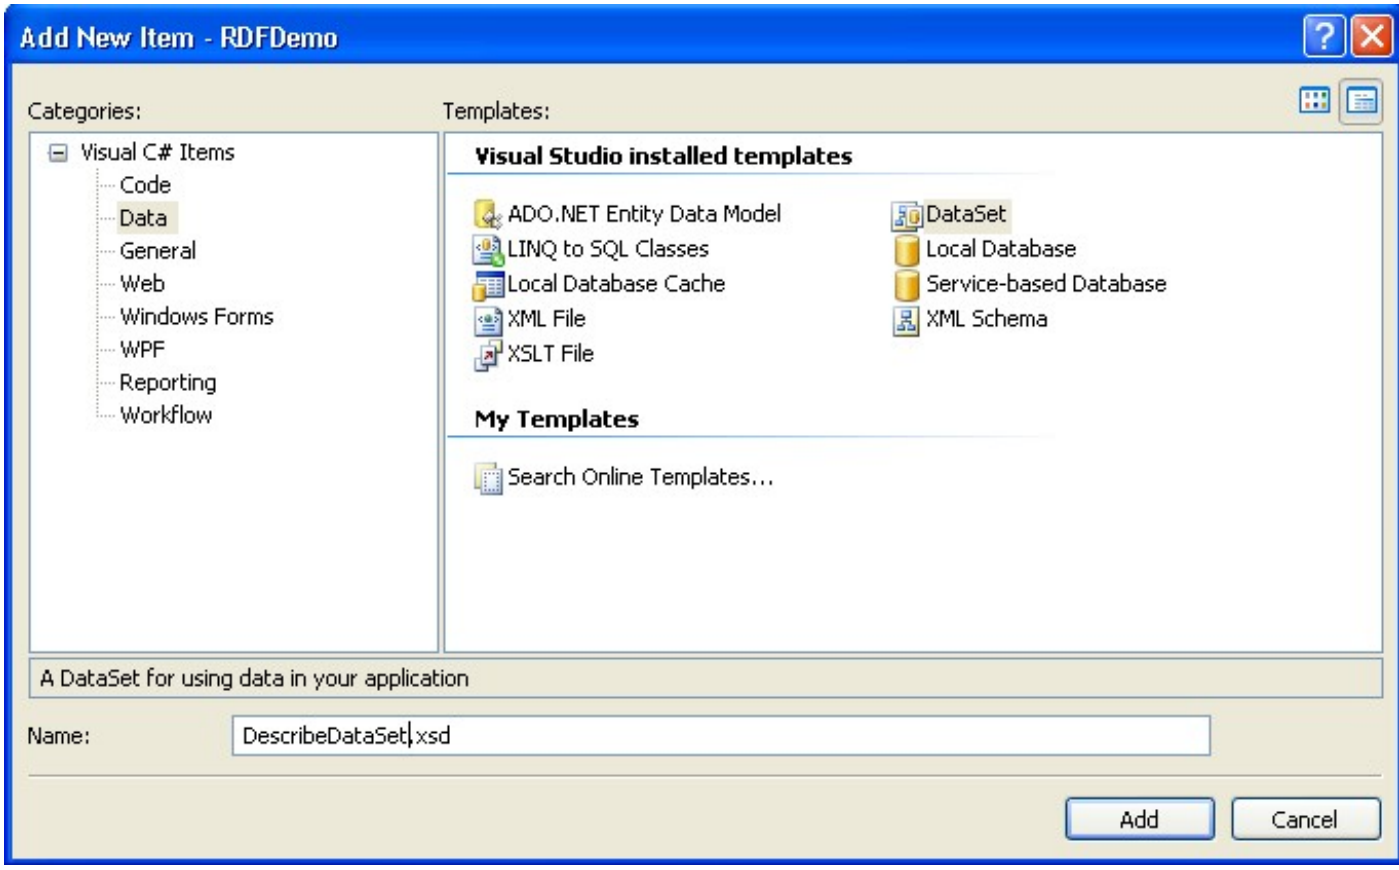
   DataSet

   . Call the new

   DataSet

   DescribeDataSet.

   Figure 2.140. Add a new DataSet



2. Double click on DescribeDataSet in the

   Solution Explorer

   to open the

   DataSet

   Designer and drag a

   DataTable

   from the

   Toolbox

   into it.
3. Add two columns, p and o, to the

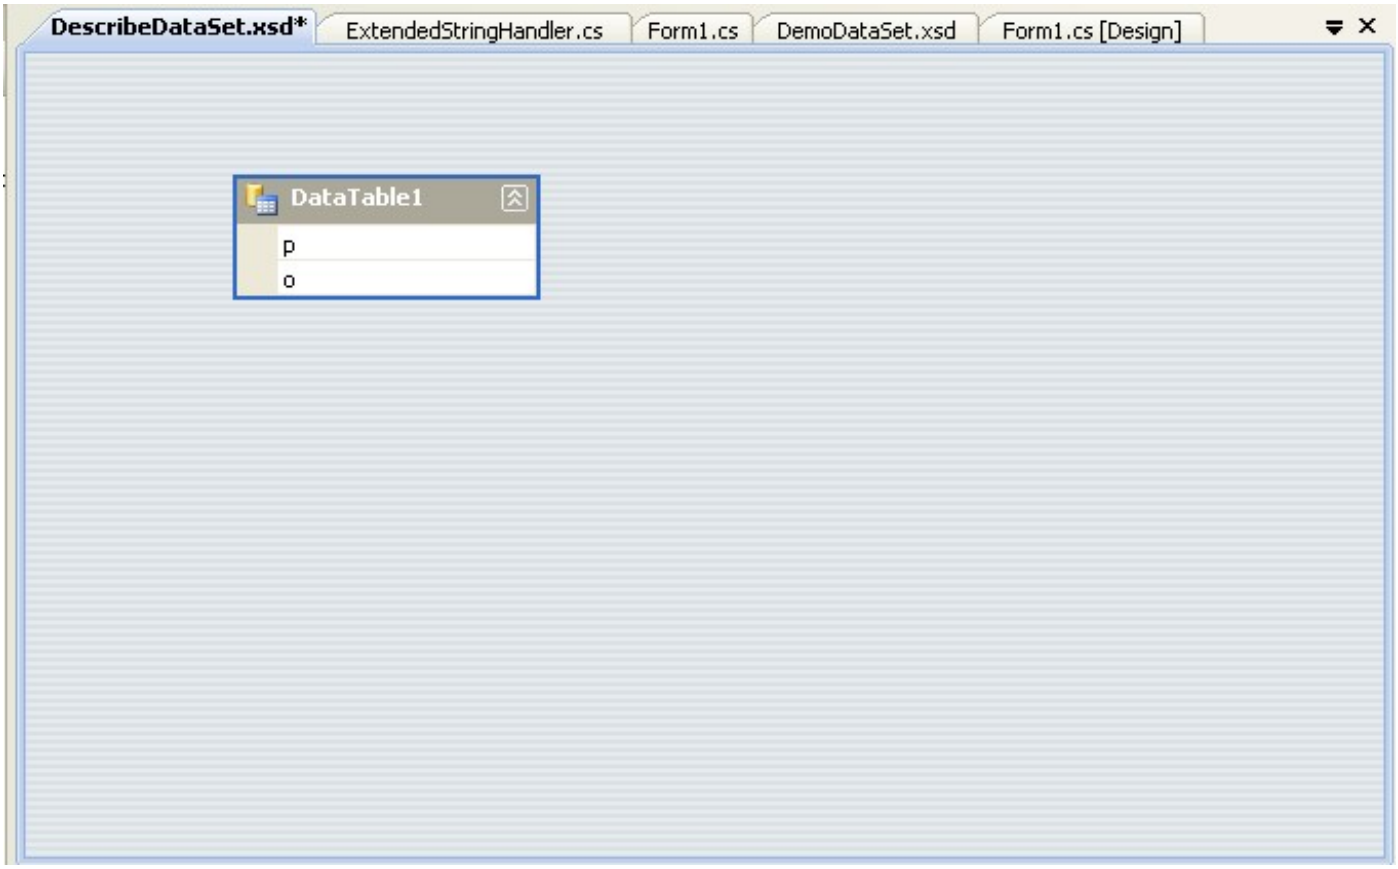
   DataTable

   and set the

   DataType

   of each column to System.Object.

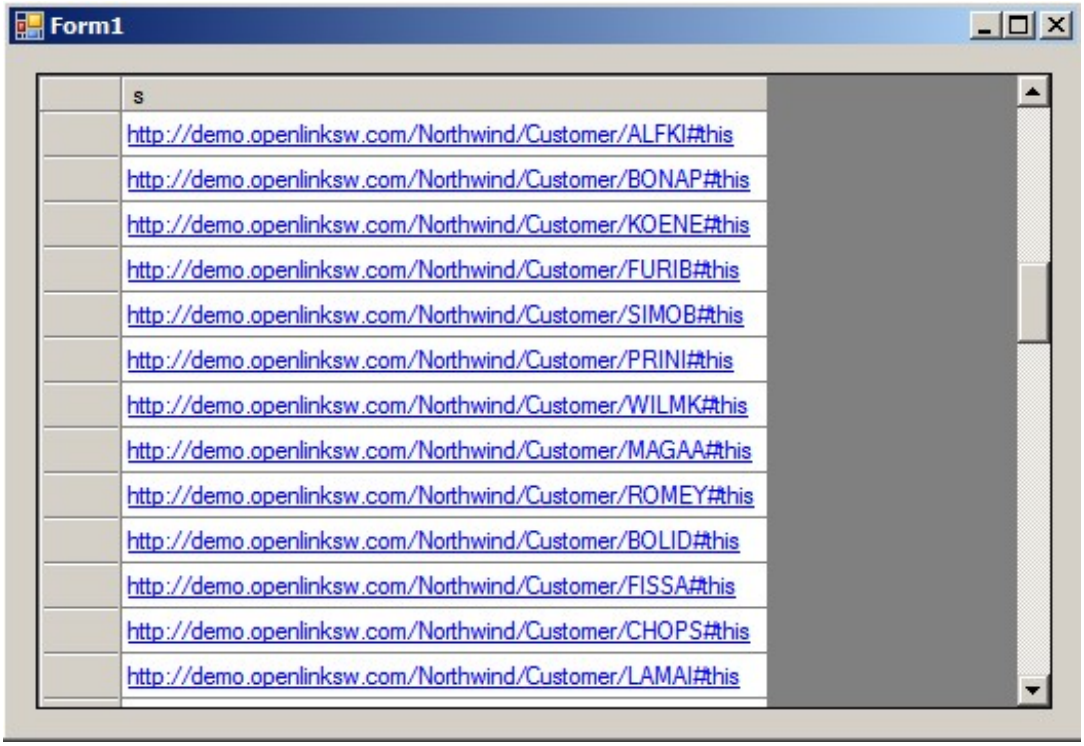
Figure 2.141. Add two columns



Step 7 - Build and run the application.

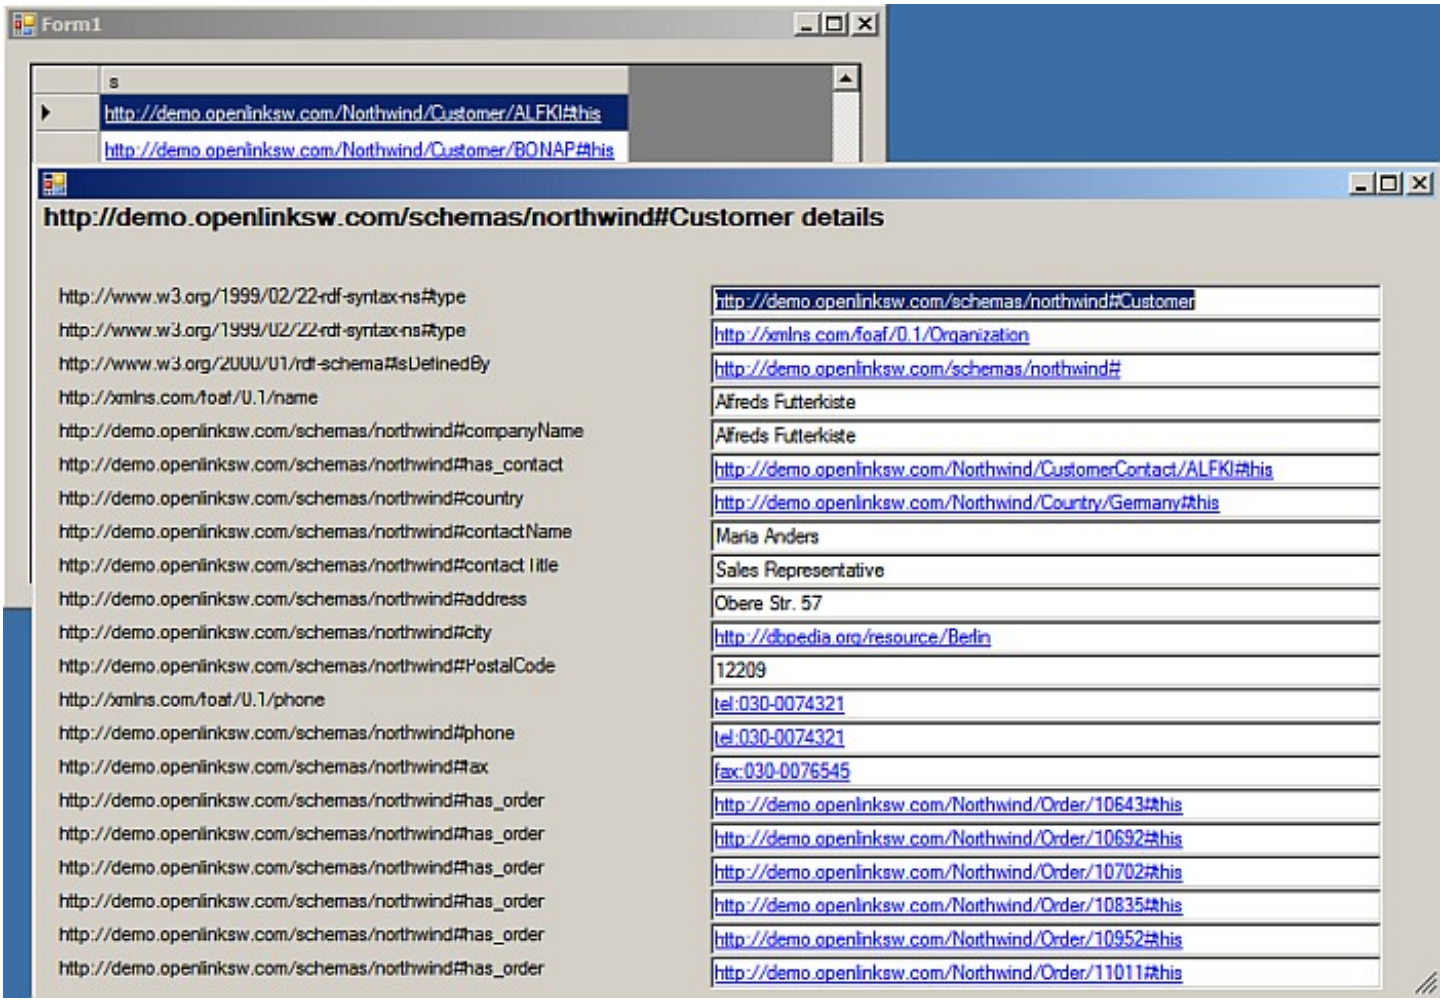
You should see a form displaying all the Northwind customers, like this.

Figure 2.142. Northwind customers



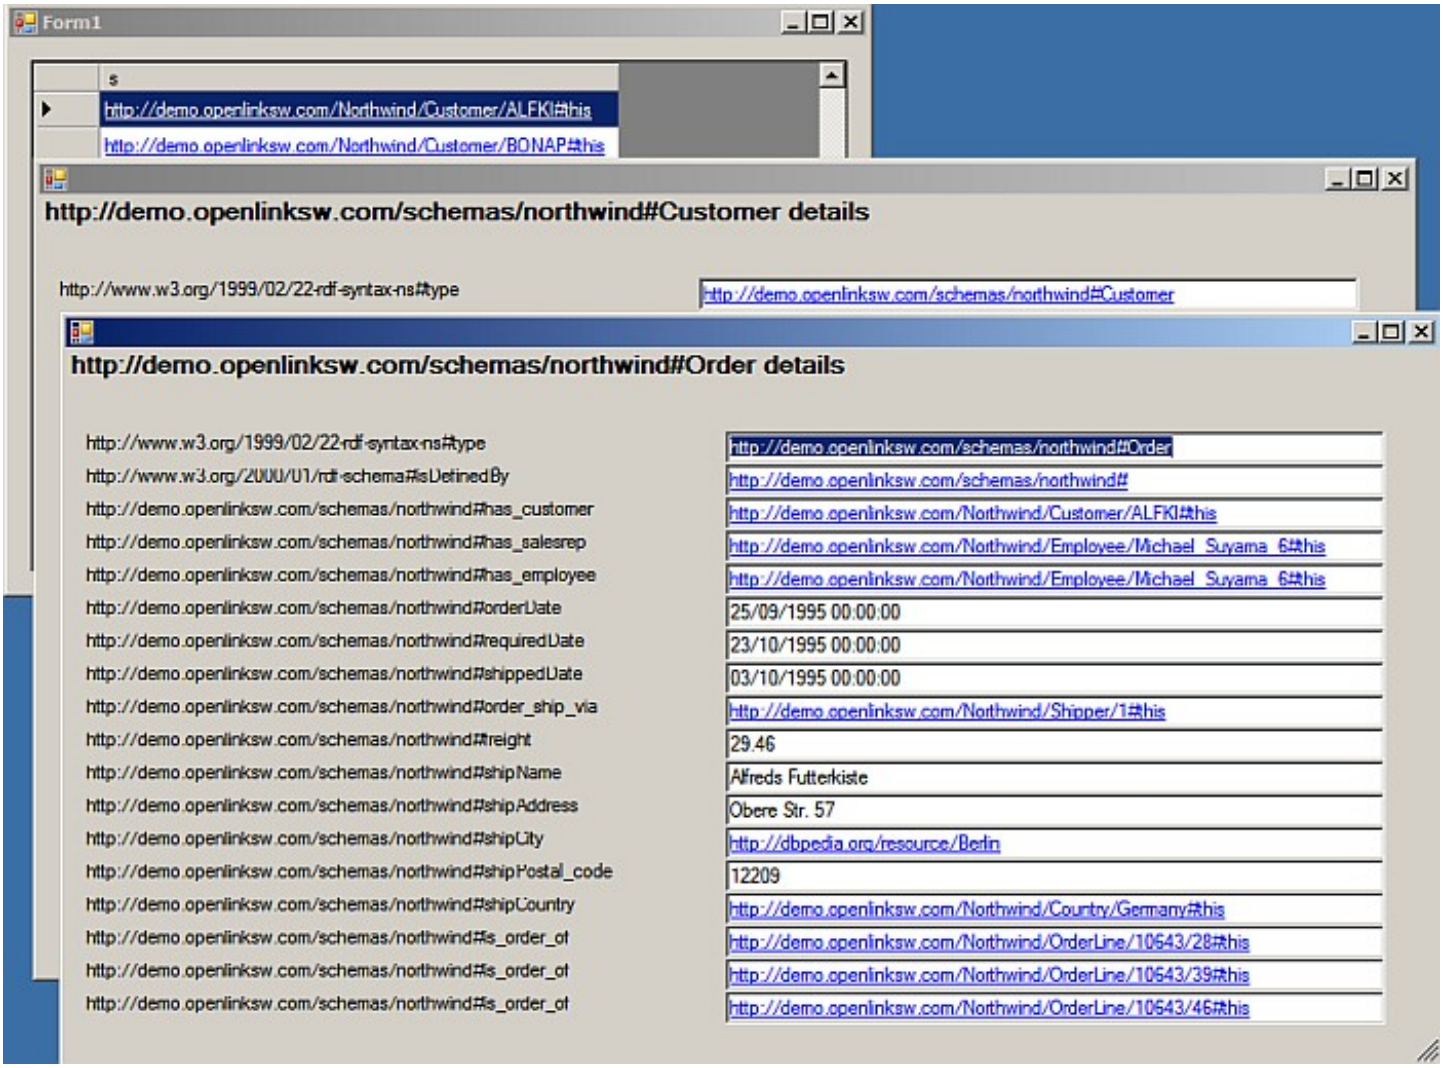
When any customer is clicked it opens a new form showing customer details.

Figure 2.143. Customer details



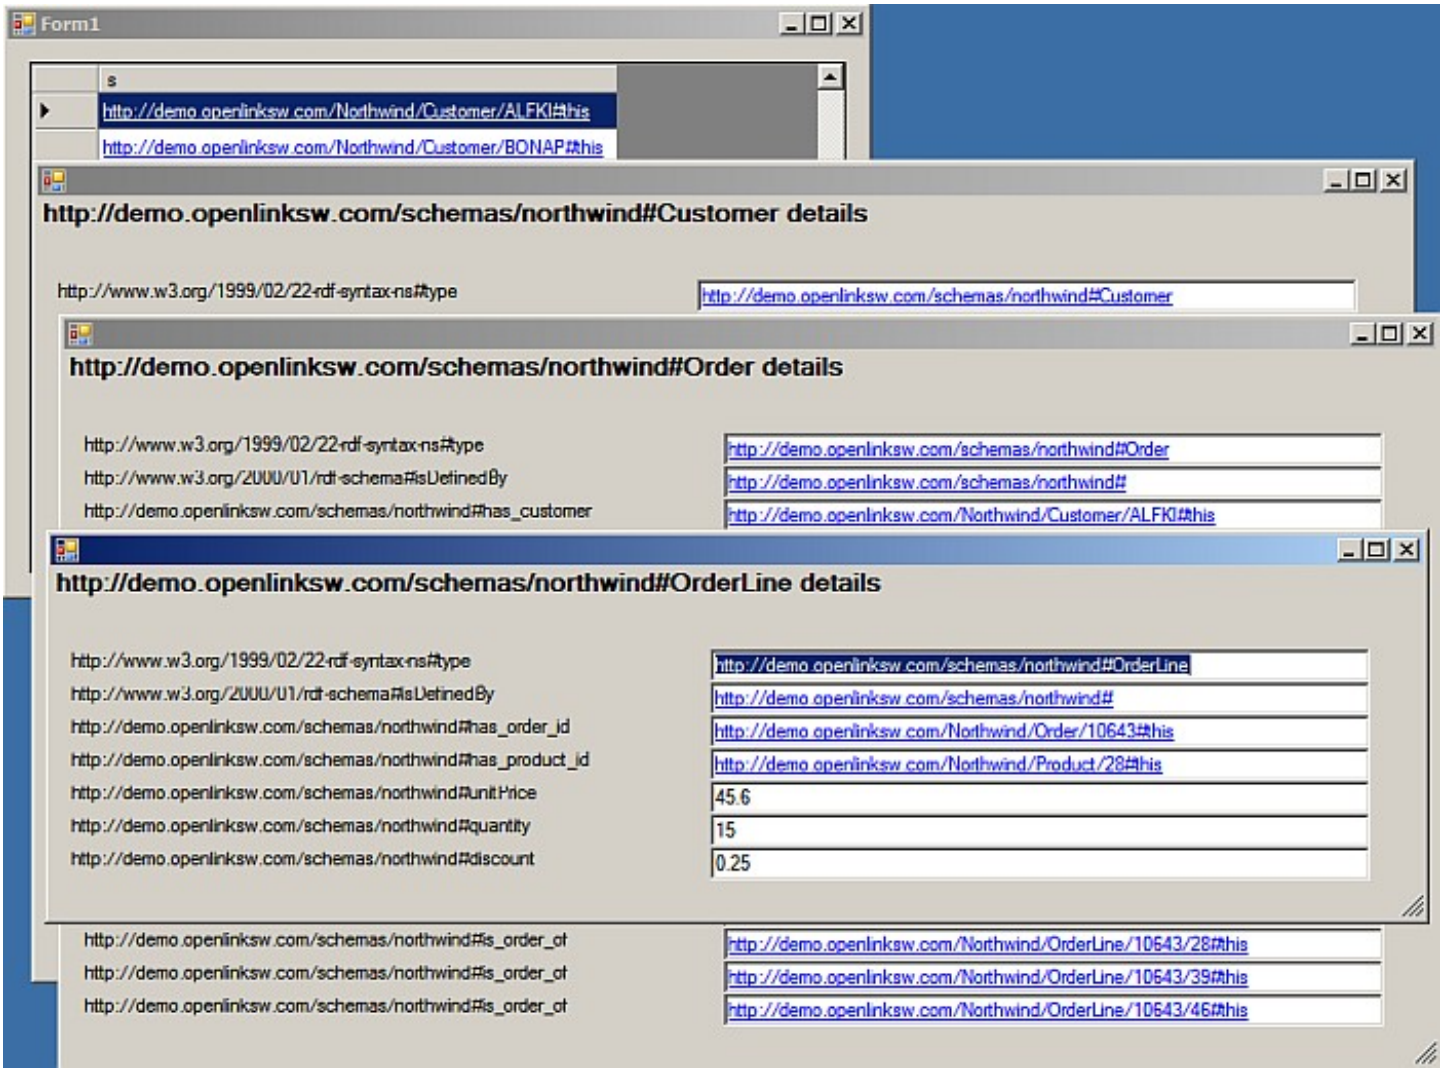
Clicking on the links in the new form allows you to drill down further to get order, product, location details etc.

Figure 2.144. Order, product, location details



and

Figure 2.145. Order, product, location details



Next Steps

You will notice if you keep clicking on the links that this application will only display data that is held in the Northwind graph. Clicking on an external link, for example the link to Berlin in dbpedia, http://dbpedia.org/resource/Berlin, results in a empty window and an error message. The next step is to extend this application so that it can handle dereferencing external IRIs.

2.9.3. Extending RDFDemo to Allow Dereferencing of External IRIs

This section will guide you through extending the application created in Creating a Windows Forms Application To Access RDF Data Using The Virtuoso ADO.Net Provider so that it will dereference external IRIs.

Pre-requisites

1. A working copy of the RDFDemo application created in Creating a Windows Forms Application To Access RDF Data Using The Virtuoso ADO.Net Provider.

Extending the Application

In RDFDemo when the sparql endpoint is queried to get the description of the selected item it executes a query that is restricted to the local Northwind dataset. The query is something like

```
SPARQL
PREFIX nwind: <http://demo.openlinksw.com/schemas/northwind#>
SELECT DISTINCT  ?s
FROM <http://demo.openlinksw.com/Northwind>
WHERE {?s a nwind:Customer}
```

If you examine the ExtendedStringHandler class you will see that the dataset clause, from <http://example.com/Northwind>, is hard coded. This means that when when the selected IRI is a link to an external data store, such as dbpedia, there is no matching data and an error is displayed. If the application is to be able to dereference external IRIs then the hard coded dataset clause needs to be removed and then we can use a Virtuoso extension to SPARQL, get:soft, that tells Virtuoso that it needs to go and look elsewhere for the graph. However, this will result in a loss of performance when exploring the local Northwind dataset. To minimize the impact on performance we will first query the local Northwind dataset and if there are no matching triples returned then we will use a more generic query that will look elsewhere for matching data.

Step 1 - Add the alternative query to the ExtendedString Class.

- Open the RDFDemo project in Visual Studio
- Open the ExtendedStringHandler class.
- Remove DescribeCommand by removing the line

```
StringBuilder DescribeCommand;
```

  and substitute the following:

```
StringBuilder DescribeCommandSimple, DescribeCommandGeneral;
```

- In the ExtendedStringHandler constructor the sparql query that was DescribeCommand becomes DescribeCommandSimple and we define a new query for DescribeCommandGeneral.

```
DescribeCommandSimple = new StringBuilder("sparql select * from <http://demo.openlinksw.com/Northw
DescribeCommandGeneral = new StringBuilder("sparql define get:soft " + '"'.ToString() + "soft" + "
```

- The single describeCommand property needs to be replaced with the two new properties, DescribeCommandSimple and DescribeCommandGeneral

```
public string describeCommandSimpleText
{
    get
    {
        return DescribeCommandSimple.ToString();
    }
}
public string describeCommandGeneralText
{
    get
    {
        return DescribeCommandGeneral.ToString();
    }
}
```

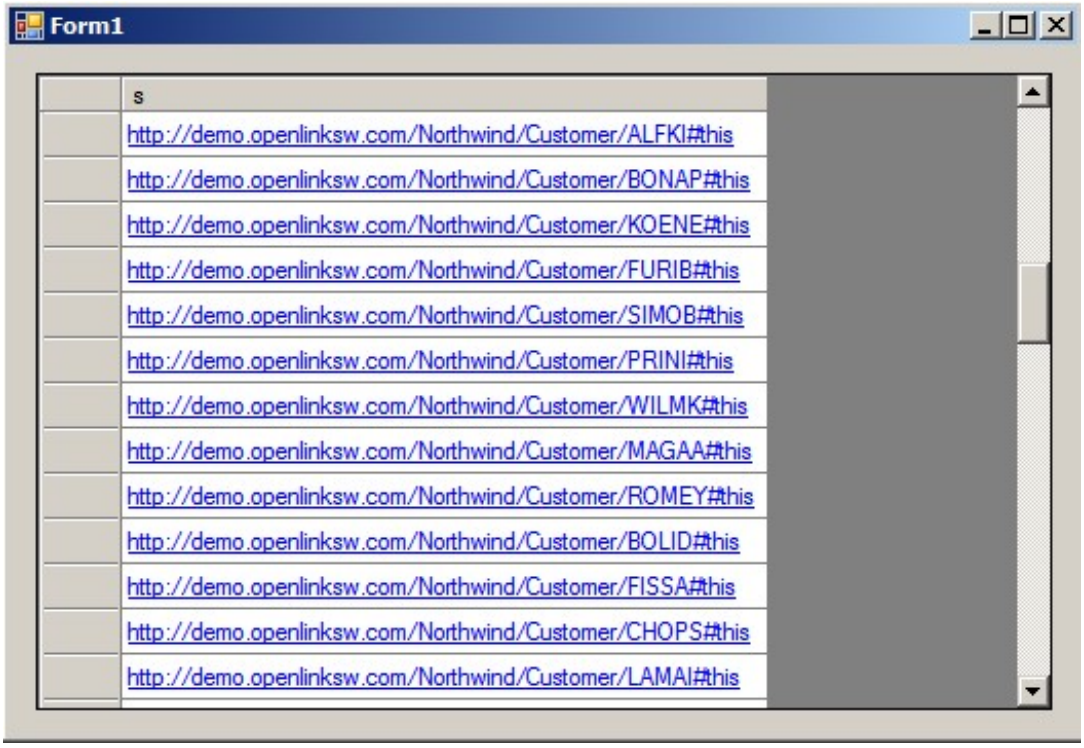
- Finally, the getDescribeData method needs changing to:

```
public void getDescribeData()
{
    VirtuosoCommand myCommand = new VirtuosoCommand(this.describeCommandSimpleText, this.ParentCon
    VirtuosoDataAdapter myAdapter = new VirtuosoDataAdapter();
    myAdapter.SelectCommand = myCommand;
    myAdapter.Fill(describeDataSet.DataTable1);
    // Tried the simple version if fails to get the data try
    // to look elsewhere.
    if (describeDataSet.DataTable1.Rows.Count == 0)
    {
        myCommand.CommandText = describeCommandGeneralText;
        myAdapter.Fill(describeDataSet.DataTable1);
    }
}
```

Step 2 - Build and Run the Application

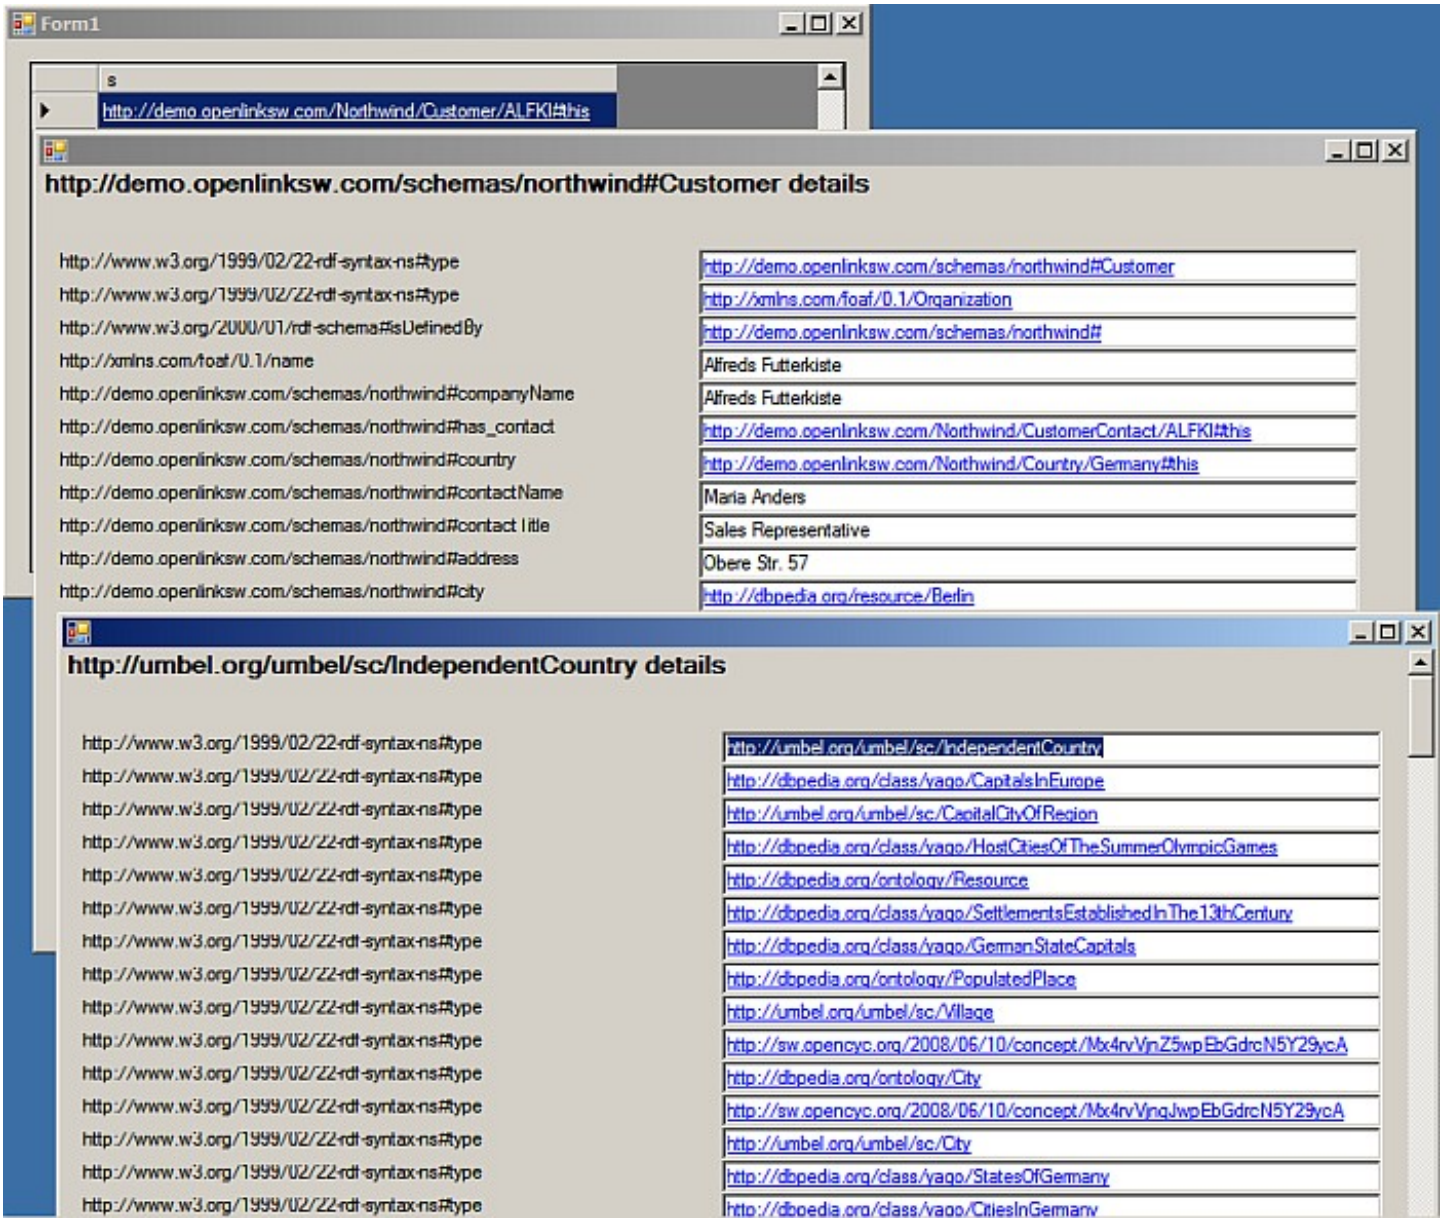
You will see the same starting form:

Figure 2.146. Build and Run the Application



Select a Customer and then select the link to the City in dbpedia. This will now open up another window displaying information about the city from dbpedia. Be patient as it may take a little while to open.

Figure 2.147. Customer



Step 3 - Changing the Form Title

Notice that in displayData method that we look for a http://www.w3.org/1999/02/22-rdf-syntax-ns#type and create a title for the form from it.

```
foreach (DataRow row in table1.Rows)
  if (row[0].ToString() == "http://www.w3.org/1999/02/22-rdf-syntax-ns#type")
  {
      StringBuilder title = new StringBuilder(row[1].ToString() + " details");
      label1.Text = title.ToString();
      break;
  }
```

This worked well for the Northwind subjects but less well now we are getting data from other graphs. To change the title of the forms used to display the data:

- Add an new member variable to hold the IRI that we exploring to the bock of member variables

```
StringBuilder DescribeCommandSimple, DescribeCommandGeneral;
VirtuosoConnection ParentConnection;
List<Label> labelList = new List<Label>();
List<TextBox> textBoxList = new List<TextBox>();
DescribeDataSet describeDataSet = new DescribeDataSet();
Boolean isIRI = false;
SqlExtendedString ParentIRI;
```

- Assign a value to ParentIRI in the constructor:

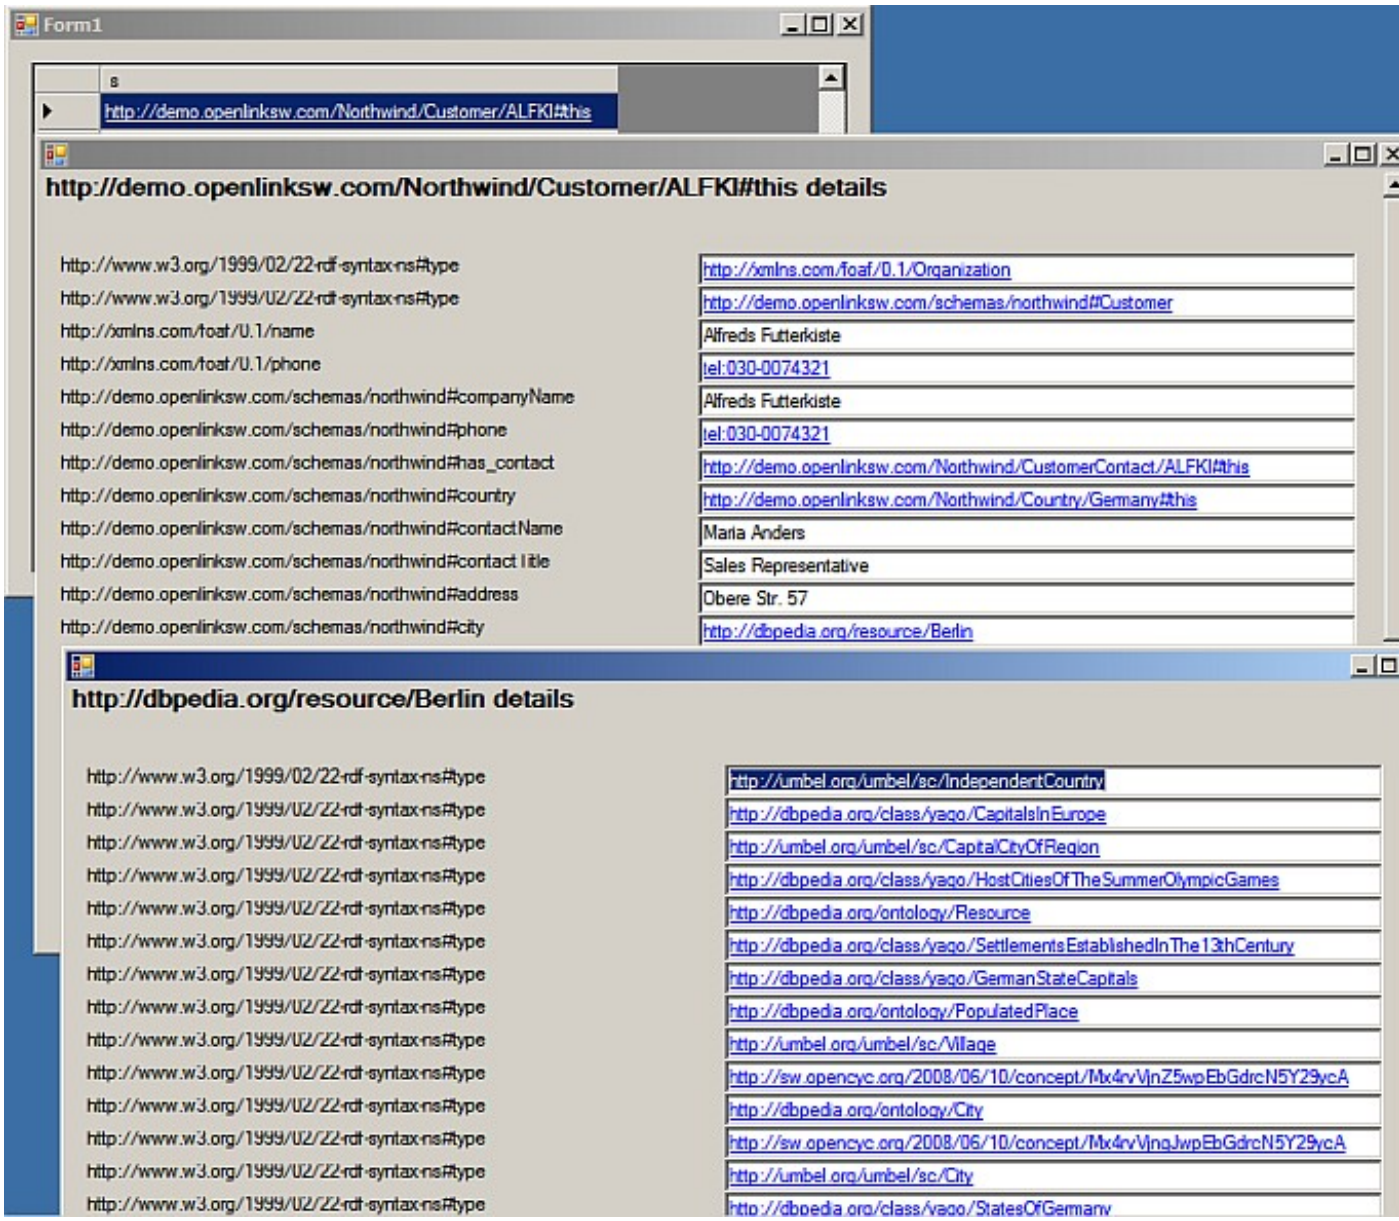
```
public ExtendedStringHandler(SqlExtendedString iri, VirtuosoConnection parentConnection)
  {
      ParentConnection = parentConnection;
      if (iri.IriType == SqlExtendedStringType.IRI)
      {
          ParentIRI = iri;
          isIRI = true;
          DescribeCommandSimple = new StringBuilder("sparql select * from <http://demo.openlinksw.
          DescribeCommandGeneral = new StringBuilder("sparql define get:soft " + '"'.ToString() +
      }
  }
```

- Remove the existing foreach block that sets the form title and replace with the following lines:

```
StringBuilder title = new StringBuilder(ParentIRI.ToString() + " details");
label1.Text = title.ToString();
```

- Build and run the application.

Figure 2.148. Build and run the application



Next Steps

The application now allows you to explore data and follow links from your locally held data into the external web of data. Looking at the data displayed in the form it would be nice to make the labels for the properties more compact. The label http://dbpedia.org/property/population is a very precise definition but for our purposes it would be clearer to label the property just population. In the next step will be to modify the application so that it displays more readable labels.

2.9.4. Extending RDFDemo to Display More Compact Labels

This section will guide you through extending the application created in Extending RDFDemo to Allow Dereferencing of External IRIs so that the data is displayed in a more readable form.

Pre-requisites

1. A working copy of the RDFDemo application created in Extending RDFDemo to Allow Dereferencing of External IRIs

Extending the Application

The RDF demo application presents the user with a list of Customers from the Northwind database in the form of dereferenceable IRIs. When a customer is selected from the list the application uses a sparql query to describe that customer and the results are displayed in a form as rows of labels and data. The labels correspond to RDF predicates and the data corresponds to RDF objects while the subject is the customer initially selected. In many cases the objects are dereferencable IRIs which are then used as the subject when the 'drilling down' into the data. However, the predicates are also IRIs so it is possible to gain more information about these as well.

The RDF Schema defines a property http://www.w3.org/2000/01/rdf-schema#label that may be used to provide a human-readable version of a resource's name. We can obtain further details of each of the predicates in a resultset and check to see if one of the properties is an http://www.w3.org/2000/01/rdf-schema#label. If it is we can use the associated text as the label in our form instead of the the predicate IRI. The benefit should be a more human readable form.

Step 1 - Add a New Method to Get the Label Text

This method takes the predicate IRI and issues a sparql query to get its description. It then cycles through the returned dataset to find a http://www.w3.org/2000/01/rdf-schema#label. If there is one then the associated text is returned by the method. Otherwise the method returns the IRI string.

- Add the following method to the ExtendedStringHandlerClass

```
private string getLabelText(Object label)
  {
      string labelText = label.ToString();
      if (label is SqlExtendedString)
      {
          SqlExtendedString se = (SqlExtendedString)label;
          StringBuilder getLabelCommandText = new StringBuilder("sparql define get:soft \"soft\" s
          VirtuosoCommand getLabelCommand = new VirtuosoCommand(getLabelCommandText.ToString(), Pa
          VirtuosoDataAdapter getLabelAdapter = new VirtuosoDataAdapter();
          getLabelAdapter.SelectCommand = getLabelCommand;
          DataSet getLabelDataSet = new DataSet();
          try
          {
              getLabelAdapter.Fill(getLabelDataSet);
              foreach (DataRow getLabelRow in getLabelDataSet.Tables[0].Rows)
              {
                  if (getLabelRow[0].ToString() == "http://www.w3.org/2000/01/rdf-schema#label")
                  {
                      labelText = getLabelRow[1].ToString();
                      break;
                  }
              }
          }
          catch
          {
          }
      }
      return labelText;
  }
```

- Change the line in displayData from

```
propertyLabel.Text = row[0].ToString();
```

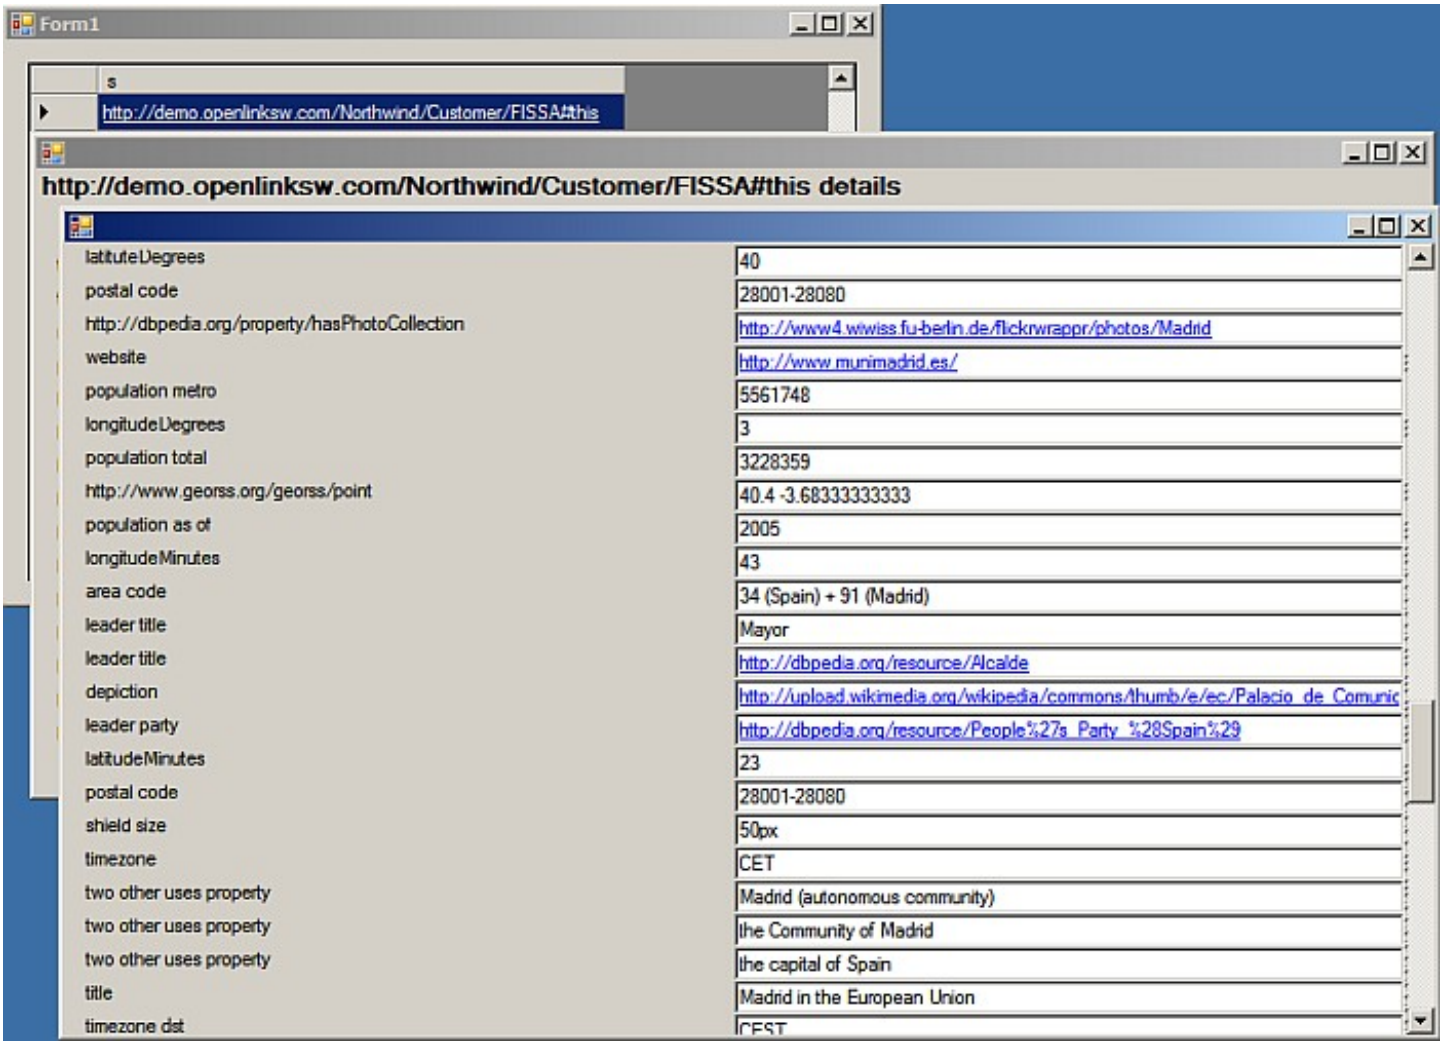
- to

```
propertyLabel.Text = getLabelText(row[0]);
```

Step 1 - Add a New Method to Get the Label Text

When you run the application you will see that the initial form is the same. In fact, when you select the Customer you will also see that the customer details are also the same. It is only when you start exploring data outside the Northwind graph that you will see the labels in the form change.

Figure 2.149. Northwind graph



Next Steps

It is clear from running the application that the Northwind ontology does not define an http://www.w3.org/2000/01/rdf-schema#label for its members. In order to benefit from this modified version of RDFDemo we need to update our Northwind ontology so that http://www.w3.org/2000/01/rdf-schema#label is defined for each resource. The next step will be to modify our Northwind ontology.

2.9.5. Modifying the Northwind Ontology to Add Labels

This section will guide you through modifying the Northwind Ontology created when you installed the demo database VAD package so that each resources is identified by an http://www.w3.org/2000/01/rdf-schema#label. This will improve the readability of the information displayed by the application created in Extending RDFDemo to Display More Compact Labels .

Pre-requisites

1. A working copy of the RDFDemo application created in Extending RDFDemo to Display More Compact Labels

Editing the Ontology

Get a Working Copy of the Northwind Ontology

The the file describing the Northwind Ontology, nw.owl, is installed in the DAV when the demo vad is loaded. To get a working copy open the Virtuoso Conductor and log in as dba. Select WebDAV Browser in the navigation panel on the left. This will open a window that allows you to browse the WebDAV Repository. The Northwind Ontology file can be found in DAV/VAD/demo/sql. Take a copy of the file.

Editing nw.owl

In the first instance is edited nw.owl so that the property name consistently begin with a lower case letter. This matches the results for describing resources held in the Northwind database. Also are added missing properties so that there should be a label in all cases.

Registering the Changes in Virtuoso

There are two methods for registering the changes in Virtuoso:

1. Method I:

   - Copy the edited version of nw.owl back into the DAV.
   - In isql, load the script load_ontology_dav.sql and execute it. The new version of nw.owl will then be used
2. - Ensure that your new version of nw.owl is in a folder accessible by Virtuoso. You may need to edit your virtuoso.ini file and restart the server.
   - In isql, load the script load_ontology_file.sql and edit it so that it has the full path to the new version of nw.owl
   - Run the script. The new version of nw.owl will then be used.

Modify RDFDemo so that it looks for the graph used to describe the Northwind data and searches that graph for the predicate details:

1. Add a new member variable to the ExtendedStringHandler class to hold the graphs that we need to search for the predicate information.

```
StringBuilder DescribeCommandSimple, DescribeCommandGeneral;
VirtuosoConnection ParentConnection;
List<Label> labelList = new List<Label>();
List<TextBox> textBoxList = new List<TextBox>();
List<String> graphList = new List<String>();
DescribeDataSet describeDataSet = new DescribeDataSet();
Boolean isIRI = false;
SqlExtendedString ParentIRI;
```

2. In displayData, after we have set the title of the form, add the following block of code:

```
// Later we will want to get property labels and for that
 // we will need the graph where the resource is defined.
foreach (DataRow row in table1.Rows)
     if (row[0].ToString() == "http://www.openarchives.org/ore/terms/isDescribedBy"
    && row[1].ToString() != ParentIRI.ToString())
     {
         String graph = row[1].ToString();
         graphList.Add(graph);
     }
```

3. Replace the existing getLabelText method with an extended version

```
 private string getLabelText(Object label)
  {
      string labelText = label.ToString();
      if (label is SqlExtendedString)
      {
          Boolean foundLabel = false;
          SqlExtendedString se = (SqlExtendedString)label;
          VirtuosoDataAdapter getLabelAdapter = new VirtuosoDataAdapter();
```

```
            DataSet getLabelDataSet = new DataSet();

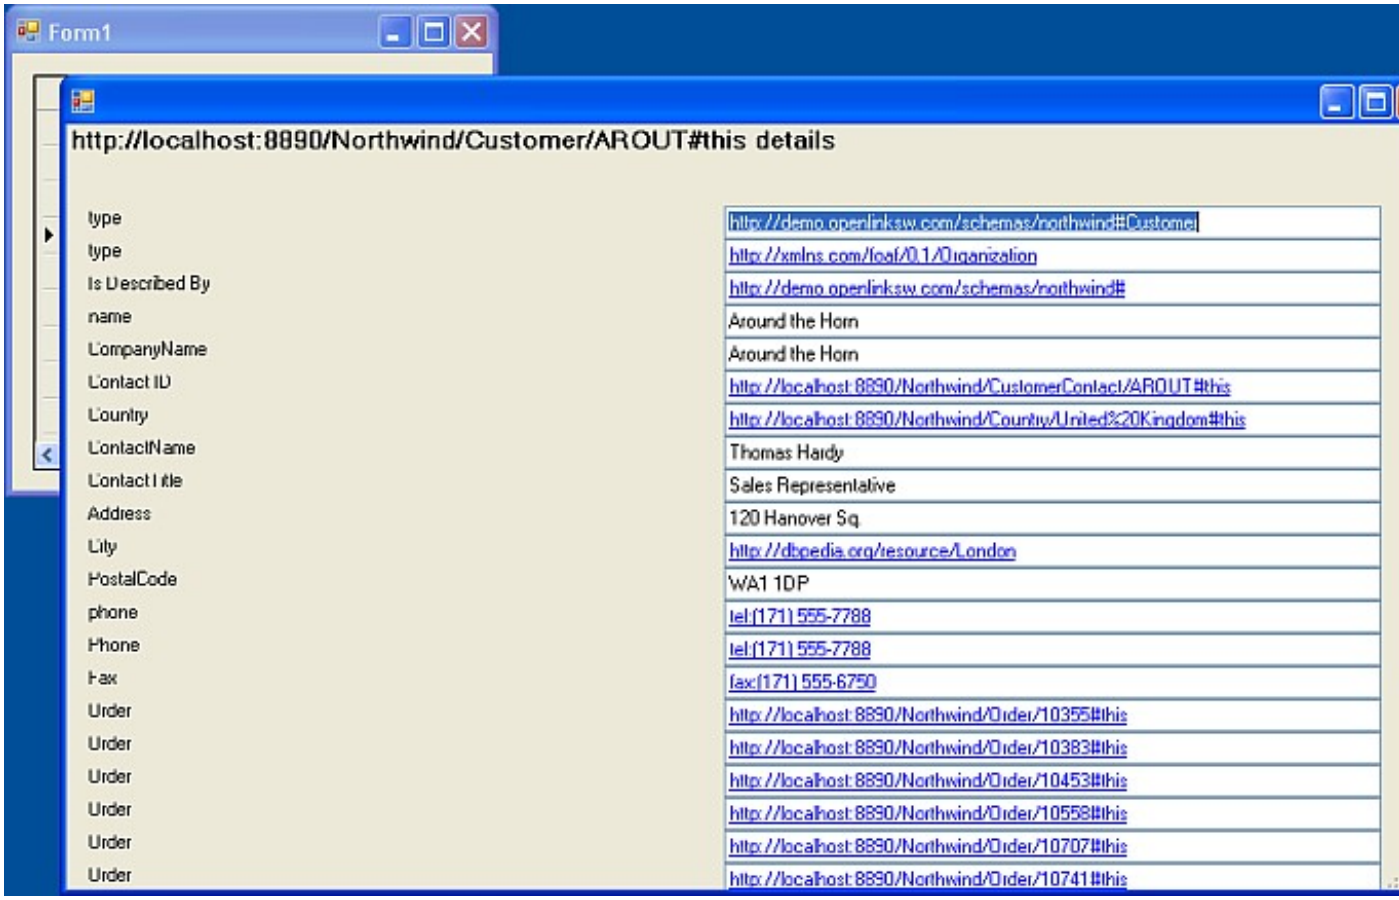
            //Try finding it in resources graph first
            foreach (String graph in graphList)
            {
                StringBuilder getLabelCommandText = new StringBuilder("sparql select * from <" + gra
                VirtuosoCommand getLabelCommand = new VirtuosoCommand(getLabelCommandText.ToString()
                getLabelAdapter.SelectCommand = getLabelCommand;

                try
                {
                    getLabelAdapter.Fill(getLabelDataSet);
                    foreach (DataRow getLabelRow in getLabelDataSet.Tables[0].Rows)
                    {
                        if (getLabelRow[0].ToString() == "http://www.w3.org/2000/01/rdf-schema#label
                        {
                            labelText = getLabelRow[1].ToString();
                            foundLabel = true;
                            break;
                        }
                    }
                }
                catch
                {
                }
                if (foundLabel)
                    break;
            }
            // If we still have no label try the predicate itself as the graph
            if (!foundLabel)
            {
                StringBuilder getLabelCommandText = new StringBuilder("sparql define get:soft \"soft
                VirtuosoCommand getLabelCommand = new VirtuosoCommand(getLabelCommandText.ToString()
                getLabelAdapter.SelectCommand = getLabelCommand;
                try
                {
                    getLabelAdapter.Fill(getLabelDataSet);
                    foreach (DataRow getLabelRow in getLabelDataSet.Tables[0].Rows)
                    {
                        if (getLabelRow[0].ToString() == "http://www.w3.org/2000/01/rdf-schema#label
                        {
                            labelText = getLabelRow[1].ToString();
                            break;
                        }
                    }
                }
                catch
                {
                }
            }
        }
        return labelText;
    }
```

This extended method first checks the graphs in the graph list for the predicate information then if no label has been found tries the predicate itself as the graph.

4. Build and run, the Northwind resources should now be correctly and concisely labeled

Figure 2.150. Northwind resources



Improving The Appearance of the Form

The following changes are not strictly necessary but improve the appearance of the form:

- Line up the right hand edge of the labels with the text boxes by setting TextAlign to MiddleRight and reduce the width of the labels.

```
propertyLabel.Text = getLabelText(row[0]);
propertyLabel.AutoEllipsis = true;
propertyLabel.AutoSize = false;
propertyLabel.Width = 130;
propertyLabel.TextAlign = ContentAlignment.MiddleRight;
```

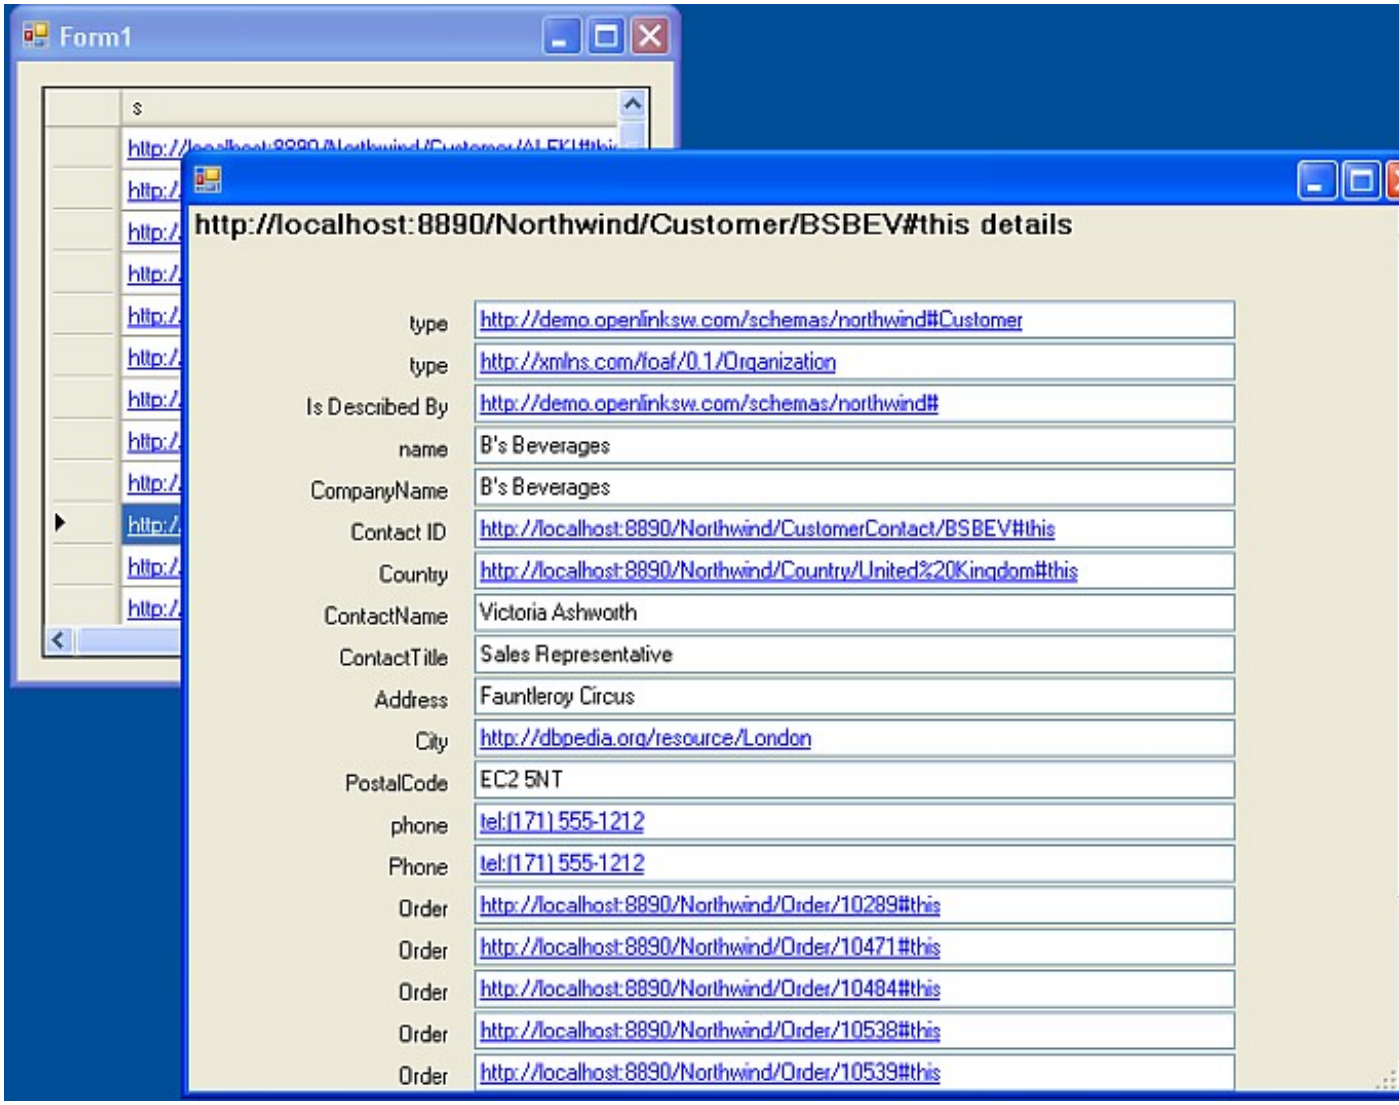
- Make the form narrower:

```
describeForm.Width = 660;
```

- Alter the positioning of the labels and TextBoxes on the form:

```
textBoxList[i].Click += new EventHandler(this.iri_Click);
labelList[i].Location = new Point(10, i * 22 + 50);
textBoxList[i].Location = new Point(150, i * 22 + 50);
describeForm.Controls.Add(labelList[i]);
describeForm.Controls.Add(textBoxList[i]);
```

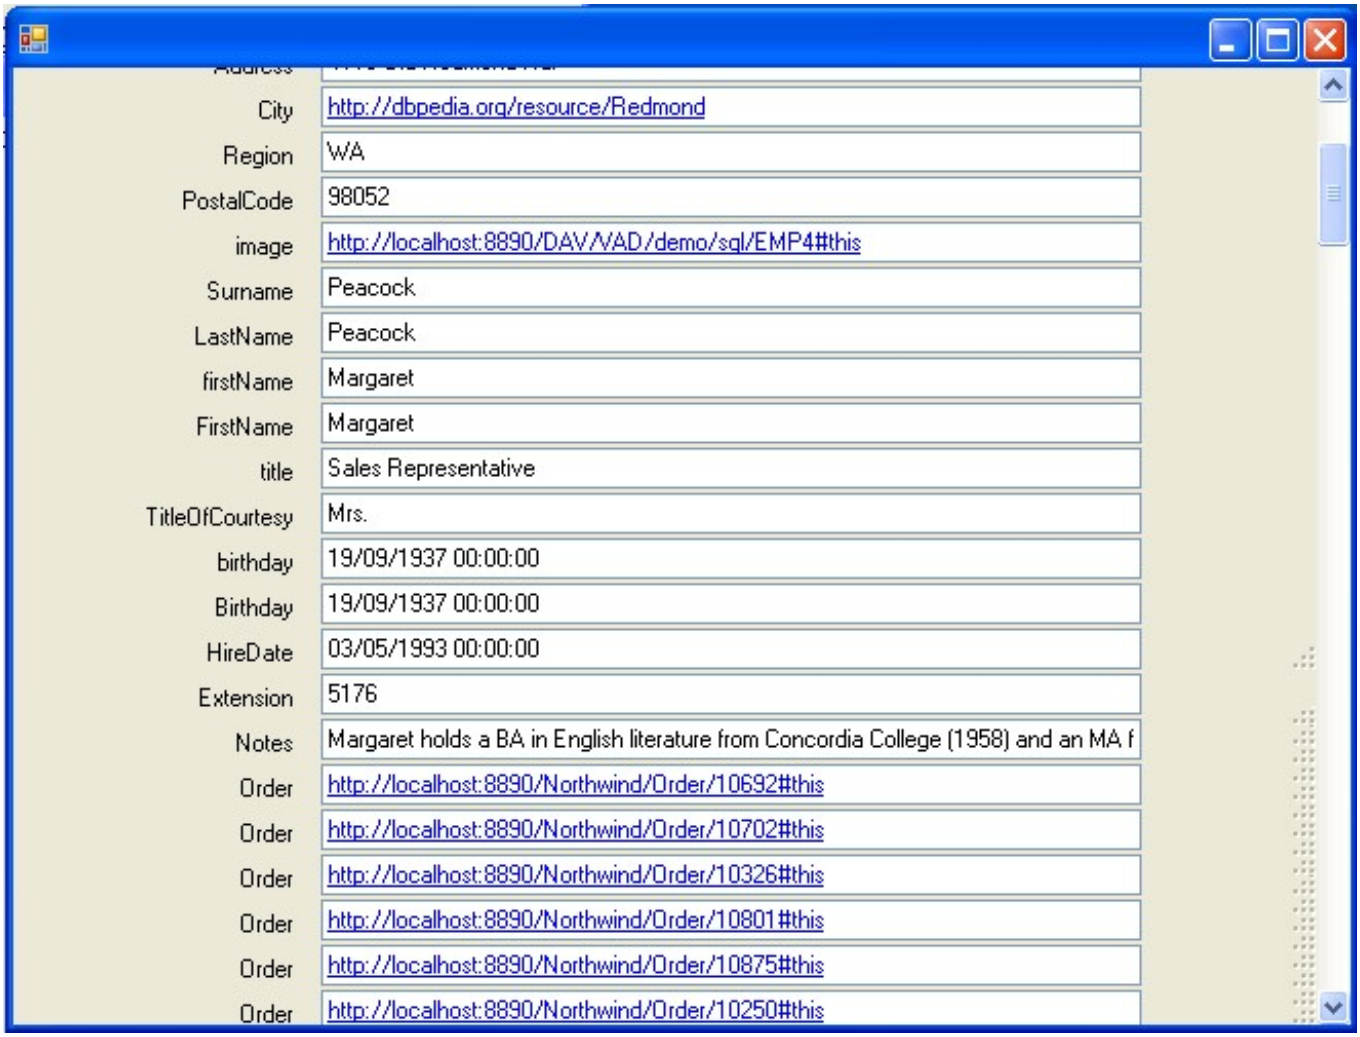
Figure 2.151. Alter the positioning



Next Steps

The image below shows some of the information about an employee in the Northwind dataset.

Figure 2.152. employee



In the next step we will extend the application so the images and web pages can be viewed and long text fields are displayed in full.

2.9.6. Extending RDFDemo to Display Images and Longer Text Fields.

This section will guide you through extending RDFDemo so that longer text fields can be displayed as a block of text and so that links to images and web pages can be viewed in a browser window.

Pre-requisites

1. A working copy of the RDFDemo application created in Modifying the Northwind Ontology to Add Labels

Modifying the Application

Displaying Text

We will modify the form that show the details of the selected item so that when the text in the boxes is too long to be seen in full a button will appear beside the box on the form and if you click the button the complete text will be displayed in a separate window.

1. Add a new class, MoreButton that extends System.Windows.Forms.Button.

    - In the

      Solution Explorer

      right click on the RDFDemo project and select

      Add

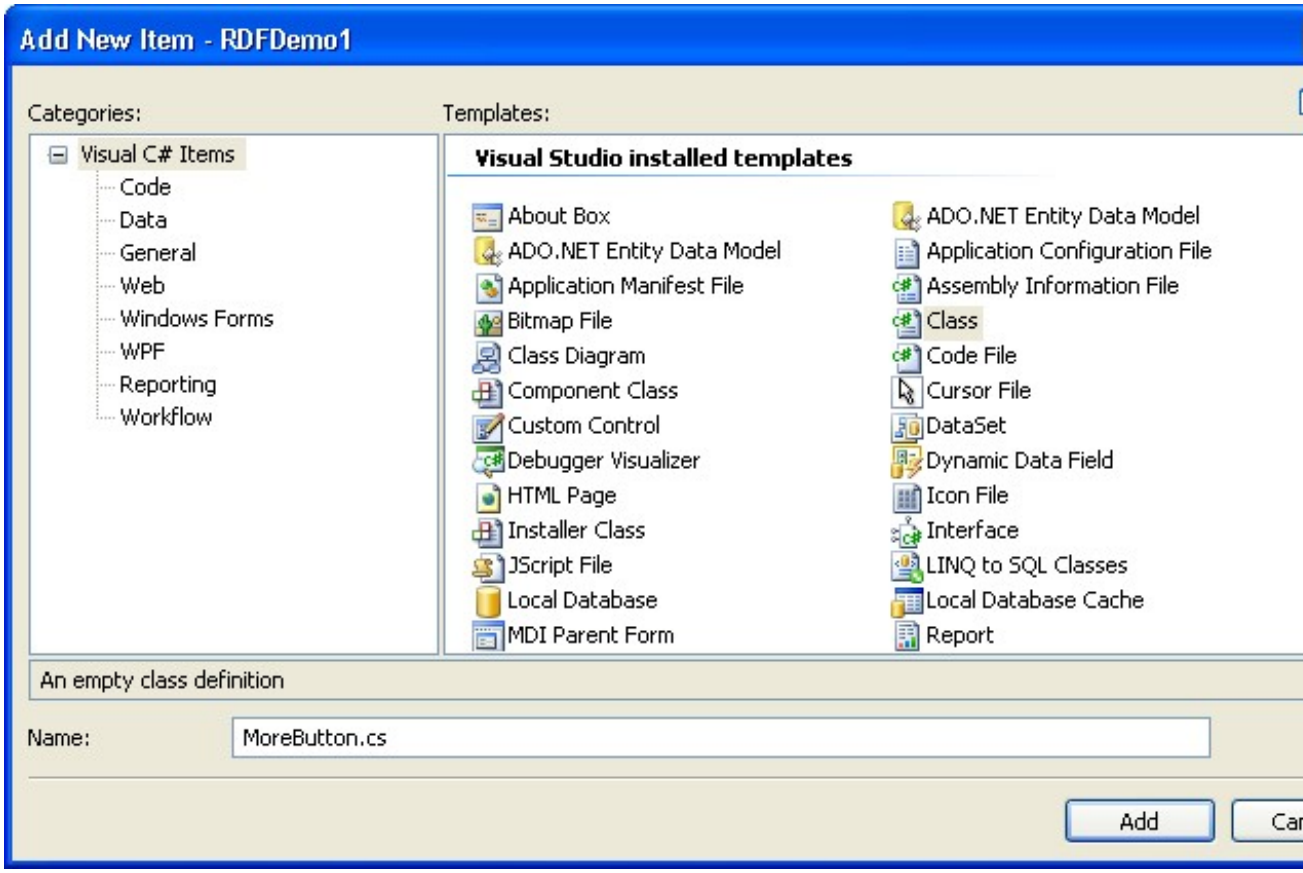
then

New Item

.

- Add a new class called MoreButton.cs.

Figure 2.153. Add a new class



- The following using statement goes at the top of the file:

```
using System.Windows.Forms;
```

- The MoreButton class must inherit from System.Windows.Forms.Button so the class definition line should look like this:

```
class MoreButton : Button
```

- Add the following code to the body of the MoreButton class:

```
String longText;

public MoreButton(String text)
{
    longText = text;
    this.Text = "More";
}

protected override void  OnClick(EventArgs e)
{
    Form moreForm = new Form();
    TextBox moreBox = new TextBox();
    moreBox.Text = longText;
    moreBox.Width = 300;
    moreBox.Height = 250;
    moreBox.ScrollBars = ScrollBars.Vertical;
    moreBox.Multiline = true;
    moreBox.WordWrap = true;
    moreBox.Select(0, 0);
```

```
            moreBox.ReadOnly = true;
            moreForm.Controls.Add(moreBox);
            moreForm.Width = 320;
            moreForm.Height = 280;
            moreForm.ShowDialog();
        }
```

2. In displayData in the ExtendedStringHandler class, when the labels and TextBoxes are added to the form check if the text is too big for the box. If it is then add a MoreButton that will display all the text in a separate window.

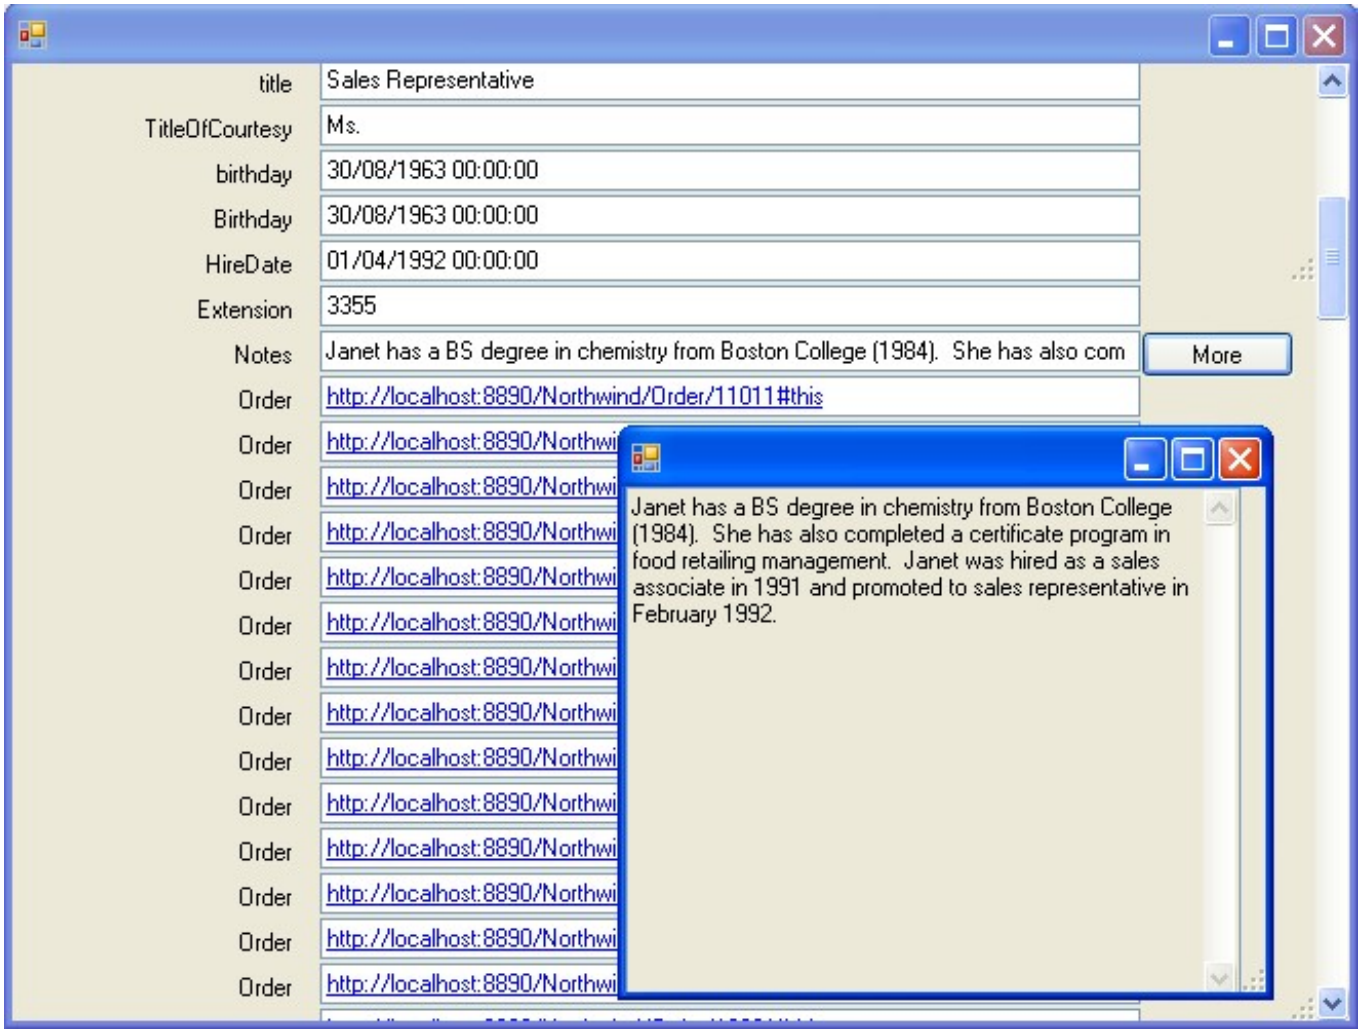
```
if (textBoxList[i].DataBindings[0].DataSource.ToString().Length > 80
    && !(textBoxList[i].DataBindings[0].DataSource is SqlExtendedString))
{
    moreButtonList.Add(new MoreButton(textBoxList[i].DataBindings[0].DataSource.ToString()));
    moreButtonList[moreButtonList.Count - 1].Location = new Point(550, i * 22 + 50);
    describeForm.Controls.Add(moreButtonList[moreButtonList.Count -1]);
}
```

3. We will also need a list to hold the buttons as they are created so the following needs to be added to the member variables at the top of the ExtendedStringHandler class.

```
List<MoreButton> moreButtonList = new List<MoreButton>();
```

4. Build and run the application. If you click through to an Employee page you will see the Notes field now has a button labeled More next to it. If you click on that button the text from the Notes field is displayed in a new window.

Figure 2.154. Notes



Displaying Images and Web Pages

Next we will modify the form so that item identified as images or web pages will be opened in a browser window. Again we will do this by adding a button beside the box on the form that will open the browser window.

1. Add a new class, OpenButton that extends System.Windows.Forms.Button.

   - In the

     Solution Explorer

     right click on the RDFDemo project and select

     Add

     then

     New Item
   - Add a new class called OpenButton.cs.
   - The following using statement goes at the top of the file:

     ```
     using System.Windows.Forms;
     ```
   - The OpenButton class must inherit from System.Windows.Forms.Button so the class definition line should look like this:

     ```
     class OpenButton : Button
     ```
   - Add the following code to the body of the OpenButton class:

     ```
     String urlText;

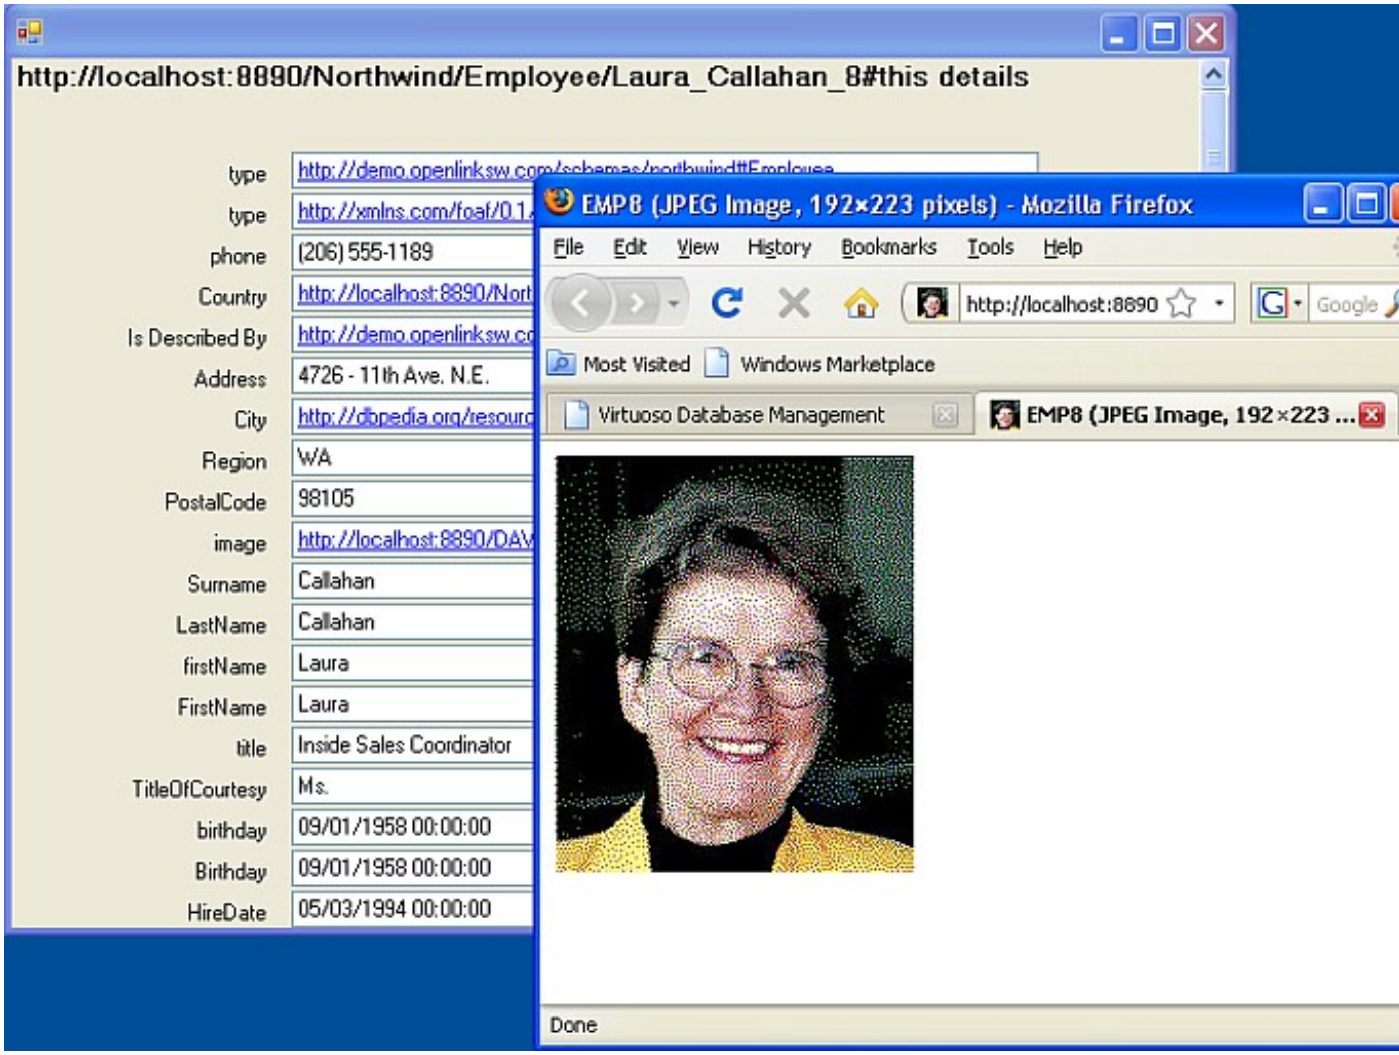
     public OpenButton(String text)
     {
         urlText = text;
         this.Text = "Open";
     }

     protected override void  OnClick(EventArgs e)
     {
         System.Diagnostics.Process.Start(urlText);
     }
     ```
2. In displayData in the ExtendedStringHandler class, where we added the code to check for long text fields we now need to check for IRIs that identify images and web pages. As a simple first attempt we will check for matching labels. So for example, if a property label is 'image' or 'webpage', we will assume it can be opened in a browser window and put an OpenButton beside it.

   ```
   if (labelList[i].Text == "website"
       || labelList[i].Text == "image"
       || labelList[i].Text == "depiction"
       || labelList[i].Text == "page"
       || labelList[i].Text == "url"
       || labelList[i].Text == "image skyline")
   {
       openButtonList.Add(new OpenButton(textBoxList[i].DataBindings[0].DataSource.ToString()));
       openButtonList[openButtonList.Count - 1].Location = new Point (550, i * 22 + 50);
       describeForm.Controls.Add(openButtonList[openButtonList.Count - 1]);
   }
   ```
3. We will also need a list to hold the buttons as they are created so the following needs to be added to the member variables at the top of the ExtendedStringHandler class.

   ```
   List<OpenButton> openButtonList = new List<OpenButton>();
   ```
4. Build and run the application. If you click through to an Employee page now you will see that the Image field now has a button labeled Open next to it. If you click on that button the image is opened in your default browser.

Figure 2.155. Image



Next Steps

It has already been mentioned that the property labels are also dereferenceable IRIs. We used this feature to find a short name to display rather that the complete IRI. The next step is to make the labels clickable so the ontology itself can also be explored.

2.9.7. Extending RDFDemo To Make The Property Labels Clickable

This section will guide you through extending RDFDemo to make the property labels clickable. Clicking on the property label will take you to a page describing that property.

Pre-requisites

1. A working copy of the RDFDemo application created in Extending RDFDemo to Display Images and Longer Text Fields

Modifying the Application

Making the Labels Clickable

Making the property labels clickable is fairly straight forward. We will use basically the same code as is used to make the values clickable.

1. First we need to add a new event handler. In the ExtendedStringHandler class modify displayData to add an event handler for each of the property labels.

```
for (int i = 0; i < table1.Rows.Count; i++)
{
    textBoxList[i].Click += new EventHandler(this.iri_Click);
```

```
    labelList[i].Location = new Point(10, i * 22 + 50);
    textBoxList[i].Location = new Point(150, i * 22 + 50);
    describeForm.Controls.Add(labelList[i]);
    describeForm.Controls.Add(textBoxList[i]);
```

becomes

```
for (int i = 0; i < table1.Rows.Count; i++)
{
    textBoxList[i].Click += new EventHandler(this.iri_Click);
    labelList[i].Location = new Point(10, i * 22 + 50);
    labelList[i].Click += new EventHandler(this.label_Click);
    textBoxList[i].Location = new Point(150, i * 22 + 50);
    describeForm.Controls.Add(labelList[i]);
    describeForm.Controls.Add(textBoxList[i]);
```

2. Then we need to add the EventHandler method. Add the following to the ExtendedStringHandler Class:

```
public void label_Click(object sender, EventArgs e)
  {
      int labelNum = 0;

      for (int i = 0; i < labelList.Count; i++)
      {
          if (sender == labelList[i])
          {
              labelNum = i;
              break;
          }
      }

      Object o = describeDataSet.DataTable1.Rows[labelNum][0];
      if (o is SqlExtendedString)
      {
          SqlExtendedString se = (SqlExtendedString)o;
          ExtendedStringHandler seHandler = new ExtendedStringHandler(se, ParentConnection);
          seHandler.displayData();
      }
      else if (o is SqlRdfBox)
      {
          //doesn't do anything at the moment
      }
  }
```

If you compare this method to the EventHandler for the values, iri_Click, you will see that it is basically the same. The only difference is that it uses the property element from the data table rather than value.

3. Finally, to make it clear that the labels are now active links, we will change the label colour to blue and underline them.

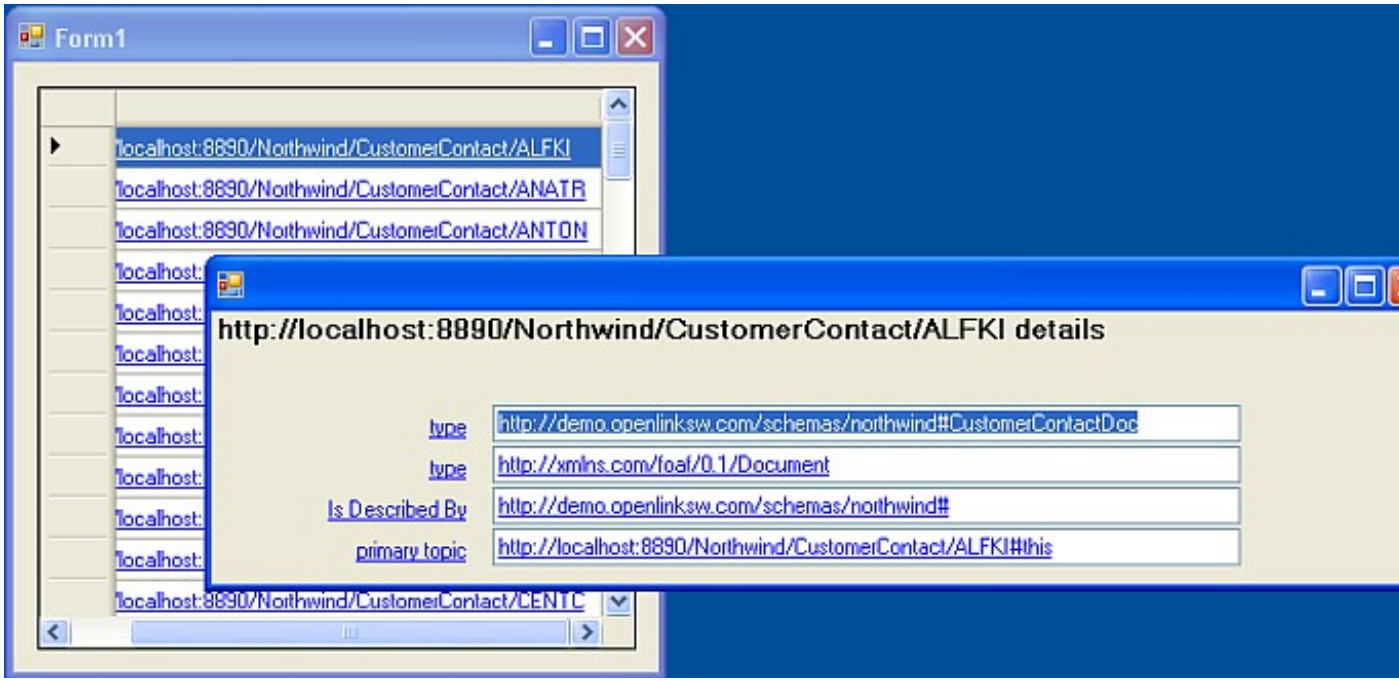
```
 propertyLabel.Text = getLabelText(row[0]);
 propertyLabel.AutoEllipsis = true;
 propertyLabel.AutoSize = false;
 propertyLabel.Width = 130;
 propertyLabel.TextAlign = ContentAlignment.MiddleRight;
```

becomes:

```
propertyLabel.Text = getLabelText(row[0]);
propertyLabel.ForeColor = Color.Blue;
propertyLabel.Font = new Font(propertyLabel.Font.FontFamily, propertyLabel.Font.Size, propertyLabe
propertyLabel.AutoEllipsis = true;
propertyLabel.AutoSize = false;
propertyLabel.Width = 130;
propertyLabel.TextAlign = ContentAlignment.MiddleRight;
```

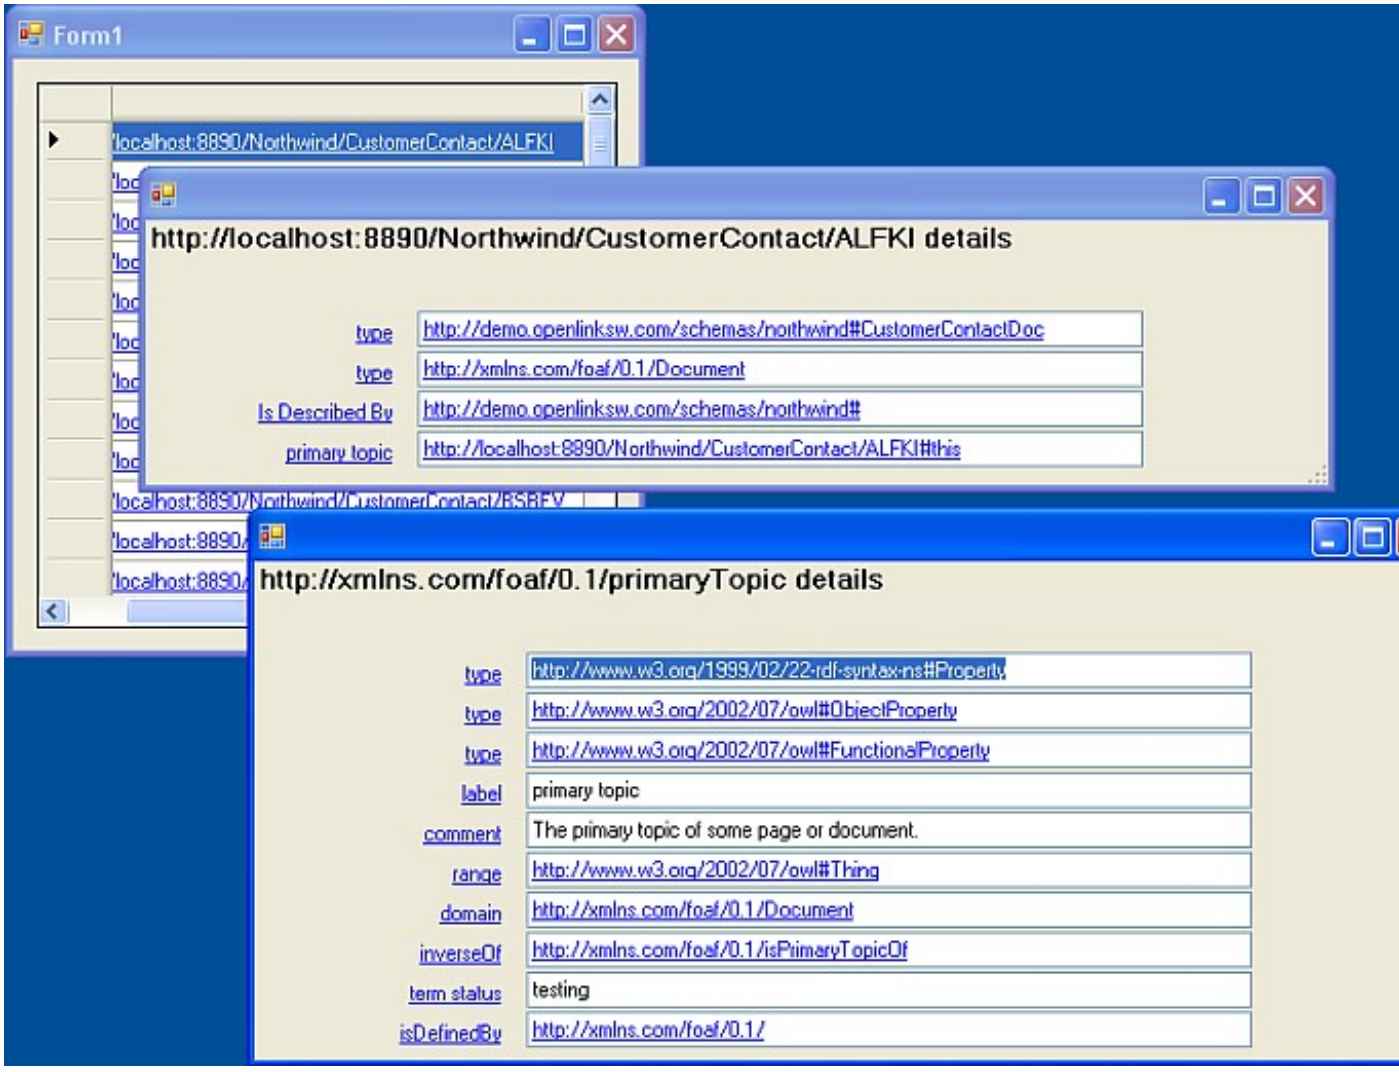
4. Build and run the application. You will see the familiar starting page. If you then select one of the Customers you will notice the property labels now look like hyperlinks.

Figure 2.156. hyperlinks



If you click on one of the label hyperlinks you will see a new form showing detailed information about the property which can itself be explored further by clicking on labels and values.

Figure 2.157. labels and values



These simple changes work up to a point but are not robust. If you explore the properties used by the local Northwind graph you quickly find that the property details are not found. The application needs some further changes to work consistently. The problem is finding the graph where the property information is defined. The general handler for Extended Strings first checks the local Northwind graph, http://example.com/Northwind, where the Northwind data is held, and then uses the IRI itself as the graph and tries to load that dynamically. This is not working for information about the Northwind properties. These properties are defined in the Northwind ontology, http://demo.openlinksw.com/schemas/northwind. We have already had to find this graph when getting the short label name. We need to be able to associate the property label with the graph where its definition is stored. Then we can search this graph for details about the property when the label is clicked.

Using the Graph Where the Property Label was Found to Find the Property Details

1. Create a new class, IRILabel, that inherits from System.Windows.Forms.Label.

   - In the

     Solution Explorer

     right click on the RDFDemo project and select

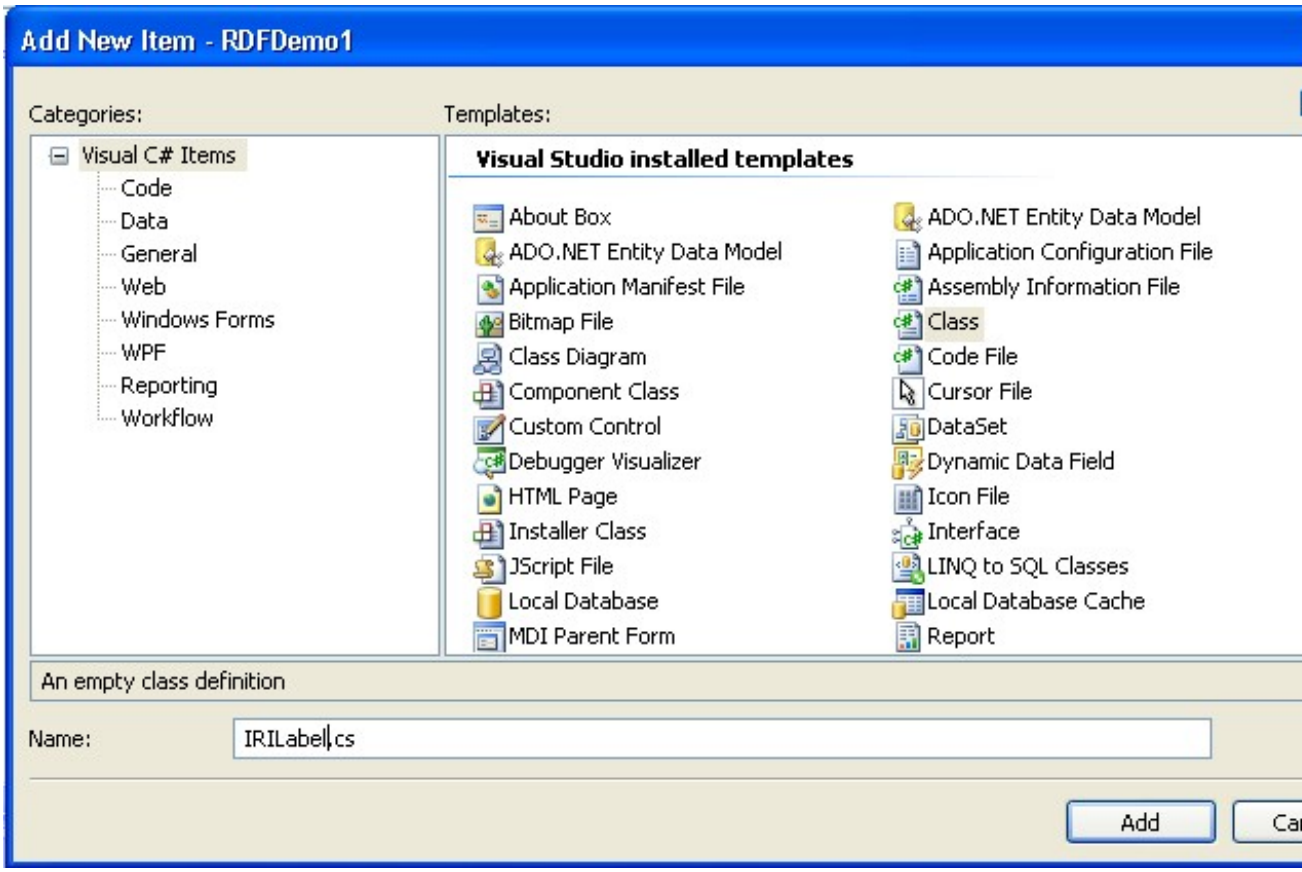
     Add

     then

     New Item

     .
   - Add a new class called IRILabel.cs.

     Figure 2.158. Add a new class

2. We need to reference System.Windows.Forms, System.Data and OpenLink.Data.Virtuoso so add

```
using System.Windows.Forms;
using OpenLink.Data.Virtuoso;
```

```
using System.Data;
```

to the using block at the top of the class file. The class definition should look like this:

```
class IRILabel : Label
```

3. Paste the following code into the body of the class:

```
SqlExtendedString SourceIRI;
String GraphUsed;
VirtuosoConnection ParentConnection;

public IRILabel(Object iri, List<String> graphList, VirtuosoConnection parentConnection)
{
    ParentConnection = parentConnection;
    if (iri is SqlExtendedString)
    {
        SourceIRI = (SqlExtendedString)iri;
        Text = this.getLabelText(graphList);
    }
    else
        Text = iri.ToString();
}

public SqlExtendedString iri
{
    get
    {
        return SourceIRI;
    }
}

public String graph
{
    get
    {
        return GraphUsed;
    }
}

private string getLabelText(List<String> graphList)
{
    string labelText = SourceIRI.ToString();
    Boolean foundLabel = false;
    VirtuosoDataAdapter getLabelAdapter = new VirtuosoDataAdapter();
    DataSet getLabelDataSet = new DataSet();

    //Try finding it in resources graph first
    foreach (String graph in graphList)
    {
        StringBuilder getLabelCommandText = new StringBuilder("sparql select * from <" + graph + "
        VirtuosoCommand getLabelCommand = new VirtuosoCommand(getLabelCommandText.ToString(), Pare
        getLabelAdapter.SelectCommand = getLabelCommand;

        try
        {
            getLabelAdapter.Fill(getLabelDataSet);
            foreach (DataRow getLabelRow in getLabelDataSet.Tables[0].Rows)
            {
                if (getLabelRow[0].ToString() == "http://www.w3.org/2000/01/rdf-schema#label")
                {
                    labelText = getLabelRow[1].ToString();
                    foundLabel = true;
                    break;
                }
            }
        }
        catch
        {
        }
        if (foundLabel)
        {
            GraphUsed = graph;
```

```
                break;
            }
        }

        // If we still have no label try the predicate itself as the graph
        if (!foundLabel)
        {
            GraphUsed = SourceIRI.ToString();
            StringBuilder getLabelCommandText = new StringBuilder("sparql define get:soft \"soft\" sel
            VirtuosoCommand getLabelCommand = new VirtuosoCommand(getLabelCommandText.ToString(), Pare
            getLabelAdapter.SelectCommand = getLabelCommand;
            try
            {
                getLabelAdapter.Fill(getLabelDataSet);
                foreach (DataRow getLabelRow in getLabelDataSet.Tables[0].Rows)
                {
                    if (getLabelRow[0].ToString() == "http://www.w3.org/2000/01/rdf-schema#label")
                    {
                        labelText = getLabelRow[1].ToString();
                        break;
                    }
                }
            }
            catch
            {
            }
        }
        return labelText;
    }
```

Notice that the getLabelText method has been moved into this new class and is now called from the constructor. When the IRILabel is constructed the label text is found using the list of graphs provided to the constructor. The graph containing the label is noted. We need to alter ExtendedStringHandler so that the labels are the new IRILabel type and so that the correct information is supplied to the constructor.

4. Change the labelList member variable declaration so it looks like this:

```
List<IRILabel> labelList = new List<IRILabel>();
```

5. Each propertyLabel created must be the new IRILabel type so the line:

```
Label propertyLabel = new Label();
```

becomes:

```
IRILabel propertyLabel = new IRILabel(row[0], graphList, ParentConnection);
```

6. As getLabelText is now called by the IRILabel constructor we can remove the line:

```
propertyLabel.Text = getLabelText(row[0]);
```

from describeData in ExtendedStringHandler.

7. Now we modify the label_Click EventHandler so that it uses the graph information. Replace the existing method with:

```
public void label_Click(object sender, EventArgs e)
  {
      int labelNum = 0;

      for (int i = 0; i < labelList.Count; i++)
      {
          if (sender == labelList[i])
          {
              labelNum = i;
              break;
          }
      }

      SqlExtendedString se = labelList[labelNum].iri;
      ExtendedStringHandler seHandler = new ExtendedStringHandler(se, ParentConnection, labelList[
          seHandler.displayData();

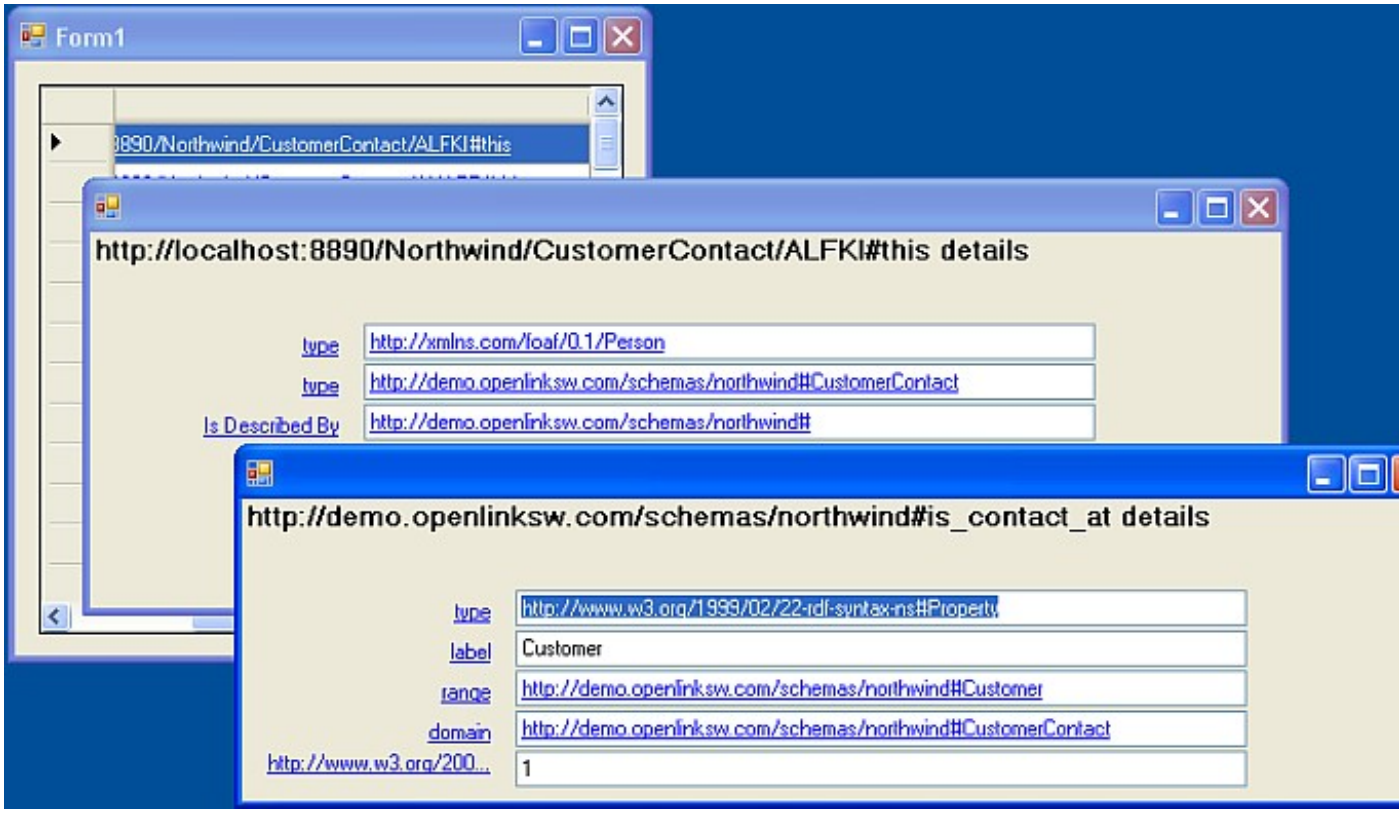
  }
```

8. Note that this method uses a new constructor for the ExtendedStringHandler that takes the graph as an additional argument. We need to add this new constructor.

```
public ExtendedStringHandler(SqlExtendedString iri, VirtuosoConnection parentConnection, String gr
  {
      ParentConnection = parentConnection;
      if (iri.IriType == SqlExtendedStringType.IRI)
      {
          ParentIRI = iri;
          isIRI = true;
          DescribeCommandSimple = new StringBuilder("sparql select * from <http://example.com/Nort
          DescribeCommandGeneral = new StringBuilder("sparql define get:soft " + '"'.ToString() +
      }
  }
```

   This new constructor uses the supplied graph to build the alternative sparql select statement that looks for the details about the supplied IRI. With these changes in place the application will find the description of the Northwind properties.
9. Build and run. As you explore the data you will see that you can find descriptions of the properties used to describe the entities in the Northwind dataset:

Figure 2.159. Northwind dataset



2.10. Creating a Web Browser Application to Access RDF Data Using The Virtuoso ADO.Net Provider

This section will guide you through creating first a Web Service that exposes RDF data from Virtuoso and then a simple web browser application that consumes the Web Service and allowing you to access and explore the RDF data by clicking on dereferenceable IRIs .

2.10.1. Pre-requisites

1. The example assumes that you have a local Virtuoso server with the Northwind demo database installed. If the demo database is not already installed then download the demo database VAD package (demo_dav.vad) and install it. The VAD package will create a new database in Virtuoso called demo containing the familiar Northwind tables. It will also creates Linked Data Views of the Northwind tables. In the example we assume the database is accessible on a hostname

of "demo.openlinksw.com" on the default port 80, where an actually live instance of the Virtuoso Demo database is hosted. Users would use the appropriate hostname and port number of their Virtuoso installation to create the sample application, and would be would be example.com for a default installation or whatever the URIQA DefaultHost Virtuoso configuration parameter is set to when the demo database VAD package is installed.

2. The Virtuoso ADO.Net provider for .Net 3.5 and the Entity Framework.
3. Microsoft Visual Studio 2008
4. The Virtuoso Cartridges VAD package .

2.10.2. Creating the Web Service

Step 1 - Create a view of the RDF data

To create a view of the customers in the Northwind first open the Virtuoso Conductor and log in as dba. Then open iSQL from the menu on the left and execute the following statement.

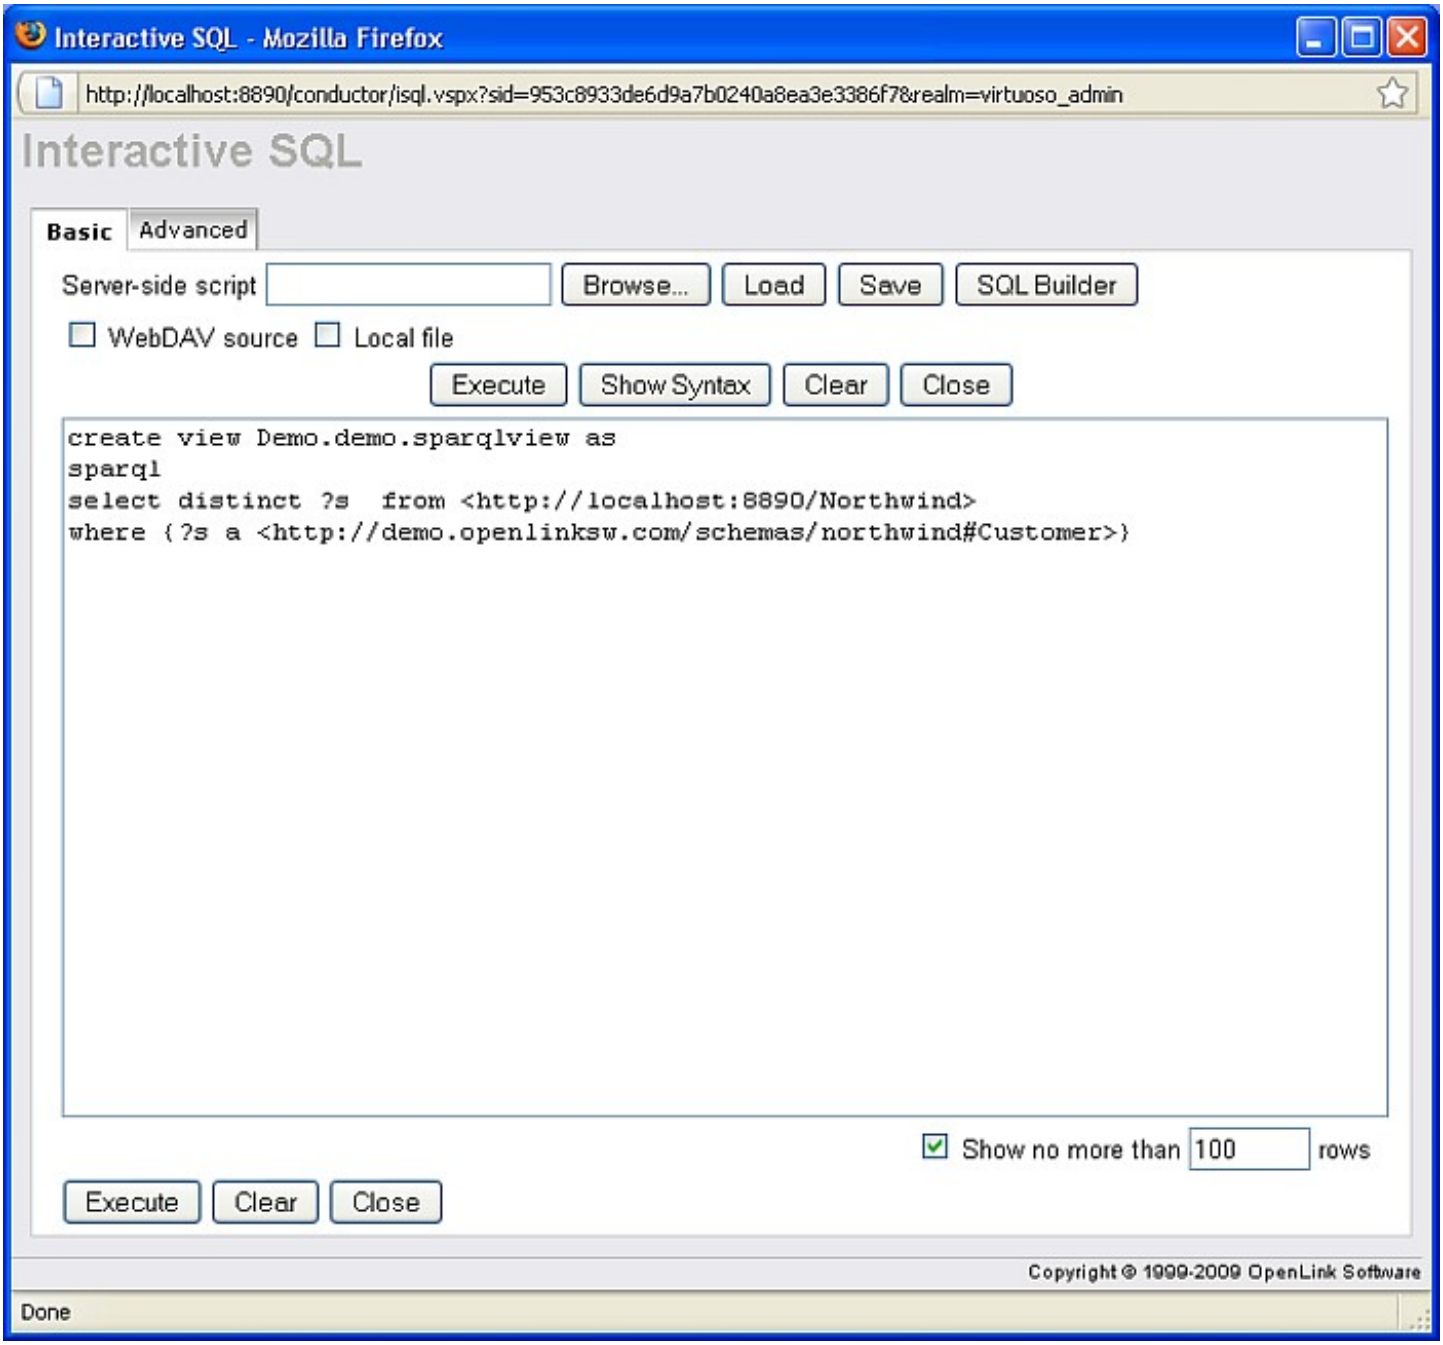
```
create view Demo.demo.sparqlview as
sparql
select distinct ?s  from <http://example.com/Northwind>
where {?s a <http://demo.openlinksw.com/schemas/northwind#Customer>}
```

Note:

- If the view is added to the Visual Studio project as user "demo" (or any other than "dba'), then it must be ensured that the "SPARQL_SELECT" and "SPARQL_SPONGE" roles are assigned to this user, which can be done via the Virtuoso Conductor in the "System Admin" -> "User Accounts" tab.
- Execute permissions will also need to be granted to the following procedure:

```
grant execute on DB.DBA.RDF_MAKE_LONG_OF_SQLVAL to "demo"
```

Figure 2.160. create a view



Step 2 - Create the Visual Studio Project and Add the Model

1. Open

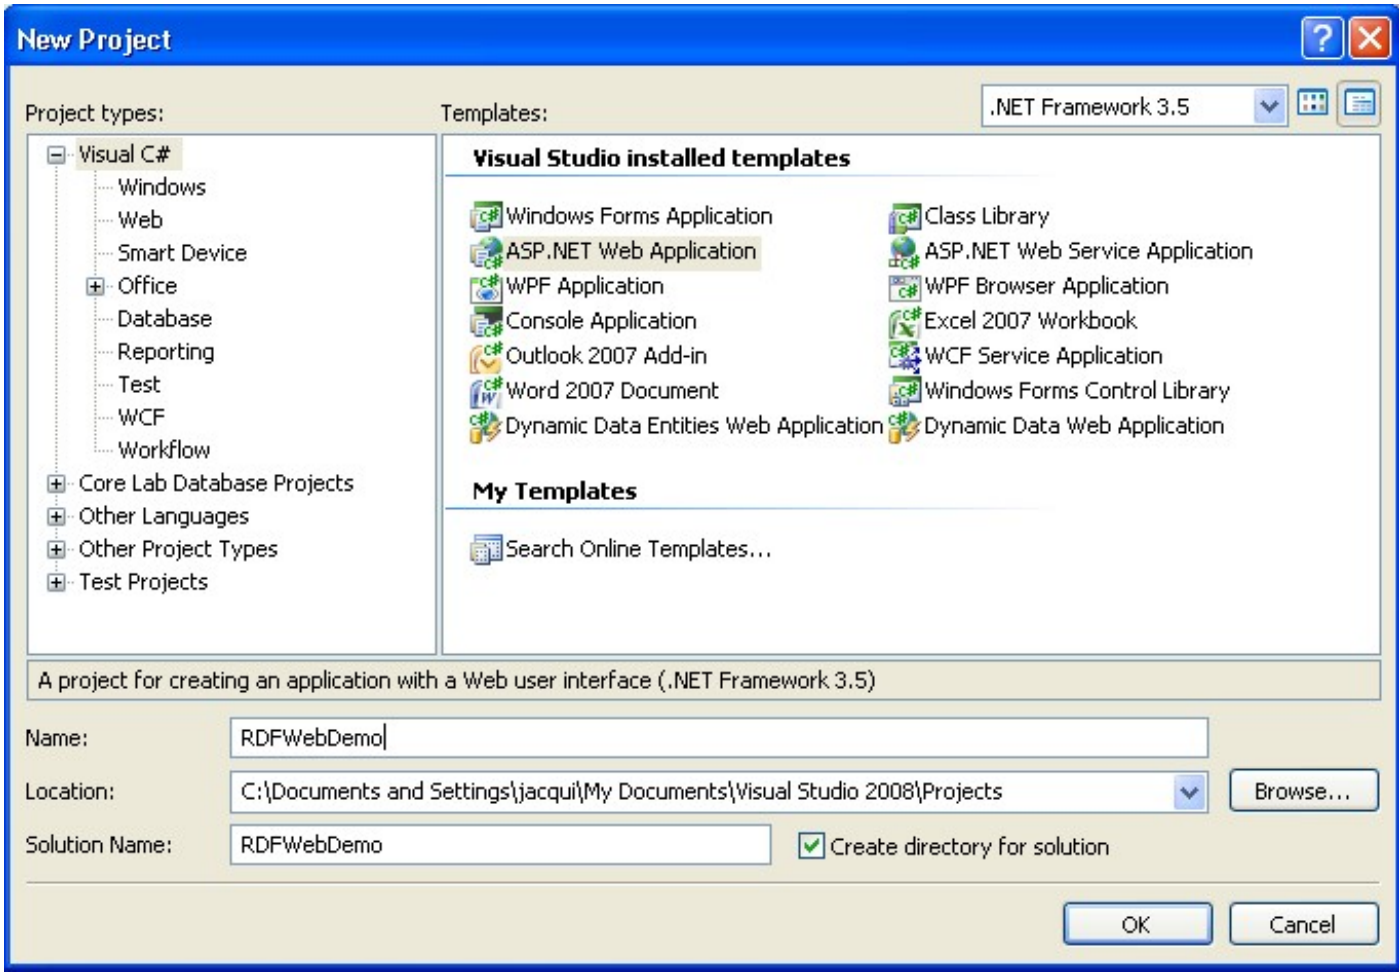
   Visual Studio

   and create a new

   ASP .NET Web Application

   called RDFWebDemo.

   Figure 2.161. create new application



2. Right click RDFWebDemo in the

   Solution Explorer

   and add a new

   ADO.NET Entity Data Model

   called Model1.edmx. This will open the Entity Data Model Wizard.
3. Choose

   Generate From Database

   and click

   Next

   .
4. Set up a connection to the Demo database on your local Virtuoso Server, select

   Yes, include the sensitive data in the connection string

   and set the name of the entities to DemoEntities. Click

   Next

   .
5. On the

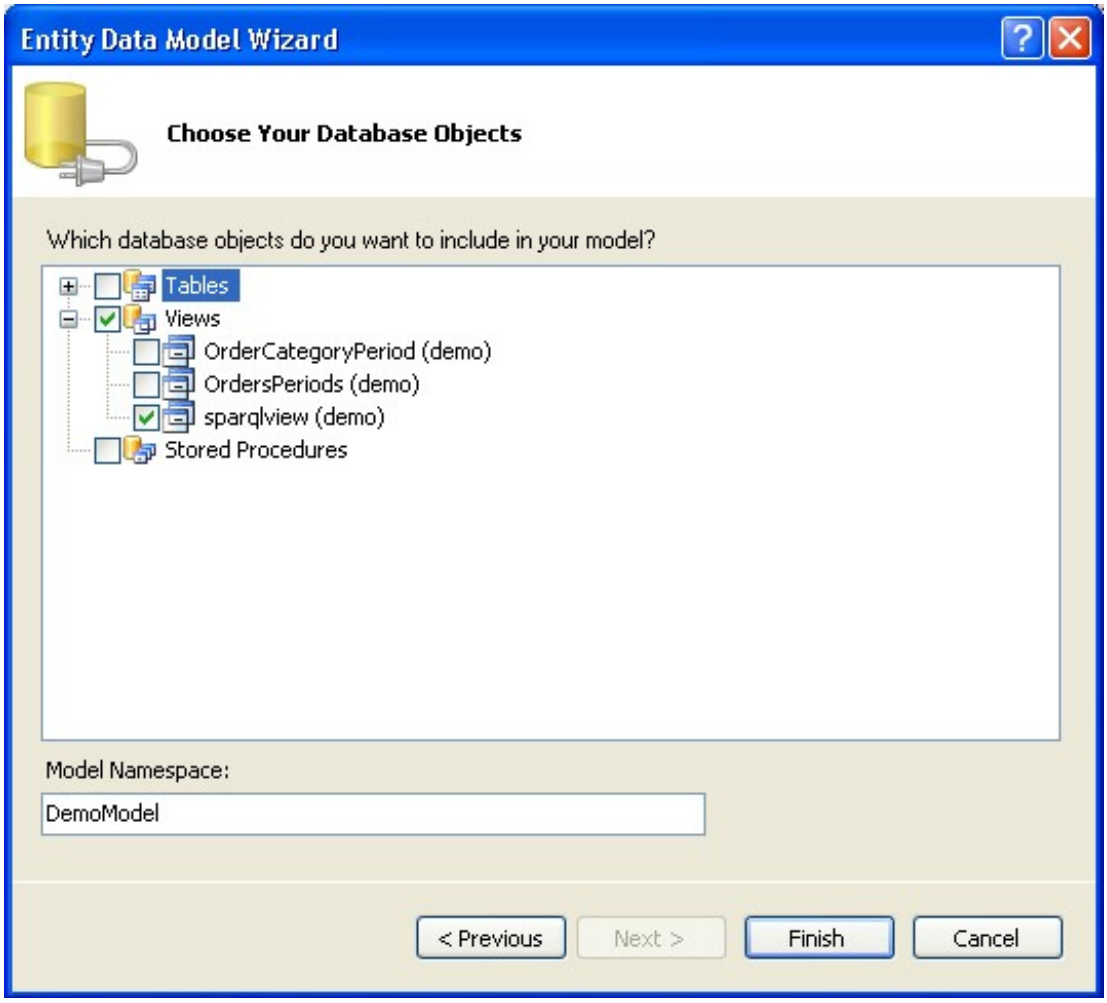
   Choose Your Database Objects

page expand

Views

and select sparqlview. Check that the Model Namespace is DemoModel and click Finish.

Figure 2.162. Model Namespace



Step 3 - Add the Web Service

1. Right click RDFWebDemo in the

   Solution Explorer

   and add a new

   ADO.NET Data Service

   called WebDataService1.svc. Click

   Add

   .
2. In the class definition of WebDataService1 in the newly created file WebDataService1.svc.cs replace /* TODO: put your data source class name here */ with the name of our model, DemoEntities.

   ```
   public class WebDataService1 : DataService<DemoEntities>
   ```
3. In the InitializeService method add the line:

```
config.SetEntitySetAccessRule("*", EntitySetRights.All);
```

The method should look like this:

```
public static void InitializeService(IDataServiceConfiguration config)
  {
      // TODO: set rules to indicate which entity sets and service operations are visible, updata
      // Examples:
      // config.SetEntitySetAccessRule("MyEntityset", EntitySetRights.AllRead);
      // config.SetServiceOperationAccessRule("MyServiceOperation", ServiceOperationRights.All);

      config.SetEntitySetAccessRule("*", EntitySetRights.All);
  }
```

Step 4 - Compile and Run

Hit *F5* to compile and run the service. Select *OK* when prompted to enable debugging. The default browser will be launched showing a page like:

```
  <?xml version="1.0" encoding="utf-8" standalone="yes" ?>
- <service xml:base="http://example.com/WebDataService1.svc/" xmlns:atom="http://www.w3.org/2005/Atom" xm
- <workspace>
  <atom:title>Default</atom:title>
- <collection href="sparqlview">
  <atom:title>sparqlview</atom:title>
  </collection>
  </workspace>
  </service>
```

The service is now running.

Note the address on which the service is made available. You will need to know this when creating the app to consume the service. Look in the Address Bar of the browser. It will be something like: http://example.com/WebDataService1.svc/

2.10.3. Creating the Browser Application

Step 1 - Create the Visual Studio Project.

1. Open

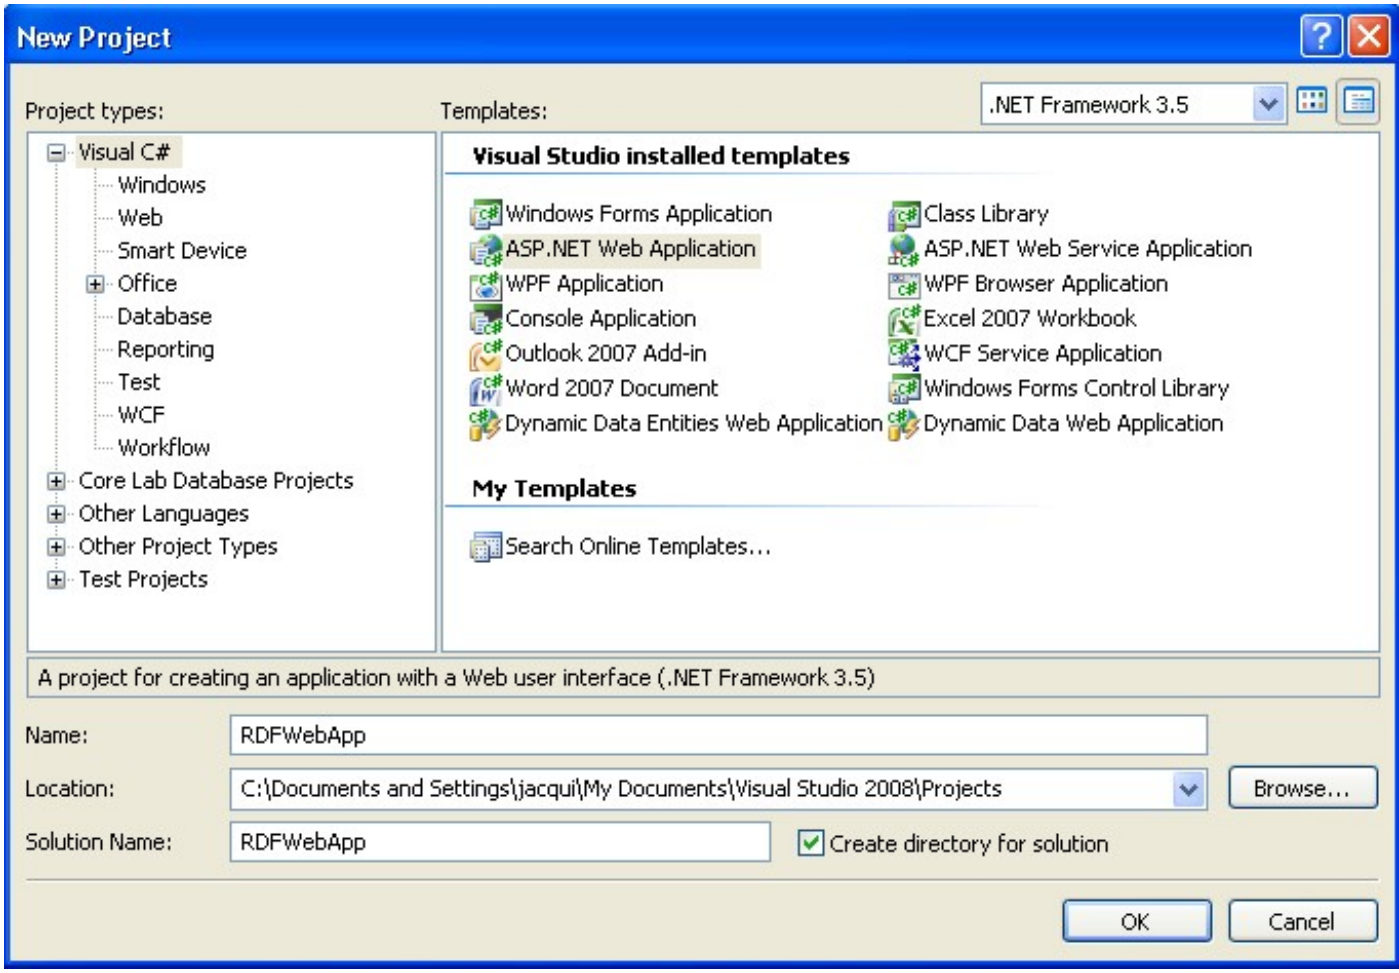
   Visual Studio

   and create a new

   ASP.NET Web Application

   called RDFWebApp.

   Figure 2.163. New Web Application



2. Create client side entities with datasvcutil.exe

    - Open a command prompt.
    - Navigate to *C:\WINDOWS\Microsoft.NET\Framework\v3.5*.
    - Generate the client classes using the following command:

        ```
        datasvcutil.exe /uri:http://example.com/WebDataService1.svc /out:DemoEntities.cs
        ```

        Note the address of the service - you may need to change the port number to match the one seen in the address at the end of Step 4 in Creating the Web Service.
3. Add the classes to RDFWebApp.

    - Right click RDFWebApp
    - Choose to add an existing item and add c:\WINDOWS\Microsoft.NET\Framework\v3.5\DemoEntities.cs.
4. Add a reference to System.Data.Services.Client to the project.

Step 2 - Display the contents of sparqlview as a table on the page

To display the RDF data on the web page we create a table with a row for each item in sparqlview. We then use each IRI from sparqlview to create a hyperlink. The hyperlinks are displayed in the table cells. To do this add the following block of code to the page_load method in Default.aspx.cs.

```
DemoModel.DemoEntities svc = new DemoModel.DemoEntities(new Uri("http://example.com/WebDataService1.svc"

 var query = svc.sparqlview;
 Table iriTable = new Table();
 this.Controls.Add(iriTable);

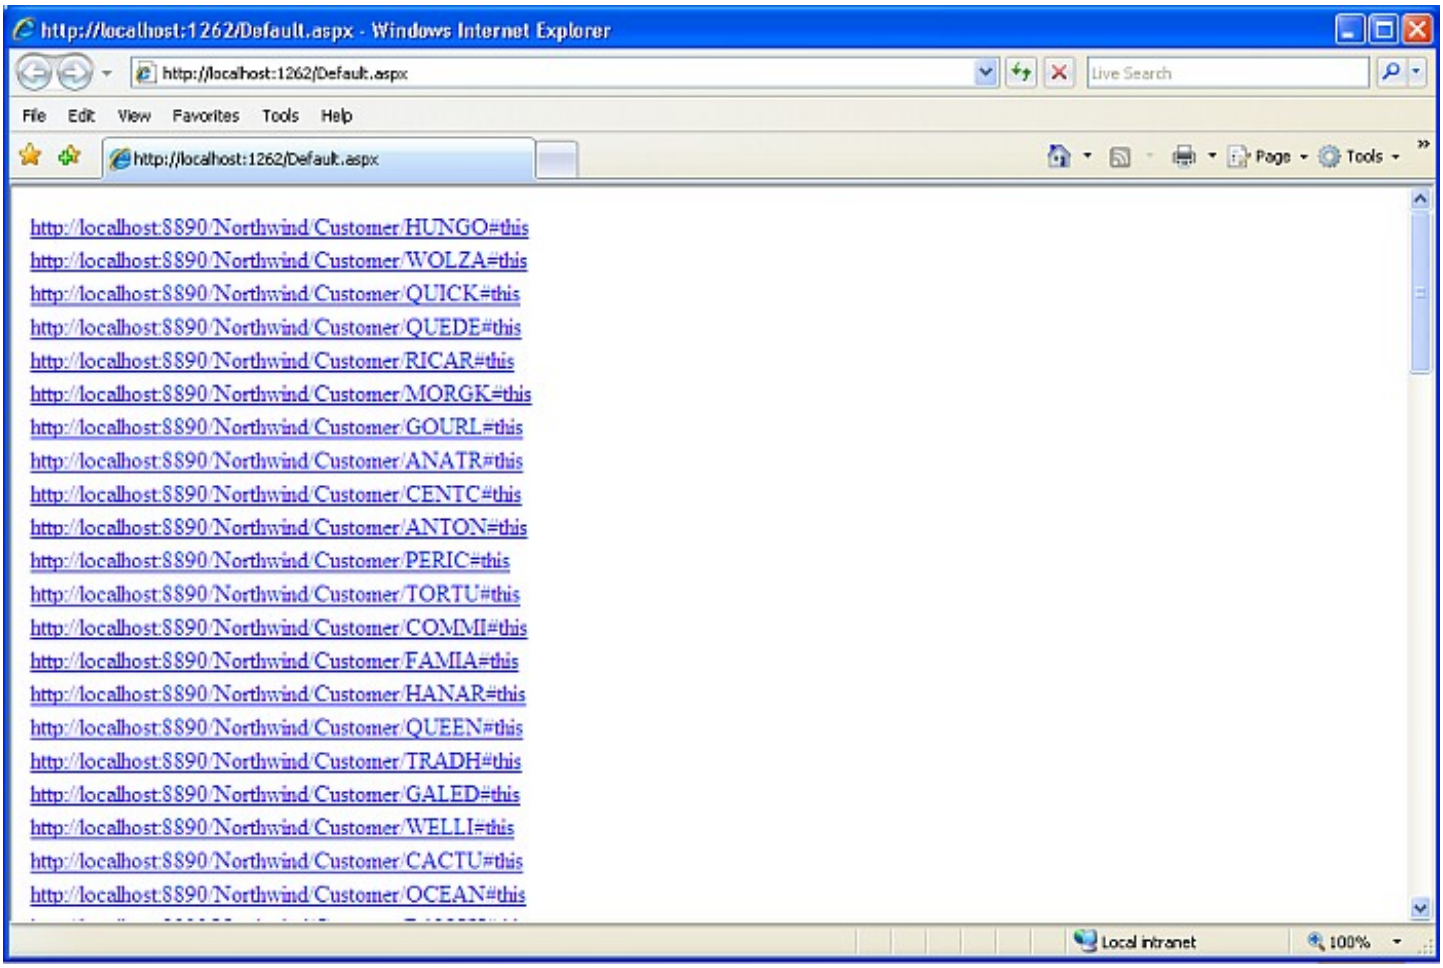
 foreach (DemoModel.sparqlview sv in query)
 {
     TableRow tRow = new TableRow();
     iriTable.Rows.Add(tRow);
```

```
        TableCell tCell = new TableCell();
        tRow.Cells.Add(tCell);
        HyperLink h = new HyperLink();
        h.Text = sv.s;
        h.NavigateUrl = sv.s;
        tCell.Controls.Add(h);
    }
```

Note the address of the service in the first line - you may need to change the port number to match the one seen in the address at the end of Step 4 in Creating the Web Service.

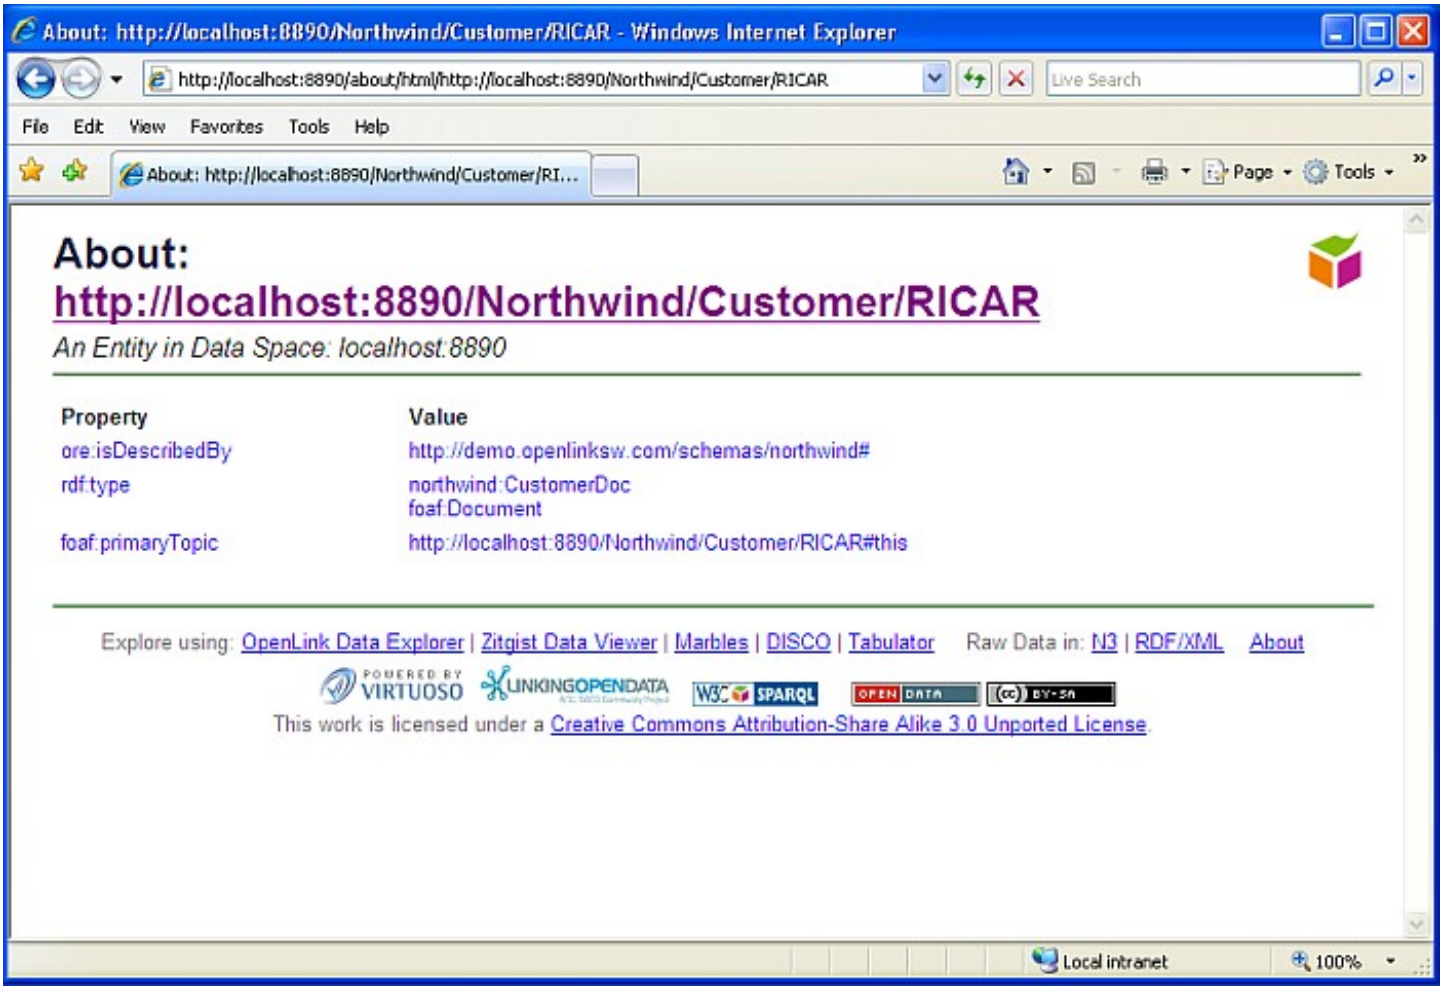
Compile and run RDFWebApp (ensuring that the service created above is still running). This will launch a browser and display the IRIs from sparqlview as a list of hyperlinks.

Figure 2.164. list of hyperlinks



With the Cartridges VAD package installed in Virtuoso, clicking on these links will take you to a description page of the referenced resource. The description page is created using description.vsp .

Figure 2.165. Description page



2.10.4. Deploy With IIS

To create and test this simple Web Service we have used the Visual Studio Development Server. This section describes how to deploy the service using IIS.

Web Service

To deploy the service using IIS:

- Open the RDFWebDemo project in Visual Studio, go to the

  Project

  menu and select RDFWebDemo

  Properties

  .
- Select the

  Web

  tab and scroll down to the

  Servers

  section. Select

  Use local IIS Server

. The project URL defaults to using localhost.
- Click the

  Create Virtual Directory

  button then check that the Service works on localhost.
- Build the project then start without debugging (ctrl F5).

The start page that you see when you test the service will look the same as before but the address in the browser bar will be something like http://example.com/RDFWebDemo1/WebDataService1.svc/. You can now access your service remotely using the hostname or IP address of your server.

If at this point you get an Access is denied error, 401.3, then you will need to add the Internet Guest Account (IUSR_XXX where XXX is your computer name) to the users allowed to access the folder containing the RDFWebDemo project.

Web Application

You will now need to modify RDFWebApp to access the service at the new address. At the same time we will also change RDFWebApp so that it too is deployed using IIS

- Open The RDFWebApp project in Visual Studio.
- Go to the

  Project

  menu and select RDFWebApp

  Properties

  .
- Select the

  Web

  tab and scroll down to the

  Servers

  section. Select

  Use local IIS Server

  . The project URL defaults to using localhost.
- Click the

  Create Virtual Directory

  button. The web application will then run on the local IIS.

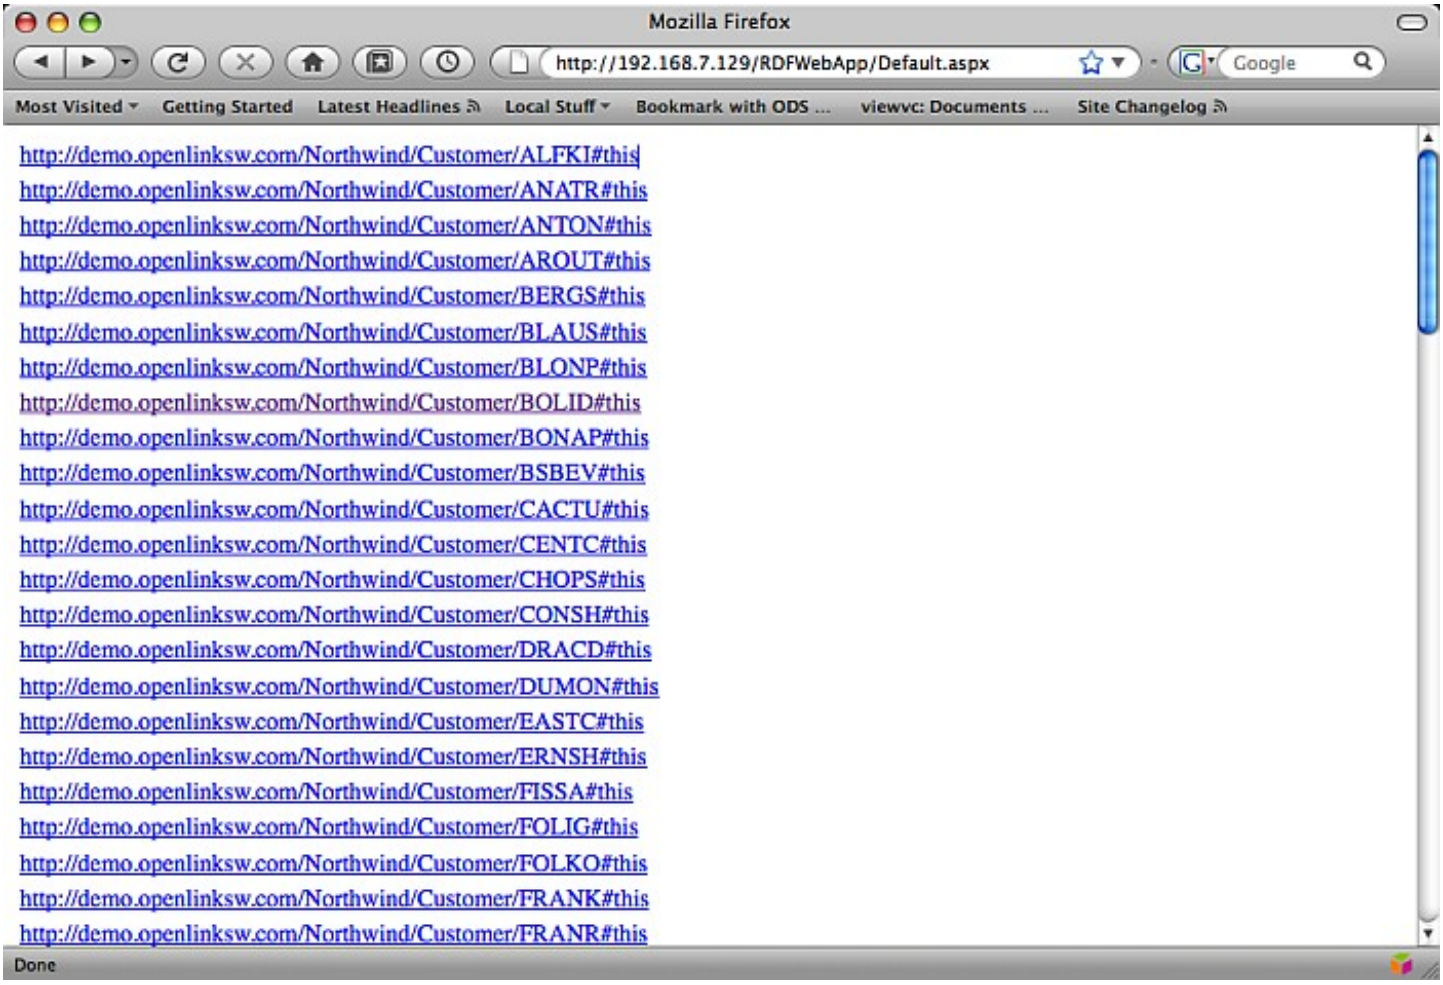
  ```
  DemoModel.DemoEntities svc = new DemoModel.DemoEntities(new Uri("http://example.com/WebDataService
  ```

  to

  ```
  DemoModel.DemoEntities svc = new DemoModel.DemoEntities(new Uri("http://example.com/RDFWebDemo/Web
  ```
- To reference the web service running on IIS you will need to edit Default.aspx.cs. Change
- Build the project then start without debugging (ctrl F5).

The web application is accessible on http://example.com/RDFWebApp/Default.aspx and can also be accessed using the hostname or IP address of you server e.g. http://192.168.7.129/RDFWebApp/Default.aspx

Figure 2.166. Default.aspx



Next Steps

The next example shows you how to quickly create an ADO.Net Data Service that exposes RDF data in Virtuoso and how to create a basic Web application to consume that service. The next step is to create a Silverlight Application to consume the same service .

2.11. Creating a Silverlight Application to consume the service

This section will guide you through creating an application for Silverlight that will consume the ADO.Net Data Service created in Creating a Web Browser Application to Access RDF Data Using The Virtuoso ADO.Net Provider.

2.11.1. Pre-requisites

1. The Microsoft Silverlight 2 Tools for Visual Studio 2008 SP1
2. The ADO.Net Data Service created in Creating a Web Browser Application to Access RDF Data Using The Virtuoso ADO.Net Provider.
3. The Visual Studio project used to create the ADO.Net Data Service.

2.11.2. Creating the Application for Silverlight.

1. Open the ADO.Net Data Service project in

   Visual Studio
2. In the

   Solution Explorer

   right click on the RDFWebDemo solution and add a new Project.
3. In the

Add New Project

dialog select

Silverlight Application

and click

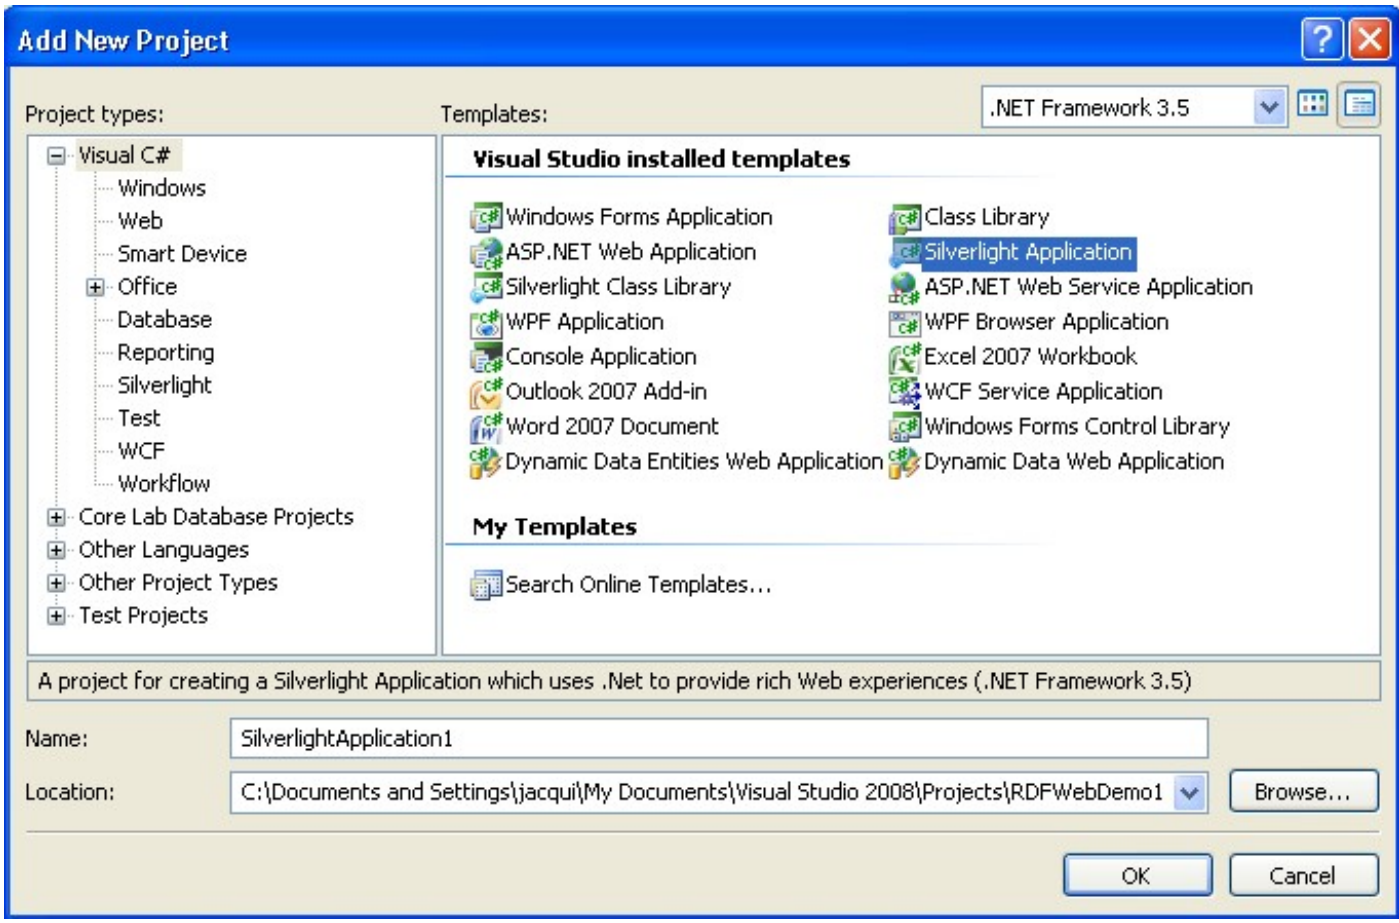
OK

. This will open the

Add Silverlight Application

dialog.

Figure 2.167. Add Silverlight Application



4. Select

   Link this Silverlight Control into an existing Web Site

   and make sure the Web Site selected is RDFWebDemo. Select

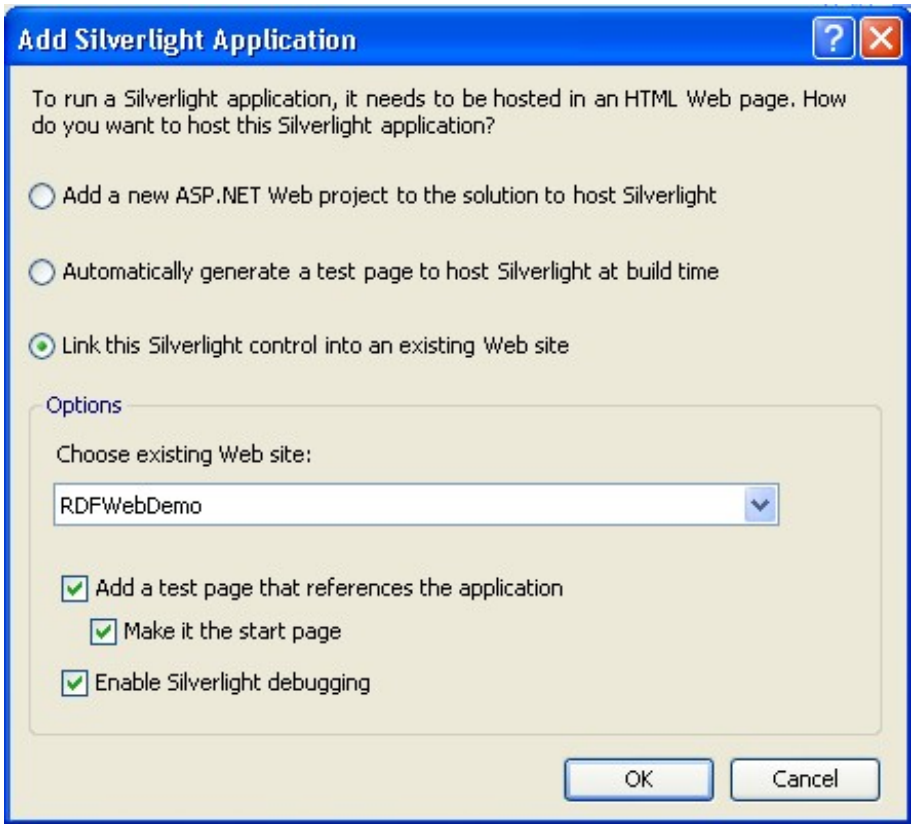
   Add a test page that references the application

   and

   Make it the start page

   .

Figure 2.168. Add a test page



5. In Solution Explorer, select RDFWebDemo, open the Project menu and select Properties.
6. Select the

   Web

   tab, and select

   Specific Page

   in the

   Start Action

   section. Click on the ellipsis and select SilverlightApplication1TestPage.html as the start page.
7. Add a reference to the data service. In the

   Solution Explorer

   right click on SilverlightApplication1 and select

   Add Service Reference
8. In the

   Add Service Reference

   dialog click the

   Discover

   button. Your ADO.Net Data Service should appear in the Address box and the Services box.
9. Select the service and click

OK

. ServiceReference1 will now be added to the ServiceReferences.

10. Open page.xaml.cs and add references to the service and to the System.Data.Services.Client assembly by adding the following using statements at the top of the file:

```
using System.Data.Services.Client;
using SilverlightApplication1.ServiceReference1;
```

11. We need at create a data service context to reference the data from the service and to load data from the view, sparqlview, exposed by the service. Add the following lines to the page constructor after InitializeComponent()

```
DataServiceContext svcCtx = new DataServiceContext(new Uri("WebDataService1.svc", UriKind.Relative
svcCtx.BeginExecute<sparqlview>(new Uri("sparqlview", UriKind.Relative), loadSCallback, svcCtx);
```

12. Add the loadSCallback method to the page class. The method loads the data from sparqlview and puts it in a List. This List populates a list box on the page.

```
private void loadSCallback(IAsyncResult asyncResult)
{   List<Uri> uList = new List<Uri>();
    DataServiceContext ctx = asyncResult.AsyncState as DataServiceContext;
    foreach (sparqlview sv in ctx.EndExecute<sparqlview>(asyncResult))
     uList.Add(new Uri(sv.s));
    listBox1.DataContext = uList;
}
```

13. Add the list box to the page. In the

Solution Explorer

double click on page.xaml to open it in the editor. Add the following code between the <grid> and </grid> tags.

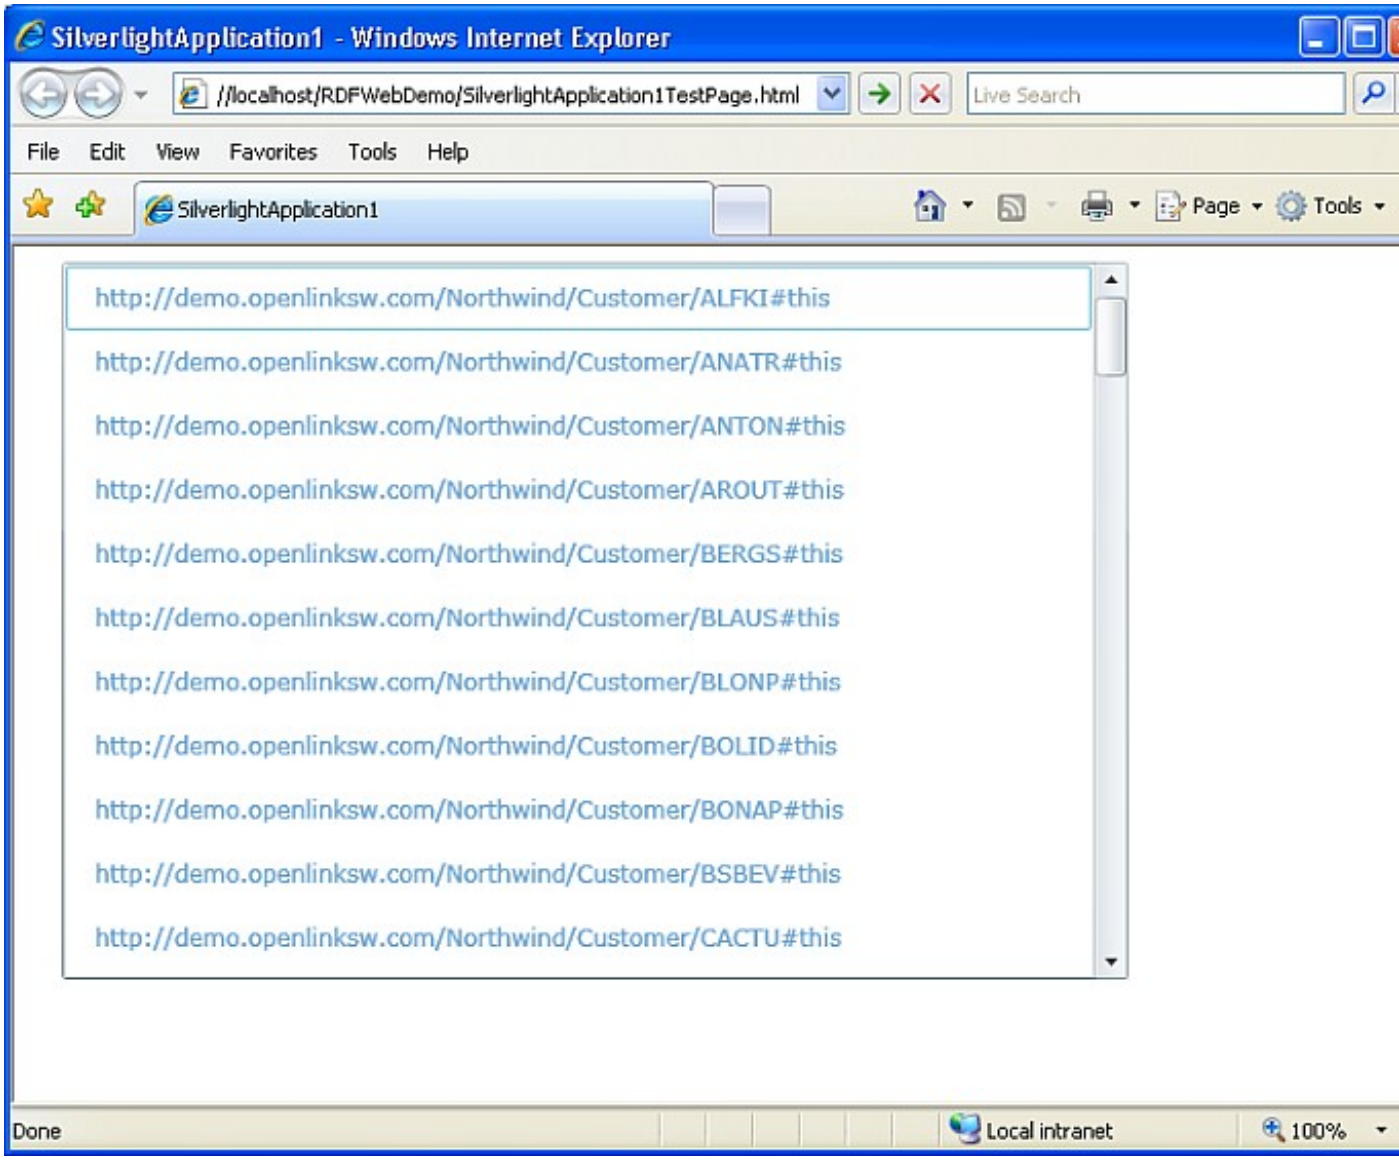
```
<ListBox x:Name="listBox1"
    HorizontalAlignment="Stretch"
    Margin="25,8,26,-78" Grid.RowSpan="1"
    Grid.Row="0" VerticalAlignment="Stretch"
    ItemsSource="{Binding Mode=OneWay}" >
    <ListBox.ItemTemplate>
        <DataTemplate>
            <StackPanel x:Name="DisplayListData"
             Orientation="Horizontal"
             VerticalAlignment="Bottom"
             Margin="5" >
                <HyperlinkButton
                 Content ="{Binding}"
                 NavigateUri="{Binding}"
                 Margin="5,0,0,0"
                 VerticalAlignment="Bottom"
                 HorizontalAlignment="Left"
                 FontSize="12">
                </HyperlinkButton>
            </StackPanel>
        </DataTemplate>
    </ListBox.ItemTemplate>
</ListBox>
```

14. Build the Silverlight application and launch without debugging using

Ctrl F5

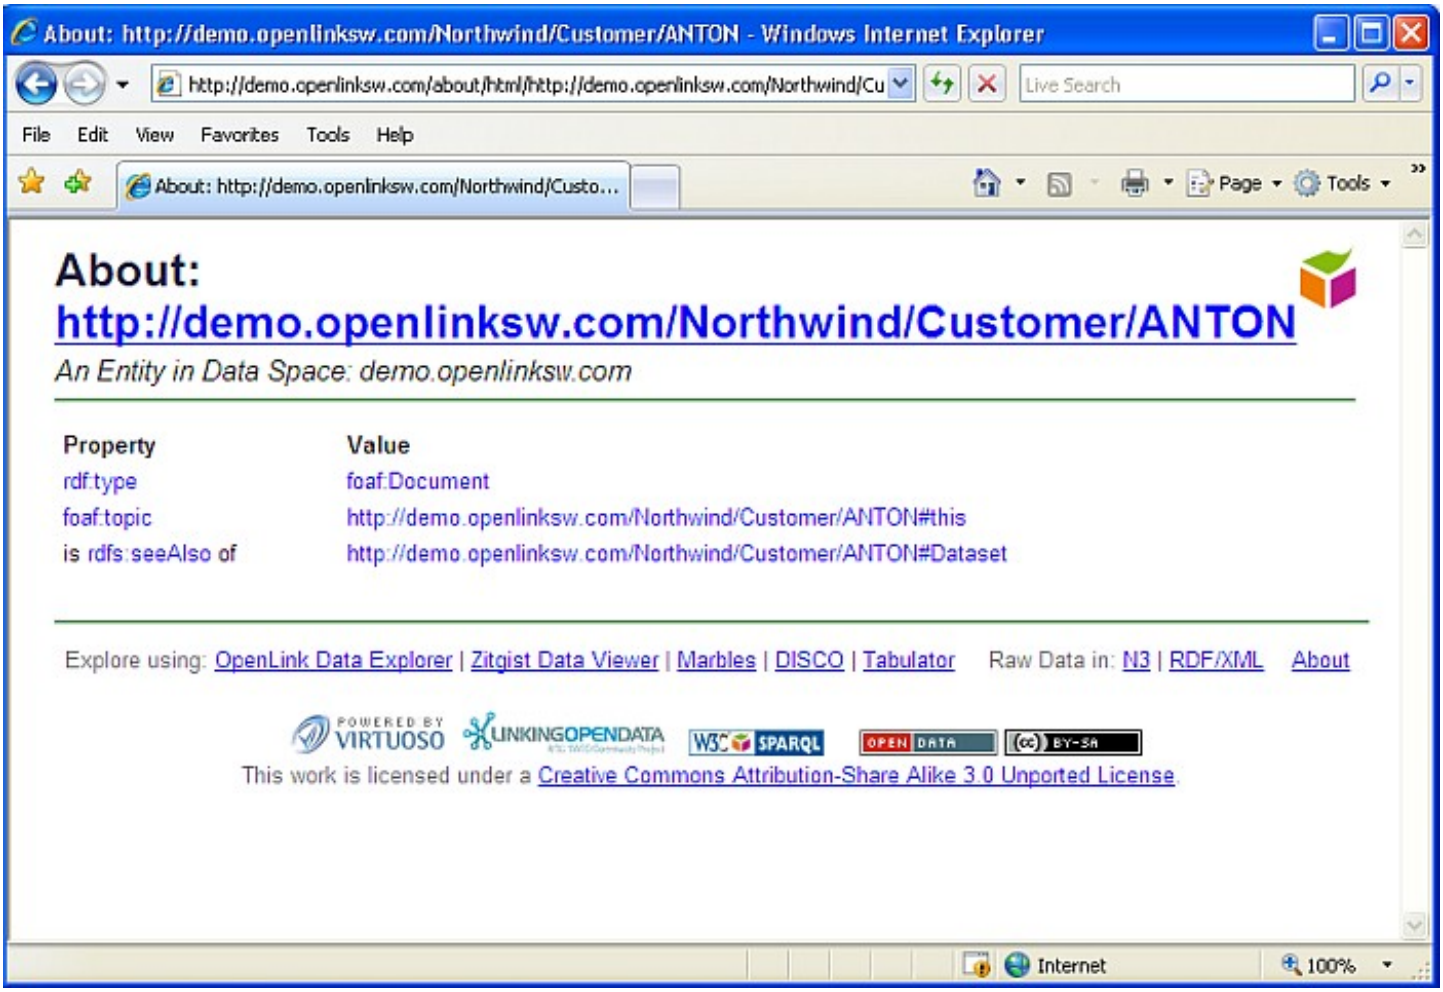
. This will launch the browser and open SilverlightApplication1TestPage.aspx.

Figure 2.169. SilverlightApplication1TestPage.aspx



Clicking on one of the IRIs will open the page using description.vsp.

Figure 2.170. using description.vsp



2.12. Creating A Simple .NET RIA Services Application To Display Data From Virtuoso

.NET RIA Services is a new framework from Microsoft that simplifies the development of n-tier web applications. A typical application will consist of a presentation layer, application logic and a data access layer. In these examples a combination of Silverlight 3 and .NET RIA Services will provide the presentation layer and application layer while the data will reside in Virtuoso and be accessed using the Virtuoso ADO.NET provider. The first example demonstrates how to display data from the Employee table in the Demo database in a grid on a web page. The second example shows how to display IRIs from the Linked Data Views of the demo data. The IRIs are used to create hyperlinks that are the starting point for exploring the linked data.

2.12.1. Pre-requisites

1. The example assumes that you have a local Virtuoso server with the Northwind demo database installed. If the demo database is not already installed then download the demo database VAD package (demo_dav.vad) and install it. The VAD package will create a new database in Virtuoso called demo containing the familiar Northwind tables. It will also creates Linked Data Views of the Northwind tables. In the example we assume the database is accessible on a hostname of "demo.openlinksw.com" on the default port 80, where an actually live instance of the Virtuoso Demo database is hosted. Users would use the appropriate hostname and port number of their Virtuoso installation to create the sample application, and would be would be example.com for a default installation or whatever the URIQA DefaultHost Virtuoso configuration parameter is set to when the demo database VAD package is installed.
2. The Virtuoso ADO.Net provider for .Net 3.5 and the Entity Framework.
3. Microsoft Visual Studio 2008
4. The Virtuoso Cartridges VAD package .
5. Silverlight 3 Tools for Visual Studio 2008 SP1 .
6. Microsoft .NET RIA Services July 2009 Preview .

2.12.2. Creating the Application

Step 1 - Create the Visual Studio Projects.

1. Open

   Visual Studio

   and create a new

   Silverlight Application

   project. Call the project DemoApplication.
2. In the New Silverlight Application dialog ensure that

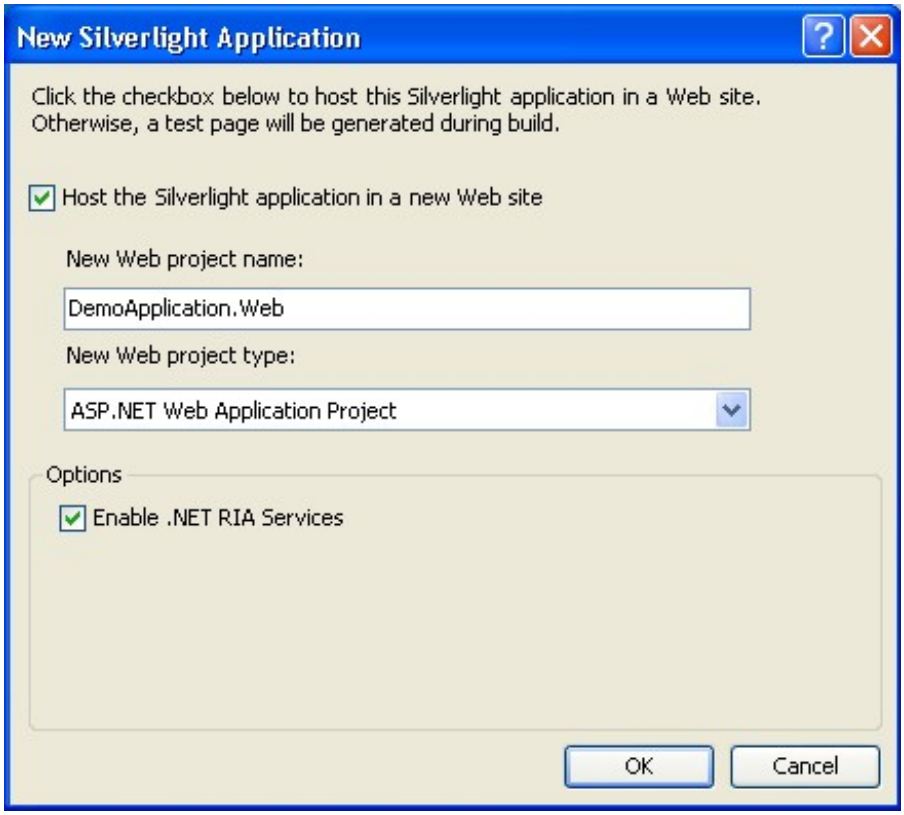
   Enable .NET RIA Services

   is checked. Click the

   OK

   button.

   Figure 2.171. .NET RIA Services Application



At this point a skeleton solution is created that consists of a client project called DemoApplication and a server project called DemoApplication.Web. This application will use data from the Virtuoso database. We add the data and its schema to the application by adding an ADO.NET entity data model to the server project.

Step 2 - Add the Data Model

1. Right click the server project in the

   Solution Explorer

and

Add New Item

. In the dialog box select

ADO.NET Entity Data Model

and call it demo.edmx. Click the

Add

button. This will open the

Entity Data Model Wizard

.

2. Choose

   Generate From Database

   and click

   Next

   .
3. Set up a connection to the Demo database on your local Virtuoso Server, select

   Yes, include the sensitive data in the connection string

   and set the name of the entities to DemoEntities. Click

   Next

   .
4. On the

   Choose Your Database Objects

   page expand

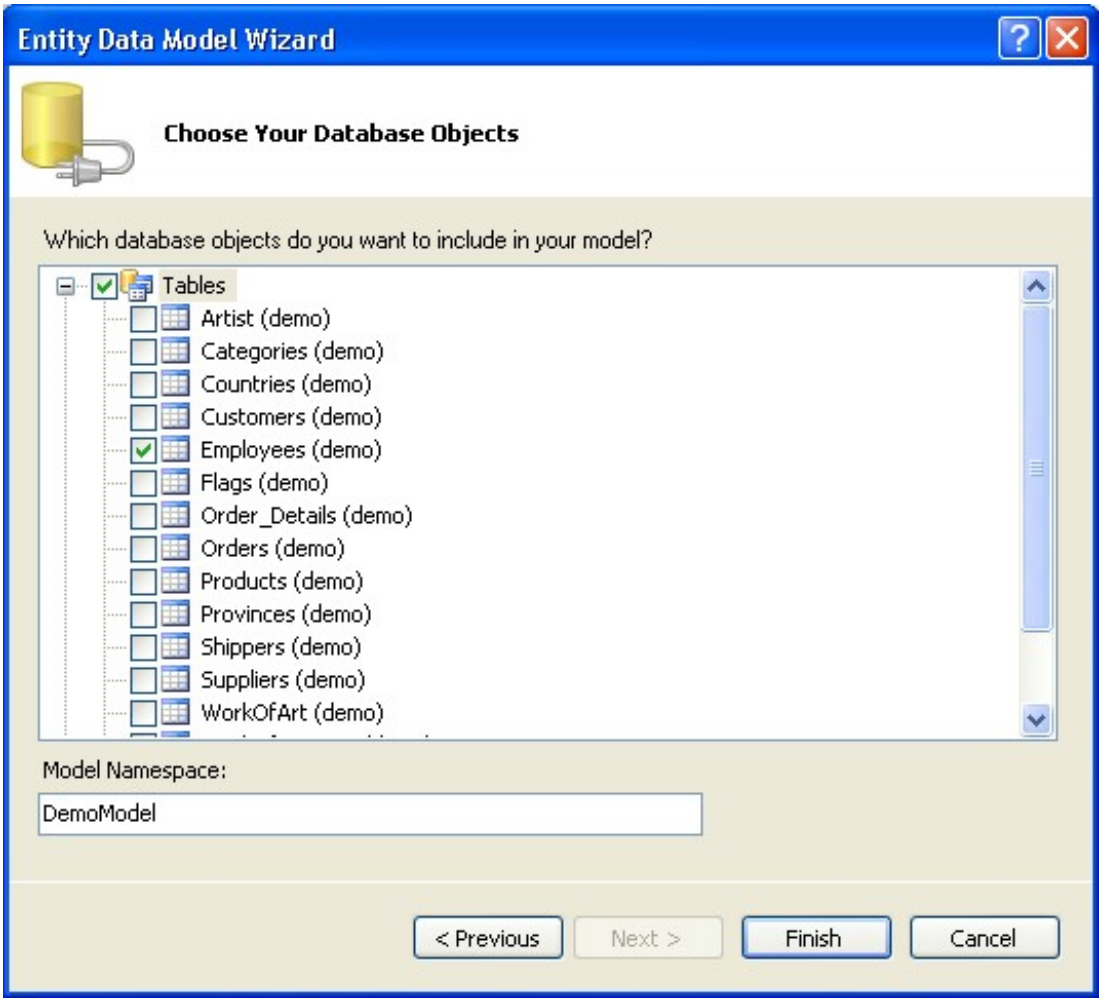
   Tables

   and select Employees. Check that the Model Namespace is DemoModel and click

   Finish

   .

Figure 2.172. .NET RIA Services Application



We want to make the entities in the model available to both the client and server parts of the solution. To do this we need to add a DomainService to the solution. However, to make the entities from the data model available to the domain service we must first build the solution.

Step 3 - Add a Domain Service.

1. First build the solution.
2. Right click the server project in the

   Solution Explorer

   and

   Add New Item

   . In the dialog box choose

   Domain Service Class

   from the Templates pane and call it EmployeeService.cs. Click

   Add

   . This will open the

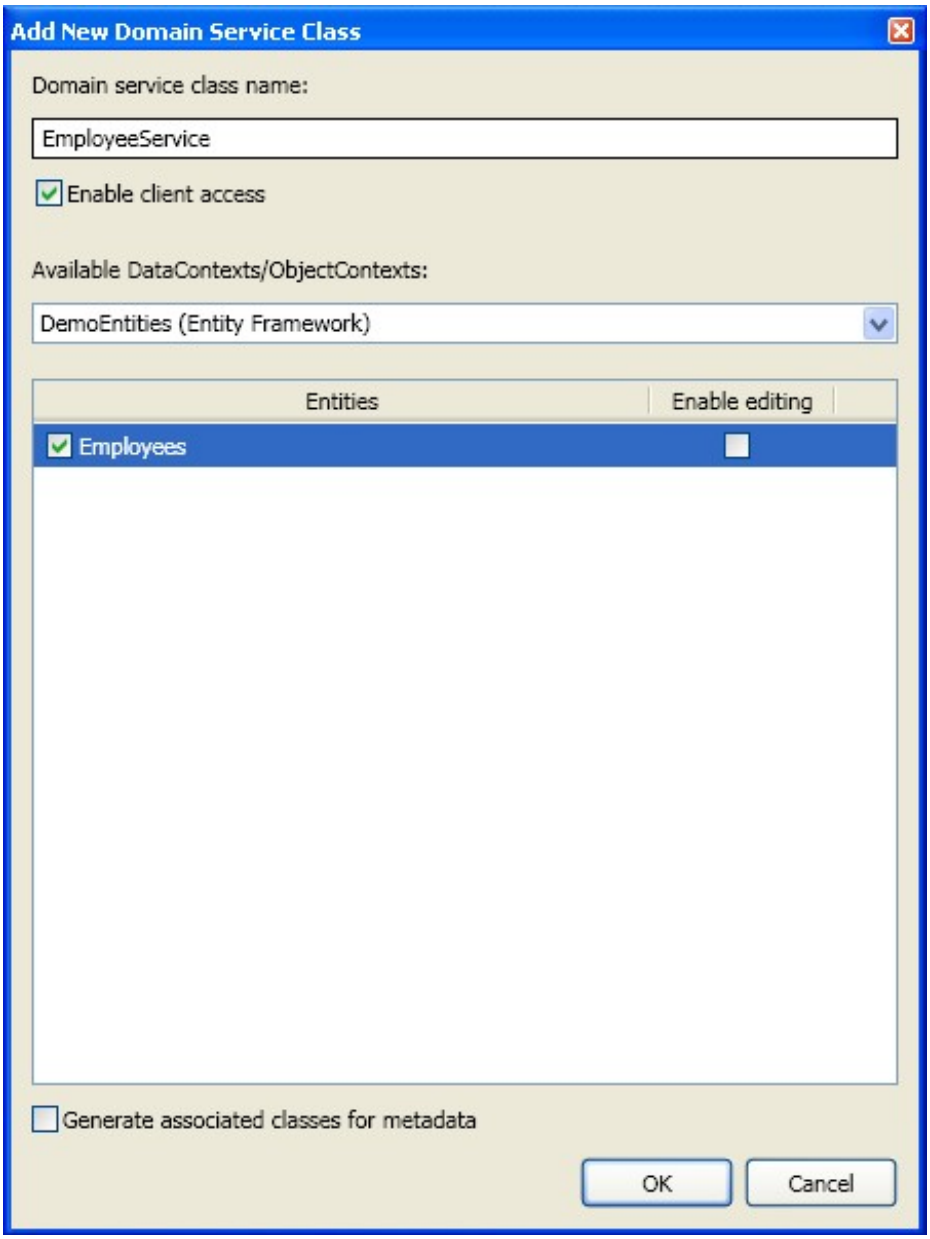
   Add New Domain Service Class

   dialog.
3. The entities from the model we have just added to the project are listed under

Entities

. Tick the box next to Employees. and click OK.

Figure 2.173. .NET RIA Services Application



This will create the DomainService class and generated code in both the client and server parts of the application. The Silverlight client can now interact with the data through the DomainContext class in the client project. At this point you need to build the solution again.

Step 4 - Display The Data

1. From the

   Silverlight XAML Controls

   in the

   Toolbox

   drag a

DataGrid

between the <Grid> </Grid> tags on MainPage.xaml in the client. Call the grid EmployeeGrid.

```
<data:DataGrid Name="EmployeeGrid"></data:DataGrid>
```

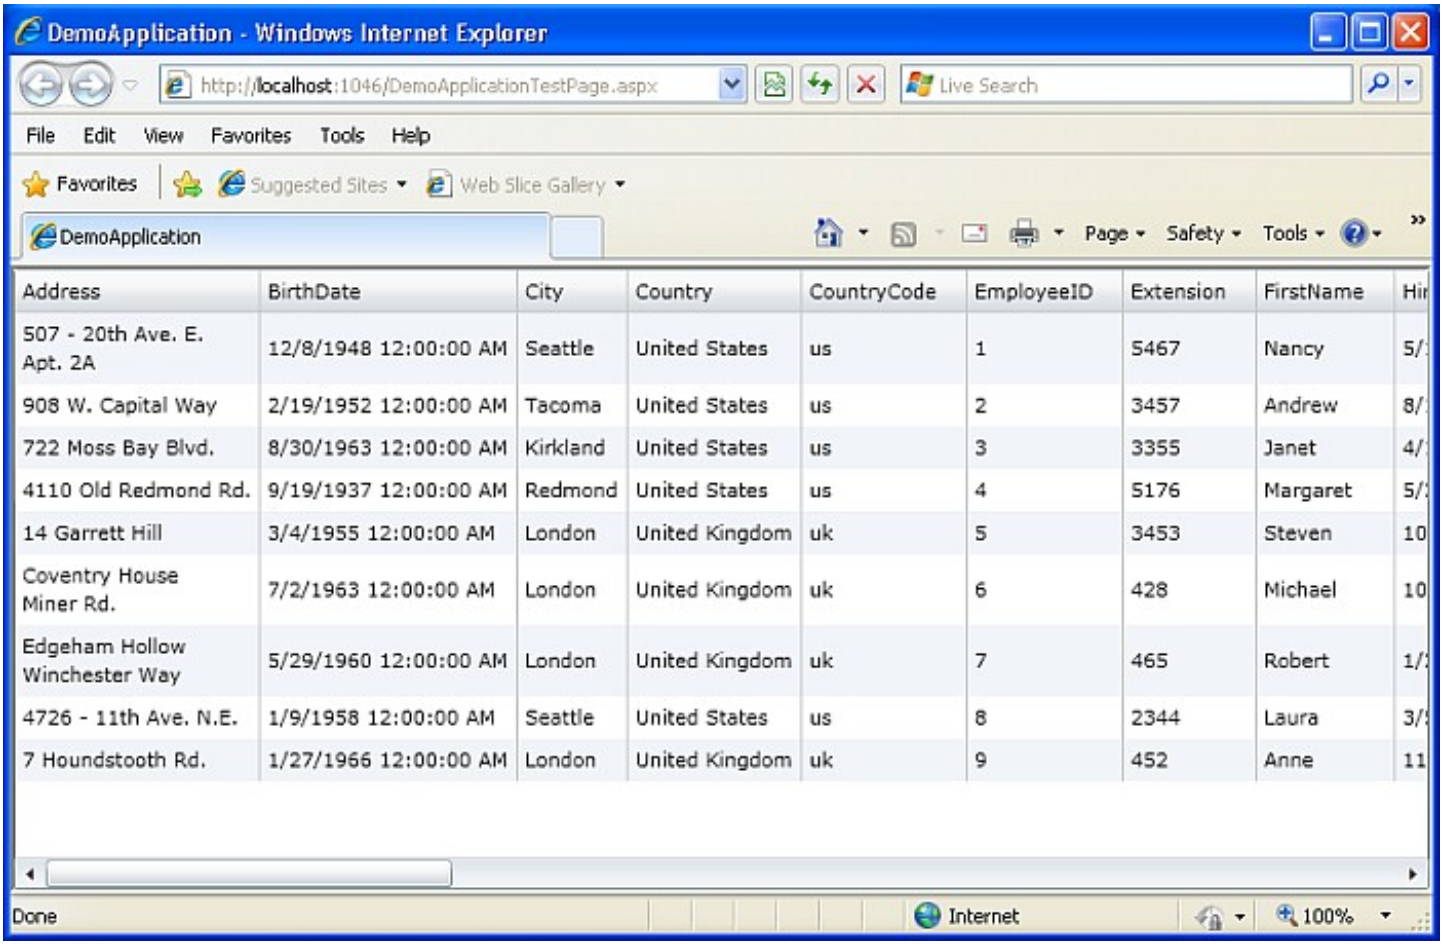
2. Instantiate the DomainContext to get the list of employees and add them to the grid by adding code to MainPage.xaml.cs so it looks like this:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Net;
using System.Windows;
using System.Windows.Controls;
using System.Windows.Documents;
using System.Windows.Input;
using System.Windows.Media;
using System.Windows.Media.Animation;
using System.Windows.Shapes;
using DemoApplication.Web;
using System.Windows.Ria.Data;

namespace DemoApplication
{
    public partial class MainPage : UserControl
    {
        private EmployeeContext _employeeContext = new EmployeeContext();
        public MainPage()
        {
            InitializeComponent();
            LoadOperation<Employees> LoadOp =
                this._employeeContext.Load(this._employeeContext.GetEmployeesQuery());
            this.EmployeeGrid.ItemsSource = LoadOp.Entities;
        }
    }
}
```

3. Build and run the application. Internet Explorer will be launched and you will see the data displayed on the page as a grid.

Figure 2.174. .NET RIA Services Application



Address	BirthDate	City	Country	CountryCode	EmployeeID	Extension	FirstName	Hir
507 - 20th Ave. E. Apt. 2A	12/8/1948 12:00:00 AM	Seattle	United States	us	1	5467	Nancy	5/
908 W. Capital Way	2/19/1952 12:00:00 AM	Tacoma	United States	us	2	3457	Andrew	8/

2.12.3. Displaying RDF Data

One advantage of using Virtuoso as the data store is the seamless way in which we can use this use this application to display dereferencable IRIs and explore RDF linked data.

The Virtuoso SPASQL interface allows RDF data in the Virtuoso Quad store to be queried using SPARQL from any SQL interface by simply prefixing the SPARQL query with the keyword SPARQL. We will use the SPASQL interface to create a view containing the IRIs of the Employees in the the Demo RDF data in Virtuoso.

Step 1 - Create the View in Virtuoso

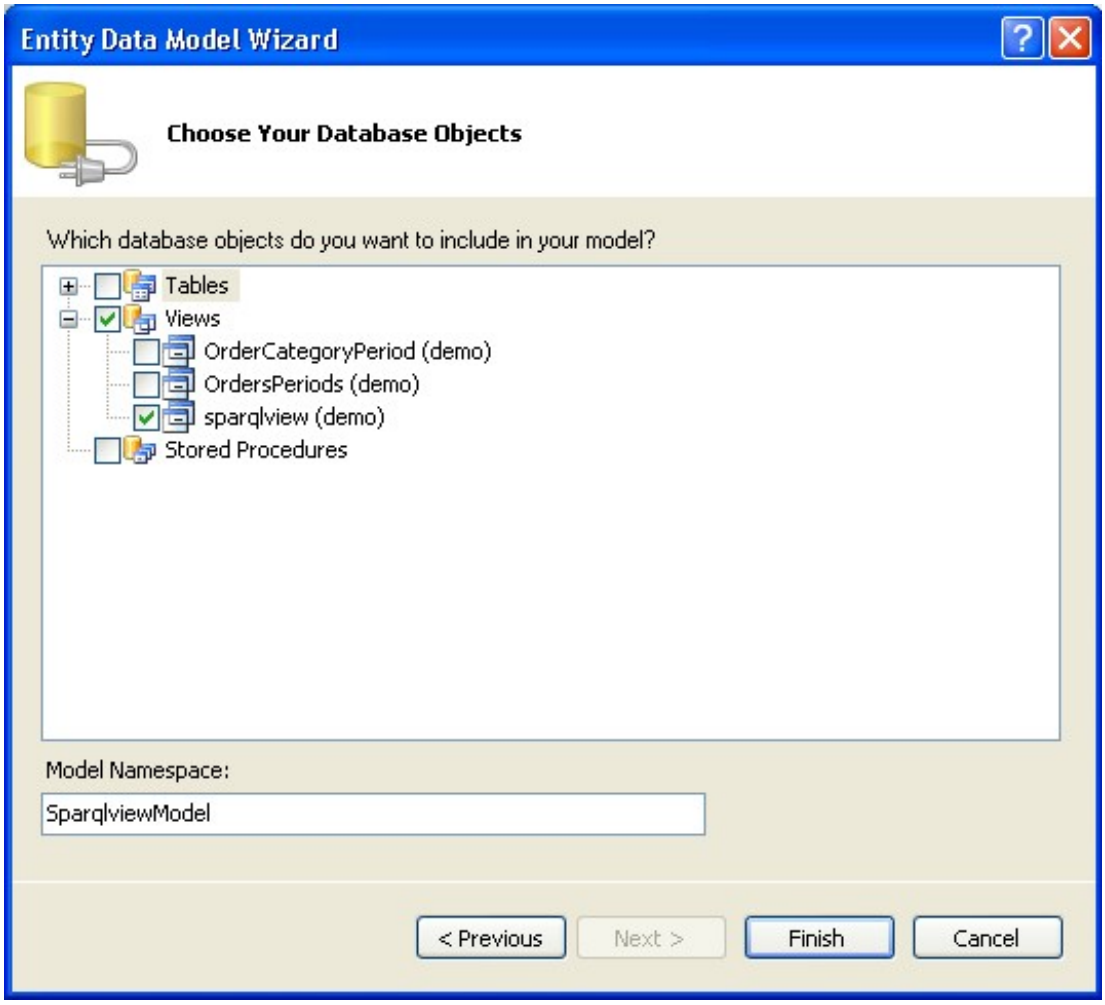
1. Open the Virtuoso Conductor.
2. In isql execute the following statement. Remember to use the appropriate hostname and port number of your Virtuoso installation, typically example.com for a default installation or whatever the URIQA DefaultHost Virtuoso configuration parameter was set to when the demo database VAD package was installed.

```
CREATE VIEW Demo.demo.sparqlview as
SPARQL
PREFIX nwind: <http://demo.openlinksw.com/schemas/northwind#>
SELECT DISTINCT  ?s
FROM <http://demo.openlinksw.com/Northwind>
WHERE
  {
    ?s a nwind:Employee
  }
```

Step 2 - Modify the Solution To use the View

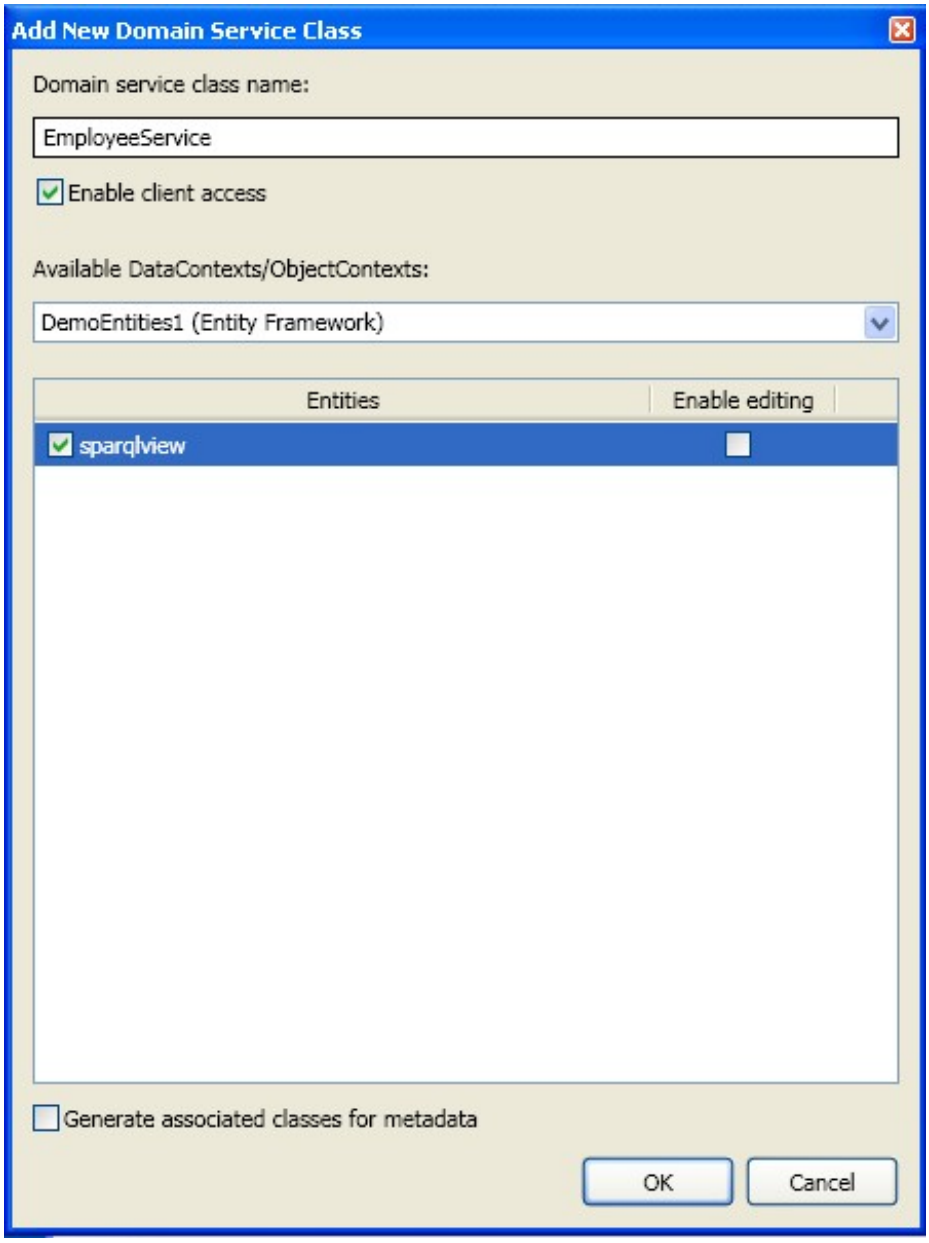
1. Delete the existing Employee model and add a new one that comprises this new view.

Figure 2.175. .NET RIA Services Application



2. Delete the DomainService. Build the solution and add a new DomainService called EmployeeService. Select the sparqlview entity. Build the solution.

Figure 2.176. .NET RIA Services Application



3. Modify the code in mainpage.xaml.cs so it uses the sparqview entity. It should look like this:

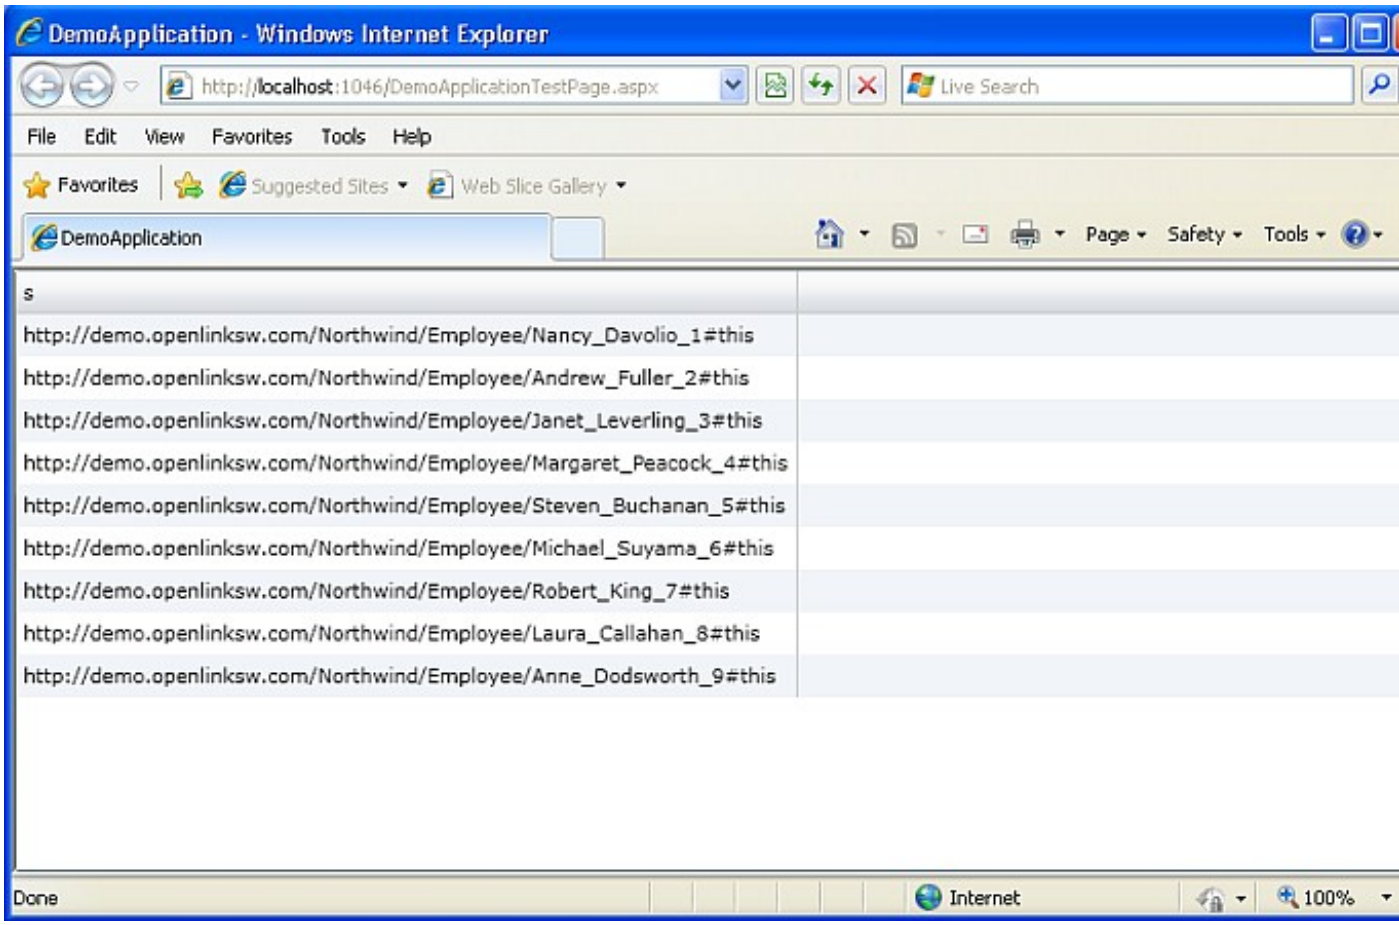
```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Net;
using System.Windows;
using System.Windows.Controls;
using System.Windows.Documents;
using System.Windows.Input;
using System.Windows.Media;
using System.Windows.Media.Animation;
using System.Windows.Shapes;
using DemoApplication.Web;
using System.Windows.Ria.Data;

namespace DemoApplication
{
    public partial class MainPage : UserControl
    {
        private EmployeeContext _employeeContext = new EmployeeContext();
        public MainPage()
        {
            InitializeComponent();
            LoadOperation<sparqlview> LoadOp =
                this._employeeContext.Load(this._employeeContext.GetSparqlviewQuery());
```

```
                this.EmployeeGrid.ItemsSource = LoadOp.Entities;
            }
        }
    }
```

4. Build and run the application. You will see a list of IRIs that identify the Northwind employees.

Figure 2.177. .NET RIA Services Application



To realize the power of linked data we would now liked to begin exploring this data by clicking on these IRIs.

Step 3 - Make Hyperlinks From IRIs

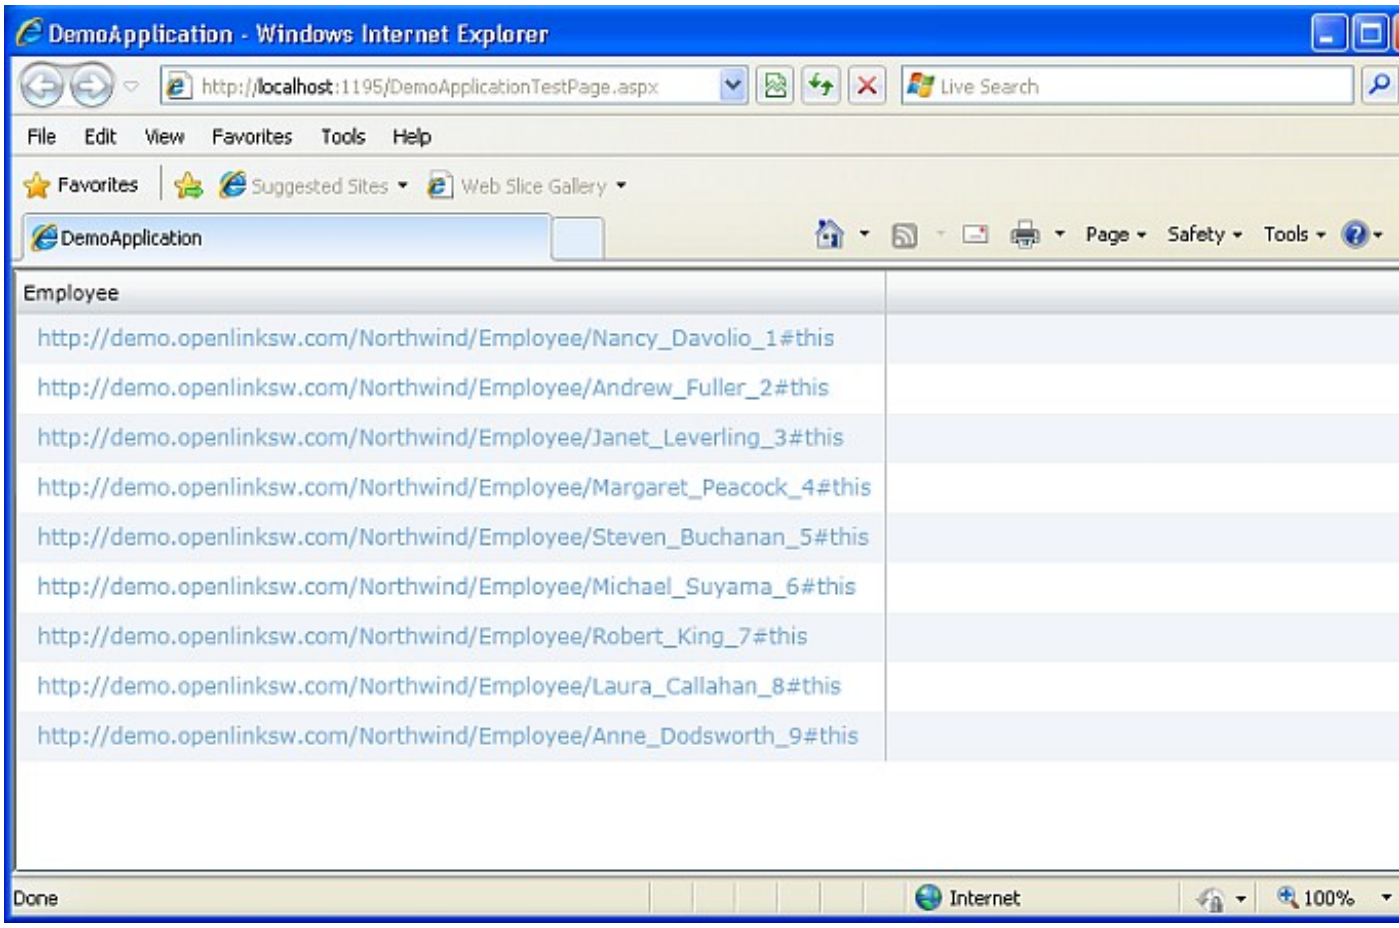
1. Modify the DataGrid in MainPage.xaml to bind the IRI in each cell of the grid to a Hyperlink button. We set the AutoGenerateColumns property of the DataGrid to False then add our own Template for the column. MainPage.xaml should look like this:

```
<UserControl xmlns:data="clr-namespace:System.Windows.Controls;assembly=System.Windows.Controls.Da
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    xmlns:d="http://schemas.microsoft.com/expression/blend/2008" xmlns:mc="http://schemas.openxmlf
    mc:Ignorable="d" d:DesignWidth="640" d:DesignHeight="480">
  <Grid x:Name="LayoutRoot">
      <data:DataGrid Name="EmployeeGrid" AutoGenerateColumns="False">
            <data:DataGrid.Columns>
                <data:DataGridTemplateColumn Header="Employee">
                    <data:DataGridTemplateColumn.CellTemplate>
                        <DataTemplate>
                            <StackPanel x:Name="DisplayEmployeeData"
                                        Orientation="Horizontal"
                                        VerticalAlignment="Bottom"
                                        Margin="5" >
                                <HyperlinkButton Content ="{Binding s}"
                                                 NavigateUri="{Binding s}"
                                                 Margin="5,0,0,0"
```

```
                                                VerticalAlignment="Bottom"
                                                HorizontalAlignment="Left"
                                                FontSize="12">
                                    </HyperlinkButton>
                                </StackPanel>
                            </DataTemplate>
                        </data:DataGridTemplateColumn.CellTemplate>
                    </data:DataGridTemplateColumn>
                </data:DataGrid.Columns>
            </data:DataGrid>
        </Grid>
    </UserControl>
```

2. If we build and run the project now each IRI in the list appears as a hyperlink.

Figure 2.178. .NET RIA Services Application



3. Clicking on each of the links takes you to a new document that contains further links to information about each Employee. The Demo dataset can be explored further by following the dereferenceable IRIs in the description pages.

Figure 2.179. .NET RIA Services Application

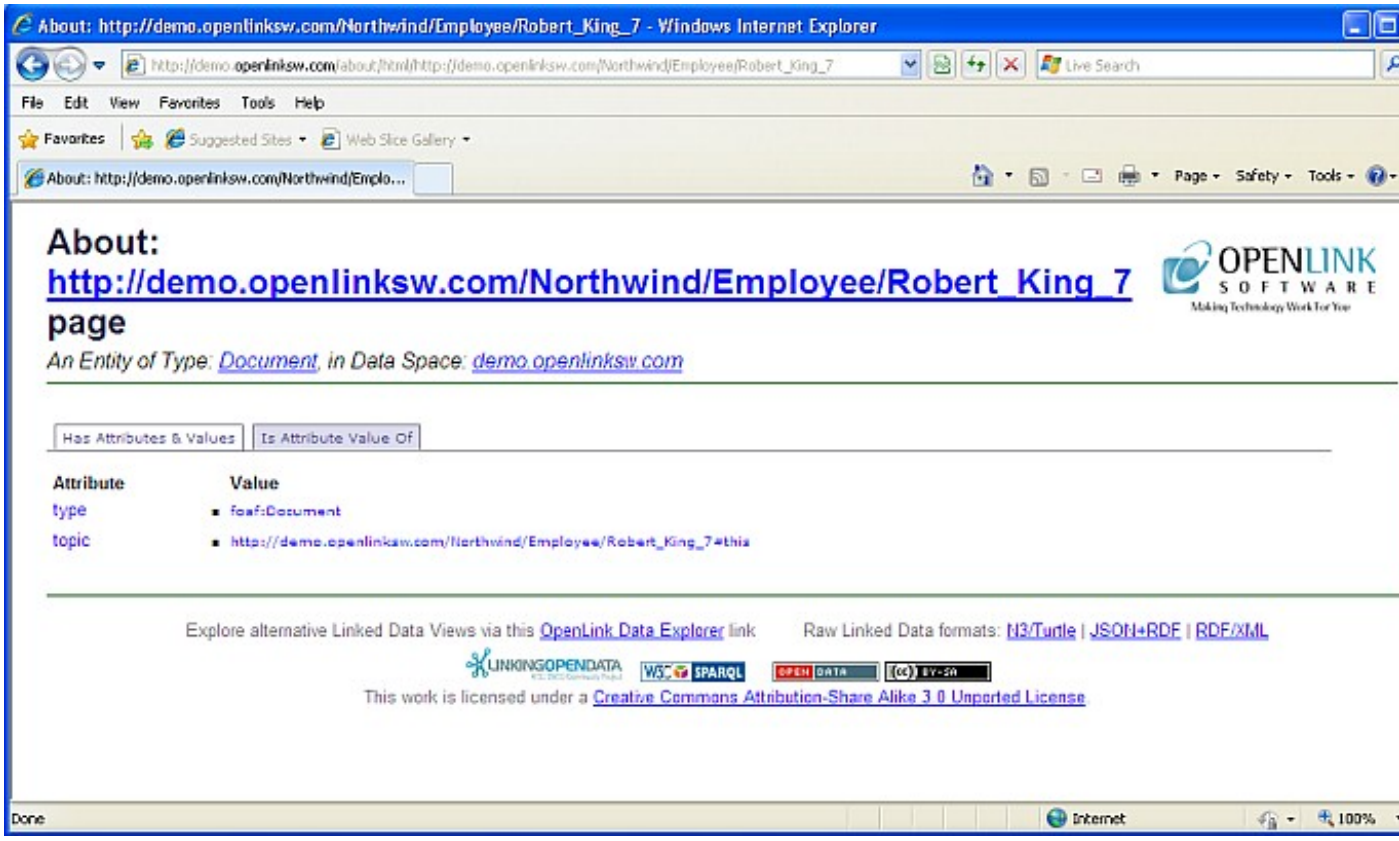


Figure 2.180. .NET RIA Services Application

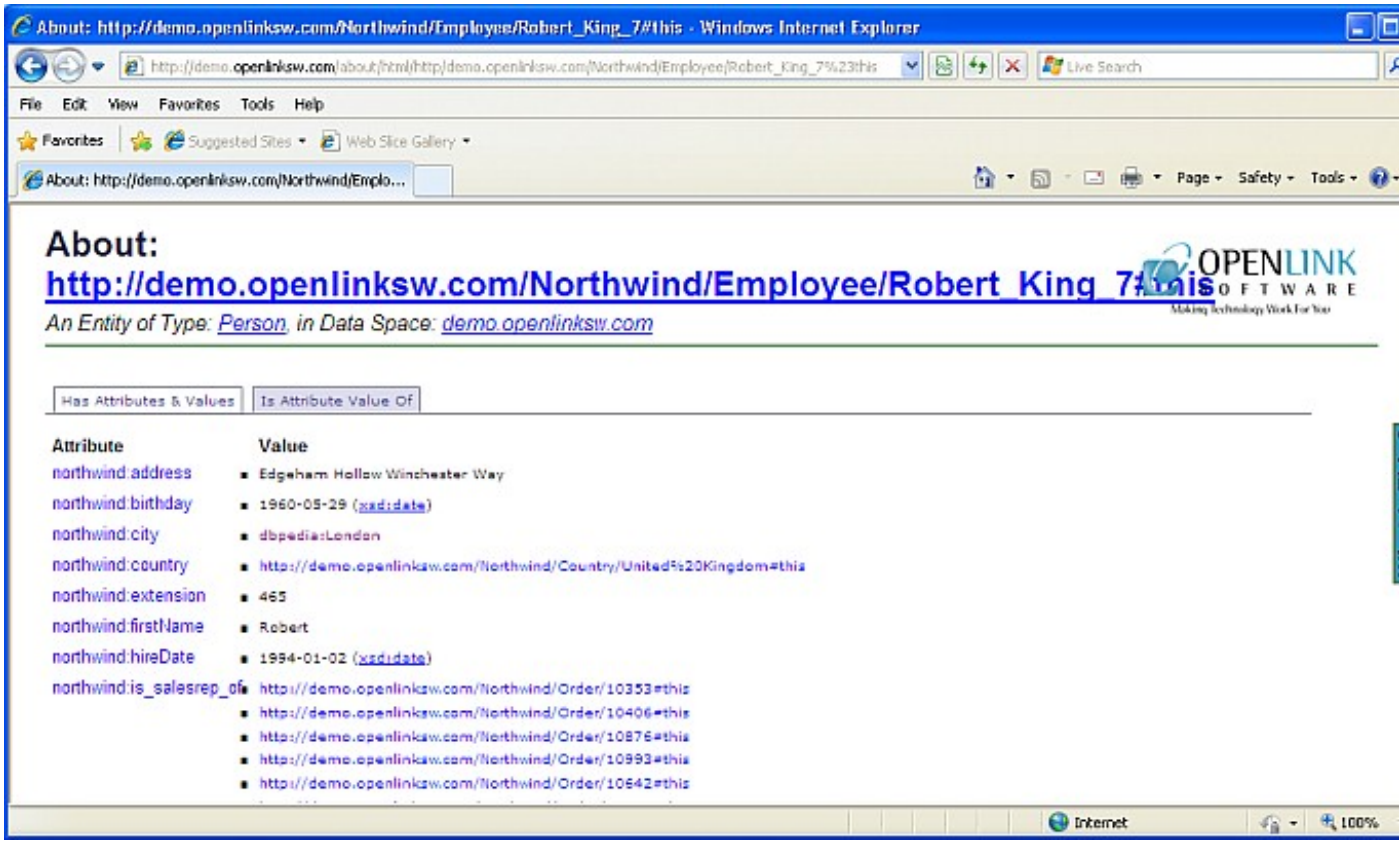


2.12.4. Next Steps

The examples in this document show you how to simply display data in a browser using Silverlight 3 and .NET RIA Services. See an example of a more complicated application.

2.13. Creating a .Net RIA Services Application That Will Update Virtuoso Data

This example demonstrates how data in Virtuoso can be updated from a Microsoft .NET RIA Services application. The example is a continuation of the first example in Creating a Simple .Net RIA Services Application to Display Data From Virtuoso .

2.13.1. Pre-requisites

1. A working copy of the application created in Creating a Simple .Net RIA Services Application to Display Data From Virtuoso .

2.13.2. Creating the Application

Step 1 - Add A New Domain Service Class

The EmployeeService Domain Service Class was only used to display data so was created read only. In this example we need to be able to update the data so we need to remove the read only Domain Service Class and create a new on.

1. In the

   Server Explorer

   right click EmployeeService and select

   Delete
2. Right click the server project and

   Add New Item

   . In the dialog box choose Domain Service Class from the Templates pane and again call it EmployeeService.cs. Click Add.
3. Select the Employees entity and tick

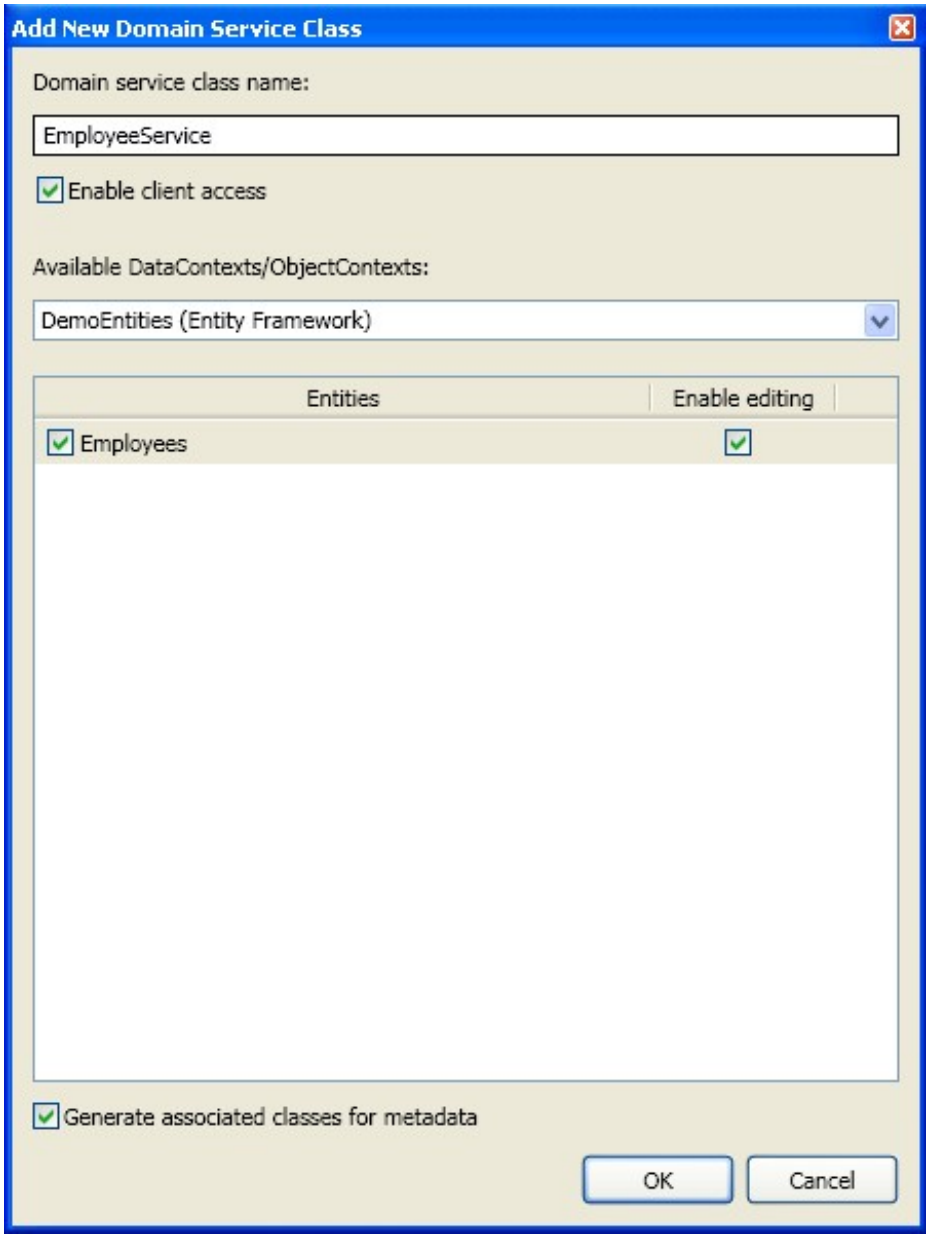
   Enable editing

   . Also tick

   Generated associated classes for metadata

   .

   Figure 2.181. .NET RIA Services Application



4. Update MainPage.xaml.cs to use EmployeeService2 the new domain service rather than EmployeeContext.

We want to create a master detail style page. To do this we will use the DomainDataSourceComponent from the Silverlight Components. But first we will add a pager so only 5 records are displayed at a time.

Step 2 - Add a DataPager

1. Add two new namespaces to MainPage.xaml

```
xmlns:riaControls="clr-namespace:System.Windows.Controls;assembly=System.Windows.Ria.Controls"
xmlns:ds="clr-namespace:DemoApplication.Web"
```

2. Use a DomainDataSource to provide the data to fill the grid. Add the following to MainPage.xaml before the DataGrid.

```
<riaControls:DomainDataSource x:Name="EmployeeDataSource"
                              QueryName="GetEmployeesQuery"
                              LoadSize="10"
                              AutoLoad="True">
    <riaControls:DomainDataSource.DomainContext>
        <ds:EmployeeService2/>
    </riaControls:DomainDataSource.DomainContext>
</riaControls:DomainDataSource>
```

3. Update the MainPage.xaml.cs code behind file. Using the DomainDataSource means you no longer need to instantiate the context and load the grid in MainPage.xaml.cs so it becomes:

```
public partial class MainPage : UserControl
{
    public MainPage()
    {
        InitializeComponent();
    }
}
```

4. Set the binding source of the DataGrid to the DomainDataSource

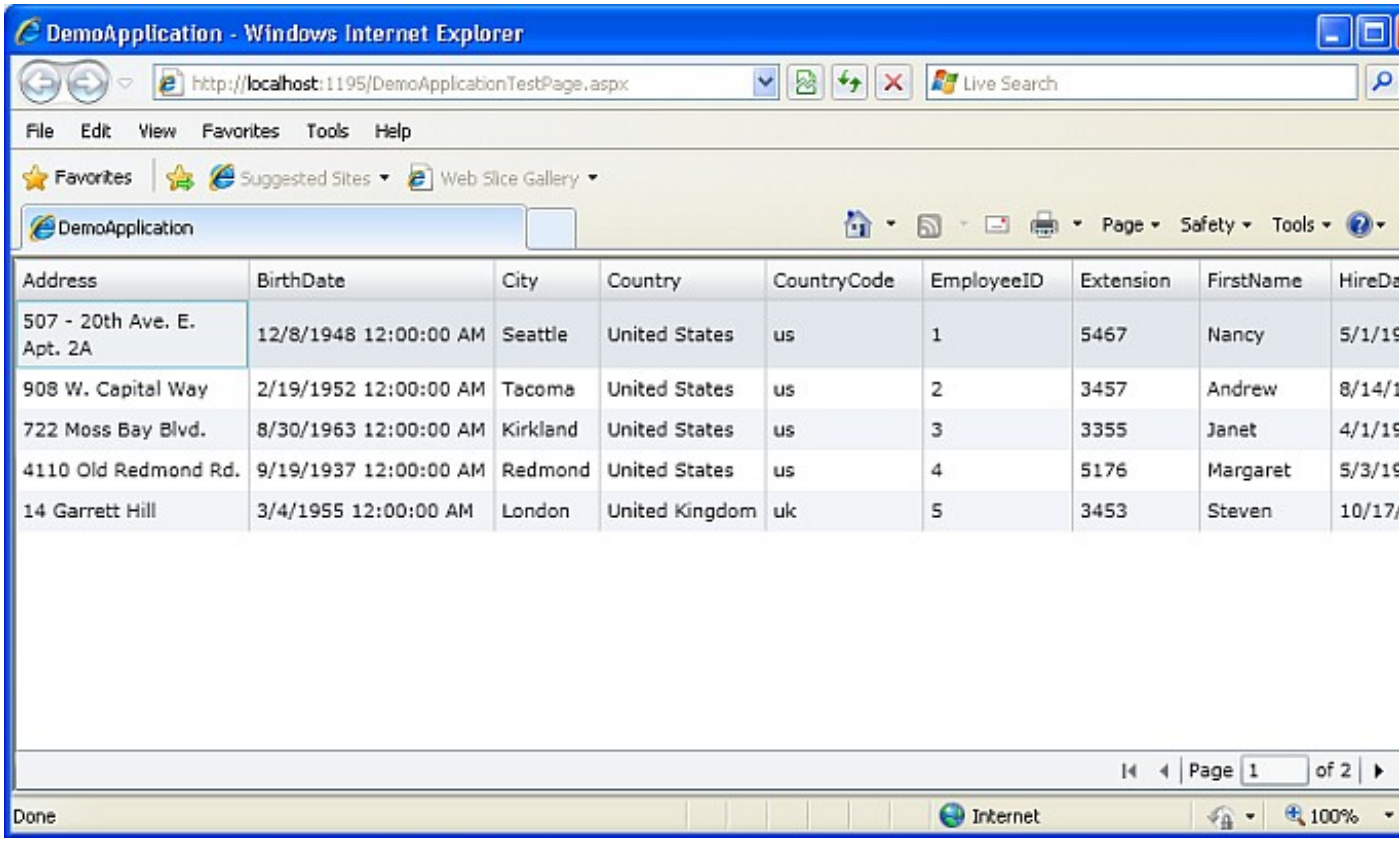
```
<data:DataGrid MinHeight="100"  IsReadOnly="True" ItemsSource="{Binding Data, ElementName=Employee
```

5. Drag a DataPager form the tool box onto MainPage.xaml just after the DataGrid.
6. Add a page size and binding element to the DataPager.

```
<data:DataPager PageSize="5" Source="{Binding Data, ElementName=employeeDataSource}"
                    Margin="0,-1,0,0"></data:DataPager>
```

7. Build and run the application. The data should be displayed 5 rows at a time.

Figure 2.182. .NET RIA Services Application



We now need to add a DataForm to display the details.

Step 3 - Add a DataForm

1. Add the following namespace to MainPage.xaml

```
xmlns:dataForm="clr-namespace:System.Windows.Controls;assembly=System.Windows.Controls.Data.DataFo
```

2. Add the form to MainPage.xaml

```
<dataForm:DataForm x:Name="dataForm1" Header="Employee Information"  AutoGenerateFields="False" Au
   <dataForm:DataForm.EditTemplate>
       <DataTemplate>
           <StackPanel>
               <dataForm:DataField Label="Employee ID">
                   <TextBox Text="{Binding EmployeeID, Mode=TwoWay}" />
               </dataForm:DataField>
               <dataForm:DataField Label="First Name">
```

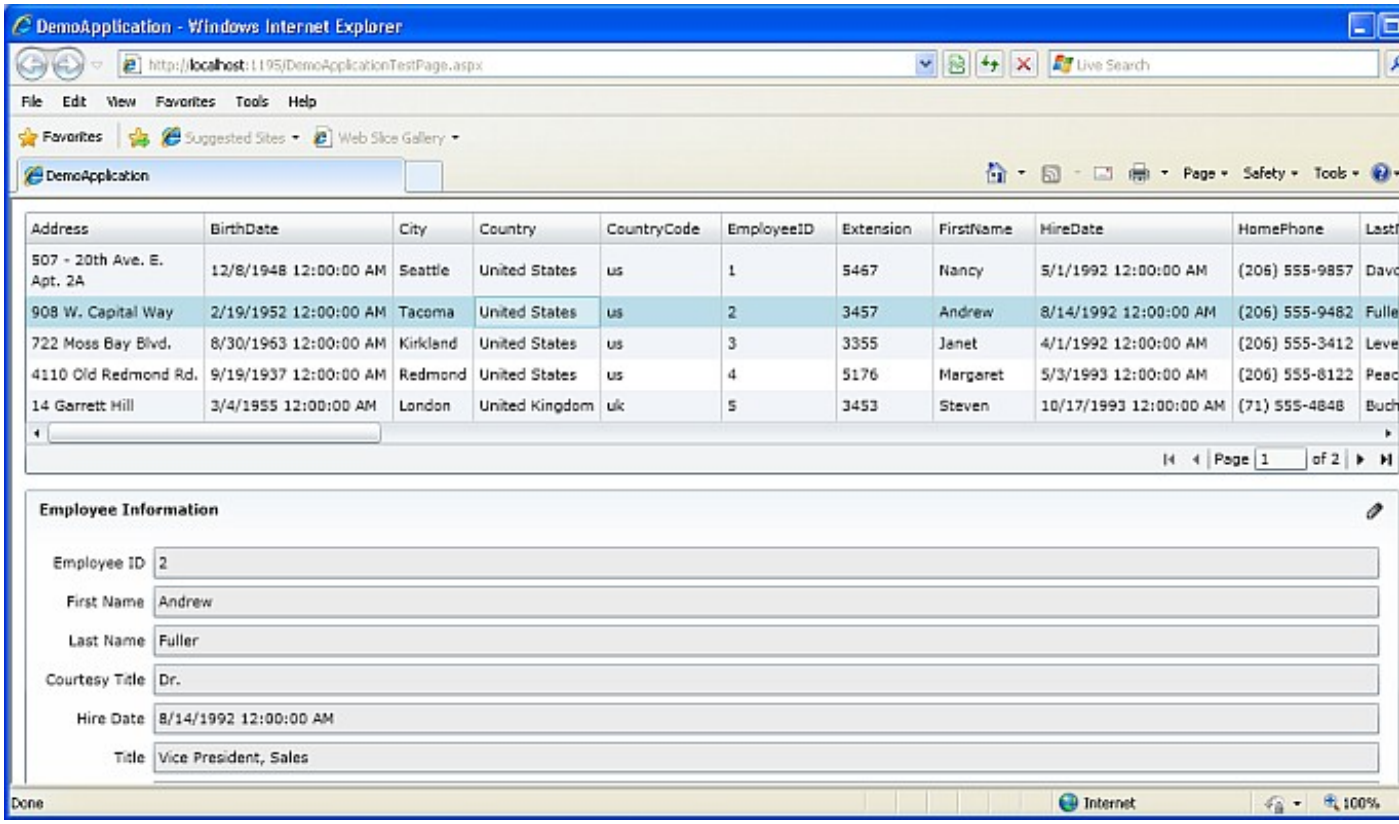
```
                    <TextBox Text="{Binding FirstName, Mode=TwoWay}" />
                </dataForm:DataField>
                <dataForm:DataField Label="Last Name">
                    <TextBox Text="{Binding LastName, Mode=TwoWay}" />
                </dataForm:DataField>
                <dataForm:DataField Label="Courtesy Title">
                    <TextBox Text="{Binding TitleOfCourtesy, Mode=TwoWay}" />
                </dataForm:DataField>
                <dataForm:DataField Label="Hire Date">
                    <TextBox Text="{Binding HireDate, Mode=TwoWay}" />
                </dataForm:DataField>
                <dataForm:DataField Label="Title">
                    <TextBox Text="{Binding Title, Mode=TwoWay}"  />
                </dataForm:DataField>
                <dataForm:DataField Label="Reports To">
                    <TextBox Text="{Binding ReportsTo, Mode=TwoWay}"  />
                </dataForm:DataField>
                <dataForm:DataField Label="Region">
                    <TextBox Text="{Binding Region, Mode=TwoWay}"  />
                </dataForm:DataField>
                <dataForm:DataField Label="Address">
                    <TextBox Text="{Binding Address, Mode=TwoWay}"  />
                </dataForm:DataField>
                <dataForm:DataField Label="City">
                    <TextBox Text="{Binding City, Mode=TwoWay}"  />
                </dataForm:DataField>
                <dataForm:DataField Label="Country Code">
                    <TextBox Text="{Binding CountryCode, Mode=TwoWay}"  />
                </dataForm:DataField>
                <dataForm:DataField Label="Postal Code">
                    <TextBox Text="{Binding PostalCode, Mode=TwoWay}"  />
                </dataForm:DataField>
                    </StackPanel>
            </DataTemplate>
        </dataForm:DataForm.EditTemplate>
    </dataForm:DataForm>
```

3. Surround the DomainDataSource, DataGrid and DataForm with

```
        <ScrollViewer BorderThickness="0"  VerticalScrollBarVisibility="Auto" Padding="12,0,12,0"
            <StackPanel Margin="0,12,0,12" Orientation="Vertical" >
.
.
.
            </StackPanel>
        </ScrollViewer>
```

4. Build and run the application. As each employee is selected the data form fill with their details

Figure 2.183. .NET RIA Services Application



By clicking on the pencil symbol in the top right hand corner the data in the form can be edited but it is not propagated back to the database.

2.13.3. Propagate Updates to Virtuoso

1. Add a 'Submit' button just after the DataForm in MainPage.xaml by adding the following code.

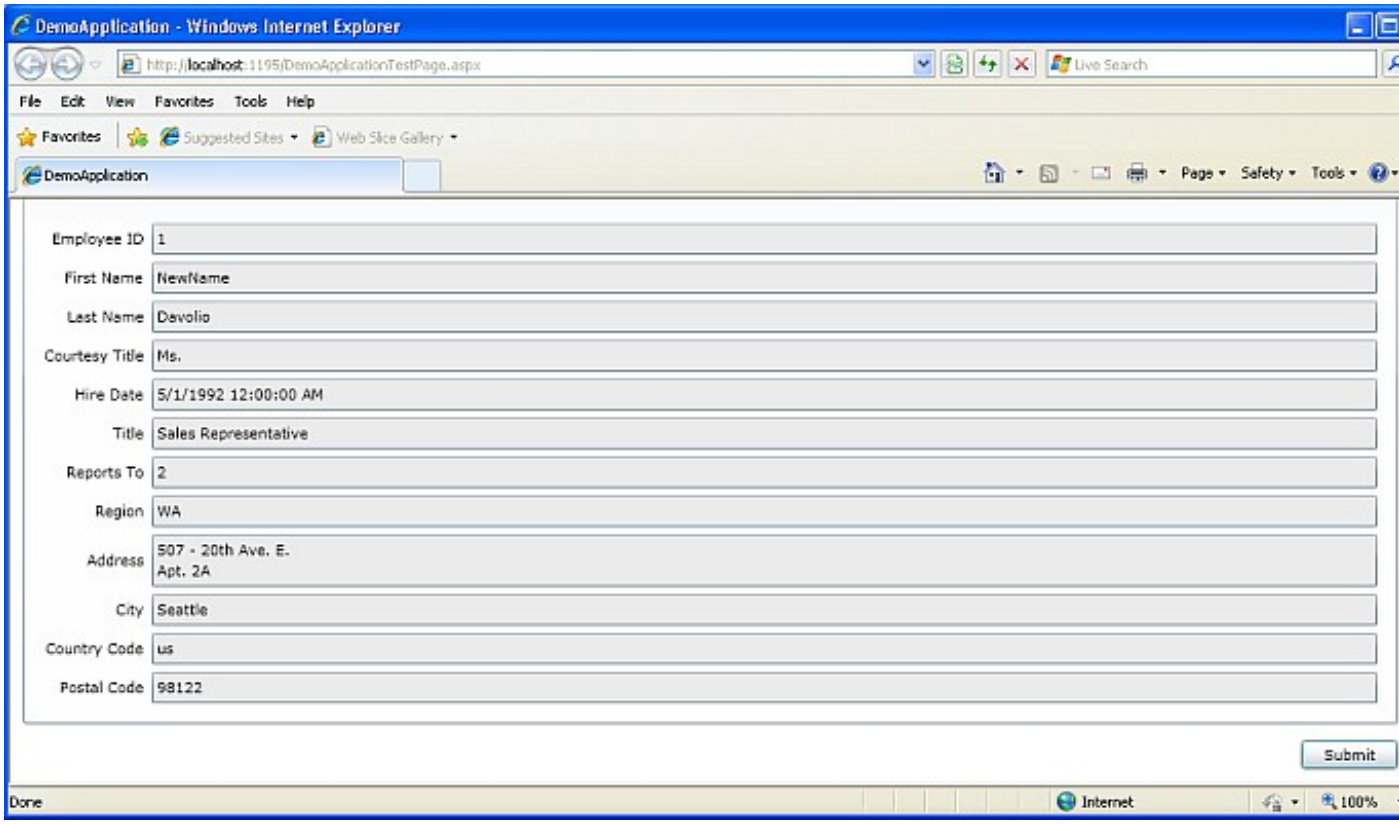
```
<StackPanel Orientation="Horizontal" HorizontalAlignment="Right" Margin="0,12,0,0">
  <Button x:Name="submitButton" Width="75" Height="23"  Content="Submit"  Margin="4,0,0,0" Click="
</StackPanel>
```

2. Handle the button click event in MainPage.xaml.cs by adding the following code:

```
private void submitButton_Click(object sender, RoutedEventArgs e)
        {
            EmployeeDataSource.SubmitChanges();
        }
```

3. Build and run the application. If you now edit data in the form and click the submit button the data in Virtuoso will be updated.

Figure 2.184. .NET RIA Services Application



2.14. Cluster Installation and Configuration

2.14.1. Virtuoso Elastic Cluster Installation & Configuration -- Version 7.x

These sections apply to Virtuoso as of version 7.x .

What

Virtuoso 7 and later versions can be configured in Elastic scale out cluster mode. The data is sharded in a large number of self-contained partitions. These partitions are divided among a number of database server processes and can migrate between them.

Why

An Elastic cluster can be dynamically resized with new partitions or shards dynamically added to the same or new hardware resources as the need to increase the size of the scale cluster or relocation of partitions is required.

How

This documentation details the steps for the installation and configuration of a Virtuoso Elastic Cluster on Unix:

1. Perform Virtuoso 7 Unix installation
2. Determine Elastic Cluster size
3. Enable Elastic Cluster mode
4. Start Elastic Cluster
5. Splitting Cluster nodes across different machines.

Virtuoso 7 Unix installation

Step 1 : Perform Virtuoso 7 Unix installation

```
$ tar xvf virtuoso-universal-server-7.x.tar
x install.sh
x universal-server.taz
```

```
$ sh install.sh

- Extracting Virtuoso Universal Server v7.x

- Creating default environment settings

- Creating default database settings
Configuring: database
Creating directory $VIRTUOSO_HOME/database/backup
Installing new virtuoso.ini in $VIRTUOSO_HOME/database
Installing new php.ini in $VIRTUOSO_HOME/database
Creating symlink to $VIRTUOSO_HOME/bin/virtuoso-iodbc-t

- Registering ODBC drivers

- Registering .NET provider for Mono

- Installing VAD packages in database (this can take some time)

- Checking where license should be stored

- Starting OpenLink License Manager

- Checking for initial Virtuoso license

- Starting Virtuoso server instance

- Finalizing installation

This concludes the first part of the installation.

- Attempting to start browser

Please start a browser manually and open the following URL to finalize
the installation process:

     http://cname:8890/install/

Installation completed
$
```

Determine Elastic Cluster size

Step 2 : Determine Elastic Cluster size

1. Determine how many nodes you want to start the elastic cluster with: 2, 3, 4, 5, 6, 7, 8 etc. Note: the number of the nodes must be >= 2
2. Setup Virtuoso environment and stop default database:

```
$ . ./virtuoso-environment.sh
$ virtuoso-stop.sh
Shutting down Virtuoso instance in [database]
$
```

3. Optionally remove the default database such that is does not get started with the cluster:

```
rm  -rf database
```

4. Full list of supported options for the script "virtuoso-mkcluster.sh":

```
  -cluster-size       Number of nodes in cluster
  -cluster-node       Node number in a cluster
  -cluster-port       Base portnumer for cluster
  -cluster-ipc-port   Base portnumer for cluster IPC
  -cluster_size       Size of the cluster
  -virtuoso_home      Virtuoso home path
```

5. Run the virtuoso-mkcluster.sh script to create the cluster, note the default number of nodes is 4, but this can be changed by setting the environment variable CLUSTER_SIZE to the required number of nodes to be created before running the script:

```
$ virtuoso-mkcluster.sh
Configuring cluster node: 1/4
```

```
Creating directory $VIRTUOSO_HOME/cluster_01
Creating directory $VIRTUOSO_HOME/cluster_01/backup
Creating directory $VIRTUOSO_HOME/cluster_01/logs
Installing new virtuoso.ini in $VIRTUOSO_HOME/cluster_01
Installing new php.ini in $VIRTUOSO_HOME/cluster_01
Creating symlink to $VIRTUOSO_HOME/bin/virtuoso-iodbc-t
Configuring cluster node: 2/4

Creating directory $VIRTUOSO_HOME/cluster_02
Creating directory $VIRTUOSO_HOME/cluster_02/backup
Installing new virtuoso.ini in $VIRTUOSO_HOME/cluster_02
Removing unneeded sections from virtuoso.ini
Creating symlink to $VIRTUOSO_HOME/bin/virtuoso-iodbc-t
Configuring cluster node: 3/4

Creating directory $VIRTUOSO_HOME/cluster_03
Creating directory $VIRTUOSO_HOME/cluster_03/backup
Installing new virtuoso.ini in $VIRTUOSO_HOME/cluster_03
Removing unneeded sections from virtuoso.ini
Creating symlink to $VIRTUOSO_HOME/bin/virtuoso-iodbc-t
Configuring cluster node: 4/4

Creating directory $VIRTUOSO_HOME/cluster_04
Creating directory $VIRTUOSO_HOME/cluster_04/backup
Installing new virtuoso.ini in $VIRTUOSO_HOME/cluster_04
Removing unneeded sections from virtuoso.ini
Creating symlink to $VIRTUOSO_HOME/bin/virtuoso-iodbc-t
$
```

6. In each cluster_XX directory the following the `cluster.ini` files are created for cluster internal communication:

```
$ more cluster_01/cluster.ini
[Cluster]
Threads             = 20
Master              = Host1
ThisHost            = Host1
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 1000
Host1               = localhost:22201
Host2               = localhost:22202
Host3               = localhost:22203
Host4               = localhost:22204
MaxHosts            = 5
$ more cluster_02/cluster.ini
[Cluster]
Threads             = 20
Master              = Host1
ThisHost            = Host2
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 1000
Host1               = localhost:22201
Host2               = localhost:22202
Host3               = localhost:22203
Host4               = localhost:22204
MaxHosts            = 5
$ more cluster_03/cluster.ini
[Cluster]
Threads             = 20
Master              = Host1
ThisHost            = Host3
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 1000
Host1               = localhost:22201
Host2               = localhost:22202
```

```
Host3               = localhost:22203
Host4               = localhost:22204
MaxHosts            = 5
$ more cluster_04/cluster.ini
[Cluster]
Threads             = 20
Master              = Host1
ThisHost            = Host4
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 1000
Host1               = localhost:22201
Host2               = localhost:22202
Host3               = localhost:22203
Host4               = localhost:22204
MaxHosts            = 5
$
```

Enable Elastic Cluster mode

Step 3 : Enable Elastic Cluster mode

1. The `cluster.ini` files need to be reconfigured as detailed below for elastic cluster and file slicing/sharding to be enabled.
2. A common file called `cluster.global.ini` can be created and placed in the home directory of the Virtuoso installation:

```
[Cluster]
Threads             = 300
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 100
RDFLoadBytes        = 52428800
Host1               = localhost:22201
Host2               = localhost:22202
Host3               = localhost:22203
Host4               = localhost:22204
```

3. This file can then be sym-linked to each of the `cluster_XX` directories of the cluster, and its content will be merged with the `cluster.ini` in the respective directory of each node when starting the cluster.

```
ln -s cluster.global.ini cluster_01/cluster.global.ini
ln -s cluster.global.ini cluster_02/cluster.global.ini
ln -s cluster.global.ini cluster_03/cluster.global.ini
ln -s cluster.global.ini cluster_04/cluster.global.ini
```

4. Edit each of the the `cluster.ini` files in the `cluster_XX` directories as follows to enable, elastic cluster mode:

```
$ more cluster_01/cluster.ini
[Cluster]
Master              = Host1
ThisHost            = Host1

[ELASTIC]
Segment1 = 4G, database.db = q1
Slices = 6
MaxSlices = 2048

$ more cluster_02/cluster.ini

[Cluster]
Master              = Host1
ThisHost            = Host2

[ELASTIC]
Segment1 = 4G, database.db = q1
Slices = 6
MaxSlices = 2048
```

```
$ more cluster_03/cluster.ini

[Cluster]
Master              = Host1
ThisHost            = Host3

[ELASTIC]
Segment1 = 4G, database.db = q1
Slices = 6
MaxSlices = 2048

$ more cluster_04/cluster.ini

[Cluster]
Master              = Host1
ThisHost            = Host4

[ELASTIC]
Segment1 = 4G, database.db = q1
Slices = 6
MaxSlices = 2048
```

5. The `[ELASTIC]` section in the `cluster.ini` files above, enables the elastic cluster mode, where multiple `segments` and `stripes` as detailed in the standard Virtuoso documentation database striping .
6. The `Slices` parameter above should be set to the number of hardware threads on the CPUs running on. Thus in the example above where it is set to 6, this assumes all nodes are running on the same physical machine with 12 cores with hyper-threading enabled i.e. 24 threads, thus 6 per cluster node.
7. The `MaxSlices` parameter above sets the the maximum number of physical slices in the cluster.

Start Elastic Cluster

Step 4 : Start Elastic Cluster

1. Start the Elastic cluster using the standard `virtuoso-start.sh` script run from the home directory of the Virtuoso installation,which automatically detects the number for nodes to be started:

```
$ virtuoso-start.sh
Starting Virtuoso instance in [cluster_01]
Starting Virtuoso instance in [cluster_02]
Starting Virtuoso instance in [cluster_03]
Starting Virtuoso instance in [cluster_04]
$
```

2. The default SQL port of the master node is 12201, as indicated in the virtuoso.ini file of the cluster_01 directory, and can then be used for connecting to the newly created cluster and check its status to ensure all nodes are online:

```
$ isql 12201
Connected to OpenLink Virtuoso
Driver: 07.10.3211 OpenLink Virtuoso ODBC Driver
OpenLink Interactive SQL (Virtuoso), version 0.9849b.
Type HELP; for help and EXIT; to exit.

```

3. The `database.log` of the master node can be checked to verify the Elastic cluster mode has been enable on server startup, which will contain the entry *PL LOG: Elastic cluster setup* :

```
$ more cluster_01/database.log

$
```

Splitting Cluster nodes across different machines

Step 5 : Splitting Cluster nodes across different machines

1. To split the node across across physical machines for better scale out performance, scalability and growth, simply perform a parallel Virtuoso installation on the additional physical machines and move the cluster nodes required to the designated machine. Example, for the default 4 node cluster to be split across two identical machines it would make sense to split 2 nodes across each machine, thus you would move say the cluster_03 and cluster_04 directory nodes to the new machine (removing them from the original). The `cluster.global.ini` file on each node would then need to be updated to set the HostXX parameters to point to the new locations for nodes 03 and 04:

```
$ more cluster.global.ini

[Cluster]
Threads             = 300
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 100
RDFLoadBytes        = 52428800
Host1               = hostname1:22201
Host2               = hostname1:22202
Host3               = hostname2:22203
Host4               = hostname2:22204

Machine 1 (hostname1)

$ more cluster_01/cluster.ini
[Cluster]
Master              = Host1
ThisHost            = Host1

[ELASTIC]
Segment1 = 4G, database.db = q1
Slices = 12
MaxSlices = 2048

$ more cluster_02/cluster.ini

[Cluster]
```

```
Master              = Host1
ThisHost            = Host2

[ELASTIC]
Segment1 = 4G, database.db = q1
Slices = 12
MaxSlices = 2048

Machine 2 (hostname2)

$ more cluster_03/cluster.ini

[Cluster]
Master              = Host1
ThisHost            = Host3

[ELASTIC]
Segment1 = 4G, database.db = q1
Slices = 12
MaxSlices = 2048

$ more cluster_04/cluster.ini

[Cluster]
Master              = Host1
ThisHost            = Host4

[ELASTIC]
Segment1 = 4G, database.db = q1
Slices = 12
MaxSlices = 2048
```

2. Note assuming the same number of CPU threads on each machine i.e. 24, then the `Slices` param can be doubled to 12 for each node in `cluster.ini` , as above.
3. The cluster nodes can then be started on each machine, with 2 nodes being started on each in this case to form the cluster:

```
Machine 1 (hostname1)

$ virtuoso-start.sh
Starting Virtuoso instance in [cluster_01]
Starting Virtuoso instance in [cluster_02]
$

Machine 2 (hostname2)

$ virtuoso-start.sh
Starting Virtuoso instance in [cluster_03]
Starting Virtuoso instance in [cluster_04]
$
```

4. To stop the cluster use the standard `virtuoso-stop.sh` script on each machine, which automatically detects the number for nodes to be stopped:

```
Machine 1 (hostname1)

$ virtuoso-stop.sh
Stopping Virtuoso instance in [cluster_01]
Stopping Virtuoso instance in [cluster_02]

Machine 2 (hostname2)

$ virtuoso-stop.sh
Stopping Virtuoso instance in [cluster_03]
Stopping Virtuoso instance in [cluster_04]
$
```

5. The `cl_exec('shutdown')` command can also be run from `isql` on any node of the cluster to shutdown all nodes at once:

```
$ isql 12201
Connected to OpenLink Virtuoso
Driver: 07.10.3211 OpenLink Virtuoso ODBC Driver
OpenLink Interactive SQL (Virtuoso), version 0.9849b.
Type HELP; for help and EXIT; to exit.
```

```
SQL> cl_exec ('checkpoint');

Done. -- 2487 msec.
SQL> cl_exec ('shutdown');

*** Error 08S01: VD CL065: Lost connection to server
at line 2 of Top-Level:
cl_exec ('shutdown')
$
```

2.14.2. Virtuoso default Cluster Installation and Configuration

These sections apply to Virtuoso as of version 6.x and higher.

1. Run the Virtuoso 6 Unix (MacOsX) installer to perform a default installation:

```
$ tar xvf virtuoso-universal-server-6.1.tar
x install.sh
x universal-server.taz
$ sh install.sh

- Extracting Virtuoso Universal Server v6.1

- Creating default environment settings

- Creating default database settings
Configuring: database
Creating directory $VIRTUOSO_HOME/database/backup
Installing new virtuoso.ini in $VIRTUOSO_HOME/database
Installing new php.ini in $VIRTUOSO_HOME/database
Creating symlink to $VIRTUOSO_HOME/bin/virtuoso-iodbc-t

- Registering ODBC drivers

- Registering .NET provider for Mono

- Installing VAD packages in database (this can take some time)

- Checking where license should be stored

- Starting OpenLink License Manager

- Checking for initial Virtuoso license

- Starting Virtuoso server instance

- Finalizing installation

This concludes the first part of the installation.

- Attempting to start browser

Please start a browser manually and open the following URL to finalize
the installation process:

     http://cname:8890/install/

Installation completed
$
```

2. Determine how many nodes you want to start the cluster with: 2, 3, 4, 5, 6, 7, 8 etc.

   Note

   : the number of the nodes should be >= 2
3. Setup Virtuoso environment and stop default database:

```
$ . ./virtuoso-environment.sh
$ virtuoso-stop.sh
Shutting down Virtuoso instance in [database]
$
```

4. Optionally remove the default database such that is does not get started with the cluster:

```
rm  -rf database
```

5. Full list of supported options for the script

   "virtuoso-mkcluster.sh"

   :

```
  -cluster-size       Number of nodes in cluster
  -cluster-node       Node number in a cluster
  -cluster-port       Base portnumer for cluster
  -cluster-ipc-port   Base portnumer for cluster IPC
  -cluster_size       Size of the cluster
  -virtuoso_home      Virtuoso home path
```

6. Run the virtuoso-mkcluster.sh script to create the cluster, note the default number of nodes is 4, but this can be changed by setting the environment variable CLUSTER_SIZE to the required number of nodes to be created before running the script:

```
$ virtuoso-mkcluster.sh
Configuring cluster node: 1/4

Creating directory $VIRTUOSO_HOME/cluster_01
Creating directory $VIRTUOSO_HOME/cluster_01/backup
Creating directory $VIRTUOSO_HOME/cluster_01/logs
Installing new virtuoso.ini in $VIRTUOSO_HOME/cluster_01
Installing new php.ini in $VIRTUOSO_HOME/cluster_01
Creating symlink to $VIRTUOSO_HOME/bin/virtuoso-iodbc-t
Configuring cluster node: 2/4

Creating directory $VIRTUOSO_HOME/cluster_02
Creating directory $VIRTUOSO_HOME/cluster_02/backup
Installing new virtuoso.ini in $VIRTUOSO_HOME/cluster_02
Removing unneeded sections from virtuoso.ini
Creating symlink to $VIRTUOSO_HOME/bin/virtuoso-iodbc-t
Configuring cluster node: 3/4

Creating directory $VIRTUOSO_HOME/cluster_03
Creating directory $VIRTUOSO_HOME/cluster_03/backup
Installing new virtuoso.ini in $VIRTUOSO_HOME/cluster_03
Removing unneeded sections from virtuoso.ini
Creating symlink to $VIRTUOSO_HOME/bin/virtuoso-iodbc-t
Configuring cluster node: 4/4

Creating directory $VIRTUOSO_HOME/cluster_04
Creating directory $VIRTUOSO_HOME/cluster_04/backup
Installing new virtuoso.ini in $VIRTUOSO_HOME/cluster_04
Removing unneeded sections from virtuoso.ini
Creating symlink to $VIRTUOSO_HOME/bin/virtuoso-iodbc-t
$
```

7. For each of the cluster_XX directories created edit the cluster.ini file and set the HostXX parameter to the hostname:portno to be used by the cluster nodes for internal communication.

```
$ more cluster_01/cluster.ini
[Cluster]
Threads             = 20
Master              = Host1
ThisHost            = Host1
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 1000
Host1               = hostname:22201
Host2               = hostname:22202
Host3               = hostname:22203
Host4               = hostname:22204
MaxHosts            = 5
$ more cluster_02/cluster.ini
[Cluster]
```

```
Threads             = 20
Master              = Host1
ThisHost            = Host2
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 1000
Host1               = hostname:22201
Host2               = hostname:22202
Host3               = hostname:22203
Host4               = hostname:22204
MaxHosts            = 5
$ more cluster_03/cluster.ini
[Cluster]
Threads             = 20
Master              = Host1
ThisHost            = Host3
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 1000
Host1               = hostname:22201
Host2               = hostname:22202
Host3               = hostname:22203
Host4               = hostname:22204
MaxHosts            = 5
$ more cluster_04/cluster.ini
[Cluster]
Threads             = 20
Master              = Host1
ThisHost            = Host4
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 1000
Host1               = hostname:22201
Host2               = hostname:22202
Host3               = hostname:22203
Host4               = hostname:22204
MaxHosts            = 5
$
```

8. Start the cluster using the standard virtuoso-start.sh script which automatically detects the number for nodes to be started:

```
$ virtuoso-start.sh
Starting Virtuoso instance in [cluster_01]
Starting Virtuoso instance in [cluster_02]
Starting Virtuoso instance in [cluster_03]
Starting Virtuoso instance in [cluster_04]
$
```

9. The default SQL port of the master node is 12201, as indicated in the virtuoso.ini file of the cluster_01 directory, and can then be used for connecting to the newly created cluster and check its status to ensure all nodes are online:

```
$ isql 12201
Connected to OpenLink Virtuoso
Driver: 06.01.3127 OpenLink Virtuoso ODBC Driver
OpenLink Interactive SQL (Virtuoso), version 0.9849b.
Type HELP; for help and EXIT; to exit.
SQL> status ('cluster');
REPORT

```

10. To split the node across across physical machines for better performance and scalability, simply perform a parallel Virtuoso installation on the additional physical machines and move the cluster nodes required to the designated machine. Example, for the default 4 node cluster to be split across two identical machines it would make sense to split 2 nodes across each machine, thus you would move say the cluster_03 and cluster_04 directory nodes to the new machine (removing them from the original). The cluster.ini file on each node would then need to be updated to set the HostXX parameters to point to the new locations for nodes 03 and 04:

```
Machine 1 (hostname1)

$ more cluster_01/cluster.ini
[Cluster]
Threads             = 20
Master              = Host1
ThisHost            = Host1
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 1000
Host1               = hostname1:22201
Host2               = hostname1:22202
Host3               = hostname2:22203
Host4               = hostname2:22204
MaxHosts            = 5
$ more cluster_02/cluster.ini
[Cluster]
Threads             = 20
Master              = Host1
ThisHost            = Host2
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 1000
Host1               = hostname1:22201
Host2               = hostname1:22202
Host3               = hostname2:22203
Host4               = hostname2:22204
MaxHosts            = 5
$

Machine 2 (hostname2)

$ more cluster_03/cluster.ini
[Cluster]
Threads             = 20
Master              = Host1
ThisHost            = Host3
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 1000
Host1               = hostname1:22201
Host2               = hostname1:22202
Host3               = hostname2:22203
Host4               = hostname2:22204
MaxHosts            = 5
$ more cluster_04/cluster.ini
[Cluster]
Threads             = 20
Master              = Host1
ThisHost            = Host4
```

```
ReqBatchSize        = 10000
BatchesPerRPC       = 4
BatchBufferBytes    = 20000
LocalOnly           = 2
MaxKeepAlivesMissed = 1000
Host1               = hostname1:22201
Host2               = hostname1:22202
Host3               = hostname2:22203
Host4               = hostname2:22204
MaxHosts            = 5
$
```

11. The nodes can then be started on each machine, with 2 nodes being started on each in this case to form the cluster:

```
Machine 1 (hostname1)

$ virtuoso-start.sh
Starting Virtuoso instance in [cluster_01]
Starting Virtuoso instance in [cluster_02]
$

Machine 2 (hostname2)

$ virtuoso-start.sh
Starting Virtuoso instance in [cluster_03]
Starting Virtuoso instance in [cluster_04]
$
```

12. To stop the cluster use the standard virtuoso-stop.sh script which automatically detects the number for nodes to be stopped:

```
$ virtuoso-stop.sh
Stopping Virtuoso instance in [cluster_01]
Stopping Virtuoso instance in [cluster_02]
Stopping Virtuoso instance in [cluster_03]
Stopping Virtuoso instance in [cluster_04]
$
```

2.14.3. Backup and Restore

Backup

There are 2 ways to backup Virtuoso Cluster DB:

1. Backup every node using `back_online` *For example, for every cluster in its backup folder execute:*

```
SQL> backup_online('dbp',10000000,0,vector('backup'));

Done. -- 272 msec.
```

2. Make backup of all nodes at once using cl_exec() . For example, execute:

```
SQL> cl_exec ('backup_online (''dbp'', 10000000, 0,  vector (''backup''))');

Done. -- 573 msec.
```

Restore from Backup

After backup is done for every node in its backup folder, in order to restore, execute from the ..\bin folder the virtuoso-restore.sh:

```
# . ./virtuoso-restore.sh all dbp
```

where the second parameter is the restore prefix.

2.14.4. Cluster Configuration

1. Set "FAST_START=1" in the viruoso-start.sh file and then run:

```
viruoso-start.sh
```

or

2. Execute the following line:

```
# /etc/init.d/virtuoso start
Starting OpenLink Virtuoso:                                    [  OK  ]
```

3. In order to check the nodes, connect to port 12201 using the ISQL tool:

```
isql 12201
```

4. To check the cluster status, execute the following command:

```
SQL> status('cluster');
REPORT
VARCHAR
_______________________________________________________________________________

Cluster 4 nodes, 293 s. 0 m/s 0 KB/s  0% cpu 0%  read 0% clw threads 1r 0w 0i buffers 1781 0 d 0 w

1 Rows. -- 4 msec.
```

2.14.5. HTTP Service Configuration on Subordinate Nodes of a Virtuoso Cluster

This section applies to Virtuoso as of version 6.x and higher.

What

This documentation details how to configure the Subordinate (also called Slave) Nodes of a Virtuoso Elastic Cluster to service HTTP clients.

Why

By default, only the Primary (also called Master) instance of a Virtuoso Elastic Cluster is configured to provide HTTP services.

The Subordinate (also called Slave) nodes of the cluster may also be configured to provide HTTP services, enabling load balancing by spreading HTTP requests across the cluster's nodes.

How

This documentation details the steps for the installation and configuration of a Virtuoso Elastic Cluster on Unix:

1. *Step 1*

   : Set up each instance as a HTTP Server;
2. *Step 2*

   : Install and configure HTTP services on each instance;
3. *Step 3*

   : Configure load balancing.

Set up each instance as an HTTP Server

Step 1 : Set up each instance as a HTTP Server

Each node can be configured to provide HTTP services as follows:

1. Copy the `[HTTP Server]` section from the Primary instance's configuration file (by default, `virtuoso.ini`) to the configuration file of each Subordinate instance:

```
[HTTPServer]
ServerPort                 = 8890
ServerRoot                 = ../vsp
DavRoot                    = DAV
EnabledDavVSP              = 0
HTTPProxyEnabled           = 0
```

```
TempASPXDir                 = 0
DefaultMailServer           = localhost:25
MaxClientConnections        = 5
MaxKeepAlives               = 10
KeepAliveTimeout            = 10
MaxCachedProxyConnections   = 10
ProxyConnectionCacheTimeout = 15
HTTPThreadSize              = 280000
HttpPrintWarningsInOutput   = 0
Charset                     = UTF-8
;HTTPLogFile                 = logs/http.log
MaintenancePage             = atomic.html
EnabledGzipContent          = 1
```

2. Edit the `ServerPort` parameter to make it unique on the machine hosting this instance; i.e., if a subordinate instance is running on same physical node as the primary instance, then the subordinate's HTTP port must to be changed (from 8890, for instance) to a unique port (e.g., 8891).
3. Install the Virtuoso Conductor to enable HTTP Administration of the instance being configured. Note: if the subordinate instance is not on the same machine as the primary instance, then the vad directory may also need to be copied from the primary instance to the subordinate instance.:

```
SQL> vad_install ('../vad/conductor_dav.vad', 0);
SQL_STATE  SQL_MESSAGE
VARCHAR  VARCHAR
_______________________________________________________________________________

00000    No errors detected
00000    Installation of "Virtuoso Conductor" is complete.
00000    Now making a final checkpoint.
00000    Final checkpoint is made.
00000    SUCCESS

6 Rows. -- 10263 msec.
SQL>
```

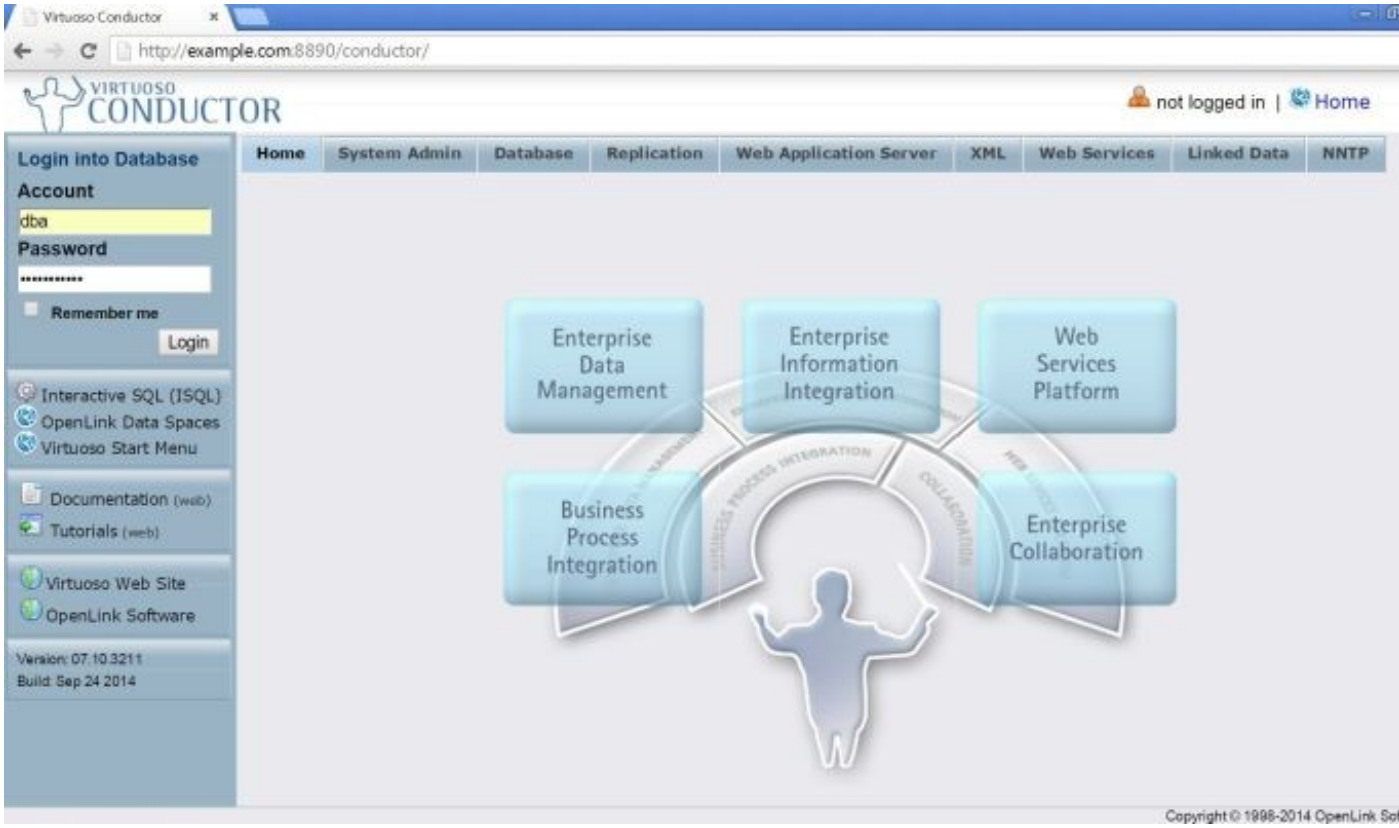
Install and configure HTTP services on each instance

Step 2 : Install and configure HTTP services on each instance

Any HTTP services required on the subordinate instance will need to specifically installed or configured on that physical node. For example, the Virtuoso default SPARQL endpoint (`/sparql`) may be configured by:

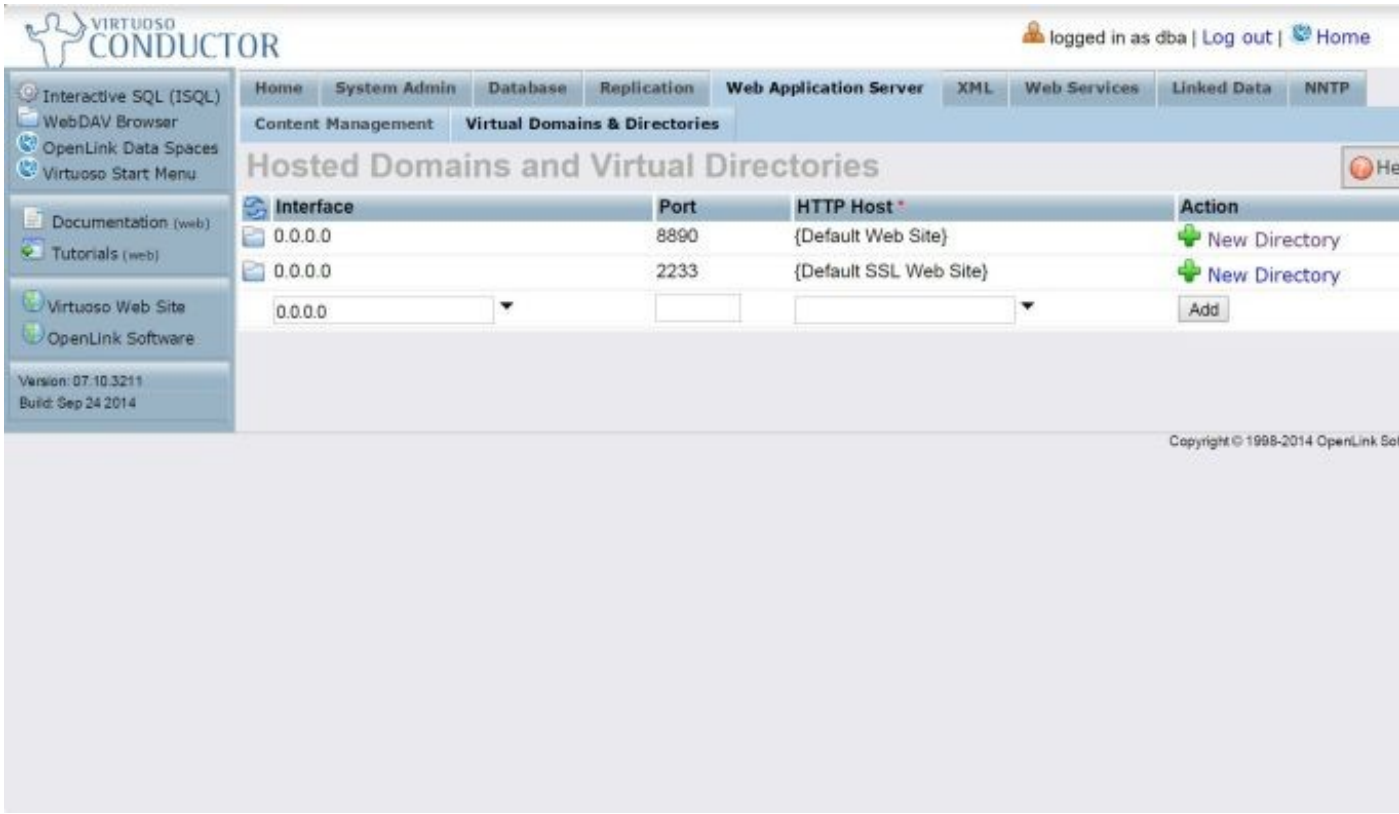
1. Log in into the Virtuoso Conductor http://hostname:port/conductor :

Figure 2.185. Configure SPARQL Endpoint: log in



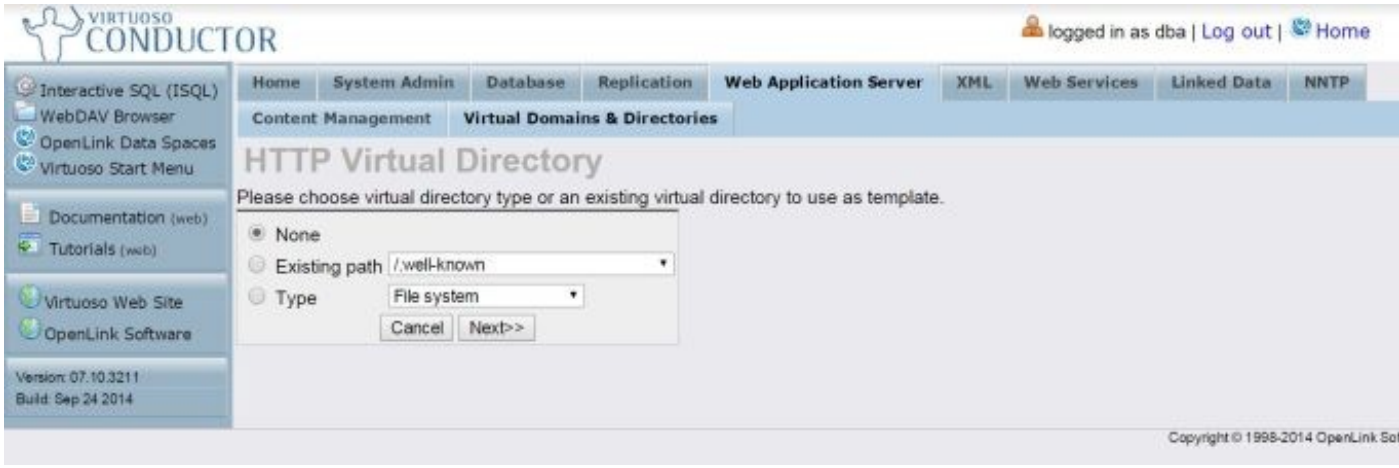
2. Go the the Web Application Server -> Virtual Domains & Directories tab:

Figure 2.186. Configure SPARQL Endpoint: Virtual Domains and Directories



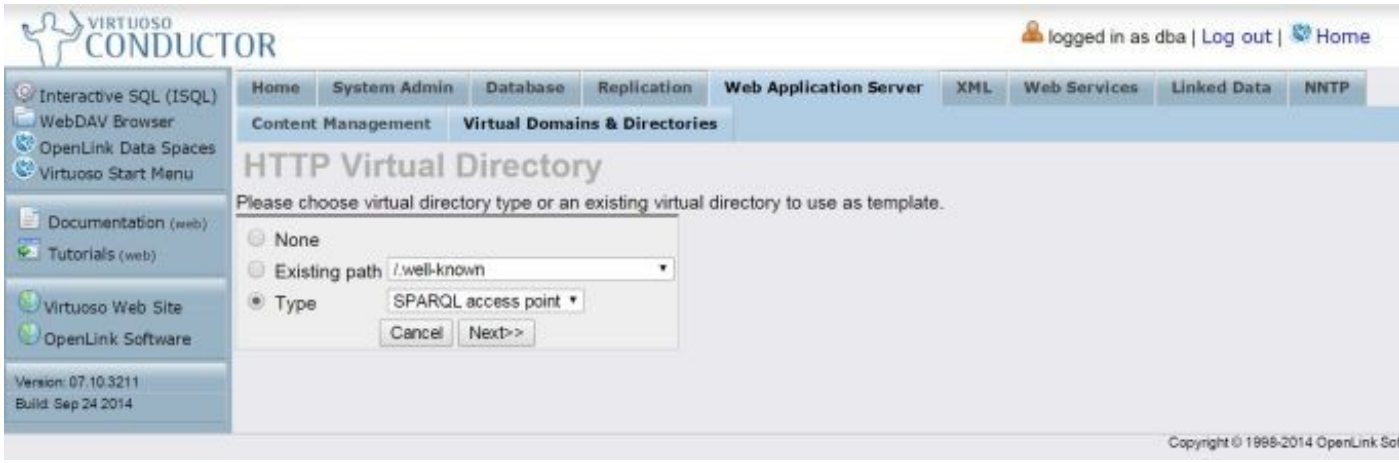
3. Select the New Directory Action for the Default Web Site HTTP host:

Figure 2.187. Configure SPARQL Endpoint: new directory



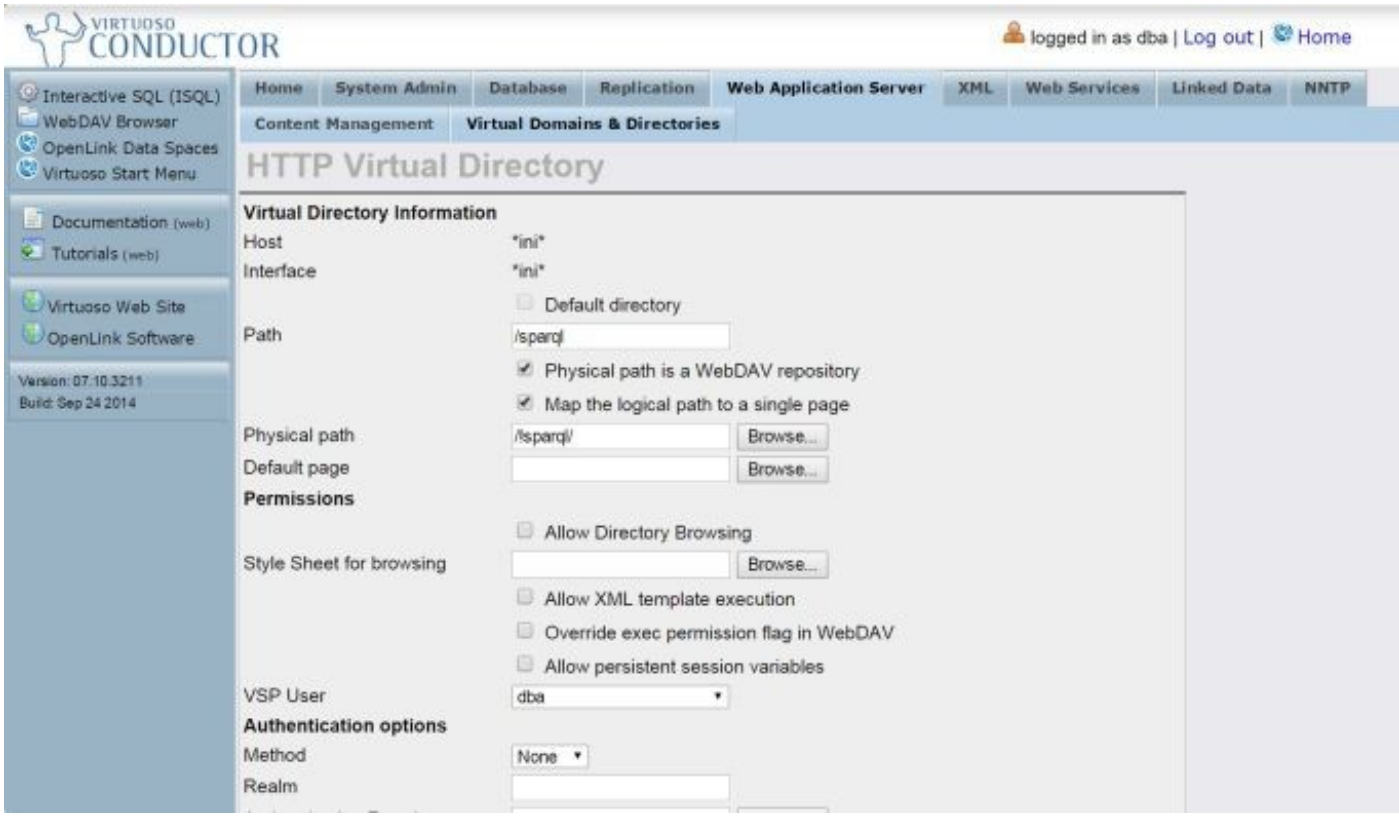
4. Select the Type radio button and SPARQL access point item from the drop down list box:

Figure 2.188. Configure SPARQL Endpoint: set type SPARQL



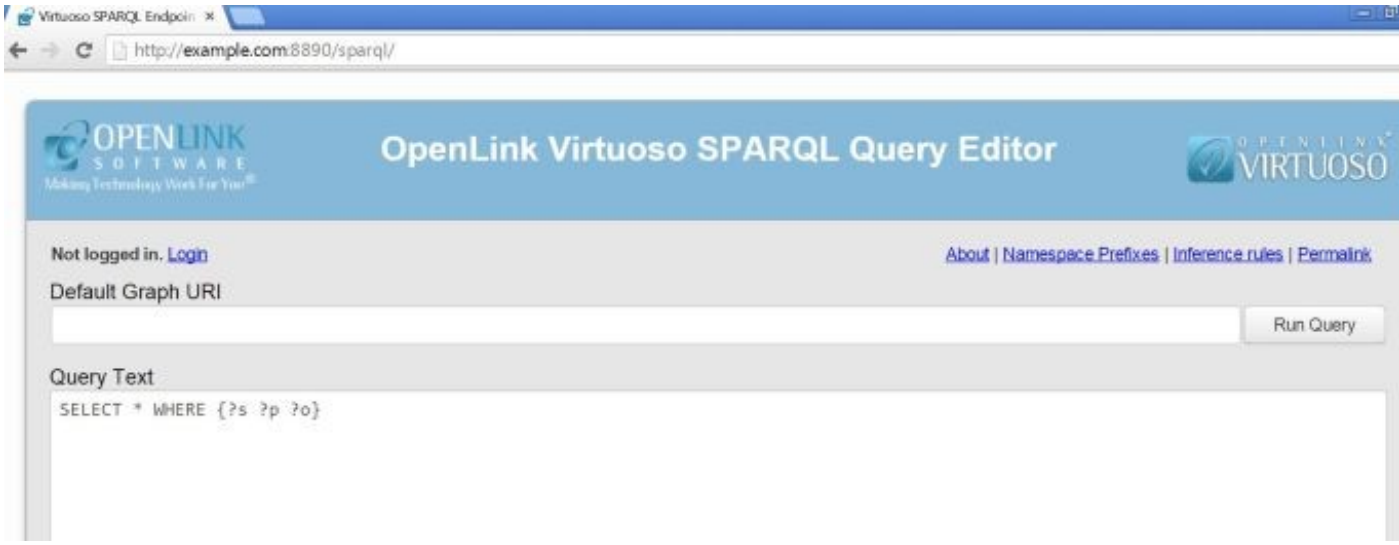
5. Click "Next".
6. Enter /sparql as the Path param in the Virtual Directory Information section and click Save Changes:

Figure 2.189. Configure SPARQL Endpoint: set /sparql virtual directory



7. The SPARQL endpoint will not be accessible on http://hostname:port/sparql the the newly configured slave nodes:

Figure 2.190. Configure SPARQL Endpoint: SPARQL Endpoint



8. Further details on SPARQL endpoint configuration can be found in Service Endpoint documentation section.
9. Typical Virtuoso server log output from a slave node when started, showing the HTTP server running on port 8890, being:

```
20:12:49 OpenLink Virtuoso Universal Server
20:12:49 Version 07.10.3209-pthreads for Linux as of Apr 26 2014
20:12:49 uses parts of OpenSSL, PCRE, Html Tidy
20:12:49 Registered to OpenLink Virtuoso (Internal Use)
20:12:49 Personal Edition license for 500 connections
20:12:49 Issued by OpenLink Software
20:12:49 This license will expire on Sun May 17 06:18:35 2015 GMT
20:12:49 Enabled Cluster Extension
20:12:49 Enabled Column Store Extension
20:12:57 Database version 3126
20:12:57 SQL Optimizer enabled (max 1000 layouts)
```

```
20:12:58 Compiler unit is timed at 0.000208 msec
20:12:58 Roll forward started
20:12:58 Roll forward complete
20:12:59 Checkpoint started
20:12:59 Checkpoint finished, log reused
20:12:59 HTTP/WebDAV server online at 8890
20:12:59 Server online at 12202 (pid 15969)
```

Configure load balancing

Step 3 : Configure load balancing

A reverse-proxy service (like Nginx or Apache) can then be configured such that requests are proxied across as any or all nodes of the cluster, to provide the desired load balancing.

Additional Information

- Only the Primary Node of an Elastic Cluster may be configured as a Publisher for Virtuoso Replication Cluster purposes.
- The Virtuoso 500 billion triple Berlin SPARQL Benchmark (BSBM) dataset runs were performed on a 24-node Elastic Cluster. Each node was configured to provide HTTP services and a SPARQL endpoint, and the query load was spread over the entire cluster.

2.14.6. Troubleshooting Tips

If an operation seems to hang, see the output of:

```
status ()
```

Check for the presence of the following conditions:

- The cluster line shows 0% CPU, no message traffic and an unchanging number of buffers wired, this is probably a bug. To reset, restart the cluster or the offending process if found. Restart is done by executing:

  ```
  raw_exit ();
  ```

  over an SQL connection to the process in question.
- The cluster line shows many threads waiting compared to total threads. If CPU is 0 and this does not change there could be a transaction that holds locks indefinitely. To clear, execute:

  ```
  txn_killall (1);
  ```

  Do this at a node that has local threads waiting. This is seen in the Lock Status paragraph of status (") when connected to the node in question.
- The cluster line shows a changing number in the pfs field. The system is swapping and slowed down.
- If the status () itself hangs, try another process of the cluster. See that there is no temporary atomic activity like a long checkpoint. If the situation persists there is a bug. The checkpoint can be seen by the presence of the

  checkpinmt_in_progress

  file in each server's working directory.
- To check the integrity of database files, do:

  ```
  cl_exec ('backup ''/dev/null''');
  ```

  If this returns, the databases are OK. If one is found to be corrupt the corresponding server exits.

Chapter 3. Quick Start & Tours

Abstract

This chapter is aimed at getting Virtuoso up and running quickly with a few basic examples to demonstrate key concepts.

The Virtuoso quick start tour is designed to familiarize you with some of the components in Virtuoso. After completing the tour, you should be able to link new tables into Virtuoso, and query the tables.

3.1. Where to Start

3.1.1. Default Passwords

When you start up Virtuoso for the first time, there are 3 user accounts defined:

Table 3.1. Default users of Virtuoso

User Name	Default Password	Usage
dba	dba	Default Database Administrator account.
dav	dav	WebDAV Administrator account.
vad	vad	WebDAV account for internal usage in VAD (disabled by default).
demo	demo	Default demo user for the demo database. This user is the owner of the Demo catalogue of the demo database.
soap	soap	SQL User for demonstrating SOAP services.
fori	fori	SQL user account for 'Forums' tutorial application demonstration in the Demo database.

One database user and 2 WebDAV users. These users have their passwords set to default values. It is therefore important to change them immediately after the installation.

The one database user is the database administrator with username "dba" and password "dba". This can be changed using the Interactive SQL utility. When started without parameters, the ISQL tries to log on as dba with the default password. The SQL statement to change a user's password is:

```
set password <old password> <new password>
```

The password is an identifier, so take care to use proper quotation.

You can also use the graphical Virtuoso Administration Interface to administer Virtuoso database users.

The 2 WebDAV user accounts, dav and davuser also have their password set to their username. There are 2 easy ways to change them. Either use the GUI in Administration Interface under WebDAV Administration / WebDAV services / Users Administrator or use the SQL statement:

```
update WS.WS.SYS_DAV_USER set U_PASSWORD='<new password>'
where U_NAME='<username>'
```

Note quotation around varchar values. Please remember to perform these operations for all Virtuoso server instances installed. By default these are the Virtuoso with an empty database and Virtuoso [demo] with the demo database.

3.1.2. Post-Installation Sanity Check

Verify by ISQL

Verify usability of your Virtuoso server by executing the following command from your command line prompt:

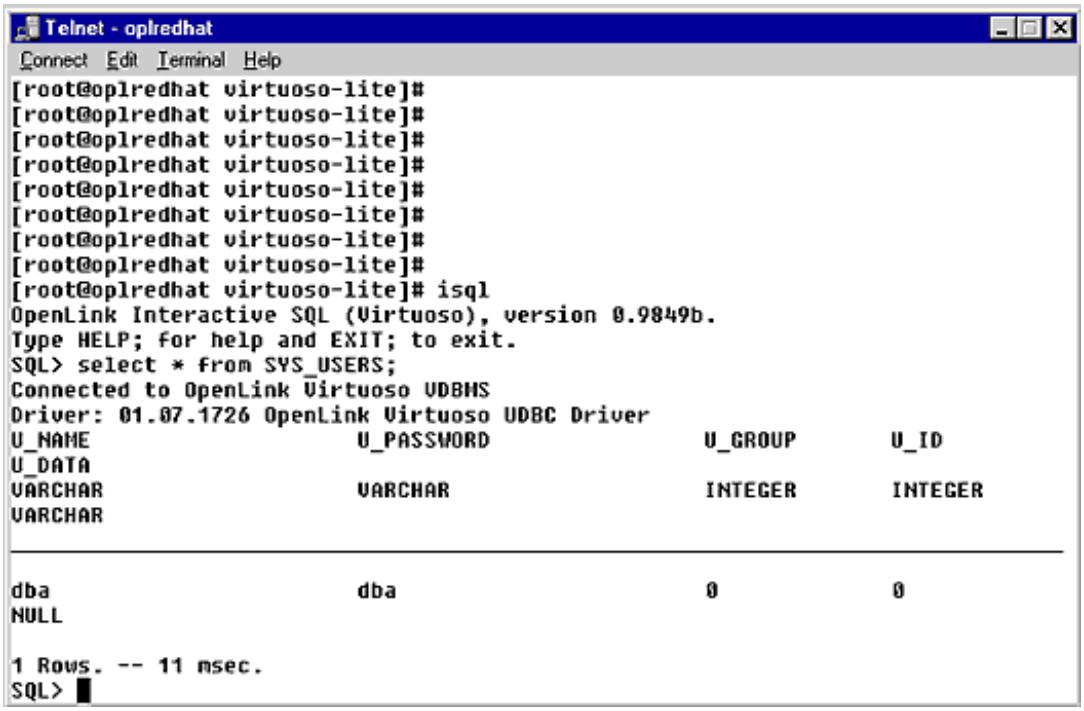
```
isql
```

From the ISQL prompt enter the following SQL command:

```
select * from DB.DBA.SYS_USERS;
```

This should produce a resultset containing one record if everything has been implemented correctly to this point.

Figure 3.1. ISQL in Telnet



Verify by HTTP

A quick way to check that the database is running, is to point a browser to the http port. The following example URLs will show the System Manager for the default, and the demo Virtuoso databases:

```
http://example.com:8889/
http://example.com:8890/
http://a_virtuoso_server.org:8890/
```

On a Windows Client there is a shortcut to the *OpenLink Virtuoso Conductor* in the OpenLink Virtuoso program group.

You will be presented with the OpenLink Virtuoso Conductor screen:

Figure 3.2. Virtuoso Conductor

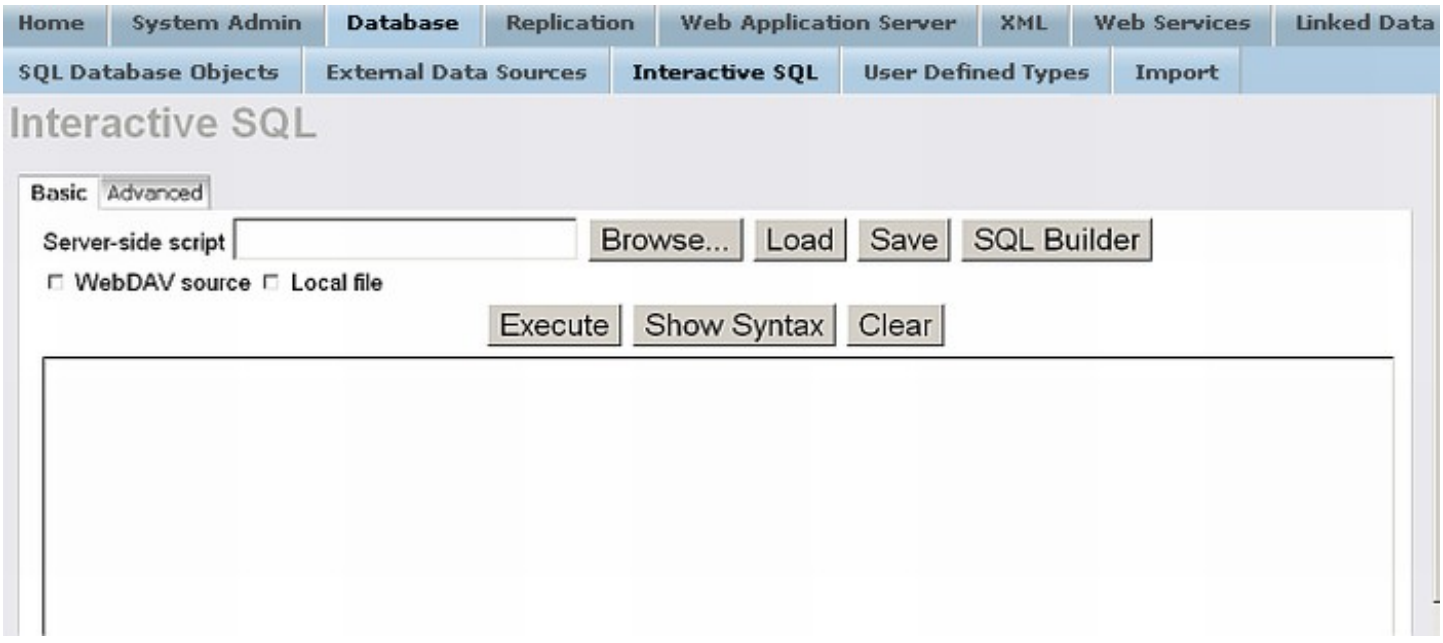
Verify by web based SQL query

Click on the *Conductor* link to enter the Virtuoso Server Administration Conductor Interface. You will be presented with a login form, type in the correct details for the database DBA user, by default this is username=dba; password=dba.

Figure 3.3. Virtuoso Conductor - Login Form

Got to tab "Database" and then go to tab "Interactive SQL".

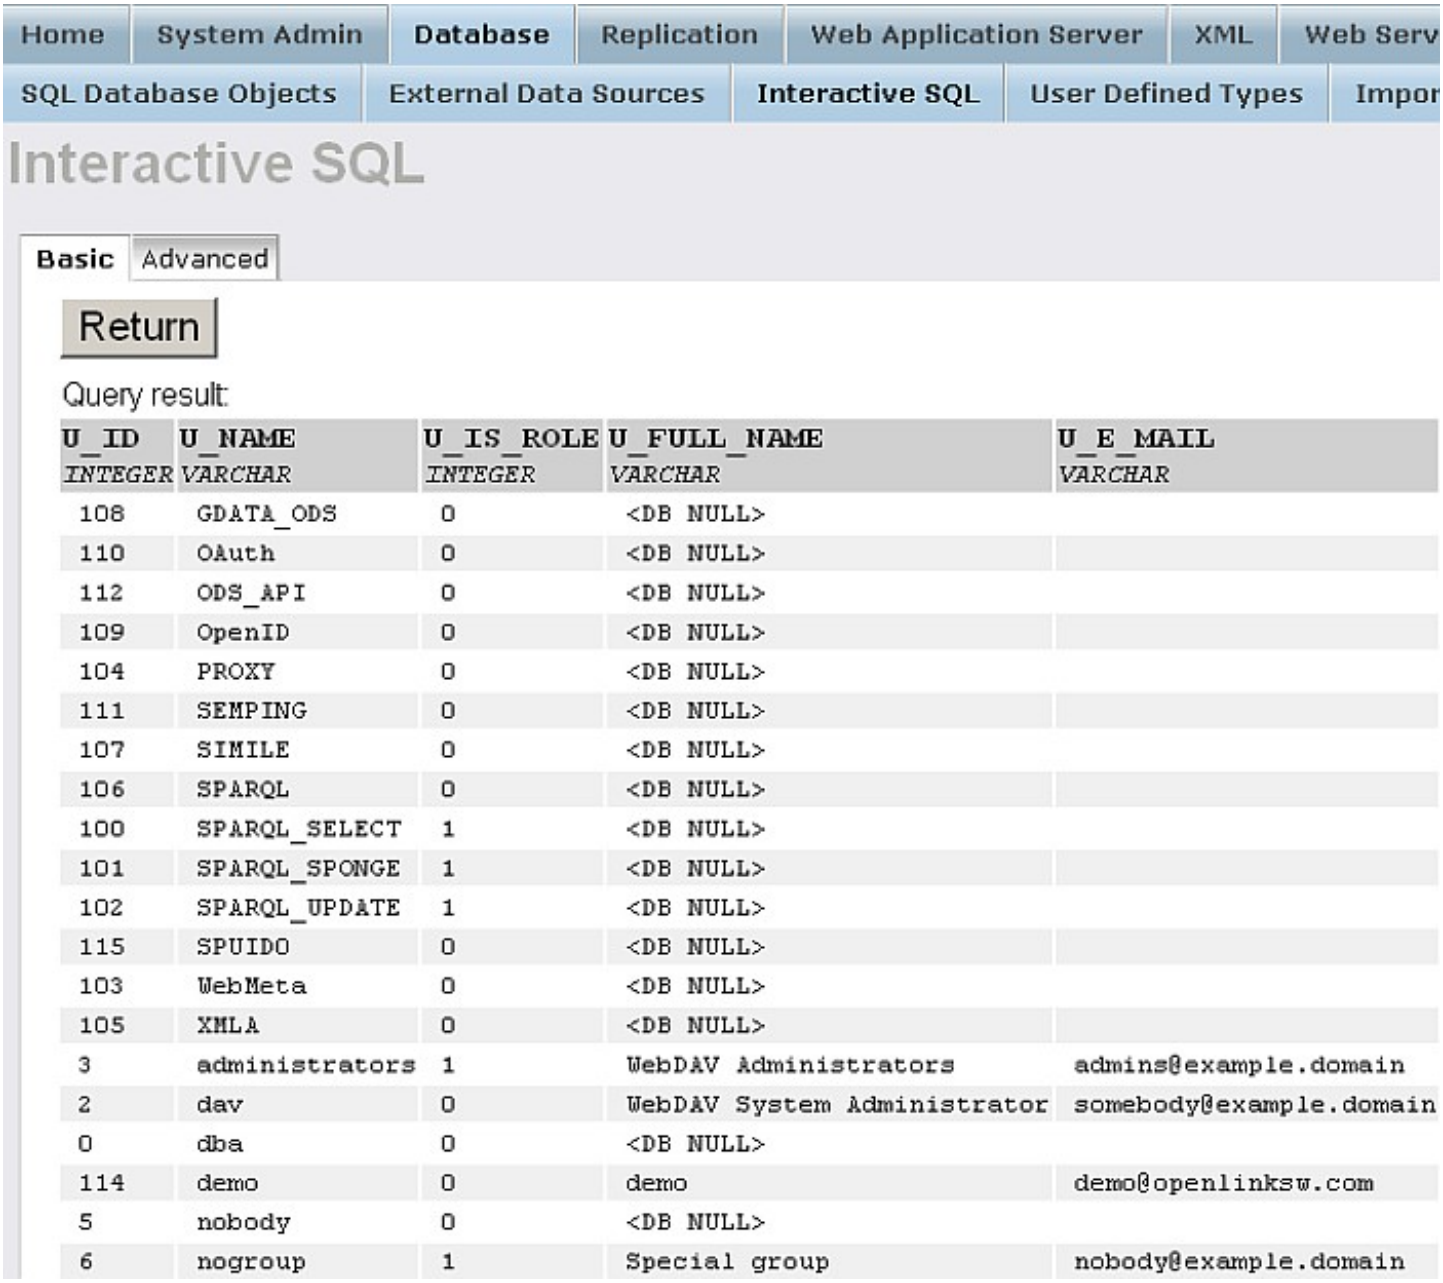
Figure 3.4. Virtuoso Conductor - Interactive SQL



Enter the SQL Statement command "SELECT * FROM SYS_USERS" in the SQL Statement text area. Note that only valid SQL can be supplied, so you cannot type a database command such as "tables;". Also, note that the ";" is not valid in this context. Press *Execute* .

You should see the SQL results, as shown below.

Figure 3.5. Virtuoso Conductor - SQL Results



U_ID *INTEGER*	U_NAME *VARCHAR*	U_IS_ROLE *INTEGER*	U_FULL_NAME *VARCHAR*	U_E_MAIL *VARCHAR*
108	GDATA_ODS	0	<DB NULL>	
110	OAuth	0	<DB NULL>	
112	ODS_API	0	<DB NULL>	
109	OpenID	0	<DB NULL>	
104	PROXY	0	<DB NULL>	
111	SEMPING	0	<DB NULL>	
107	SIMILE	0	<DB NULL>	
106	SPARQL	0	<DB NULL>	
100	SPARQL_SELECT	1	<DB NULL>	
101	SPARQL_SPONGE	1	<DB NULL>	
102	SPARQL_UPDATE	1	<DB NULL>	
115	SPUIDO	0	<DB NULL>	
103	WebMeta	0	<DB NULL>	
105	XMLA	0	<DB NULL>	
3	administrators	1	WebDAV Administrators	admins@example.domain
2	dav	0	WebDAV System Administrator	somebody@example.domain
0	dba	0	<DB NULL>	
114	demo	0	demo	demo@openlinksw.com
5	nobody	0	<DB NULL>	
6	nogroup	1	Special group	nobody@example.domain

3.1.3. Administering Your Virtuoso Installation

Virtuoso has been designed for Web based Administration. With your Virtuoso server running you will be able to point a Web browser at the servers listening address and port. The installation will include the default server and optionally the demo database server. The default server listens on port 8890 whilst the demo server listens on port 8889. If you are using the machine where Virtuoso was installed then the server address can be localhost or the hostname otherwise you will need to know the hostname or IP address of the machine where Virtuoso was installed. The URL that you will want to point your browser may be:

```
http://example.com:8890/
```

Note that that trailing / is important and may be required for older browsers

Figure 3.6. Visual Server Administration Interface

The "Conductor" link will take you to the Visual Server Administration Interface. Information about Visual Server Administration Interface can be found in the Server Administration chapter , which describes all the Interfaces available for configuring your server.

3.2. Client Connections

Virtuoso supports a number of data access API's such as ODBC and JDBC. They both provide high performance native connectivity to the Virtuoso database system.

3.2.1. ODBC

The Virtuoso driver for ODBC is available for Windows and most Unix operating systems. For Windows the you can configure a data source that utilizes the driver in the familiar way via the ODBC Administrator. This is very easy windows and wizards based process. On Unix the process has historically not been so simple. We have been trying to a achieve the same level of usability under Unix through our support of the iODBC project . For more information and details about how to configure the Virtuoso driver for ODBC please go to the Virtuoso Driver for ODBC section.

3.2.2. JDBC

The Virtuoso driver for JDBC is a type 4 native driver which is available for all Java platforms. This means that you have a single jar file, for which to include into your classpath, and then the driver is ready for use by your applications. The connection URL typically consists of:

```
jdbc:virtuoso://hostname:port/UID=uid/PWD=pwd
```

More information about the JDBC driver can be found in the Virtuoso Driver for JDBC section. The JDBC driver also supports SSL encrypted connections. This JDBC driver is an excellent companion to any web enabled applications especially when combined with Virtuoso's other features such as WSDL and SOAP.

3.2.3. OLEDB

Virtuoso gives application developers an opportunity to utilize OLE DB interfaces for their database programming needs. OLE DB is a Microsoft developed and promoted technology for uniform data access across diverse data sources. Many applications make indirect use of OLE DB through a higher level ADO interface.

VIRTOLEDB is the native OLE DB provider for Virtuoso . This enables applications to access a Virtuoso server using OLE DB interfaces. VIRTOLEDB provides implementation for all required and many optional OLE DB interfaces.

3.3. Virtual Database Server

Virtuoso's Virtual Database Engine enables you to produce Dynamic Web Content from any major database management system. This enables dynamic, real-time HTML and XML generation from any number of different database engines concurrently. The Visual Server Administration Interface of Virtuoso allows you to effortlessly remotely choose and configure remote data sources to be linked into Virtuoso. Once a table is linked into Virtuoso then it is usable like any native table leaving you free to perform join queries without ever worrying about the underlying data source.

The Virtual Database (VDB) Engine section of the Conceptual Overview chapter explains the concepts in more details.

Visit the Visual Server Administration Interface section to see how to link tables into Virtuoso, or follow the small example below to get you started:

3.3.1. Configuring Your ODBC Data Sources

Before you can link a table into Virtuoso, you need to configure an ODBC datasource. It is quite likely that you already have ODBC data sources defined. If so, you can skip this part of the tour.

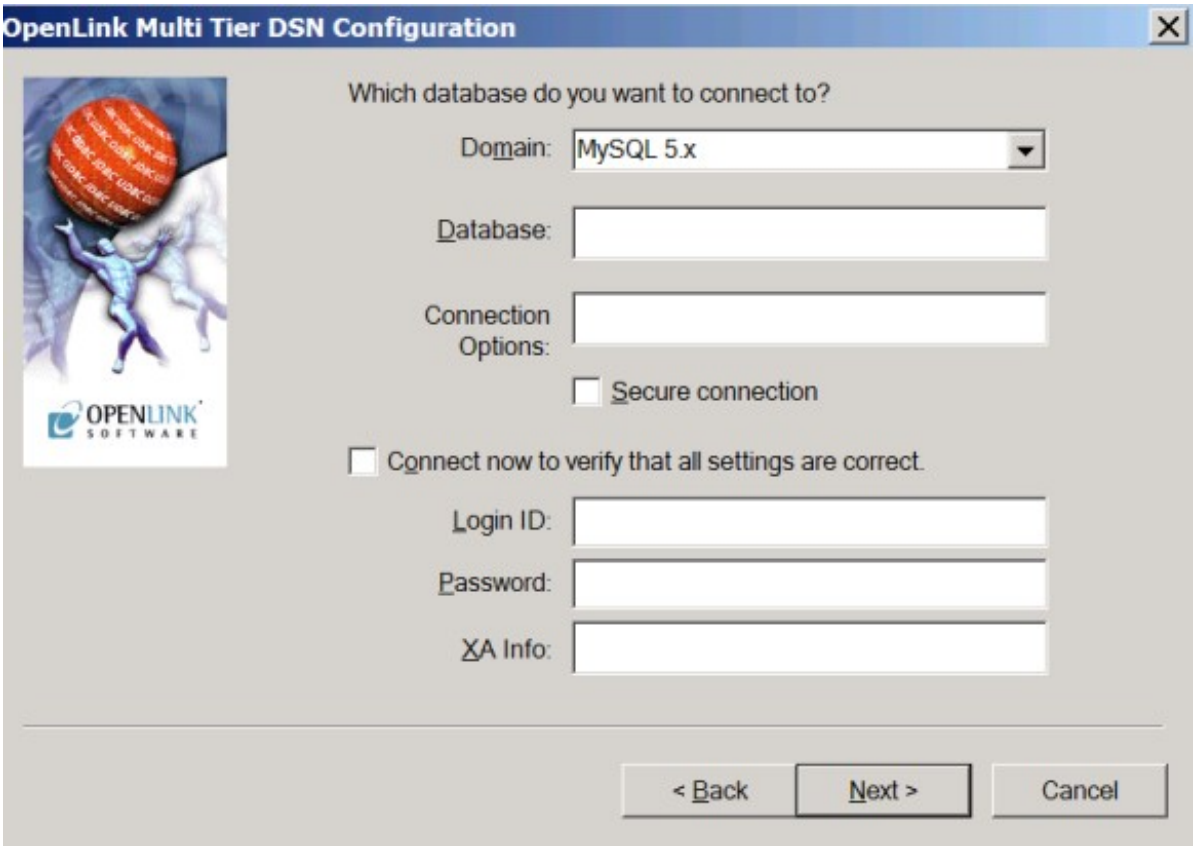
If you do not have any data sources defined, you should configure your datasource using an appropriate ODBC driver. The ODBC driver may come from the database vendor or a third-party middleware vendor, such as OpenLink Software. You will need to configure your ODBC datasource in accordance with the directions from your driver vendor.

In this part of the tour, we show sample DSN configuration information for some database vendor drivers. These examples of working data sources are not meant to replace the instructions from the driver vendor. In your specific installation other parameters may be necessary.

To define ODBC data sources on Windows XP/95/98/NT, in the Control Panel go to Administrative Tools and then click the Data Sources (ODBC) icon.

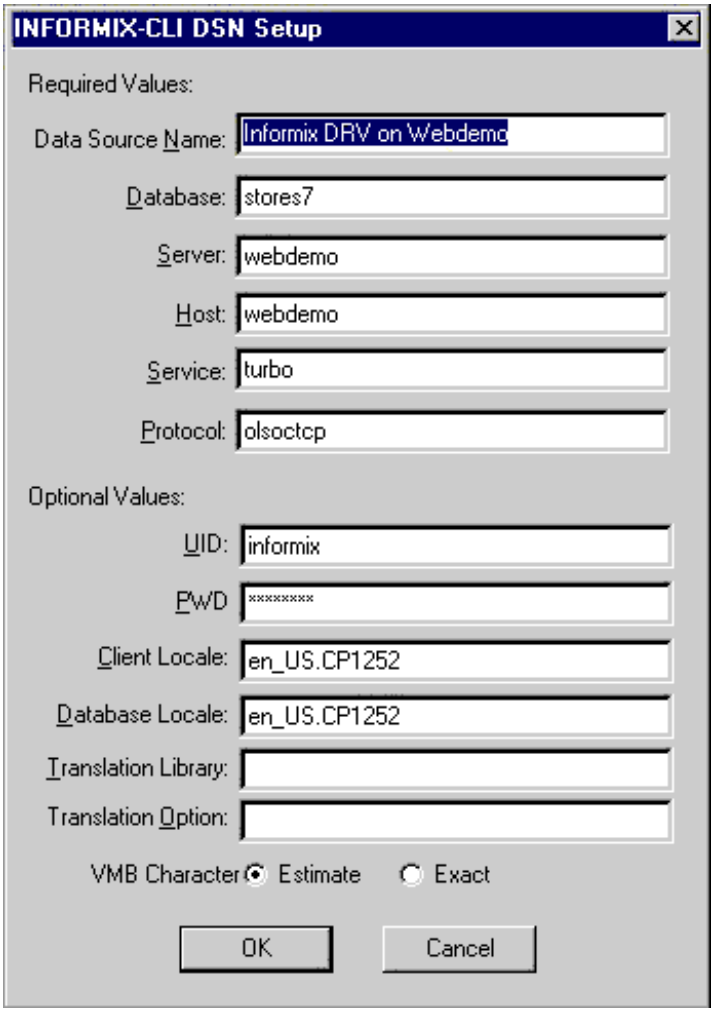
This first datasource uses OpenLink Generic ODBC Driver V6.0 to create DSN to a MySQL 5.x database.

Figure 3.7. OpenLink Mutli Tier DSN Configuration with database MySQL 5.x



The next example is an Informix 7 datasource using the driver from Informix Software, Inc.

Figure 3.8. Informix Driver DSN Configuration



The next few images show a Microsoft SQL Server 6.5 datasource using the Microsoft Corporation SQL Server driver.

Figure 3.9. MS SQL Server DSN Configuration

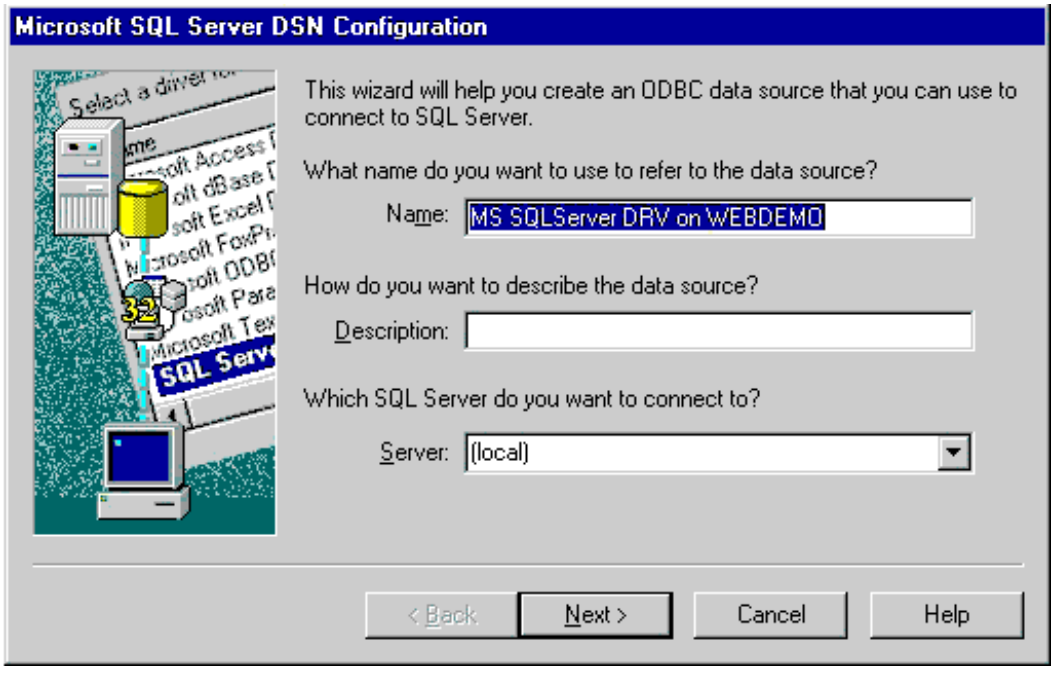


Figure 3.10. MS SQL Server DSN Configuration

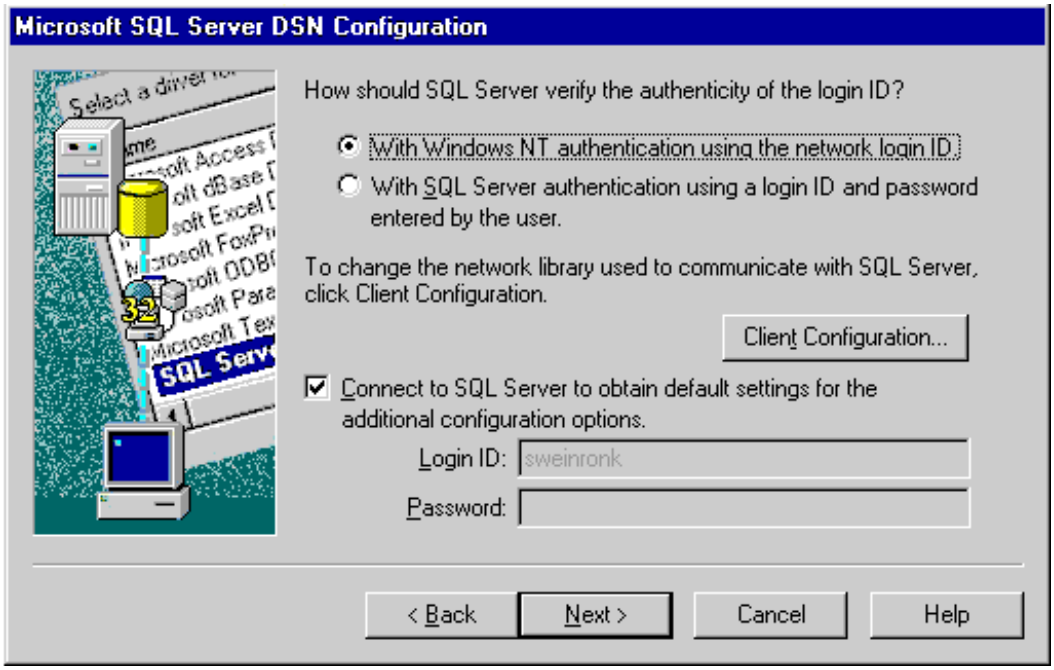

Figure 3.11. MS SQL Server DSN Configuration

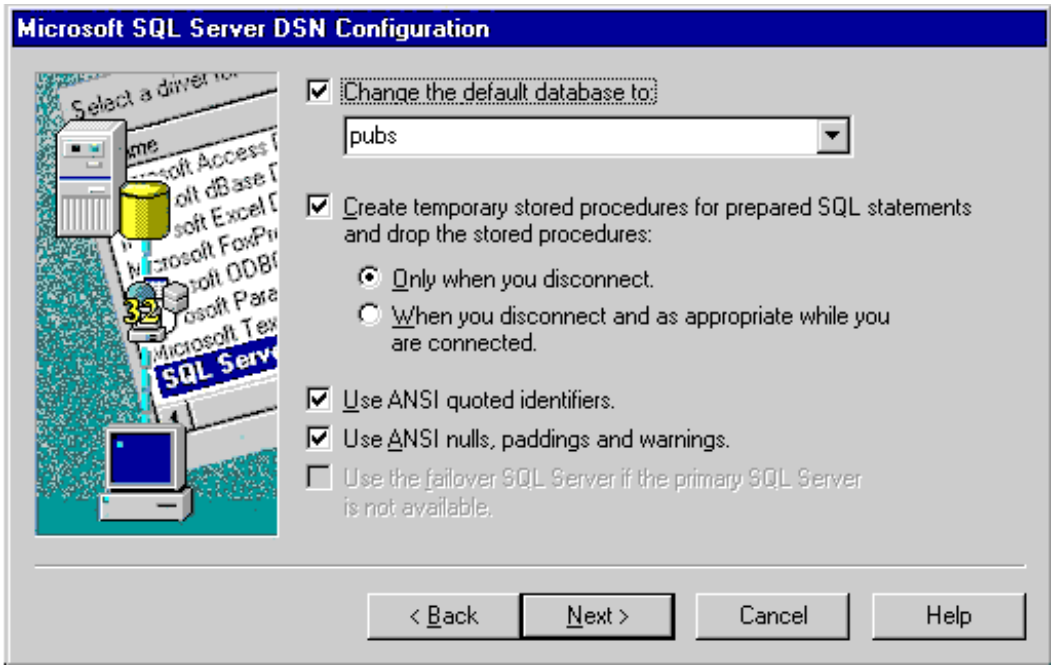

Figure 3.12. MS SQL Server DSN Configuration

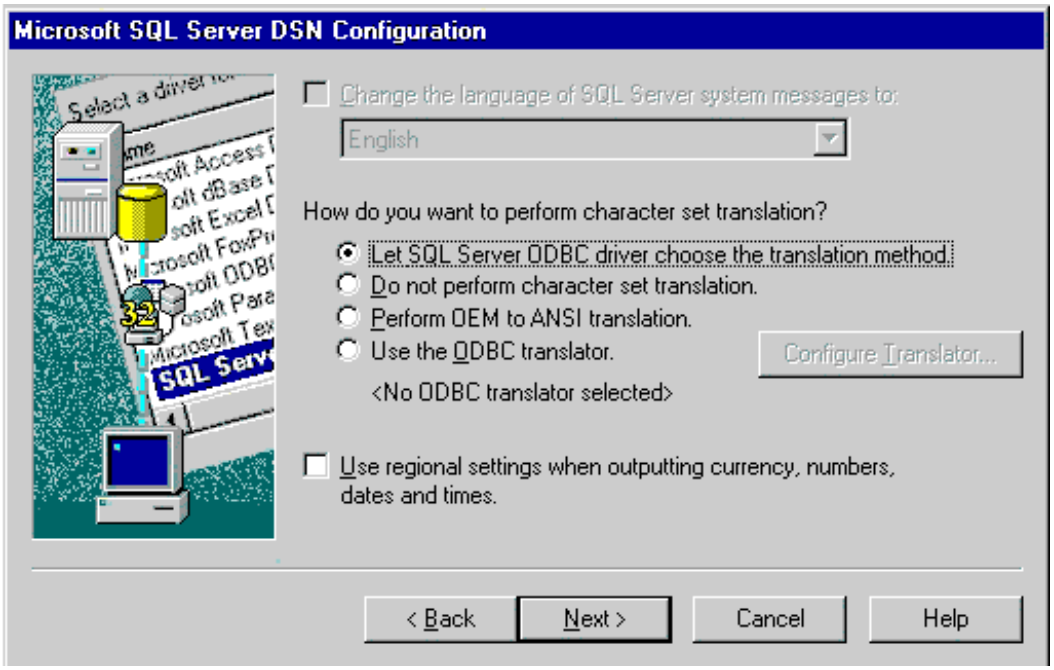

Figure 3.13. MS SQL Server DSN Configuration

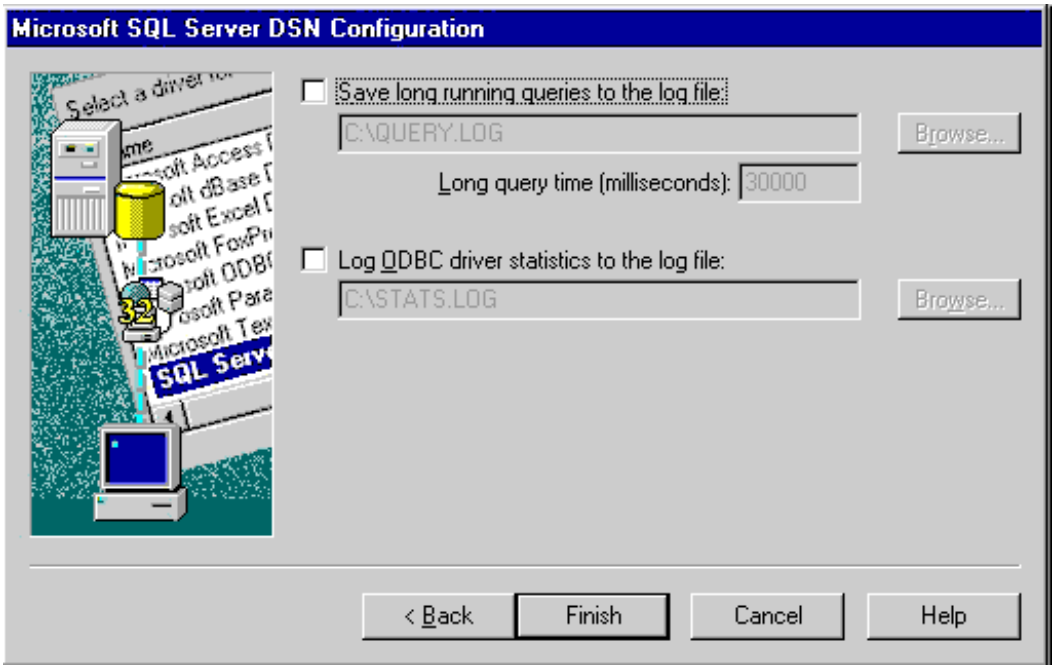
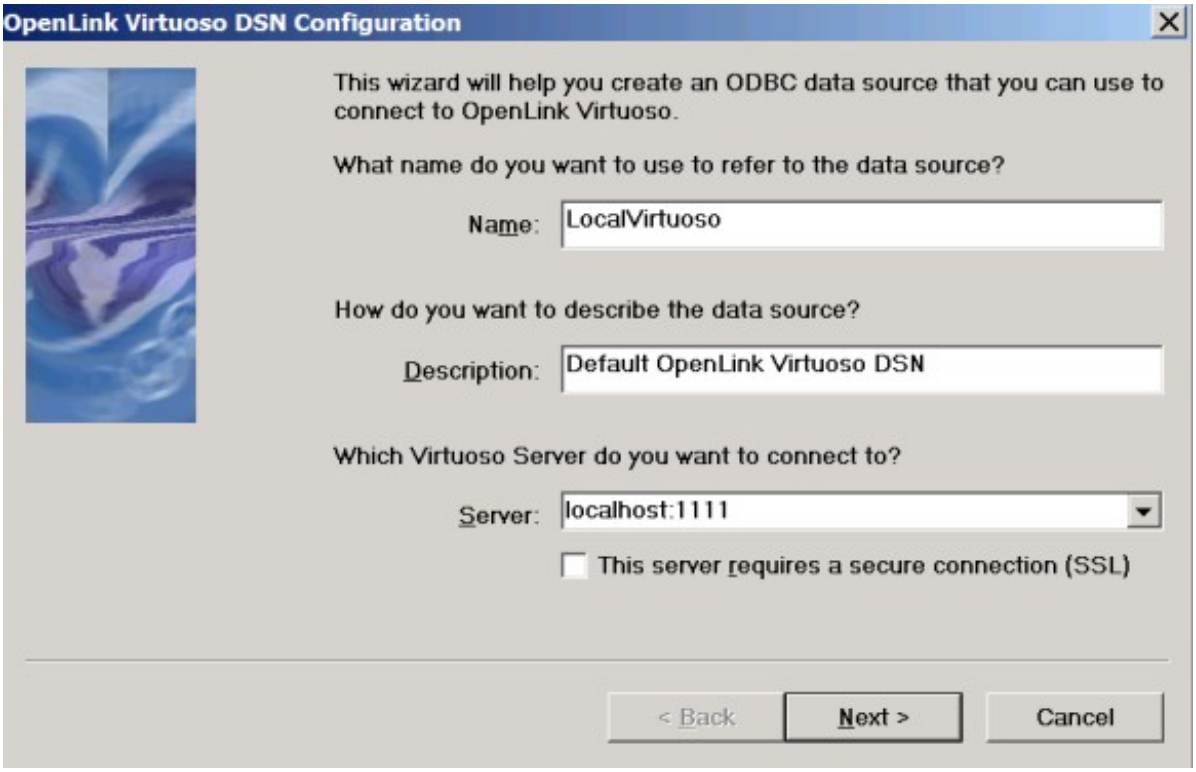


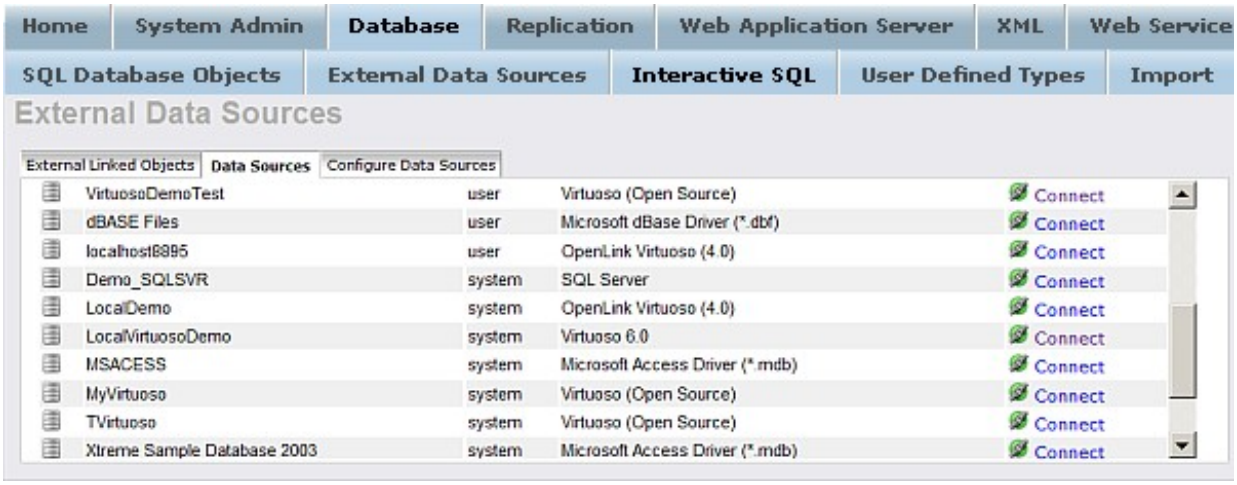
Finally, review the configuration information for your default local Virtuoso datasource, named "*Local Virtuoso* ".

Figure 3.14. OpenLink Virtuoso DSN Configuration



DSNs can be created and configured within the Virtuoso Conductor. Go to "Database", then to "External Data Sources" and then go to "Configure Data Sources" tab. Click the "Add System DSN", or "Add User DSN", or "Add File DSN" button.

Figure 3.15. Creating a new DSN



3.3.2. Datasource Check

Before trying to link a table into Virtuoso, you should verify that the datasource is working correctly. Use a tool such as Microsoft Access, or ODBCtest to test your datasource. Your sanity check will verify that the datasource is correctly configured, that all necessary software is installed, that the database is running, and that there are no permission related problems. In addition, it will verify that the driver that you are using works correctly with the underlying datasource.

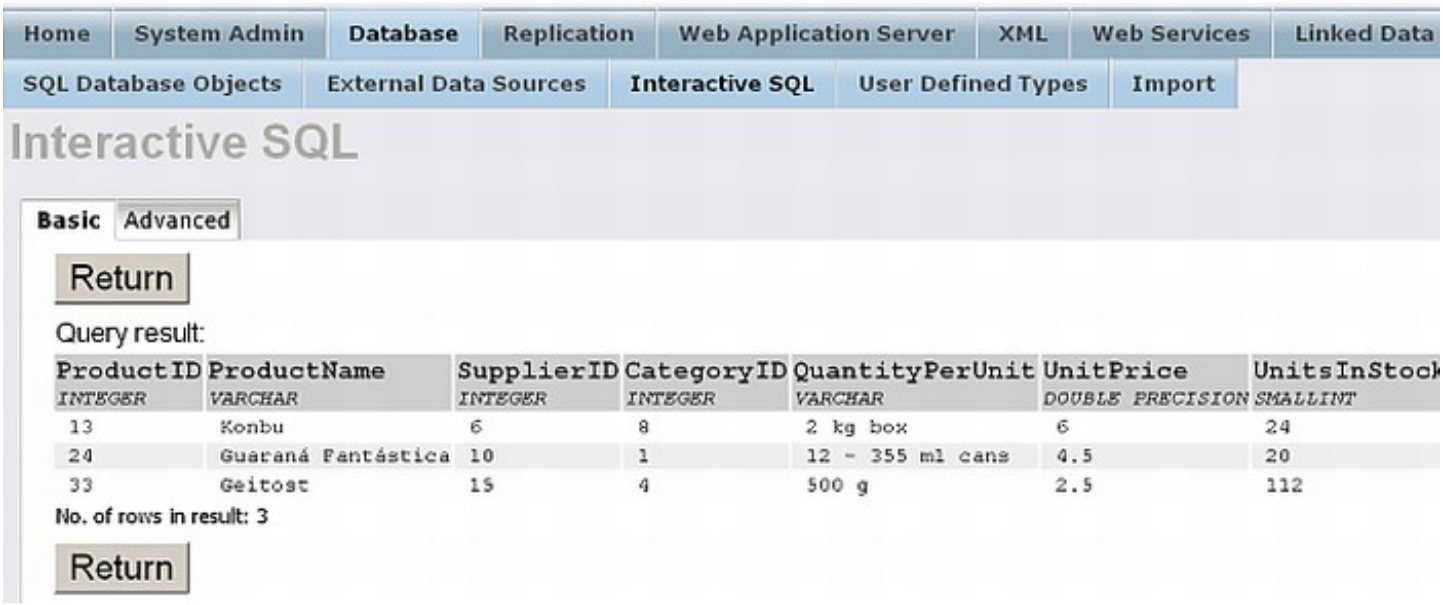
If there is a problem using a specific tool such as Microsoft Access with a specific driver, then that same problem will be manifested when the datasource is exposed via Virtuoso.

3.3.3. Demo Datasource Query

To query the sample data in the Demo Database make sure the web browser is pointing to the Demo database HTTP port which is typically 8890. From Conductor go to tab "Database" and then select the tab "Interactive SQL". Enter a SQL statement and click the button "Execute". For example:

```
SELECT * FROM DEMO..products WHERE UnitPrice < 7
```

Figure 3.16. Demo Database Query



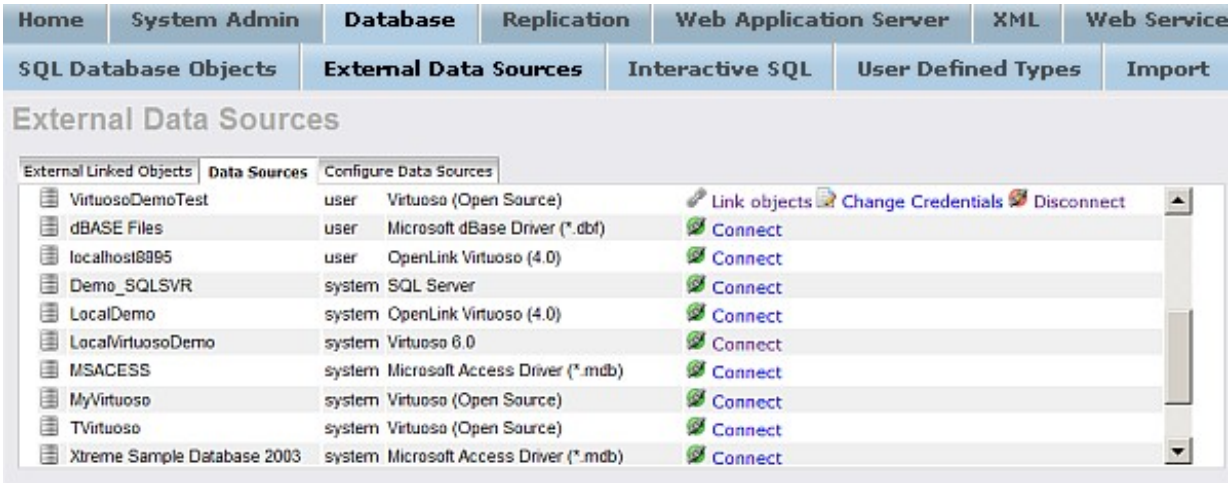
3.3.4. Linking Remote Tables Into Virtuoso

A table on a remote datasource may be linked into the Virtuoso database so that it appears as a local table. Start a browser and point to Conductor, for ex. http://example.com:8890/conductor/. Go to tab "Database", then select "External Data Sources" and then "Sata Sources". Specify the remote datasource that you wish to link to Virtuoso. For example, click the link "connect" for DSN "VirtuosoDemoTest".

Figure 3.17. Enter login name and password.

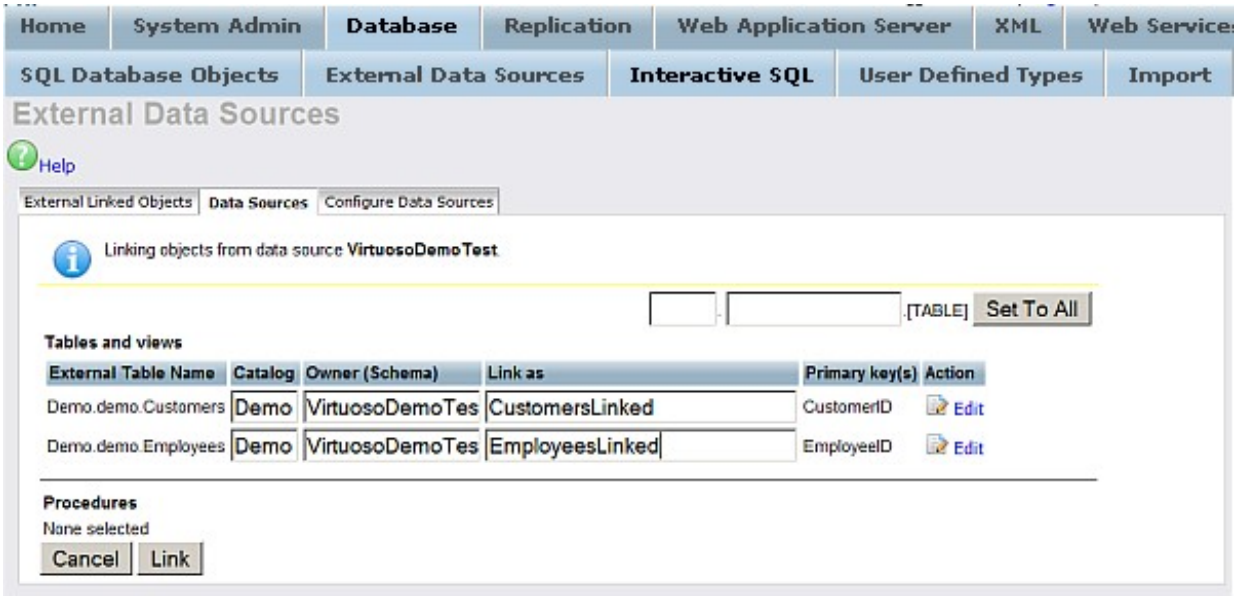
As result should be shown for DSN "VirtuosoDemoTest" the links "Link objects", "Change Credentials", "Disconnect". Click the "Link objects" link.

Figure 3.18. Connected to datasource.



Pick the tables to be linked, and define the names to use.

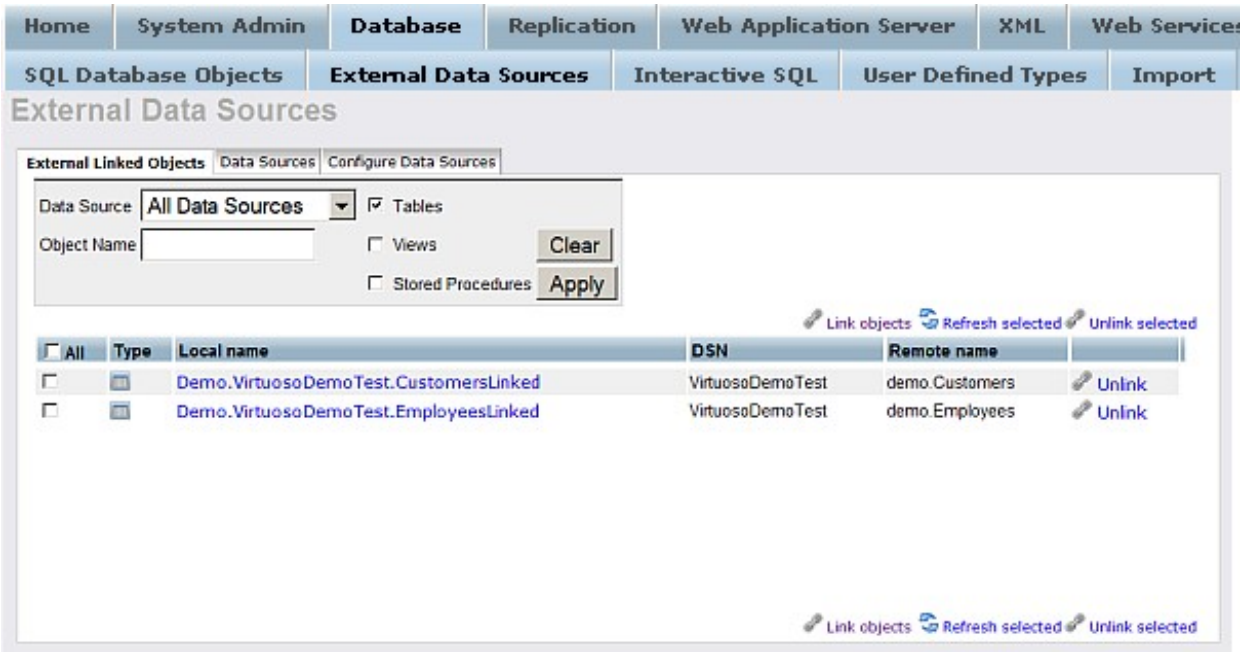
Figure 3.19. Define tables to link



3.3.5. Listing or Unlinking Tables

To list the tables that have been linked into Virtuoso, from Conductor go to *Databases/ External Data Sources/ External Linked Objects* . A table may be unlinked by pressing its "Unlink" icon.

Figure 3.20. List of Connected Data Sources

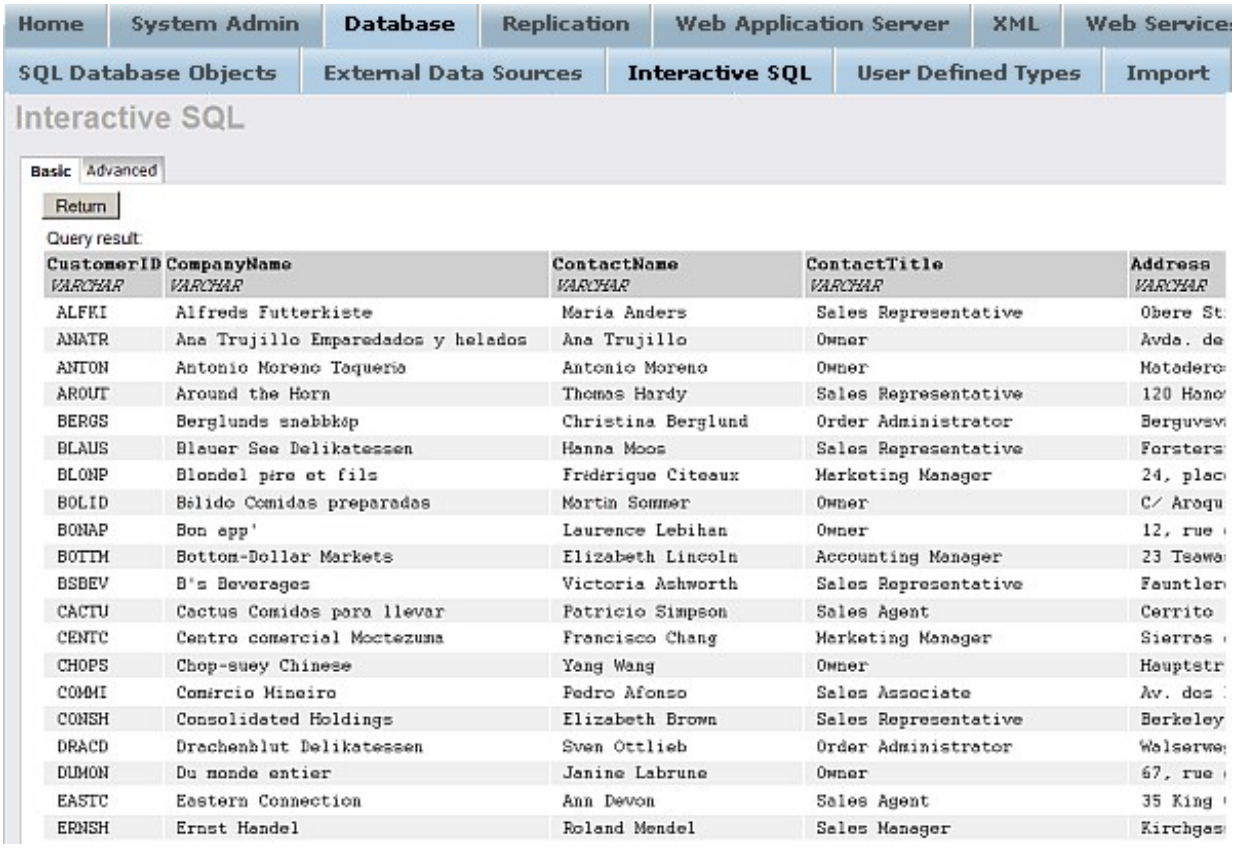


3.3.6. Querying Linked Tables

Once the tables have been linked into Virtuoso, they can be queried using the Interactive SQL query. From the Conductor UI go to *Database/Interactive SQL* . Type a SQL that accesses a remote table such as: SELECT * FROM Demo.VirtuosoDemoTest.CustomersLinked. Click the "Execute" button.

Press the Execute button and review the results.

Figure 3.21. Remote Table Query



3.4. Web Server

3.4.1. Virtual Directories

The term virtual directory applies to the mechanism to hide the physical location of a Web resource under different path which user agents use to retrieve it. This mechanism in virtuoso is a part of host definition.

This method is useful when one server has to keep many Web sites. Using a redirect mechanism is not a universal way to do this. It is better to define virtual hosts and paths to the directory entries which contain Web pages.

Creating Virtual Directories Programmatically

For an overview of virtual directories, and how to configure them in PL, refer to the Virtual Directories Section .

Setup in Administration Interface

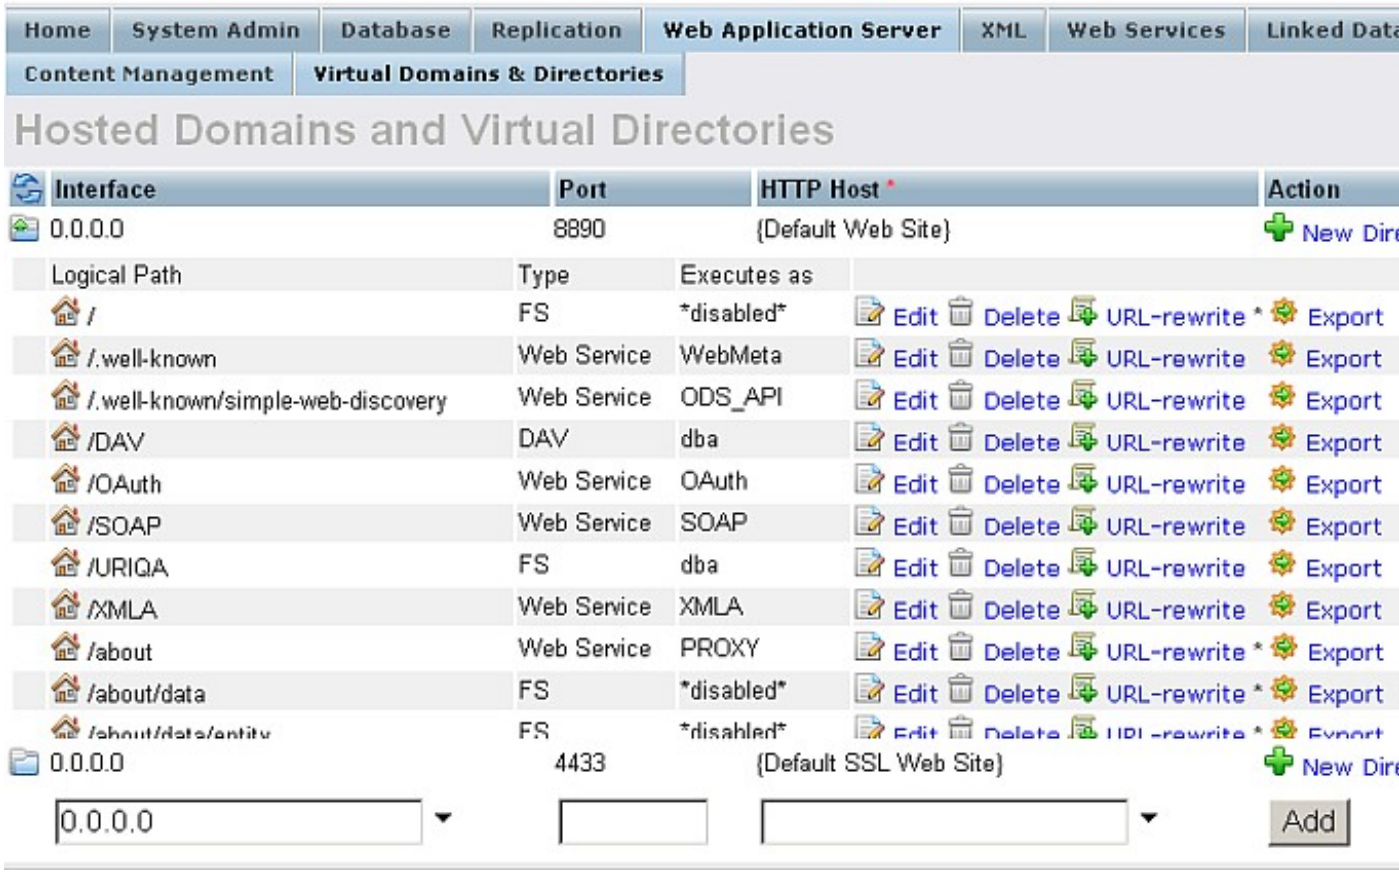
This step by step example will define a virtual directory /help that will point to the directory /departments/support/

1. From the Conductor UI go to Web Application Server/ Virtual Domains & Directories.

   Figure 3.22. Http Hosts and Directories

2. Open the "folder" icon for your {Default Web Site}.

   Figure 3.23. Edit URL mappings

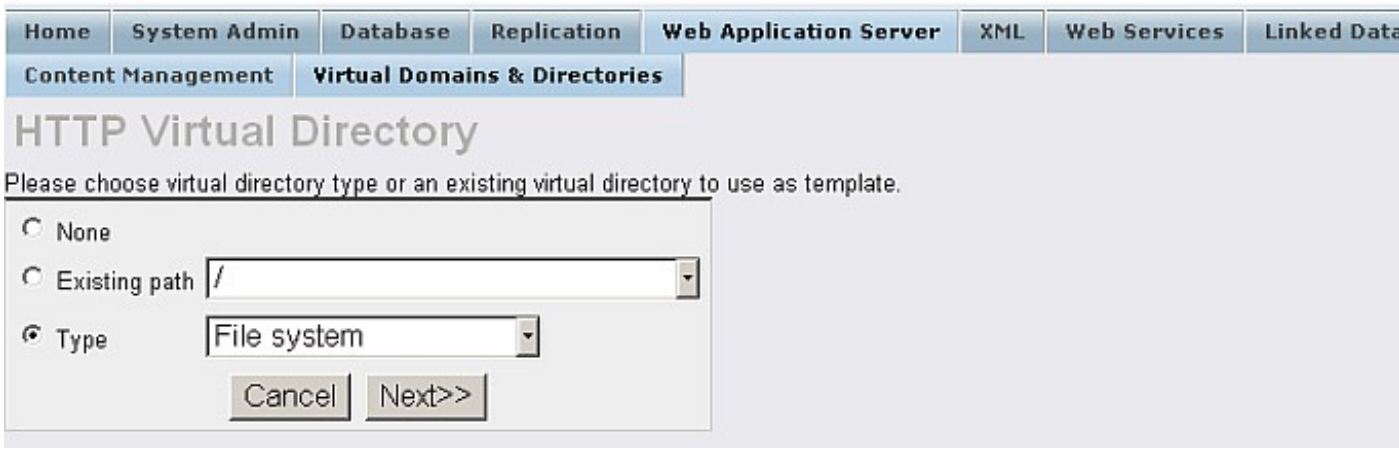


3. Click the link "New Directory" to add a new virtual directory.

Figure 3.24. Add virtual directory

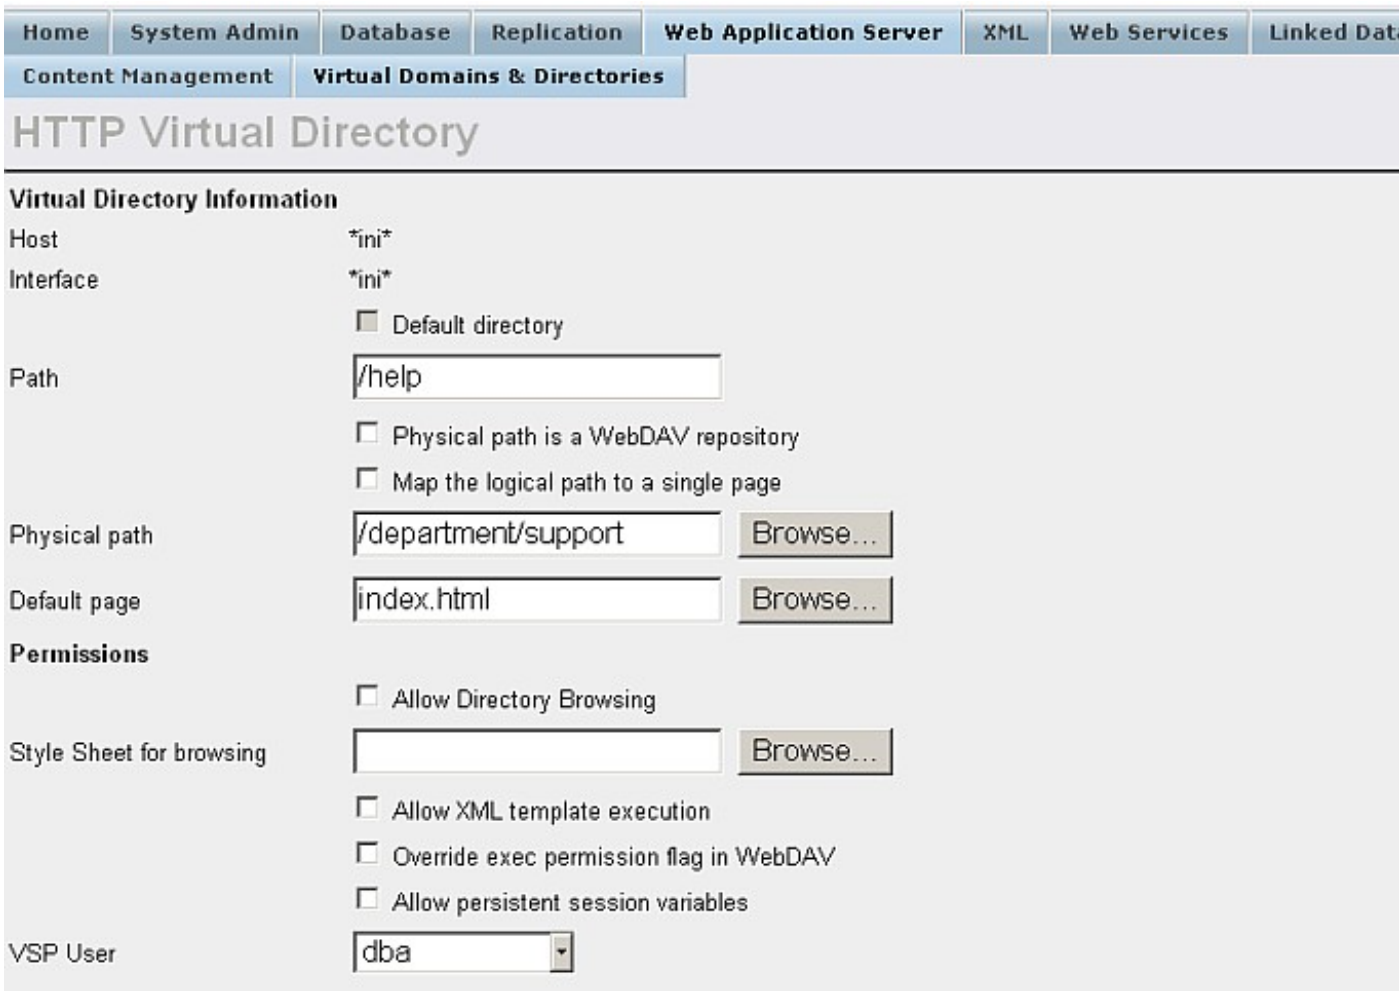
4. Select for "Type" File system, as this mapping example will be from one directory to another, and click "Next".

Figure 3.25. Use File system template



5. Enter details in the form to define the mapping. Most of the fields are optional. In this example, only the logical and physical paths and the default page name are required. Click finally the button "Save Changes".

Figure 3.26. Mapping details



6. The following URLs will then be equivalent:

   http://example.com:8890/help
   http://example.com:8890/departments/support/index.html

3.4.2. Multi Homing

The term Multi Homing refers to the practice of maintaining more than one server on one machine, differentiated by their apparent host name. It is often desirable for companies sharing a web server to have their own domains, with web servers accessible as www.company1.com and www.company2.com, without requiring the user to know any extra path information.

Creating Multiple Homes Programmatically

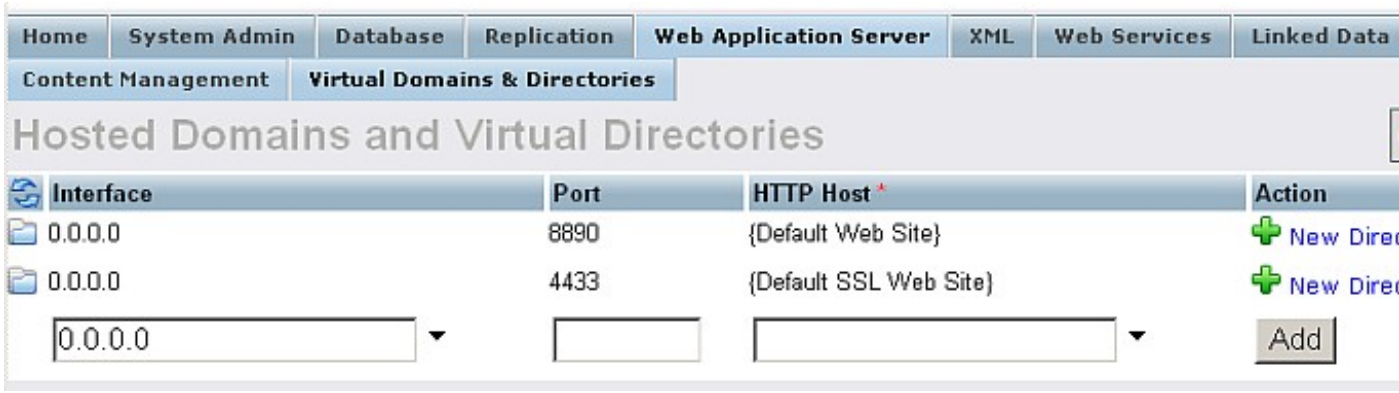
For an overview of Multi Homing, and how to configure it with PL, refer to the Virtual Hosting and Multi Hosting section.

Setup in Administration Interface

This step by step example will define a virtual home for the URL http://www.ahelp.com/ to the server www.a.com and directory /departments/support/

1. Have a domain name allocated in the DNS for the ahelp.com that points to the same IP address of the a.com that is hosting a Virtuoso server.
2. From the Conductor UI go to Web Application Server/ Virtual Domains & Directories.

   Figure 3.27. Http Hosts and Directories.

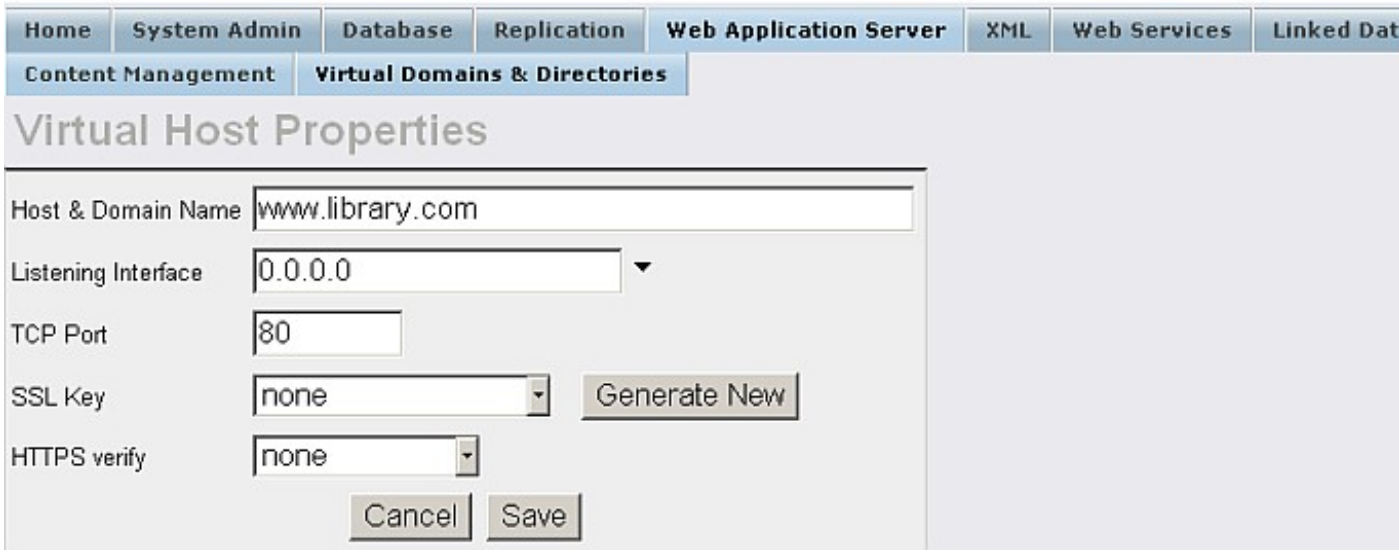


3. To add a new host definition, enter for "Port" 80, enter for "HTTP Host" www.ahelp.com and select the "Add" button.

   Figure 3.28. Add new site

4. Click for the new defined site the "Edit" link in order to define the mapping between the virtual host and the actual listening host domain names.

   Figure 3.29. New site mapping

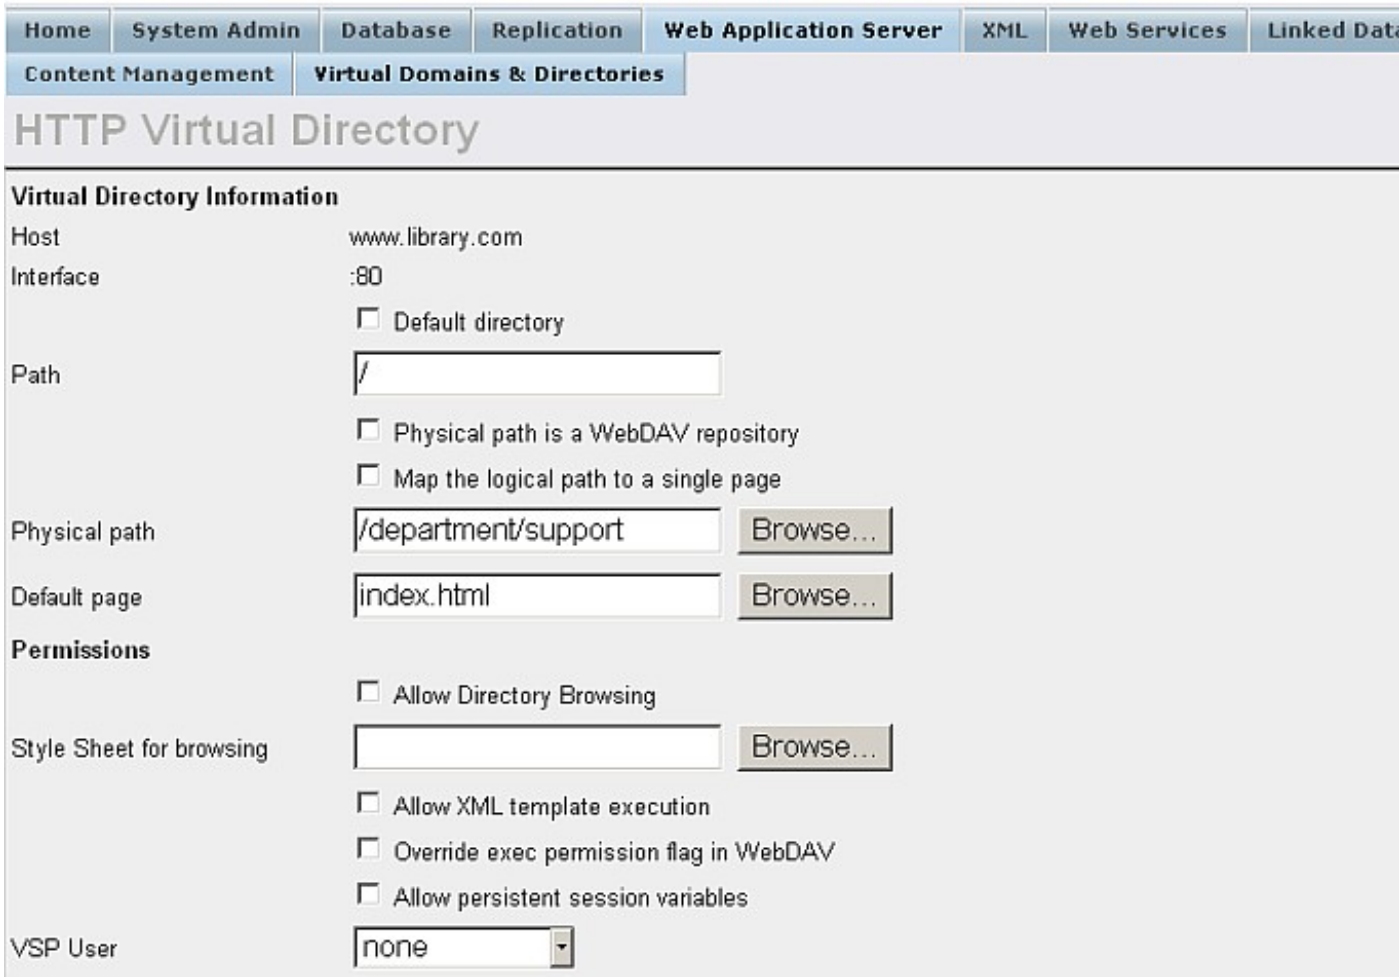


5. Click the "folder" icon for the new defined site and then click the "Edit" link for the Logical Path "/".

Figure 3.30. Set Logical Path

6. Enter details in the form to define the mapping. Most of the fields are optional. In this example, only the logical and physical paths and the default page name are required.

Figure 3.31. Mapping details



7. The following URLs will then be equivalent:

   http://www.ahelp.com/
   http://www.a.com/departments/support/index.html

3.5. WebDAV

WebDAV support enables Virtuoso to act as the Web Content Store for all of your eBusiness data, this includes Text, Graphics and Multimedia files. WebDAV support also enables Virtuoso to play the familiar roles of a FILE & WEB SERVER, hosting entire Web sites within a single database file, or across multiple database files. Virtuoso's WebDAV provides file system like access to its non SQL data repository.

Files contained in the DAV repository are stored in a database table. Free text indexing and replication mechanisms may be applied to the DAV repository as well as the regular database. Standards based WebDAV methods are used to access resources stored in the repository based on Virtuoso's full-featured SQL-92 database engine with performance that matches or exceeds that of current major players in the DB market. Typical WebDAV clients that can access the repository for content management include Network Places on Windows through Explorer, Nautilus on Gnome (Linux and Solaris), and the Mac OS X desktop. Many web development tools also support WebDAV directly.

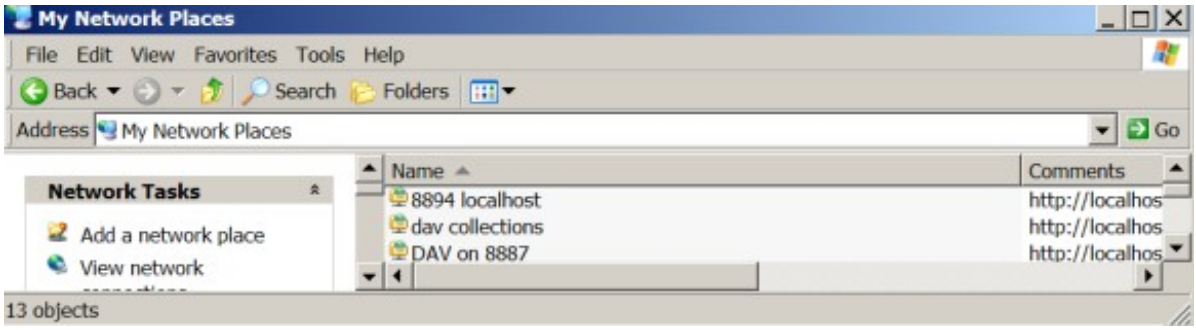
See the WebDAV Administration section, to setup the WebDAV in the Visual Server Administration Interface.

3.5.1. Web Folders

Microsoft Windows has a notion of a Web Folder. This is how Windows connects to a WebDAV store which can then be traversed like any other file system. Files can be copied and moved to and from the DAV using normal drag-and-drop methods.

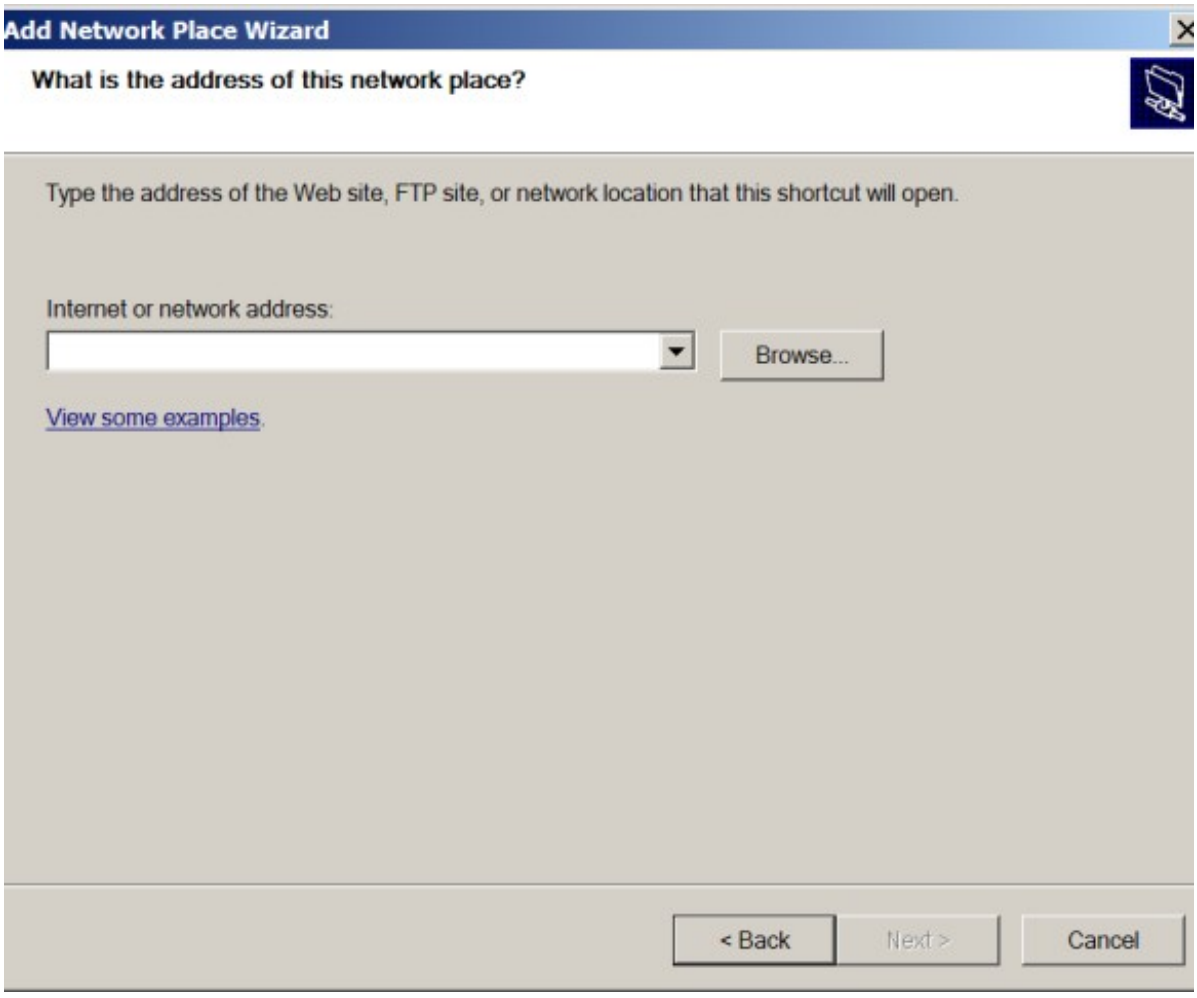
1. To create a Web Folder open the *Windows Explorer* and navigate to *My Network Places* .

Figure 3.32. My Network Places



2. You will find an icon or option to *Add Network Place* which when double-clicked will lead you to the wizard.

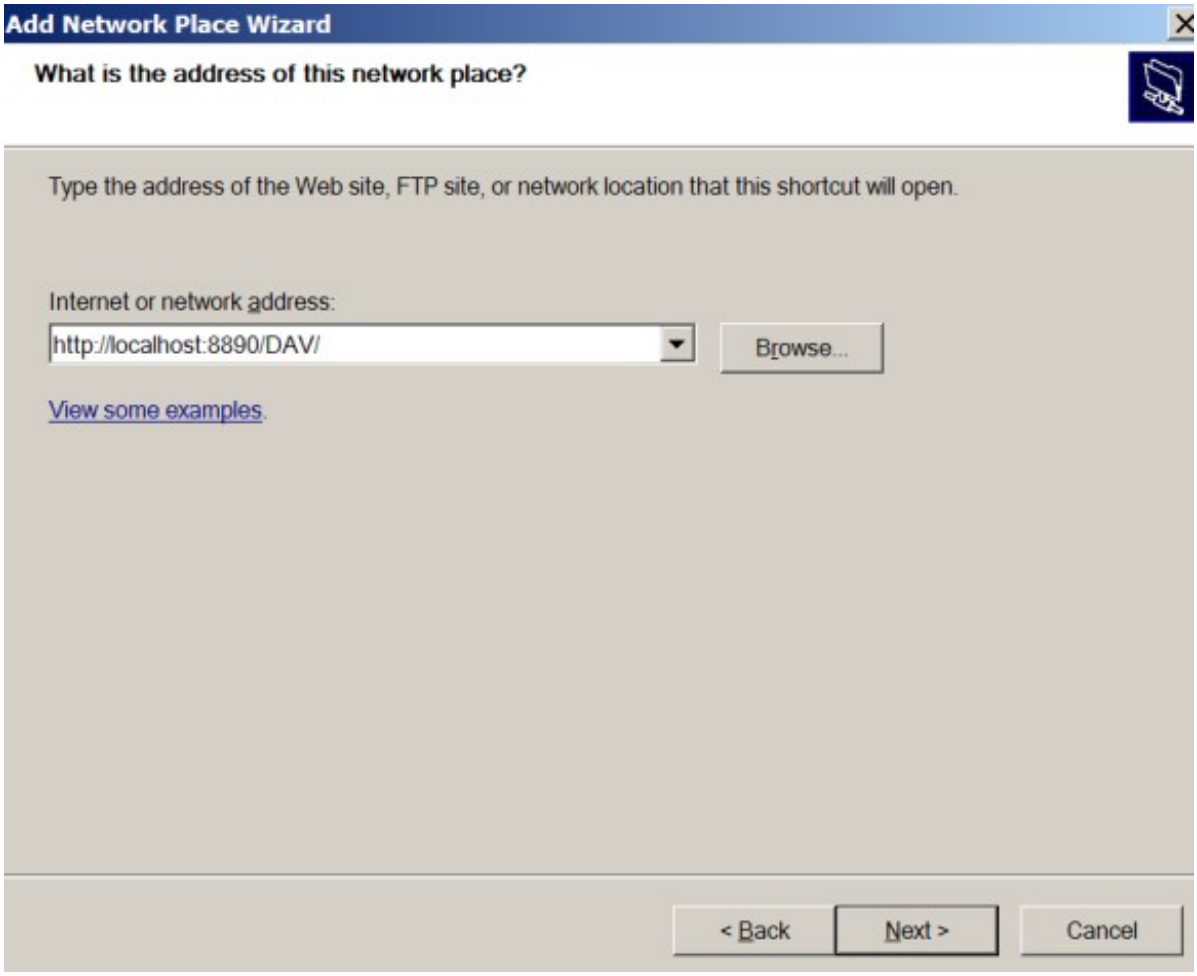
Figure 3.33. Web Folder Wizard



3. The first screen encourages you to type the location of the network place, for connecting to a Virtuoso DAV you will need to know the server location and port number. If you installed Virtuoso on to your local machine taking default options then you would probably be typing:

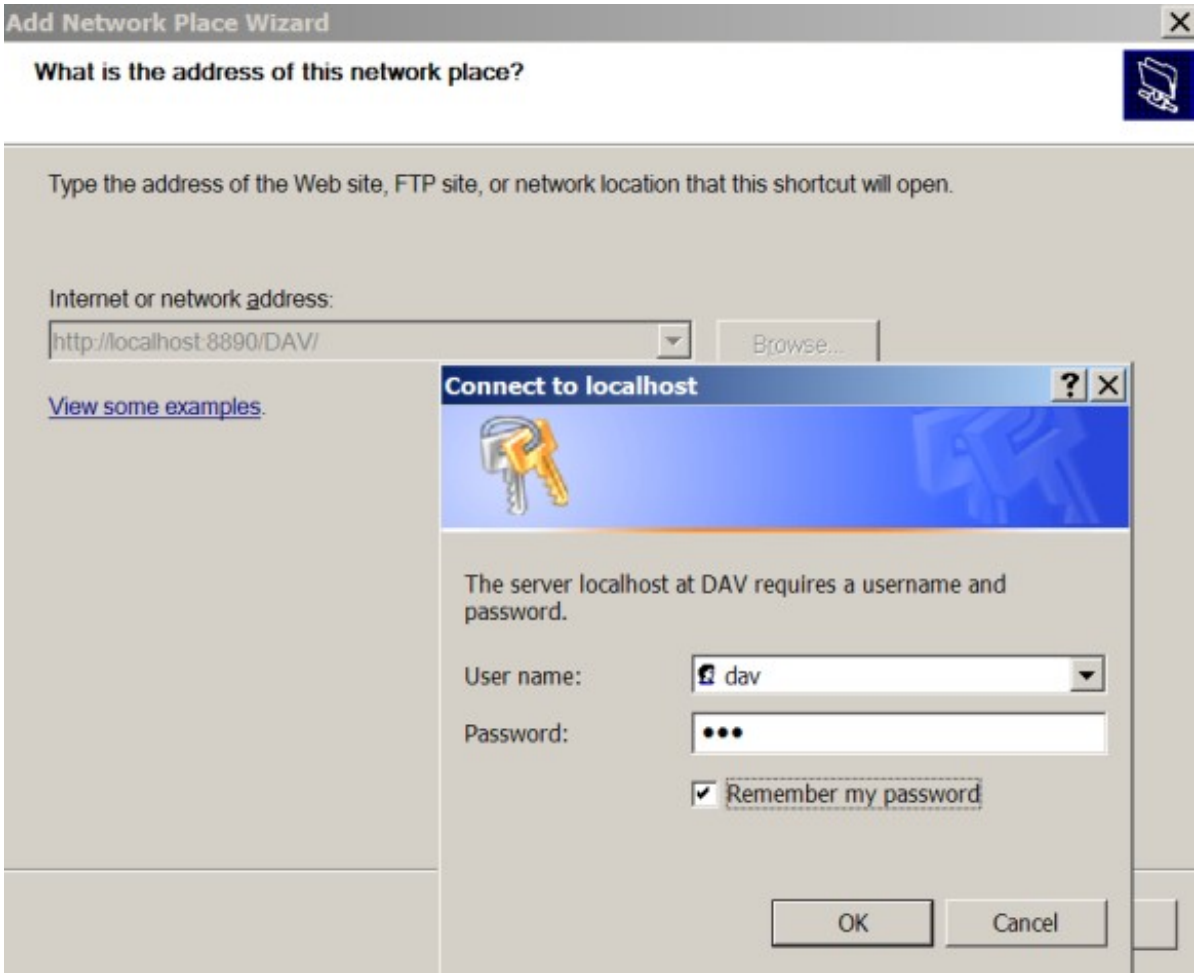
```
http://example.com:8889/DAV/
```

Figure 3.34. WebDAV location



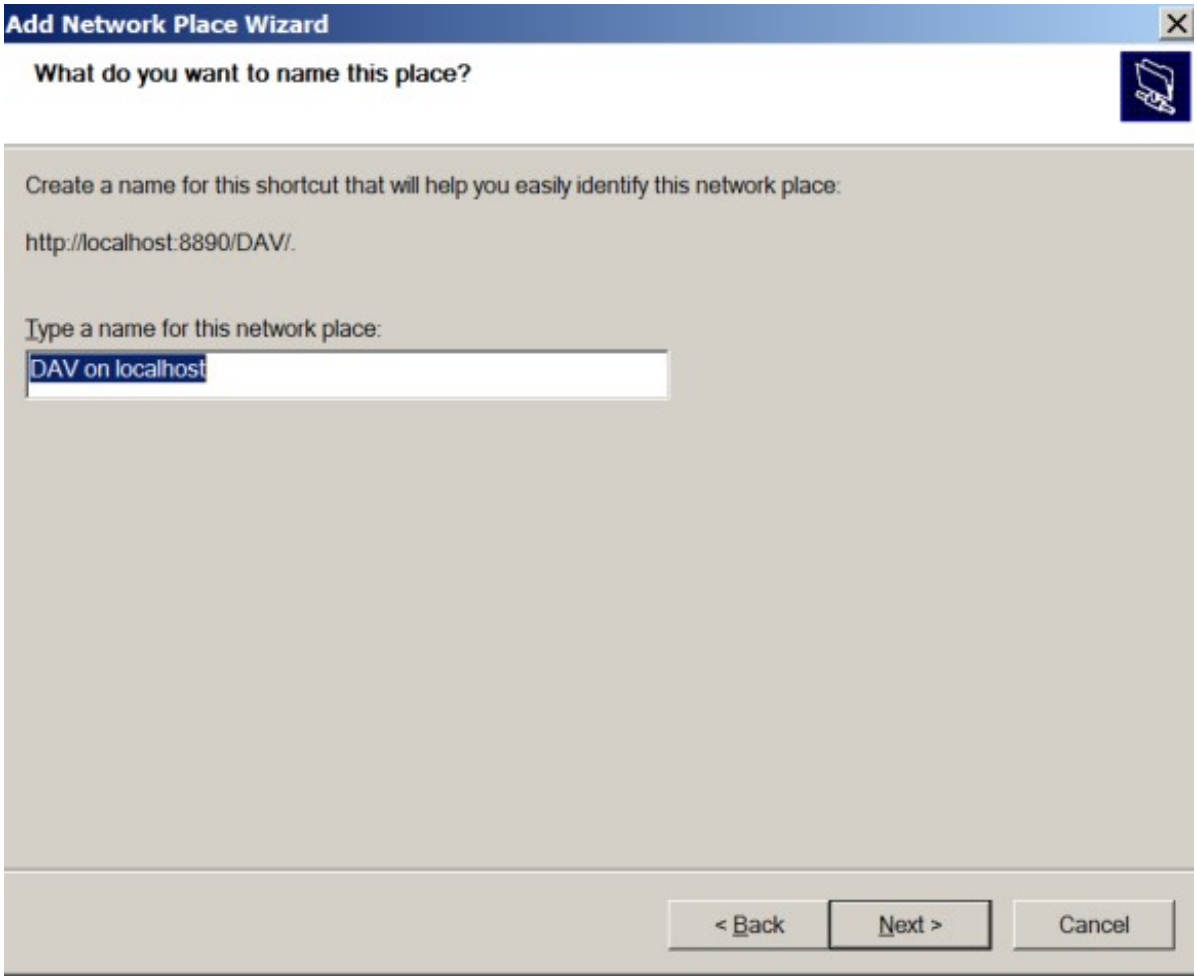
4. You will then be asked for authentication information which will require a username and a password. If defaults are taken then this would simply be dav and dav for both.

Figure 3.35. WebDAV authentication



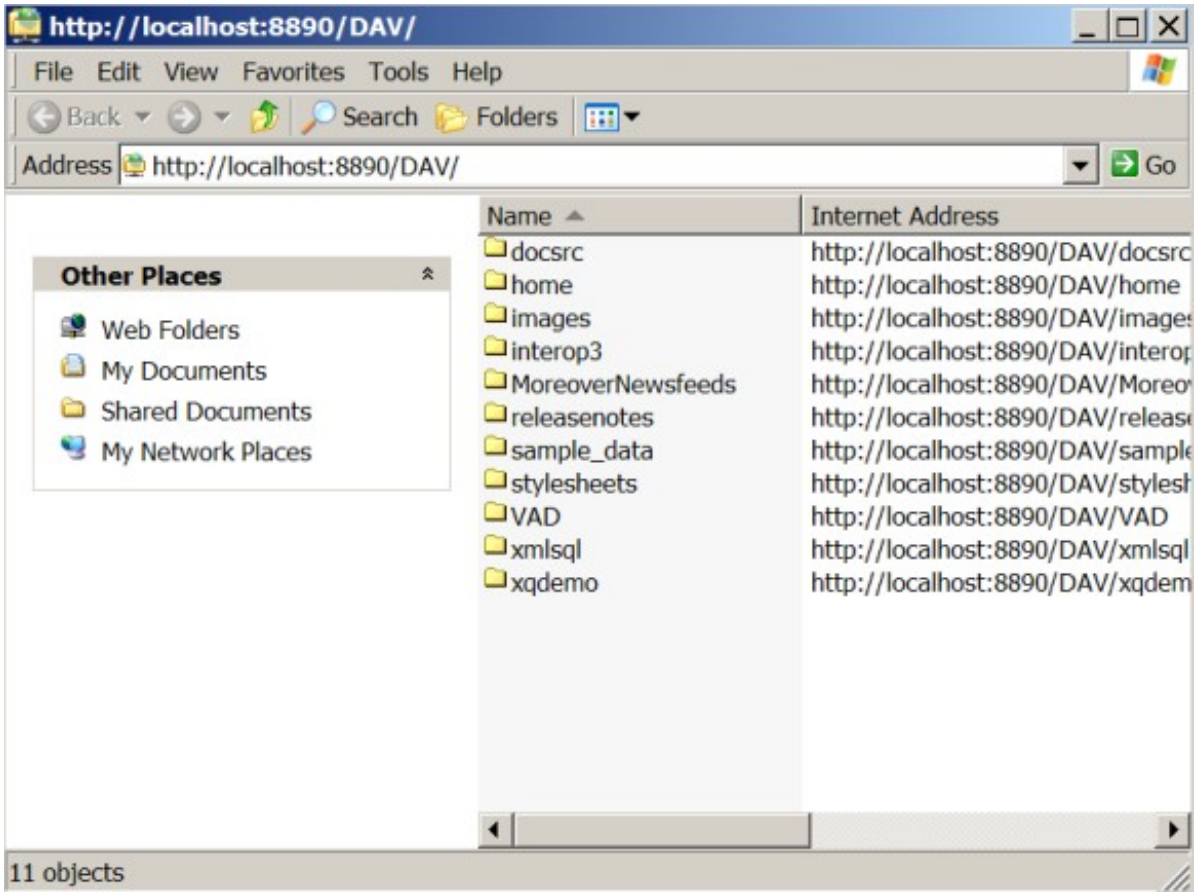
5. To complete the creation of a Web Folder you be asked to supply a name for the network place.

Figure 3.36. Name of your WebDAV Web Folder



6. Once provided Explorer will automatically open a new Window over looking the new location.

Figure 3.37. Files contained in your DAV



7. You can find your new Web Folder again from My Network Places where the link will be saved.

3.6. Web Services

SOAP is a lightweight, extensible, XML-based protocol for information exchange in a decentralized, distributed environment. Primarily, SOAP defines a framework for message structure and a message processing model. SOAP also defines a set of encoding rules for serializing data and a convention for making remote procedure calls. The SOAP extensibility model provides the foundation for a wide range of composable modules and protocols running over a variety of underlying protocols such as HTTP.

By Supporting the Simple Object Access Protocol (SOAP) , Virtuoso enables you to integrate business processes within and across organization boundaries. Virtuoso's SOAP Support implementation enables you to execute Virtuoso Stored Procedures over HTTP. This is a significant component in any B2B development and implementation effort. Development is very rapid and is directly incorporated within the database environment required for keeping B2B processes running accurately.

3.7. Exposing Persistent Stored Modules as Web Services

Virtuoso SQL stored procedures and functions can be exposed as SOAP services very simply from Virtuoso, whether they are native Virtuoso or on remote data sources. This powerful ability means that any database servers already existing within an organization can easily become a component in an eBusiness solution using Virtuoso. All you need is a few simple steps that typically take mere minutes to complete:

- **Choose your stored procedure(s).** The procedures that you want to expose can either be native Virtuoso stored procedures, or remote stored procedures that can be linked in using the Remote Procedures user interface.
- **Choose a virtual directory.** Because SOAP services need to be exposed and accessed via HTTP a Virtuoso virtual directory must be used. Either use the existing SOAP virtual directory or create a new one.
- **Publish procedures to virtual directory.** The user specified as SOAP account on the virtual directory must have execute privileges on the procedures. Use the Publish options on the virtual directory user interface.
- **Test the VSMX output.** Once procedures have been published as SOAP services they are automatically described by WSDL and testable using Virtuoso's VSMX feature.

XML Query Templates provide a direct way to store SQL in an XML file on the Virtuoso server that when executed, i.e. fetched from a web browser, actually returns the results of the query.

The C Interface chapter describes how users can define custom built-in functions, from C or other programming languages, that can be used from within Virtuoso PL. This also means that VSE's can also be published as a Web Service!

3.7.1. Publishing Stored Procedures as Web Services

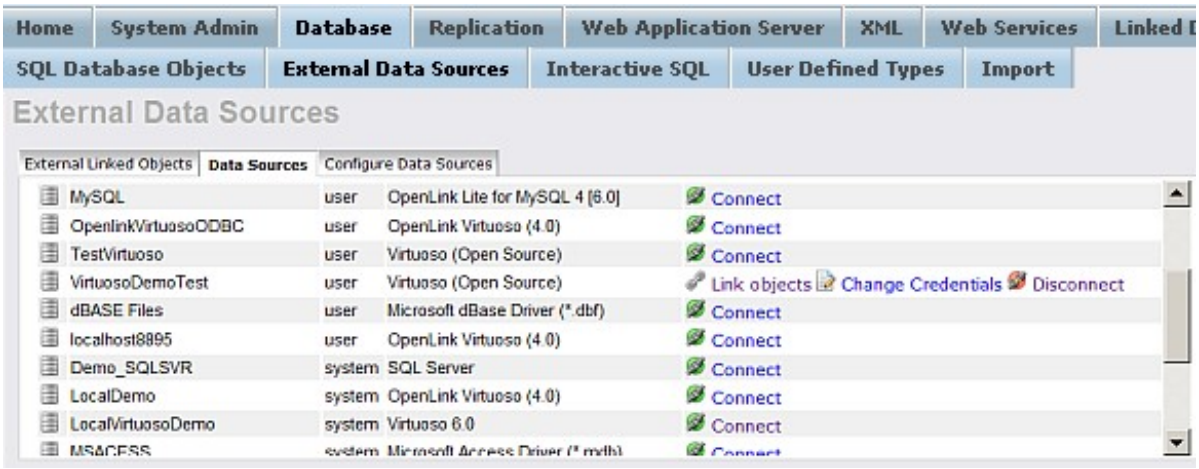
Choosing Stored Procedures to Expose

You can either expose native Virtuoso stored procedures (previously defined or newly created) using the CREATE PROCEDURE statement, or stored procedures from other database types can be linked into Virtuoso using an ODBC datasource.

Virtuoso lists available stored procedures for each catalog in Conductor under: */Database/External Data Sources/External Linked Objects / with checked "Stored Procedures"* .

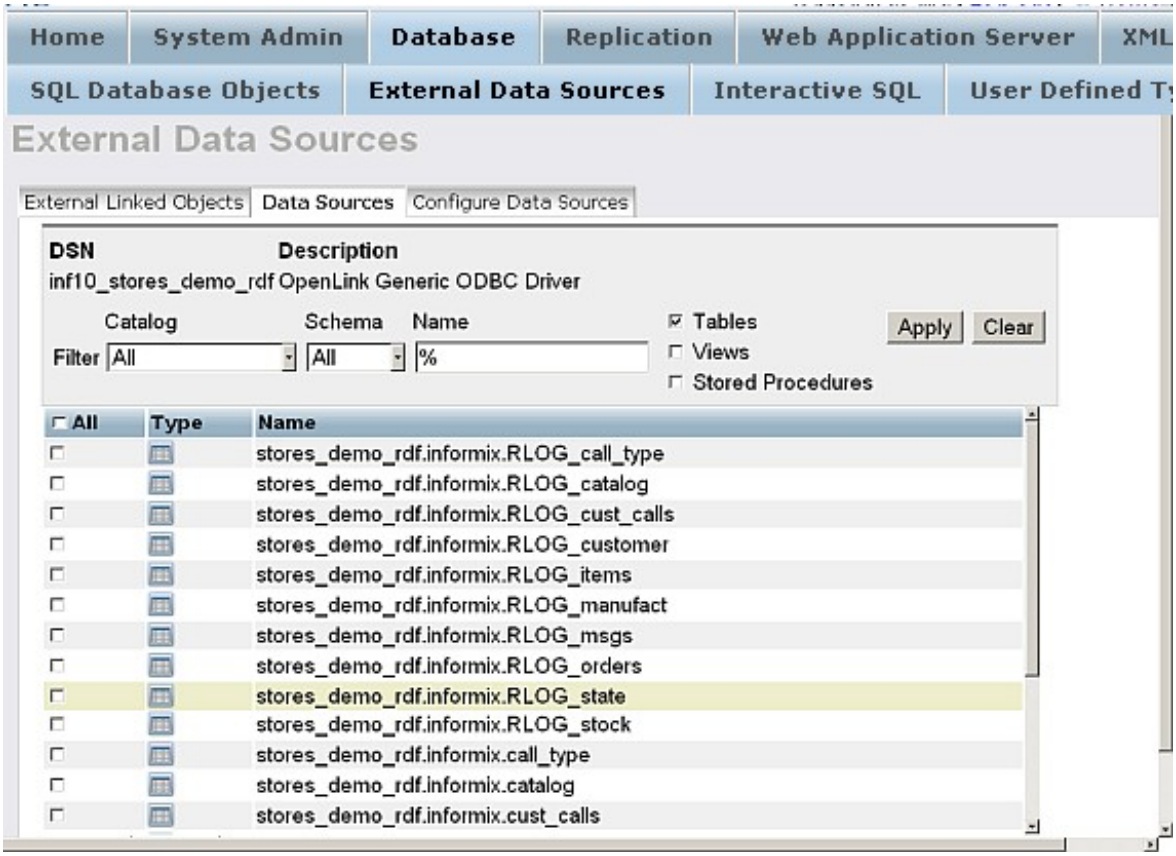
To link a stored procedure from another database system we must first create a valid data source that leads to a connection to that database. Once verified proceed to the Remote Procedures page. Select the "Link objects" link for a data source.

Figure 3.38. Linking Procedures from Remote Data Sources



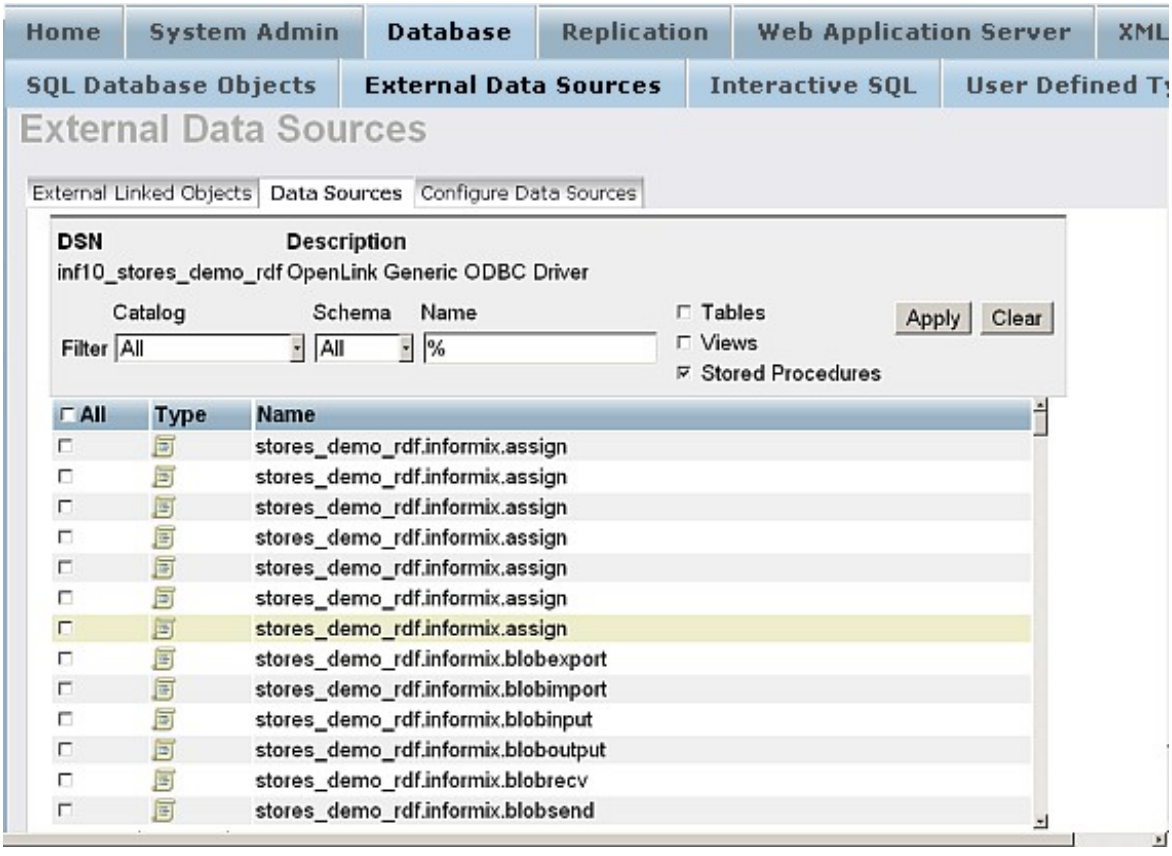
Select the check-box "Store Procedures". Click the "Apply" button. As result will be shown the list of available procedures.

Figure 3.39. Linking Procedures from Remote Datasources



Select the check-boxes for the procedures you want to link and click the "Link" button.

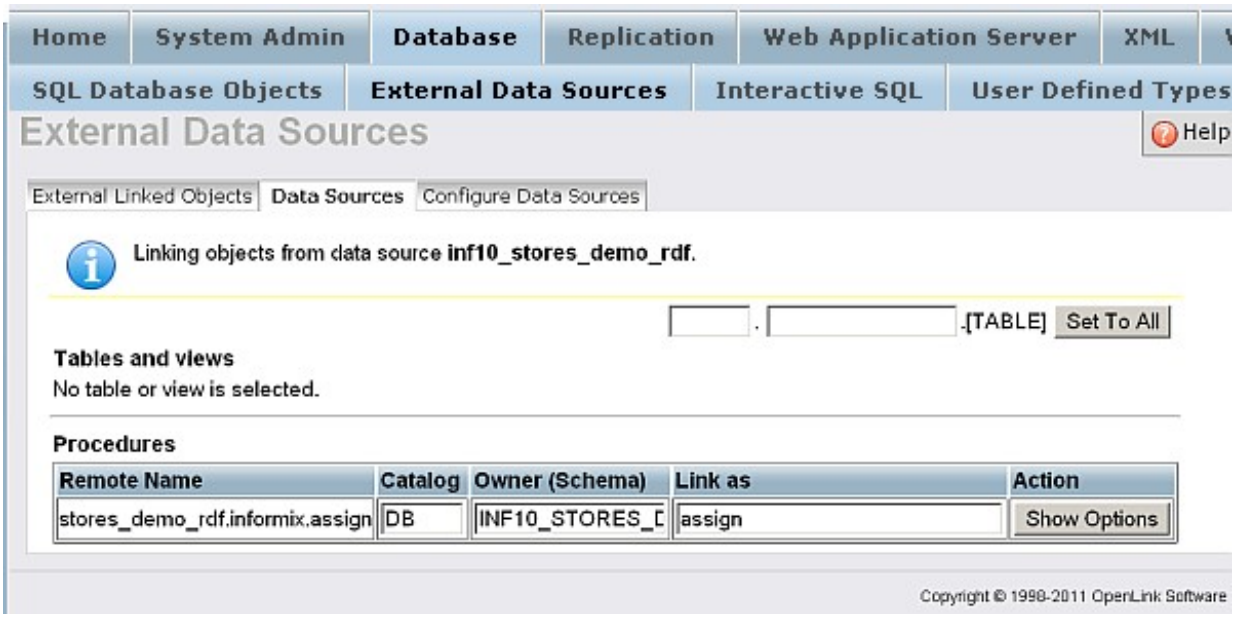
Figure 3.40. Linking Procedures from Remote Datasources



You will be presented with a new page listing the chosen procedures and their data type information. This gives you an opportunity to alter the data type mappings that Virtuoso will use both internally and for any future interactions with the SOAP

server. If you do not want to specify any special type information the details can be left as default.

Figure 3.41. Linking Procedures from Remote Datasources



For each remote procedure you may change how they will be referenced within Virtuoso by making changes to the fields for *Catalog* , *Owner* , *Link as* , and *Description* fields. These fields define how you will find the linked procedure locally to Virtuoso only and do not affect the remote data source.

For each procedure there is an option to *PL Wrapper Requirement* . This option is required if your remote procedure is capable of returning a resultset that you want to process via Virtuoso. Can be *SOAP Execution* , *SQL Execution* or *None* . Also you can specify *Return Type* , *Data Type* , *SOAP Type* .

Once the details are correct press the "Link" button.

See Also:
Linking Remote Procedures

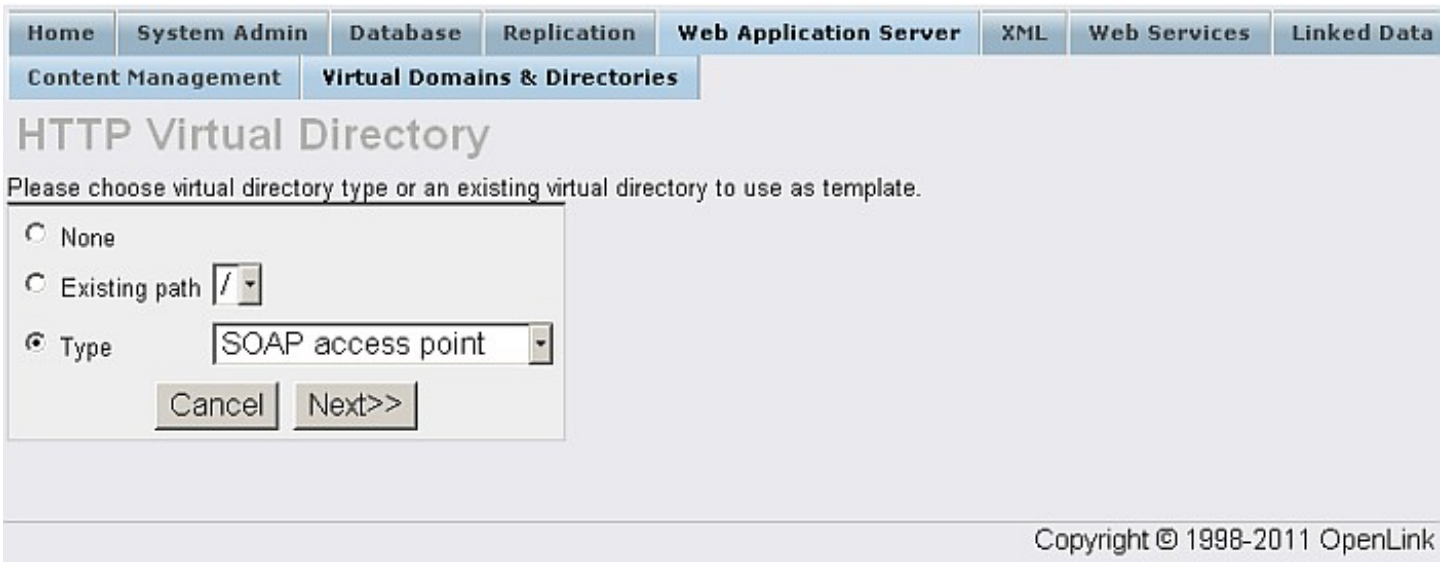
Defining Virtual Directories

Before any procedures native or linked can be exposed as SOAP Services a location in HTTP space must be defined. From Conductor *Web Application Server/Virtual Domains & Directories* you make a new URL Mappings. Click on the *New Directory* link for the {Default Web Site} line to begin defining a new SOAP mapping.

Figure 3.42. Virtual Directories

Select for "Type" from the list the value "SOAP access point" and click the "Next" button.

Figure 3.43. Virtual Directories Mappings

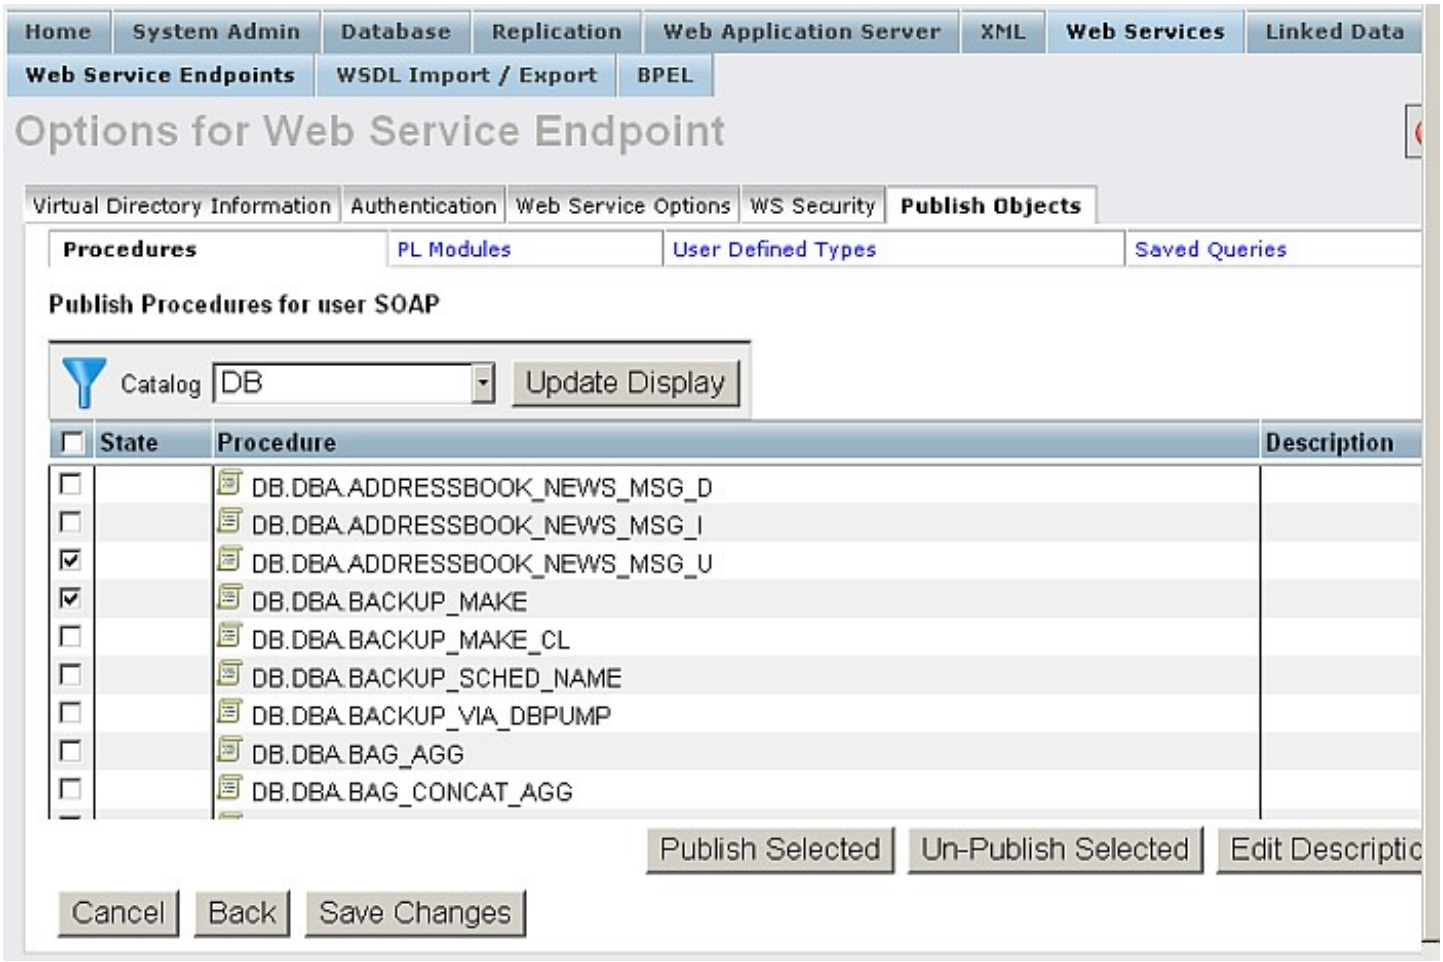


You will then be presented with the following tabs: "Virtual Directory Information", "Authentication", "Web Service Option", "WS Security" and "Publish Objects". Particular options to note are "Virtual Directory Information" and "Publish Objects".

Figure 3.44. Virtual Directories

In *Publish Objects* you can select Virtuoso stored procedures, or remotely linked procedures to be published as SOAP web services. Also you can publish Pl Modules, User Defined Types, or Saved Queries.

Figure 3.45. Publish Objects

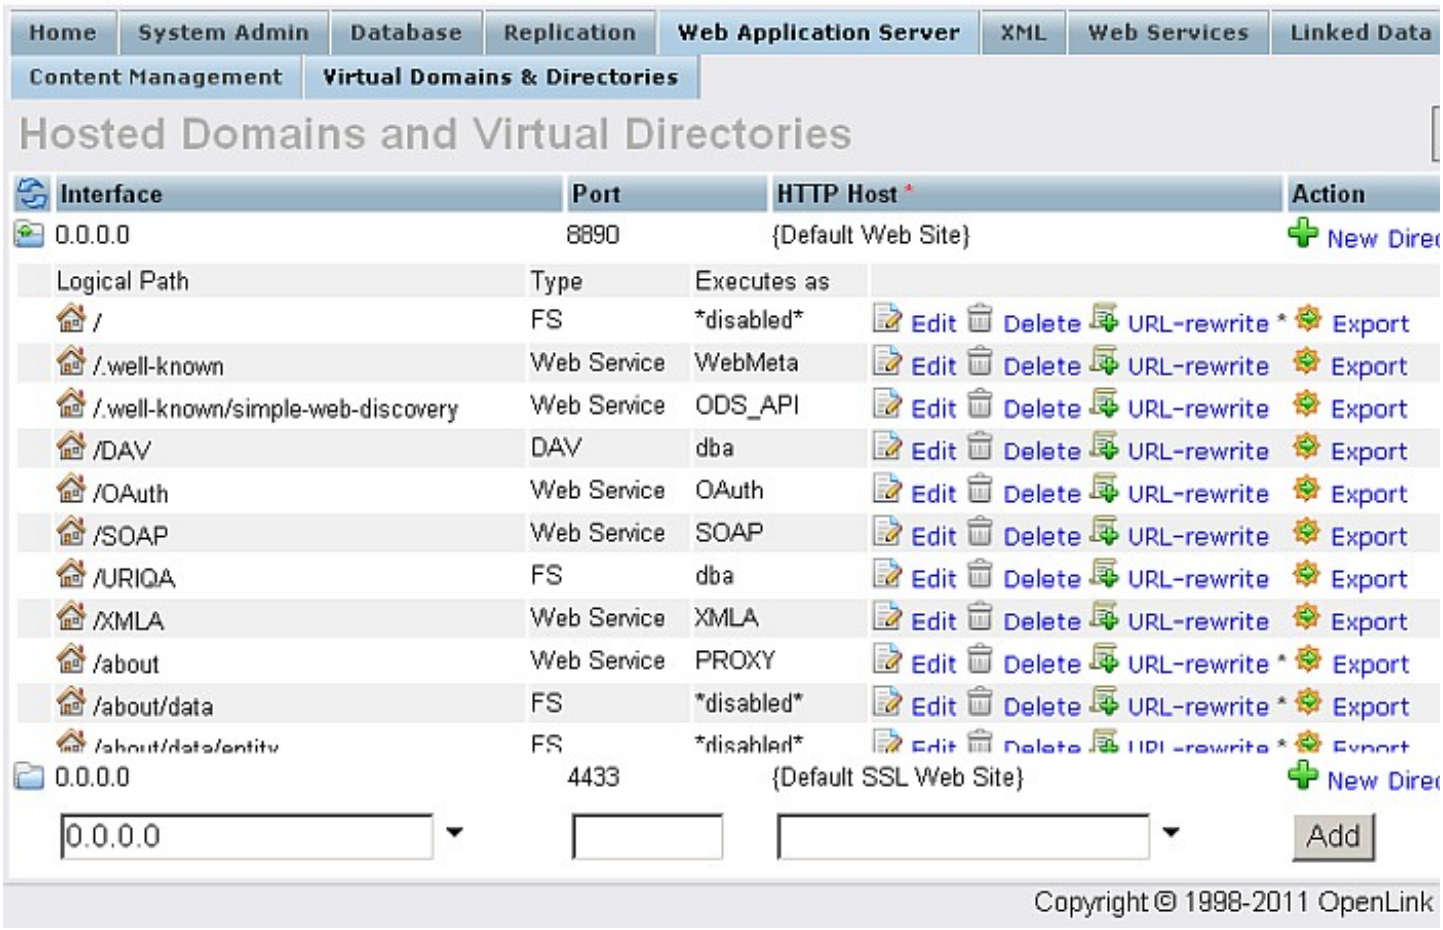


See Also:
Virtual Directories

Publishing Procedures to a Virtual Directory

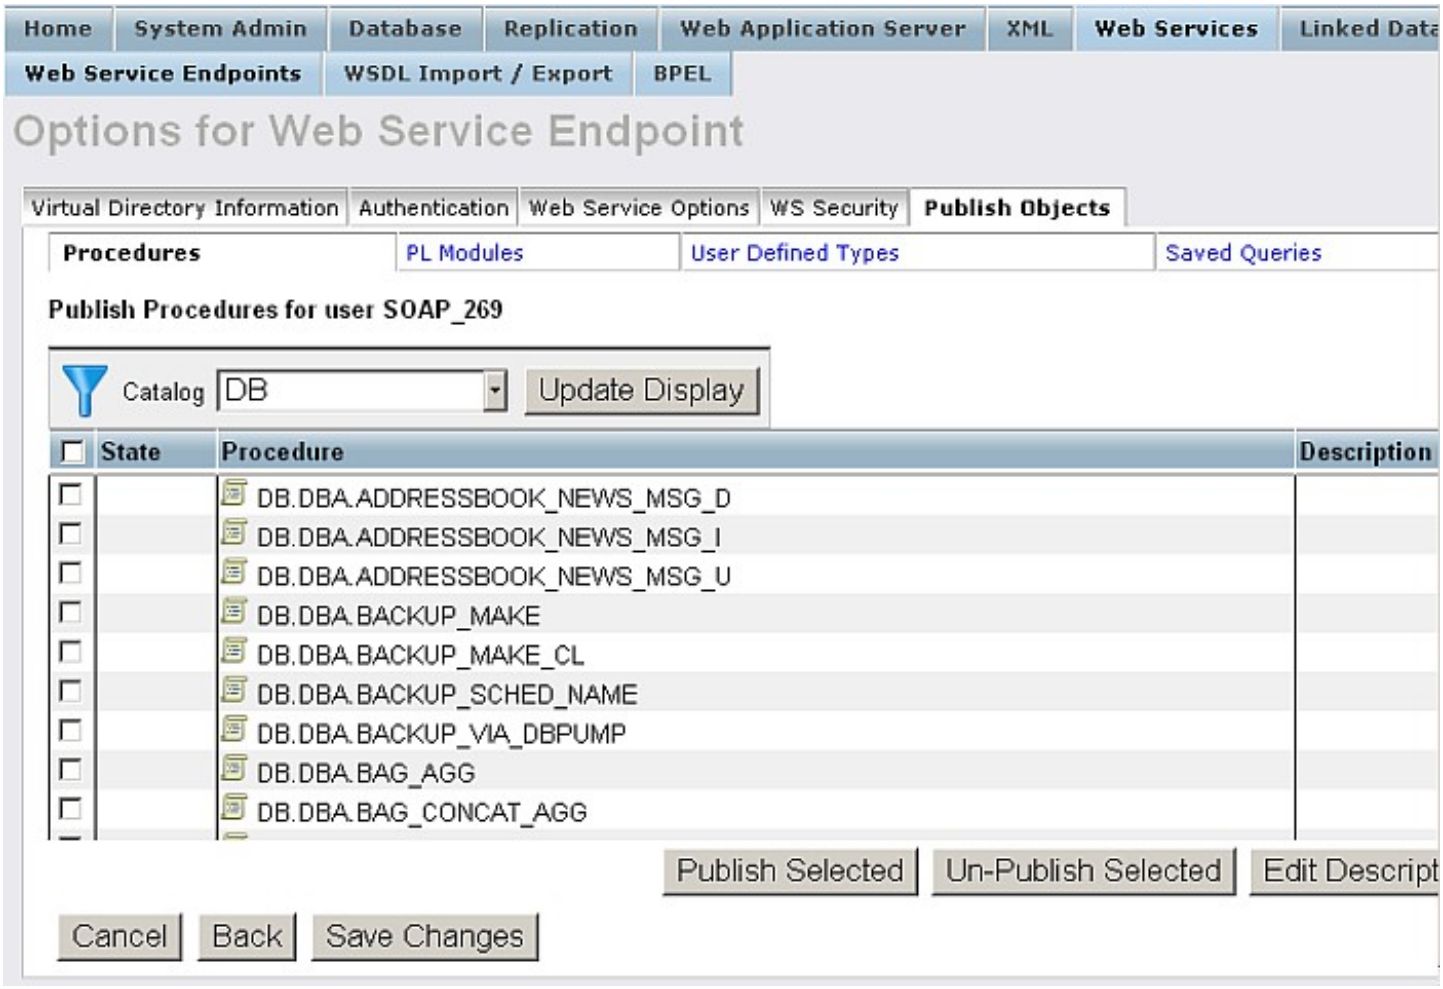
If you already have a virtual directory defined and know what procedures you want to expose as web services you will have to repeat some of the steps in the section above. From Conductor go to *Web Application Server/Virtual Domains & Directories* . Click on the "folder" icon for your {Default Web Site}. You will find the list of previously existing mappings, from which you can select the mapping that you want to edit by pressing on its *Edit* link. Note, the virtual directory should have type "SOAP".

Figure 3.46. Virtual Directories



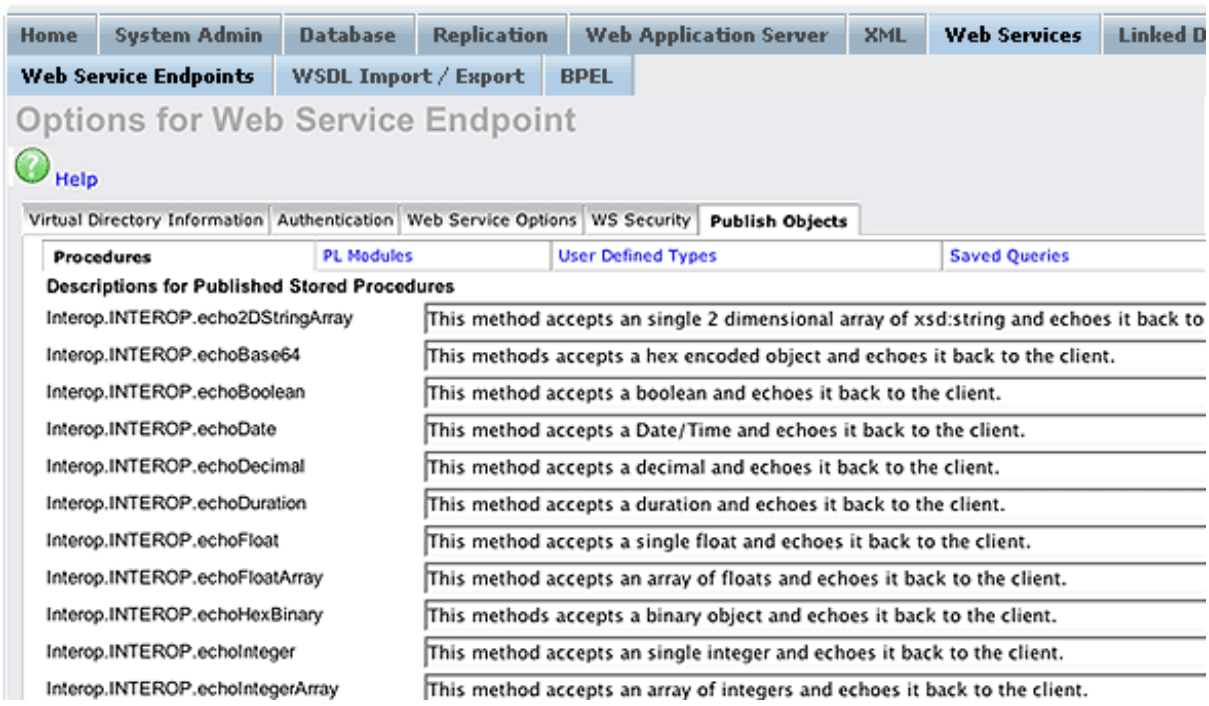
Go to tab "publish Objects" to expose/hide your procedures, Pl Modules, User Defined Types and Saved Queries.

Figure 3.47. Publish Objects



The "Procedures" tab presents the list of available procedures. You can select a catalogue in order to list the procedures you want to publish. When the procedures to be published are selected, you can either click the "Publish Selected" button, or before this to click the "Edit Description" button.

Figure 3.48. Choosing Procedure aPublish



Testing SOAP Services Using VSMX

Virtual directory definitions have a *Logical Path* field, which is reference in URL to find the correct SOAP services. If you connect to Virtuoso on *http://example.com:8890/* , and defined your virtual directory with the logical path of */mysoap* then you will be able to test the following URLs:

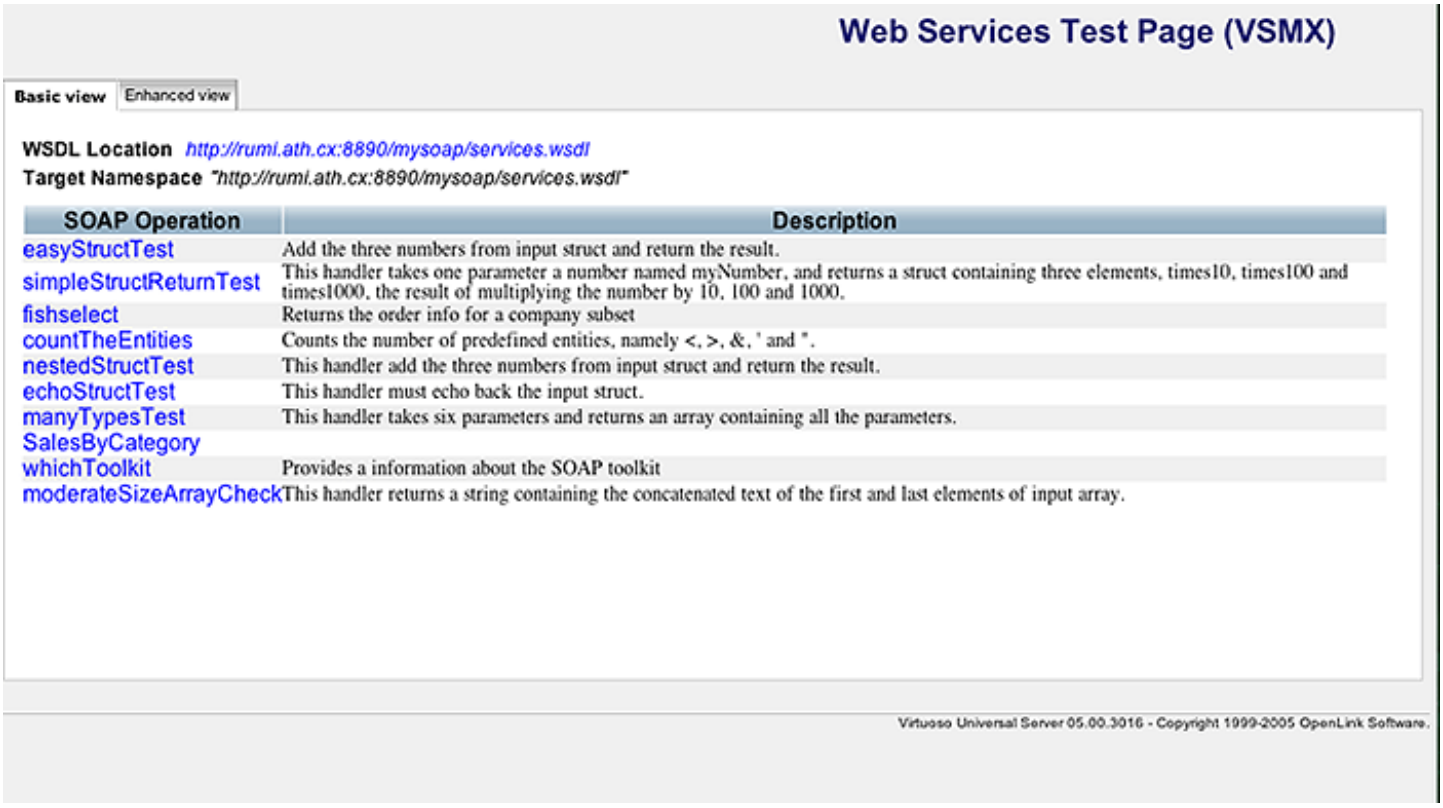
http://example.com:8890/mysoap/services.wsdl

http://example.com:8890/mysoap/services.vsmx

Figure 3.49. Services.wsdl

```
- <definitions targetNamespace="http://rumi.ath.cx:8890/mysoap/services.wsdl" name="SOAP">
  - <types>
    - <schema targetNamespace="http://tempuri.org/">
        <import namespace="http://schemas.xmlsoap.org/soap/encoding/"/>
      - <complexType name="ArrayOfstring">
        - <complexContent>
          - <restriction base="soapenc:Array">
            - <sequence>
                <element name="item" type="string" minOccurs="0" maxOccurs="unbounded" nillable="true"/>
              </sequence>
              <attributeGroup ref="soapenc:commonAttributes"/>
              <attribute ref="soapenc:arrayType" wsdl:arrayType="string[]"/>
            </restriction>
          </complexContent>
        </complexType>
      - <complexType name="toolkit_info">
        - <all>
            <element name="toolkitDocsUrl" type="string"/>
            <element name="toolkitName" type="string"/>
            <element name="toolkitVersion" type="string"/>
            <element name="toolkitOperatingSystem" type="string"/>
          </all>
        </complexType>
      - <complexType name="ctc">
        - <all>
            <element name="ctLeftAngleBrackets" type="int"/>
            <element name="ctRightAngleBrackets" type="int"/>
            <element name="ctAmpersands" type="int"/>
            <element name="ctApostrophes" type="int"/>
            <element name="ctQuotes" type="int"/>
```

Figure 3.50. Services.vsmx



The WSDL description is a standards-based description of the Web Services available from /mysoap. The VSMX page is a Virtuoso generated test page allowing you to test SOAP services. This feature should improve your development time.

See Also:
VSMX ; SOAP ; WSDL .

3.7.2. XML Query Templates

Virtuoso XML templates allow execution of SQL/XML queries over HTTP to obtain an XML document in response and/or perform some operation in the database using updategrams . XML templates can be executed from within Virtuoso procedure language using the `xml_template()` function. XML templates support two types of action: SQL based or updategram based. SQL query based templates must contain the FOR XML clause used in a SELECT statement and hence cannot update the database. Updates to the database can only occur from an updategram. The XML document returned from calling an XML template can be served either raw, or transformed using XSLT.

XML templates provide quick easy access to results from a SQL query as usual, but now this can be saved to a file. The results are not saved, just the query definition. You can use this feature to rapidly produce dynamic reports that can potentially be rendered in different ways by providing an alternate stylesheet. The report can be refined on the fly by providing parameters for the query. The output is reachable via HTTP directly by providing the URL to the template.

See Also:
The XML Templates Section

XML Templates can also be published just like normal store procedures. This is achieved by using a PL wrapper around the XML template. Then the store procedure is published in the normal way.

Stylesheets transformations with be inactive for published XML templates invoked from SOAP.

See Also:
The Publishing Stored Procedures Section above for a further description of publishing XML Templates.

3.7.3. Publishing VSE's as Web Services

The Virtuoso distribution includes the sample VSE, bif_sample.c. It is thus possible to create a function such as:

```
.....
static caddr_t
bif_hello_world (caddr_t * qst, caddr_t * err_ret, state_slot_t ** args)
{
  return box_dv_short_string ("Hello world.");
}
....
```

Then declare it in the init_func() by adding the following code:

```
...
  bif_define_typed ("hello_world", bif_hello_world, &bt_any);
...
```

The next step is creating a stored procedure that calls this function and you are back to publishing a Virtuoso stored procedure again, as in the above section.

```
create procedure BIF_HELLO_WORLD () { return hello_world (); };
```

See Also:
The C Interface Chapter

3.8. VSMX - Virtuoso Service Module for XML

Every WSDL file generated by Virtuoso is automatically accompanied by a SOAP Operations Test page known as a VSMX file, which has the extension .vsmx. You find this file in the same place as the WSDL file. For a SOAP enabled virtual directory you have the facility to find the WSDL file:

```
http://[host:port]/[SOAP Virtual Directory]/services.wsdl
```

likewise you also get a VSMX file:

```
http://[host:port]/[SOAP Virtual Directory]/services.vsmx
```

You simply point your web browser to this file for the test page. The demo database contains samples that can be found as:

```
http://[host:port]/SOAP/services.vsmx
```

Figure 3.51. VSMX Test Page

See Also:
The VSMX section for more details

3.9. SQL to XML

Virtuoso enables you to develop eBusiness solutions that use XML as both a Data Source and Data Interchange format. Your XML Data documents can take the form of Pure XML Documents, or documents that are transformed from SQL-XML on the fly. By supporting the XPATH query language for XML Data, you are able to use an industry standard query language to query entire XML Documents or portions of XML Documents stored within Virtuoso. Virtuoso's inclusion of an XSLT transformation engine then allow you to transform XML data for other needs. These XML documents are openly accessible to user agents such as Web Browsers via HTTP and/or WebDAV. These XML documents are described as being dynamic because they have varying degrees of sensitivity to changes that occur in the underlying database tables from which the XML data originates. Virtuoso allows you to create two types of XML documents from homogeneous or heterogeneous SQL Data on the fly:

Transient The materialization of the XML Document occurs at the time of file opening, this implies that data from the original SQL database(s) is retrieved and then transformed into XML in one operation. This format of SQL-XML document is highly sensitive to source database(s) changes.

Persistent (Time Synchronized) - The materialization of the XML Document re-occurs at a user configurable interval after initial creation. This is a caching scheme which is less sensitive to changes in the source databases(s) in favor of performance.

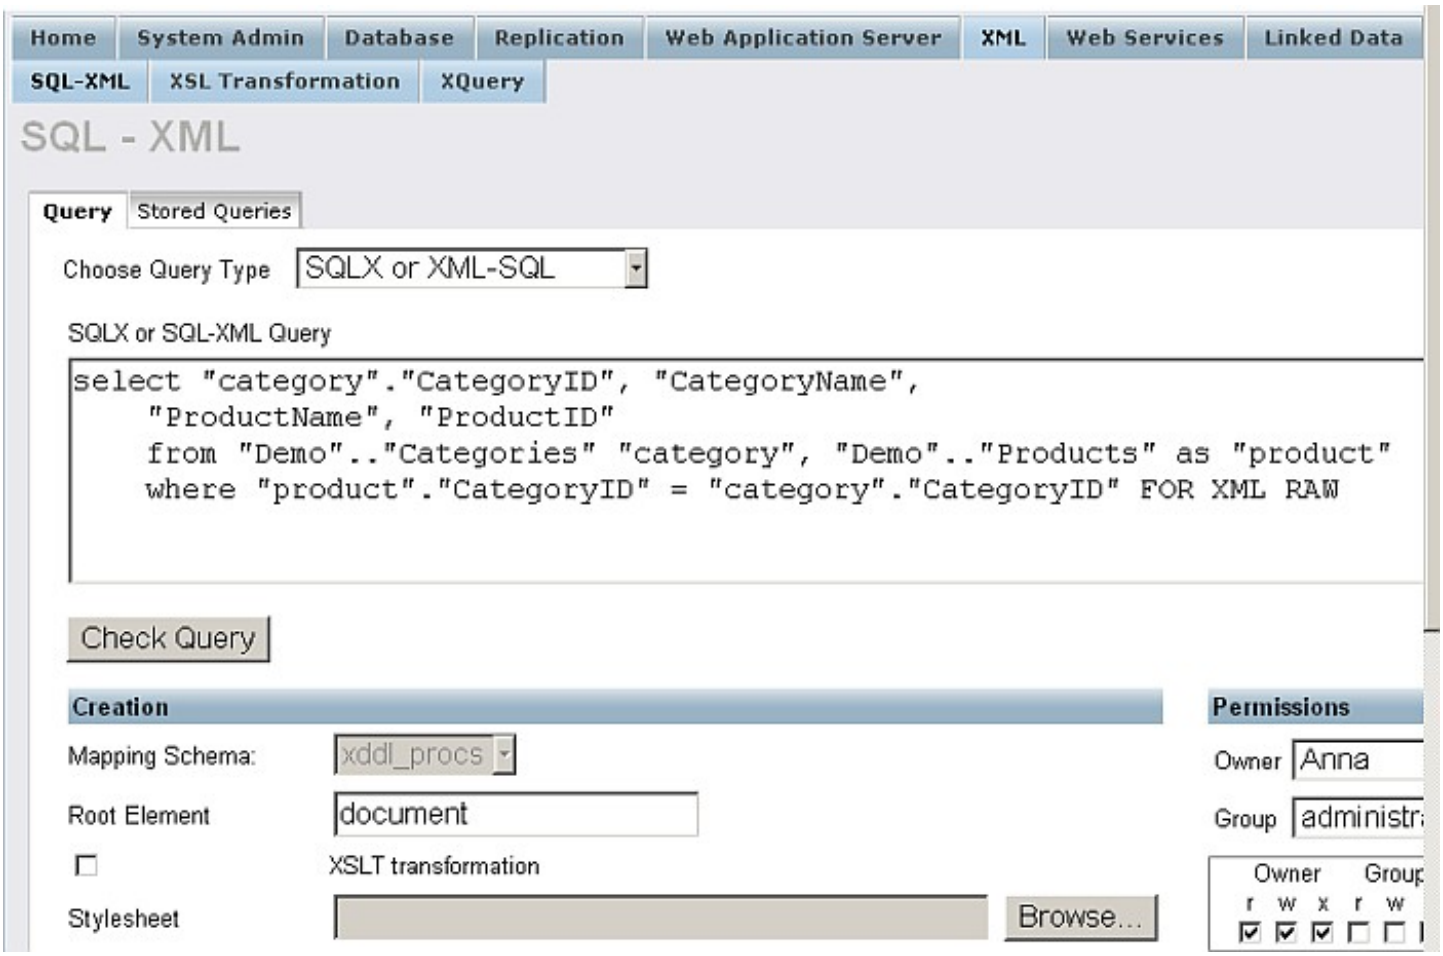
SQL-XML documents may be Valid or Well Formed XML documents, this includes support for both DTDs and XML Schemas which my be external entity references or inlined within the XML Documents prologue in the case of DTDs.

Virtuoso supports an extended SQL syntax that is identical to that implemented by Microsoft SQL Server for the purpose of creating SQL-XML documents. These SQL extensions take the form of a new "FOR XML" clause that includes three main options which control the structure of the resulting XML document tree. These options are *RAW* , *AUTO* and *EXPLICIT* .

Virtuoso's HTML based graphical interface includes a user friendly mechanism for creating dynamic XML documents from SQL data using the "FOR XML" extended SQL syntax. The dynamic XML documents created by this process are typically stored in Virtuoso's WebDAV repository. Documents stored in this repository are accessible by any XML consuming client application via HTTP, Windows Web Folders, or any other WebDAV or HTTP compliant environment. A description of the interface in general can be found in the SQL-XML Statements in the Visual Server Administration Interface section.

From Conductor *XML/SQL_XML* you can execute SQL query with options on how to produce XML structures from the results.

Figure 3.52. SQL to XML



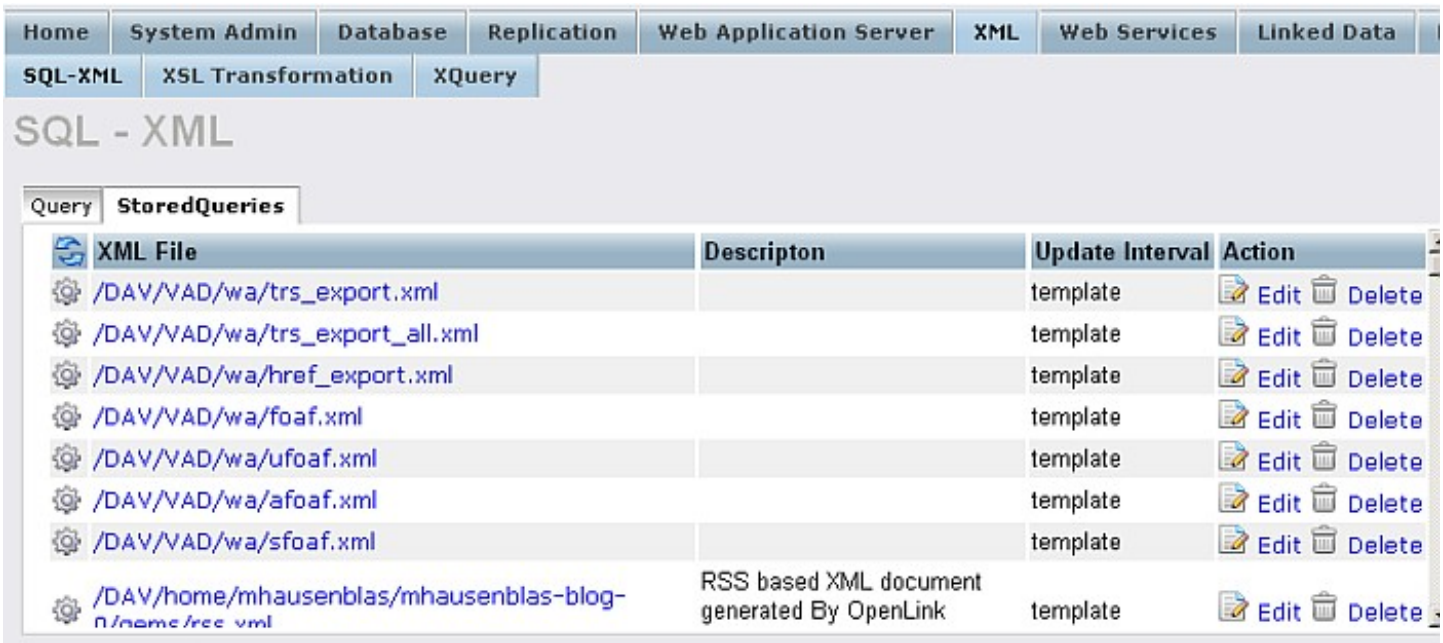
The illustration above depicts the fact that only minor changes to standard SQL are required in order to create powerful dynamic XML documents from SQL. It also illustrates how the entire process of controlling the type and format of the XML documents and their actually WebDAV storage is all achieved without any programming. The XML document extract below is a depiction of the XML document tree produced using the "FOR XML" AUTO option.

Figure 3.53. SQL to XML results

```
- <document>
  - <Customers Customers.CustomerID="ALFKI">
    - <Orders Orders.OrderID="10643">
        <Employees EmpLastName="Suyama"/>
      </Orders>
    - <Orders Orders.OrderID="10692">
        <Employees EmpLastName="Peacock"/>
      </Orders>
    - <Orders Orders.OrderID="10702">
        <Employees EmpLastName="Peacock"/>
      </Orders>
    - <Orders Orders.OrderID="10835">
        <Employees EmpLastName="Davolio"/>
      </Orders>
    - <Orders Orders.OrderID="10952">
        <Employees EmpLastName="Davolio"/>
      </Orders>
    - <Orders Orders.OrderID="11011">
        <Employees EmpLastName="Leverling"/>
      </Orders>
    </Customers>
  - <Customers Customers.CustomerID="ANATR">
    - <Orders Orders.OrderID="10308">
        <Employees EmpLastName="King"/>
      </Orders>
    - <Orders Orders.OrderID="10625">
        <Employees EmpLastName="Leverling"/>
      </Orders>
    - <Orders Orders.OrderID="10759">
        <Employees EmpLastName="Leverling"/>
      </Orders>
    - <Orders Orders.OrderID="10926">
```

The Virtuoso Demo database provides a set of sample tables in the Demo catalogue, and some sample XML views that use them. The "StoredQueries" tab lists saved XML Views as shown below.

Figure 3.54. SQL to XML save views



You can press *Edit* to edit them, or *Delete* to remove them or click on the XML FILE itself to see the results in your default browser, a sample of the output is shown above.

3.9.1. FOR XML Execution Modes

Now we will consider the programmatical approach along side the visual interface approach. We will have one example of each of the modes of FOR XML combined with the `xml_auto()` function to help us display the results simply.

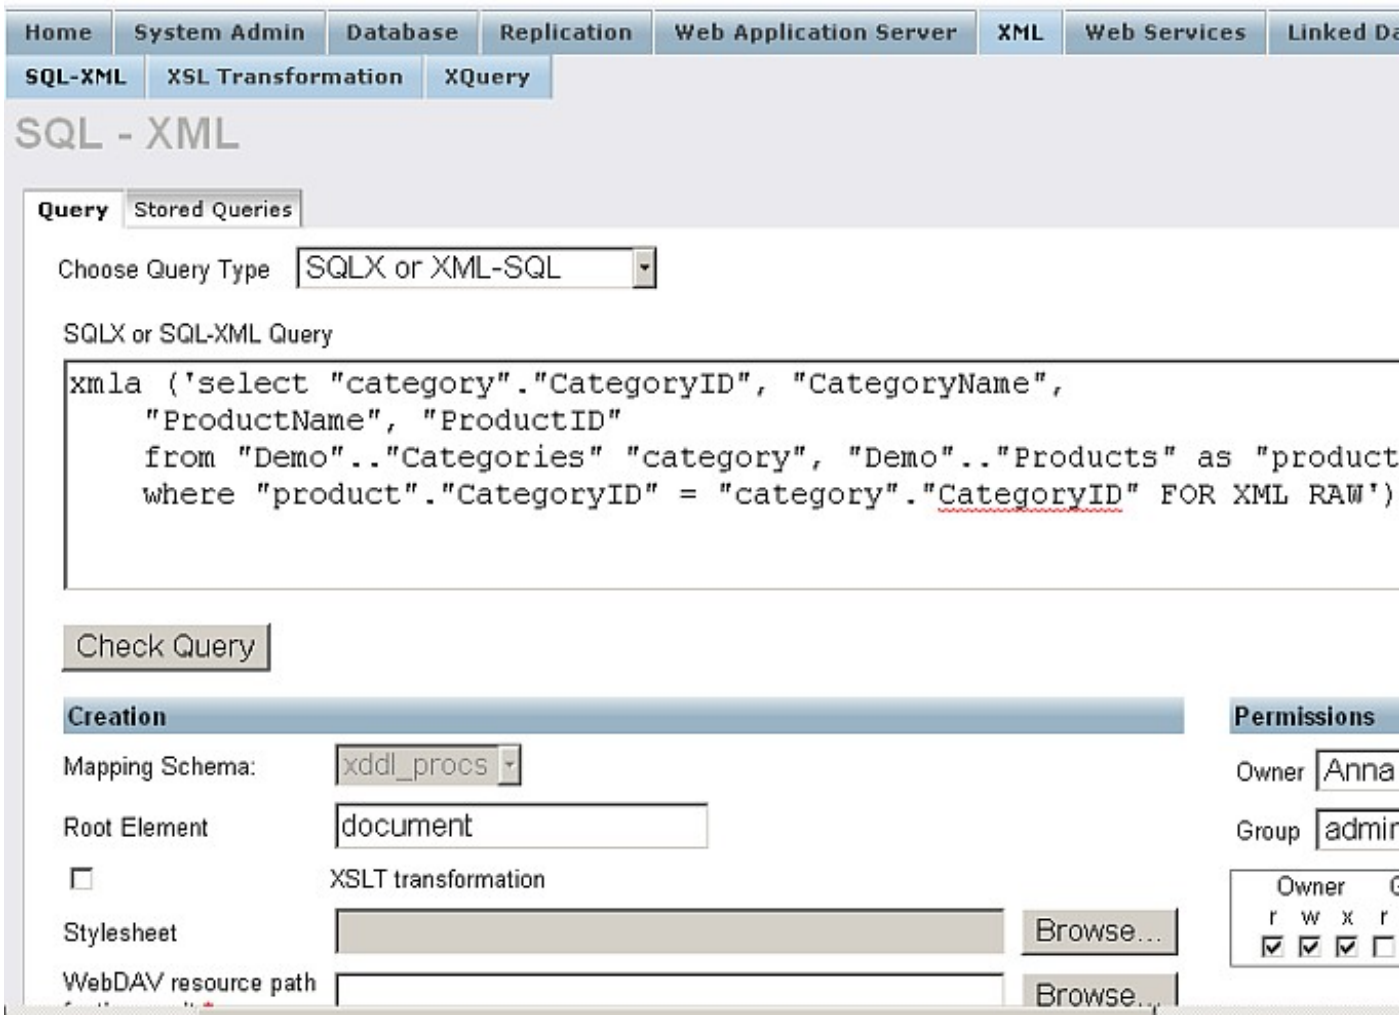
For the programmatical examples to run smoothly using ISQL a number of steps are required to obtain textual output from the xml_auto() function which usually is expected to output directly to an HTTP target. To make the demonstration simpler a utility

procedure will be created that will simply enable us to supply SQL and return XML using the `xml_auto()` function.

```
create procedure xmla (in q varchar)
{
  declare st any;
  st := string_output ();
  xml_auto (q, vector (), st);
  result_names (q);
  result (string_output_string (st));
}
```

- *RAW* mode produces an XML entity from each row of the result set, and does not attempt to construct hierarchies. Each row's data is enclosed in a ROW element and each column is either an attribute or child element.

Figure 3.55. SQL to XML using FOR XML RAW mode



The same SQL statement containing the FOR XML syntax is used in the visual interface shown above, and in the programmatical version shown below. This is because both use the xml_auto() function for generating results. In the visual interface once the settings and query have been confirmed you press the "Execute" button to store the query in the specified DAV location.

```
xmla ('select "category"."CategoryID", "CategoryName",
    "ProductName", "ProductID"
    from "Demo".."Categories" "category", "Demo".."Products" as "product"
    where "product"."CategoryID" = "category"."CategoryID" FOR XML RAW');
```

Note:

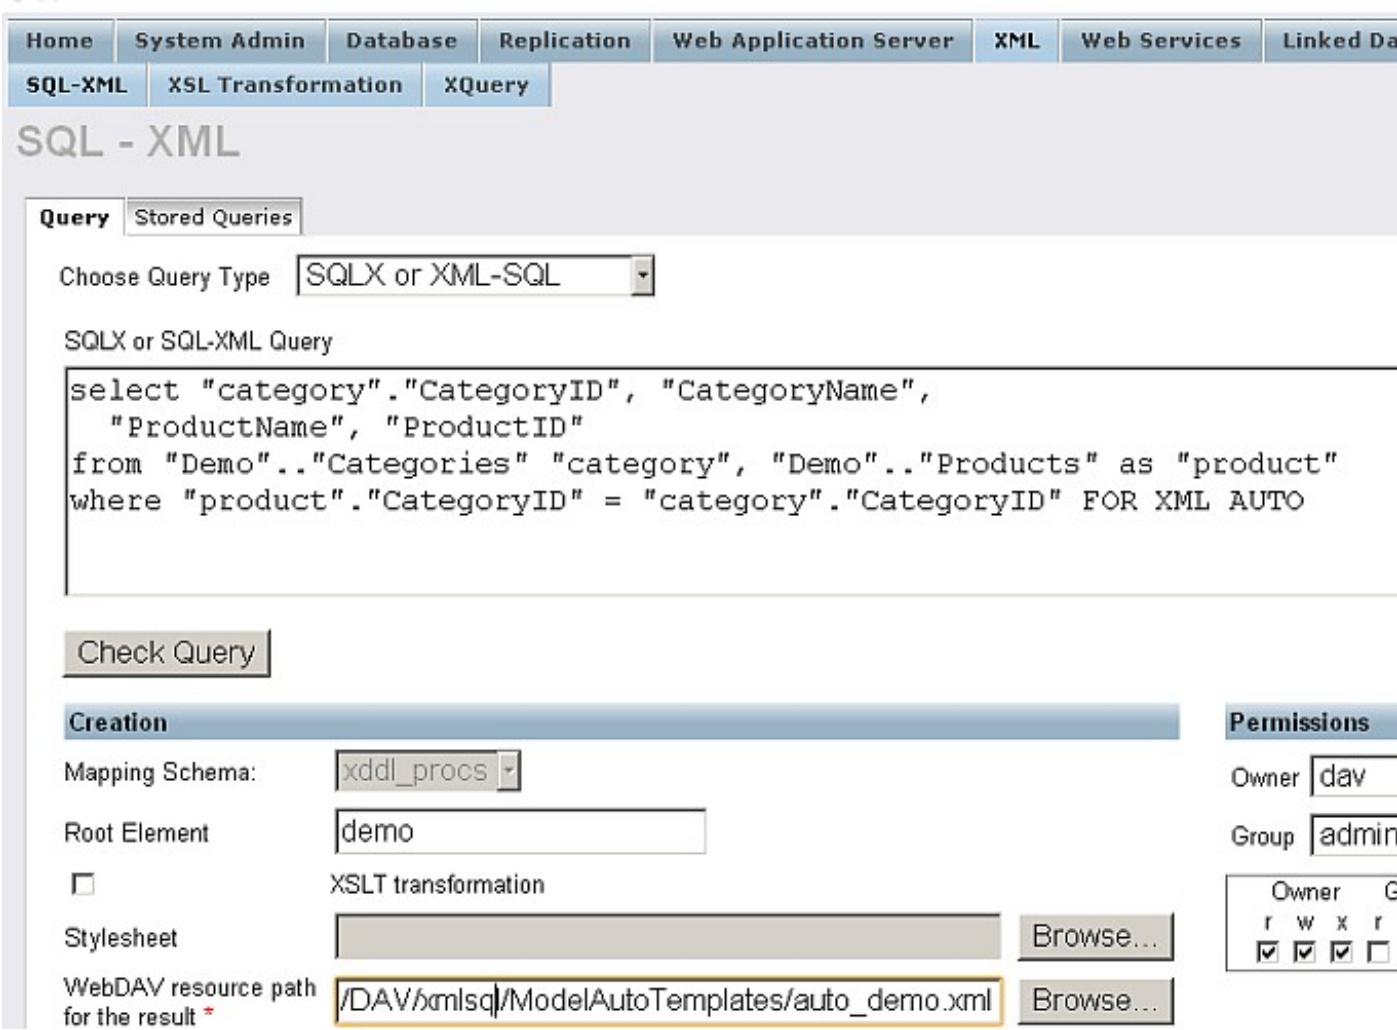
The xmla function is not a standard function but quick utility for quickly rendering a text output for the `xml_auto()` function. The definition is at the top of this section

The resulting XML from either ISQL or the saved links on the visual interface will yield:

```
<ROW CategoryID="1" CategoryName="Beverages" ProductName="Chai" ProductID="1">
</ROW>
<ROW CategoryID="1" CategoryName="Beverages" ProductName="Chang" ProductID="2">
</ROW>
<ROW CategoryID="1" CategoryName="Beverages" ProductName="Guaran Fantastica" ProductID="24">
</ROW>
<ROW CategoryID="1" CategoryName="Beverages" ProductName="Sasquatch Ale" ProductID="34">
</ROW>
<ROW CategoryID="1" CategoryName="Beverages" ProductName="Steeleye Stout" ProductID="35">
</ROW>
<ROW CategoryID="1" CategoryName="Beverages" ProductName="C(te de Blaye" ProductID="38">
</ROW>
<ROW CategoryID="1" CategoryName="Beverages" ProductName="Chartreuse verte" ProductID="39">
</ROW>
<ROW CategoryID="1" CategoryName="Beverages" ProductName="Ipoh Coffee" ProductID="43">
</ROW>
.....
```

- *AUTO* mode. A hierarchy is constructed with one level for each table of the join for which at least one column is selected. The table whose column is first mentioned in the selection will be the topmost element, the next table its child etc. Each level of the tree will consist of one type of element. A parent element will have multiple children if consecutive rows do not differ in the column values coming from the parent element. When a table's column values differ from the previous row, the element and all children thereof are closed and a new element is started, with children filled out from other columns of the result set.

Figure 3.56. SQL to XML using FOR XML AUTO mode



The same SQL statement containing the FOR XML syntax is used in the visual interface shown above, and in the programmatical version shown below. This is because both use the xml_auto() function for generating results. In the visual interface once the settings and query have been confirmed you press the execute button to store the query in the specified DAV location.

```
xmla ('select "category"."CategoryID", "CategoryName",
    "ProductName", "ProductID"
    from "Demo".."Categories" "category", "Demo".."Products" as "product"
    where "product"."CategoryID" = "category"."CategoryID" FOR XML AUTO');
```

Note:

The xmla function is not a standard function but quick utility for quickly rendering a text output for the `xml_auto()` function. The definition is at the top of this section

The resulting XML from either ISQL or the saved links on the visual interface will yield:

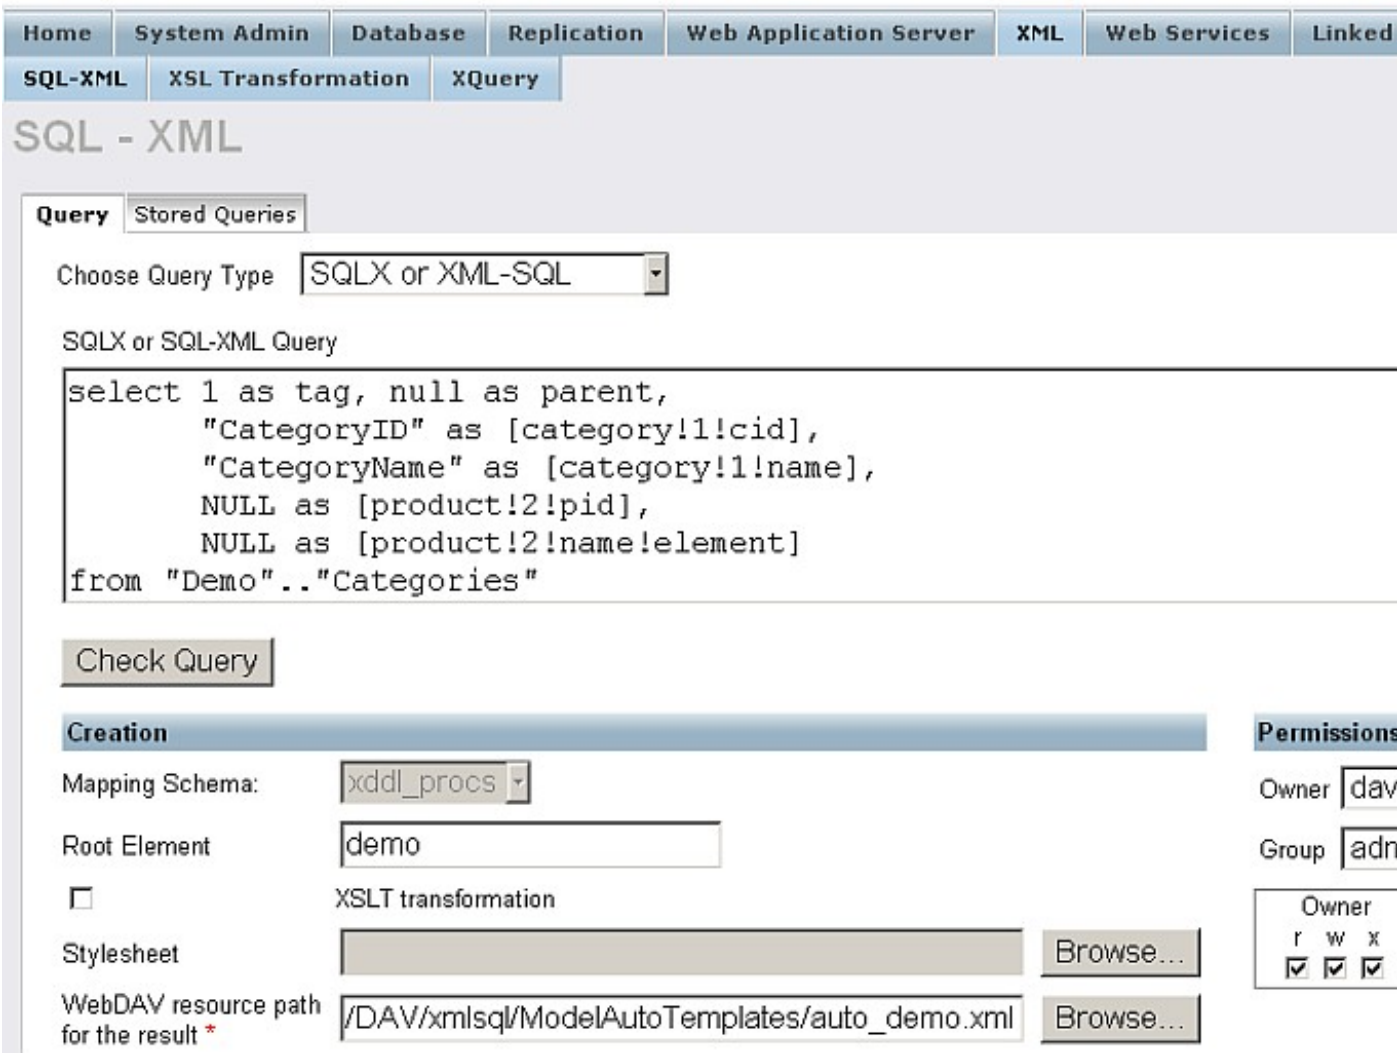
```
<category CategoryID="1" CategoryName="Beverages">
<product ProductName="Chai" ProductID="1">
</product>
<product ProductName="Chang" ProductID="2">
</product>
<product ProductName="Guaranß Fantßstica" ProductID="24">
</product>
<product ProductName="Sasquatch Ale" ProductID="34">
</product>
<product ProductName="Steeleye Stout" ProductID="35">
</product>
<product ProductName="C(te de Blaye" ProductID="38">
</product>
<product ProductName="Chartreuse verte" ProductID="39">
</product>
<product ProductName="Ipoh Coffee" ProductID="43">
</product>
<product ProductName="Laughing Lumberjack Lager" ProductID="67">
</product>
.....
```

Note:

In contrast to the RAW mode AUTO produces results that are more reasonable and intuitive. Only one category element is used for each category which contains all the children of that category.

- *EXPLICIT* mode gives more control on the resulting tree's structure while requiring a more elaborate query structure. In this mode, the query will be a UNION ALL of many joins and each row will specify exactly one element. Which type of element this is and where in the tree it will be placed are determined by the values of the 2 first columns, TAG and PARENT.

Figure 3.57. SQL to XML using FOR XML EXPLICIT mode



The same SQL statement containing the FOR XML syntax is used in the visual interface shown above, and in the programmatical version shown below. This is because both use the xml_auto() function for generating results. In the visual interface once the settings and query have been confirmed you press the execute button to store the query in the specified DAV location.

```
xmla ('
select 1 as tag, null as parent,
       "CategoryID" as [category!1!cid],
       "CategoryName" as [category!1!name],
       NULL as [product!2!pid],
       NULL as [product!2!name!element]
from "Demo".."Categories"
union all
select 2, 1, "category" ."CategoryID", NULL, "ProductID", "ProductName"
    from "Demo".."Categories" "category", "Demo".."Products" as "product"
    where "product"."CategoryID" = "category"."CategoryID"
order by [category!1!cid], 5
FOR XML EXPLICIT');
```

Note:

The xmla function is not a standard function but quick utility for quickly rendering a text output for the `xml_auto()` function. The definition is at the top of this section

The resulting XML from either ISQL or the saved links on the visual interface will yield:

```
<CATEGORY CID="1" NAME="Beverages">
<PRODUCT PID="1">
 <NAME>Chai</NAME></PRODUCT>
<PRODUCT PID="2">
 <NAME>Chang</NAME></PRODUCT>
<PRODUCT PID="24">
```

```
 <NAME>Guaran&#225; Fant&#225;stica</NAME></PRODUCT>
<PRODUCT PID="34">
 <NAME>Sasquatch Ale</NAME></PRODUCT>
<PRODUCT PID="35">
 <NAME>Steeleye Stout</NAME></PRODUCT>
<PRODUCT PID="38">
 <NAME>C&#244;te de Blaye</NAME></PRODUCT>
<PRODUCT PID="39">
 <NAME>Chartreuse verte</NAME></PRODUCT>
<PRODUCT PID="43">
 <NAME>Ipoh Coffee</NAME></PRODUCT>
<PRODUCT PID="67">
 <NAME>Laughing Lumberjack Lager</NAME></PRODUCT>
<PRODUCT PID="70">
 <NAME>Outback Lager</NAME></PRODUCT>
<PRODUCT PID="75">
 <NAME>Rh&#246;nbr&#228;u Klosterbier</NAME></PRODUCT>
<PRODUCT PID="76">
 <NAME>Lakkalik&#246;&#246;ri</NAME></PRODUCT>
</CATEGORY>
<CATEGORY CID="2" NAME="Condiments">
<PRODUCT PID="3">
.....
```

Note:
In contrast again, the EXPLICIT mode produces exactly what we asked for.

For more details about 'FOR XML, refer to Rendering SQL Queries as XML section of the XML Support chapter.

3.9.2. Tables With XML Columns

XML is a new native Virtuoso datatype, based on an extension of LONG VARCHAR for compatibility with ODBC clients, allows direct storage, retrieval and querying of XML stored in a database table. This has always been possible with Virtuoso utilizing `xml_tree_doc()` and friends but now you can easily concentrate on what more important, the data, and not which datatype to convert it to next.

See Also:
XML Column Type

3.10. NNTP

Virtuoso supports the Network News Transfer Protocol used by Internet newsgroup forums. NNTP servers manage the global network of collected newsgroup postings and represent a vast repository of targeted information archives. As an NNTP aggregator, Virtuoso enables integration of multiple news forums around the world. All news content in Virtuoso is dynamically indexed to provide keyword searches, enabling rapid transformation of disparate text data into information. Virtuoso also acts as an NNTP server, enabling creation of new Internet and Intranet News Forums to leverage the global knowledge base into eBusiness Intelligence.

3.10.1. NNTP Server Setup

Enable Server

Before the NNTP server can be used, it has to be enabled to listen on the NNTP port. This change is made in the configuration file.

For more details, refer to Enable NNTP Server section.

Create/Attach News Groups

The definition of news groups is held in system tables.

For more details on inserting news groups by SQL command, refer to Add Groups to NNTP Server section. See also the Conductor News Server and Newsgroups Administration section, to setup the groups in the Visual Server Administration Interface.

Limit Groups

This is an optional step, appropriate if a news group is to be limited for internal use only, or by a group of IP addresses. This is achieved by creating an Access Control List (ACL) in the DB.DBA.NEWS_ACL table. If no ACL is defined, then all groups are public readable and writable.

For table details, refer to NNTP Server Tables section.

3.10.2. Local & Remote Groups

News groups may be Local such that they are the only instance, or a master instance of a group. Remote groups are ones that are replicated from other news servers.

See the Conductor News Server and Newsgroups Administration section, to setup the groups in the Visual Server Administration Interface.

3.10.3. NNTP Client Setup

Virtuoso can make a client connection to an external news server to receive newsgroup postings.

For more details, refer to the NNTP Client section.

3.11. Dynamic Web Pages

Virtuoso provides an extensible array or dynamic methods for creating data driven web pages. Through runtime hosting Virtuoso can directly host, store and drive:

PHP
JSP
ASP.Net
Perl
Python
Ruby
Natively - VSP and VSPX:
Virtuoso Server Pages (VSP) is Virtuoso's specification for creating dynamic database driven Web pages, these files have the extension ".vsp" and are identical in functionality to: ASP, PHP, and JSP pages. A fundamental difference between VSP pages and others (PHP, ASP. and JSP pages) is the fact that VSPs are specialized forms of Virtuoso Stored procedures which implies that data is in-process rather than out-of-process, you do not have to complete a client-server connection in order to actually bind to the data being used in a VSP page. The obvious benefit being significant performance improvements over ASP, PHP, and JSP pages (which all bind to data out-of-process).

Since VSP is essentially Virtuoso PL in a web page you can do anything that PL can from or part of a web page either directly or from interaction with the user. A massive advantage of using VSP is that you do not have to worry about making connections to the database or the overhead of RPC's because the HTTP server is built into Virtuoso. When you write a VSP page the connection is assumed since you are already in Virtuoso! VSP is server script and is therefore executed in the server as it is encountered on the page. For this reason client (JavaScript) and server script cannot directly interact but can supplement each other. You can call JavaScript inside a VSP loop, for example, to manipulate something that already exists on the page but you cannot pass variables by reference from VSP directly to JavaScript or vice versa. Page flow control is managed using FORMs. The state of the page is defined in form fields such as INPUT boxes and TEXTAREA boxes and then passed on to the next form or page using POST.

Virtuoso Server Pages for XML (VSPX) is an XML based framework and state-managed system similar to ASPX. Pages are written in XML to describe templates of data-aware web-widgets. This massively reduces the code-effort and avoids many bugs by providing the functionality for you, of which you specify the data-source, be it XML, SQL or other, and which predefined control you want it represented by. VSPX allows for custom-designed controls too. Since XML is a key factor for VSPX so does XSLT for providing total separation between the data, business logic and the layout on the web page.

The Web Application Development Chapter.

3.12. VSP Examples

3.12.1. Simple HTML FORM usage

We will start with a small example that shows a page that constitutes a FORM with data from the user being sent when a submit button is pressed and then examine the elements and attributes that are important to us at this stage.

Consider the following piece of HTML:

```
<HTML>
  <HEAD>
    <TITLE>Simple FORM demo</TITLE>
  </HEAD>
  <BODY>
  <FORM METHOD="POST" ACTION="formdemo_receiver.vsp">
    <P>Test form, type some info and click Submit</P>
    <INPUT TYPE="TEXT" NAME="myInput" />
    <INPUT TYPE="SUBMIT" NAME="submit" VALUE="Submit" />
  </FORM>
  </BODY>
</HTML>
```

All elements contained in the FORM tag are associated with that form. This is how the data and the submit button know what to do next, and which data to send, by the attributes of the FORM tag.

The METHOD attribute of the FORM TAG can be either GET or POST. The GET method allows the form submission to be contained completely in a URL which can be advantageous in that it permits bookmarking in browsers, but it also prevents form data from containing non-ASCII characters and restricts the amount of form data that can be handled. The get method is limited by the maximum length of the URL that the server and browser can process. To be safe, any form whose input might contain non-ASCII characters or more than 100 characters should use METHOD="POST".

With the POST method, the form input is submitted as an HTTP POST request with the form data sent in the body of the request. Most current browsers are unable to bookmark POST requests, but POST does not entail the character encoding and length restrictions imposed by GET.

The ACTION attribute of FORM specifies the URI of the form handler. This will usually be another web page that performs some action based on the data that is sent from the originating form. The URI could point to the same page as the data originated and for pages that perform a well defined small set of functions it usually does. When a page needs to manage multiple states there needs to be some flow control that can determine how the page was reached whether it arrived as a result of someone clicking on the submit button or it is the first time the page has been visited.

Now we will add some VSP to check the values of the parameters in the form. VSP markup is typically contained in <?vsp ... VSP ... ?> blocks.

```
<HTML>
  <HEAD>
    <TITLE>Simple FORM demo</TITLE>
  </HEAD>
  <BODY>
  <P>Last value sent:</P>

  <?vsp
    http(get_keyword('myInput', params, 'no value'));
   ?>

  <FORM METHOD="POST" ACTION="formdemo.vsp">
    <P>Test form, type some info and click Submit</P>
    <INPUT TYPE="TEXT" NAME="myInput" />
    <INPUT TYPE="SUBMIT" NAME="submit" VALUE="Submit" />
  </FORM>
  </BODY>
</HTML>
```

This is the same example as above that now uses the same page for the form handler and displays the parameters each time. The first time you click the button will take you to the same page and will display whatever you typed in the field last time.

The VSP block uses two functions nested. The http function allows you to send data to the HTTP client, the browser. What we send to the browser is the result of the get_keyword function. The get_keyword function has 3 parameters, it searches for the keyword-value pair (keyword=value) where keyword matches the first parameter (in this case 'myInput') in array passed in the second parameter, and returns the value if one is found otherwise will return the 3rd parameter in the function 'no value'. The params array is a special array that contains all page parameters.

Now we will extend this further to add some conditional control so that if a value was entered we can respond directly to it. We will also use a variable this time, which must be declared first.

```
<HTML>
  <HEAD>
    <TITLE>Simple FORM demo</TITLE>
  </HEAD>
  <BODY>

  <?vsp
        declare _myInput varchar;

        _myInput := get_keyword('myInput', params, 'no value');

    if (_myInput <> 'no value')
        {       http('<P>Hello, ');
                http(_myInput);
                http('</P>');
        }
        else
        {       http('<P>Please enter you name</P>');
        }
   ?>

  <FORM METHOD="POST" ACTION="formdemo.vsp">
    <P>Test form, type some info and click Submit</P>
    <INPUT TYPE="TEXT" NAME="myInput" />
    <INPUT TYPE="SUBMIT" NAME="submit" VALUE="Submit" />
  </FORM>
  </BODY>
</HTML>
```

We will now extend this even further to control the whole contents of the page. In this example we will see that VSP and HTML can be interleaved.

```
<HTML>
  <HEAD>
    <TITLE>Simple FORM demo</TITLE>
  </HEAD>
  <BODY>

  <?vsp
        declare _myInput varchar;
        declare Mode varchar;

        _myInput := get_keyword('myInput', params, 'no value');
        Mode := get_keyword('submit', params, '');

    if (Mode = 'submit')
        {
   ?>

    <P>Hello, <?vsp http(_myInput); ?>
        </P>

  <?vsp
        }
          else
        {
   ?>

  <P>Please enter you name</P>
  <FORM METHOD="POST" ACTION="formdemo.vsp">
    <INPUT TYPE="TEXT" NAME="myInput" />
    <INPUT TYPE="SUBMIT" NAME="submit" VALUE="Submit" />
```

```
  </FORM>

  <?vsp
    }
  ?>

  </BODY>
</HTML>
```

3.12.2. Manipulating Database Data in VSP

The following example demonstrates a basic page that has form based flow control, takes input from the user to put into the database and then displays the results. This simple example can be extended to perform more substantial operations by adding a few more inputs, buttons and states.

Things to look at:

get_keyword is used to extract parameters from the form that were posted last time

the current mode is determined by the value of the submit parameter

straight HTML can be inline with VSP flow control which is how the whole page is contained in an *if* condition.

```
<HTML>
<HEAD></HEAD>
<BODY>
<form method="POST" action="simpletest.vsp">

<?vsp
-- assumes that you have a table db..test_table(txt varchar(2000))

-- declare variables for use
declare _mode varchar;
declare _theValue varchar;
declare _stmt varchar;

-- get the current mode and continue accordingly
_mode := get_keyword ('submit', params, 'default');

if (_mode = 'Submit')
{
  -- if a submit was detected then insert the value into the DB
  _theValue := get_keyword('myTxtBox', params, 'no comment');
  _stmt := sprintf('insert into db..test_table(txt) values(\'%s\')', _theValue);
  exec (_stmt, '', '', '', '', '', '');

?>
   <P>Thank you for your submission.</P>
<?vsp
} else {
?>
   <DIV>
   <DIV>Simple test form, enter some text and hit submit.</DIV>
   <DIV><textarea name="other" rows="3" cols="64"></textarea></DIV>
   </DIV>

   <DIV><input type="submit" name="submit" value="Submit"></DIV>

   <HR />
   <H2>Values currently in table</H2>
   <TABLE>
   <?vsp
   for (select txt from db..test_table) do
     http(sprintf('<TR><TD>%s</TD></TR>', txt));
   ?>
   </TABLE>

<?vsp
}
?>
</form>
</BODY>
</HTML>
```

You may wish to offload some of the functionality of the page to a stored procedure and call that from that page. You may do this to improve readability of the page or there may be a series of functions that you repeat such as displaying a particular table in some format.

You could used a procedure as follows:

```
create procedure table_list()
{
   http('<H2>Values currently in table</H2>');
   http('<TABLE>');
   for (select txt from db..test_table) do
      http(sprintf('<TR><TD>%s</TD></TR>', txt));
   http('</TABLE>');
};
```

You could then call this in instead of defining the query and table layout as above.

The aspects of VSP are explained in more detail in the following sections.

3.12.3. Simple Tutorial

The following example prints the result from executing explain:

```
<?vsp
  declare meta, data any;
  exec ('explain (?)', null, null, vector ('select * from sys_users'),  0, meta, data);
  foreach (any row in data) do
  {
     http_value (row[0], 'p');
  }
?>
```

The vsp can be also written like this:

```
<?vsp
  declare meta, data any;
  exec ('explain (?)', null, null, vector ('select * from sys_users'), 0, meta, data);
  for (declare i,l int, i := 0, l := length (data); i < l; i := i + 1)
   {
     http_value (data[i][0], 'p');
   }

?>
```

3.13. Third-Party Runtime Typing, Hosting & User Defined Types

All barriers are broken. If Virtuoso does not readily provide the data type that you require, then make your own. If you want a database trigger to test data against existing externally developed logic, then do that too. Virtuoso has been designed with open-design in mind giving ultimate flexibility. These are the systems current available (linked to the appropriate section of this documentation):

- Runtime Hosting

  support other environments and/or languages in-process with Virtuoso and utilizing Virtuoso storage methods such as DAV for replication and roll-out benefits.

  - CLR & Mono
  - Java & Jakarta JSP
  - PHP
- Plugins

  enable support for other scripting langauges.

  - Perl
  - Python

- Ruby
- Extensibility

  the above features are applications of one or another of these interfaces, which are provided so that you have the potential to enhance Virtuoso further for more custom requirements.

  - Virtuoso Server Extension Interface (VSEI)
  - VSEI Plugins
  - User-Defined Types (UDT)
  - Hosted/Imported Assemblies/Classes
- Web/Service Exposure

  every part of Virtuoso can be view, interacted with or consumed by some third-party via a plethora of interfaces, to name a few:

  - SOAP
  - WSDL
  - Static/Dynamic Web Content
  - XML/XSLT

    XML Storage System

    XML RPC

3.14. Troubleshooting Tips

3.14.1. General Tips

The following sections are some common faults and tips. For a complete list of troubleshooting tips, please visit sources that are listed in the Product Support section of the Appendix .

3.14.2. DBMS Server will not start

If the Virtuoso DBMS server won't start, there could be 3 reasons.

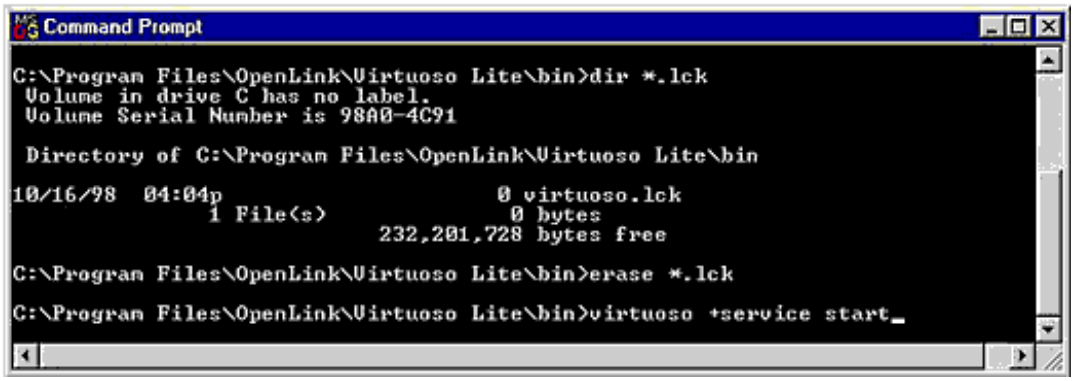
It is already running

It died earlier

It terminated normally earlier, but the virtuoso.lck file was not deleted

When the DBMS server starts up, it creates a file in the bin directory named "virtuoso.lck". If this file is present, a new instance cannot run. If you are certain that the DBMS isn't running, then you can delete the virtuoso.lck file and then start it from the Services icon in the Control Panel, or by using the command "*virtuoso +service start* " in the virtuoso directory. You can check if virtuoso is running from the Task Manager, and you can shut it down using the command "*virtuoso +service stop* ".

Figure 3.58. Command Prompt

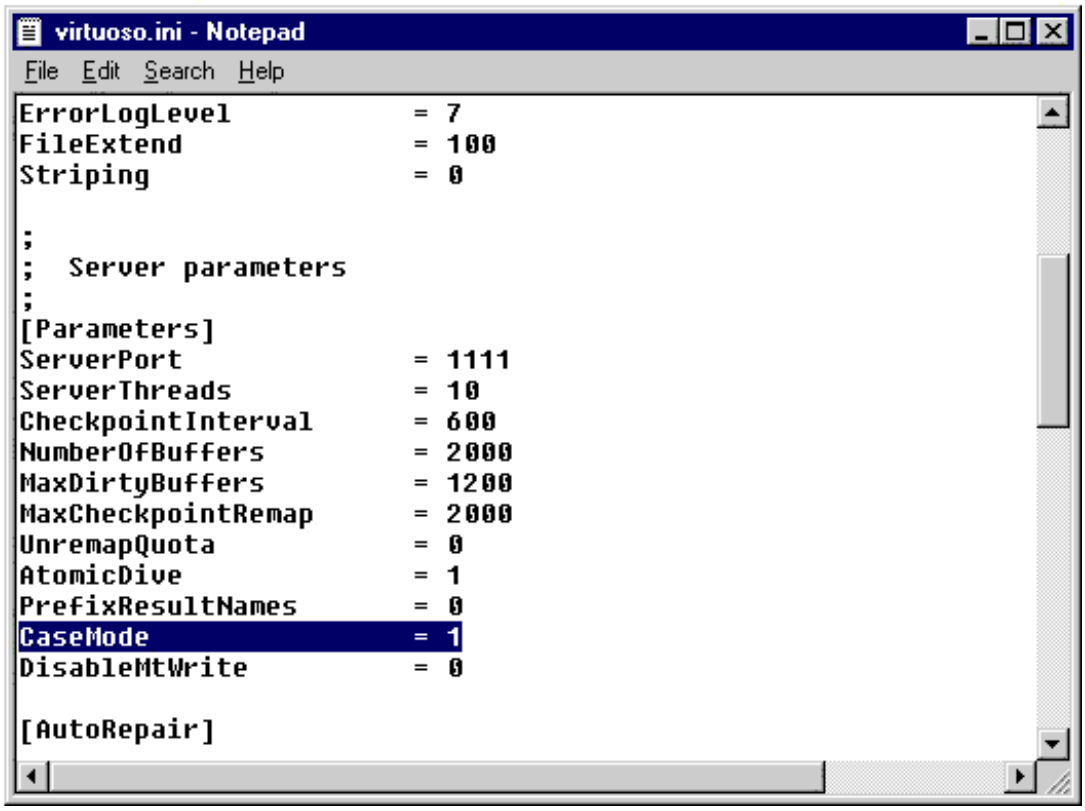


3.14.3. Case Mode

Whenever a database object is referenced, all names (schema, owner, table and column) should preferably be placed in double-quotes, exactly as it appears in the catalog. This way, the object name in the Virtuoso catalog will be correctly referenced. If names are not quoted, then the case of the object name will be determined by the value of the CaseMode property in the virtuoso.ini file:

- The default files supplied with Virtuoso specify a CaseMode of 2, which is a case insensitive mode that preserves the declaration case of identifiers. If there is no supplied ini file, the default value of CaseMode is 1.
- A CaseMode of 1 specifies the upper case mode, which is most commonly used in SQL databases, e.g. Oracle. In the upper case mode, all unquoted identifiers are converted to upper case by the SQL parser. If identifiers are not quoted, the case in which they are entered is irrelevant.
- The identifier quote character is the double quote ("). Quoted identifiers are processed in the case they are written in and are thus case sensitive.
- SQL reserved words are case insensitive in all case modes.
- If CaseMode is 0 or absent, identifiers will be treated as case sensitive in all situations, whether quoted or not.
- If an identifier's name is equal to a SQL reserved word, e.g. TABLE, it must be quoted ("TABLE") in order to be used as an identifier.
- If an identifier contains non-alphanumeric characters, e.g. space, '-' etc. it must be quoted regardless of CaseMode.
- Although CaseMode can be changed at any time it should only be set at database creation. Changing the CaseMode may result in view or procedure code becoming invalid if it relies on specific case conventions.

Figure 3.59. Virtuoso.ini file in notepad



Chapter 4. Sample ODBC & JDBC Applications

Abstract

This chapter applies exclusively to the various commercial releases of Virtuoso. If you are working with the open source version, please refer to the instructions on the web site where you obtained it.

The OpenLink Virtuoso Installation provides sample applications to help you get quick and easy results from you installation. This chapter explains how to use these applications.

A number of sample applications are bundled with your Virtuoso installation for the following purposes:

To simplifying the process of getting Virtuoso up and running

To accelerate the support case creation and resolution process

To demonstrate Virtuoso's unique product features highlighting the benefits it brings to your organization

To demonstrate application programming techniques that can used to aid and assist your ODBC and JDBC programmers

Virtuoso's services are consumed primarily via ODBC and JDBC applications (OLE-DB applications connect to Virtuoso via ODBC Data Providers for OLE-DB), thus separate ODBC & JDBC sample applications (including source code) have been packaged and integrated into the Virtuoso installer. The current list of sample applications include:

- **C++ Demo.** an ODBC based Interactive SQL processor written in C++.
- **ODBC Bench Test.** a 32 Bit C++ program based on the industry standard TPC-A benchmark (we will be extending this program to include the TPC-C and TPC-D benchmarks also). This program helps you compare the performance of Virtuoso against other backend database engines as well as compare the performance of various ODBC Drivers connecting to any ODBC compliant backend database.
- **ODBCTEST.** ODBC based Interactive SQL processor written in 'C' for Linux & UNIX

- **JDBCDemo.** a JDBC sample application that demonstrates Virtuoso's SQL query.
- **ScrollDemo2.** a JDBC 2.0 sample application that demonstrates Virtuoso's support of Scrollable Cursors and its ability to perform scrollable cursor operations across heterogeneous databases.
- **JBench.** a Java and JDBC based adaptations of the industry standard TPC-A and TPC-C benchmarks. This program helps you compare the performance of Virtuoso against other backend database engines, it also helps you to compare the performance of various JDBC Drivers connecting to any JDBC compliant backend database.
- **JTADemo.** a sample based on the TPC-A benchmark as well but implemented as a J2EE application which shows the use of XA distributed transactions as defined in JDBC 3.0 and JTA 1.0 specifications.

4.1. Binary & Source File Locations

4.1.1. ODBC Demonstration Applications

Windows 95/98/NT/2000, Linux & UNIX:

The binary executables of these sample applications reside under the following directory structure:

```
<VIRTUOSO_INSTALLATION_DIRECTORY>\samples\odbc
```

The source code of some of these sample applications, when available, reside under the following directory structure, for example:

```
<VIRTUOSO_INSTALLATION_DIRECTORY>\samples\odbc\cppdemo
```

4.1.2. JDBC Demonstration Applications

Windows 95/98/NT/2000, Linux & UNIX:

The binary executables (Java class files), and sources for these sample applications reside under the following directory structure:

```
<VIRTUOSO_INSTALLATION_DIRECTORY>\samples\jdbc\<JDK_Version>\<Demo_name>
```

4.2. Sample ODBC Applications

4.2.1. Mac OS X

ODBCTEST:

This is a simple 'C' based and ODBC compliant Interactive SQL processor.

1. Open a Terminal session, and start ODBCTEST by executing the following command:

   ```
   /Library/iodbc/bin/odbctest
   ```
2. At the SQL command prompt enter "?" for a list of ODBC DSNs on your machine or enter a valid ODBC Connect String. If you have a DSN named "Marketing" you would enter:

   ```
   DSN=Marketing;UID=username;PWD=password
   ```

   Note: If there is no password, you must include a semicolon at the end:

   ```
   DSN=Marketing;UID=sa;PWD=;
   ```
3. Any valid SQL or ODBC command may be executed through this interface. The following example shows a connection to Microsoft SQL Server 2000, making a simple query against the sample Northwind database:

   ```
   [localhost:~] openlink% /Library/iodbc/bin/odbctest
   iODBC Demonstration program
   This program shows an interactive SQL processor

   Enter ODBC connect string (? shows list, or DSN=...): DSN=user_tthib_sql2k

   SQL>select au_lname, au_fname, state from authors where au_id < '333-33-3333'
   au_lname                                |au_fname            |state
   ----------------------------------------+--------------------+-----
   White                                   |Johnson             |CA
   Green                                   |Marjorie            |CA
   Carson                                  |Cheryl              |CA
   O'Leary                                 |Michael             |CA
   Straight                                |Dean                |CA
    5 row(s) fetched.

   SQL>quit
   Again (y/n) ? n

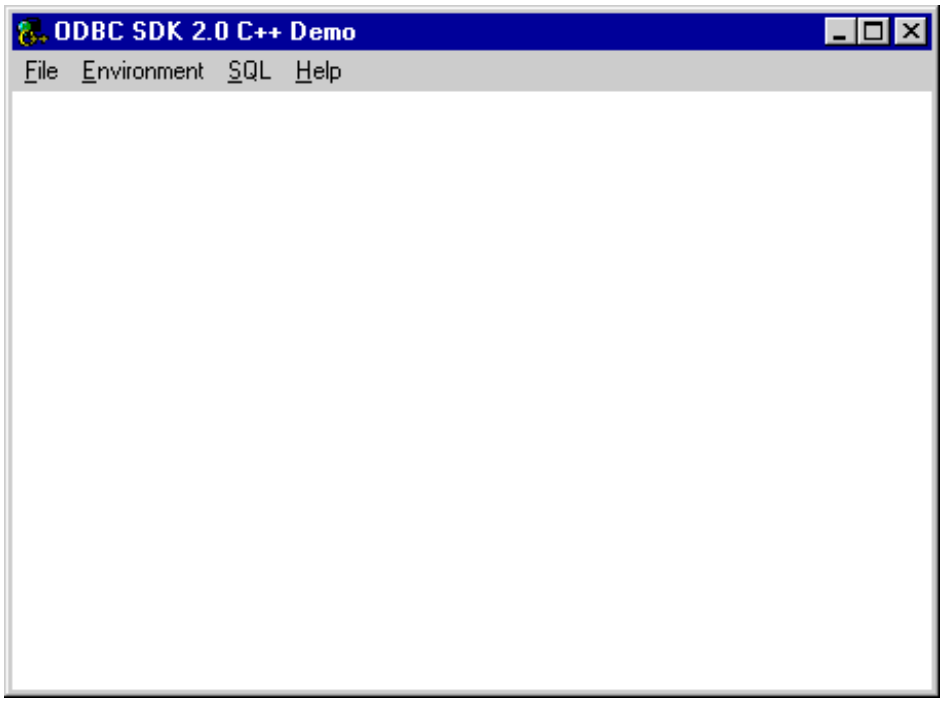
   Have a nice day.
   [localhost:~] openlink%
   ```

4.2.2. Windows 95/98/NT/2000

C++ Demo

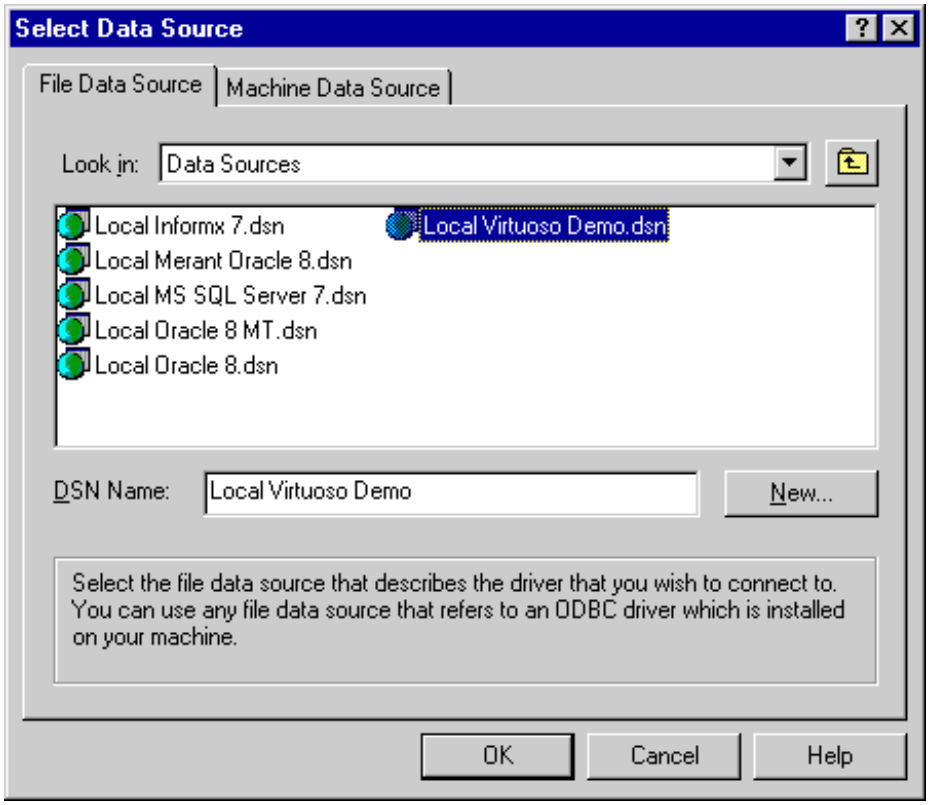
1. Go to the Virtuoso "Start Menu" item, then click on the "C++ Demo 32 Bit" menu item.

Figure 4.1. C++ Demo



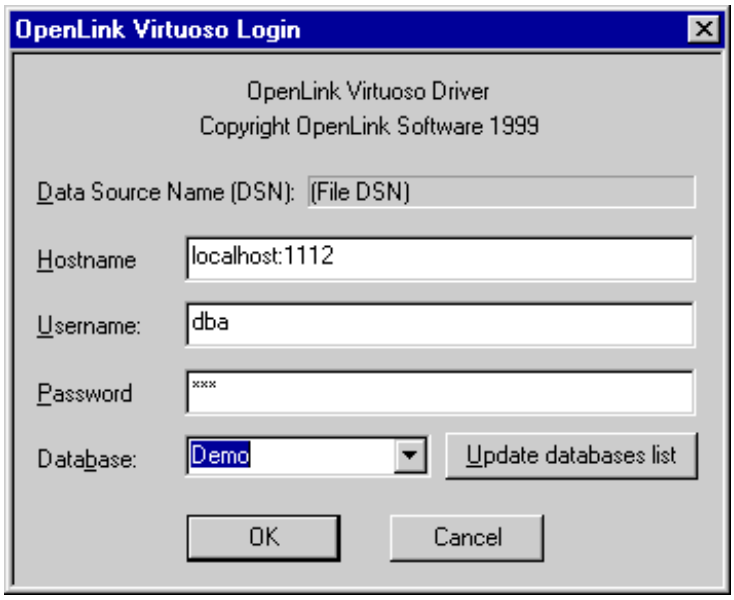
2. Follow the Environment->Open Connection menu path. Selecting the "Open Connection" menu item results in the ODBC Driver Manager presenting you with a list of ODBC DSNs on your machine as depicted by the screen capture below:

Figure 4.2. C++ Demo



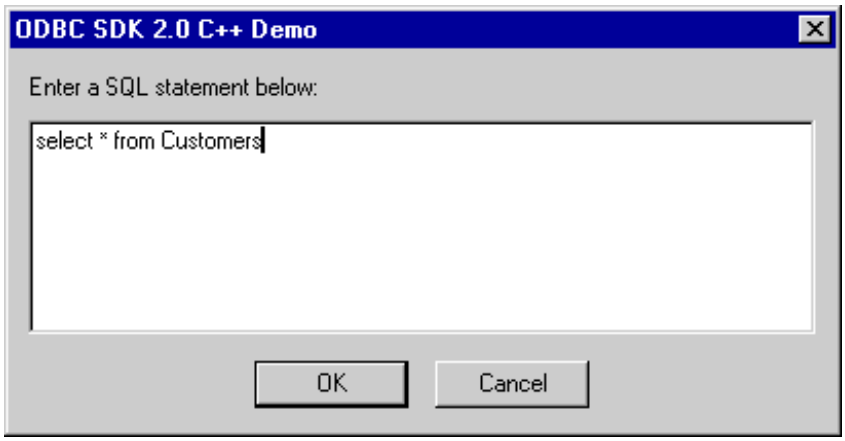
3. Select the ODBC DSN that you want to be connecting to, in this case "Local Virtuoso Demo" has been chosen since this will connect you to a sample Virtuoso database that has been populated with data.
4. You are then presented with a Login Dialog by the Virtuoso driver for ODBC, enter a valid user name and password (default being user: demo and password: demo) into the appropriate fields.

Figure 4.3. C++ Demo



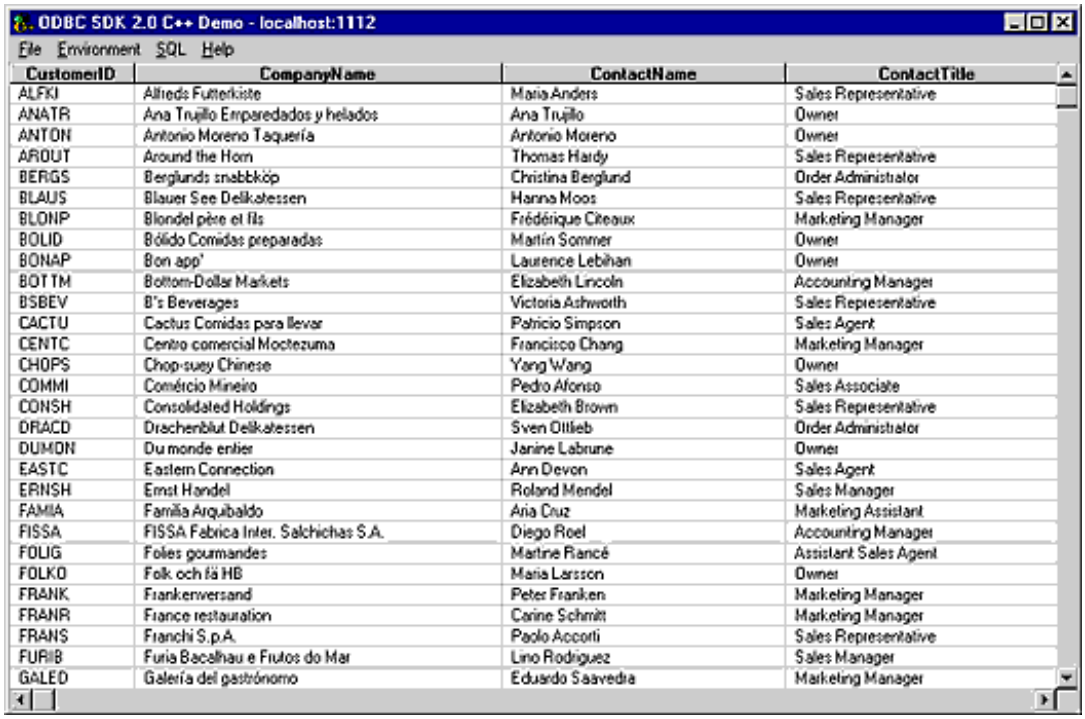
5. At this point you will be connected to the Virtuoso demonstration database, you can now use the SQL-->Execute SQL menu path to open up the Interactive SQL input dialog. Enter a valid SQL statement (see example in screen shot) and then click on the "OK" button.

Figure 4.4. C++ Demo



6. You will be presented with the results of your query.

Figure 4.5. C++ Demo



CustomerID	CompanyName	ContactName	ContactTitle
ALFKI	Alfreds Futterkiste	Maria Anders	Sales Representative
ANATR	Ana Trujillo Emparedados y helados	Ana Trujillo	Owner
ANTON	Antonio Moreno Taquería	Antonio Moreno	Owner
AROUT	Around the Horn	Thomas Hardy	Sales Representative
BERGS	Berglunds snabbköp	Christina Berglund	Order Administrator
BLAUS	Blauer See Delikatessen	Hanna Moos	Sales Representative
BLONP	Blondel père et fils	Frédérique Citeaux	Marketing Manager
BOLID	Bólido Comidas preparadas	Martín Sommer	Owner
BONAP	Bon app'	Laurence Lebihan	Owner
BOTTM	Bottom-Dollar Markets	Elizabeth Lincoln	Accounting Manager
BSBEV	B's Beverages	Victoria Ashworth	Sales Representative
CACTU	Cactus Comidas para llevar	Patricio Simpson	Sales Agent
CENTC	Centro comercial Moctezuma	Francisco Chang	Marketing Manager
CHOPS	Chop-suey Chinese	Yang Wang	Owner
COMMI	Comércio Mineiro	Pedro Afonso	Sales Associate
CONSH	Consolidated Holdings	Elizabeth Brown	Sales Representative

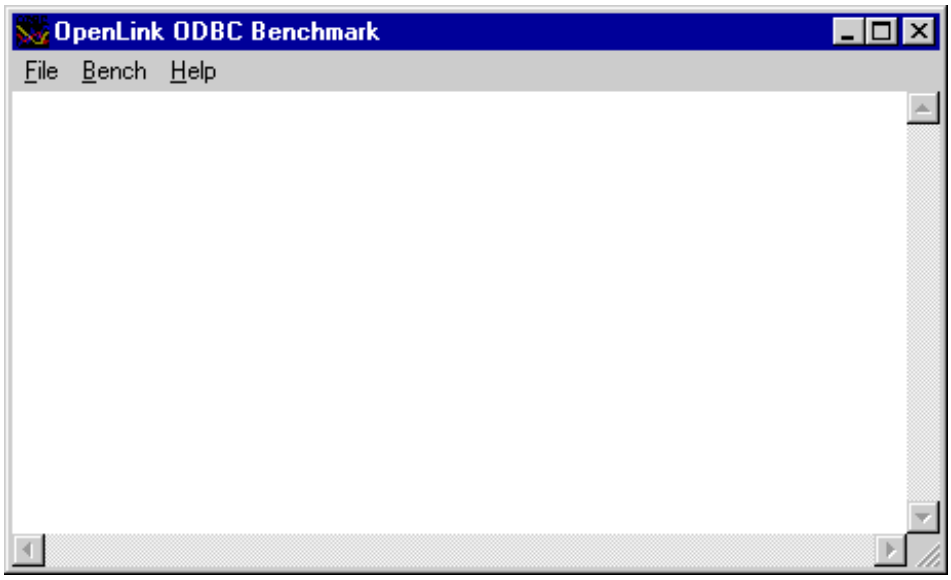
GALED	Galería del gastrónomo	Eduardo Saavedra	Marketing Manager

7. You exit this demo by following the Environment-->Close Connection menu path.

ODBC Bench Test 32

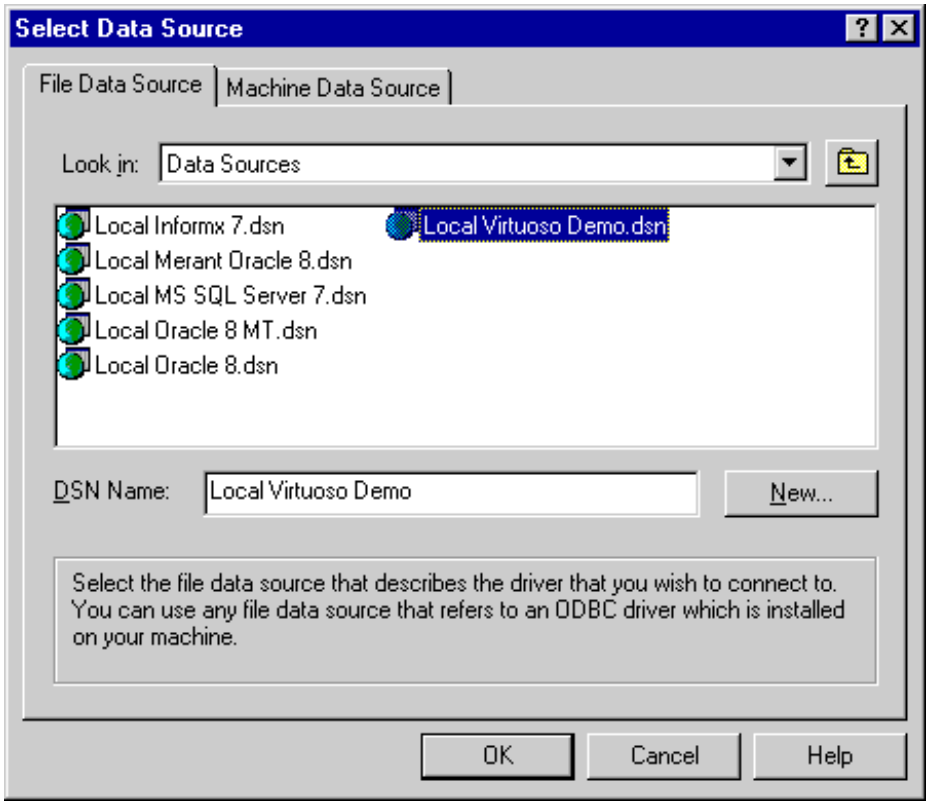
1. Go to the Virtuoso "Start Menu" item, then click on the "ODBC Bench Test 32 Bit" menu item. You will be presented with the "Bench Test" interface.

Figure 4.6. ODBC Bench



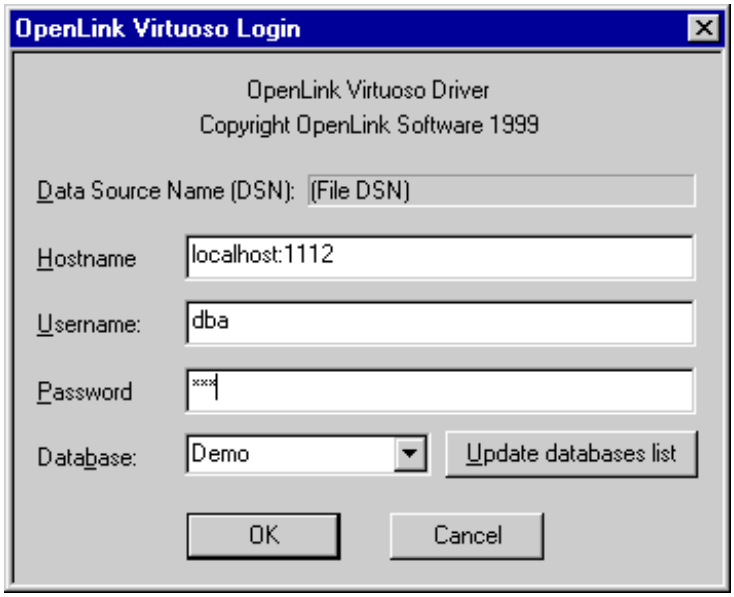
2. Follow the File-Connect menu path which initializes the ODBC Driver Manager which in turn presents you with a list of ODBC DSN's installed on your machine. Select the DSN that you want to benchmark, remember that by benchmarking a DSN you are benchmarking the ODBC Driver that serves the DSN in question and the backend database engine that serves the ODBC Driver. Choose the "Local Virtuoso Demo" DSN if you want to benchmark Virtuoso.

Figure 4.7. ODBC Bench



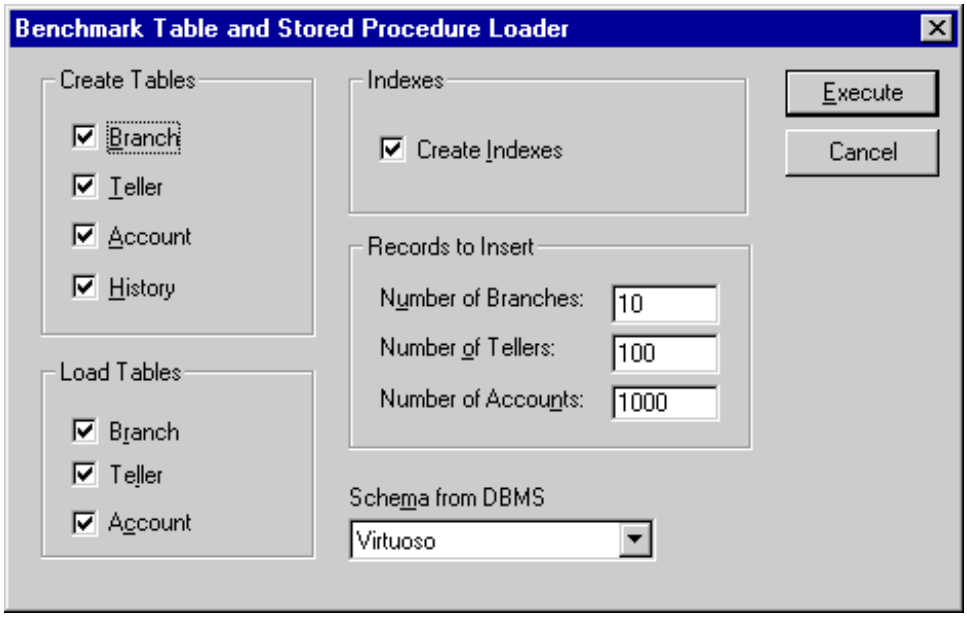
3. You will then be presented with a Login Dialog by the Virtuoso driver for ODBC, enter a valid user name and password (default being user: demo and password: demo for the Demo database) into the appropriate fields.

Figure 4.8. ODBC Bench



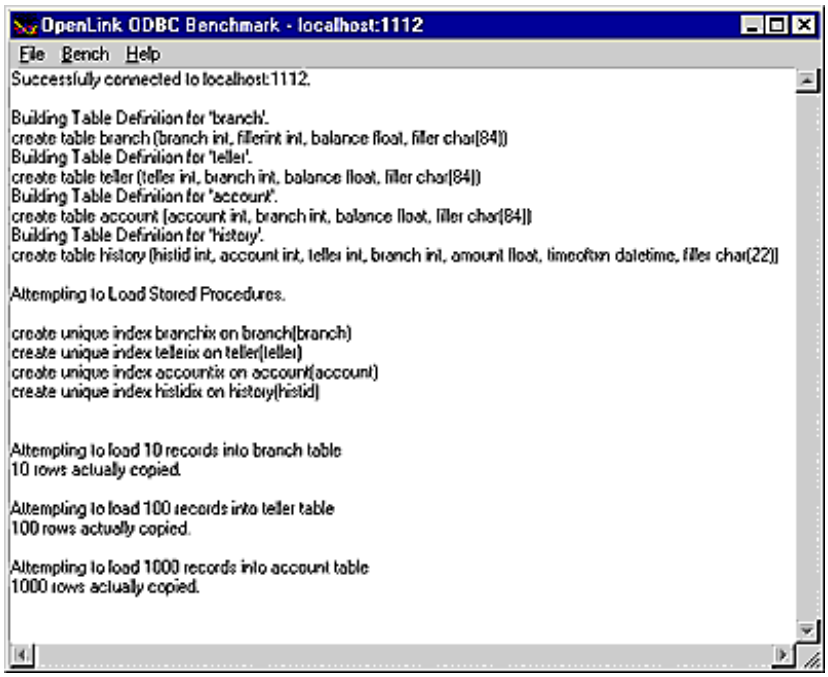
4. Now follow the Bench-->Load Tables menu path and you will be presented with a dialog that enables you to configure key elements of your benchmark. Click the "Execute" button to commence the process of setting up your database for the benchmark tests.

Figure 4.9. ODBC Bench



5. As the process of loading data occurs, all the way up to completion, the benchmark program will provide status information into the benchmark output pane as shown below:

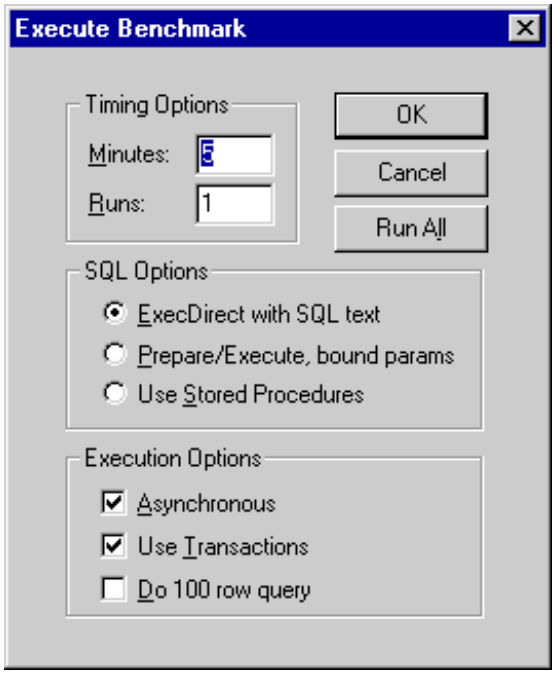
Figure 4.10. ODBC Bench



6. Now that all the benchmark data has been loaded into your database, follow the Bench-->Run Benchmark menu path and then configure your actual benchmark session parameters:

   These benchmark parameters fall into 3 categories, Timing Options, SQL Options, and Execution Options.

Figure 4.11. ODBC Bench



Timing Options: These setting allow you to configure the duration related aspects of this benchmark program

Minutes - this is the duration of each benchmark run

Runs - this controls how many iterations of the benchmarks you actually run (the default is one benchmark iteration with a duration of 5 minutes)

SQL Options: These setting allow you to configure how your benchmark's SQL instructions are actually handled.

ExecDirect with SQL Text - this means that no form of repetitive SQL execution optimization is being applied (SQL statements are prepared and executed repetitively)

Prepare/Execute Bound Params - this means that the Parameter Binding SQL execution optimization is being applied (SQL is prepared once but executed many times without the overhead of re-preparing statements prior to execution)

Use Stored Procedures - this means that the Stored Procedure SQL optimization is being applied (benchmark instructions are stored within database being benchmarked)

Execution Options: These setting allow you to configure the tone of your benchmark, for instance it could have Transaction scoping and a mix of record retrieval queries, or it could simply be input and update intensive with a minimal amount of record retrieval queries (the case when the 100 row query checkbox is unchecked a typical OLTP scenario)

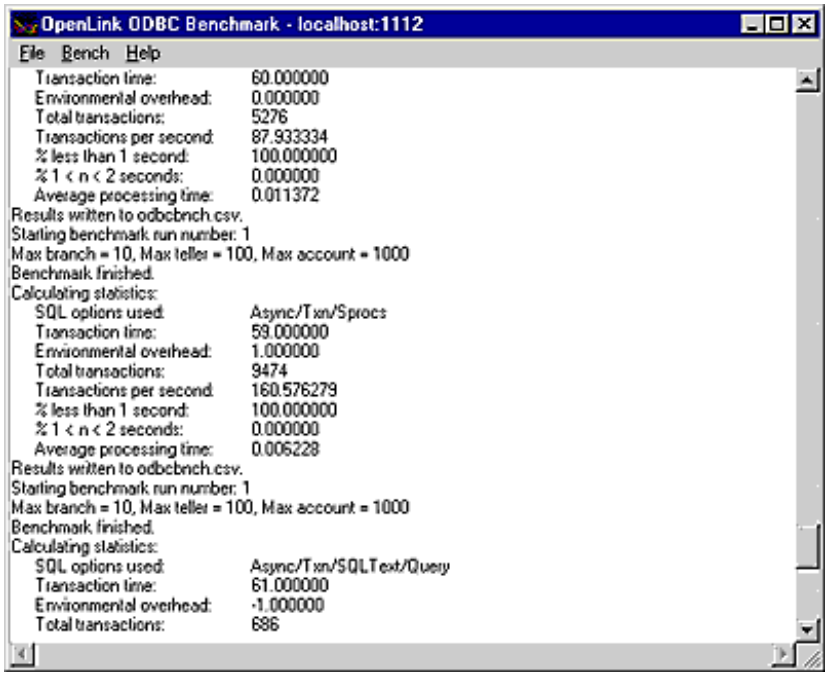
Asynchronous - execute the benchmark instructions asynchronously

Use Transactions - make the benchmark use transaction control (instructions are scoped to transaction blocks)

Do 100 row Query - perform a simulation of a 100 record retrieval as part of the benchmark activity.

1. Click on the "Run All" button if you would like all the different benchmark type combinations to be performed.
2. When benchmark run complete benchmark data is written to the benchmark program's output pane.

Figure 4.12. ODBC Bench



The key pieces of benchmark data that you need to look out for are:

Total Transactions: total number of transactions completed during the benchmark run

Transactions Per Second number of transaction completed per second for the benchmark run

Information from this benchmark is automatically written to an Excel format CSV (the file odbcbnch.csv) which makes it easy for you to graph and pivot data collated from several benchmark runs. A later version of this demo will actually write the benchmark data into an ODBC DSN that you provide thereby offering even more flexibility and accessibility to benchmark data.

4.2.3. Linux & UNIX

ODBCTEST:

This is a simple 'C' based and ODBC compliant Interactive SQL processor.

1. Run the script virtuoso-enterprise.sh to set up your environment:

   ```
   . virtuoso-enterprise.sh
   ```
2. Start ODBCTEST by executing the following command:

   ```
   odbctest
   ```
3. At the SQL command prompt enter "?" for a list of ODBC DSNs on your machine or enter a valid ODBC Connect String. If you have a DSN named "Marketing" you would enter:

   ```
   DSN=Marketing;UID=username;PWD=password
   ```

   Note: If there is no password, you must include a semicolon at the end:

   ```
   DSN=Marketing;UID=sa;PWD=;
   ```
4. Any valid SQL or ODBC command may be executed through this interface. The following example shows a connection to Microsoft SQL Server 2000, making a simple query against the sample Northwind database:

   ```
   [localhost:~] openlink% odbctest
   iODBC Demonstration program
   This program shows an interactive SQL processor

   Enter ODBC connect string (? shows list, or DSN=...): DSN=test_sql2k

   SQL>select au_lname, au_fname, state from authors where au_id < '333-33-3333'
   ```

```
au_lname                                |au_fname            |state
----------------------------------------+--------------------+-----
White                                   |Johnson             |CA
Green                                   |Marjorie            |CA
Carson                                  |Cheryl              |CA
O'Leary                                 |Michael             |CA
Straight                                |Dean                |CA
 5 row(s) fetched.

SQL>quit
Again (y/n) ? n

Have a nice day.
[localhost:~] openlink%
```

4.2.4. MS DTC ODBC Sample Application

The MS DTC demo is located in the

```
<VIRTUOSO_INSTALLATION_DIRECTORY>\samples\odbc\MSDTCdemo1
```

folder. This demo shows usage of distributed transactions driven by MS DTC through the ODBC API.

Setup

The sample works with two instances of Virtuoso server. The running MS DTC service is needed. The servers must be started with MS DTC support (see Virtuoso documentation).

First of all, edit the virt.odbc file. By default this file contains two connection strings of local Virtuoso servers running on port 1111 and port 1112, Each line begins with connection string to appropriate Virtuoso server. Initially this file contains the following lines:

```
1111 dba dba 00.sql
1112 dba dba 01.sql
```

where 1111, 1112 are ports of two Virtuoso servers. "dba dba" - user and password.

Initialization

Start

```
 mtstest.exe +load
```

in the

```
<VIRTUOSO_INSTALLATION_DIRECTORY>\samples\odbc\MSDTCdemo1
```

folder. This must check whether all needed servers are running, create and initialize tables, procedures, etc.

Test

Run the command in the demo's working directory:

```
mtstest.exe   +exec N
mtstest.exe   +exec 0
```

where N - is a number of test iterations. The second command checks logical consistency of the tables.

Description

The demo source is

```
start.c
```

file in the

```
<VIRTUOSO_INSTALLATION_DIRECTORY>\samples\odbc\MSDTCdemo1
```

directory. Several highlights of the most significant parts of code are presented below:

```
ITransactionDispenser *disp;
ITransaction *transaction;

...
HRESULT hr =
    DtcGetTransactionManagerC (0, 0, &IID_ITransactionDispenser, 0, 0, 0,
    &, disp);
```

The code above creates Dispenser object which represents the local instance of MS DTC. If MS DTC is not available

```
DtcGetTransactionManagerC
```

fails. The Dispenser is needed to create distributed transaction objects later.

Begin new distributed transaction:

```
disp->lpVtbl->BeginTransaction (disp, 0, ISOLATIONLEVEL_ISOLATED,
      0, 0, &transaction);
```

Enlist connection in the transaction:

```
SQLSetConnectOption (hdbc, SQL_COPT_SS_ENLIST_IN_DTC,
      (DWORD) transaction);
```

And, finally, commit the transaction:

```
transaction->lpVtbl->Commit (tran, 0, 0, 0);
```

4.2.5. MS DTC OLE DB Sample Application

The MS DTC OLE DB demo is located in the

```
<VIRTUOSO_INSTALLATION_DIRECTORY>\samples\odbc\MSDTCdemo2
```

folder. This demo shows usage of distributed transactions driven by MS DTC through OLE DB.

Setup

The sample works with two instances of Virtuoso server. Running MS DTC service is needed. The servers must be started with MS DTC support (see Virtuoso documentation).

The test needs two Virtuoso server instances running on ports 1111 and 1112

Run

Run the command in the demo's working directory:

```
voledbtest.exe
```

Description

The demo source is

```
voledbtest.cs
```

file in the

```
<VIRTUOSO_INSTALLATION_DIRECTORY>\samples\odbc\MSDTCdemo
```

directory. Several highlights of the most significant parts of code are presented below:

```
[TransactionAttribute(TransactionOption.Required)]
```

It is significant to set this attribute of class to enable automatic transaction initialization.

Create connections to appropriate servers:

```
string strConn = "Provider=VIRTOLEDB;Data Source=" + dsn1
    + ";User Id=dba;Password=dba;Initial Catalog=Demo;Prompt=NoPrompt;";
string strConn2 = "Provider=VIRTOLEDB;Data Source=" + dsn2 +
    ";User Id=dba;Password=dba;Initial Catalog=Demo;Prompt=NoPrompt;";
obj_conn = new OleDbConnection(strConn);
obj_conn2 = new OleDbConnection(strConn2);
```

And, finally, execute the SQL code in the context of distributed transaction:

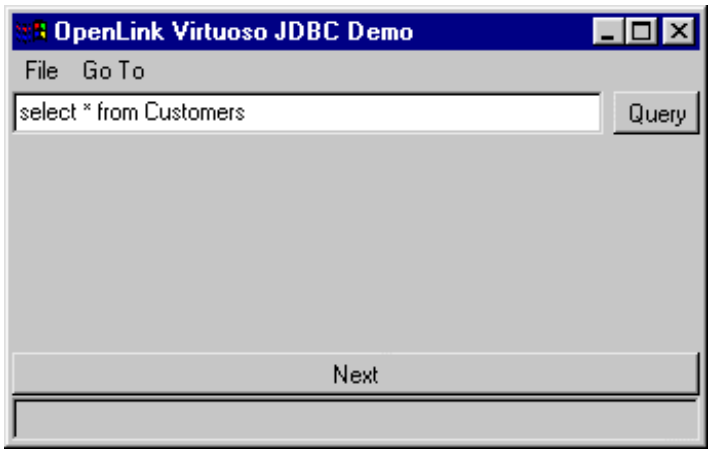
```
OleDbCommand sqlc = new OleDbCommand ("ODBC_BENCHMARK(" + idx + ",1,1,12.00,\'noone\')");
sqlc.Connection = obj_conn;
sqlc.ExecuteNonQuery();
sqlc = new OleDbCommand ("ODBC_BENCHMARK(" + idx + ",1,1,-12.00,\'noone\')");
sqlc.Connection = obj_conn2;
sqlc.ExecuteNonQuery();
```

4.3. Sample JDBC Applications & Applets

4.3.1. JDBCDemo Java Application

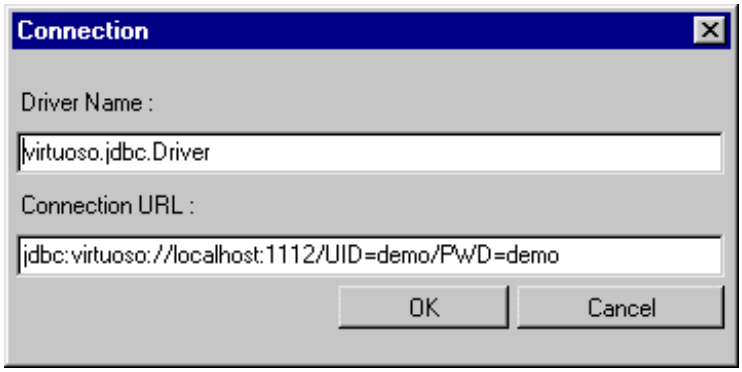
1. Go to the Virtuoso "Start Menu" program group and then follow the JDBC Samples-->JDBCDemo (JDK1.1&1.2) menu path, this will execute a DOS batch program that initializes the Java demo application.

   Figure 4.13. JDBC Demo

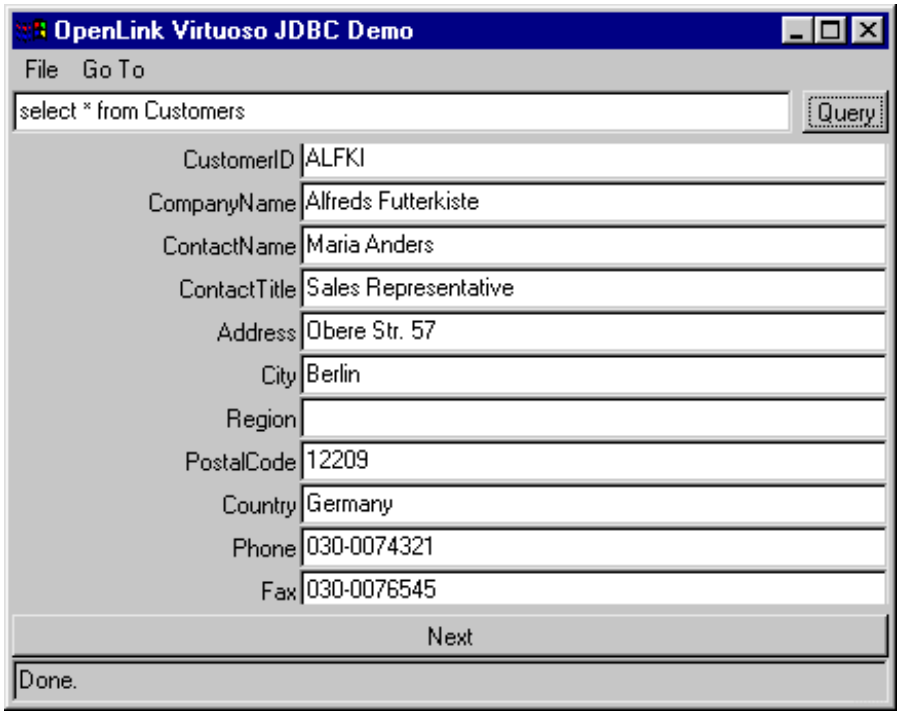
2. Set the JDBC Driver Name and URL settings for your connection to the Virtuoso demonstration database. The "Driver Name" field identifies the Virtuoso Driver. If it is left blank, then it defaults to "virtuoso.jdbc.Driver", which is the Virtuoso Driver for JDBC 1.0. The "Connection URL" field requires a valid Virtuoso JDBC URL.

   Figure 4.14. JDBC Demo



3. Enter a valid SQL statement and then click the "Query" button, the example below uses a fully qualified Virtuoso SQL statement requesting all records from the "Demo" database table "Customers" owned by the Virtuoso user "DBA".

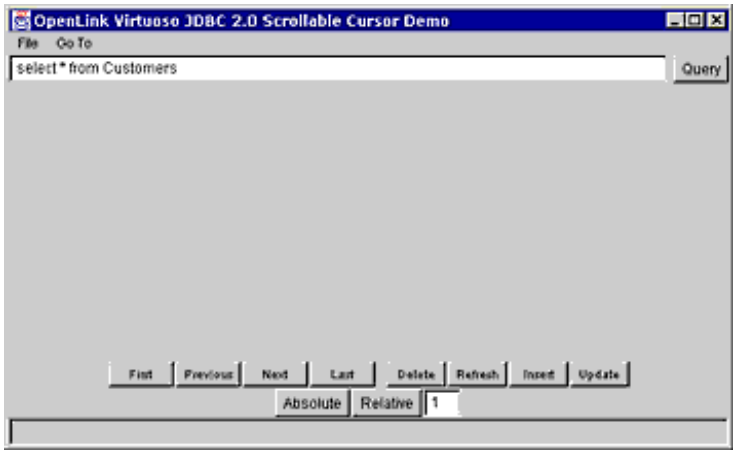
Figure 4.15. JDBC Demo



4.3.2. ScrollDemo2 Java Application

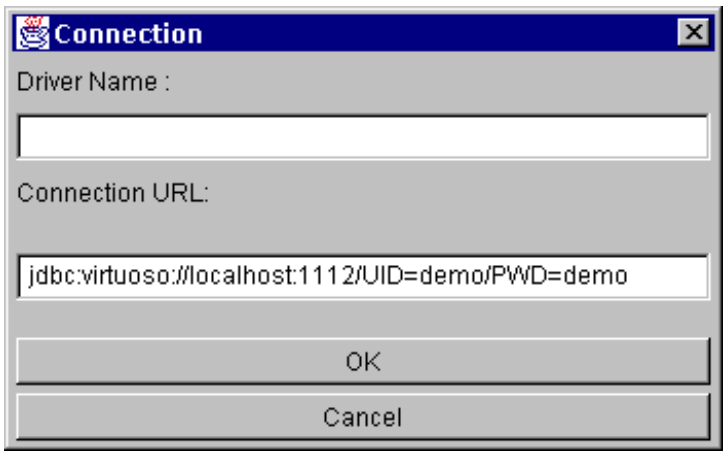
1. Go to the Virtuoso Lite "Start Menu" program group and then follow the JDBC Samples-->ScrollDemo2 (JDK1.2) menu path, this will execute a DOS batch program that initializes the Java demo application.

Figure 4.16. Scroll Demo 2



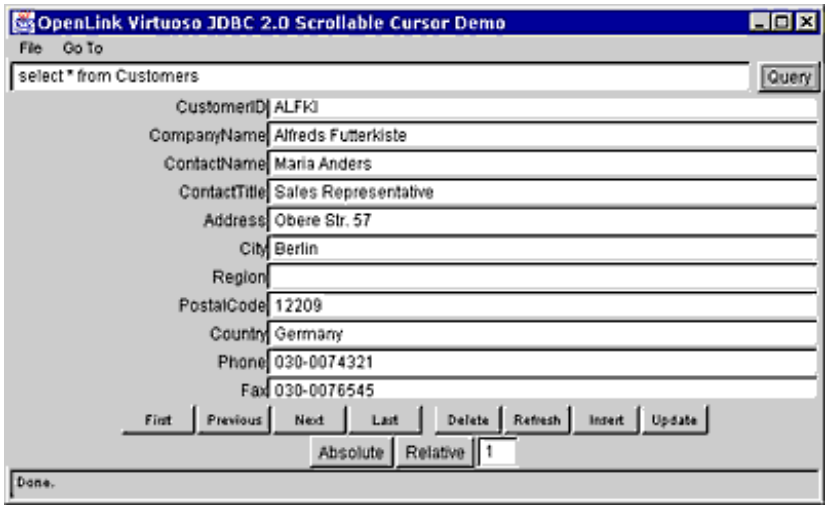
2. Set the JDBC Driver Name and URL settings for your connection to the Virtuoso demonstration database. The "Driver Name" field identifies the Virtuoso Driver. If it is left blank, then it defaults to "virtuoso.jdbc2.Driver", which is the Virtuoso Driver for JDBC 2.0. The "Connection URL" field requires a valid Virtuoso JDBC URL.

Figure 4.17. Scroll Demo 2



3. Enter a valid SQL statement and then click the "Query" button, the example below uses a fully qualified Virtuoso SQL statement requesting all records from the "Demo" database table "Customers" owned by the Virtuoso user "DBA".

Figure 4.18. Scroll Demo 2

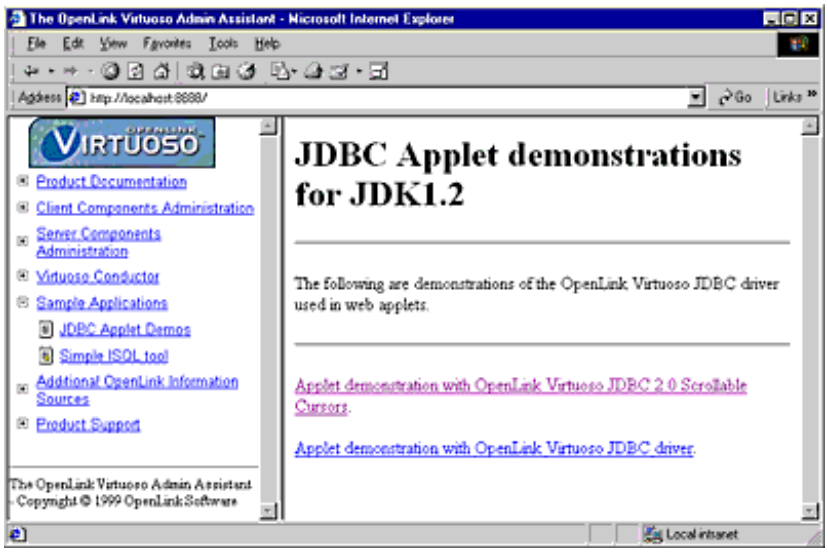


4. You can now use the navigational buttons to Scroll backwards and forwards, each of these navigational buttons highlights Virtuoso's full implementation of the JDBC 2.0 Scrollable Cursors specifications.

4.3.3. ScrollDemo2 Java Applet

1. Start the Virtuoso Admin Assistant and then follow the Sample Applications-->JDBC Applet Demos menu path.

   Figure 4.19. Scroll Demo 2

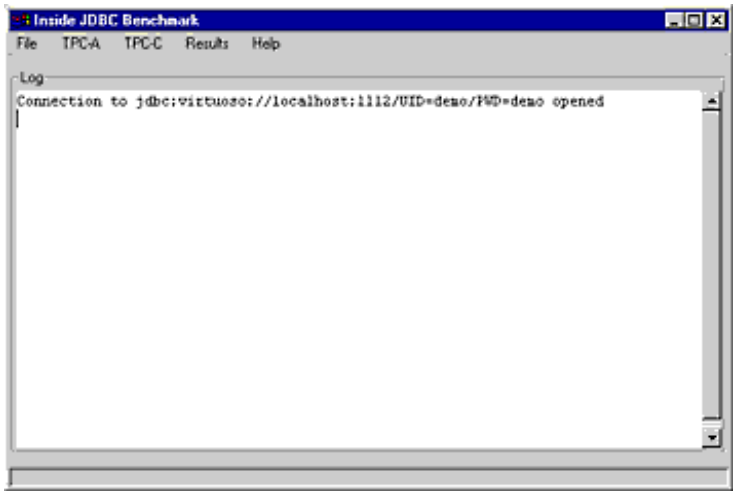


2. Click on the "ScrollDemo2" hyperlink which initializes the ScrollDemo2 applet, if you do not have a Java 1.2 or Java 2.0 compliant browser you will not be able to run this Applet demo. The other way to experience this demo is to run the Application version which uses your operating systems Java Virtual Machine (JVM) instead of a JVM inherently linked to a Web Browser.

4.3.4. JBench Application

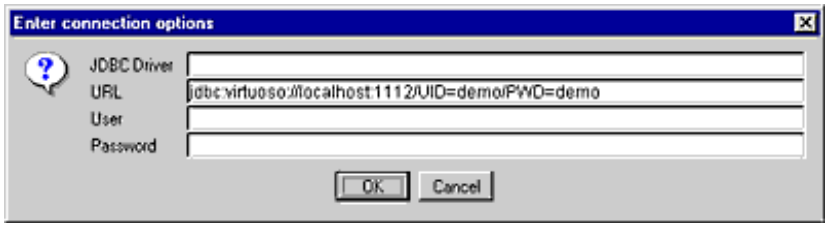
1. Go to the Virtuoso "Start Menu" program group and then follow the JDBC Samples-->Jbench (JDK1.1) or Jbench (JDK1.2) menu path, depending on the JVM you have installed. This will execute a DOS batch program that initializes the JBench application.

   Figure 4.20. JBench



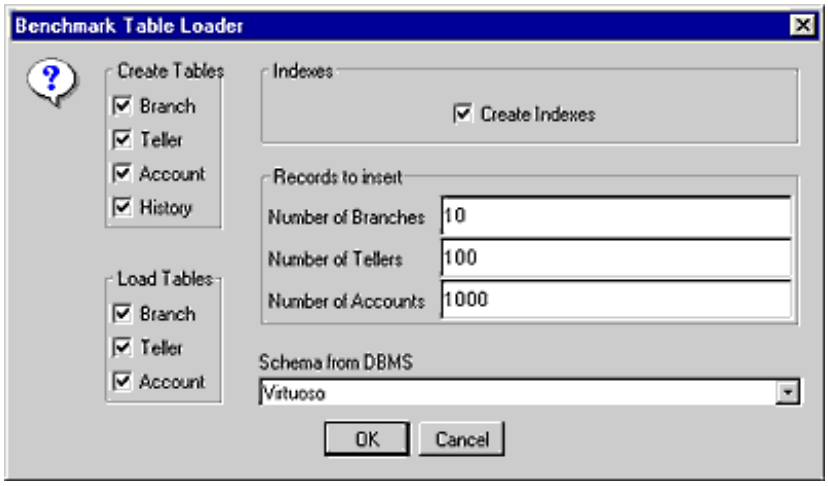
2. The follow the File-->Connect menu path to make your initial connection. You will need to identify your JDBC Driver (by providing appropriate Driver Name values in the JDBC Driver field) and then provide a valid JDBC URL for your specific JDBC Driver (Jbench uses a valid Virtuoso Driver for JDBC URL that points to the demonstration database listening at port 1112 as its default).

   Figure 4.21. JBench



3. Follow the Results-->Table URL menu path, this is how you identify (using a JDBC URL) the location of the "Results" tables into which you will be storing your benchmark data. The default URL is the current JDBC URL (the one used to establish your initial connection), but this can be a totally different database to the one being benchmarked.
4. Follow the Results-->Create menu path, this is how you actually perform the "Results" table creation in the database identified by the URL in the previous step.
5. Follow the TPC-A-->Load Tables menu path to prepare your database for the TPC-A benchmark, select a database schema type that matches the database engine that you are benchmarking. If your database is not listed ANSI should suffice (as long as this is an ANSI SQL compliant database).

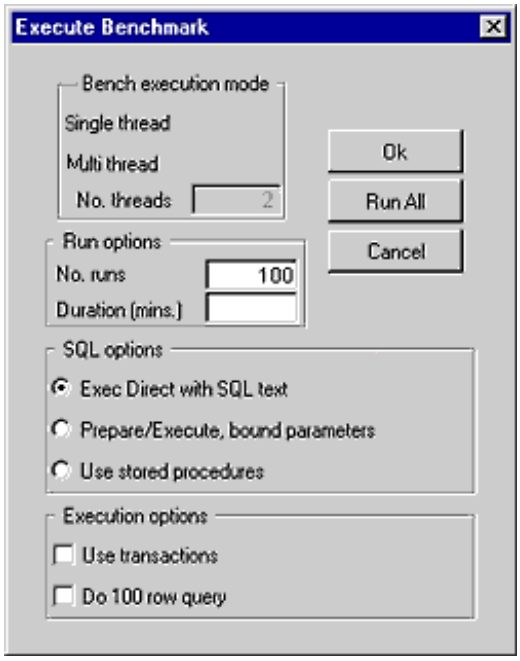
Figure 4.22. JBench



6. Follow the TPC-A-->Load Procedures menu path to Load the Virtuoso TPC-A stored procedures.
7. Now that all the benchmark data and stored procedures have been loaded into your database, follow the TPC-A-->Run Benchmark menu path and then configure your actual benchmark session parameters:

   The benchmark parameters fall into 4 categories, Bench execution mode, Run Options, SQL Options, and Execution Options.

Figure 4.23. JBench



Bench execution mode: These setting allow you to configure the threads used for the benchmark.

Decide on a single or multiple threads test.

No. Threads - this is the number of concurrent threads to be used during the benchmark.

Run Options: These setting allow you to configure the duration related aspects of this benchmark program.

No. runs - this controls how many iterations of the benchmarks you actually run (the default is 100 benchmark iterations).

Duration (mins.) - this is the duration in minutes of each benchmark run.

SQL Options: These setting allow you to configure how your benchmark's SQL instructions are actually handled.

ExecDirect with SQL Text - this means that no form of repetitive SQL execution optimization is being applied (SQL statements are prepared and executed repetitively)

Prepare/Execute Bound Params - this means that the Parameter Binding SQL execution optimization is being applied (SQL is prepared once but executed many times without the overhead of re-preparing statements prior to execution)

Use Stored Procedures - this means that the Stored Procedure SQL optimization is being applied (benchmark instructions are stored within database being benchmarked)

Run All - this implies you want to perform all of the above benchmarks

Execution Options: These setting allow you to configure the tone of your benchmark, for instance it could have Transaction scoping and a mix of record retrieval queries, or it could simply be input and update intensive with a minimal amount of record retrieval queries (the case when the 100 row query checkbox is unchecked a typical OLTP scenario)

Use Transactions - make the benchmark use transaction control (instructions are scoped to transaction blocks)

Do 100 row Query - perform a simulation of a 100 record retrieval as part of the benchmark activity.

8. Run your TPC-A benchmark.
9. Follow the TPC-A-->Cleanup menu path to clean up your database so that you can then run other benchmarks (TPC-C like benchmark).
10. To run the TPC-C benchmark simply follow the appropriate menu path, create the benchmark tables & stored procedures, load the benchmark data and then run the TPC-C benchmark.

4.3.5. JTA Demo Application

The JTA demo is located in the

```
<VIRTUOSO_INSTALLATION_DIRECTORY>\samples\jdbc\JTADemo
```

folder.

Software Setup

1. The sample requires 2 or 3 Virtuoso instances and an instance of a J2EE 1.3.1 server properly set up and running on the same computer or on the network. To build the sample it's also necessary to have a J2SE 1.4 SDK installed.
2. The JAVA_HOME and J2EE_HOME environment variables must be set to the J2SE SDK and J2EE installation path respectively.
3. The virtjdbc3.jar file must be in the classpath of the J2EE server. The setting of the classpath differs across different J2EE servers. For J2EE Reference Implementation (RI) the J2EE_CLASSPATH variable might be set in %J2EE_HOME%\bin\userconfig.bat on Windows or $(J2EE_HOME)/bin/userconfig.sh on Unix.

   ```
   set J2EE_CLASSPATH=C:/Virtuoso/lib/virtjdbc3.jar
   ```

   or

   ```
   J2EE_CLASSPATH=/home/login/virtuoso/lib/virtjdbc3.jar
   export J2EE_CLASSPATH
   ```
4. Add the Virtuoso XA datasources to J2EE server. For J2EE RI this is done like this:

   ```
   j2eeadmin -addJdbcXADatasource jdbc/Virtuoso1 virtuoso.jdbc3.VirtuosoXADataSource dba dba -pro
   j2eeadmin -addJdbcXADatasource jdbc/Virtuoso2 virtuoso.jdbc3.VirtuosoXADataSource dba dba -pro
   j2eeadmin -addJdbcXADatasource jdbc/Virtuoso3 virtuoso.jdbc3.VirtuosoXADataSource dba dba -pro
   ```

   Please note that the newly added datasources take effect only after restart of the J2EE server.

Configuration

The sample folder contains the jtademo.properties file which can be used to configure the sample application. The configuration options are described within the file.

Building and Deployment

The sample folder contains build and deploy scripts (build.sh and deploy.sh for Linux and Unix and build.bat and deploy.bat for Windows).

Use the build script to build the sample application from the source files.

Deploy the application to the J2EE server. The deploy script performs this task for J2EE RI. Other J2EE application servers might provide different ways for application deployment.

Running the Sample

The sample folder contains the run scripts for Linux/Unix and Windows.

The run script accepts the following commands:

create
: Creates and populates the necessary tables.

check
: Verifies data consistency.

drop
: Removes data and tables from the databases.

run
: Executes a number of transactions over database tables.

The first action to do is to initialize the data with the create command. After this the command might be used one or more times. This executes a series of concurrent updates on the distributed data. The check command verifies that this updates left databases in the consistent state.

For instance, for Unix:

```
run.sh create
run.sh run
run.sh check
```

And for Windows:

```
run.bat create
run.bat run
run.bat check
```

Chapter 5. Conceptual Overview

Abstract

Virtuoso provides both a native database capability and a virtual database that integrates remote or third-party ODBC data sources seamlessly with Virtuoso's own. The virtual database (VDB) allows transparent unified queries across all linked data sources. The Virtuoso server supports ANSI SQL92, object extensions, and a significant set of PL extensions. The most important extensions include support for modern Internet standards for communication, data, and document exchange. Virtuoso supports communications protocols such as HTTP, SMTP and NNTP as well as a full suite of XML-based protocols including XML, XSL, SOAP, and WSDL.

5.1. Core Database Engine

5.1.1. Logical Data Model

Virtuoso provides an extended Object Relational model which offers all the flexibility of relational access with inheritance, run time data typing, late binding, identity based access.

Table

A table is a uniquely named entity that has the following characteristics:

- Zero or more columns
- One primary key
- Zero or more keys (indices)
- An optional super table from which this inherits properties
- An optional object ID key, which may or may not be the primary key
- Various SQL table constraints, e.g. CHECK's

A table will then have zero or more rows. The relationship of a table and its rows can be thought of as a class-instance relationship.

Column

A column is always defined in one table and has a name that is unique within that table. A column may appear in more than one table as a result of inheritance but always has one place of definition. i.e. one database wide 'identity'.

A column has the following characteristics:

- Table
- Name inside the table
- database wide ID
- Data type
- Various SQL constraints, e.g. DEFAULT, CHECK etc.

Key

A key or index is the means by which tables manifest themselves in the physical database. A key is always defined with respect to one table but may occur in several as a result of inheritance. Keys have unique names inside the table. A key has the following characteristics:

- A database wide key ID
- One or more 'significant' key parts, which are columns of the defining table or super tables
- Zero or more 'trailing' key parts, columns of the defining table or supertables.
- Whether the key is primary
- Whether the key is unique
- How the key is clustered
- Whether the key is an object ID key

Subtable

A subtable is a table that inherits all columns, the primary key and all other keys from another table, called the super table.

A subtable can define its own columns and keys which add themselves to those of the super table. No primary key can be redefined, though.

The inheritance relationship between tables is manifested by a key-subkey relationship between the tables' primary and other keys.

A table has at most one supertable.

Object ID

A table does not necessarily declare a primary key. Even so, the table must have a primary key - in this case a synthetic record ID which is defined as primary key. The record ID is an autoincrementing column that is normally invisible but, if present, can be accessed by explicit reference. One should not rely on this feature being available, though.

Thus

```
create table nokey (a integer);
```

expands to

```
create table nokey (a integer, _IDN integer identity, primary key (_IDN));
```

The first unique index to be defined will become the primary key if the table is empty at the time of definition.

Thus

```
create unique index a on nokey (a);
```

will change the nokey table to be as if defined by

```
create table nokey (a integer, primary key (a));
```

Having a primary key other than _IDN is always better than the default primary key. Declaring a primary key is therefore always advisable.

5.1.2. Data Types

Virtuoso supports most SQL 92 data types.

CHARACTER & VARCHAR

- CHARACTER
- VARCHAR
- VARCHAR '(' INTNUM ')'

- VARCHAR
- NVARCHAR '(' INTNUM ')'
- CHARACTER '(' INTNUM ')'

The CHAR, CHARACTER and VARCHAR datatypes are implemented as a single string type with dynamic length. The precision that may be specified controls how the column is described by `SQLColumns()` , `SQLDescribeCol()` and so on. If a precision is not specified for a VARCHAR then the default precision will be 0, which means do not check. If a precision is not specified for a CHARACTER then Virtuoso sets the precision to 1. An explicit precision of 0 can be specified to turn off length checking for values stored in the column. If a value other than string or NULL is assigned to the column it is cast to a varchar (using CAST internally) and then stored into the column. If the value is not castable to a varchar then Virtuoso returns an error. Additionally if the column precision is greater than 0 and the value string length is greater than the column precision Virtuoso will also return an error.

The length is stored separately. Space required is 2+length for

A varchar column may contain binary 0 bytes.

A string literal is delimited by single quotes.

ANY

- ANY

The ANY datatype is implemented as a single binary string type with dynamic length. It is reported as a VARCHAR in `SQLColumns()` , `SQLDescribeCol()` and so on. The precision returned by these columns is 24 but has no effect. This type can contain arbitrary binary data, including zeros.

The length is stored separately. The space required is 2+length

NUMERIC & DECIMAL

- NUMERIC
- NUMERIC '(' INTNUM ')'
- NUMERIC '(' INTNUM ',' INTNUM ')'
- DECIMAL
- DECIMAL '(' INTNUM ')'
- DECIMAL '(' INTNUM ',' INTNUM ')'

The various forms of NUMERIC and DECIMAL refer to one variable-precision floating point decimal data type that provides accurate arithmetic and decimal rounding. The default maximum precision and scale are 40 and 20. The precision is the number of decimal digits used in the computation. The scale is the maximum number of decimal digits to the right of the decimal point. Internal calculations are always precise but numbers are truncated to the column's precision and scale when stored. If a value being stored has more digits to the left of the decimal point than allowed in the column, Virtuoso signals an error. If a number being stored has more digits to the right of the decimal point than allowed in a column the decimal part is rounded to the precision of the column.

The space consumption of a number is

```
3 + precision / 2
```

bytes. The precision and scale of a column of this type are returned by functions such as `SQLColumns()` and `SQLDescribeCol()` .

A DECIMAL or NUMERIC with precision <= 9 and scale = 0 is transformed to INTEGER.

Literal numbers outside of the 32 bit signed integer range are of type decimal. Any numeric literals with a decimal point are of type decimal. Literals with an exponent are of type double precision.

INTEGER & SMALLINT

- INT
- INTEGER
- SMALLINT

These types are represented as a 32-bit signed binary integer, described as having a precision of 9 and a scale of 0, although the range is +/- 2**31. Storage space is 2 bytes for SMALLINT and 4 bytes otherwise.

A column declared SMALLINT is described as SQL_SMALLINT. A column declared INTEGER or INT is described as SQL_INTEGER.

Literals composed of of an optional sign and digits are of the integer type if they fit in the 32 bit range.

FLOAT & DOUBLE

- FLOAT
- FLOAT '(' INTNUM ')'
- DOUBLE PRECISION

These types refer to the 64-bit IEEE floating-point number, the C *double* type. This is a fixed-precision binary floating point number is described as having a precision of 15 and a scale of 0. This type is preferable to NUMERIC if decimal rounding is not required since it is precise enough for most uses and more efficient than NUMERIC. The storage requirement is 8 bytes.

Any number literal with an exponent has the double type, e.g. 2e9.

REAL

- REAL

This type is the 32-bit IEEE floating point number corresponding to the C *float* type. The storage requirement is 5 bytes.

LONG VARCHAR & LONG VARBINARY

- LONG VARCHAR
- LONG VARBINARY

These types implement a binary large object (BLOB) type. The length can be up to 2**31 bytes (2GB). If manipulated with the `SQLGetData()` and `SQLPutData()` ODBC functions a BLOB need not fit in the DBMS's or the client's memory. The LONG VARCHAR and LONG VARBINARY types are distinct only because certain ODBC applications gain from being able to distinguish long text from long binary. The types are described as SQL_LONGVARCHAR and SQL_LONGVARBINARY respectively, with a precision of 2GB.

Several long columns may exist on a single row. A long column may not be a key part in an index or primary key.

Data in long columns is stored as a linked list of database pages. Thus, a long column that does not fit in-line on the containing row will require an integer number of 8K database pages. If a long column's value is short enough to fit within the row containing it, the BLOB will be stored on the row and will not take more space than a VARCHAR of the same length. A long column fits on a row if the sum of the lengths of columns, including the long column, is under 4070 bytes.

ORDER BY, GROUP BY and DISTINCT may not reference long data types. Comparison of long data is not allowed unless first converted to the corresponding short type (varchar, nvarchar or varbinary). This conversion is only possible if the value is under 10MB in size. String functions accept long varchars and long nvarchars and convert them to varchar and nvarchar automatically. There is no long literal type per se, the corresponding character or binary type is assignable to a long type.

VARBINARY

- VARBINARY

This type is internally like VARCHAR but is distinct for compatibility with ODBC applications. A VARBINARY column is described as SQL_BINARY to ODBC clients. The storage requirement is the same as for a corresponding VARCHAR column.

VARBINARY and VARCHAR data are never equal even if the content is the same, but they can be cast to each other. VARBINARY data sorts in the unsigned order of the bytes comprising the data.

A varbinary literal is introduced by 0x followed by a hexadecimal representation of the bytes, 2 characters per byte, e.g. 0x0123456789abcdef.

TIMESTAMP; DATE & TIME

- TIMESTAMP
- DATETIME
- TIME
- DATE

All the time- and date-related types are internally represented as a single 'datetime' type consisting of a Julian day, hour, minute, second, 6-digit fraction and timezone. The range of the year is from 0 to over 9999. This type can accommodate all values of any SQL92 time-related type.

Although the internal representation is the same, a column of a time-related type is described as being of the appropriate ODBC type, i.e. SQL_TIMESTAMP for TIMESTAMP and DATETIME and SQL_DATE for DATE and SQL_TIME for TIME.

A DATETIME is described as precision 19, a DATE as precision 10 and a TIME as precision 8.

A column declared a TIMESTAMP is automatically set to the timestamp of the transaction that inserts or updates any column of the table containing it. The timestamp of a transaction is guaranteed to be distinct from that of any other transaction. For compatibility reasons a TIMESTAMP column is described to ODBC clients as a binary of 10 bytes. It is possible to use any date-related functions on TIMESTAMPs and to bind a TIMESTAMP column to a DATE or DATETIME variable (SQL_C_TIMESTAMP type in ODBC). Binding to a binary will also work but the data will then be opaque.

SQL92 provides for types with a timezone. Although the ODBC API does not expose the timezone, it is stored with these types and can be retrieved with the `timezone()` function. The timezone has a precision of minutes from UTC.

The storage requirement for these types is 10 bytes.

There is no date literal per se, but the ODBC shorthand for datetime literals can be used. The datetime/timestamp literal is of the form {dt 'YYYY-MM-DD HH:MM.SS'}. The date literal is of the form {d 'YYYY-MM-DD'}. Dates and datetimes may be compared between themselves but not with other types without explicit casting.

Timezoneless Datetimes

Some traditional relational databases keep all values of DATETIME type as combination of time and timezone data. Other keep time in some specific timezone without paying any attention to timezone at all. In RDF, the incoming triples may contain literals of types like xsd:dateTime with arbitrary values matching ISO 8601, and this standard permits the use of time values with optional timezone. Thus there should be a way of handling both "timezoned" and "timezoneless" datetimes inside one database. Virtuoso server supports this starting from version 07.20.3214.

Important note: The use of timezoneless datetimes may result in subtle errors in data processing. Applications that worked fine with timezoned datetimes may work incorrectly if timezoneless datetimes are used. The related application errors may stay unnoticed during local testing and reveal after worldwide use. To stay on safe side, the use of timezoneless datetimes with pre-07.20.3214 databases remains blocked even after the server executable is upgraded, so old applications will continue to work as before. When developing new applications, please pay attention to the check-list at the end of this section.

Enabling Timezoneless Support

Different applications may require different behavior when input data contain timezoneless values. In some cases it is better to "cast" all of them to timezoned than to upgrade existing code. Virtuoso offers 5 different modes of support. The mode is selected by `TimezonelessDatetimes` parameter in `[Parameters]` section of virtuoso.ini . This should be set before creating the database and the set value is stored in the database. After database is created, an attempt to change the mode by patching virtuoso.ini will have no effect and virtuoso.log will contain a warning about mismatch between virtuoso.ini and the database file.

The possible variants are:

- Never use timezoneless, as it was in old databases. Always set local timezone on parsing strings if no timezone specified. An attempt to set timezoneless by calling function `forget_timezone()` will signal error. Timezoneless values still may come from outside as dezerializations of timezoneless DATETIME values, serialized by other database instances, but not in any other way:

  ```
  TimezonelessDatetimes=0
  ```
- When parsing strings, set timezoneless if ISO format tells so:

  ```
  TimezonelessDatetimes=1
  ```
- Set timezoneless always, exception is when the parsed string contains explicit timezone or when RFC requires the use of GMT or when timezone is set by function `adjust_timezone()` . This is default for new databases if `TimezonelessDatetimes` parameter is missing in virtuoso.ini

  ```
  TimezonelessDatetimes=2
  ```
- Never use timezoneless. Always set local timezone on parsing strings if not timezone specified. An attempt to set timezoneless by calling function `forget_timezone()` will signal error. Timezoneless values still may come from outside as deserializations of timezoneless DATETIME values, serialized by other database instances, but not in any other way. The difference with `TimezonelessDatetimes=0` is that timezones are always printed on cast datetimes to strings etc. so timezoneless-aware clients will get unambiguous data.

  ```
  TimezonelessDatetimes=3
  ```
- On parsing string, set timezone to GMT if no timezone specified. However, timezoneless can be set by calling function `forget_timezone()` . This mode can be convenient for global web services when real "local" timezones of specific users are not known.

  ```
  TimezonelessDatetimes=4
  ```

For new applications, consider the use of `TimezonelessDatetimes=2` as primary variant, `TimezonelessDatetimes=1` as the second best.

Formats of Datetime Strings

Traditional SQL strings are of format "`YYYY-MM-DD hh:mm:ss` " with optional decimal fraction at the end and optional timezone data. Depending on software, the timezone can be specified as "timezone offset", i.e. the difference with GMT in minutes or as "timezone label", i.e. an identifier of timezone in special system dictionary that contains not only an offset in minutes but also information about daylight saving changes of the offset. Virtuoso does not support timezone labels, only numerical timezone offsets. Depending on system, the notation without the timezone data at the end means timezoneless value or, more probably, the value in some "default" timezone, such as local timezone of the server or GMT.

ISO 8601 introduced format "`YYYY-MM-DDThh:mm:ss` ", with "`T` " character between "`date` " and "`time` " parts. It also prescribed an unambiguous difference between timezoneless and timezoned values: absent timezone means timezoneless value.

The timezone offset is written as "`+hh:mm` " or "`-hh:mm` ", the "`+00:00` " is usually shortened to "`Z` ". Oracle Java may use 1 to 4 digits without delimiting ":", in that case 1 or 2 digits mean whole hours whereas 3 or 4 digits mean an 1 or 2 digits of hour and two digits of minutes. For historical reasons, "`-00:00` " notation differs from "`+00:00` " and mean timezoneless, not GMT datetime.

Comparison of Datetimes

ISO 8601 explicitly warns that comparison of timezoned and timezoneless datetime is not always possible. Valid timezones vary from -14:00 to +14:00, the fact that the span can exceed 24 hours may be not obvious. Nevertheless, storing rows in a database table require some unambiguous order; any order is OK as soon as it does not break the rules and common sense, but it should be well-defined. Virtuoso's order for mix of timezoned and timezoneless datetimes is very simple.

1. All timezoned datetimes are sorted in natural chronological order, like if they are converted to GMT first. The value of timezone offset does not matter.
2. All timezoneless datetimes are sorted in natural chronological order, like they are in GMT already.
3. For each GMT calendar day, all timezoned datetimes are placed before all timezoneless datetimes.

Related Functions

- `is_timezoneless()` -- The function returns 1 for timezoneless arguments, zero for timezoned.

```
integer is_timezoneless (in dt datetime)
```

- `timezone()` -- The function returns timezone offset of its first argument, as an integer value in minutes. If the first argument is timezoneless and second argument is missing or zero then the returned value is NULL. If the first argument is timezoneless and second argument is nonzero then the returned value is 0.

```
integer timezone (in dt datetime [, in ignore_tzl integer])
```

- `adjust_timezone()` -- The function returns its first argument with unchanged GMT value but new timezone offset, as it is specified by the second argument. If the first argument is timezoneless and third argument is missing or zero then error 22023 is signaled. If the first argument is timezoneless and third argument is nonzero then no error is signaled and the argument is handled like it is a GMT value.

```
datetime adjust_timezone (in dt datetime, in tz_offset integer [, in ignore_tzl integer])
```

- `dt_set_tz()` -- The function returns its first argument with unchanged GMT value but new timezone offset. Unlike `adjust_timezone()` , if the argument is timezoneless then no error is signaled.

```
datetime dt_set_tz (in dt datetime, in tz_offset integer)
```

- `forget_timezone()` -- The function returns its first argument as a timezoned value. If the first argument is timezoneless then it is returned unchanged. If the first argument is timezoned and second argument is missing or zero then the result is timezoneless value that "looks like" local time notation. If the first argument is timezoned and second argument is nonzero then the value is first made GMT and then it becomes timezoneless.

```
datetime forget_timezone (in dt datetime [, in ignore_timezone integer])
```

- `now()` -- returns the current transaction timestamp:

```
datetime now ()
```

- `rdf_now_impl()` -- returns the timestamp associated with current transaction as a DATETIME . Alias of `now()` :

```
datetime        rdf_now_impl ()
```

- `getdate()` -- returns the current transaction timestamp, alias of `now()` :

```
datetime getdate ();
```

- `get_timestamp()` -- returns the timestamp of the current transaction:

```
datetime get_timestamp ()
```

- `current_timestamp()` -- All these names refer to one function that returns the timestamp of current transaction. It is the datetime of the beginning of current transaction with the fractional part of seconds replaced with serial number of a transaction within the second. If `TimezonelessDatetimes=0` then the time has local timezone offset (as it was set at the time of last server start); otherwise it is timezoneless.

```
datetime current_timestamp ()
```

- `curdatetime()` -- The function returns current datetime, like `now()` , but fractional part of seconds can be adjusted by providing the number of "microseconds" as the argument.

```
datetime curdatetime ([in fraction_microseconds integer])
```

- `curdatetimeoffset()` -- The function is like `curdatetime()` but the returned datetime is in GMT timezone.

```
datetime curdatetimeoffset ([in fraction_microseconds integer])
```

- `curutcdatetime()` -- Refers to function that is similar to `curdatetime()` but the returned datetime is in GMT timezone.

```
datetime curutcdatetime ([in fraction_microseconds integer])
```

- `sysutcdatetime()` -- Refers to function that is similar to `curdatetime()` but the returned datetime is in GMT timezone.

```
datetime sysutcdatetime ([in fraction_microseconds integer])
```

Unicode Support

Virtuoso allows 30-bit Unicode data to be stored and retrieved from database fields. The data are stored internally as UTF-8 encoded strings for storage space optimization. Unicode fields are easily intermixable with other character data as all SQL

functions support wide-string case and convert to the most wide character representation on demand. The native width of the wide character type may differ between platforms. Windows has a 16 bit wide character, whereas some Unixes have a 32 bit wide character type. The native width applies to the Virtuoso NVARCHAR data type when used as SQL data.

There are 3 additional data types to enable storing of Unicode data:

- NCHAR
- NVARCHAR
- LONG NVARCHAR

All the Unicode types are equivalent to their corresponding "narrow" type - CHAR, VARCHAR and LONG VARCHAR - except that instead of storing data as one byte they allow Unicode characters. Their lengths are defined and returned in characters instead of bytes. They collate according to the active wide character collation, if any. By default this is the order of the Unicode serialization values. These types can be used anywhere the narrow character types can be used, except in LIKE conditions.

Unicode literals are introduced by n' and closed with ' (single quote). See Internationalization section on the interpretation of wide literals. This may be either UTF-8 according to some character set.

When there is a need to convert a wide string to a narrow one or vice versa, a character set is used. A character set returns a wide string code for a wide char. For example there can be a definition of the ISO-8859-5 "narrow" character set which describes mapping of non-ASCII character codes to their Unicode equivalents. Virtuoso relies on the fact that the ASCII character codes are represented in Unicode by type-casting and in UTF8 as one-byte tokens with the same value as in ASCII.

When conversion is done on the server-side using cast or some of the SQL built-in functions, the wide characters are converted to narrow using a system-independent server-side character set. In the absence of such a character set, Virtuoso uses the Latin1 character set to project narrow character codes into the Unicode space as equally valued wide-character codes.

When conversion is done client-side - for example, when binding a VARCHAR to a wide buffer - the default client's system character set is used.

Wide-character literals have ANSI SQL92 syntax: N'xxx' (prefixing normal literals with the letter N). These strings process escapes with a values large enough to represent all the Unicode characters.

User Defined Types

Virtuoso supports user-definable data types that can be based on any hosted language or classes such as C#. New types can be further derived producing sub-types. User-defined types can include methods and constructors to create any potentially complicated system to house data as exactly required.

User defined types can be used to defined database table columns.

See Also:

The User Defined Types section.

Built-in SQL Functions and Wide Characters

All the built-in SQL functions that take character attributes and have a character input calculate their output type such that if any attribute is a wide string or a wide BLOB, then the result is a wide string; otherwise, the output character type is narrow.

Functions like `make_string()` that have character result types but that do not have character parameters produce narrow strings. Virtuoso provides equivalent functions for wide output, such as `make_wstring()` .

Client-side changes to support wide characters

Virtuoso' ODBC client implements the SQL...W functions (like `SQLConnectW()`) that take Unicode arguments. This enables faster wide-character processing and allows binding of the SQL_C_WCHAR output type. Since Virtuoso's SQL parser does not allow Unicode data in SQL commands, they should be bound as parameters or should be represented as escapes.

Virtual Database and National Language Support

Attached tables use the default collation of the data source for narrow strings. Virtuoso maps Wide-string columns in remote tables to the appropriate local wide-character type. The data are then passed intact in case of wide-to-wide mapping. When data are converted client-side in the VDB the Server's system character set is used (where available).

Operations Between Large Objects, Varchars and String Outputs

The built-in data types denoting sequences of characters, wide or narrow, long or short, are:

Varchar : a string of 8-bit characters, including 0's, up to 16MB long. These are contiguously stored, so long contents, such as in the megabytes, will be inefficient.

NVARCHAR : A string of wide characters, of 2 or 4 bytes each, depending on the platform. Because of the 16MB limit, the longest strings will be of 4M or 8M characters, depending on the platform. Again long strings are not recommended due to inefficiencies.

Binary : A string of 8-bit bytes, up to 16 MB long, like a varchar but not usable for character functions. There is a distinct binary type only for compatibility with the SQL92 standard and ODBC, where the binary type is treated differently in parameter binding.

Long varchar, long nvarchar : These are long data types, stored persistently as a series of linked pages and accessible to clients in fragments using the `SQLGetData()` and `SQLPutData()` calls. The length limit is 2GB. The wide variant, LONG NVARCHAR, is internally stored as UTF8.

String_output : This is not a database column type but a run-time object that can be used in stored procedures for accumulating a long sequence of 8-bit bytes, including 0's. This type is not contiguously stored, hence it stays efficient for large output and has no built-in size limit; however, it is not automatically paged to disk, so it will consume virtual memory for all its length. This type is useful for buffering output for a next processing step.

Long varbinary : This is a binary BLOB, identical to long varchar but distinct for reasons of compatibility with SQL92 and ODBC, where this can behave differently from long varchar for parameter binding.

XML Entity : This type is a pointer to an element of an XML tree. The XML tree itself may be either memory- or disk-based. In both cases there is a reference-counted set of XML entities for each tree that Virtuoso uses to reference individual elements of the tree. These are used for navigating an XML tree in XPath or XSLT; hence, one entity gives access to it parents, siblings, and so on. This is not properly a string type, but it can be converted to one, producing the XML string value.

All these types have the common trait of representing sequences of characters and hence some common operations and conversions are possible between them.

Storage in Database

The descriptions below apply to insert and update operations for these types:

- Long varchar = x, where x is:

  varchar - The text is stored as is.

  Long varchar - the text is stored as is.

  string output - the contents in the string output are stored as the value, unchanged. The state of the string output is not changed.

  XML entity - The XML tree rooted at the entity is stored as persistent XML (disk-based) if the entity references a persistent XML tree. Note that this may either extract a subtree or copy a tree, depending on whether the entity references the root. If the entity references a memory-based tree, the text of the tree with the element as the topmost (document) element is produced and set as the value of the column.

  Nvarchar - The text is stored as wide, thus the value is internally a long nvarchar although the declared column type is long varchar.

  Long nvarchar - The value is stored as a long nvarchar, as with an nvarchar.
- Long nvarchar = x

  The cases are identical to long varchar. Thus a wide value stays wide and a narrow value stays narrow. Specifically, a string output and XML entity result in a narrow value, although the character combination in the XML entity may be interpreted as wide.
- Long varbinary = x

Identical to long varchar. The binary type is only distinct in column metadata for ODBC clients, where its type conversions may be different.

- Varchar = x, where x is:

  long varchar, string output, XML entity - as with long varchar.

  Nvarchar, Long nvarchar - the text is stored as wide; no information is lost.

- Nvarchar = x, where x is:

  Long varchar, varchar - the string is converted to wide according to the character set effective in the connection.

  Long nvarchar, Nvarchar - The text is stored as is.

'String output' and 'XML entity' are not valid types for a column. These types are only created by evaluating SQL expressions and are converted as specified above if stored as a column value.

Retrieving Column Values

A BLOB column (long varchar, long nvarchar, long varbinary) may return either a long varchar or a long nvarchar BLOB handle. If the actual value is short enough to be inlined, a varchar or nvarchar value can be returned as the column value instead. These are indistinguishable for assignment and as arguments to SQL functions or for returning to a client application. Only specific SQL functions (`isblob()` , `isstring()` , etc.) allow you to determine the difference at run time. One exception is persistent XML entities, which come back as persistent XML entities and are not compatible with string functions but are assignable to various character columns.

An nvarchar column is always nvarchar.

A varchar value is either varchar or nvarchar. If the value stored was a memory-based XML tree entity it comes back as a long varchar. If it was a persistent XML tree, it comes back as an XML entity.

Assignment

PL variables are typed at run time.

A string (varchar, nvarchar, or varbinary) can be freely assigned and passed as parameter. This makes a copy, except for reference (inout) parameters.

A BLOB (long varchar, long nvarchar, long varbinary) is a reference to a disk based structure, unless stored inline. Therefore, passing these as parameters does not take significant time. If these are inline, these are strings of under 4K bytes; hence assigning them is still efficient, although it involves copying.

A string output cannot be assigned between two variables, though it can be passed as a reference (inout) parameter in a PL procedure call. Copying streams has problematic semantics and can be very resource-consuming.

An XML entity can be assigned and passed as parameter without restrictions.

Built-In SQL Functions

All SQL92 string functions will accept varchar, long varchar, nvarchar or long nvarchar arguments. If the argument is long and its actual length is above the maximum length of a varchar, the conversion fails and Virtuoso signals an error. You can interchange long and varchar types as long as the length remains under the varchar maximum of 16MB.

Note:

Varchars or nvarchars stored in columns have a much lower limit due to the 4K row length limit. Intermediate results or values converted from long columns are not affected by this limit.

If Virtuoso converts a value from long varchar to varchar or from long nvarchar to nvarchar when passing the value as an argument to a string function, the value changes in place. This has the effect of replacing the handle with the string. Users normally do not see this, but may detect it with type test functions such as `isblob()` .

Long Strings and Row Length Limit

You can declare string values that might be long and that do not have to be key parts in indices as long varchar. These will automatically be inlined if the row with the data inlined will fit within the 4K limit. Otherwise the long values will be stored as separate LOBs. The difference between varchar and long varchar is distinguishable only with special test functions if the length is under the varchar limit.

A varchar column is sometimes substantially faster on update than a long varchar column, even if the value ends up inlined. If the value is inlined there is no difference in retrieval speed.

Handling Long Data for Input and Output

LOBs of up to 2GB can be handled as streams without demand on memory from ODBC clients using `SQLGetData()` and `SQLPutData()` . All other ways of processing long data will need to make either a contiguous or non-contiguous copy in memory.

To transfer long data between PL procedures and files one can use the `string_to_file()` function, which will accept a handle and will not need to copy the content to memory in order to write it.

To read a large object from a file to a table, you can use the `file_to_string_output()` function to get contents that may be longer than the varchar limit into a string output. This can then be assigned to a BLOB column.

For long file-resident XML data you can use the `xml_persistent()` function with the file:// protocol.

The XML Support chapter.

5.1.3. Virtuoso Column Store

Note: This feature only applies to Virtuoso 7.0 and later.

As of version 7, Virtuoso offers a column-wise compressed storage format alongside its traditional row-wise storage format.

In the column-wise storage model, each column of a table or index is stored contiguously, so that values of a single column on consecutive rows are physically adjacent. In this way, adjacent values are of the same type, and if the index is sorted on said value, the consecutive values often form an ascending sequence. This organization allows the use of more powerful compression techniques than could be used for rows where consecutive values belong to different columns, and thus are of disparate data types with values in different ranges.

Furthermore, when queries only access a subset of columns from one table, only those columns actually being accessed need to be read from disk, thereby making better use of I/O throughput and memory. Unreferenced columns will not take space in the memory based cache of the database. Further, the traffic between CPU cache and main memory is reduced when data is more compact, leading to better CPU utilization.

The column-wise format is substantially more compact and offers substantially greater sequential-access performance, as well as greater random-access performance in situations where many rows are accessed together in a join. For single-row random-access, a row-wise format offers higher performance as long as the data is in memory. In practice, for large tables, the higher compression achieved with column-wise storage allows a larger portion of the data to be kept in memory, leading to less frequent I/O and consequently higher performance.

One should not use column-wise storage in cases where columns are frequently updated, especially if a single row is updated per statement. This will give performance substantially worse than row-wise storage. However, bulk inserts and deletes are efficient with column-wise storage.

Creating Column Store Tables and Indices

Any index or primary key, i.e., any table, can be declared to be stored column-wise. A single table can have multiple indices, of which some are stored column-wise and some are not. As with tables stored row-wise, the table row itself is stored following the primary key index entry on the index tree leaf corresponding to the entry. This arrangement is sometimes called a *clustered index* .

One can specify column-wise storage as the default for any new tables or indices by adding ColumnStore = 1 to the [Parameters] section of the virtuoso.ini file. Otherwise, tables and indices are created tow-wise unless the column option is specified, as

described below.

The statement below declares the table xx to be stored column-wise:

```
CREATE TABLE xx ( id    INT,
                  data  VARCHAR,
                  PRIMARY KEY (id) COLUMN
                );
```

This statement adds a column-wise stored index to the table:

```
CREATE COLUMN INDEX xxi
  ON xx (data);
```

The *COLUMN* keyword can come after the column list of the primary key declaration of a table or anywhere between the *CREATE* and *INDEX* keywords of a create index statement.

Note that the *BITMAP* keyword cannot be used together with the *COLUMN* keyword. Column-wise indices will automatically use bitmap compression when appropriate without this being specified. A column-wise index is likely to be more space-efficient than a row-wise bitmap index with the same key parts.

The directives for column compression in *CREATE TABLE (NO COMPRESS, COMPRESS PREFIX)* have no effect on column-wise stored tables. Data is compressed in a manner chosen at run time based on the data itself.

Column Store Transaction Support

All SQL operations work identically for column- or row-wise tables and indices. The locking behavior is also identical, with row-level locking supported on all isolation levels. The behavior of the *READ COMMITTED* isolation is non-locking, showing the pre-image of updated data when reading pages with uncommitted inserts or updates.

Recovery is by roll forward, and checkpoints will only store committed states of the database, even if started when there are uncommitted transactions pending.

Column Space Utilization

The system table *DB.DBA.sys_col_info* holds information about space utilization of column-wise indices.

This table is updated only after the *DB.DBA.sys_index_space_stats* procedure view has been accessed. Thus, one must first make a selection from *DB.DBA.sys_index_space_stats* .

The columns of *sys_col_info* have the following meaning:

- *COI_TABLE*

  - The table in question.
- *COI_INDEX*

  - The index in question.
- *COI_NTH*

  - The ordinal position of the column in question in the key.
- *COI_TYPE*

  - This indicates the type of compression entry the rest of the row concerns. For each column in the key, there is a row with

  coi_type

  set to -1, representing the total of the remaining fields.
- *COI_COLUMN*

- The name of the column concerned.

- *COI_PAGES*

  - This is the number of database pages allocated for storing data of this column.

- *COI_CES*

  - The count of compression entries for the column. A compression entry is logically an array of consecutive values that share a common compression format. Different parts of the same column may have different compression.

- *COI_VALUES*

  - This is the count of values that are stored with the compression format in question.

- *COI_BYTES*

  - The is the number of bytes actually occupied by the compression entries concerned. Pages may not always by full, thus this metric can be used to measure the page fill ratio, i.e.:

```
100 * coi_bytes / (coi_n_pages * 8192.0)
```

To see which columns take the most space, and how full the pages are, as well as the overall effectiveness of compression, one can do:

```
SELECT                                      coi_column         ,
                        coi_pages * 8192  AS  total_bytes        ,
         coi_bytes / (coi_pages * 8192.0)  AS  page_fill          ,
                                           coi_bytes          ,
             1.0 * coi_bytes / coi_values  AS  ce_bytes_per_value ,
            8192.0 * coi_pages / coi_values  AS  bytes_per_value
    FROM sys_col_info
   WHERE coi_type = -1
ORDER BY coi_pages DESC ;
```

Note that issuing a query like:

```
 SELECT TOP 20 *
    FROM sys_index_space_stats
ORDER BY iss_pages DESC;
```

will update the *sys_col_info* table which is initially empty.

The *sys_index_space_stats* view shows the number of pages used for the sparse row-wise index tree top for column-wise indices.

The number of rows shown there for column-wise indices is the number of entries of the sparse index, not the row-count of the index. The space utilization here will be under 1% of the total for a column-wise index.

Below we look at space utilization of the *O* column of the primary key of the *RDF_QUAD* table.

```
SELECT *
  FROM sys_col_info
 WHERE  coi_index = 'DB.DBA.RDF_QUAD'
   AND coi_column = 'O' ;
 coi_table             coi_index           coi_nth           coi_type          coi_column    coi_pages
 VARCHAR NOT NULL      VARCHAR NOT NULL    INTEGER NOT NULL  INTEGER NOT NULL  VARCHAR       INTEGER
 ________________________________________________________________________________________________

 DB.DBA.RDF_QUAD       DB.DBA.RDF_QUAD     2                 -1                O             654663
 DB.DBA.RDF_QUAD       DB.DBA.RDF_QUAD     2                 1                 O             0
 DB.DBA.RDF_QUAD       DB.DBA.RDF_QUAD     2                 3                 O             0
 DB.DBA.RDF_QUAD       DB.DBA.RDF_QUAD     2                 4                 O             0
 DB.DBA.RDF_QUAD       DB.DBA.RDF_QUAD     2                 6                 O             0
 DB.DBA.RDF_QUAD       DB.DBA.RDF_QUAD     2                 8                 O             0
 DB.DBA.RDF_QUAD       DB.DBA.RDF_QUAD     2                 10                O             0
```

The top line is the overall summary across all the compression types.

The lines below give information per-compression-type. The values of *coi_type* mean the following:

- 1 -

  run length

  . The value occurs once, followed by the number of repetitions.
- 3 -

  array

  . Values are stored consecutively without compression. The array elements are 4- or 8-byte depending on range. For variable length types, some compression applies because values differing only in their last byte will only have the last byte stored.
- 4 -

  bitmap

  . For closely-spaced unique ascending values, the bitmap has a start value in full, and a bitmap with the nth bit set if start + nth occurs in the column.
- 6 -

  dictionary

  . For non-ordered, low-cardinality columns, there can be a dictionary with either 4 or 8 bytes per entry, depending on the number of distinct values being encoded. The compression entry is prefixed by an array with the values in full, followed by an array of positions in the dictionary.
- 8 -

  run length with small deltas

  . For repeating, closely-spaced ascending values, the run-length-delta format stores a start value in full, followed by an array of bytes of which 4 bits are a delta to the previous value, and 4 bits are a run length.
- 10 -

  integer delta with large deltas

  . This format stores an initial value followed by stretches of non-ordered values within 64K of the base value. There can be multiple such stretches, each prefixed with a 32-bit delta from the base value. This is useful for closely-spaced medium- cardinality values like dates, or for relatively sparse ascending sequences, e.g., ascending sequences with a step of 1000 or more.

5.1.4. Explicit Vectoring of Procedural Code

Note: This feature only applies to Virtuoso 7.0 and later.

Vectored execution can be explicitly controlled for Virtuoso PL code, either by declaring a whole procedure to be vectored or by executing a block inside a procedure on multiple values at one time. See more detailed description, respectively for:

- Vectored Procedures
- FOR VECTORED Statement
- Limitations on Vectored Code
- Data Types and Vectoring

5.1.5. Locking

Virtuoso offers a dynamic locking strategy that combines the high resolution of row-level locking with the performance of page locking for large transactions.

Isolation Levels

Virtuoso has a full range of isolation options, ranging from *dirty read* to *serializable*. The default isolation is *repeatable read*, which is adequate for most practical applications.

Isolation is set at the connection, i.e. transaction, level. Variously isolated transactions may coexist and each will behave consistently with its semantic.

Repeatable read and *serializable* transactions are susceptible at any time to termination by deadlock, SQL state 40001. Other transactions are susceptible to deadlock if they own locks as a result of insert, update or delete. Deadlocks are resolved in favor of the older of the contending transactions. A transaction's age is the count of reads performed + 2 * the count of rows inserted, deleted or updated.

Any transaction that has modified the database may be rolled back; all transactions maintain a rollback log. This is a memory-based data structure that contains the state of changed rows as they were before the transaction first affected them. This leads to potential transient memory consumption. All transactions that have changed the database also have a roll-forward log, used to recreate the effects of the transaction during roll-forward recovery.

Read Uncommitted

This corresponds to SQL_TXN_READ_UNCOMMITTED. A read is never prevented by locking, nor do read rows stay locked. The data being read may or may not be committed, hence there is no guarantee of transaction integrity.

Read Committed

Historical Read Committed

Starting with release 5.0, Virtuoso has a non-locking, versioned *read committed* transaction mode. This is similar to Oracle's default isolation.

If a locked row is read without FOR UPDATE being specified and another transaction owns the lock, the reading transaction will see the row in the state it had before being modified by the transaction owning the lock. There will be no wait. If a row has been inserted but the insert not committed, the row will not be seen by the *read committed* transaction. If a row has been updated or deleted, the row will be seen as it was before the uncommitted modifying transaction.

If a row is read in *read committed* mode with FOR UPDATE specified or as part of a searched update or delete statement, the *read committed* transaction will wait for a locked row and will set an exclusive lock on the row if the row matches the search criteria. This exclusive lock will be held until the *read committed* transaction terminates.

Hence, if FOR UPDATE is specified, a *read committed* transaction will have repeatable read semantics, otherwise it guarantees no repeatable read but does guarantee that uncommitted data are never seen.

To make this the default mode, set DefaultIsolation in the Parameters section of virtuoso.ini to 2.

Row-by-Row Autocommit

This transaction mode causes all DML statements to commit after every modified row. This is useful for single user situations where one does large batch updates on tables. For example, an update of every row of a multi gigabyte table would be likely to run out of rollback space before completing. In practice, one can end up in a thrashing situation where a large transaction is in progress, is interrupted by a checkpoint which must temporarily roll back the changed pages, then again resume the transaction etc., leading to serious server unavailability. Note that normally the ini parameter TransactionAfterImageLimit places a cap on transaction size, catching situations of this type before they lead to thrashing.

The row by row autocommit mode prevents this from happening by committing each updated, inserted or deleted row as soon as all the indices of the row are updated. This mode will still maintain basic row integrity, i.e. if the row's data is in one index, it will be in all indices.

This mode is good for any batch operations where concurrent updates are not expected or are not an issue. Examples include bulk loading of data, materialization of RDF inferred data etc.

This mode is enabled with the log_enable function. If the bit of 2's is set in the argument, row-by-row autocommit is enabled and the setting will persist until modified with log_enable or the calling connection is disconnected or the calling web request

terminates. Thus, an argument of 2 enables row-by-row autocommit and disables logging. An argument of 3 enables row-by-row autocommit and enables logging. This will cause every updated row to be logged in the transaction log after it is updated, which is not very efficient.

Since transaction-by-transaction recovery is generally not an issue in batch updates, a value of 2 is usually better. If the server is killed during the batch operation, it may simply be restarted and the operation redone. Losing the first half through no logging will not be an issue since the operation will anyway have to be redone.

There is a slight penalty to row-by-row autocommit in comparison with making updates in larger batches but this is under 10%.

Repeatable Read

The transaction will wait for access to exclusively locked rows and will lock all rows it reads. The locking of read rows can be shared or exclusive depending on the FOR UPDATE clause in the SELECT or the SQL_CONCURRENCY statement option. In the case of a select over a range of rows where not all rows match selecting criteria, only matching rows are locked. This mode guarantees that any row locked by the reading transaction can be re-read on the basis of its identity (primary key) and will not have been changed by any other transaction while the locking transaction is in progress. This mode does not prevent another transaction from inserting new rows (phantoms) between rows locked by the original transaction.

Serializable

This mode guarantees that concurrent transactions will look as if the next transaction started only after the previous terminated. This is like `repeatable read` but prevents phantoms. Space found to be empty in one read will remain empty in the next read while the transaction is ongoing.

Serializable isolation is implemented by locking all ranges of rows matching criteria pertaining to the ordering index in a select. The range here includes the last row before the first in the range. An empty range can be locked by locking the row before the range by a special follow lock, which prevents insertions to the right of the locked row. A by-product of this is that serializable locking guarantees that a select count will give the same result repeatedly unless the transaction itself affect the rows counted.

`Serializable` isolation is slower than `repeatable read` and not required by most applications.

All insert, delete and update operations make an exclusive row lock on the rows they operate on, regardless of specified isolation.

Lock Extent

If a transaction is the exclusive owner of locks on a database page and a sufficient percentage of the rows are locked, it makes sense to replace distinct row locks with a single page lock. The LOCK_ESCALATION_PCT parameter controls the threshold for doing this. See the SET statement for details.

If a cursor reads data serially and has a history of locking a high percentage of rows on each page it traverses, it will start setting page level locks as its first choice. It will do this when entering a new page where there are no row-level locks.

Transaction Size

There is no limit in Virtuoso to the transaction size, though the underlying software or hardware may impose limits. Memory consumed by a transaction is proportional to its number of locks held and number of changed rows (insert, update, delete). BKLOBs manipulated by a transaction do not contribute to memory consumption, because they are always disk-based.

5.1.6. Internationalization & Unicode

National strings are best represented as Unicode (NCHAR/LONG NVARCHAR) columns. There is no guarantee that values stored inside narrow (VARCHAR/LONG VARCHAR) columns will get correctly represented. If the client application is also Unicode then no internationalization conversions take place. Unfortunately, most current applications still use narrow characters.

The national character set defines how strings will get converted from narrow to wide characters and back throughout Virtuoso. A character set is an array of 255 (without the zero) Unicode codes describing the location of each character from the narrow character set in the Unicode space. It has a "primary" or "preferred" name and a list of aliases.

Character sets in Virtuoso are kept inside the system table SYS_CHARSETS. Its layout is :

```
CREATE TABLE SYS_CHARSETS (
    CS_NAME varchar,                    -- The "preferred" charset name
    CS_TABLE long nvarchar,             -- the mapping table of length 255 Wide chars
    CS_ALIASES long varchar             -- serialized vector of aliases
);
```

The CS_NAME and CS_ALIASES columns are SELECTable by PUBLIC. To simplify retrieval of all official and unofficial names of character sets, Virtuoso provides the following function:

`charsets_list()`

There are a number of character set definitions preloaded in the SYS_CHARSETS table. Currently these are:

GOST19768-87

IBM437, IBM850, IBM855, IBM866, IBM874

ISO-8859-1, ISO-8859-2, ISO-8859-3, ISO-8859-4, ISO-8859-5, ISO-8859-6, ISO-8859-7, ISO-8859-8, ISO-8859-9, ISO-8859-10, ISO-8859-11, ISO-8859-13, ISO-8859-14, ISO-8859-15

KOI-0, KOI-7, KOI8-A, KOI8-B, KOI8-E, KOI8-F, KOI8-R, KOI8-U

MAC-UKRAINIAN

MIK

WINDOWS-1250, WINDOWS-1251, WINDOWS-1252, WINDOWS-1257

New character sets can be defined using the following function:

`charset_define()`

User-defined character sets can be dropped by deleting the row from the SYS_CHARSETS table and restarting the server.

Virtuoso performs all translations in accordance with a "current charset". This is a connection attribute. It gets its value as follows:

1. If the client supplies a CHARSET ODBC Connect string attribute either from the DSN definition or as an argument to a `SQLDriverConnect()` call, Virtuoso searches for the name in SYS_CHARSETS and, if there is a match, that character set becomes the default.
2. If the database default character set ('Charset' parameter in the 'Parameters' section of virtuoso.ini) is defined, it becomes the default.
3. If neither of these conditions is met, then Virtuoso uses ISO-8859-1 as the default character set; this maps the narrow chars as wide using equality.

At any time the user can explicitly set the character set either with a call to

```
SQLSetConnectAttr (HDBC, SQL_CHARSET (=5002), CharacterSetString, StringLength)
```

or by executing the interactive SQL command:

```
SET CHARSET='<name>|<alias>'
```

The current character set "preferred" name (as a string) is returned by the following system function:

`current_charset()`

Virtuoso has a default character set that gets used if the client does not supply its own and in some special cases, like XML Views and FOR XML AUTO statements.

The HTTP character set can be changed during an HTTP session using:

```
SET HTTP_CHARSET='<name>|<alias>'
```

Example:

```
<?vsp
    set http_charset = 'ISO-CELTIC';
?>
<html><body><h1>Cén chaoi 'bhfuil tú?</h1></body></htm
```

Virtuoso supports the following types of translations from Unicode characters to narrow characters:

- String translation:

  If the Unicode represents a part of the US-ASCII (0-127) character set then its value gets used;
  If the Unicode has a mapping to narrow in the character set then use it;
  If neither of the above then the narrow '?' is returned.
- Command translation:

  If the Unicode represents a part of the US-ASCII (0-127) character set then its value gets used;
  If the Unicode has a mapping to narrow in the character set then use it;
  If neither of the above then the Unicode gets escaped using the form \xNNNN (hexadecimal).
- HTTP/XML translation:

  If the Unicode represents a part of the US-ASCII (0-127) character set then its value gets used after replacing the special symbols (<, >, & etc.) with their entity references;
  If the Unicode has a mapping to narrow in the character set then use it. The narrow char is then checked to see if needs to be escaped;
  If none of the above then the Unicode gets escaped using the form &#DDDDDD; (decimal)

Character Set Use in ODBC/UDBC/CLI Clients

This section describes where a translation is done in the case of an ODBC/UDBC/CLI client. These are described as solution because the Virtuoso CLI is the same as the ODBC/UDBC interface.

For the functions `SQLPrepareW()` , `SQLExecDirectW()` , and `SQLNativeSQLW()` any Unicode arguments will become narrow strings by using the command translation described above.

When doing the bindings

```
SQL_C_WCHAR -> SQL_xxx
```

and

```
SQL_Nxxx -> SQL_C_xxx (except SQL_C_WCHAR)
```

Virtuoso converts Unicode strings to narrow strings using the string translation described above.

Character Set Use in the ODBC/UDBC/CLI Server

The server uses the character set in the CAST operator when converting NCHAR/LONG NVARCHAR to any other type.

Character Set Use in the HTTP Server

The HTTP server appends a

```
charset=xxxx
```

attribute to the

```
Content-Type:
```

HTTP header field when returning the HTTP header to the client. This can be overridden by calling functions such as `http_header()` .

The HTTP server uses the character set mainly to format correctly values using the `http_value()` function or its VSP equivalent <?= ...>. In these cases wide values and XML entities - the result of XML processing function like `xpath_contains()` - get represented using the HTTP/XML translation rules described above. The same rules apply for

results returned by the FOR XML directive, by XML Views, and for WebDAV content.

Character Set Use in the XML Processor

The Virtuoso embedded XML parser correctly processes all encodings defined in the SYS_CHARSETS table and UTF8.

Generation of SQL

The `xpath()` and `xpath_contains()` functions translate their expressions as follows:

Input Processing

Narrow strings are these get translated to Unicode as per the character set and then to UTF-8, which is the internal encoding used by the Virtuoso XML tools.

SQL Views and FOR XML directives take their values from narrow columns by firstly converting them to Unicode based on the database character set and then to UTF-8.

Output Processing

Almost all the XML processors and generators return their values as type DV_XML_ENTITY (__tag() 230). If such a value's character representation is requested either by CAST or by `http_value()` then Virtuoso converts it to narrow characters using the HTTP/XML translation rules given above.

XPath expressions that return string values are returned as NCHAR values to the clients, which then convert them to narrow character if needed.

5.1.7. Creating A Collation

Virtuoso supports collation orders for CHAR and VARCHAR fields that are different from the binary, as per ANSI SQL92. When comparing strings using a collation, Virtuoso compares the "weights" of the characters instead of their codes. This allows programs to make different characters compare as equal (example: case-insensitive comparisons).

A collation can be created by supplying a collation definition text file to the `collation_define()` SQL function. The collation definition file contains a list of the exceptions to the binary collation order. An exception consists of <character code> = <collation weight> pairs. For example a case-insensitive collation can be defined by specifying all the lower case letters to have the same collation weights as the corresponding uppercase ones.

Collation Definition File

The collation definition file should follow the following guidelines:

- Each definition should reside on a separate line.
- The format of the definition is: <CHAR>=<CODE>, where *CHAR* and *CODE* can be either the letters themselves, or their decimal codes. For example: '67=68' is the same as 'C=D' using the ASCII character set. For Unicode collations the codes can exceed the byte boundary.

You can define a new collation using the following function:

```
collation_define ( COLLATION_NAME FILE_PATH ADD_TYPE )
```

Collations System Table

The SYS_COLLATIONS system table holds the data for all defined collations. It has the following structure:

```
CREATE TABLE SYS_COLLATIONS (
    COLL_NAME VARCHAR,
    COLL_TABLE LONG VARBINARY,
    COLL_IS_WIDE INTEGER);
```

COLL_NAME is the fully qualified name of the collation - its identifier.

COLL_TABLE holds the collation table itself. This is 256 bytes or 65536 wide chars.

COLL_IS_WIDE holds the collation's type: 0 for CHAR and 1 for NCHAR. An 8-bit collation cannot be used by anything that requires NCHAR data and vice versa.

A collation can be deleted by deleting its row from SYS_COLLATIONS.

Note

The collation will still be available until the server is restarted, as it's definition is cached in memory.

Collations and Column Data

The collation is a property of the column holding the data. This means that all comparisons including that column will use its collation. SQL functions will strip collation data from the column; for example, if a column "CompanyName" has an assigned collation "Spanish" then the SQL call

```
LEFT (CompanyName, 10);
```

will use the default collation).

Collations can be defined on a per-column basis, at table creation time, and on a per-database basis as a configuration parameter. There is a special form of the CAST operator that allows casting a column to a collation.

A collation identifier has the same form as any other SQL identifier (<qualifier>.<owner>.<name>) and it can be escaped with the same syntax as other identifiers.

Defining a Collation for a Table Column

You may assign a collation to a column at table creation using the following syntax:

```
create table TABLE_NAME (
...
COLLATED   VARCHAR(50) COLLATE Spanish,
COLLATED   CHAR(20) COLLATE DB.DBA.Spanish,
....
)
```

Assigning a collation to a non-character column gives an error.

If the COLLATE is omitted, the default database collation is used.

On database start-up the collation for each table's column is loaded from the SYS_COLLATIONS table and if not found, the COLLATE attribute is ignored until the next restart.

Defining Database-Wide Collations

The database's default collation is defined by the configuration parameter "Collation" in the "Parameters" section of the virtuoso.ini file. This database wide collation is the default system collation used where none other is specified. This setting can only be changed in the virtuoso.ini file and hence requires a Virtuoso server restart. As with all collations, legal values are those contained in the DB.DBA.SYS_COLLATIONS table. The list can be retrieved using `charsets_list(1)`

5.2. Virtual Database (VDB) Engine

- The Need for VDB Engines
- First Generation Virtual Database Products
- VDB Implementation Issues
- VDB Engine Components

5.3. Web & Internet Protocol Support

Virtuoso provides direct access to a number of Internet protocols through built in procedures. These protocols include SMTP, NNTP, POP3, HTTP, XML and many more. Combined with Virtuoso's native database and virtual database capabilities applications can be developed very rapidly from scratch or existing systems can be enhanced with a rich set of tools. An old customer table can be used to create a mail shot; a products table can now generate an XML file which can be converted to plain

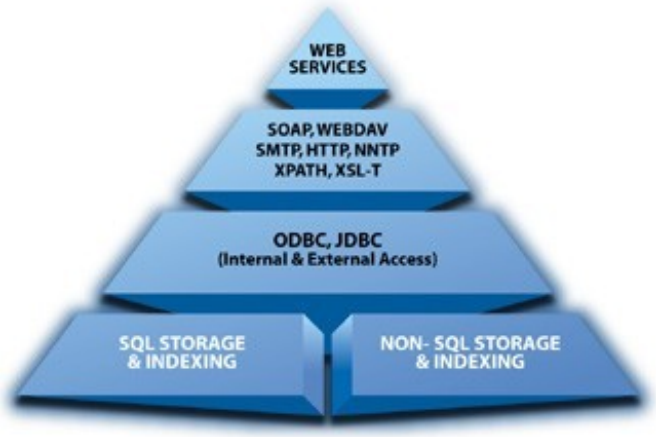
text and or HTML via XSLT which can be emailed to the customers every week automatically using the scheduler, or on request from a VSP page served by the HTTP server. The possibilities are endless and all these abilities are contained within a single server.

5.4. Web Services Protocol Support

The Internet is reaching a stage where automatic processes want to rely on other sites and services presenting their uses in a standard way. This is Web Services. What ever an organization or repository of data contains the it needs to be exploited as fully as possibly. This is exposing existing systems as Web Services. These need to be accessible over well known protocols which combine to provide a service over the web.

SQL provides the means to query data within a database. This is a very well known and supported operation. The query may or may not be able to make use of free text indexes to obtain results faster and more accurately from textual sources. The source could even come from a remote database contacted over ODBC, JDBC or OLEDB - more well supported standards. The results may be shipped to another server for further processing. Further processing could include transformations into various XML's directly or via an XSLT stylesheet. This collaboration of services can be enhanced further with other Web and Internet protocols for the grand objective of making parts of useful information or ability consumable over the Internet as a Web Service.

Figure 5.1. Towards Web Services...



5.5. Architecture

The base of Virtuoso is the Virtuoso Data Management. This handles the normal tasks of the database and virtual database collaborating between local native and remote SQL and XML based resources. Web and Internet services and protocols then sit atop of this layer to expose Virtuoso to the Web and its users.

Chapter 6. Administration

6.1. Database Server Administration

Abstract

This section explains the use of the server executables, configuration files and general administration procedures. These include backup, server tuning and profiling, installing extension packages etc. See the Access Interfaces chapter for a discussion of the command line SQL interface.

6.1.1. Database

See details for Installation Requirements , Operational Requirements , Operating System Support and Limits .

Server Instance Creation

Multiple Virtuoso server instances may coexist on a single machine. Each database will need to be assigned a unique TCP port number. On the windows platforms (except 95,98,ME) the Virtuoso can be configured for multiple services. For further details,

see the Creating and Deleting Virtuoso Services in the Installation chapter.

To run Virtuoso on a machine, only the Virtuoso server executable and a valid virtuoso.ini file are needed. An empty database file will be created automatically at first startup. None of the other files in the installation are needed for basic operation. Client interfaces may additionally need ODBC drivers or the like to be set up in system configuration files or the Windows registry but the server itself does not depend on these.

Installing Application Packages

Virtuoso comes with optionally installable SQL application packages (VAD packages) for web based admin, on-line documentation, programming tutorials and a BPEL processor. The installer typically asks whether to install these into the demo or the default empty database. Depending on the OS and form of installer, also depending on whether the installation is the commercial or open source one, the package files will be in different locations. To locate them, look for *.vad. The packages are typically made in two variants, where one keeps the installed items in the DAV repository and the other in the file system. They are functionally equivalent in most cases, except for some tutorials that will only work in the file system. Keeping installed resources in DAV has advantages when moving the database or backing up, since the installed items will not have to be treated separately. To install these on a database, login as dba using the isql utility and issue the SQL command:

```
# at the OS command line prompt, assuming the dba password is dba and the server is at the default port 1

$ isql 1111 dba dba

--  At the SQL prompt:
SQL> vad_install ('conductor_dav.vad', 0);
-- The path is relative to the server's working directory.
```

Since the packages are read from and sometimes the extracted contents are written to the file system, the server must have access to the directories in question. Checjk OS permissions and set the DirsAllowed parameter in the ini file to allow the needed access.

After the packages are installed, they can be used by pointing the web browser to their start page. The start pages are listed on the root page of the demo database and at the Getting Started section of the Open Virtuoso web site. The start page for the Conductor web admin interface is /conductor, the docs are at /doc/html, the tutorials at /tutorial, the BPEL admin and demos at /BPELGUI. All these are directly under the default Virtuoso web listener, the port is shown in the messages log and read from the HTTP Server section of the virtuoso.ini file.

Server Licensing

The Virtuoso server requires a valid license file before it will successfully start. The license file is a file always called *virtuoso.lic* and must reside in the working directory of the database instance - where the <database-name>.db file resides for the instance.

Evaluations versions of Virtuoso come without a license file, however the registration procedure takes your email address, which will be used to email a new license file for you evaluation.

Server Logging - Detecting Errors

Virtuoso provides extensive log information for resolving problems. Should any problems arise Virtuoso logs should always be consulted.

The Virtuoso server by default will send log information to two places, the appropriate system log for the operating system and the virtuoso.log file. On Unix based operating systems, including Linux, this information will appear in the system log files. On Windows the Virtuoso log information will appear in the Application Event Log.

Virtuoso logs information in the system logs before the Virtuoso.log file is open. This advantageously will log errors that cannot be placed in the virtuoso.log file, such as when the virtuoso.ini file cannot be located during Virtuoso startup.

The system log feature can be disabled using the "Syslog" parameter in the [Database] section. This is described in more detail in the following section.

Configuring Server Startup Files

Virtuoso Configuration File

The virtuoso.ini file is read from the directory that is current at server startup. This file contains an entry for all user settable options in the server. It is divided into the following sections:

- [Database] Location of database files
- [Parameters] Server tuning, options
- [HTTPServer] Settings in this section control the web server component of the Virtuoso Server.
- [URIQA] Settings in this optional section control URIQA semantic web enabler.
- [Flags] Settings for options that are generally used with `__dbf_set` as temporally valid (such as enable_joins_only), to be set as permanent.
- [SPARQL] Settings in this optional section control SPARQL protocol endpoint default parameters and limits.
- [I18N] encoding settings
- [Replication] The replication section sets the transactional replication parameters for the server.
- [Mono] The Mono section contains settings for Virtuoso with Mono Runtime CLR support.
- [Client] Client default settings
- [AutoRepair] Corrupted database recovery
- [Striping] Multi-file / multi-disk databases
- [VDB] Virtual database functionality related options
- [Ucms] location of UCM files describing multi-byte encodings such as Far East languages
- [Zero Config] ZeroConfig related options
- [Plugins] VSEI plugin modules

Below are the descriptions for each parameter

[Database]

- **DatabaseFile=virtuoso.db.** For a single file database, this is the relative path of the file in the format appropriate to the platform. The path is resolved relative to the directory that is current at server startup. All other paths are interpreted similarly.
- **TransactionFile=virtuoso.trx.** This is the transaction log file. If this parameter is omitted, which should never be the case in practice, the database will run without log, meaning that it cannot recover transactions committed since last checkpoint if it should abnormally terminate. There is always a single log file for one server. The file grows as transactions get committed until a checkpoint is reached at which time the transactions are applied to the database file and the trx file is reclaimed, unless CheckpointAuditTrail is enabled.
- **ErrorLogFile=virtuoso.log.** This file logs database error messages, e.g. 'out of disk'. By viewing this the dba can trace problems and see at which times the server has started, checkpoints have been made, etc.
- **ErrorLogLevel=7.** This controls what events get logged into the database error log. This should always be 7.
- **LockFile=virtuoso.lck.** This optional parameter can be used to manually specify the location of the Virtuoso lock (.lck) file. This can be relative or the full path to the lock file. Virtuoso, by default, creates a file with the same name as the DatabaseFile but with the extension of .lck. This file exists when the Virtuoso server is running to prevent it starting multiple times using the same parameters, and should be automatically removed by the server upon exit. However, not all file systems support file locking, such as NFS, therefore this parameter can be set to keep the lock file on a more appropriate file system.
- **FileExtend=100.** This is the size that the database file automatically grows (in 8k pages) when the current file is not large enough. Default = minimum = 100. The parameter has no effect if striping is set.
- **Striping=0.** A non-zero value will enable the settings in [Striping] to take effect. If this is the case the DatabaseFile parameter is ignored and the files in [striping] are used.
- **LogSegments.** If this is non-zero log segmentation is enabled. This is only used for crash dumps where several files may be needed to accommodate the recovery logs. If non-zero, this will be followed by entries of the form Log1=...
- **Log1=/tmp/log1.trx 100M.** The number in Log<n> is the ordinal number of the log, starting at 1. The entry consists of the file name and allocated size with an optional size modifier. Available modifiers are B for blocks of 4k (default if unspecified, K for kilobytes, M for megabytes, and G for gigabytes. The log is filled up to the first transaction that exceeds the size. The log therefore will be longer than the allocated size. If blobs are involved, this amount can be quite substantial. It is therefore advisable to have some extra space available on the storage device used for recovery logs.
- **crashdump_start_dp, crashdump_end_dp.** These options make it possible to produce a crash dump of a specified range of disk pages. In case the server runs out of disk space during a dump, the error message indicates the page at which the next dump should be started after the user has made more space available. In this case it is important to rename the already produced crash dump or change the Logx= -entries in virtuoso.ini to avoid overwriting said files. If none of

these options are provided, the server will attempt a crash dump of the entire database storage.

- **TempStorage = <TempDatabase_Name>.** The name of a section in the INI file containing temporary database details. If this parameter is omitted or the section does not exist the default values for temporary storage are used.
- **Syslog = 1/0 (default 0).** Virtuoso can writes log worthy messages to the system log (Unix based operating systems including Linux) or the Windows Event Log (Windows operating systems). Messages are written in the system/event log before the virtuoso.log file is opened, therefore errors due to absence of virtuoso.ini log are loggable there. This system/event logging can be enabled using this option, by default it is set to 0 meaning off.

  On Unix/Linux messages are written as "Virtuoso" events.

  On Windows messages are written in the Application event log.

[<TempDatabase_Name>]

This section name must match the TempStorage parameter in the Database section of the Virtuoso INI file to be of any use. Otherwise this section will be ignored.

- **DatabaseFile = <database file name>.tdb.** Name of temporary database file.
- **TransactionFile = <transaction file name>.ttr.** Name of temporary transaction file.
- **FileExtend = NNN.** Increment amount by which the database file will dynamically grow. This setting is identical in use and purpose to parameter in the Database section with the same name.

[Parameters]

- **SingleCPU=0.** This is a Win32 specific option that forces Virtuoso to only run on one CPU in a multiprocessor environment.
- **ServerPort=[<IP Address>]:<port>.** This is the IP Address and port number where the server will start listening. You do not need to specify the listening IP Address but can do in a situation that you want the server to bind to a specific address only.
- **ServerThreads=10.** This is the maximum number of threads used in the server. This should be close to the number of concurrent connections if heavy usage is expected. Different systems have different limitations on threads per process but a value of 100 should work in most places.
- **ServerThreadSize=50000.** Stack size of thread used for reading client messages and accepting connections.(default : 50 000 bytes)
- **MainThreadSize=100000.** Stack size of the main thread (default : 100 000 bytes)
- **ThreadCleanupInterval.** The interval in minutes (default : 0) after which threads in the thread pool should be released.
- **ThreadThreshold.** The maximum number of threads (default : 10) to leave in the thread queue after thread clean-up interval has expired.
- **SchedulerInterval.** Defines the scheduler wake-up interval (in minutes). By default is 0 i.e. the scheduler is disabled.
- **ResourcesCleanupInterval.** The interval in minutes (default : 0) after which allocated resources will be flushed..
- **FutureThreadSize=100000.** Stack size of worker threads. This is the stack size for serving any client SQL statements or HTTP requests. This can be increased if the application uses recursive stored procedures or links in external code needing a large stack. (default 100 000 bytes)
- **TempAllocationPct.** A Percentage that may be greater than 100%. This gives a percentage of the main .db file to which the temp db file may grow before starting to reclaim the oldest persistent hash index. Basically if a particular hash index is reusable (i.e. it references only table columns and the values in these columns have not changed) the engine keeps the hash index defined into the temp db for reuse. This parameter allows some control over the temp db file size.
- **O_DIRECT.** If this is non-zero, the database file(s) will be opened with the O_DIRECT option on platforms where this is supported. This has the effect of doing file system I/O from application buffers directly, bypassing caching by the operating system. This may be useful if a large fraction of RAM is configured as database buffers. If this is on, the file system cache will not grow at the expense of the database process, for example it is less likely to swap out memory that Virtuoso uses for its own database buffers. Mileage will vary according to operating system and version. For large databases where most of system memory is used for database buffers it is advisable to try this.
- **CheckpointInterval=60.** This is the interval in minutes at which Virtuoso will automatically make a database checkpoint. The automatic checkpoint will not be made if there is less than MinAutoCheckpointSize bytes in the current transaction log. A checkpoint interval of 0 means that no periodic automatic checkpoints are made.

  Setting the value to -1 disables also the checkpoints made after a roll forward upon database startup. This setting should be used when backing up the database file(s). This guarantees that even if the server dies and restarts during the copy, no checkpoints that would change these files will take place and thus the backup is clean.

  the checkpoint_interval SQL function may be used to change the checkpoint interval value while the database is running.

- **CheckpointSyncMode=2.** This controls how the file system is synchronized after a checkpoint. Once the checkpoint has issued all write system calls it needs it can do one of the following depending on this setting:

  0. - Continue, leave the OS to flush buffers when it will.

  1. - Initiate the flush but do not wait for it to complete.

  2. - Block until the OS has flushed all writes pertaining to any of the database files.
- **PageMapCheck=0.** This controls the check of page maps:

  0. - disables the check of page maps.

  1. - enables the check of page maps.
- **NumberOfBuffers=2000.** This controls the amount of RAM used by Virtuoso to cache database files. This has a critical performance impact and thus the value should be fairly high for large databases. Exceeding physical memory in this setting will have a significant negative impact. For a database-only server about 65% of available RAM could be configured for database buffers.

  Each buffer caches one 8K page of data and occupies approximately 8700 bytes of memory.
- **MaxCheckpointRemap=2000.** Specifies how many pages Virtuoso is allowed to remap. Remapping means that pages can consume the space of two actual pages until checkpoint. See the Checkpoint & Page Remapping section in the SQL Reference chapter for more information.
- **PrefixResultNames=0.** This setting should always be 0.
- **CaseMode=1.** This controls the case sensitivity of the Virtuoso SQL interpreter. The following values are supported:

  - 0 - SQL is case sensitive and identifiers are stored in the case they are entered in. This is similar to the Progress or Informix default.
  - 1 - SQL is case sensitive and Unquoted identifiers are converted to upper case when read. To use non-upper case identifiers, the identifiers must be quoted with double quotes ("). This is similar to Oracle.
  - 2 - SQL is case-insensitive and identifiers are stored in the case where first seen. Unlike the situation in other modes, two identifiers differing only in case cannot exist. This is similar to the MS SQL Server 7 default behavior.

  

  Note:

  Once a database is created in one case mode the case mode should not be changed as that may change the interpretation of stored procedures etc.
- **MinAutoCheckpointSize=4000000.** See CheckpointInterval.
- **AutoCheckpointLogSize.** This is the size of transaction log in bytes after which an automatic checkpoint is initiated. If this is non-zero, whenever the transaction log size exceeds this size an automatic checkpoint is started. This will result in approximately like sized logs to be generated. This is useful with the CheckpointAuditTrail option for generating a trail of equal sized consecutive logs.
- **CheckpointAuditTrail=1.** If this is non-zero each checkpoint will start a new log and leave the old transaction log untouched. A 0 value indicates that the transaction log may be reused once the transactions in it have been written in a checkpoint.

  If it is important to keep an audit trail of all transactions in the database's life time then this option should be true. A new log file will be generated in the old log file's directory with a name ending with the date and time of the new log file's creation. Old log files can be manually copied into backup storage or deleted. Only one log file is active at one time. The newest log file may at any time be written to by the server, but that is the only log file Virtuoso has open at each time. Thus reading any logs is safe. Writing or deleting the active log file will result in loss of data, and possibly referential integrity, in the database. See the Back and Recovery chapter for more information on this and related parameters.
- **AllowOSCalls=0.** If non-zero the system SQL function is enabled. This will allow a dba group user to run shell commands through SQL. This poses a potential security risk and hence the setting should normally be 0.
- **MaxStaticCursorRows=5000.** This is the maximum number of rows returned by a static cursor. Default = 5000
- **FreeTextBatchSize=10000000.** This is the amount of text data processed in one batch of the free-text index when doing a batch update or non-incrementally reindexing the data. Default : 10,000,000
- **NullUnspecifiedParams.** When set to 1, if an application prepares a statement with insufficient number of input parameters, the unspecified ones are assumed to be NULL.
- **Collation.** Defines a sorting order according to SYS_COLLATIONS. The name supplied to this parameter must be in `charsets_list(1)`.

- **DirsAllowed=<path> [, <path>].** <path> := <absolute_path> or <relative_path> comma-delimited list of OS directories allowed for file operations such as `file_to_string()` . The server base directory (the directory containing this INI file) must appear in this list to enable File DSNs to work. On Windows, use "\" as the path separator; on Unix-like OS including Linux and macOS 10.x and later, use ":". The Virtuoso ISQL utility can be used to check the Server DirsAllowed params as described below. The following should show the server's working directory and INI file name in the result.

  ```
  SQL> select server_root (), virtuoso_ini_path ();
  ```

  You can also check the relevant INI setting by running the following statement:

  ```
  SQL> select cfg_item_value (virtuoso_ini_path (), 'Parameters',
  'DirsAllowed');
  ```
- **DirsDenied=<path> [, <path>].** <path> := <absolute_path> or <relative_path> OS directories denied for file operations. See Virtuoso ACL's for information on functions that are restricted.
- **VADInstallDir=<path>.** <path> := <absolute_path> or <relative_path> OS directory containig VADs files. When set, enables automatic update of vads on server startup. On Windows use in the path "\".
- **SSLServerPort.** Specifies the port on which the server listens for incoming SSL CLI requests.
- **SSLCertificate.** The SSL certificate to use (same meaning as the SSLCertificate in HTTPServer section)
- **SSLPrivateKey.** The server's private key (same meaning as the SSLCertificate in HTTPServer section)
- **MaxOptimizeLayouts = 1000.** This parameter governs the maximum number of partial or full join orders that the Virtuoso SQL Optimized compiler will calculate per select statement. When MaxOptimizeLayouts has been reached, the best execution plan reached thus far will be used. The default value is 1000, specifying 0 will try all possible orders and guarantee that the best plan is reached.
- **StopCompilerWhenXOverRunTime = 0.** The default value is 0. If non-zero, this specifies that the SQL compiler should stop considering alternative execution plans after the elapsed compilation time exceeds the best run time estimate times the parameter. For example, if this is 2, then compilation stops after using twice the time of the best plan reached thus far. Enabling this option increases performance when processing short running queries that are each executed once. Using this with long running queries or prepared parametrized queries is not useful and may lead to non-optimal plans being selected.
- **TraceOn = option1 [, option2 [, ..]].** This parameter accepts a comma-delimited list of tracing options to activate by default. Enabled trace options will list there respective errors in the virtuoso.log file when encountered. Valid options are:

  user_log
  failed_log
  compile
  ddl_log
  client_sql
  errors
  dsn
  sql_send
  transact
  remote_transact
  exec
  soap

  

  See Also:

  The functions: `trace_on()` and `trace_off()` which use the same options and can turn logging options on/off while the server is running.

Example 6.1. Using the TraceOn ini file option

```
[Parameters]
....
TraceOn = soap, errors
...
```

This will enable logging of additional information regarding SOAP calls and SQL run-time errors into the virtuoso.log file.

Example 6.2. Using the ThreadCleanupInterval and ResourcesCleanupInterval ini file option

```
[Parameters]
....
ThreadCleanupInterval    = 1
ResourcesCleanupInterval = 1
...
```

Set both to 1 in order to clean up unused threads/resources and reduce memory consumption of the Virtuoso server, which can otherwise be construed as memory leaks.

If an invalid option is set then this error will be listed in the virtuoso.log file upon server startup. Virtuoso will continue to log selected options unless the trace_off() function is called for that item.

- **AllowPasswordEncryption = 1/0.** Determines whether Virtuoso encryption should be accepted from client connections. The default value is 1 - on. If set to 0 then only clear text and digest authentication will be accepted.
- **JavaClasspath.** This parameter is applied to the environment prior to the server's startup. It is valid only for binaries hosted in the Virtuoso Java VM. This has the same format as the Java CLASSPATH environment variable for the platform being used.

  Virtuoso searches for classes in the following order:

  The java_vm_create VSE parameter list

  This "JavaClasspath" in [Parameters] INI section

  The CLASSPATH environment variable

  If none of the above the CLASSPATH is the current directory.
- **JavaVMOption1..N = <opts>.** These can be used for setting Java options for the Java runtime hosted in Virtuoso. These options work as if provided as command line options to the JRE's Java command line.

  More than one line of options can be specified by using consecutively numbered options:

  ```
  JavaVMOption1  = -Ddt1=val1
  JavaVMOption2  = -Ddt2=val2
  ...
  JavaVMOption5  = -Ddt5=val5
  ```
- **PLDebug = 0.** The PLDebug switch controls the type of debugging enabled:

  PLDebug = 0 - default debugging information and test coverage disabled.

  PLDebug = 1 - debugging information enabled.

  PLDebug = 2 - debugging information enabled, test coverage data will be written to file specified in TestCoverage Virtuoso ini file parameter.
- **TestCoverage = cov.xml.**
- **CallstackOnException = 0.** Controls whether Virtuoso will report call stack on errors.

  This parameters takes the following values:

  0 (default) - Call stack reporting disabled.

  1 - Call stack reporting enabled.
- **CompileProceduresOnStartup = 1.** This controls whether Virtuoso will recompile all stored procedures listed in SYS_PROCEDURES and internal PL procedures defined during server startup. By default Virtuoso will recompile all procedures, with this setting set to 0 Virtuoso will defer compilation until procedures' first call. The benefits of this are that Virtuoso may start up up to 2-3 times faster, also the initial memory consumption will be significantly reduced as it does not need to analyze all the long varchar data allocating memory for execution. This setting is a boolean, either 1 or 0. This setting does not apply to attached VDB procedures or modules.

- **FDsPerFile = 1.** Controls the number of file descriptors per file to be obtained from the OS. The default and minimum value is 1. This parameter only effects databases that use striping. Having multiple FDs per file means that as many concurrent I/O operations may simultaneously be pending per file. This allows more flexibility for the OS to schedule the operations, potentially improving file I/O throughput
- **RecursiveFreeTextUsage = 1/0 default 1.** This option controls the behavior of free-text triggers in super-tables. If this option is set to 1 then Virtuoso will scan the hierarchy of tables until a free-text index is used to use when compiling SQL statements involving contains, xcontains or xpath_contains.
- **RecursiveTriggerCalls = 1/0 default 1.** This option controls the behavior of super-table triggers. When this option is set to 1 then triggers in the super-table will be called before its own (sub-table) triggers. This behavior is recursive and will continue up the branch of recursion, hence the triggers in the top most table in the chain will be called first.
- **MaxSortedTopRows = 10000.** The TOP select statement clause caches in memory the rows pertinent to the result. The number of rows allowed to be cached within memory is limited by this parameter.

  Simple example using OFFSET and LIMIT:

  Virtuoso uses a zero index in the OFFSET. Thus in the example below, will be taken position at record 9000 in the result set, and will get the next 1000 rows starting from 9001 record. Note that the MaxSortedTopRows in parameters Virtuoso ini section needs to be increased (default is 10000).

  ```
  select ?name
  ORDER BY ?name
  OFFSET 9000
  LIMIT 1000
  ```
- **DisableUnixSocket = 0/1 default 0.** This parameter is only applicable to Unix servers. Virtuoso clients on the `localhost` of the server can benefit from using Unix Domain sockets to improve connection performance. By default (DisableUnixSocket = 0) Virtuoso will open a Unix Domain listen socket in addition to the TCP listen socket. The name of the UD socket is `/tmp/virt-<tcp-listen-port>` . When a client attempts to connect to the Virtuoso server using the specific address `localhost` it will first try connecting to the UD socket, failing that it will silently revert to the TCP socket. See the Unix Domain Socket Connections section for more details.
- **TransactionAfterImageLimit = N bytes default 50000000.** When the roll-forward log entry of a transaction exceeds this size, the transaction is too large and is marked as uncommittable. This work as upper limit otherwise infinite (transactions). The default is 50Mb . Then also note that transaction roll-back data takes about 2x of roll-forward data. Hence when the transaction roll-forward data which is 50Mb the total transient consumption is closer to 150 Mb.
- **TempSesDir.** Directory for storing temporary data for large object handled in replication and HTTP server. Defaults to server home directory.
- **DbevEnable = 0/1 default 1.** Enable or disable Database Event Hooks .
- **RunAs.** Specifies the OS user name to which the server will switch after opening the listen ports. Has an effect only on the operating systems that support it.
- **MaxMemPoolSize = 200000000.** This parameter specifies the limit of the memory to be used for compiling a SQL statement. If the query compilation requires more memory an error will be signalled. If this is a zero then no limit will be applied. The default is 200000000. i.e. when no parameter is specified, also if negative number or less than 5000000 is given then it would be set to 5000000 bytes.
- **DefaultIsolation.** This specifies the default transaction isolation. This isolation is used unless overridden by a client setting it using the SQL_TXN_ISOLATION or equivalent connection option or a stored procedure locally setting it with the SET statement. The values are as by the SQL_TXN_ constants in ODBC, that is, 1 for read uncommitted, 2 for read committed, 4 for repeatable read and 8 for serializable. If nothing is specified, the default is repeatable read.
- **UseAIO.** This specifies whether to use asynchronous file I/O on supporting Unix systems. A value of 0 means not using it. A value of 1 means using lio_listio for any background write or read ahead if available. A value of 2 means to use the regular blocking read and write but to merge adjacent operations into a single system call when possible.
- **TempDBSize.** Controls the acceptable size of the temp database file. If on startup it's size (in MB) is greater than TempDBSize the file gets deleted and reset. This feature can be turned off by setting TempDBSize to 0. Note that the temp db file serves as an optimization storage only and doesn't have any client data that are not in either the main database files or the corresponding transaction log files.
- **LiteMode = 0/1 (default 0).** Runs server in lite mode. When Lite mode is on:

  - the web services are not initialized i.e. no web server, dav, soap, pop3 etc.
  - the replication is stopped
  - the pl debugging is disabled
  - plugins are disabled
  - rendezvous is disabled
  - the relevant tables to the above are not created
  - the index tree maps is set to 8 if no other setting is given

- memory reserve is not allocated
- affects DisableTcpSocket. So DisableTcpSocket setting is treated as 1 when LiteMode=1, regardless of value in INI file

- **RdfFreeTextRulesSize = 10 or more.** The size of hash to control rdf free text index
- **IndexTreeMaps = 2 -1024 (power of 2).** Size of index tree maps, larger is better for speed but consume memory, in lite is 2 in 'normal' mode is 256 by default.
- **DisableTcpSocket = 1/0.** Default = 0. If set to 1, disables database listener on TCP port; unix socket must be used for data access connections (ODBC, JDBC, ADO.NET, OLE DB). When LiteMode=1, DisableTcpSocket setting in INI file is ignored and treated as if set to 1.
- **ExtentReadThreshold.** Controls speculative read of disk pages. If pages are read in close succession from an extent of 256 consecutive pages, the system may decide to speculatively read the entire extent.

  ExtentReadThreshold parameter gives how many consecutive reads are needed to trigger this.

  When is set to 0, this means that anytime a page is read, the whole extent is read along with it

  When is set to 1, this means that if the first read is at time *t* and the next one at time *t1* and *t1-t* < ini_ExtentReadWindow msec, then 2nd read triggers the speculative read.

  Default is 2.

  Takes effect after the buffer pool is full.
- **ExtentReadWindow.** Controls speculative read of disk pages. If pages are read in close succession from an extent of 256 consecutive pages, the system may decide to speculatively read the entire extent.

  ExtentReadWindow parameter gives the time within which the reads must fall.

  Default is 1000.

  Takes effect after the buffer pool is full.
- **ExtentReadStartupThreshold.** Controls speculative read of disk pages. If pages are read in close succession from an extent of 256 consecutive pages, the system may decide to speculatively read the entire extent.

  ExtentReadStartupThreshold parameter value applies while the server is freshly started and the buffer pool is not yet full. It can be set to preread more aggressively.

  Default is 0.
- **ExtentReadStartupWindow.** Controls speculative read of disk pages. If pages are read in close succession from an extent of 256 consecutive pages, the system may decide to speculatively read the entire extent.

  ExtentReadStartupWindow parameter value applies while the server is freshly started and the buffer pool is not yet full. It can be set to preread more aggressively.

  Default is 40000.
- **ColumnStore.** If 1, all create table and create index statements will create column-store structures by default.

  Note: Only effective with Virtuoso 7.0 and later.
- **AsyncQueueMaxThreads.** Sets the number of threads in a pool that is used for getting extra threads for running queries and for aq_request. Each running statement has at least one thread that is not allocated from this pool plus zero or more threads from this pool.

  See Also:
  Configuring Vectored Execution

  Setting the pool size to the number of cores plus a few is a reasonable default. On platforms with core multithreading, one can count a core thread as a core for purposes of this parameter.

  If one expects to run many slow `aq_requests()` (see `async_queue()` , `aq_request()` , etc.), then the number of threads should be increased by the number of slow threads one expects.

Slow threads are typically I/O bound threads used for web crawling or similar long-latency, low-CPU activity.

Note: Only effective with Virtuoso 7.0 and later.

- **ThreadsPerQuery.** This is maximum number of threads that can be claimed from the thread pool by a single query. A value of one means that no query parallelization will take place, and all queries will run single threaded.

See Also:

Configuring Vectored Execution

The number of cores on the machine is a reasonable default if running large queries.

Note that since every query is served by at least one thread, a single query taking all the extra threads will not prevent other queries from progressing.

Note: Only effective with Virtuoso 7.0 and later.

- **VectorSize.** This the number of simultaneous sets of query variable bindings processed at one time. The default is 10,000, which is good for most cases.

```
SELECT COUNT (*)
FROM t1 a,
     t1 b
WHERE a.row_no + 1 = b.row_no
OPTION (LOOP, ORDER)
```

See Also:

Configuring Vectored Execution

If we are evaluating the query:

with vector size of 10,000, then 10,000 rows of t1 a will be fetched first; 1 will be added to the 10,000 row_no values; and then the corresponding row of t1 b will be fetched for the 10,000 row_no of t1 a. This process will repeat until enough batches of t1 a have been fetched to come to its end.

Note: Only effective with Virtuoso 7.0 and later.

- **AdjustVectorSize.** Using a larger vector size when evaluating large queries with indexed random-access can yield up to a 3x speed-up relative to using the default vector size. However, always using a large vector size will prohibitively increase the overhead of running small queries. For this reason, there is the option to adaptively select the vector size. Set AdjustVectorSize = 1 to enable this feature. The SQL execution engine will increase the vector size when it sees an index lookup that does not get good locality, (e.g., after sorting the keys to look for, too few consecutive lookups fall on the same page). Having more keys to look up increases the chance that consecutive keys should be found on the same page, thus eliminating much of the index lookup cost.

See Also:

Configuring Vectored Execution

Note: Only effective with Virtuoso 7.0 and later.

- **MaxQueryMem.** This controls the maximum amount of memory that can be used across the server process for large vectors, i.e. if the memory in use is near this limit, a query will not switch to large vector size even if it finds it useful. The event counter tc_no_mem_for_longer_batch counts how many times this situation is detected. A size letter of G or M follows the value.

See Also:

Configuring Vectored Execution

Note: Only effective with Virtuoso 7.0 and later.

- **HashJoinSpace.** This controls the maximum amount of memory that can be used across the server process for hash join hash tables. This is followed by a size letter M or G. A single hash join hash table will only claim a percentage of the remaining hash join space, by default 50. This is controlled by the chash_per_query_pct setting, see section on vectored execution tuning. If there is not enough memory, a partitioned hash join will be used, making as many passes over the data as needed so that the hash table will fit within the set limits.

See Also:
Configuring Vectored Execution

Note: Only effective with Virtuoso 7.0 and later.

- **MaxVectorSize.** When AdjustVectorSize is on, this setting gives the maximum vector size. The default is 1,000,000 and the largest allowed value is about 3,500,000.

See Also:
Configuring Vectored Execution

Note: Only effective with Virtuoso 7.0 and later.

- **TimezonelessDatetimes.** Enables Timezoneless Support. Different applications may require different behavior when input data contain timezoneless values. In some cases it is better to "cast" all of them to timezoned than to upgrade existing code. Virtuoso offers 5 different modes of support -- 0, 1, 2, 3 and 4. This should be set before creating the database and the set value is stored in the database. After database is created, an attempt to change the mode by patching virtuoso.ini will have no effect and virtuoso.log will contain a warning about mismatch between virtuoso.ini and the database file.

    - TimezonelessDatetimes=0 -- Never use timezoneless, as it was in old databases. Always set local timezone on parsing strings if no timezone specified. An attempt to set timezoneless by calling function `forget_timezone()` will signal error. Timezoneless values still may come from outside as dezerializations of timezoneless DATETIME values, serialized by other database instances, but not in any other way:
    - TimezonelessDatetimes=1 -- When parsing strings, set timezoneless if ISO format tells so:
    - TimezonelessDatetimes=2 -- Set timezoneless always, exception is when the parsed string contains explicit timezone or when RFC requires the use of GMT or when timezone is set by function `adjust_timezone()` . This is default for new databases if `TimezonelessDatetimes` parameter is missing in virtuoso.ini
    - TimezonelessDatetimes=3 -- Never use timezoneless. Always set local timezone on parsing strings if not timezone specified. An attempt to set timezoneless by calling function `forget_timezone()` will signal error. Timezoneless values still may come from outside as deserializations of timezoneless DATETIME values, serialized by other database instances, but not in any other way. The difference with `TimezonelessDatetimes=0` is that timezones are always printed on cast datetimes to strings etc. so timezoneless-aware clients will get unambiguous data.
    - TimezonelessDatetimes=4 -- On parsing string, set timezone to GMT if no timezone specified. However, timezoneless can be set by calling function `forget_timezone()` . This mode can be convenient for global web services when real "local" timezones of specific users are not known.

    The possible variants are:

    For new applications, consider the use of `TimezonelessDatetimes=2` as primary variant, `TimezonelessDatetimes=1` as the second best.

Note: The default for startup behavior is to always read full extents and the default for the normal behavior is to trigger preread on the third read inside one second.

[HTTPServer]

Settings in this section control the web server component of the Virtuoso Server.

- **ServerPort.** This specifies the initial HTTP listen port for the HTTP server. Can be specified also as ipaddress:port. Once Virtuoso is started it is possible to create multiple listeners using virtual directories.
- **HTTPThreadSize = 120000.** The stack size of the HTTP thread used for reading/processing HTTP client requests and accepting connections. The default is 120,000 bytes. This parameter cannot have value less than the default; if a smaller value is specified the default will be used.
- **ServerThreads.** This specifies the number of concurrently serviced HTTP requests. Its alias is *MaxClientConnections* . If there are more concurrent requests, accepting the connections will be deferred until there is a thread ready to serve each. If an attempt to exceed the number of licensed connections is found. the latter will be used. When the number of threads is low some of the tutorials may perform poorly and appear not to work; this is due to the demonstration licensing. When testing Virtuoso with the demonstration license it can be quite easy to hit the limits unless remote connections and HTTP connections are conserved. You may wish to either wait for previous transactions to finish or restart the server to be sure.

- **HTTPThreadSize = 120000.** The stack size of HTTP thread used for reading/processing HTTP client requests and accepting connections. The default setting, if not supplied, is 120,000 bytes. The default value is the minimum; lesser values will be rounded up.
- **ServerRoot = ../vsp.** This is the file system path of the root directory of files served by the Virtuoso web server. The index.html in that directory will be served for the / URI. If relative, the path is interpreted relative to the server's working directory.
- **ServerIdString = Virtuoso.** String passed as Server: header to HTTP client. This string is not required, in its absence the above default will be assumed. This string can be set to anything required.
- **ClientIdString = Mozilla/4.0 (compatible; Virtuoso).** String passed as User-Agent: header to server by HTTP client. This string is not required, in its absence the above default will be assumed. This string can be set to anything required.
- **Charset = [CHARSET-NAME].** Allows you to set the default server character set. If no default is specified then ISO-8859-1 will be used automatically by the server.
- **EnabledGzipContent = 0.** This sets the default behavior of HTTP transmission. If set to 1 The Virtuoso HTTP server will send GZipped content to user agents. Otherwise content will be sent as is. The function `http_enable_gz()` lets you change the server mode on the fly.
- **MaxKeepAlives = 10.** Connections by HTTP 1.1 clients can remain open after the initial response has been sent. This parameters sets a cap on how many socket descriptors will at most be taken by keep alive connections. Such connections will be dropped by the server ahead of timeout if this number would be exceeded. Thus the maximum number of open sockets for the Virtuoso HTTP server is this number plus the number of threads. A keep alive connection is by definition not associated to any pending processing on any thread.
- **KeepAliveTimeout = 10.** This is a timeout in seconds before Virtuoso closes an idle HTTP 1.1 connection.
- **HTTPProxyEnabled = 0.** Setting this to 1 activates Virtuoso proxy service capabilities. The default value of 0 deactivates the proxy service.

Note:
Ports on which proxying is enabled should not be presented to the outside world under any situation.

- **HTTPProxyServer = proxylocal:3128.** HTTP proxy server name and port
- **HTTPProxyExceptions = localhost:8890, 127.0.0.1:8890.** HTTP proxy exceptions name and port.
- **HTTPLogFile = log.out.** If specified, Virtuoso will produce an HTTP server log file with the date appended to the name given in the parameter and the files extension as ".out". The log file is rotated daily.

  It will contain the following information:

  `logDDMMYYYY.out` :-

  Client IP address

  Date and time of request/response

  Timestamp (milliseconds)

  Request/response line

  An example of which is:

```
127.0.0.1 - - [12/Sep/2006:12:31:17 +0300] "GET /ods/ HTTP/1.1" 200 19453 "" "Mozilla/5.
127.0.0.1 - - [12/Sep/2006:12:31:18 +0300] "GET /ods/default.css HTTP/1.1" 200 41389 "ht
127.0.0.1 - - [12/Sep/2006:12:31:19 +0300] "GET /ods/common.js HTTP/1.1" 200 7481 "http:
```

- **HTTPLogFormat = format string like apache mod_log.** "HTTPLogFormat" INI file param works in conjunction with the "HTTPLogFile" INI file param. In http log we support format string like Apache Module mod_log_config . For example:

```
...
[HTTPServer]
...
HTTPLogFormat = %h %u %t "%r" %s %b "%{Referer}i" "%{User-agent}i" "%{NetId}e"
```

  In this example we have %{User-Agent}i which means to log the HTTP header for user-agent. In similar way can log other input headers, "e" modifier is for environment variable NetId in this case.

  Note that not all escapes from Apache Module mod_log_config are supported.
- **MaxCachedProxyConnections = 10.** When Virtuoso is acting as a proxy or HTTP client, as is the case with the http_get or the SOAP client functions, it caches connections to HTTP 1.1 servers. This is the maximum population of said cache.

- **ProxyConnectionCacheTimeout = 15.** This is a timeout in seconds for dropping idle connections to other HTTP servers. These result from http_get, SOAP client functions and proxying.
- **DavRoot = DAV.** This specifies the root path of DAV resources. If DAV specific HTTP methods are used on Virtuoso, these should only reference resources with paths starting with this. This is the top level DAV collection. Other paths can be declared as managed in DAV using the virtual directory mechanism, but this applies to the default virtual directory.
- **DAVQuotaEnabled = 1/0.** The Virtuoso administrator can enforce a quota on all DAV accounts, apart from the "dav" administration user, that restricts that amount of space a DAV user can consume in their DAV home directory. When this parameter is set to one (1) quotas are enabled, when this parameter is set to zero (0), they are disabled. The default quota value is five Megabytes (5MB) but can be uniquely defined for each user. Every user has a quota except "dav", which is unlimited. Dav quotas are disabled if this parameter is not specified for backwards compatibility.
- **DAVChunkedQuota = 1000000.** Virtuoso send resources to from WebDAV to the requesting client in chunked encoding to save memory if the request is in HTTP/1.1 and the files size is greater then the `DAVChunkedQuota` number of bytes. The default chunked-quota value is approximately one-megabyte.
- **SSLPort=4433.** this is the port on which SSL HTTPS connections will be accepted. Can be specified also as ipaddress:port. If unspecified then the service will be disabled.
- **SSLCertificate=./virtuoso_cert.pem.** the option must point to the file with the server certificate in PEM format.

  If the option begins with 'db:' e.g. 'db:id_server', then certificate and key will be loaded from DBA key space.
- **SSLPrivateKey=./virtuoso_key.pem.** points to the file containing the RSA private key in PEM format.

  the certificate/key pair must be valid (eq. certificate is generated on base of key)

  If the option begins with 'db:' e.g. 'db:id_server', then certificate and key will be loaded from DBA key space. Note: in the case of database stored key, both SSLCertificate and SSLPrivateKey settings MUST be same.
- **X509ClientVerify=0.** Whether the server will require X509 certificates from the browsers.

  X509ClientVerify = 0 - no certificate verification required

  X509ClientVerify = 1 - ask for trusted certificates

  X509ClientVerify = 2 - optionally ask for trusted certificates, if trusted certificate is presented it will be verified

  X509ClientVerify = 3 - optionally accept any certificate including self-signed certificates

  See Also:

  WebID Protocol ODBC Login
- **X509ClientVerifyDepth=1.** Specifies how deep the client certificate verification process will traverse the Issuer chain before giving up. The default value of 0 means that only verification of the client certificate itself being in the server's CA list is performed. Setting this option to -1 will ignore the depth checks
- **X509ClientVerifyCAFile=./calist.pem.** a PEM file of all the X509 certificates of the Certification Authorities (CA) which the server will use for verifying the client's client certificate. A list of these will be sent to the client as a part of the SSL handshake so the client will know which certificate to send.

  Note this option is in effect when X509ClientVerify is 1 or 2. If X509ClientVerify is 3 and X509ClientVerifyCAFile is given, server will send certificated during handshake, thus some clients may restrict user to send any certificate.
- **POP3Port=1234.** Defines the TCP port number on which the Virtuoso POP3 server will listen. The POP3 server will be disabled if this value is 0 or undefined.
- **NewsServerPort=1235.** Defines the TCP port number on which the Virtuoso NNTP server will listen. The NNTP server will be disabled if this value is 0 or undefined.
- **FTPServerPort.** The Virtuoso FTP server can be enabled by supplying this parameter with a value. This value will then be the listening port of the FTP server. The usual port for FTP is port 21.
- **FTPServerMinFreePort = 20000.** The Virtuoso FTP client and server use FTPServerMinFreePort and FTPServerMaxFreePort parameters as lower and upper bounds for active and passive connections. This parameters sets the lower bound.
- **FTPServerMaxFreePort = 30000.** The Virtuoso FTP client and server use FTPServerMinFreePort and FTPServerMacFreePort parameters as lower and upper bounds for active and passive connections. This parameters sets the upper bound.
- **FTPServerLogFile = ftpserver.** If specified Virtuoso will produce an FTP server log file with the date appended to the name given in the parameter and the files extension as ".log". The log file is rotated daily.

  It will contain the following information:

  `ftpserverDDMMYYYY.log`:-

Client Host Name

Authorized User

Time

User Command

Server Response Code

Bytes Transferred

An example of which is:

```
hostname anonymous [22/Oct/2003:15:21:43 +0300] "PASS user@domain.com" 230 0
hostname anonymous [22/Oct/2003:15:23:11 +0300] "LIST" 226 162
hostname dav [22/Oct/2003:15:25:00 +0300] "PASS <hidden>" 230 0
```

- **FTPServerAnonymousLogin = 0.** Allows the FTP server to be accessible via the "anonymous" user login. The anonymous user is not a real user, it has no SQL or DAV login ability. The anonymous user can only access collections or resources that are set to public.
- **DefaultMailServer=localhost:25.** Default SMTP server name and port, this is used when the first parameter of the smtp_send function is omitted or NULL.
- **TempASPXDir.** Allows you to choose what file system directory to be used for temporary storage of ASPX files hosted in DAV.
- **PersistentHostingModules = [1/]0.** When set to "1" prevents Virtuoso from removing the plugin interpreters from the HTTP threads after each request. The default setting is "0".
- **HttpSessionSize = size in bytes, default 10000000.** The size threshold for large objects received by HTTP server. When this limit is exceeded by incoming or outgoing data, this will be stored in a temp file, see 'TempSesDir' parameter in 'Parameters' section.
- **MaintenancePage = file_name.** The name of a HTML page or other static content to be returned to the user agents when server is running in atomic mode. Note that this page should be self-contained, i.e. no image or CSS not JavaScript references can be used.

[Flags]

- **enable_joins_only = 0.** Setting enable_joins_only will cause the optimizer to only consider next plan candidates that are connected by a join to the existing partial plan. In other words, no cartesian products will be considered. This may save some space and time.

[URIQA]

The URIQA section sets parameters of both URIQA HTTP extension and URIQA web service. Section URIQA Semantic Web Enabler contains detailed description of this functionality, including more details about URIQA configuration parameters . This section should stay commented out as long as URIQA is not in use.

- **DefaultHost = canonical name of the server, used by default for metadata retrieval, no default value.** The server name, including domain and port if needed, such as "www.example.com" or "www.example.com:8088".
- **LocalHostNames = comma-delimited list of names of the server, that can be used for retrieval of metadata, no default value.** List of various allowed spellings of the server name, such as "www.example.com, mail.example.com, mail, localhost, localhost.localdomain".
- **LocalHostMasks = comma-delimited list of name masks of the server, no default value.** List of various allowed spellings of the server name in form of pattern strings for SQL "like" operator, not in form of exact strings.
- **Fingerprint = unique fingerprint string of the server or group of identical servers, no default value.** Do not use this without an explicit need, to let server configure itself. Please refer to detailed description before use.
- **DynamicLocal = 1/0 default 0, allow dynamic hostname translation in the IRIs.** If DynamicLocal is on and the host part of the IRI matches the Host header of the HTTP request in context or the DefaultHost if outside of HTTP context, then this is replaced with local: before looking up the IRI ID.

[SPARQL]

The SPARQL section sets parameters and limits for SPARQL query protocol web service service. This section should stay commented out as long as SPARQL is not in use. Section RDF Data Access and Data Management contains detailed description of this functionality.

- **ExternalQuerySource = 1 or 0 .** This controls processing of the "query-uri" parameter of the SPARQL query protocol webservice, means enable 1 or prohibited 0.

- **MinExpiration = 86400 .** Sponger caching parameter in seconds. It will cause sponger to use this value as minimal expiration of the pages, which would help in cases where source document's server do not report expiration or it reports no caching at all.
- **MaxCacheExpiration = 1 .** Cache Expiration time in seconds that overrides Sponger's default cache invalidation.
- **MaxDataSourceSize = 20971520 .** Controls the max size that can be sponged. Default is 20 MB.
- **ExternalXsltSource = 1 or 0 .** This controls processing of the "xslt-uri" parameter of the SPARQL query protocol webservice, means enable 1 or prohibited 0.
- **ResultSetMaxRows = number .** This setting is used to limit the number of the rows in the result. The effective limit will be the lowest of this setting, SPARQL query 'LIMIT' clause value (if present), and SPARQL Endpoint request URI &maxrows parameter value (if present).
- **DefaultGraph = IRI .** IRI of the default graph to be used if no "default-graph-uri" parameter is specified.
- **MaxQueryCostEstimationTime = seconds .** This setting is used to limit the estimate time cost of the query to certain number of seconds, the default is no limit.
- **MaxQueryExecutionTime = seconds .** This setting is used to set the transaction execution timeout to certain limit in number of seconds, the default is no limit.
- **ImmutableGraphs = URI .** IRI of graphs over which the sponger not to be able able to write.
- **PingService = URI .** IRI of notification service to which the sponger results will be send.
- **DefaultQuery = SPARQL Query .** Default SPARQL Query.
- **DeferInferenceRulesInit = 1 .** Defer Loading of inference rules at start up.
- **ShortenLongURIs = 1 .** Shorten extremely long URIs in datasets when loading with the RDF Bulk Loader. Default is 0.

  Note : This parameter is only in the Virtuoso 06.03.3131+ commercial builds, at the time of writing it is not included in the open source 6.1.4 archives but will be in the next 6.1.5 release. A patch to enable this feature is however available from the Virtuso patches page on source forge , which can be applied to a 6.1.4 archive from source forge and the Virtuoso server binary rebuilt.
- **MaxMemInUse = 0 .** Maximum amount of memory that is allowed for temporary storing parts of a SPARQL query result. Default is zero for no limit. ResultSetMaxRows is maximum length of a SPARQL query result. Default is zero for no limit. These two options may be useful for protecting public web service endpoints against DOS attacks, but at the same time it may cause returning incomplete results without reporting errors. When used, it is strongly advised to set the value orders of magnitude larger than the expected size of longest reply. As a rule of thumb, timeout should happen before this limit has reached. Values less than 1000000 bytes are impractical in all cases.

The SPARQL INI can be get as RDF via http://cname/sparql?ini service.

[I18N]

- **XAnyNormalization = 1/2/3/0.** 0: default value. It means not to normalize anything, so, for example, "José" and "Jose" are two distinct words.

  
  See Also:
  How Can I Control the normalization of UNICODE3 accented chars in free-text index?

  1: Any pair of base char and combining char (NSM, non-spacing modifier) is replaced with a single combined char, so if character "é" is written as a sequence of "base" character "e" and a unicode char U+0301 ("combining acute accent"), then the pair will be replaced with a single U+00E9 ("latin small letter e acute").

  2: Any combined char is converted to its (smallest known) base, so, "é" will lose its accent and become plain old ASCII "e".

  3: This is equal to 1+2, and when set, both conversions are performed. As a result, any pair of base char and combining char loses its second char, and any chars with accents will lose accents.

  If the parameter is required at all, the needed value is probably 3, so the fragment of virtuoso.ini should be:

  ```
  [I18N]
  XAnyNormalization=3
  ```
- **WideFileNames = 1/0.** Default is 0. When 1 then file access and directory listing functions may use wide strings as file names. If a file name contains non-ASCII characters then directory listing result set will contain a wide string instead of narrow string with question marks. Note, however, that most of existing applications do not support wide strings for that purposes, so the feature should be used with extreme care.

- **VolumeEncoding.** Encoding identifier. If set, file names are translated from wide strings and default server encoding to the specified encoding before using them in file manipulation BIFs. This is useful when server's filesystem is in some national encoding or in UTF-8. The translation is bi-directional: directory listing items are translated from volume encoding to the default server encoding or wide.
- **VolumeEmergencyEncoding.** Encoding identifier. If set, this encoding is used when the use of VolumeEncoding causes encoding errors. The most popular case is when an UNIX filesystem tree with UTF-8 contains some mounts of legacy storages with KOI or CP encoding. Less popular is UTF-8 volume encoding and UTF-8QR as emergency encoding to recover poorly encoded filenames.
- **VolumeEmergencyEncodingDirs.** List of directories in same syntax as DirsAllowed, default is empty. If set, all file names in the listed directories are supposed to be in VolumeEmergencyEncoding and VolumeEncoding is even not tried. The most popular case is when an UNIX filesystem tree with UTF-8 contains some mounts of legacy storages with KOI or CP encoding.

[Replication]

The replication section sets the transactional replication parameters for the server.

- **ServerEnable=0/1.** A boolean parameter controlling whether a Virtuoso can or cannot act as a transactional replication publisher.
- **ServerName = log1.** This identifies the server instance. The entries in SYS_REPL_ACCOUNTS where SERVER equals this name are considered locally published accounts. This is the value returned by repl_this_server () SQL function.
- **QueueMax = 50000.** This controls how much synchronized transactional subscribers may fall behind before being disconnected. This controls how much memory the server will use to buffer undelivered replication casts. If the queue exceeds this byte amount subscribers are disconnected and must request re-synchronization. The byte count refers to the total length of the replay records being buffered. The actual memory usage is somewhat greater.

[Mono]

- **MONO_ROOT.** A path to the directory where the Mono system assemblies are located. Usually it is a compile time setting, but the MONO_ROOT overrides it. This ini setting overrides the Mono environment variable of the same name.
- **MONO_PATH.** A colon separated list of directories where the assemblies are located to be found by Assembly.Load (equivalent to MS.NET Global assembly cache). This ini setting overrides the Mono environment variable of the same name.
- **MONO_CFG_DIR.** A path where the 'machine.config' file is to be found while running the ASPX code in Mono. This ini setting overrides an environment variable of the same name. This is also usually a Mono compile time default.
- **virtclr.dll.** A fully qualified path and filename of the virtclr.dll virtuoso helper assembly.
- **MONO_TRACE = Off.** Mono debug tracing can be enabled by setting this parameter to On. When tracing is On, Mono debug output with be sent to the Virtuoso debug console.

[Client]

- **SQL_QUERY_TIMEOUT=0.** This sets the initial value of the SQL_QUERY_TIMEOUT statement option in connected clients. The ODBC standard value is 0, meaning indefinite, which is impractical in many applications. This allows overriding the default. The timeout is expressed in seconds. If the client application sets this option in a statement, this default is overridden for the statement in question.
- **SQL_TXN_TIMEOUT=0.** This is an ODBC extension option allowing setting a maximum duration for a transaction. 0 means that there is no maximum.
- **SQL_PREFETCH_ROWS=100.** For a forward only cursor, this option sets the number of rows prefetched at the execute and on subsequent fetch requests. A high value will speed up long selects but will be a disadvantage if only the first few rows are fetched from a cursor that has a large result set.

  This should not be confused with the SQL_ROWSET_SIZE setting for scrollable cursors.
- **SQL_PREFETCH_BYTES=16000.** This option specifies the maximum number of bytes the server will send as prefetched rows on a forward only cursor. If long rows are being prefetched this will cut off the prefetch after this many bytes even if the number of rows is less than SQL_ROWSET_SIZE.
- **SQL_NO_CHAR_C_ESCAPE=0.** This options is 0 by default and can be either 1 or 0. This option controls Virtuoso's interpretation of the backslash in PL text which is normal interpreted as escaping rather than literal.
- **SQL_UTF8_EXECS = 0.** Setting SQL_UTF8_EXECS = 1 enables UTF-8 identifier storage and retrieval, whereas setting SQL_UTF8_EXECS = 0 disables it. The default setting is 0: disabled for backwards compatible. See the Wide Character Identifiers section for more information

- **SQL_BINARY_TIMESTAMP = 1.** When SQL_BINARY_TIMESTAMP is set to 1 Virtuoso will describe all TIMESTAMP columns as SQL_BINARY. If it is set to 0 then Virtuoso will report the TIMESTAMP columns as SQL_TIMESTAMP
- **SQL_NO_SYSTEM_TABLES = 0.** This setting can be used to prevent SQLTables from returning system tables. The default value of this setting is 0, which is allow system tables to be returned in the normal way. Setting this to 1 will prevent system tables from being returned from SQLTables. The client can also issue a "set SQL_NO_SYSTEM_TABLE = 1/0" statement to set this in-connection.

[AutoRepair]

- **BadParentLinks=0.** As a result of an internal error in the database the physical integrity of references may be lost. Enabling this option causes the database to automatically repair such faults without having to go through a crash dump plus restore. A value of 0 should be normally used.

[VDB]

- **ArrayOptimization=0/1.** Boolean parameter which allows the Virtuoso VDB to use Array parameters if the remote data source supports these.
- **UseMTS = 0.** This parameter turns on/off MTS support in Virtuoso. It is applicable to windows multithreaded version of the Virtuoso server only.
- **NumArrayParameters.** Specifies a size of the parameter batch used by the VDB (default = 10)
- **VDBDisconnectTimeout.** The time (in seconds) after which a VDB connection is considered timed-out and closed. Default : 1000
- **VDBOracleCatalogFix=0/1.** This setting can be enabled to improve compatibility with the MS Oracle Driver which has problems with mixed case table names in catalog calls.

  Boolean parameter : allows a special mode for the ORACLE ODBC drivers which do not return correct catalog data for mixed case tables. When this is on and the return from the catalog functions is empty, then a Catalog function is issued to take the same catalog data and the result is filtered on the client side.
- **AttachInAutoCommit.** An boolean parameter controlling whether the VDB Catalog functions called while attaching a table will be called in AutoCommit mode (required by some Sybase drivers).
- **NumArrayParameters=10.**
- **ReconnectOnFailure=0 [1|0].** The default setting of 0 instructs the VDB layer to return underlying DB errors to the client rather than automatically reconnecting without reporting the error, which would be setting 1.
- **KeepConnectionOnFixedThread=1 [0|1|2|4|8].** The default option is 1, this forces the VDB to map a single thread to each ODBC session in the VDB rather than multiple threads. Some ODBC drivers expect that calls concerning a particular connection all take place on one thread. For example, the Oracle 8.xx ODBC driver can produce flaky crashes if this option is not set.

  0 - If a second request comes while a thread is processing the epilogue or previous request for same connection the second request is scheduled for the same thread. This is called burst mode. Once this mode is active all requests on this connection will be processed in the same thread. until there is a break at delay more than 'PrpcBurstTimeoutMsecs' elapses between ending the last and receiving the next in same connection. This break in activity return the thread to the thread pool. The burst mode optimization saves thread switching time and may improve performance by up to 30% in situations involving short requests immediately following each other.

  "ForcedFixedThread" mode (4). This is the same as VDBFixedThread mode, except that the thread enters this state immediately on connection (as opposed to doing that on the first VDB activity). Otherwise the scheduling stays the same as in VDB FixedThread.

  "Forced Burst" mode (8). When a connection is initially made it's added to the select thread for monitoring. When an RPC comes in it causes the select thread to take the connection out of the select thread and assign that connection to designated worker thread. That thread from now on will read the data coming in from that connection directly (not depending on the select thread to detect the incoming data and wake the worker thread up). That mode saves the thread switch done handling each RPC (from the select thread to the worker thread). When the connection terminates the thread is unbound from it and returned to it's default idle state. If an lengthy RPC is being processed the server will switch the thread from burst mode to default mode while running the RPC, so the asynchronous cancellation requests can be processed.

  To disable ever going to burst mode, this option can be set to 2
- **PrpcBurstTimeoutMsecs=100 (milliseconds).** RPC burst mode timeout in milliseconds. (see above)

- **SerializeConnect=0 [1|0].** When enabled causes Virtuoso to wrap SQLAllocConnect/SQLConnect calls sequence in a mutex, thus preventing abnormal program exits when there are a large number of connection requests to the VDB. Certain ODBC drivers have been noted to produce flaky errors when a large number of threads is concurrently inside one of the ODBC connect calls..
- **SkipDMLPrimaryKey=0 [1|0].** This setting controls SQL compilation (not execution) for conditions where rows in a local table are used to determine rows of a remote table to be deleted (e.g. delete from rmt1 where rmc1 = 12 and rmc2 in (select lc1 from lt1)) where the remote table was linked without a Primary Key primary key specified. Normally the primary key is used, even when not in the original select select, to identify the rows to be deleted. When the primary key is false or not available and SkipDMLPrimaryKey = 1 then the original where clause will be used instead.
- **RemotePKNotUnique=0 [1|0].** This option controls the SQL compiler ability to do some optimizations when it knows it will receive 1 row from a remote table (using the applicable WHERE clause). In some cases the remote is not providing any info about a primary key (or is providing wrong data for the primary keys and unique indices of a table) through ODBC API and the Virtuoso SQL optimizer may get fooled into thinking that a given SQL query over a remote table will return no more than 1 row. To avoid that turn on the above parameter to stop the compiler from doing that optimizations.
- **UseGlobalPool=0 [1|0].** This option controls the aggregation point of the VDB connection pools. When it is off (=0, the default) the VDB connections that are no longer needed after transaction end are collected server-side in a per-user connection cache. This (together with the `KeepConnectionOnFixedThread` INI option) ensures conformance even with older ODBC drivers that require that connections must be used only within the OS thread that initiated them. This however may result in somewhat low reuse rate for the pooled connections. That's why when this option is 1 (On) the connections are stored in a server-side per-DSN connection cache. Keep in mind that this may not work with all the ODBC drivers, but it may provide lower ratio between virtuoso client connections and VDB-to-remote DBMS connections, thus requiring smaller number of active connections on the remotes and faster execution of VDB operations.

[Ucms]

- **UcmPath.** String parameter which specifies the path where UCM files are located. If this parameter is not specified, UCM files cannot be loaded.
- **Ucm1, Ucm2,... Ucm99.** Every UcmN parameter specifies one UCM file to load. The value of UcmN is a pair of comma delimited strings. The first string is a name of the UCM file to load, (relative to the path specified in UcmPath), the second string is a name of the encoding as it was used by the server. E.g. Ucm1 = java-Cp933-1.3-P.ucm,Cp933 will load the encoding from the file java-Cp933-1.3-P.ucm and associate it with the identifier 'Cp933'. You can register one encoding with more than one name, if they are delimited by '|' (with no white spaces in the string). e.g. Ucm2 = java-Cp949-1.3-P.ucm,Cp949|Korean will load the encoding from the file java-Cp949-1.3-P.ucm and associate it with two identifiers, 'Cp949' and 'Korean'. See UCM Encodings for more details.

[Zero Config]

- **ServerName.** Name used to advertise the Virtuoso ODBC service details in ZeroConfig. This is the name that will be shown to clients amongst other ZeroConfig datasources.
- **ServerDSN.** An ODBC style connect string to preset the values of the parameters when the ODBC service offered by this server is selected by the Virtuoso ZeroConfig enabled clients.
- **SSLServerName.** Name used to advertise the Virtuoso ODBC SSL encrypted service details in ZeroConfig.
- **SSLServerDSN.** An ODBC style connect string to preset the values of the parameters when the ODBC SSL encrypted service offered by this server is selected by the Virtuoso ZeroConfig enabled clients.

See Also:

The Zero Config section.

[Plugins]

- **LoadPath = /home/virtuoso/hosting.** The directory containing shared objects/libraries for use as Virtuoso VSEI plugins.
- **Load<number> = <module type>, <module name>.** `<number>` is the module load number, required and starting with 1. `<module type>` specifies the type of module that is to be loaded, and hence how Virtuoso is to use it. So far "Hosting" and "attach" types exist. `<module name>` is the file name of the modules shared library or object.

  Example:

```
Load6 = attach, libphp5.so)

Load7 = Hosting, hosting_php.so)
```

"Attach" is used for now for the php library. It can be used to load other libraries in future too. The reason is to load PHP5 functionality into virtuoso namespace, so when actually is loaded the hosting plugin, it can bind to the already available symbols for php5.

See Also:
VSEI Plugins

[Striping]

- **Segment<number> = <size>, <stripe file name> [, <stripe file name> ..].** <number> must be ordered from 1 upwards; The <size> is the size of the segment which is equally divided across all stripes comprising the segment.

This section is only effective when `Striping = 1` is set in the `[Database]` section. When striping is enabled the Virtuoso database spans multiple segments where each segment can have multiple stripes.

Striping can be used to distribute the database across multiple locations of a file system for performance. Segmentation can be used for expansion or dealing with file size limitations. To allow for database growth when a file system is near capacity or near the OS file size limitation, new segments can be added on the same or other file systems.

Striping only has a potential performance benefit when striped across multiple devices. Striping on the same file system is needless and unlikely to alter performance, however, multiple segments do provide convenience and flexibility as described above. Striping across partitions on the same device is likely to reduce performance by causing high unnecessary seek times on the physical disk.

Database segments are pre-allocated as defined. This can reduce the potential for file fragmentation which could also provide some performance benefit.

Virtuoso striping alone does not allow for any fault tolerance. This is best handled at the I/O layer or by the operating system. File system RAID with fault-tolerant striping defined should be used to host the Virtuoso files if striping based protection is desired.

The segments are numbered, their segment <number> must be specified in order starting with segment1.

The <size> is the total size of the segment which is that will be divided equally across all stripes comprising the segment. Its specification can be in gigabytes (g), megabytes (m), kilobytes (k) or in database blocks (b) the default.

Note:
The segment size must be a multiple of the database page size which is currently 8k. Also, the segment size must be divisible by the number of stripe files contained in the segment.

Segments can be added to a database, however once defined they should never be altered. Databases that were created without striping cannot automatically be restarted with striping. You can convert a non-striping database to striping by dumping the contents of the database to a transaction file and replaying it with striping enabled. An on-line backup made with backup_online () can be restored on a database with a different striping configuration as long as the total number of pages is no less than the number of pages of the backed up database.

Striping can be useful for the temporary objects database if large hash join temporary spaces or such are expected. This is enabled by the Striping setting in the Temp Database section of the ini file. The stripes will be declared in the TempStriping section.

;
;  Striping setup
;
;  These parameters have only effect when Striping is set to 1 in the
;  [Database] section, in which case the DatabaseFile parameter is ignored.
;
;  With striping, the database spans multiple segments
;  where each segment can have multiple stripes.
;
;  Format of the lines below:
;    Segment<number> = <size>, <stripe file name> [, <stripe file name> .. ]
;
;  <number> must be ordered from 1 up.
;
;  The <size> is the total size of the segment which is equally divided
;  across all stripes comprising  the segment. Its specification can be in
;  gigabytes (g), megabytes (m), kilobytes (k) or in database blocks
```

```
;  (b, the default)
;
;  Note that the segment size must be a multiple of the database page size
;  which is currently 8k. Also, the segment size must be divisible by the
;  number of stripe files constituting the segment.
;
;  The example below creates a 200 meg database striped on two segments
;  with two stripes of 50 meg and one of 100 meg.
;
;  You can always add more segments to the configuration, but once
;  added, do not change the setup.
;
[Striping]
Segment1        = 100M, db-seg1-1.db, db-seg1-2.db
Segment2        = 100M, db-seg2-1.db
```

Configuring Vectored Execution

Note: Only effective with Virtuoso 7.0 and later.

A Virtuoso 7 executable executes all SQL statements in vectored mode, except for positioned updates and deletes in stored procedures. Procedures are executed without vectoring unless they are declared vectored using the vectored keyword. A scalar (non-vectored) procedure can have a vectored block introduced with the for vectored construct. These are discussed in the SQL reference section on vectoring.

Vectored execution is controlled by the following virtuoso.ini settings:

- *VectorSize = 10000*

  : This is the default number of concurrent variable bindings that are generated for a column in a batch of bindings.
- *MaxQueryMem = 1G*

  : This controls the maximum amount of memory that can be used across the server process for large vectors, i.e. if the memory in use is near this limit, a query will not switch to large vector size even if it finds it useful. The event counter tc_no_mem_for_longer_batch counts how many times this situation is detected. A size letter of G or M follows the value.
- *AdjustVectorSize = 1*

  : If non-zero, this enables automatic increasing of vector size whenever the system notices a random access pattern that is not benefiting from vectoring due to too few consecutive hits falling on the same page. The vector size can be increased up to MaxVectorSize if the situation warrants. This is the case if there is enough unprocessed state in the query.
- *MaxVectorSize = 1000000*

  : This is the maximum vector size. This can reach up to 4000000 but values in excess of 1000000 have not been found useful in practice. If the server is running out of memory with multiuser workloads involving long queries, dropping the MaxVectorSize to a lower value is a means of curtailing per query memory consumption.
- *ThreadsPerQuery = 8*

  : This controls the maximum number of parallelizable work units a query will have outstanding at any one time. A value of 8 means that a scan or vector of lookups is maximally divided into 8 units, of which 7 will be allocated to a pool of worker threads and one will be processed by the thread coordinating the query. Each query will always have one thread running, which is the thread allocated for serving the client-server or HTTP request initiating the query. Extra work units are serviced by threads from a parallel execution thread pool. If there are unstarted parallel work units that have not started at the time the coordinated thread finishes its own work unit, it will execute any of its own pending work units locally.
- *AsyncQueueMaxThreads = 16*

  : This is the maximum number of worker threads that can be started for running parallelized work units generated by queries or functions requested with the aq_request () PL function. Thus the number of threads running on a server at any time is the number of client server or HTTP threads that have a running request plus this number. These threads consider the totality of all async execution requests across all async queues and each thread picks a unit of work from the oldest queue that has unstarted work units. The age of the queue is the timestamp of its creation. A queue is created whenever a query operator decides to split its work. This scheduling favors thus old queries over new ones. However any request is guaranteed one thread, that on which its initiating request is served.

For a query processing workload, one should set AsyncQueueMaxThreads to the number of cores minus the expected number of concurrent queries, this would in principle use all cores or core threads. In practice for machines with large numbers of cores, e.g. 32 cores, a lower value may serve in practice better, subject to experimentation. For a web crawling situation where threads are waiting for the network for most of the time, a larger number will do better.

These parameters can be set at run time by a dba group user using the `__dbf_set()` function.

Index Defragmentation

When data is inserted into tables, database pages are split and typically pages end up not being fully utilized. If data is inserted in ascending order of key value, which is often the case, space utilization is more efficient. Still, gaps can be left by updates, deletions and page splitting. Virtuoso has an autocompact feature which will take groups of adjacent dirty pages and see if it can fit the same content on a smaller number of pages. It will rewrite the pages to save space before writing these to disk. This operates automatically. Statistics on autocompaction are shown beside the Read ahead status line of the result set of status ('');. The number of pages affected by autocompaction and the number of resulting pages are shown. The numbers are cumulative since the start of the instance.

Autocompact is non-locking and if pages are busy, they will not be touched. Only relatively old dirty pages, about to be written to disk are considered for compaction, not interfering with the hottest part of the working set.

The automatic compaction is not however effective if pages are updated singly, never making stretches of consecutive dirty pages. Therefore a manual compaction function called DB.DBA.VACUUM () is also offered.

The vacuum stored procedure gets an optional table and index name and will read the index from beginning to end. If neither argument is given, all indices of all tables will be compacted. If only the table is given, all indices of this table will be compacted.

If consecutive leaves can be fit on fewer pages than they now occupy, this will rewrite them and free the pages left over. This does however require transient space since the pages are not really replaced until the next checkpoint, hence a vacuum operation can run out of disk. Using the checkpoint statement to force a checkpoint will free the space.

The effects and need for explicitly vacuuming a database can be assessed with the DB.DBA.SYS_INDEX_SPACE_STATS view.

Running:

```
select * from DB..SYS_INDEX_SPACE_STATS order by ISS_PAGES desc;
```

produces a result set with the most space consuming index on top. ISS_PAGES is the total count of pages. ISS_ROW_BYTES is the byte count of the rows. If dividing the total count of bytes by the count of pages is much below 8172, (8K - 20), chances are that vacuuming the index may save space. Note that blobs are not affected by vacuuming. If the blobs are small enough to fit on the row as normal strings they are already there. Otherwise they occupy the needed number of pages and cannot be made more compact.

Note that querying the SYS_INDEX_SPACE_STATS view will always read through all the allocated pages of the database and may take a while. The operation is not locking. Only the state as of the last checkpoint will be shown, hence it is a good idea to run the checkpoint statement before querying this view.

Examples:

```
DB..VACUUM ();
-- Compact all tables and indices of the Virtuoso instance

Db..VACUUM ('WS.%');
-- compact all tables of the WS. qualifier

DB..VACUUM ('DB.DBA.RDF_QUAD', 'RDF_QUAD_PGOS');
-- compact the rdf_quad_pgos index of the rdf_quad table.
```

Virtuoso has an autocompact feature.

Server Startup Command Line Options

Virtuoso Server

This section presents the command line switches of the Virtuoso server executable. Depending on the model and virtual database middleware the server will have different names, all starting with virtuoso-. All these however have the same options for UNIX systems and slightly different for Windows platform.

on Windows platform are available following server command line options:

```
Usage:
  virtuoso-odbc-t.exe [-clnCbDARf---dSIMKmrd] [+configfile arg] [+licensefile arg]
                  [+no-checkpoint] [+checkpoint-only] [+backup-dump]
                  [+crash-dump] [+crash-dump-data-ini arg]
                  [+restore-crash-dump] [+foreground] [+pwdold arg]
                  [+pwddba arg] [+pwddav arg] [+debug] [+service arg]
                  [+instance arg] [+mode arg] [+dumpkeys arg] [+manual]
                  [+restore-backup arg] [+debug]
  +configfile             specify an alternate configuration file to use,
                         or a directory where virtuoso.ini can be found
  +licensefile            specify an alternate license file to use,
                         or a directory where virtuoso.ini can be found
  +no-checkpoint          do not checkpoint on startup
  +checkpoint-only        exit as soon as checkpoint on startup is complete
  +backup-dump            dump database into the transaction log, then exit
  +crash-dump             dump inconsistent database into the transaction log,
                         then exit
  +crash-dump-data-ini    specify the DB ini to use for reading the data to dump
  +restore-crash-dump     restore from a crash-dump
  +foreground             run in the foreground
  +pwdold                 Old DBA password
  +pwddba                 New DBA password
  +pwddav                 New DAV password
  +debug                  allocate a debugging console
  +service                specify a service action to perform
  +instance               specify a service instance to start/stop/create/delete
  +mode                   specify mode options for server startup (onbalr)
  +dumpkeys               specify key id(s) to dump on crash dump (default : all)
  +manual                 specify when create a service to make it for manual startup
  +restore-backup         restore from online backup
  +debug                  Show additional debugging info

The argument to the +service option can be one of the following options
  start          start a service instance
  stop           stop a service instance
  create         create a service instance
  screate        create a service instance without deleting the existing one
  delete         delete a service instance
  list           list all service instances
```

The below are switches for server for UNIX platforms:

```
Usage:
  virtuoso-iodbc-t [-fclnCbDARwMKr---d] [+foreground] [+configfile arg]
                   [+licensefile arg] [+no-checkpoint] [+checkpoint-only]
                   [+backup-dump] [+crash-dump] [+crash-dump-data-ini arg]
                   [+restore-crash-dump] [+wait] [+mode arg] [+dumpkeys arg]
                   [+restore-backup arg] [+pwdold arg] [+pwddba arg]
                   [+pwddav arg] [+debug]
  +foreground              run in the foreground
  +configfile              use alternate configuration file
  +licensefile             use alternate license file
  +no-checkpoint           do not checkpoint on startup
  +checkpoint-only         exit as soon as checkpoint on startup is complete
  +backup-dump             dump database into the transaction log, then exit
  +crash-dump              dump inconsistent database into the transaction log, then exit
  +log6                    If you're starting with a Virtuoso 5 server, and migrating to a Virtuoso 6 or
                           later server, append +log6 after +backup-dump or +crash-dump.
                           Note: The extra +log6 argument is not needed, and may have unexpected effect,
                           so please leave it off if starting with a Virtuoso 6 server and moving to
                           Virtuoso 6 or later.
```

```
+crash-dump-data-ini   specify the DB ini to use for reading the data to dump
+restore-crash-dump    restore from a crash-dump
+wait                  wait for background initialization to complete
+mode                  specify mode options for server startup (onbalr)
+dumpkeys              specify key id(s) to dump on crash dump (default : all)
+restore-backup        restore from online backup
+pwdold                Old DBA password
+pwddba                New DBA password
+pwddav                New DAV password
+debug                 Show additional debugging info
```

The +*crash-dump* option will make use of the segmented log defined in virtuoso.ini for storing the recovery log. See Crash Recovery and virtuoso.ini below for more information. The other options will not use the segmented log.

The +*restore-crash-dump* option will alter the server startup sequence so that the recovery log produced by +crash-dump will be re-played correctly.

The +*mode* option can be a combination of the following letters:

o - only open the database and define the SYS_KEYS, SYS_COLS, SYS_KEY_PARTS, SYS_CHARSETS AND SYS_COLLATIONS system tables.

n - leaves out the initialization of the system tables.

b - do not process anything except the transaction log and system tables when restoring a crash dump (+restore-crash-dump).

a - leaves out the initialization of the replication, users, compilation or stored and system procedures, as well as the caching of the grants.

l - write only the schema tables in the backup or crash dump.

r - don't do the complete initialization (useful for performing a crash dump).

On Unix platforms the executable will detach itself from the console and run in the background as a daemon unless the +*foreground* switch is specified.

For Windows NT and Windows 2000, the Virtuoso server will normally be installed as a Windows service and can be started from the Control Panel or automatically at system startup.

Ordinarily the Windows service will be a system process that runs in the background. If you want the Virtuoso service on Windows to allocate a debugging console the you can use the +*debug* (-d) switch. This switch is only applicable to starting a service.

Virtuoso on Windows can be run directly from the command line using the +*foreground* (-f) switch. The server will then start in the foreground of the current "cmd" session. If this switch is not used then the executable on Windows will assume that you are attempting to start a Virtuoso service.

Windows services can be created and removed from the system as required. The default installation under Windows will create a service by the name: *OpenLink Virtuoso VDBMS Server* , and optionally another service with the name *OpenLink Virtuoso VDBMS Server [demo]* . The Demo service is a supplied demonstration database that can be installed.

The following options are available to the +*service* switch for configuring Virtuoso services:

The argument to the +service option can be one of the following options *start* start a service instance

stop stop a service instance

create create a service instance

screate create a service instance without deleting the existing one

delete delete a service instance

list list all service instances

They are used with the +*instance* <*name*> where <*name*> is the instance name to configure a particular instance. All instances are listed in the services applet, with their name in square brackets.

+*service list* can be used to obtain the list if services that are registered with Windows.

For each service listed you can start, stop, or delete the service.

+service create can be used to create a new service. In this case you also need to specify other start up options that would be associated with the new service entry. If you were using an alternative configuration file this must be specified using *+configfile* switch.

Note:

Make sure the Services Control Panel is closed, before attempting to modify services from the command line, otherwise locking may occur.

ZeroConfig ("Zero Configuration") Support

The "ZeroConfig" protocol, also known as "Zeroconf" or "Zero Configuration" is a protocol that allows discovery of services on the network that are advertised by their hosts. It also has provisions for automatic discovery of computers and various devices. The main benefit of ZeroConfig is that it does not require DHCP, DNS or directory servers.

ZeroConfig is an open protocol that Apple submitted to the IETF for a standard-creation process.

The Virtuoso server and ODBC driver use the capabilities of ZeroConfig to facilitate DSN (Data Source Name) setup and usage. This is divided in two parts: Server-side and Client-side.

The Virtuoso server (Server-side) is configured via the Virtuoso INI file to advertise its availability on a network with a given name. This allows applications, and in particular the Virtuoso ODBC driver, to receive information about a server, such as its network address, default login, etc, and use it for configuring a data source or directory making a connection.

The Virtuoso ODBC driver (Client side) uses ZeroConfig to locate the desired Virtuoso server during the set-up phase of a data source, and determine available connection options such as:

secure connection options

default database

default user

default password (if public/demo login is required)

default character set

ZeroConfig provides the client with a service name, which must be bound to the IP address/port of a host of the chosen service during DSN configuration. This is used when existing DSN using a ZeroConfig name is used to connect, it will map name with IP address and port before making a connection.

Setting-up the Server for Service Advertising

The Virtuoso server is configured to advertise itself based on the details specified in the `[Zero Config]` section of the Virtuoso INI file. Below is an example of such:

```
...
[Zero Config]
ServerName    = Virtuoso Server
ServerDSN     = UID=demo;PWD=
SSLServerName = Virtuoso Server (via SSL)
SSLServerDSN  = UID=dba;PWD=;ENCRYPT=1
...
```

The ServerName and SSLServerName are human readable strings chosen by the administrator to provide clients with a suitable description of the service being provided.

Note:

If the Virtuoso does not have the SSL listener enabled then the SSL service will not be advertised automatically. The SSL* keys will simply be ignored and do not need to be removed.

The ServerDSN and SSLServerDSN are default connection strings that can be used by clients to make the advertised connection. You only need to to specify default username and password in these strings. The default database can be specified or left to the setting for the username. You cannot specify the server hostname, IP address or port number, these are supplied by Virtuoso automatically.

ZeroConfig service advertising is multicast, hence it is advertised on all available network interfaces.

Using the Windows ODBC Driver with ZeroConfig

Upon DSN set-up the ODBC driver listens for advertising servers, and compiles a roster. This is displayed for the user to choose the desired service to connect to.

If ZeroConfig is used to for data source set-up then the set-up dialog will be initialized based on the details in the connection string configured on the server.

When a DSN is configured based on a ZeroConfig service, the driver will resolve the service name before making the connection to the server. The driver does not store the network address or port number of the Virtuoso server, only the ZeroConfig server name, so if the server's physical address is changed the client DSNs associated with it do not all have to reconfigured; they will resolve to the new address automatically on next use.

Server Status Monitoring

The database status report is divided into 6 sections:

Server
Database
Locks
Clients
Replication
Index Usage

Server

This section shows how many connections are open and how many threads the process has and how many are running at the present time. This also displays the number of requests that have been received but are not yet running on any thread.

Database

```
  File size 203161600, 24800 pages, 259 free.
  7000 buffers, 6987 used, 3884 dirty 8 wired down, repl age 8251 .
  Disk Usage: 14246 reads avg 6 msec, 74% read last  10 s, 14457 writes,
    4 read ahead, batch = 5.
Gate:  2729 2nd in reads, 0 gate write waits, 3372547 in while read 0 busy scrap.
Log = wi.log, 9851835 bytes
14950 pages have been changed since last backup (in checkpoint state)
Current backup timestamp: 0x0000-0x00-0x00
Last backup date: unknown
Clients: 18 connects, max 17 concurrent, 1024 licensed
RPC: 54441 calls, 17 pending, 17 max until now, 0 queued, 53988 burst reads (99%), 0 second
Checkpoint Remap 7646 pages, 0 mapped back. 0 s atomic time.
    DB master 24800 total 259 free 7646 remap 3415 mapped back
   temp  200 total 196 free
```

The status consists of the following items:

File size: The database file size in bytes or 0 if the database consists of statically allocated files. The total number of 8K database pages follows, then the number of free pages. The number of buffers shown the total count of 8K file cache buffers, followed by the number of used buffers and the number of buffers that are dirty at the time. The wired down count is normally zero but can be transiently other if pages are wired down for processing by threads in the server.

Disk Usage: Shows the cumulative total number of reads and writes and the average length of time spent inside the read system call for the database files.

The percentage is the percentage of the real time spent inside read between this status report and the previous status report. This may exceed 100% if several reads are taking place concurrently on different stripes in a multi-file database.

The Gate: Lists concurrent events. The *2nd in read* is the count of concurrent requests for the same page, the *gate write waits* is the count of times a modify operation had to wait for exclusive access to a page being read by another thread, the *in while read* is the count of file cache hits that have taken place while a read system call was in progress on another thread.

Databases. Thus section shows the count of pages, free pages, checkpoint remap and mapped back for the main database and the space for temporary data such as sort results and hash indices. The page count is the total size, the free count is the count of free pages, the checkpoint remap is the count of pages that occupy two pages in checkpoint space instead of one, the mapped back count is the number of pages that will return to their original place in checkpoint space at the next checkpoint. Understanding these is not necessary.

See:
The Disk Configuration section for a discussion of checkpoint remapping.

Locks

The lock section shows various locking statistics accumulated since the server was started. The deadlock count is divided into deadlocks caused by a situation where several transactions read a page and one wants to get write access and all other deadlock situations. The first is called 2r1w deadlock in the report.

The lock section also shows the total number of threads running, i.e. engaged in performing some operation for a SQL or web client. The number of threads waiting is the number of running threads that are presently waiting for a lock. The number of threads in vdb is the number of threads engaged in remote database operations or other 'slow' I/O, such as access to outside HTTP or SOAP services.

All locks currently in effect are listed with the owners (a) and possibly waiting transactions. The transactions are named after their client. A log or replication replay transaction is here named 'INTERNAL'.

Clients

Each connected client is listed with the number of bytes sent and received from the client. The transaction status is either PENDING for OK or BLOWN OFF or DELTA ROLLED BACK for a transaction killed by deadlock or timeout. The locks owned by the transaction are listed following the status. IE means exclusive and IS shared lock.

Replication

This section shows the server in question and a list of replication accounts either provided or received by this server. Accounts where the server name (left column) is the same as the server name are those provided by this.

The columns are server name, account name, last transaction number and status. The status is OFF for a local account or a replicated account where the remote is not available. It is SYNCING if a resync is in progress, IN SYNC if the account is up to date or REMOTE DISCONNECTED if there was a connection to a remote party which subsequently disconnected.

See Also:
RDF Graph Replication

Index Usage

This part of the report summarizes the database's access statistics. The output is a table with a row for each index in the database. Each row is composed of the following columns:

```
Table           The name of the table
Index           The name of the index. Same as the table for primary key.
Touches         The number of touches since startup. Each time the database
                engine looks at an entry of the index is counted as a touch.
                Not all touched entries are selected. For instance if the
                engine scans a table with non-indexed selection criteria it
                will touch each row but might select none.
Reads           The number of disk reads caused by reading this index.
%Miss           The percentage of touches that required a read. This can be
                over 100% since getting one entry may required more than one
                read if the top levels of the index are not in memory.
Locks           The number of times a lock is set on an entry of the index.
Waits           The number of times the engine has to wait for another
                transaction to finish in order to set a lock on this index.
%W              The percentage of waits of all locks set.
```

In interactive SQL

```
SQL> status();
```

Will print out the report.

Re-labeling Server Executable on Win32 Platforms

The Virtuoso Service name can be altered using the key *Win32ServiceName* in the *Parameters* section. The default name is 'OpenLink Virtuoso VDBMS Server'

To change the name of services:

stop the service
delete the service
change the name in file virtuoso.ini
create the service
start the service

Services with old names must be deleted before creating service with the new name, i.e. with the Win32ServiceName setting set to the current name of the service.

The name displayed in the ODBC Administrator, Setup and Configuration dialogs is taken from the driver section in the ODBCINST. This can be directly edited in the registry using the regedt32 Windows utility, or a registry import file can be created which can be applied by simply double-clicking the .reg file. Always exercise extreme caution when making changes to the registry.

Transport Level Security

Encryption

Virtuoso has the ability to encrypt it's CLI network connections using SSL. The server listens on a separate port for SSL CLI connections and handles them just as the normal CLI connections, vut now providing transport level security.

Server-side Support

Server side secure connections utilizes three parameters in the [Parameters] section of the virtuoso.ini:

SSLServerPort - Specifies the port on which the server listens for incoming SSL CLI requests.
SSLCertificate - The SSL certificate to use (same meaning as the SSLCertificate in HTTPServer section)
SSLPrivateKey - The server's private key (same meaning as the SSLCertificate in HTTPServer section)

These parameters should be all set in order to enable the SSL CLI server.

If SSLServerPort is not specified, then the Virtuoso server ignores the other two and does not listen for SSL CLI connections.

If a non-SSL connection is attempted to the SSL server port, the server rejects the connection. If an SSL connection is attempted against the non-SSL port the server rejects the connection.

Client-side Support

The client does not require any SSL-specific files (like Certificates or Private keys) in the SSL connection process.

Native Clients (e.g. ISQL). There is an custom ODBC connect option SQL_ENCRYPT_CONNECTION (=5004) supported by the Virtuoso CLI. It should be set before issuing the SQLConnect call. Values are 'NULL' (no encryption - default), '1' (encryption with no server X509 certificate checking and no X509 certificate sent to the server) and a valid file path to a PKCS#12 certificate file (protected with the same password as the one used to log in. Note that with the iODBC/ODBC clients this connect option is not applicable since the driver managers don't cache or pass through the custom ConnectOptions set before connecting to the data source. The ISQL has an additional option (-E) to do encrypted connects using the encryption option '1') and -X <file> to set the above option to the file supplied.

ODBC & iODBC Driver. The drivers support an additional DSN attribute:

```
ENCRYPT=<string>
```

If this attribute is not specified then it defaults to "No".

It has the same meaning as the SQL_ENCRYPT_CONNECTION options (see above). If this is not specified then it defaults to NULL.

The corresponding iODBC odbc.ini & ODBC Registry DSN attribute name is:

```
"Encrypt"= <string>
```

The Windows Connect & Setup dialogs have an additional wizard page to configure encryption.

X509 Certificate Support

Virtuoso supports X509 certificate validation: server side for both ODBC and HTTPS connections, and client side for the ODBC connections.

Server Side. To enable this option there are three new INI file parameters added the HTTPServer section for the HTTPS, and the Parameters section for ODBC):

X509ClientVerify - Whether the server will require X509 certificates from the browsers. If set to 1 a client should send a X509 certificate which will be validated against the server CA list.

X509ClientVerifyDepth - Specifies how deep the client certificate verification process will traverse the Issuer chain before giving up. The default value of 0 means that only verification of the client certificate itself being in the server's CA list is performed. Setting this option to -1 will ignore the depth checks.

X509ClientVerifyCAFile - a PEM (base64) file of all the X509 certificates of the Certification Authorities (CA) which the server will use for verifying the client's client certificate. A list of these will be sent to the client as a part of the SSL handshake so the client will know which certificate to send.

ODBC Client Side. In order for verification of the server certificate to take place a PKCS#12 file should be supplied to the ODBC client. It will use the CA list in this PKCS#12 to verify the server certificate. It will set the verification depth to -1 (unlimited) while performing such a check.

If the server certificate is not verified correctly it will refuse to connect to the server. When the ENCRYPT parameter is set to "1" (do SSL without X509 validation) the client will return a SQL_SUCCESS_WITH_INFO in SQLConnect/SQLDriverConnect with the Server's certificate subject and the verification result as the server will always send it's X509 certificate to the client as a part of the SSL connect handshake.

If the PKCS#12 file is supplied the ODBC client will try to open it using the login password. In order for the file to be successfully opened it should be encrypted with the same password used for logging in.

Normally when exporting a PKCS#12 file from other programs it will contain only the CAs of the Certificate validation chain. This means that client and server certificates should have common CA in their certificate chains in order to be used for ODBC X509 validation. The client certificate from the PKCS#12 file will not take place in the server certificate validation process.

`get_certificate_info()`

File System Access Control Lists

Access Control Lists (ACL) are used to restrict file system access.

These lists are maintained in the Virtuoso INI file under the Parameters section with entries such as:

```
DirsAllowed = <path> [, <path>]
DirsDenied = <path> [, <path>]

<path> := <absolute_path> or <relative_path>
```

Note:

A relative path is relative to the servers current working directory.

The Virtuoso ISQL utility can be used to check the Server DirsAllowed params as follows:

```
SQL> select server_root (), virtuoso_ini_path ();
```

The above should show in the result the server working directory and INI file name.

Also you can check the relevant INI setting by running following statement via ISQL command line utility:

```
SQL> select cfg_item_value (virtuoso_ini_path (), 'Parameters',
'DirsAllowed');
```

See Also:
Virtuoso INI File Configuration

ACL's work in the following way:

All paths are converted from relative to absolute paths.

The path beginning with <http_root> is always allowed.

All DB files are always access denied (.db, db segments, .trx, log segments, .ini specified in INI file etc.)

If a path is not allowed or exists as denied then access to the file is rejected.

If a requested path is allowed and not in denied then access is allowed.

ACL's are inherited. If a directory allows access so does its subdirectories.

The following functions are restricted by file Access Control Lists (ACL) in the virtuoso.ini file:

file_to_string

file_to_string_output

sys_mkdir

sys_dirlist

string_to_file

cfg_write

Note:
the cfg_write function has restrictions against changing file access control lists in ini file

6.1.2. Virtual Database

Linking Remote Tables & Views

The Virtuoso Server supports linking in of tables, views, procedures and other components from a remote ODBC data-source, enabling them to be queried as native objects in Virtuoso; this process is called "attaching" or "linking". The easiest way to link to an external table is to use the Linking Remote Tables Wizard , part of the Visual Server Administration Interface. Alternatively you can attach these objects programmatically, as this section explains; finally you can attach tables manually - see Manually Setting Up A Remote Data Source which is useful for connections to less-capable ODBC data-sources.

ATTACH TABLE Statement

```
ATTACH TABLE <table> [PRIMARY KEY '(' <column> [, ...] ')']
  [AS <local_name>] FROM <dsn> [USER <uid> PASSWORD <pwd>]
  [ON SELECT] [REMOTE AS <literal_table_name>]
```

table
: Adequately qualified table name of the form: identifier | identifier.identifier | identifier.identifier.identifier | identifier..identifier

column
: column to assume primary key

local_name
: fully qualified table name specifying local reference.

dsn
: scalar_exp

user
: scalar_exp

password
: scalar_exp

literal_table_name
: scalar_exp

This SQL statement defines a remote data source, copies the schema information of a given table to the local database and defines the table as a remote table residing on the data source in question.

The table is a designation of the table's name on the remote data source dsn. It may consist of an optional qualifier, optional owner and table names, separated by dots. This must identify exactly one table on the remote dsn. The optional local_name is an optionally qualified table name which will identify the table on the local database. If qualifier or owner are omitted, these default to the current qualifier 'dbname()' and the logged in user, as with CREATE TABLE. If the local_name is not given it defaults to the <current qualifier>.<dsn>.<table name on dsn>. The <dsn> will be the dsn with all alphabetic characters in upper case and all non-alphanumeric characters replaced by underscores. The <table name on dsn> will be the exact name as it is on the remote dsn, case unmodified.

The PRIMARY KEY option is only required for attaching views or tables where the primary key on the remote table cannot be ascertained directly from the remote data source.

If a dsn is not previously defined with vd_remote_data_source or ATTACH TABLE, the USER and PASSWORD clauses have to be given.

The *REMOTE AS* option allows you to provide a string literal for referencing the remote table. This is useful when linking tables from sources that do not support three-part qualification correctly.

Attaching views

A view can be attached as a table if a set of uniquely identifying columns is supplied.

This is done with the PRIMARY KEY option to ATTACH TABLE as follows:

```
attach table T1_VIEW primary key (ROW_NO) from 'somedsn';
```

Note:

Views cannot be attached unless the PRIMARY KEY options is used.

Examples for Linking Remote Tables into OpenLink Virtuoso

- Oracle
- Progress
- Ingres
- IBM Informix
- IBM DB2
- Sybase
- MySQL
- PostgreSQL
- JDBC
- ODBC to ODBC
- Firebird
- Microsoft SQL Server

Linking Remote Procedures

ATTACH PROCEDURE Statement

```
ATTACH (PROCEDURE|FUNCTION) <proc_name> ([<parameter1>[,<parameter2>[...]]])
  [ RETURNS <rettype> ] [AS <local_name>] FROM <dsn>
```

dsn
: scalar_exp

proc_name
: identifier | identifier.identifier | identifier.identifier.identifier | identifier..identifier

parameter1..parameterN
: parameters declaration (as in CREATE PROCEDURE)

local_name
: table

The ATTACH PROCEDURE statement allows you to associate stored procedures from remote datasources with Virtuoso so they can be used as if they were defined directly within Virtuoso. Much like the ATTACH TABLE statement, this SQL statement creates a local alias for a procedure on a given remote data source so it can be considered locally defined. When this alias is called called the procedure at the remote data source will actually be called.

Procedure generated result sets are not supported by the ATTACH PROCEDURE statement. The only portable way to return values from a remote procedure is to use INOUT or OUT parameters. Remote procedure result sets can be used by combination of `rexecute()` and Virtuoso PL, but this is left for the user to implement as required.

The ATTACH PROCEDURE statement is not able to define new connections to remote data sources, the connection should be defined prior using either vd_remote_data_source or by attaching a table or view using the ATTACH TABLE statement with USER/PASSWORD supplied.

Note that when generating pass-through statements to a given remote, any procedure call for an attached procedure is passed through if the current DSN is the same as the remote procedure's DSN.

The *proc_name* is the designation of the procedure's name on the remote data source, DSN. The remote procedure name supplied should always be fully qualified to avoid ambiguity, it may consist of an optional qualifier/catalog, optional owner and finally procedure name, separated by dots. This must identify exactly one procedure on the remote data source.

The optional *local_name* is an optionally qualified procedure name which will identify the procedure on the local Virtuoso database. If the local_name is not given it defaults to the <current qualifier>.<dsn>.<proc name on dsn>. The <dsn> will be the data source name in upper case and with all non-alphanumeric characters replaced by underscores. The <proc name on dsn> will be the exact name as it is on the remote dsn, case unmodified.

If a dsn is not previously defined with vd_remote_data_source or ATTACH TABLE, the ATTACH PROCEDURE will fail.

Example 6.3. Example:

On remote Virtuoso (DSN name : remote_virt):

```
CREATE PROCEDURE RPROC (IN PARAM VARCHAR) returns VARCHAR
{
  return (ucase (PARAM));
}
```

On the local virtuoso (DSN name : local_virt) :

```
vd_remote_data_source ('remote_virt', '', 'demo', 'demopwd');
ATTACH PROCEDURE RPROC (IN PARAM VARCHAR) RETURNS VARCHAR from 'remote_virt';
```

will result in creation of an procedure alias for RPROC in local_virt named DB.REMOTE_VIRT.RPROC

Calling it from the local_virt (using ISQL)

```
select REMOTE_VIRT.RPROC ('MiXeD CaSe') as rproc_result;

rproc_result
---------------
MIXED CASE
1 rows
```

Tip

The Virtuoso Visual Server Administration Interface provides a graphical user interface for linking remote stored procedures .

Data Type Mappings

If a statement is passed through to a remote data source, the types returned by SQLDescribeCol are taken directly from the remote prepare and converted to the closest Virtuoso supported type.

If a statement involves both local and remote resources all types are taken from the Virtuoso copy of the data dictionary.

In executing remote selects Virtuoso binds output columns according to the type and precision given by SQLDescribeCol after preparing the remote statement.

When a table is attached from a remote data source the catalog is read and the equivalent entries are created in Virtuoso. Since the types present on different DBMS's vary, the following logic is used to map ODBC types to Virtuoso types.

Table 6.1. Attach Table Type Mappings

SQL Type	Mapped Type
SQL_CHAR	varchar (precision)
SQL_VARCHAR	varchar (precision)
SQL_BIT	smallint
SQL_TINYINT	smallint
SQL_SMALLINT	smallint
SQL_INTEGER	integer
SQL_BIGINT	decimal (20)
SQL_DECIMAL	
SQL_NUMERIC	smallint if precision < 5 and scale = 0 integer if precision < 10 and scale = 0 double precision if precision < 16 decimal (precision, scale) otherwise
SQL_REAL	real
SQL_FLOAT	double precision
SQL_DOUBLE	double precision
SQL_BINARY	varbinary (precision)
SQL_VARBINARY	varbinary (precision)
SQL_LONGVARCHAR	long varchar
SQL_LONGVARBINARY	long varbinary
SQL_DATE	date
SQL_TIME	time
SQL_TIMESTAMP	datetime

Note:
The general case of decimal and numeric both revert to the Virtuoso decimal type, which is a variable precision decimal floating point.

Transaction Model

One transaction on the Virtuoso VDBMS server may contain operations on multiple remote data sources. As a general rule remote connections are in manual commit mode and Virtuoso either commits or rolls back the transaction on each of the remote connections as the main transaction terminates.

ODBC does not support two phase commit. Therefore a transaction that succeeds on one remote party may fail on another.

A transaction involving local tables and tables on one remote data source will always complete correctly since the remote is committed before the local and the local is rolled back if the remote commit fails.

Note that even though the client to Virtuoso connection may be in autocommit mode the continuing connections will typically not be autocommitting.

A remote connection is in autocommit mode if the Virtuoso connection is and the statement is passed through unmodified. In all

other cases remote connections are in manual commit mode.

Virtuoso supports 2PC - Two Phase Commit. See the Distributed Transaction & Two Phase Commit section for more information.

Virtual Database and SQL Functions

Different DBMS's support slightly different sets of SQL built-in functions with slightly differing names. For example, what is called substring on Virtuoso is called substr on Informix. Virtuoso allows declaring equivalences between local user-defined or built-in functions and user defined or built-in functions on remote servers. Knowing that a function exists on a remote database allows passing processing closer to the data, resulting in evident gains in performance.

To declare that substring is called substr on DSN inf10, you can execute:

```
db..vd_pass_through_function ('inf10', 'substring', 'substr');
```

The first argument is the name of the remote database, as used with attach table and related statements. If user defined functions with qualified names are involved, the names should be qualified in the vd_pass_through_function call also. If many qualified or unqualified forms of the name are in use, one should declare the mapping for them all.

To verify whether this declaration takes effect, one can use explain to see the query execution plan, for example:

```
explain ('select substring (str, 1, 2) from inf10.sample_table');
```

The declarations are persistent and can be dropped by using a last argument of NULL for a given function. The declarations are kept at the level of a DSN and not at the level of the type of DBMS because different instances can have different user defined functions defined.

Virtual Database and SQL Optimizer Statistics

If a query can be executed in its entirety on a single remote database, then optimizing this query is exclusively the business of the remote database, as it gets the whole query text. Virtuoso rewrites some things and suggests a join order but these are not binding on the remote database.

If a query involves tables from multiple remote databases or a a mix of local and remote tables, knowing basic SQL statistics on the tables is essential for producing a meaningful query plan. Virtuoso has information on indices existing on remote tables and if the remote table is attached from a known type of DBMS, Virtuoso may read the DBMS specific statistics at attach time.

Note that the statistics of the remote database should be up to date before attaching.

The function sys_db_stat can be used for forcing a refresh of Virtuoso's statistics on remote tables.

```
sys_db_stat (5, 0)
```

will go through all tables, local and remote. For local tables, it will update statistics with a 5 percent sampling rate and for remote tables it will refresh the statistics if the type of the host DBMS is among the supported ones. If the remote DBMS is of an unknown type, Virtuoso will take the count of the remote table and select the 1000 first rows to get a sample of data lengths and column cardinalities. This is not very precise but will be better than nothing.

In order to force a full read of a remote table for statistics gathering, one can use

```
db..sys_stat_analyze ('fully qualified table name', 0, 0);
```

The table name is case sensitive, with all qualifiers, as it appears in SYS_KEYS and other system tables. This will read the whole table.

Statistics on local as well as remote tables are kept in SYS_COL_STAT. One may look at this table to see the effects of remote statistics collection. In special cases, if a special effect is desired or the information is not otherwise available, as in the case of a very large table on an unsupported type of server, it is possible to manually update the contents of the table. Shutting down and restarting Virtuoso will force a reload of the statistics information.

Presently Oracle, Informix and Virtuoso are supported for direct access to the remote database's statistics system tables. It is possible to define hook functions for accessing this same information from any other type of DBMS. Please contact support for

instructions on this.

Distributed Query Optimization

When a query contains mixes of tables from different sources, the compiler must decide on an efficient execution plan that minimizes the number of round trips to remote servers and evaluates query conditions close to the data when possible. Additionally, any normal query optimization considerations such as choice of join order and join type apply. See the section on SQL optimization and optimizer hints for more on this. Additionally, the SQL optimizer uses round trip time statistics for the servers involved in the query.

In the following examples, we use the tables r1..t1, r2..t1 and t1, of which r1..t1 is on a server close by, r2..t1 on a server farther away and t1 on the local server. The column row_no is a unique key and the string1 column is in indexed with 300 distinct values, the column fs1 has 3 distinct values. The tables all have 100000 rows. A round trip to r1 takes 10 ms and a round trip to r2 takes 100 ms.

Consider

```
select * from r1..t1 a, t1 b where a.row_no = b.row_no and a.fs1 = 'value1';
```

The compiler notices that 33333 rows will be selected from r1..t1 based on fs1. It will decide to read these into a hash table, causing one linear scan of r1..t1 with relatively few round trips. Then it will read t1 locally and select the rows for which there is a matching entry in the hash. This is slightly faster than doing 33333 random lookups of t1. If fewer rows were selected from r1..t1, the compiler would do a loop join with the local t1 as the inner loop.

The absolute worst plan would be a loop join with t1 as the outer loop, with 100000 round trips to r1.

Now, if many tables are accessed from the same data source, the compiler tries to bundle these together into one statement. Thus, for:

```
select * from r1..t1 a, r1..t1 b, t1 c where c.string1 = '111' and b.row_no = c.row_no and a.row_no = b.r
```

The compiler will probably do the outer loop for t1, which is expected to select 100000/300 rows. Then it will do a round trip to r1 with the statement.

```
select * from t1 a, t1 b where a.row_no = b.row_no + 1 and a.row_no = ?.
```

This is likely better than doing the remote part as an outer loop, bringing all the approx 100000 results in. 333 round trips selecting 1 row is better than 100000 rows transferred. If the data source were further away, this could be otherwise, hence the importance of the round trip time statistic.

In distributed queries, the compiler will honor the option (order) and the join types e.hg. table option *(hash) insofar the tables are local.

Thus, if we wrote

```
select * from r1..t1 a, t1 b, r1..t1 c where c.string1 = '111' and b.row_no = c.row_no and a.row_no = b.r
```

the compiler could not merge the two tablesfrom r1 into a single query because the order were given and there is an intervening table not located on r1.

Use of Array Parameters

ODBC and other data access API's usually offer a mechanism for executing a single parametrized statement multiple times with a single client-server round trip. This is usually called support of array parameters.

Virtuoso can make use of array parameter support in ODBC drivers when available. Consider the statement:

```
insert into r1..t1 select * from t1;
```

Without array parameters, this would make a round trip to r1 for each row inn t1. With array parameters enabled, with a batch size of 100, this would make only 1000 round trips for 100000 rows, resulting in dramatic increase in performance. Typically, if the remote server is on the same machine, array parameters make such batch operations about 3x faster. If the remote is farther away,

the gain is greater.

Array parameters are used if the remote database and its ODBC driver support them. The feature is globally disabled in the default configuration because some ODBC drivers falsely claim to support array parameters. To enable this feature, the the ArrayOptimization entry in the [VDB] section of the ini file to 1. To set the batch size, use the NumArrayParameters setting. 100 is a reasonable value.

Some ODBC drivers also support array parameters for select statements. To enable using this, you can set the ArrayOptimization setting to 2. This may however not work with some drivers even if DML (insert/update/delete) statements do work with array parameters.

Timestamps & Autoincrement

A transaction timestamp is not the same across the transaction if the transaction has branches in different databases.

The data type and precision of a time stamp will also vary between different types of databases.

Hence timestamp columns coming from tables on different servers are not comparable for equality.

In inserts and updates of remote tables timestamps are assigned by the database where the table in question is physically located.

Identity or autoincrement columns are likewise handled by the database holding the remote table.

Note that MS SQL Server and Virtuoso describe a timestamp column as a binary column in ODBC catalog and meta data calls. Thus remote SQL Server or Virtuoso timestamps will not appear as timestamps at all.

In the case of a Virtuoso remote database the binary timestamp can be cast into a DATETIME data type and it will appear as a meaningful datetime.

VDB Stored Procedures & Functions

These procedures allow you to manually manage remote data sources and their tables.

- vd_remote_data_source()
- vd_remote_table()
- rexecute()
- rnext()
- rmoreresults()
- rclose()
- rstmtexec()

Functions capable of returning a result-set make use of the *results_set* parameter. To prevent them from returning a result-set, the *results_set* parameter should be set to 'null'. If Virtuoso finds an awaiting parameter to contain *results_set* it will fetch the result set regardless of *cursor_handle* parameter.

Unless explicitly granted, only the DBA group is permitted to use the `rexecute()` to maintain security. Caution is required here since any user granted use of `rexecute()` has full control of the remote data source set-up by the DBA, however limited to the overall abilities of the remote user on the remote data source. Users can be granted and denied access to this function using the following commands:

```
GRANT REXECUTE ON '<attached_dsn_name>' TO <user_name>
REVOKE REXECUTE ON '<attached_dsn_name>' FROM <user_name>
```

The following remote catalogue functions help you to obtain information about the remote datasources that you are using. These could be especially useful in Virtuoso PL later on if you are not able to know everything about the remote tables ahead of time for the ATTACH TABLE statement

- sql_data_sources()
- sql_tables()
- sql_columns()
- sql_statistics()

- sql_primary_keys()

Manually Setting Up A Remote Data Source

Defining a remote table involves declaring the table as a local table and then defining the data source if not already defined and associating the new table with the remote data source.

The data source on which a table resides is declared at the table level. This has no connection to the table's qualifier.

Assume a remote ODBC data source named test containing a table xyz declared as follows:

Example 6.4. Example:

```
CREATE TABLE XYZ (
A INTEGER,
     B INTEGER,
     C INTEGER,
     PRIMARY KEY (A));
```

To defined this as a remote table on the data source Virtuoso, first define the table locally, using the above CREATE TABLE statement above.

Then define the data source:

```
DB..vd_remote_data_source ('test', '', 'sa','');
```

And the table:

```
DB..vd_remote_table ('test', 'DB.DBA.XYZ', 'master.dbo.XYZ');
```

This assumes that the remote data source has a login 'sa' with an empty password and no special connection string options. The table names in vd_remote_table have to be fully qualified. We here assume that the Virtuoso table was created by DBA in under the default qualifier DB and the remote XYZ was created by dbo in master.

The vd_remote_table declaration does not affect statements or procedures compiled prior to the declaration.

Additional indices of remote tables may optionally be defined. They do not affect the operation of the SQL compiler. The remote data source makes the choice of index based on the order by clause in the statement passed through.

Caveats

- Never attempt to attach a local table as a remote. The server will hang if it tries to make a remote commit on itself.
- If the schema of the remote table is changed it will need to be re-attached to Virtuoso.
- The Virtuoso server treats dots (.) in the double-quotes escaped names as name element separators. For example : the table name "a.b.c" is treated as "a"."b"."c" . Because of this remote tables with dots in their table name (like tables from MS Text driver) require the dot inside the table name to be replaced with the VDB "non-delimiting-dot" (\x0A) and the vd_attach_table (in dsn varchar, in remote_name varchar, in local_name varchar, in uid varchar, in pwd varchar) to be used instead of ATTACH TABLE statement.

  The statement ATTACH TABLE "datafile.txt" as 'test' from 'text' user 'a' password 'b' should become :

  ```
  vd_attach_table ('text', 'datafile\x0Atxt', 'test', 'a', 'b');
  ```

When Virtuoso interacts with a table or view attached from a remote data source, it must be able to uniquely identify each row of the query. At the attach time Virtuoso will query remote data source for the tables primary keys and indices. These will be used to construct a copy of the table definition in Virtuoso which is then used in reference to the remote data source. At query time this information is used as much as possible. This information may need to be supplemented by calls to SQLStatistics() for further indicies or primary key information, as a last resort Virtuoso will use SQLColAttribute() to determine which columns are SQL_DESC_SEARCHABLE.

6.1.3. Virtuoso User Model

The Virtuoso User Model is designed to support:

Use of an external server for password and user account base maintenance for example an LDAP server, another database server etc. This allows user accounts to be verified against security information stored in some centralized repository, allowing integration into existing security infrastructure .

Single namespace for users and groups for SQL and web service access. In this way the local security info is stored in one place and allows enabling SQL account to work as a web account or a web account as an SQL account. This enforces unique names for users and roles in the database.

Extensibility of user information retrieval and checking.

Extensibility of user account and group attributes.

There is a set of functions for administering the users and groups (roles) of a Virtuoso database. All the user administration functions are restricted to members of the dba group only.

Note:
The terms 'role' and 'group' are identical in their usage in this document. The terms security object or grantee refer collectively to users and groups.

User manipulation functions do not generally return values. In case of error an error condition will be signaled.

Users and roles are in the same namespace and are identified by name. One name will not both designate a user and a group. A user or group may be SQL enabled. A name that identifies a role (group) does not have a password and is not a valid login name.

A user may belong to multiple roles. A role may inherit multiple other roles. One role may be inherited or directly granted to a security object multiple times. The order of granting is not relevant. The effective privileges of a user are those granted to public, those granted to the user plus those granted to a direct or indirect role of the user. The relationship between users and roles is many to many. A role can be granted multiple other roles as well as direct permissions. Cycles in granting roles are not allowed, an error will be signaled if an operation would result in a cycle in the role inheritance graph.

When SQL procedures or queries are executing, the effective privileges are those granted to the owner of the procedure or view. A top level dynamic SQL statement executes with the effective privileges of the logged in user. If a SQL statement executes as a result of an HTTP request, the applicable virtual directory specifies on behalf of which SQL account the SQL is executed. A role cannot be the owner of procedures, views or other executable SQL entities.

Security Objects Management

The following functions allow for creation and deletion of security objects and roles, and for assigning or removing roles from security objects:

```
USER_CREATE()
USER_ROLE_CREATE()
USER_DROP()
USER_ROLE_DROP()
USER_CHANGE_PASSWORD()
USER_SET_QUALIFIER()
USER_GRANT_ROLE()
USER_REVOKE_ROLE()
USER_SET_OPTIONS()
USER_GET_OPTIONS()
```

The security objects and roles data are contained in the system tables described in the User System Tables Section of the Appendix

User Options

- **PASSWORD_MODE.** Function for checking a given password on SQL or DAV login. See below.
- **PASSWORD_MODE_DATA.** Application specific data for the Password Mode hook.
- **LOGIN_QUALIFIER.** Default qualifier for SQL session.

- **SQL_ENABLE.** If set SQL login is granted.
- **DAV_ENABLE.** If set the user account can be user for web authentication.
- **DISABLED.** If set the user account is locked and cannot be used to login as SQL or Web user (depends of SQL_ENABLE and DAV_ENABLE flags). If the account in question is SQL enabled the DBA group can switch the execution identity to it (see set_user_id () function). This is useful when we need an account to execute Web pages (VSP/VSPX) with some execution permissions but we do not want to allow it to login via SQL/ODBC.
- **PRIMARY_GROUP.** This is the primary group of the user. This is no different from other group memberships.
- **GET_PASSWORD.** Function that will retrieve the password. If not defined the password is assumed to be in the SYS_USERS table. This allows for custom encrypted storage of passwords etc. This is simpler to use than the check hook. Note that for security configurations where the server never does know the passwords of user accounts, no digest based authentication schemes can be used, including the HTTP digest authentication, since the digests cannot be computed and checked without knowing the password. Possible users of this feature are DBEV_LOGIN or HTTP login hooks.
- **E-MAIL.** informative: e-mail of that user.
- **FULL_NAME.** informative: full name of the user.
- **HOME.** WebDAV home directory of the account, it is meaningful only if the account is web enabled.
- **PERMISSIONS.** WebDAV default permissions for new WebDAV objects created by the user. This is only meaningful when web access is enabled.

The functions for setting/getting these options will accept any other named values, the above list only being those reserved for Virtuoso so far.

Login Extension PL Hook

```
DB.DBA.USER_FIND (in name varchar, )
```

This is a user-defined PL function hook which, if it exists, will be executed before doing the SQL/ODBC login. In this hook the user can find a user account from some other server and register it in the local database. Or, this can be used to perform some pre-login actions. It is similar to the DBEV_LOGIN, but it does not change any account validation rule, it is purely for pre-processing.

See Also:

The Database Event Hooks chapter.

PL Hooks Examples

Example 6.5. Querying an LDAP Server

```
create procedure DB.DBA.LDAP_SEARCH (inout user_name varchar, in digest varchar)
{
  whenever sqlstate '28000' goto ldap_validation_failure;
  if (lcase(user_name) <> 'dba'))
    {
      ldap_search('foo.bar.com', 0, 'o=organization', '(cn=a*)',
                sprintf('uid=%s,ou=users,o=organization', user_name), pwd_magic_calc(user_name,digest,1))
      user_name := 'dba';
      return 1; -- force validation as dba
    }
  else
    {
      -- bypassing ldap authentication for dba, let validation occur normally
      return -1;
    }

ldap_validation_failure:
  return -1; -- try to validate normally
}

create procedure DB.DBA.DBEV_LOGIN (inout user_name varchar, in digest varchar, in session_random varchar
{
  declare get_pwd varchar;
  get_pwd := user_get_option (user_name, 'PASSWORD_MODE');
  if (get_pwd is not null)
    {
      declare rc integer;
      rc := call (get_pwd) (user_name, digest);
```

```
      return rc;
    }
  return -1;
};

user_create ('test_ldap', 'secret', vector ('PASSWORD_MODE', 'DB.DBA.LDAP_SEARCH'));
```

Example 6.6. USER_FIND PL Hook Example

```
create table
MY_DBA_USERS (M_NAME varchar primary key, M_PASSWORD varchar);

create procedure
DB.DBA.USER_FIND (in name varchar)
{
  -- do nothing for existing users
  if (exists (select 1 from SYS_USERS where U_NAME = name))
    return;
  -- if there is in custom table
  if (exists (select 1 from MY_DBA_USERS where M_NAME = name))
    {
      declare pwd varchar;
      -- get password
      select M_PASSWORD into pwd from from MY_DBA_USERS where M_NAME = name;
      -- create a new SQL user based on external data
      USER_CREATE (name, pwd, NULL);
    }
};
```

SQL Role Semantics

The terms user group and role are used interchangeably. Roles can be nested. There is a many to many relationship between users and roles. There is likewise a similar, acyclic many to many relationship between roles. Each role has a component role list of its granted (parent) roles, recursively, no cycles allowed.

All role grants are listed in the roles system table whether they be explicitly granted or only as a result of granting a group with groups granted to it. The role grant graph has an explicit edge for each role membership, direct or otherwise. The GI_DIRECT flag is true if the grant is direct. Only direct role grants can be revoked.

See Also:

The role system table description can be found in the appendix under System Tables .

The following SQL statements deal with roles. To create a new role (group) object the following statement can be used:

```
CREATE ROLE <NAME>
```

The <NAME> is a name of role to be created. It must be unique in space of all security objects.

Example 6.7. Creating a security role

```
SQL> create role admins;
```

Use the following statement to remove an existing role from the security schema.

```
DROP ROLE <NAME>
```

Example 6.8. Removing a security role

```
SQL> drop role admins;
```

The GRANT and REVOKE statements are used for controlling role membership as follows: To assign a new group, or list of groups (<ROLE>,...) to user <USER> use:

```
GRANT <ROLE> [, <ROLE>] TO <USER> [WITH ADMIN OPTION];
```

If the admin option is specified, the grantee can grant this same privilege further to other grantees.

Roles can be revoked using:

```
REVOKE <ROLE> [, <ROLE>] FROM <USER>;
```

Example 6.9. Granting & revoking security roles

```
SQL> grant admins, users to demo;

SQL> revoke admins from demo;
```

Only the dba group accounts may administer roles.

The dba group is not physically a role. When an empty database is created, it will have the dba account with full privileges. To grant these same full privileges to another user, the dba uses the grant all privileges to <grantee>. statement. This will give the grantee full dba privileges, or in other words, add to the dba group. This may be reversed with the revoke all privileges from <grantee> statement.

The GRANT statement accepts any valid SQL security object in the TO clause. One cannot log in or perform any operations as a role. Roles are exclusively shorthand for specific sets of permissions which are changed together and are needed for multiple users.

6.1.4. VAD - Virtuoso Application Distribution

VAD provides a package distribution framework for installation, management, dependency checking and un-installation of Virtuoso applications. A VAD package contains all required Virtuoso components, which would constitute an application or hosted solution, within a single distributable file. A VAD package cannot contain any system parts independent of Virtuoso thus excluding operating system executables, shared objects, installers or settings.

Virtuoso and VAD provide the following abilities:

List all installed VAD packages.

List all completed operations over VAD packages.

Dependency checking - Check preconditions for installation of a package.

Install a VAD package.

Verification of installed package, compare to distribution state with ability to build of list of locally changed parts of the package.

Check preconditions for un-installation of a package.

Uninstall a VAD package.

Summary of VAD Operations

The following is what the dba needs to know about VAD packages.

A VAD package is installed from a file with the db..vad_install SQL function. The first argument is the file path, which must be in a location that the server process can open, i.e. it is in the DirsAllowed list in the virtuoso.ini file. The second argument is 0, meaning that we are installing from a file.

```
SQL> vad_install ('conductor_dav.vad', 0);
```

is an example. If the package installation fails, the server exits and will have to be restarted. No effects of a failed installation will remain in the database after restart. Contact the supplier of the VAD package for further instructions.

To know what is installed, do:

```
SQL> vad_list_packages ();
```

VAD package installations are not recorded in the transaction log. Thus, if there is a backup followed by archived transaction logs produced if CheckpointAuditTrail is on in virtuoso.ini, the VAD install must be performed before replaying any logs that were made after the VAD installation. The package installation must be just in the right place in the replay sequence. In practice it is simplest to make an incremental backup after installing and packages, see backup_online () or the section on backing up.

For any further information, including how to make VAD packages, see the rest of this chapter.

VAD Package Composition

A VAD package has no developer tie-ins; it is built in a development environment from source code that can be managed and versioned in the developers system of preference.

The VAD package is described by an XML structure called the 'VAD Sticker'. The VAD sticker describes items to deploy, procedures to execute at install and uninstall time and all conditions to be checked to ensure correct installation. The VAD Sticker consists of the following:

- VAD package meta data
    - Names of package, developer, copyright holder etc.
    - Version number of package, build date, build number, build type (e.g. sort of optimization performed).
    - Dependency information: minimal/maximal allowed version numbers of Virtuoso server and depending VAD packages. Every required package may include hint-text that may help the administrator determine (a) why the dependent package is required, and (b) how to obtain the required package.
    - Information regarding known conflicts between packages; conflicting package names and version number, with optional troubleshooting hints.
    - Ability to uninstall, a flag and list of reasons why it may be impossible to uninstall the package.
    - Custom configuration data to be placed in the VAD Registry
- Locations of SQL files containing main and installation code:
    - Pre-install code, used to check application-specific installation preconditions.
    - Application specific table and view definitions.
    - Application specific stored procedure and trigger definitions.
    - Post-install (initialization) code, such as initial contents of tables.
    - Pre-uninstall code, used to check that it is safe to uninstall a package.
    - Post-uninstall code, used for removal of cached resources unusable or meaningless without the package.
- Locations of Resources:
    - Documentation files.
    - Samples data for demonstration or package sanity check.
    - VSP/VSPX pages, related graphics, Java scripts, stylesheets, other web content.
    - XML docs, XSLT sheets, DTDs and Schemas.

Package Versioning

All required packages should be listed in the VAD sticker. Known conflict may be listed in either of the conflicting VAD packages stickers, hence VAD stickers of all installed packages should be checked.

Later versions of a package may be installed replacing earlier versions of the same package. This however can be prohibited by listing either version (or limit) as a known conflict in either VAD package sticker in the usual way. Furthermore, it is possible to prevent re-installation of a package by stating that it conflicts with itself. This provides some security against exploits involving attempts to upgrade, downgrade or re-install a package, in the hope that the administrator may corrupt the existing installation by installing new packages and working through installing their dependencies.

Packages may differ in language and encoding of documentation and resource files, even though the version number remains the same. If a package is sensitive to internationalization issues, the developer should either assign different names to various localizations of the package, or divide it into kernel package for any language-independent parts and set of language-specific packages, with some dependency between them.

Processing of Resources

During creation of a VAD package, the "location" mentioned above may be name of a file in file system or URI or DAV path. Upon package-time, URIs will be resolved and resources under them will be copied into the package. The resulting sticker will thus contain the location of resource within the package, the resource itself, and the target location.

All SQL files have a specific order of loading. Tables, views etc. must be defined before being referenced.

Unsupported Features of VAD

The VAD specification explicitly does not define the following:

Method of development or environment. There are no specific restrictions for the schema or Virtuoso/PL code of the package. The VAD system does not make assumptions on the method of software development.

Method of source code control or versioning. Version numbers used in the sticker have nothing common with tag labels in a developers versioning system. Procedures edited directly within the database using a web interface or CASE tools should be exported to a file for inclusion in a VAD package. If the application developer uses some script to export such code, this script is not usually part of sticker or the resulting package.

Shipping/Deployment the VAD package from vendor to user. VAD provides no methods for downloading dependent packages, or check for package updates etc.

Concurrent running of multiple versions of the same VAD package on a single server. There can be no guarantee that pre- or post-installation checks will provide valid results if more than one VAD is being processed at the same time. VAD does however guarantee that a package installation will be either entirely successful or entirely rolled back.

Installation or maintenance of non-Virtuoso hosted components. Unlike Virtuoso-based packages, these components are usually operating system specific, they may require some complex tuning, and their usage from within Virtuoso applications may even require changes in virtuoso.ini configuration file. VAD packages may contain test calls in pre-installation SQL procedures to check that required external executables are available and provide the functionality required.

Data migration. Some installations may require several days to complete migration/conversion of stored data. Whilst it may be possible to provide a restricted service during such time, VAD contains no tools to simplify such a process, this is left to the administrator or developer. VAD completes its work right after the execution of the post-installation code.

Synchronous installation of a package on all hosts of a distributed system or cluster. VAD has no standardized metadata regarding replication issues, hence package-specific code may be required. Similarly, if a cluster uses "round-robin" or a "director" loading management system and the server should be stopped for VAD installation, the administrator should explicitly inform the cluster manager about this event.

Security

Since VAD packages are run by an administrator as the database DBA user, care must be taken to ensure the package comes from a safe source. Any new package installed may violate the security regulations of the target database and may even inflict damage to files under the web-root of the Virtuoso Server or in directories specified in the "DirsAllowed" parameter of the virtuoso.ini. If the virtuoso.ini parameter "AllowOsCalls" is enabled then the installation procedures of the package may call operating executables. It is the responsibility of the database administrator to control this via the "AllowOsCalls", "SafeExecutables" and "DbaExecutables" parameters of the virtuoso.ini.

VAD packages do not offer any automatic protection against unauthorized modifications. Although ever VAD package contains a checksum, its purpose is to guard against data transfer errors, it may not be sufficient to detect unwanted modification.

Building VAD Packages

Initially, the VAD sticker and resources may reside in the file system, DAV directory and or other locations available through the `DB.DBA.HTTP_URI_GET()` function.

The VAD creation operation parses the VAD sticker's XML description and constructs the VAD file by calling `DB.DBA.VAD_PACK`.

This function reads the VAD sticker identified by the *sticker_uri* which contains the vad:package root element. Then the resources identified in the sticker are retrieved. All resource URIs are interpreted in the context of the *base_uri_of_resources* and are parsed and checked to be syntactically correct. Resources are appended to generated package that will be stored at the *package_uri* . DB.DBA.VAD_PACK returns a human readable log of error and warning messages, it will signal errors if any resource or database objects are unavailable at build time.

By convention, VAD package files have the extension '.vad'.

VAD Utilities

An optional VAD package named VADutils provides various tools for capturing changes made in the database after some point in time. The result of a capture consists of:

- Database object additions whose names match given patterns (e.g. all tables and procedures within a particular catalog/qualifier).
- Resource additions under particular locations.
- Post-install local customizations of selected packages.

The capture results may be useful for the following purposes:

- Archival of changes for replaying later.
- Creating a special package of the changes for applying against a fresh installation of the package.
- Creating a new complete package containing both the original and changes that will be included in the package sticker.

These mechanisms provide good support for centralized development and custom deployment methodology. If a site is localized to contain local links, graphics, custom layout and such, then VAD capabilities offer help to the developer to define the specific overlay of customizations over another VAD package. When the underlying VAD package is updated the local customizations will be overwritten. Being saved in a VAD package, customizations can be reapplied over the updated base package.

VAD Administrator Responsibilities

VAD package installation, upgrade and uninstallation requires a temporary break of service. The package checks may be performed on the fly if it can be guaranteed that the resources being inspected will not be altered by any users. The package check is a read-only process and operates solely within the VAD Registry using read-only functions.

All VAD operations are logged in the server event log. All completed operations are reflected in the DB.DBA.VAD_HISTORY system table.

The optional VADutils package provides some additional administrative tools, mostly for troubleshooting. These include special installation and de-installation functions that can ignore error signals, and provide an interactive editor for the VAD Registry etc.

All operations described below require DBA access to the database.

Check if a VAD package may be installed by calling DB.DBA.VAD_CHECK_INSTALLABILITY .

Checks the presence and correct versions of required packages and of the Virtuoso platform. It does not executes any pre-install Virtuoso/PL code from the package, so there's no guarantee that installation will be successful if the check found no error. If *package_uri* is DAV path, *is_dav=1* , else *is_dav=0* .

Perform VAD Package Installation by calling DB.DBA.VAD_INSTALL .

If *package_uri* is DAV path, *is_dav=1* , else *is_dav=0* .

The administrator performs the following operations when installing:

- Invoke the install procedure from the web user interface or interactive SQL. This will perform the following:
  - Install documentation files.
  - Check for version and prerequisite package compatibility.
  - Disconnect SQL users and terminate web processing.
  - Make a database checkpoint.

    - Run the pre-install SQL script.
    - Load SQL code in the VAD package, in the order specified by the developer.
    - Copy web resources (VSP, VSPX, XSLT, etc.) into their designated places in WebDAV or file system Web root.
    - Run any post-install SQL code.
  - If the installation was successful, the server will come back on-line.
  - If the installation was unsuccessful, e.g., mid-install failure due to running out of disk space, or some other serious unrecoverable database error, the Virtuoso server will exit. The administrator should consult the Virtuoso log file to see what caused the failure. The installation can be completely undone manually by halting the server (if not already stopped), and removing the transaction log file (.trx). Upon Virtuoso restart, the server will continue from the last checkpoint, made prior to install, as if the installation never took place.

The return value of the `DB.DBA.VAD_INSTALL()` function is usually a sum of messages from pre- and post-installation procedures of the package. It should normally contain at least the following:

- any errors and/or warnings encountered.
- created users and catalogs/qualifiers
- root VSP page for accessing the application, if applicable.
- path to installed documentation files.
- performance optimization hints.

The VAD packages should be tested to install on an empty Virtuoso database, after any required VAD packages. Installing a package on an empty server is useful for determining that no other procedures or components were missed. Since the application would normally run on the development machine where the VAD package was built, it can be easy to overlook some components. The completeness of the source archive of the application and its independence from any ad hoc SQL objects is important, this is the only way the package can be reliably versioned, tracked or uninstalled.

Check if a VAD package may be uninstalled by calling `DB.DBA.VAD_CHECK_UNINSTALLABILITY`

Performs a preliminary read-only checks to see whether the package given can be uninstalled. This does not execute any pre-uninstall Virtuoso/PL code from within the package at this stage. Hence, the success of this function does not guarantee that uninstallation will be successful.

Perform VAD Package Uninstallation by calling `DB.DBA.VAD_UNINSTALL`.

The administrator will perform the following operations for the uninstallation process:

- Invoke the uninstall procedure from the web user interface or interactive SQL. This will initiate the following:
    - Check that no other packages are using the package to be uninstalled.
    - disconnect SQL users and terminate web processing.
    - Make a database checkpoint.
    - Run the pre-uninstall SQL script.
    - Remove web resources installed by the package (all VSP , VSPX, XSLT, etc files) in WebDAV or the filesystem under the web root.
    - Drop all SQL procedures and data. This is performed in reverse order to the install.
    - Run any post-uninstall SQL code.
    - Remove documentation files explicitly marked as removable. Usually documentation would not be deleted as part of package uninstallation in case it is needed e.g. if a set of documents is distributed as VAD package)
  - If uninstallation was successful the server will come back on-line.
  - If uninstallation was unsuccessful, the server will exit. Uninstallation could fail due to lack of disk space or some other serious unrecoverable database error. The failed uninstallation attempt can be manually reversed by halting the server (if not already) and deleting the transaction log file (.trx). Upon server restart Virtuoso will continue from the last checkpoint, made prior to uninstallation, as if the uninstallation was never attempted. The administrator should consult the log file for clues to the failure.

Check the state of VAD package installation by calling `DB.DBA.VAD_CHECK`.

This checks to see if the elements of the package are as they are defined in the original distribution. A list of differing elements is returned. Differences revealed may not indicate a corruption, such changes could have been made intentionally by another package, possibly a later version or upgrade that added some columns to tables, and some resources may be customized by the

user post-installation.

This will check for the prior existence of tables, views etc owned by other applications that are not compatible with this application. Any such schema objects found are listed, the installation will not continue. These may be dropped by the DBA to help the installation to succeed. Some such elements may not be part of some other package, hence no package uninstall would be available leading the DBA to drop them with the appropriate SQL commands.

To enable automatic vads updates on server startup, set the VADInstallDir parameter in the [Parameters] ini section with path the folder containg the vads files.

Package Overlap

Each package contains full definitions of all tables and indices. Upon installing the following outcomes can occur:

- If a table already exists with the same primary key as the new definition, additional columns are added to the table. If the primary keys differ, the installation automatically fails. Note that a pre-install SQL script can be defined to explicitly alter tables if consecutive versions of an application use different primary keys.
- Existing indexes are left untouched. New indices are added as specified in the package. If indices should be modified or dropped, the pre-install script is a reasonable place for dropping these.

Thus the same SQL schema can be loaded twice without ill effect.

The post install script should be used to populate tables and such. Inserts should be executed using the insert soft statement so that attempts to insert duplicate are silently ignored without causing the installation to fail. The post install script can perform any application level data format changes.

Packages should define their own distinct catalog or qualifier. They should not overwrite another package unless upgrading a prior version. Sometimes a package will require the use of another package's tables. This should be achieved via grants issued in a pre-install script. A schema element such as a table, view or procedure will always have at most one owner package even though it may be referenced or even modified with additional columns by another package installed later. These elements will only be dropped when the owner package is dropped. Tables created ad-hoc from interactive SQL do not have any owner package.

VAD Sticker

The VAD Sticker contains meta-data and descriptions of resources contained, or to be contained, within a VAD package. Like any XML documents, the target VAD package sticker can be sourced from more than one source file, which can aid maintenance and development.

VAD Sticker DTD

The namespace vad, used below, represents the URI `http://example.com/urn/vad`.

The top level element of a VAD Sticker is <sticker>. It must contain a <caption> element and may contain <dependencies>, <procedures>, <ddls> and <resources> elements.

```
<!--<<top>>-->

<!ENTITY % vad.source_sticker "INCLUDE">
<!ENTITY % vad.package_sticker "IGNORE">
<!ENTITY % vad.ecm.group_content "(dependencies | procedures | ddls | resources | registry)" >
<![%vad.source_sticker;[
  <!ENTITY % vad.ecm.sticker "(caption, (group | %vad.ecm.group_content;)*)">
  <!ELEMENT group ((group | %vad.ecm.group_content;)*) >
  ]]>
<![%vad.package_sticker;[
  <!ENTITY % vad.ecm.sticker "(caption, %vad.ecm.group_content;)">
  ]]>
<!ELEMENT sticker %vad.ecm.sticker; >
<!ATTLIST sticker
  version     NMTOKEN #REQUIRED
  xml:lang    CDATA   #REQUIRED
  >
    <!--<</top>>-->
```

```
    <!--<<caption>>-->

<!ELEMENT caption (name, version)>
<!ELEMENT name ((prop)*)>
<!ATTLIST name
  package NMTOKEN #REQUIRED
  >
<!ELEMENT version ((prop)*)>
<!ATTLIST version
  package NMTOKEN #REQUIRED
  >
<!ELEMENT prop EMPTY>
<!ATTLIST prop
  name NMTOKEN #REQUIRED
  value CDATA #REQUIRED
  >
    <!--<</caption>>-->
```

The caption contains one name and one version element. These elements have a package attribute for keeping requisites used by VAD procedures. Other prop-s are for keeping admin-readable info, but they will not affect the installer's behavior. Typical names of properties here are Vendor, Copyright, Release+Date, Build, Language, Encoding, but any (even non-unique) names are acceptable.

Sticker's elements for dependencies

```
<!--<<dependencies>>-->

<!ELEMENT dependencies ((require | allow | conflict)*) >
<!ATTLIST dependencies>
<!ENTITY % vad.ecm.version_list "((version | versions_earlier | versions_later)*)">
<!ELEMENT require (name, %vad.ecm.version_list;) >
<!ELEMENT allow (name, %vad.ecm.version_list;) >
<!ELEMENT conflict (name, %vad.ecm.version_list;) >
<!ATTLIST require
  group NMTOKEN #IMPLIED
  >
<!ELEMENT versions_earlier ((prop)*)>
<!ATTLIST versions_earlier
  package NMTOKEN #REQUIRED
  >
<!ELEMENT versions_later ((prop)*)>
<!ATTLIST versions_later
  package NMTOKEN #REQUIRED
  >
    <!--<</dependencies>>-->
```

Element dependencies contains an list of packages related to given one. For every version or range of versions of every package, developer may specify whether the given version is required for the package, or allowed but not required, or will cause some sort of troubles.

More precisely, to find information about some particular version of a package, the list of children of dependencies element will be scanned from top to bottom. If the first matching record is in conflict group, not in require or allow, then installation is impossible. From other side, there must be at least one installed package for every require section.

Element require may be labeled with optional group attribute. As an exception from common rule, there must be at least one installed package for every group of require sections with identical name. E.g. If an installation of package B requires either of two interchangeable packages A1 and A2, sticker should contain a pair of nodes in the same group:

```
<require group="G">
  <name package="A1">...</name>
</require>
```

...

```
<require group="G">
  <name package="A2">...</name>
```

```
</require>
```

Note:

There are no methods to specify that exactly one package, either A1 or A2, should be installed. It must be done by placing proper conflict descriptions in stickers of A1 and/or A2, but not in the sticker of B.

Sticker's elements for procedures

```
<!--<<procedures>>-->

<!ELEMENT procedures ((sql)*)>
<!ATTLIST procedures
  uninstallation (supported | prohibited) #REQUIRED
  >
<![%vad.source_sticker;[
  <!ENTITY % vad.sql.include "include CDATA #IMPLIED">
  ]]>
<![%vad.package_sticker;[
  <!ENTITY % vad.sql.include "">
  ]]>
<!ELEMENT sql (#PCDATA)>
<!ATTLIST sql
  purpose (install-check | pre-install | post-install | uninstall-check | pre-uninstall | post-uninstall)
  %vad.sql.include;
  >
    <!--<</procedures>>-->
```

Element procedures contains an list of Virtuoso/PL fragments, and every fragment is tagged by one of four values of the purpose attribute. At every stage of install or uninstall VAD procedure, a whole list of procedures will be scanned from the beginning to the end, and all procedures of appropriate sort will be executed in the same order as they are listed. In source sticker files, include attribute may be used to insert text of some external file instead of having SQL code written inside the element.

Sticker's elements for ddls

```
<!--<<ddls>>-->

<!ELEMENT ddls ((sql)*)>
<!ATTLIST ddls
  >
    <!--<</ddls>>-->
```

Element ddls is very similar to procedures and contains an list of Virtuoso/PL fragments to create schemas etc.

Sticker's elements for resources

```
<!--<<resources>>-->

<!ELEMENT resources ((file | location)*)>
<!ATTLIST resources >
<![%vad.source_sticker;[
  <!ENTITY % vad.file.source_uri "source_uri CDATA #IMPLIED">
  ]]>
<![%vad.package_sticker;[
  <!ENTITY % vad.file.source_uri "">
  ]]>
<!ELEMENT file EMPTY>
<!ATTLIST file
  type (doc | http | dav | code | special) #REQUIRED
  source (http) "http"
  target_uri CDATA #REQUIRED
  makepath (yes | no | abort) "abort"
  overwrite (yes | no | abort | equal | expected) "equal"
  package_id CDATA #IMPLIED
  location IDREF #IMPLIED
  dav_owner CDATA #IMPLIED
```

```
  dav_grp CDATA #IMPLIED
  dav_perm CDATA #IMPLIED
  %vad.file.source_uri;
  >
<!ELEMENT location ((prop)*) >
<!ATTLIST location
  id ID #REQUIRED
  default_target_uri CDATA #REQUIRED
  >
    <!--<</resources>>-->
```

Element resources lists all files to be copied onto target box. For every file, source and target URIs should be specified, and suggested behavior for cases when a directory should be created or file should be overwritten. Target URI may be relative to one of roots: for documentation, web-resources, DAV, SQL code (it's where virtuoso.ini is located) and one of special locations, additionally specified by location elements. (Installer may query administrator to allow changing of locations' roots; in such case, information from location's properties will be shown to the administrator.) By default, the value of *package_id* is a space delimited list of type, location ID (if any) and target URI.

dav_owner - DAV owner for file (used if type="dav", ignored if "filesystem");

dav_grp - DAV group for file (used if type="dav", ignored if "filesystem");

dav_perm - DAV permissions for file (used if type="dav", ignored if "filesystem").

Example 6.10. VAD installable file descriptions

To install files into DAV:

```
<file type="dav" source="http" target_uri="yacutia/yacutia_style.css" dav_owner='dav' dav_grp='administra
<file type="dav" source="http" target_uri="yacutia/yacutia_vdir_style.css"  dav_owner='dav' dav_grp='admi
```

To install files into file system:

```
<file type="http" source="http" target_uri="yacutia/yacutia_style.css" makepath="yes"/>
<file type="http" source="http" target_uri="yacutia/yacutia_vdir_style.css" makepath="yes"/>
```

Sticker's elements for registry

```
<!--<<registry>>-->

      <!ELEMENT registry ((record)*)>
      <!ATTLIST registry >
      <!ELEMENT record ANY>
      <!ATTLIST record
        key CDATA #REQUIRED
        type (STRING | INTEGER | KEY | URL | XML) #REQUIRED
        overwrite (yes | no | abort | equal | expected) "equal"
        >
    <!--<</registry>>-->
```

Element registry lists all branches to be defined in the VAD Registry. Every record element contain data of one record. The first children of record element (either a text or an element) will be serialized and stored as a value of *DB.DBA.VAD_REGISTRY.R_VALUE* cell. To prevent errors, it is recommended to keep comments to the data outside the record element: being in the wrong place inside, they may be stored in the registry instead of actually needed data.

Example 6.11. Sample Stickers

A package that contains only some commonly useful ("exported") functions, one table for internal purposes, a small sample VSP application, and small set of documentation files.

```
<?xml version="1.0" encoding="ASCII" ?>
<!DOCTYPE sticker SYSTEM "vad_sticker.dtd">
<sticker version="1.0.010505A" xml:lang="en-UK">
 <!-- Name and version; common data about the package -->
```

```
 <caption>
  <name package="rdf_lib">
   <prop name="Title" value="RDF Support Library" />
   <prop name="Developer" value="OpenLink Software" />
   <prop name="Copyright" value="(C) 2024 OpenLink Software" />

6.1.5. Data Backup & Recovery

Administering a database involves taking backups and having a readiness to recover from backups and subsequent transaction logs.

Backups can be taken in two principal ways:

Using the Virtuoso backup function/procedures.

Copying the database files.

The Virtuoso backup functions can be used from any client directly, such as ISQL. It is possible, and perhaps preferable, to create stored procedures for performing the backup functions and scheduling these with the Virtuoso scheduler.

The actual database file(s) can be copied while the database is running so long as no checkpoint is made during the copy process. Checkpointing can be disabled for this, but make sure it is re-enabled after the backup has been made.

Making a full backup of a large database can take several hours if not days just due to the speed of tapes or local area networks. Full backups must in all cases be done without an intervening checkpoint. This is why frequent full backups are not desirable. To ensure the possibility of full recovery one must have the complete set of transaction logs (audit trail log) since the last backup.

Restarting the database after restoring backed up files will show the state in effect since the last checkpoint preceding the backup. Any transaction log files made after the point of backup can be replayed to bring the state up to the last recorded transaction.

Log Audit Trail

Virtuoso can maintain a transaction audit trail. This is enabled using the CheckpointAuditTrail setting in the virtuoso.ini file. When this setting is non-zero, Virtuoso will begin a new transaction log after each checkpoint. Thus one automatically gets a full, unbroken sequence of transaction logs for the entire age of the database. These logs are named as specified in virtuoso.ini and are suffixed with their creation time.

Transaction logs older than the log that was current at the time of the last backup are superfluous for recovery, since their transactions were checkpointed before the backup started. Transactions of the log current at the time of the backup are NOT in the backed up state since they were not checkpointed, i.e. written into the read-only section of the database containing the data being backed up.

We strongly advise having the CheckpointAuditTrail enabled in any production environment.

It is good practice to have at least two generations of full backup, since the last backup may contain errors that were not known at the time of its making. If such precaution is taken then only transactions logs older than the oldest backup are safe to remove. If we needed to recover from the oldest backup for any reason we would require all audit transaction logs created during and after that backup.

A Virtuoso database can be restored from the last full backup and all Audit Trail transaction files created during and after the backup. You would need to start the database as normal with the backup version of the database file. Once the database has been started, connect using iSQL. You can then use the replay() function to replay the transaction files up to the required point. It is vital that these files are replayed in the correct order.

On-Line Backups

Backup Using Backup_Online()

Virtuoso is capable of performing online backups so that normal database operation does not have to be disrupted in order to take backups. The `backup_online()` can be used to backup the database in the state effective at the last checkpoint to a series of

backup files.

The database storage is divided into a checkpoint space that is a read only image from the time of the last checkpoint and thus can be safely backed up anytime between checkpoints and the commit space where updates subsequent to the last checkpoint data are stored. Additionally, the database records what pages have changed since the last checkpoint every time new checkpoint is made. This change tracking makes it possible to make incremental backups. The first time the backup_online function is called, it saves a compressed copy of the then current checkpoint state into one or more files. The next time it is called, it will write the changes that have come into the checkpoint space since the last time backup_online was called. It is possible to erase the change tracking data with the backup_context_clear function. The next call to backup_online will then make a full backup. Files generated by one or more calls to backup_online without intervening backup_context_clear form a series with distinct serial numbers and will be restored together. In order to restore such files, the administrator must delete the previous database files and start the server with a special flag and indicate the location of the backup files. This will bring the database to the state corresponding to the state as of the checkpoint immediately preceding the last call to backup_online, i.e. the one that wrote the newest of the backup files being restored. To restore onwards from this state, the administrator must replay transaction logs, starting with the log that was current when the last call to backup_online was made. In order to preserve all such logs, one must run with the CheckpointAuditTrail ini parameter set to 1.

A database checkpoint cannot be performed while an online backup is in progress.

Example 6.12. Performing an Online Backup

```
SQL> backup_context_clear ();
SQL> checkpoint;
SQL> backup_online ('virt-inc_dump_#', 150);
```

The `backup_online()` procedure differs from the the CheckPointAuditTrail mainly because it can be started from any point in the database. Unless CheckPointAuditTrail was enabled when the database was created, the database file at a particular state and all transaction logs created by the AuditTrail since that state would be required to restore the database. Only the backup set files would be required to restore from `backup_online()` . The `backup_online()` also makes a compressed backup, making it far more suitable for large databases.

The last optional parameter allows to point the directory(ies) where the backup files must be stored. See `backup_online()` description for details.

Restoring From an Online Backup Series

To restore from a backup series the administrator must first shutdown the Virtuoso database server and move all database files (e.g. virtuoso.db and virtuoso.trx) out of the database directory. It is recommended that copies by taken rather than deleting them entirely. Then the command:

```
<virtuoso exe> +restore-backup <FILE_PREFIX>

-- for example:
virtuoso-iodbc-t +restore-backup dump-20011010_#
```

must be issued in the directory where the "*.bp" were stored. The database will then be restored. The expression <virtuoso exe> above must be replaced with the path and filename to the Virtuoso server executable used on your system (e.g. ..\virtuoso-odbc-t.exe).

Each file in the series has a header containing a unique identifier, for the backup set and the sequence number of the file in the backup set . If an identifier in any file in the backup sequence differs from the identifier contained in the first file, the restoration process will stop and report an error, which is written to the Virtuoso log file.

At times the backup or restoration commands may return errors. Use the following list to help diagnose and resolve them:

- **Timestamp [%lx] is wrong in file %s.** The unique identifier in header of the file differs from the identifier of the first file. It is possible that the file was renamed or corrupt or belongs to another backup set.
- **Number of file %s differs from internal number [%ld].** The sequence number of the file does not correspond to the internal sequence number of file. This could be caused by the file being renamed or corrupt.

- **Prefix is wrong in file %s.** The prefix of the file does not correspond to internal information. Possible reason: file was renamed or corrupt or belongs to another backup set.
- **Could not begin online-backup.** Read error. Possible reason: Virtuoso database file was corrupt.
- **Seek/Read failure on stripe %s/database.** Read error. Possible reason: Virtuoso database file was truncated or hardware error.
- **Read of page %ld failed.** Read error. Possible reason: Virtuoso database file was truncated or hardware error.
- **Backup file writing error.** Write error. Possible reason: disk is malfunctioning or full.

Example 6.13. Restoring an Online Backup

Following the online backup example above:

```
SQL> backup_context_clear ();
SQL> checkpoint;
SQL> backup_online ('virt-inc_dump_#', 150);
```

The following command could be used to restore the database from the backup files created:

```
virtuoso-iodbc-t -c <db-ini-file> +restore-backup virt-inc_dump_#
```

or:

```
virtuoso-odbc-t.exe -c <db-ini-file> +restore-backup virt-inc_dump_#
```

Other Backup Methods

A possible way of making a full backup of a large databases is first to turn off any automatic checkpoints and make a compressed copy of the files. After the back up is complete, checkpointing should be re-enabled. The files should be compressed to make efficient use of space, and should be copied to a disk separate from the location of the database, and preferably to an external backup medium such as tape.

Manual Backup

For a large database it is best to turn off any automatic checkpoints and copy the database files to external storage. Checkpoints should be turned off by issuing the command:

```
checkpoint_interval (-1);
```

at the SQL prompt. Checkpoints can be re-enabled in a post-backup script by:

```
checkpoint_interval (<n>);
```

which sets the automatic checkpoint interval to <n> minutes. The backup will be unusable if there are checkpoints made while it is in progress. Thus it is important to guarantee that checkpoints do not occur. The only safe way of doing this is the above, since it is in principle possible to have a server crash during the backup and a roll forward following restart, all while the backup is in progress. If this happens the backup will be readable and consistent with the state of the last checkpoint if and only if there are no checkpoints between its start and completion. Setting the interval to -1 will guarantee that the server, when starting after recovery will not make a checkpoint.

The dba must make sure that clients do not issue checkpoint or shutdown statements while a backup is in progress.

The presence or absence of checkpoints at a given point in time can be ascertained from the virtuoso.log event log file.

Off-Line Backups

When Virtuoso is not running a complete and clean backup can be taken by making a copy of the database file and transaction file(s) created after the last checkpoint.

To get an up to the minute copy of a running database one can copy the database file and the associated log, i.e. the file specified in TransactionFile in the database's configuration file. When started, the log will roll forward and restore the database to the state following the last logged transaction.

Database Recovery

Rebuilding A Database

The process of rebuilding a database consists of dumping its contents into a large log file, or log files, and doing a roll forward from an empty database with that log.

The general steps to rebuild a database are as follows:

Important
It is recommended that you take a backup copy of the database file(s) prior to performing this procedure.

- Shut down the running server, making a checkpoint. This is done with the SHUTDOWN command from interactive SQL.
- Make sure there is a log file specified in virtuoso.ini.
- Start the server process virtuoso with the -b command line option: e.g. % ./virtuoso -b (+backup-dump)

  This will write the contents of the database into the log file specified in virtuoso.ini and exit when complete.
- Take a backup of the old database file.
- Change the DatabaseFile setting in virtuoso.ini to a non-existing database file or delete the old database file.
- Start the server with the +restore-crash-dump option. The option is essential.

  Important: When restore on v6 you also must give it +log6 flag i.e.: +restore-crash-dump +log6 .

  See Also:
  How can I move a Virtuoso database from one hardware and/or software platform to another?
- The server will build a new database file from the log and once completed it will, by default, perform a checkpoint of the transactions to the database file and start listening at the specified port. Virtuoso can be started without a checkpoint using the -n (+no-checkpoint) option.
- You may then connect to the database with interactive SQL and if necessary make a checkpoint. The checkpoint will write freeze the state following roll forward and delete the log used for the rebuild.
- The database is now ready for normal use.

It may sometimes be useful to rebuild a database as above to save space. Virtuoso does not relinquish space in the DB file back to the file system as records are removed, however, Virtuoso does reuse pages that are made available from a deletion of records. The steps above will build a new compact database file. You would ordinarily not have to worry about this.

Diagnosing and Recovering a Damaged Database File

It is possible to recover data from a damaged Virtuoso database by a procedure similar to rebuilding a database as described above. A database file may be corrupt if the database repeatedly crashes during a specific operation.

To determine whether a database is corrupt, you may use the backup to a null file command in isql, for Unix platforms:

```
SQL> backup '/dev/null';
```

For windows platforms you can use:

```
SQL> backup 'NUL';
```

This command will read through the database checking its integrity. If the server crashes before completing the backup process, then the database is indeed corrupt and needs to be recovered. No other activity should take place while the command is executing.

To recover the database, follow the procedure for rebuilding it, except use the -D 'capital D' or +crash-dump switch instead of -b. This will construct a log file which you can replay to make a new database. The database will contain the transactions that were committed as of the last successful checkpoint. If the database altogether fails to open it may be the case that the schema is damaged.

It is possible that the database to be recovered is too large to fit in a single log file. The crash dump feature therefore allows segmenting the recovery log into a number of files. See the virtuoso.ini configuration file documentation for details. It is possible

to make a crash dump in several pieces if there is not enough total disk space to hold the dump on the system where the database is running.

If the recovery log is split over several files it is necessary to set the transaction file in the ini to point to the first of these files, delete the database file(s) and start the server with the +restore-crash-dump option. When the server comes online, one can connect to it with isql and use the replay () function for replaying the remaining logs, one by one, in their original order.

For example,assuming the virtuoso.ini fragment:

```
Log1    = rec-1.log 100M
Log2  = rec-2.log 100M
```

we would make the dump with

```
virtuoso +crash-dump
```

and once the server has been started with +restore-crash-dump, with the ini setting TransactionFile set to rec1.log, replay the remaining log with the isql commands:

```
SQL> replay ('rec-2.log');
Done.
SQL> checkpoint;
```

Note:

If the recovery is interrupted it can be restarted at the last checkpoint made during the recovery. Note that a mid recovery checkpoint may take a very long time, e.g. 1 hour for a 10GB database, since it is possible that the delta since the previous recovery checkpoint comprise almost all the database.

Crash Recovery When The Normal Crash Recovery Fails

When the schema tables (e.g. DB.DBA.SYS_COLS, DB.DBA.SYS_KEYS) have corrupt rows the normal crash dump/crash restore procedure will not be possible because the server relies on the schema tables to know the key layouts for reading the data rows of other tables upon crash dump.

In such situations there is a special procedure to be followed to save as much data as possible from the corrupt database. The general steps are:

dump the intact schema table rows, and read them into a fresh database

read the schema from the fresh database in the normal way

proceed with dumping the rest of the tables from the corrupt database

Thus the transaction log produced from the corrupt database, when replayed on the new database file (the one holding the schema tables data) makes the closest approximation to the corrupt database's data. However, this will not produce a workable database by itself - it may possibly deny inserting of data into tables with IDENTITY columns and will lose all the data within the Virtuoso registry (accessible from `registry_get()` /`registry_set()` functions).

Because of the very nature of the crash-restore process described here and because of the fact that data is lost in the database schema, the server will not attempt to dump tables whose schema description is lost. So care should be taken when reading the data from the database.

This restoration procedure in no way replaces the regular database backup procedures, it merely tries to save whatever reasonable data there may be left from the database file.

The recovery sequence is as follows:

1. Do a crash dump of the schema tables (using the '`+crash-dump +mode oa +dumpkeys schema`' virtuoso command line options).
2. Create a new INI file to describe the layout of the new database you'll use to temporarily fill up the restored data.
3. Move the transaction log file(s) produced in step 1 to the location required by the new INI file.
4. Replay the transaction log from step 1 on an empty database using the new INI file. You will now have the schema tables readable in the new database (and nothing else):

```
Virtuoso options : -c <your new ini file> +restore-crash-dump -f
```

5. Make a crashdump of the data in the non-schema tables of the old database while having read the schema tables from the new database:

```
+crash-dump -c <your new ini file> +crash-dump-data-ini <your old ini file> +mode o -f
```

6. Move the transaction log file(s) produced in step 1 to the location required by the new INI file.
7. Replay the transaction log from the previous step into the new db file using:

```
-c <your new ini file> +restore-crash-dump
```

8. Do a normal crash dump of the new database:

```
-c <your new ini file> +crash-dump
```

9. Move away (backup) the original (old) database files and put the transaction log produced by the above step into the location specified in the original INI file. You can also delete the rest of the DB files of the new database at that point.
10. Replay the transaction log to make the old database afresh.

To automate the above procedure, a sample Unix script follows that automates it somewhat. This script expects the crashed database virtuoso.db.save and an appropriate INI file (no striping, no log segmentation, transaction log file name virtuoso.trx) in the current directory and creates the restored database. It also expects the virtuoso-iodbc-t executable to be in the operating system path. Also, make sure that you have a suitable `virtuoso.lic` license file in the current directory.

```
#!/bin/sh

rm -rf xmemdump.txt virtuoso.trx virtuoso.tdb virtuoso.log virtuoso.db virtuoso.lck core.* new.lck new.lo
cp -f virtuoso.db.save virtuoso.db
cat virtuoso.ini | sed 's/virtuoso\./new./g' > new.ini

virtuoso-iodbc-t -f +crash-dump +mode oa +dumpkeys schema

ls -la *.trx
mv virtuoso.trx new.trx

virtuoso-iodbc-t -c new -f -R
virtuoso-iodbc-t -c new +crash-dump +crash-dump-data-ini virtuoso.ini +mode o -f

ls -la *.trx
mv virtuoso.trx new.trx

virtuoso-iodbc-t -c new -R -f

virtuoso-iodbc-t -c new +crash-dump -f

rm -f virtuoso.trx virtuoso.tdb virtuoso.log virtuoso.db virtuoso.lck
ls -la *.trx
mv new.trx virtuoso.trx

virtuoso-iodbc-t -R -f
```

Crash Recovery Across Virtuoso VDBMS Server Versions

If the database was created with a version prior to the one being used for rebuilding, the system tables may be different. The creation here refers to the first time the database was made, a crash recovery does not count as a fresh start here.

If this is or may be the case, the first log must be rolled forward into the empty database BEFORE the new and possibly incompatible system tables are created. This is done by setting the TransactionFile parameter to the first of the recovery logs and starting the server with the -R or +restore-crash-dump switch. For good practice one should also specify the no checkpoint switch, so that the log will in no case be damaged after the initial step of the roll forward. After this initial step the system tables will be compatible and the dba can proceed to replay the remaining recovery logs with the replay function.

Backup and Restore individual table(s) and individual index(s) on a new fresh db

This section describes how to get a part of db tables and restore on a new db.

Additionally, part of the steps from below can be used to backup separate table and recover on same db.

Note: Only effective with Virtuoso 6.0 and later.

Basic steps:

1. Create a function for dumping the key:

```
create procedure bkp_key (in f any, in tb_name varchar, in key_name varchar)
{
  backup_prepare (f);
  backup_index (tb_name, key_name);
  backup_flush ();
  backup_close ();
}
;
```

2. On the source db execute:

```
bkp_key ('mylog.txn', 'DB.DBA.T1', 'T1');
```

   This will dump in a "mylog.txn" file the T1 table's primary key.
3. On source db stop server and do:

```
virtuoso +backup-dump +foreground +mode l   ## ( lower case L )
```

   This will dump the schema tables only into the trx file.
4. On the target db make sure there is no db file and place the trx file produced by previous step. Execute:

```
virtuoso +restore-crash-dump +foreground ;
```

   This will create a new db with same db schema as on the source db.
5. Start the target and do:

```
replay ('mylog.txn') ;
```

   This will insert the PK data into the table from the source db dump.
6. If the table in question has other indexes must drop them and re-create them, since they are empty as in previous step we have been restoring only the PK.

Note : following the steps from above can be dumped each index and then replay. Also the steps may be combined for multiple tables and keys in the backup procedure - just needs to be added the corresponding calls to the backup_index() function.

6.1.6. Performance diagnostics

This section provides a checklist for improving performance of a Virtuoso server.

If something does not work fast, this is mostly for the following reasons:

- Not enough memory
- Not the right indices, missing statistics
- Too much locking or too many threads on the same data
- Bad disk layout, for example not striped or not enough file descriptors.

Determining which is the case is simple. The result set returned by status (') has most of the information. Do this twice with some 10 seconds between the samples and see the second result set.

Memory

If there is not enough memory, there will be frequent disk access. This is seen from the buffers and disk usage lines.

The very simplest test for this is looking at the CPU % of the process in top. If there is constant load and the percent is low then the server is IO bound.

If all memory is not in use, then memory cannot be the problem. This is seen from the buffers line. If the used number is under 80% of the total or if the replace age is several times larger than the count of buffers, then things are OK. If the replace age is 0 then no buffers have ever been replaced and all that ever was read is still in memory.

If the replace age is less than or close to the buffer count times 4, then cache replacement is frequent and adding buffers is advised.

Adding more than 60-70% of system ram as buffers is not useful. The setting is NumberOfBuffers in the ini file, count 9K per buffer.

The disk access is summarized on the disk usage line. First is the number of reads since start then the average latency in N ms. If %r is high, then a lot of the time between the previous status and this is taken by disk. This can be over 100. One thread that is waiting for disk all the time counts for 100. If the percent is high then adding more disks and striping over them will be useful. Even with a single database file, adding file descriptors (FDsPerFile setting in the ini) may be useful. If the average read latency is 0 or close, then the data is cached by the OS. If it is high, then adding disks and striping may reduce it.

The read ahead line will tell if there are sequential reads. These are faster than random ones and can efficiently use striped disks.

If the workload is random access, then a high number of read ahead means that one might not have the required indices, thereby causing full table scans. More on this in the query plans section below.

Swapping

Swapping is always bad. If swapping occurs, then one has too many buffers and should decrease the number of buffers. Use an OS tool like top to see the size of the database process and its virtual memory use. Having a resident size smaller than logical size is not always bad since some code or data in the process may simply be unused but having, after running in a steady state, i.e. all buffers used, a resident size less than the amount of memory allocated for buffers is always bad. Before steady state, i.e. during cache warm-up, the resident size is normally less than the buffer pool's size.

To see the count of major page faults. i.e. ones that read the disk, do:

```
getrusage ()[]4];
```

through interactive SQL. The result is the count of major faults since starting the process. The count should not vary between samples, at least not more than a few units per minute.

This function is not available under Windows. Use the task manager instead for tracking this.

There can be an actual memory leak, specially with plugins or hosting. See the growth of the virtual size throughout the run, reaching full buffer utilization and doing a couple of checkpoints. Past this, the process should not grow. You may also see if the ThreadCleanupInterval or ResourcesCleanupInterval ini parameters have an effect. If in spite of all the process grows there can be a genuine leak. It is normal for the size to fluctuate somewhat due to varying amounts of uncommitted data, threads, connections and the like.

Locking

The lock status section indicates the count of deadlocks and waits. If the 2r1w number is high then it means that the application should read for update. It gets shared locks and cannot change them to exclusive. Adding the for update option to selects in the right place will fix this, also setting DefaultIsolation in the ini to 2 for read committed will be good. If the lock wait count increases fast, then locking may downgrade performance. The threads line below shows how many threads have some task to do. The waiting is the number of these threads that are waiting for a lock at the time of the status. The vdb number is the number of threads waiting for network io, either from virtual database or any web protocol.

Take a few samples and if these show few threads waiting and the waits or deadlocks counts do not climb much locking will not be a problem. If these numbers are high, see the sys_l_stat view for details.

```
select sum (waits), sum (wait_msecs) from sys_l_stat;
```

for the totals. The first number is the count of times a thread waited for a lock, the second is the sum of the real times spent waiting.

```
select top 10 * from sys_l_stat order by waits desc;
```

shows the keys on which most waits take place. See also the deadlocks and the wait_msecs columns. Numbers are cumulative.

For details on disk, see:

```
select top 10 * from sys_d_stat order by reads desc;
```

These views are explained in more detail in the performance meters section.

If there is a multi-user application doing random access for read or write, it is an idea to partition the data so that they do not hit the same page all the time. For example, to allow for parallel insert of orders without contention, the TPC C schema prefixes the order number with a warehouse and district number, so that simultaneous inserts will most often not hit the same page.

Even when there is no locking, there is still some serialization for database page access. This is shown in the various wait columns of SYS_L_STAT. If the sum of the waits for a key is over 1% of the touches for the key, as given in SYS_D_STAT, there is contention and a performance penalty of maybe 10%.

Such things can be improved by altering the schema design and configuration parameters do not usually help. If there is disk access, having more memory always helps because then locks will be in effect for less time.

Query Plans

To know if there is a bad query plan, see the explain output of the query.

Unless a full table scan is intended, a full table scan is pretty much always bad.

In the explain () result set, a table access is marked by a From table name. Below is mentioned the driving index, the conditions on the index and the conditions that are not indexable.

Joins are listed one after the other, the outermost first. The join order can be read from the explain output going from top to bottom.

If a table is read on a non primary key and columns not covered by the driving index are accessed, there is a second key mentioned with a full match of the primary key columns as condition.

A full table scan looks like this:

```
explain (select count (*) from t1');

...
from DB.DBA.T1 by STR2 8.4e+04 rows
Key STR2 ASC ()

 Local Code
  0: $30 "count" := artm $30 "count" + <constant (1)>
...
```

There are no conditions mentioned.

A lookup with index looks like this.

```
explain ('select fi2 from t1 where row_no = 11');
...
from DB.DBA.T1 by T1 Unique
Key T1 ASC ($26 ".FI2")
 inlined <col=1694 ROW_NO = <constant (11)>>
...
```

The condition is shown on the line below the key.

A lookup with full scan testing every row looks like this:

```
...
from DB.DBA.T1 by T1 2.5e+04 rows
Key T1 ASC ($26 ".FI2")

row specs: <col=1699 FI2 > <constant (11)>>
...
```

The condition is shown after the heading row specs. The whole key mentioned in the key will be read and the entries tested. if both indexed and row tests exist, the indexed are done first as one would think.

If your query has full table scans, consider adding an index.

If the index choice is not the right one, consider the following possibilities:

- Run statistics. This is not always necessary because the database takes dynamic samples but it can help in cases.
- specify the desired index explicitly with table option.
- Use literal constants instead of parameters, specially if the query is long running and values of the columns being compared are not evenly distributed.
- To exclude index usage for a column, write col + 0 =xx.

Hash joins can make full table scans. This is OK if the table scanned is small.

A hash join looks like this:

```
explain ('select count (*) from t1 a, t1 b where a.row_no = b.row_no + 1');
...

{
Fork
{
Fork
{
from DB.DBA.T1 by STR2 8.4e+04 rows
Key STR2 ASC ($26 "B.ROW_NO")

 Local Code
  0: $30 "temp" := artm $26 "B.ROW_NO" + <constant (1)>
  4: BReturn 0

Current of: <$28 "<DB.DBA.T1 B>" spec 5>
Sort (HASH) ($30 "temp") -> ($26 "B.ROW_NO")

}
from DB.DBA.T1 by STR2 8.4e+04 rows
Key STR2 ASC ($37 "A.ROW_NO")

Current of: <$39 "<DB.DBA.T1 A>" spec 5>
Hash source ($37 "A.ROW_NO") -> ($26 "B.ROW_NO")

After code:
  0: $44 "count" := artm $44 "count" + <constant (1)>
  4: BReturn 0
}
Select ($44 "count", <$39 "<DB.DBA.T1 A>" spec 5>, <$28 "<DB.DBA.T1 B>" spec 5>)
}
```

First t1 is read from start to end and a hash is filled with row_no + 1. Then t1 is read from start to end a second time. The hash source is the hash lookup. A hash join, if there is no index or if the whole table or a large part thereof is traversed is better than a loop join because it replaces random access with sequential. The complexity is close to O(n + n) instead of O (n * log n). Plus sequential read makes better use of read ahead.

The corresponding loop join looks like this:

```
explain ('select count (*) from t1 a, t1 b where a.row_no = b.row_no + 1 option (loop)');

{
Fork
{
from DB.DBA.T1 by STR2 8.4e+04 rows
Key STR2 ASC ($26 "B.ROW_NO")

Current of: <$28 "<DB.DBA.T1 B>" spec 5>

Precode:
  0: $29 "temp" := artm $26 "B.ROW_NO" + <constant (1)>
```

```
  4: BReturn 0
from DB.DBA.T1 by T1 Unique
Key T1 ASC ()
 inlined <col=1694 ROW_NO = $29 "temp">
 Local Code
  0: $35 "count" := artm $35 "count" + <constant (1)>
  4: BReturn 0

Current of: <$31 "<DB.DBA.T1 A>" spec 4>
}
Select ($35 "count", <$31 "<DB.DBA.T1 A>" spec 4>, <$28 "<DB.DBA.T1 B>" spec 5>)
}
```

To prevent hash joins, use table option or option at the end of the select as seen above. A hash join is very bad if a whole table is read for filling a hash and then only a small number of entries are fetched from the hash. However, if there is no index, then even this is better than a loop join.

Checkpoint Duration

A checkpoint can take a very long time in certain special conditions. Normally a log checkpoint is about a minute if flushing several G worth of buffers to disk. The flushing is mostly done online, after which there is an atomic time of a few seconds. After this operation resumes. Applications do not notice the checkpoint except as a temporary increase in response delays.

If spikes in response time are to be avoided, then making frequent checkpoints is better than making infrequent ones.

If there are long running transactions with many locks or uncommitted changes, then the checkpoint interval should anyhow be longer than several times the expected duration of such a transaction. If this is not so, the checkpoint can fall in the middle of the transaction and will internally have to rollback and again reestablish the uncommitted state so as to write a clean image on the new checkpoint. Doing this many times in the life of a transaction is very inefficient. In generally do not make long transactions with locking. Preferentially use read committed for anything long.

A checkpoint's atomic time can be prohibitively long under the following circumstances:

- There are transactions with a lot of locks and uncommitted state at the time of the checkpoint. Specially a transaction which has updated pages paged out to disk is bad. In general one should not do transactions that update a large part of the disk cache, let alone exceed its size. Use the row autocommit mode (log_enable (2)) for doing batch updates. Batch updates most often do not require isolation anyway. If they do, then break the job into smaller transactions.
- The MaxCheckpointRemap parameter in the ini is too small and the database exceeds the size of disk cache either in the Virtuoso process or the OS. This may increase the count of used pages by the value of this parameter but will make for faster checkpoints. Set this to up to 25% of the database page count.

6.1.7. Performance Tuning

I/O

Optimizing Disk I/O

Virtuoso allows splitting a database over several files that may be on different devices. By allocating database fragments onto independent disks I/O performance in both random and sequential database operations can be greatly enhanced.

The basic unit of a database is the segment. A segment consists of an integer number of 8K pages. A segment may consist of one or more files called stripes. If a segment has multiple stripes these will be of identical length and the segment size will be an integer multiple of the stripe size.

The size limit on individual database files is platform dependent, but 64 bit file offsets are used where available. For large databases use of multiple disks and segments is recommended for reasons of parallelism even though a single database file can get very large. A database can in principle grow up to 32TB (32-bit page number with 8KB per page).

When a segment is striped each logically consecutive page resides in a different file, thus for a segment of 2 stripes the first stripe will contain all even numbered pages and the second all the odd numbered pages. The stripes of a segment should always be located on independent disks.

In serving multiple clients that do random access to tables the server can perform multiple disk operations in parallel, taking advantage of the independent devices. Striping guarantees a statistically uniform access frequency to all devices holding stripes of a segment.

The random access advantages of striping are available without any specific configuring besides that of the stripes themselves.

Configuring I/O queues

Striping is also useful for a single client doing long sequential read operations. The server can detect the serial nature of an operation, for example a count of all rows in a table and can intelligently prefetch rows.

If the table is located in a striped segment then the server will read all relevant disks in parallel if these disks are allocated to different I/O queues.

All stripes of different segments on one device should form an I/O queue. The idea is that the database stripes that benefit from being sequentially read form a separate queue. All queues are then read and written independently, each on a different thread. This means that a thread will be allocated per queue. If no queues are declared all database files, even if located on different disks share one queue.

A queue is declared in the striping section by specifying a stripe id after the path of the file, separated by an equal sign.

```
[Striping]
Segment1 = 200M, disk1/db-seg1-1.db = iq1, disk2/db-seg1-2.db = iq2
Segment2 = 200M, disk1/db-seg2-1.db = iq1, (disk2/db-seg2-2.db = iq2
```

In the above example the first stripes of the segments form one queue and the second stripes form another. This makes sense because now all database files on /disk1 are in iq1 and all on /disk2 are on iq2.

This configuration could have resulted from originally planning a 200 MB database split on 2 disks and subsequently expanding that by another 200 MB.

The I/O queue identifier can be an arbitrary string. As many background I/O threads will be made as there are distinct I/O queues.

Striping and using I/O queues can multiply sequential read rates by a factor almost equal to the number of independent disks. On the other hand assigning stripes on one disk to different queues can have a very detrimental effect. The rule is that all that is physically accessed sequentially will be on the same queue.

Schema Design Considerations

Data Organization

One should keep the following in mind when designing a schema for maximum efficiency.

Index Usage

A select from a table using a non-primary key will need to retrieve the main row if there are search criteria on columns appearing on the main row or output columns that have to be fetched from the main row. Operations are noticeably faster if they can be completed without fetching the main row if the driving key is a non-primary key. This is the case when search criteria and output columns are on the secondary key parts or primary key parts. Note that all secondary keys contain a copy of the primary key. For this purpose it may be useful to add trailing key parts to a secondary key. Indeed, a secondary key can hold all the columns of a row as trailing key parts. This slows insert and update but makes reference to the main row unnecessary when selecting using the secondary key.

A sequential read on the primary key is always fastest. A sequential search with few hits can be faster on a secondary key if the criterion can be evaluated without reference to the main row. This is because a short key can have more entries per page.

Space Consumption

Each column takes the space 'naturally' required by its value. No field lengths are preallocated. Space consumption for columns is the following:

Table 6.2. Data type Space Consumption

Data	Bytes
Integer below 128	1
Smallint	2
long	4
float	4
timestamp	10
double	8
string	2 + characters
NULL	data length for fixed length column, as value of 0 length for variable length column.
BLOB	88 on row + n x 8K (see note below)

If a BLOB fits in the remaining free bytes on a row after non-LOBs are stored, it is stored inline and consumes only 3 bytes + BLOB length.

Each index entry has an overhead of 4 bytes. This applies to the primary key as well as any other keys. The length of the concatenation of the key parts is added to this. For the primary key the length of all columns are summed. For any other key the lengths of the key parts plus any primary key parts not on the secondary key are summed. The maximum length of a row is 4076 bytes.

In light of these points primary keys should generally be short.

Page Allocation

For data inserted in random order pages tend to be 3/4 full. For data inserted in ascending order pages will be about 90% full due to a different splitting point for a history of rising inserts.

Efficient Use of SQL - SQL Execution profiling

Virtuoso offers an execution profiling mechanism that keeps track of the relative time consumption and response times of different SQL statements.

Profiling can be turned on or off with the prof_enable function. When profiling is on, the real time between the start and end of each SQL statement execute call is logged on the server. When prof_enable is called for the second time the statistics gathered between the last call to prof_enable and this call are dumped to the virtprof.out file in the server's working directory.

Profiling is off by default. Profiling can be turned on with the statement:

```
prof_enable (1);
```

The virtprof.out file will be generated when prof_enable is called for the second time, e.g.

```
prof_enable (0);
```

will write the file and turn profiling back off.

Below is a sample profile output file:

```
Query Profile (msec)
Real 183685, client wait 2099294, avg conc 11.428772 n_execs 26148 avg exec  80

99 % under 1 s
99 % under 2 s
99 % under 5 s
100 % under 10 s
100 % under 30 s

23 stmts compiled 26 msec, 99 % prepared reused.

 %  total n-times n-errors
49 % 1041791  7952     53     new_order
```

```
28 % 602789    8374      490    delivery_1
12 % 259833    8203      296    payment
5  % 123162    821       35     slevel
2  % 54182     785       0      ostat (?, ?, ?, ?)
0  % 11614     4         0      checkpoint
0  % 2790      2         1      select no_d_id, count (*) from new_orde
0  % 2457      3         1      select count (*) from new_order
0  % 662       2         0      status ()
0  % 11        1         1      set autocommit on
0  % 3         1         0      select * from district
```

This file was produced by profiling the TPC C sample application for 3 minutes. The numbers have the following meanings:

The real time is the real time interval of the measurement, that is the space in time between the prof_enable call that started the profiling and the call that wrote the report. The client wait time is the time cumulatively spent inside the execute call server side, only calls completely processed between profiling start and end are counted. The average concurrency is the exec time divided by real time and indicates how many requests were on the average concurrently pending during the measurement interval. The count of executes and their average duration is also shown.

The next section shows the percentage of executes that finished under 1, 2, 5, 10 and 30 seconds of real time.

The compilation section indicates how many statements were compiled during the interval. These will be SQLPrepare calls or SQLExecDirect calls where the text of the statement was not previously known to the server. The real time spent compiling the statements is added up. The percentage of prepared statement reuses, that is, executes not involving compiling over all executes is shown. This is an important performance metric, considering that it is always better to use prepared statements with parameters than statements with parameters as literals.

The next section shows individual statements executed during the measurement interval sorted by descending cumulative real time between start and completion of the execute call.

The table shows the percentage of real time spent during the calls to the statement as a percentage of the total real time spent in all execute calls. Note that these real times can be higher than the measurement interval since real times on all threads are added up.

The second column shows the total execute real time, the third column shows the count of executes of the statement during the measurement interval. The fourth column is the count of executes that resulted in an error. The error count can be used for instance to spot statements that often produce deadlocks.

Statements are distinguished for profiling purposes using the 40 first characters of their text. Two distinct statements that do not differ in their first 40 characters will be considered the same for profiling. If a statement is a procedure call then only the name of the procedure will be considered, not possibly differing literal parameters.

The profiler will automatically write the report after having 10000 distinct statements in the measurement interval. This is done so as to have a maximum on the profiling memory consumption for applications that always compile a new statement with different literals, resulting in a potentially infinitely long list of statements each executed once. It is obvious that such a profile will not be very useful.

It cannot be overemphasized that if an application does any sort of repetitive processing then this should be done with prepared statements and parameters, for both reasons of performance and profilability.

Note:

Note that measurements are made with a one millisecond precision. Percentages are rounded to 2 digits. Timing of fast operations, under a few milliseconds, will be imprecise as a result of the 1 ms resolution. Also the cumulative compilation time may be substantially off, since the compilation may often take less than 1 ms at a time. Also note that the precision may also vary between platforms.

Reading a Query profile

A query plan is essentially a pipeline of operations that can be read from top to bottom. The operator above produces the input for the operator below. Nesting is indicated by braces. Operators enclosed in braces must completely process their input before continuing with operators after the section in braces. A case in point is aggregation which is demoted by for { ... } ... . The section in braces generates the rows to be aggregated and one it is fully evaluated the execution proceeds with the operators after the fork. These will typically read the temporary table filled by the operators inside the fork.

Query variables are demoted with <$v...>. A reference to a query variable set by an operator that is not immediately the preceding one is demoted by <r $...> via ...>. The position of the variable in the query state follows the $ sign.

After this is given the symbolic name of the variable, e.g. a column name or the name of the function of which this is the return value.

If this is a reference to a query variable assigned earlier in the plan with one or more operators between the reference and the assignment, the reference contains a via .... section which lists the operators that are between the reference and the assignment.

The operators are identified by a unique number. Internally this is the location in the query state where the operator keeps the mapping between its rows of input and output.

With vectored execution, an operator may receive any number of rows of input which it may reorder at its convenience. For this it must record for each row of output which row of input this corresponds to. Thus when referencing a query variable set earlier in the plan one must take into account the reordering and addition/dropping of rows in affected by the operators between the reference and the initial assignment. This is the meaning of the via section in the <r $xx > notation.

The last part of the query variable reference is a two letter indication of the type. If the first letter is followed by n this means that the variable is non-null. The type letters are a for any, r for IRI, i for integer, d for double, f for float, t for datetime, N for wide string, s for string.

If the plan is a profile, i.e. it is annotated with actual times and cardinalities from running the query, each operator is preceded by a passage that indicates its percentage of total CPU time of the plan, its fanout and the number of rows of input. The fanout is the number of rows of Output divided by the number of rows of input.

The principal operators in a plan are:

- *Cluster outer seq start*

  -- Queries and subqueries begin with this operator. It assigns numbers to the sets of parameter bindings the query gets as input. An optional section also begins with this. An optional section is the table or derived table on the right hand side of a left outer join.
- *From*

  -- Accessing an index
- *Sort*

  -- Group by, order by, distinct or hash join build side
- *group by read*

  -- Accessing the results of a group by filled in by a previous sort operator.
- *Top oby*

  -- Accessing a previously filled top k order by temporary space
- *Select*

  -- At the end of a plan, send the rows of input to the client. If Subq select return the rows of input as rows of output of the enclosing subquery.
- *Subquery*

  -- Indicates a SQL derived table, i.e. select in a from clause. The input is the output of the previous node.
- *Cluster ocation fragment*

  -- A set of operators partitioned and shipped to a partition in a cluster. There are single part fragments and distributed fragments (DFG). A DFG is a query fragment which begins with a stage operator. The stage is a partitioning exchange operator which routes its rows of input to the next operator in the appropriate partition based on the partitioningh columns of the row of input.
- *Outer seq end*

  -- This demotes the end of an optional section, i.e. the table/derived table on the right side of left outer join. This has the effect of making aligned vectors of all the vector query variables assigned in the optional section. When producing rows

for which there was no match in the optional section, these will be set to null. References to these variables downstream in the plan will be to the shadowing variables, listed in the shadow clause following this.

Some operators such as index access (From) have a section called vector param casts. This is used when the vector that serves as parameter is not aligned or not of the type required by the operator. For example, a vector of column values in an index lookup might not be of the type of the column but might be of a type castable to this. In any case, the para,key values for index lookup are made into solid aligned, materialized vectors. After this there is a sort step that orders the input according to key order, so that matches are generated from left to right.

In the event of a cluster partitioned operation, i.e. stage node or non-DFG location fragment (QF), the first table source (From) after the stage or fragment serves to both align and cast all inputs needed downstream in the DFG or QF. The operator first partitions the rows of input. Each partition then gets solid, aligned vectors of input values which are directly suitable for input to the first index lookup (From).

We consider an example: The setup is a cluster of 4 server processes with each 8 slices of data. There is one table, ct_c, which is joined to itself:

```
profile ('SELECT COUNT (*) from ct_c a, ct_c b WHERE a.k2 = b.k1 option (loop, order)');
```

This returns a result set in which is found the below. This is also in the ql_plan column of the sys_query_log view:

```

  set no: <V $40 set_ctr in>
}
```

Tuning Vectored Execution and Hash Joins

Note : This section applies only to versions 7.00 and up.

Query evaluation performance is significantly affected by parallelization, the vector size and the use of hash joins and fast in-memory hash tables for group by and distinct.

This section explains the configuration parameters and event counters that allow optimizing these factors.

The SQL function *cl_sys_stat* (in name varchar, in clr int := 0) allows reading and optionally resetting these counters. In the case of a cluster, the value returned is the sum of the values of the metric gathered from all server processes, for a single server this is the local value. In a cluster, to get individual counter values, use sys_stat instead when connected to the process of interest.

To do TPC H at scale 100G on a 32 thread machine, the virtuoso.ini should have the following settings. Only settings at non-default values are mentioned:

```
[Parameters]
ServerThreads              = 100
NumberOfBuffers            = 5000000

;  The working set of the 100G database when stored column-wise is 38G,
;  so configure this much for database buffers:
; 5000000 / 128             = 39G

;  Read committed
DefaultIsolation           = 2

;  SQL optimizer work space
MaxMemPoolSize             = 100000000

;  Use large vectors when appropriate
AdjustVectorSize           = 1

;  Split queries in up to 32 independently evaluable fragments,
;  so up to 32 threads per query.
ThreadsPerQuery            = 32

;  Thread pool has 32 worker threads divided across all queries
;  in addition to the client thread taken by each query.
AsyncQueueMaxThreads       = 32

;  All queries can collectively take up to 30G without space
;  saving measures being applied. Space saving measures are
;  running on small vector size when a large size would be
```

```
;  faster and the use of partitioned (multiple pass) hash join.
MaxQueryMem               = 30G

;  Of the MaxQueryMem, hash join hash tables can take up to 30G,
;  i.e. all of it. A single hash table will only take half of the
;  remaining space, though. So if 2 queries that both need a 30G
;  hash table run at the same time, the first will do 2 passes,
;  taking a hash table of 15G at a time, This leaves 20G space.
;  The second will have 15G left, of which it will take half,
;  7.5G. This will require 4 passes over the data.
HashJoinSpace             = 30G
```

To analyze the performance of a query workload:

1. Turn on query logging in sys_query_log. This view contains most metrics and the full text of the query plan with the per operator timings and cardinalities:

   ```
   SQL> prof_enable (1);
   ```
2. Print long result columns without truncating:

   ```
   SQL> set blobs on;
   ```
3. Run the query.
4. Use the profile function for a convenient overview of query execution. For example:

   ```
   SQL> profile ('SELECT COUNT (*) FROM orders, lineitem WHERE l_orderkey = o_orderkey');
   ```

   See summary of execution time, CPU%, compilation time and IO
5. Read the relevant event counters, resetting the count for the next query. For example:

   ```
   SQL> select cl_sys_stat ('tc_qp_thread', clr => 1);
   ```

   The relevant counters are:

   - *tc_qp_thread* -- How many threads were started for query parallelization. This is not the number of parallel threads as not all of these threads needed to be running at the same time.
   - *tc_part_hash_join* -- If a hash join is partitioned, i.e. needs to make multiple passes on over the data, this is the count of passes. This is incremented by 2 if the hash join does 2 passes and not incremented if the hash join goes in a single pass. Normally this should stay at 0 or the hash join space (HashJoinSpace in init, see above) should be increased.
   - *tc_no_mem_for_longer_batch* -- This is the count of times the execution engine did not switch to large vectors because there was not enough space. This should normally be 0, if this is not so, increase MaxQueryMem in the ini file.
   - *tc_slow_temp_insert* -- If a distinct or group by temporary space grows over the available query memory, a another data structure will be used so that the hash table can be paged out to disk. This is tens of times less efficient than the memory only structure. This counter is the count of rows inserted into a page-able group by or distinct hash table. This should be 0, if not, increase MaxQueryMem.
   - *mp_max_large_in_use* -- This is the maximum amount of query memory that has been allocated to date. Reset this before the query of interest, run and read the counter. This is the peak simultaneous memory use by the query.
   - *mp_large_in_use* -- This is the current amount of query memory in use. Do not reset this.
   - *c_max_large_vec* -- This is the MaxQueryMem init setting in bytes. This can be altered at run time with `__dbf_set` .

High Cardinality Group By And Distinct

There are multiple implementations of group by and distinct used in different circumstances by different versions of Virtuoso. Versions of Virtuoso 7 prior to 7.5 have a memory based cuckoo hash based group by and hash join. 7.5 and onwards have a linear hash based implementation of same. Additionally, all version 7's have a pageable, i.e. potentially disk based implementation of group by that may get used if there is no space in memory.

Partitioned Group By

Versions 7.5 and onwards have a choice of a partitioned or re-aggregated parallel group by. The group by with re-aggregation produces an intermediate result on each thread and then adds these up after the completion of each thread into a final result. This is efficient for low-cardinality cases (few distinct values of grouping columns) but inefficient for high cardinality. In the high cardinality case, it is better to use a partitioned group by operator. In the partitioned case, a hash is computed from the grouping columns and this decides which thread gets to do the aggregation. There is information exchange between threads (or processes in a scale-out setting) but there is no need for re-aggregation. This is significantly more performant with many groups. The peak memory utilization is the same.

The `c_setp_partition_threshold` setting in the *Flags* section of virtuoso.ini defines when to use a partitioned group by. The default threshold is 100000. If the cost model estimates more distinct values than this threshold, a partitioned group by will be produced. In a query plan with explain of profile, a partitioned group by is present when there is a stage <n> operator in front of the sort operator for the group by. In a cluster plan, the partitioned group by may be colocated with the table right before it, so the stage operator will be before this.

Ordered Group By

For version 7.5 onwards, a special case for ordered group by is recognized. In an ordered group by, the system takes advantage of physical data ordering to limit the memory footprint of the group by: If it is known that grouping keys will not reoccur past a certain window, then all grouping keys that are processed can be emitted as results in a continuous stream so that only a window of groups need be kept at a time.

This is recognized in a query plan by the word "streaming" occurring on the line of the sort operator for the group by.

Ordered group by is rare to non-existent with RDF, where data orderings with an application meaning do not occur, due to having no multipart keys. With a SQL schema grouping on a set of columns including the primary ordering column of the outermost scan in a plan, an ordered group by will typically be generated. An ordered group by is usually better than a partitioned or re-aggregated group by. The exception may be cases where the outermost ordering column has low cardinality, or a very biased value distribution e.g. the P in the RDF PSOG.

Memory for Group By

In Virtuoso 7 prior to 7.5, the memory for a group by is `(3 + n_keys + n_aggregates) * 8` bytes per group plus the natural length of any dates or strings in the keys or aggregates. In 7.5 onwards, the memory is 8 bytes less per entry.

Slow Group By

The use of the disk-based group by is easily 100x less efficient than the vectored memory based hash tables. Falling back to this can be considered an error in configuration and can be detected with the `tc_slow_temp_insert` counter readable with `sys_stat` . If this increases then there is not enough memory for group by/distinct as used by the application. The monitor may print a message about this in the server messages log.

The maximum size of a memory based group by hash table is by default 1/10 of the MaxQueryMem setting in Parameters in the virtuoso.ini file. If a single hash table exceeds this or if the hash table plus the amount of large query memory blocks (e.g. vectors) allocated across the process exceeds MaxQueryMem, then the switch to the slow pageable hash table takes place. This can be avoided by explicitly setting a larger MaxQueryMem or by changing the `cha_max_gby_bytes` setting in the Flags section of the ini file. We note that for parallel query plans the first condition to trigger is the condition on `mp_large_in_use` + the hash table memory exceeding MaxQueryMem. A query will have more than 10 threads and the hash tables for memory based hashes are included in `mp_large_in_use` .

To track the general memory consumption in large blocks, use the `mp_large_in_use` and `mp_max_large_in_use` `meters` accessible with `sys_stat` and `__dbf_set` . Large blocks are for example vectors, group by's and hash join build sides.

To interactively try different memory settings, one can modify `c_max_large_vec` with `__dbf_set` . This is the number of bytes of outstanding large blocks after which pageable group by's will be used and vector sizes will no longer be adjusted upward.

Tuning Parameters for Multiuser Workloads

This section describes parameters and event counters that affect memory and parallelism and are specially relevant for high concurrency situations. Different switches and event counters are described. Setting these requires dba privileges. The event counters are accessed with *sys_stat* and set with `__dbf_set` . For example:

```
select sys_stat ('tc_qp_thread');

or

__dbf_set ('dc_batch_sz', 10000);
```

Some of the parameters have corresponding INI file settings. All of these can be set in an INI file in the [Flags] section with a stanza like:

```
dc_batch_sz = 10000
```

First, make sure that the *ServerThreads* in either [Parameters] ini section (if application with connected clients) or in [HTTPServer] ini section (if over web protocols), is larger than the number of actual connections.

Next, the workload should be profiled to see its memory utilization and intrinsic use of parallelism. Splitting a query into independently executable parallel fragments increases its memory utilization, Switching to larger vector sizes also increases a query's memory utilization while providing increased locality of data access. Together these techniques can result in a 100+ fold difference in the transient memory consumption of a query. Use of hash joins may also increase the transient memory consumption since in a hash join one half of the join must be materialized.

With relatively small numbers of concurrent queries, e.g. 10, these techniques are nearly always beneficial. With hundreds of queries the memory overhead may become a limiting factor.

The *MaxQueryMem* INI file setting controls how much memory is kept for query execution. This amount of space is maintained allocated. Transient memory use may exceed this but then the memory above this amount is unmapped when no longer needed. Mapping and unmapping memory takes time. Concurrent mmap and munmap calls on different threads will serialize and bring down the CPU utilization of a process even when there is enough parallelism for full platform utiliization.

The *mp_mmap_clocks* counter is the cumulative amount of real time in CPU clocks spent in mmap or munmap systtem calls. This can increase faster than real time if multiple threads are involved.

If this value grows fast, e.g. at over 10% of real time, the monitor prints a message in the server event log. This is an indication that memory utilization may have to be tuned.

For analyzing the behavior of a workload as concerns memory, do the following:

- Run the workload once for warmup.
- Clear the following counters:
  - `mp_max_large_in_use` -- Highest to date amount of concurrently used memory
  - `tc_qp_thread` -- count of times a query made a parallel executive fragment. Not increased if running single threaded.
  - `tc_adjust_batch_sz` -- count of times vector size was switched to larger
  - `mp_mmap_clocks` -- cumulative time inside mmap or munmap.

  For example:

  ```
  __dbf_set ('mp_max_large_in_use', 0);
  ```
- Run the workload on a single thread with default settings.
- Observe the values.

Example Scenario

1. Clear the counters.
2. Set `enable_dyn_batch_sz` to 0, causing queries to only use the initial vector size, `dc_batch_sz` or `VectorSize` in the INI file.
3. Set `enable_qp` to 1, causing queries to run single threaded.

4. Run the workload on a single thread. The difference in elapsed real time will show how much benefit the workload has from intra-query parallelization and long vector sizes. If the workload used any of the memory consuming techniques the peak memory in the second case will be lower. How much lower is entirely workload dependent.

    - *Note* : One may additionally try the workload on a single thread with `hash_join_enable` set to 0 and 2, respectively. 0 means no hash join plans are made, 2 means that hash join is used when appropriate for either SQL or SPARQL queries. The peak memory utilization and run times may be significantly affected.
5. Having completed these metrics, one may move to the multi-user case. Note that `MaxQueryMem` , (`c_max_large_vec` setting with `__dbf_set`) should be set to a reasonable value, e.g. the peak consumption with the chosen settings times the number of parallel sessions.
6. Expected Results -- Experience demonstrates for example that with a 128 concurrent users `setting enable_qp` to 1 and `enable_dyn_batch_sz` to 0 increased the throughput of the sample workload by a factor of 2.5. The workload derived, even in single user mode, little benefit from dynamic vector size or multithreading, under 30%. In the case at hand, the difference in performance was mostly accounted for by `mmap` , see the `mp_mmap_clocks` counter.

    - If more concurrent queries are than CPU cores are expected, there is little point in intra-query parallelism, controlled by `ThreadsPerQuery` in the INI file or `enable_qp` in `__dbf_set` .
    - If `mp_mmap_clocks` continues to grow fast during the execution one may increase `c_max_large_vec` . This will cause more `mmap` 's to be kept in reserve, thus in principle decreasing the frequency of `mmap` and `munmap` system calls.
    - If running with hash join enabled, there is a possibility of partitioned hash joins where the query executes in multiple passes in order to build smaller hash tables. This is given by `tc_part_hash_join` , which is increased by 1 for each non-first pass over a hash join. If the counter increases the `HashJoinSpace` setting in the INI file should be increased. With `__dbf_set` this is `chash_space_avail` .
7. Notes:

    - The results from above may not happen with a single user but happen all the time with multiple users. The monitor will print a warning message about this in the message log.
    - One may also try a different default vector size, specially if very pressed on memory. The default of 10000 values is generally a good small value but smaller may be possible, however not under 1000.

Query Logging

As of version 7.00 Virtuoso offers optional server side query logging. This records a large number of execution statistics as well as the full query text and execution plan with per-operator timing and cardinality information.

This feature is enabled in the Parameters section of virtuoso.ini:

```
; virtuoso.ini
...
[Parameters]
QueryLog = filename
```

At run time, this may be enabled or disabled with prof_enable (), overriding the specification of the ini file. The default file name for the query log is virtuoso.qrl in the server's working directory, if not otherwise specified in the ini file.

The file is in binary format and is not conveniently readable as such. It is most easily accessed via the DB.DBA.SYS_QUERY_LOG system view. This view has parameters for specifying a non-default file path for the query log file as well as a datetime range for selecting the entries of interest.

For example:

```
SELECT *
  FROM sys_query_log
 WHERE qrl_file = 'other.qrl'
   AND qrl_start_dt = cast ('2011-10-1' as datetime)
   AND qrl_end_dt = cast ('2011-10-2' as datetime)
```

This will select entries from the file other.qrl that are between the given dates. Note that the qrl* columns are not actual result column of the view but are considered as parameters, hence the use of = instead of a range condition.

All statements executed over a SQL client connection (ODBC/JDBC etc) are logged, as well as any statements executed on an SPARQL end point. DAV and web services requests are not logged unless they perform an exec function call. CPU usage for

committing transactions or for background data organization such as autocompact or automatic checkpoints are not logged.

A select statement is logged at the time it produces its last row of output, not at the time this row of output is fetched by a client.

Some of the columns are in units of clocks, whose meaning varies from system to system. On Intel this corresponds to the value returned by the RDTSC instruction. All values are intervals. The relation of this to real time may vary in function of automatic variation of clock frequency.

The columns of SYS_QUERY_LOG are as follows:

- *ql_id*

  -- Serial number of the log entry. If the server was started many times with the same file these will not be unique. Combine with

  ql_start_dt

  for unique identification.
- *ql_start_dt*

  -- datetime of the start of the query
- *ql_rt_msec*

  -- real time elapsed in milliseconds between the start and the logging of the query
- *ql_rt_clocks*

  -- Clock cycles of real time spent running the query, not including time between consecutive fetches from a client if the query was a cursor fetched in multiple chunks by a client. This is the number of clocks during which there was at least one thread running on behalf of the query. The average CPU% of the query is given by:

  ```
  100 * ql_thread_clocks / ql_rt_clocks
  ```
- *ql_client_ip*

  -- Requesting client IP as dotted decimal.
- *ql_user*

  -- User account on behalf of which the query was executed.
- *ql_sqlstate*

  -- SQL state if query terminated with error, NULL otherwise.
- *ql_error*

  -- Error message if query terminated with error, NULL otherwise.
- *ql_swap*

  -- Cumulative count of major page faults since startup of this Virtuoso process.
- *ql_user_cpu*

  -- Cumulative user CPU in milliseconds for this server process.
- *ql_sys_cpu*

  -- Cumulative system CPU in milliseconds for this server process.
- *ql_text*

  -- Source text of the query
- *ql_params*

  -- NULL.
- *ql_plan_hash*

-- Hash number calculated from the execution plan, ignoring literals. Can be used for grouping executions of the same query with differing literals together. If difference of literals causes a different plan, this number will be different.

- *ql_c_clocks*

  -- CPU clocks of real time used for query compilation. This will be 0 if the query is separately prepared of if the query compilation comes from a cache of recently compiled queries. This is likely if the query is parametrized and executed multiple times.
- *ql_c_msec*

  -- Real time used for query compilation in milliseconds.
- *ql_c_disk*

  -- Count of disk reads done on behalf of the query compilation, this stands for index sampling initiated by the compilation and does not include any speculative read possibly triggered by the sampling.
- *ql_c_disk_wait*

  -- Count of clocks the compilation was blocked waiting for disk.
- *ql_c_cl_wait*

  -- Count of clocks the compilation was waiting for information from cluster peers. Such waiting indicates sampling done on remote partitions. If the run time of the query is small, this may be a significant factor in query execution real time.
- *ql_cl_messages*

  -- Count of distinct cluster messages sent on behalf of the compilation. These are all related to sampling. Many samples can be combined into one message in some situations. Samples are also cached on the requesting server so repeatedly compiling the same statement will send the messages only the first time in unless the cache has timed out in the meantime.
- *ql_c_rnd_rows*

  -- Count of rows retrieved as part of compile time sampling.

The below columns correspond directly to the fields returned by db_activity (). These are summed over all the threads in all the hosts that have done something on behalf of the logged query.

- *ql_rnd_rows*

  -- Count of random row lookups. Each sequential lookup begins with one random one for each partition concerned.
- *ql_seq_rows*

  -- Sequential rows fetched, each non-first row which is selected counts as one. A row that is looked at but does not satisfy applicable query criteria does not count.
- *ql_same_seg*

  -- Count of times the next random lookup in a vectored lookup falls on the same column-wise segment as the previous.
- *ql_same_page*

  -- Ibid, for the next lookup falling on the same row-wise leaf page.
- *ql_same_parent*

  -- Ibid, for the case of the next lookup falling on a sibling page of the row-wise leaf page of the previous lookup.

For column-wise indices, all the three above counters can be non-zero since these consist of multi-row segments each under a row on a row-wise leaf page. For a row-wise index the same seg counter is always 0.

- *ql_thread_clocks*

  -- Sum of clocks spent on any thread for the logged query. Time spent waiting for other threads, for disk or for replies from cluster peers is not counted, thus only running cycles count. These are added up across all hosts in a cluster.
- *ql_disk_wait_clocks*

-- Total clocks any thread spends waiting for disk on behalf of the query. If two threads wait for the same page which is fetched once the wait is counted double. This is not the same as the total read time of the pages since read ahead can fetch pages before they are needed, thus involving no wait.

- *ql_cl_wait_clocks*

-- Total clocks a thread running on behalf of the query spends waiting for a cluster reply. This may be zero if the coordinating thread has work until any cluster replies arrive, in which case there will be no wait. If this is high then the workload is bound by interconnect or is unevenly distributed across a cluster.

- *ql_pg_wait_clocks*

-- Count get page wait.

- *ql_disk_reads*

-- Count disc reads.

- *ql_spec_disk_reads*

-- Count of speculative disk reads triggered on behalf of the query. Any read ahead or any upgrading of a single page read into a read of a whole extent counts towards this, only allocated pages that are read are counted but merging near-adjacent reads may cause actually more disk IO to take place.

- *ql_messages*

-- Count of distinct cluster messages sent on behalf of the query. Any message is counted once. Client-server messages are not counted.

- *ql_message_bytes*

-- Total bytes sent in all cluster messages sent on behalf of the query.

- *ql_qp_threads*

-- Count of times an extra thread is created for parallelizing work on the query in question. The count may be high since consecutively launched threads are counted, this is not a maximum degree of concurrency.

- *ql_vec_bytes*

-- reserved

- *ql_vec_bytes_max*

-- reserved

- *ql_lock_waits*

-- Count of times a thread has waited for a lock on behalf of the query.

- *ql_lock_wait_msec*

-- Total milliseconds any thread has spent waiting for a lock on behalf of the query. This may be longer than real time since many threads may wait at the same time.

- *ql_plan*

-- Text representation of the execution plan, annotated with CPU time percentages and fanouts for the different operators. Fanout is the count of output rows divided by the count of input rows.

- *ql_node_stat*

-- reserved

- *ql_c_memory*

-- Count of bytes allocated for compiling the query. This is the peak size of the memory pool for query compilation.

- *ql_rows_affected*

-- Count of inserted/updated/deleted rows. If the query was a select with a top and an order by, this is is the count of produced rows before the top restriction was applied.

Meters & System Views

DB.DBA.SYS_K_STAT, DB.DBA.SYS_D_STAT, DB.DBA.SYS_L_STAT view

These views provide statistics on the database engine

```
create view SYS_K_STAT as
  select KEY_TABLE, name_part (KEY_NAME, 2) as index_name,
        key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'n_landings') as landed,
        key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'total_last_page_hits') as consec,
        key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'page_end_inserts') as right_edge,
        key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'page_end_inserts') as lock_esc
        from SYS_KEYS;

create view SYS_L_STAT as
  select KEY_TABLE, name_part (KEY_NAME, 2) as index_name,
        key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'lock_set') as locks,
        key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'lock_waits') as waits,
        (key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'lock_waits') * 100)
          / (key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'lock_set') + 1) as wait_pct,
        key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'deadlocks') as deadlocks,
        key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'lock_escalations') as lock_esc
        from SYS_KEYS;

create view sys_d_stat as
  select KEY_TABLE, name_part (KEY_NAME, 2) as index_name,
        key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'touches') as touches,
        key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'reads') as reads,
        (key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'reads') * 100)

 > / (key_stat (KEY_TABLE, name_part (KEY_NAME, 2), 'touches') + 1) as read_pct
        from SYS_KEYS;
```

These views offer detailed statistics on index access locality, lock contention and disk usage.

'reset' specified as the stat name will reset all counts for the key in question.

SYS_K_STAT - Key statistics

- KEY_TABLE The fully qualified table name, e.g. DB.DBA.SYS_PROCEDURES
- INDEX_NAME The name of the index. This will be equal to the table name for the table's primary key.
- LANDED The count of random accesses, including inserts. Any insert or select, whether empty, single line or multi- line counts as one. Updates and deletes do not count, as they imply a select in the same or previous statement.
- CONSEC The number of times a random access falls on the same page as the previous random access. This is always less than LANDED. For repetitive access to the same place or an ascending insert, this will be near LANDED. For a totally random access pattern this will be near 0.
- RIGHT_EDGE The number of times an insert has added a row to the right edge of the page where the insert was made.
- LOCK_ESC The count of lock escalations, see SYS_L_STAT.

SYS_L_STAT

- KEY_TABLE The fully qualified table name, e.g. DB.DBA.SYS_PROCEDURES
- INDEX_NAME The name of the index. This will be equal to the table name for the table's primary key.
- LOCKS The number of times a lock has been set on the index. Making a new row or page lock counts as one. Entering a row or page lock either after a wait or without wait (for a shared lock) counts as one.
- WAITS The number of times a cursor reading this index waited for a lock. Note that this can be higher than the number of locks set, e.g. a 'read committed' cursor may wait for a lock but will never make one.
- WAIT_PCT The percentage of lock set events that involved a wait.
- DEADLOCKS The number of times a deadlock was detected when trying to wait for a lock on this index. Note that one deadlock event may involve locks on several indices. Each deadlock detection counts as one.
- LOCK_ESC The number of times the set of row locks on a page of this index where escalated into one page lock or a page lock was set initially. This is always less than LOCKS. This value will be near LOCKS when there are many sequential selects which switch to page lock mode. This happens when a cursor has performed over 2 lock escalations and the page being entered has no locks, i.e. the lock can be set over the entire page.

SYS_D_STAT

- KEY_TABLE The fully qualified table name, e.g. DB.DBA.SYS_PROCEDURES
- INDEX_NAME The name of the index. This will be equal to the table name for the table's primary key.
- TOUCHES The number of times a row is located on the index. Every row retrieved by a select or inserted counts as one. All rows scanned by an select count or other aggregate counts as one.
- READS The number of times a disk read was caused by a read operation on this index. This may theoretically be higher than TOUCHES, since several levels of the index tree may have to be read to get to a leaf.
- READ_PCT The percentage of READS in TOUCHES.

Example 6.14. Examples:

```
select index_name, locks, waits, wait_pct, deadlocks
    from sys_l_stat order by 2 desc;

Get lock data, indices in descending order of lock count.

select index_name, touches, reads, read_pct
    from sys_d_stat order by 3 desc;

Get disk read counts, index with most reads first.

select index_name, (consec * 100) / (landed + 1)
    from sys_k_stat where landed > 1000  order by 2;
```

Get the percentage of consecutive page access on indices with over 1000 accesses so far, most randomly accessed first.

status SQL function - status ();

This function returns a summary of the database status as a result set. The result set has one varchar column, which has consecutive lines of text. The lines can be up to several hundred characters.

The contents of the status summary are described in the Administrator's Guide .

Virtuoso db file usage detailed info

All data in a virtuoso database are logically stored as database key rows. Thus the primary key for a table holds the entire row (including the dependent part) and the secondary keys just hold their respective key parts. So the space that the table occupies is the sum of the space occupied by it's primary key and all the secondary keys.

The main physical unit of allocation in a virtuoso db file is the database page (about 8k in virtuoso 3.x). So the server needs to map the key rows and outline blobs to database pages.

Virtuoso will store as many rows in a db page as it can, so usually one DB page will contain more than 1 row of a given key. No page contains rows from more than one key. However blobs (when not inlined on the row) will be placed in consecutive DB pages (up to their size). In addition to the blob and key pages the Virtuoso DB will hold a number of pages containing internal data. So the sum of the pages occupied by the key rows and the blobs is leas then the amount of occupied pages (as reported by the `status()` BIF).

To provide detailed information about the space consumption of each key there's a system view:

```
DB.DBA.SYS_INDEX_SPACE_STATS
    ISS_KEY_TABLE       varchar -- name of the table
    ISS_KEY_NAME        varchar -- name of the key
    ISS_KEY_ID          integer -- id of the key (corresponding to KEY_ID from DB.DBA.SYS_KEYS)
    ISS_NROWS           integer -- number of rows in the table
    ISS_ROW_BYTES       integer -- sum of the byte lengths of all the rows in the table
    ISS_BLOB_PAGES      integer -- sum of the blob pages occupied by the outline blobs on all the rows of
    ISS_ROW_PAGES       integer -- sum of all the db pages containing rows of this key
    ISS_PAGES           integer -- = ISS_BLOB_PAGES + ISS_ROW_PAGES (for convenience).
```

Each select on that view causes the server to go over all the db pages in the db file (similarly to how the crash dump operates) and collect the statistics above. The pages are traversed 1 time per select, but still on large database files that may take some time.

Transaction Metrics, Diagnostics and Optimization

Bad design and implementation of transactions affects applications in the following ways:

- Performance is lost by having to needlessly retry transactions that are aborted by deadlock.
- Concurrency is lost by having rows stay locked for too long.
- Memory is transiently consumed, adversely affecting working set, by keeping data structures for too many simultaneous locks, rollback records and uncommitted roll forward logs.

The following rules should be observed when writing transactions:

- Do not lock needlessly. For example, any report transaction that reads the data once can always be done as read committed instead of repeatable read without affecting semantics. Even if some data is read multiple times, the repeatable read semantic is typically not relevant for reports.
- Lock for what is needed. If you mean to update later, do the initial read with exclusive locks. See the for update clause in select, for example.
- Lock in constant order. If you must lock different resources in one transaction, lock them always in the same order. When updating stock for an order, update the quantity on hand in increasing order of item number, for instance.
- Lock the item with the least contention first. For example, update the detail before updating the summary. Update the quantity in stock for the ordered items before updating the orders count of the whole warehouse.
- Keep transactions short. Use stored procedures. Use the explicit commit work statement.
- For each transaction in a stored procedure, make sure that if it is deadlocked, the deadlocked transaction gets retried. For example, have a "declare exit handler for sqlstate 40001" for every transaction context. Make sure that a deadlocking transaction is never retried endlessly. Two mutually deadlocking transactions can keep retrying and again deadlocking each other endlessly. To avoid this, have a maximum count of retries and a random delay before restarting. The restart delay should be between 0 and the expected duration of the transaction.
- Always break batch updates into multiple transactions. Update a few thousand or tens of thousands of rows per transaction, never more than that. Failing to do this makes for prohibitive cost of retry with deadlocks and can cause swapping by keeping tens or hundreds of megabytes in rollback state, locks and other transaction temporary structures. This happens if one inserts, updates, deletes several million rows in a single transaction. If this is really needed and concurrency is no issue, use the atomic mode, effectively making the server single user for the transaction, thus having no locking or rollback. See the use of the

  __atomic()

  function in the Cluster Administration API .

Programming Virtuoso/PL

The isolation level is set in Virtuoso/PL with the

```
set isolation := level;
```

statement, where level is one of 'serializable', 'repeatable', 'committed', 'uncommitted'. Example :

```
set isolation = 'serializable';
```

The standard SQL syntax is also supported :

```
SET TRANSACTION ISOLATION LEVEL <isolation_level>
isolation level : READ UNCOMMITTED | READ COMMITTED | REPEATABLE READ | SERIALIZABLE
```

Example :

```
SET TRANSACTION ISOLATION LEVEL READ COMMITTED
```

The effect is for the rest of the procedure and any procedure called from this procedure. The effect stops when the procedure having executed the set isolation statement returns.

Transaction Parallelism

From Virtuoso 7.1 onwards, data manipulation statements can be multithreaded. The virtuoso.ini `[Flags]` settings `enable_mt_txn` and `enable_mt_transact` control transaction parallelism. These are 1 for enable and 0 for disable. Defaults are version dependent, off in 7.1 and 7.2 and on in subsequent. The `sys_stat()` and `__dbf_set()` functions can be used for querying and altering these.

DML statements, e.g. insert, delete, update, are automatically multithreaded according to `enable_qp` (`ThreadsPerQuery` in ini [Parameters] when `enable_mt_txn` is on).

RDF load (`DB.DBA.ttlp()` and related functions) when in transactional mode (log_enable 0 or 1) are also multithreaded when `enable_mt_txn` is on. Otherwise these are multithreaded when in non-transactional mode (`log_enable` 2 or 3) and single threaded in transactional mode.

The `enable_mt_transact` setting controls the parallelism of a commit or rollback. Specially for column store deletes, the commit may take a long time, as this is the point where the physical deletion takes place. To accelerate this, `enable_mt_transact` should be on. This is however not worthwhile for short row store transactions, as the overhead of making threads is greater than the time it takes to finalize a transaction om a page. Again, large, scattered row store deletes may justify use of `enable_mt_transact` .

Sample Deadlock Handler

The text for a deadlock handler is

```
  declare retry_count int;
  retry_count := 0;
retry:
  {
    declare exit handler for sqlstate '40001'
      {
        rollback work;
        ...
        delay (rnd (2.5));  --- if 2.5 seconds is the expected duration of
the transaction.
        ...

        retry_count := retry_count + 1;
        if (retry_count > 5)
          signal ("xxxxx", "Too many deadlock retries in xxxxx.");
        goto retry;
      }
   -- do the operations. The actual working code here.

    commit work;
  }
```

An exclusive read is done with

```
select s_quantity from stock where s_i_id = 111 for update;
```

ODBC

For the Virtuoso ODBC driver the isolation is set by :

- connection option (in either SQLSetConnectAttr () or SQLSetConnectOption ())

  ```
  rc = SQLSetConnectOption (hdbc, SQL_TXN_ISOLATION, SQL_TXN_READ_COMMITTED);
  ```

  or

  ```
  rc = SQLSetConnectAttr (hdbc, SQL_TXN_ISOLATION, SQL_TXN_READ_COMMITTED, NULL);
  ```

  Constants are : SQL_TXN_READ_UNCOMMITTED, SQL_TXN_READ_COMMITTED, SQL_TXN_REPEATABLE_READ, SQL_TXN_SERIALIZABLE
- ODBC setup dialog option : In Windows there is a drop-down combo box to set the default transaction isolation level for a connection.

- connection string element : You may specify the default transaction isolation level for a given connection in it's connect string (passed to the SQLDriverConnect () ODBC API). Example :

```
SQLDriverConnect (hdbc, hwnd,
    "DSN=MyDSN;IsolationLevel=Repeatable Read;UID=dba;PWD=dbapwd", SQL_NTS,
    NULL, 0,
    NULL,
    SQL_DRIVER_NOPROMPT).
```

  The possible options for the connection string are : "Read Uncommitted", "Read Committed", "Repeatable Read" and "Serializable"

JDBC

In the Virtuoso JDBC driver the isolation is set by the java.sql.Connection.setTransactionIsolation() JDBC API.

```
conn.setTransactionIsolation (java.sql.Connection.TRANSACTION_SERIALIZABLE)
```

The constants are described in the Java Docs

.Net

In the VirtuosoClient.NET provider the isolation is set by the System.Data.IDbConnection.BeginTransaction Method (IsolationLevel) function.

```
System.Data.IDBTransaction trx = conn.BeginTransaction (System.Data.IsolationLevel.ReadCommitted)
```

The constants are described here

Metrics and Diagnostics

Metrics are presented at the server and the table level.

The first metric to check is the output of status ('');

The paragraph titled transaction status contains the following:

- Count of deadlocks since server startup. There is a total number of deadlocks and the number of 2r1w deadlocks. The latter is a special case where two transactions both hold a shared lock on a resource and one tries to convert the lock to exclusive. This situation can kill the transaction attempting to write. Such deadlocks are essentially always needless. These are avoided by reading for update when first reading the resource.
- Count of waits since server startup. This is incremented every time some operation waits for a lock, except if this wait leads into a deadlock. If the number of deadlocks is high, let's say over 5% of the number of waits, transactions are likely badly designed and deadlock too often, either because of not locking for write at the get go (2r1w) or because of locking resources in varying order.
- Count of threads running. This is the count of all threads that are somehow occupied, whether running or waiting. This count minus the count of waiting minus the count of threads in vdb is the count of threads that in principle could be on CPU.
- Count of threads waiting. This is the count of threads that are waiting for a lock. If this is a high percentage of the count of threads running, say over 30%, resources are likely locked inefficiently, keeping too many locked.
- Count of threads in vdb. This is the count of threads that are at the time waiting for I/O either from a remote database or any sort of network operation, including access to web services on other serbers, access to web pages on other hosts etc.

The system view db.dba.sys_l_stat is used for locating bottlenecks.

The columns are:

- index - The index being locked. Note that when reading on non-primary key, the lock is set on the index first, only then on the pk, that is if the pk is accessed at all. For all updates however, the pk will always be accessed. *locks - The count of times a lock was set on this index.
- waits - The number of times there was a wait on this index. There can be more waits than locks because a read committed cursor can wait but will not lock, thus all waits do not result in locks.
- wait_pct - The percentage of times setting a lock waited. (100 * waits) / locks

- deadlocks - The number of times a deadlock was signalled when attempting to wait for a lock on this index.
- lock_esc - The number of times a set of row locks was converted into a page lock on this index.
- wait_msecs - The total amount of real time spent by some thread waiting for a lock on this index. This may be greater than elapsed time because many threads can wait at the same time.

All counts and times are cumulative from server startup.

The interpretation is as follows:

If deadlocks is high in relation to waits or locks, i.e. over 5%, there are many deadlocks and the transaction profiles may have to be adjusted. The table where deadlocks is incremented is the table where the deadlock was detected but the deadlock may involve any number of tables. So, if A and B are locked in the order A, B half of the time and B, a the rest of the time, then the deadlocks of the tables of A and B will be about the same, half of the deadlocks being detected when locking A, the other half when locking B.

If waits is high in relation to locks, for example 20%, then there is probably needless contention. Things are kept locked needlessly. Use read committed or make shorter transactions or lock items with the less contention first.

Because transaction duration varies, the place with the highest count of waits is not necessarily the place with the heaviest contention if the waits are short. Use wait_msecs in addition to waits for determining where the waiting takes place.

To get a general picture, use the Conductor's Statistics page or simply do:

```
select top 5 *
  from sys_l_statt
 order by wait_msecs desc;
```

to get a quick view of where time is spent. You can also sort by waits desc or locks desc.

SQL Issues

It is possible to get bad locking behavior if the SQL compiler decides to make linear scans of tables or indices and the isolation is greater than read committed. The presence of a linear scan on an index with locking is often indicated by having a large number of lock escalations. If lock_esc is near locks then a large part of the activity is likely sequential reads.

The general remedy is to do any long report type transactions as read committed unless there are necessary reasons to do otherwise.

To see how a specific query is compiled, one can use the explain () function. To change how a query is compiled, one can use the table option or option SQL clauses.

Observation of Dynamics

Deadlocks and contention do not occur uniformly across time. The occurrences will sharply increase after a certain application dependent load threshold is exceeded.

Also, deadlocks will occur in batches. Several transactions will first wait for each other and then retry maybe several times, maybe only one succeeding at every round. In such worst cases, there will be many more deadlocks than successfully completed transactions. Optimize locking order and make the transactions smaller.

Looking at how counts change, specially if they change in bursts is useful.

Tracing and Debugging

The most detailed picture of a system's behavior, including deadlocks nd other exceptions cn be obtained with profiling. If the application is in C, Java or some other compiled language, one can use the language's test coverage facility to see execution counts for various branches of the code.

For client applications, using the Virtuoso `trace()` function can be useful for seeing which statements signal errors. Also the profiling report produced by `prof_enable ()` can give useful hints on execution times and error frequencies. See Profiling and `prof_enable ()`.

For PL applications, Virtuoso provides a profiler and test coverage facility. This is activated by setting PLDebug = 2 in the Parameters section of the ini file and starting the server. The functions cov_store () and cov_report are used for obtaining a report of the code execution profile thus far. See the documentation on "Branch Coverage" for this. The execution counts of the lines for exception handler code will show the frequency of exceptions. If in a linear block of code a specific line has an execution count lower than that of the line above it, then this means that the line with the higher count has signalled as many exceptions as the difference of the higher and lower count indicates.

The times indicated in the flat and call graph profile reports for PL procedures are totals across all threads and include time spent waiting for locks. Thus a procedure that consumes almost no CPU can appear high on the list if it waits for locks, specially if this is so on multiple threads concurrently. The times are real times measured on threads separately and can thus exceed any elapsed real tiime.

Single stepping is not generally useful for debugging locking since locking issues are timing sensitive.

Client Level Resource Accounting

Starting with version 6, Virtuoso keeps track of the count of basic database operations performed on behalf of each connected client. The resource use statistics are incremented as work on the connection proceeds. The db_activity () function can be called to return the accumulated operation counts and to optionally reset these.

The db_activity built-in function has one optional argument. The possible values are:

- 0 - (default) - Return human readable string and reset the counts.
- 1 - return an array of numbers and reset the counts.
- 2 - return a human readable string and leave the counts.
- 3 - return an array of numbers and leave the counts.

The human readable string is of the form:

```
22.56MR rnd  1.102GR seq     10P disk  1.341GB /  102.7K messages
```

The postfixes K, M, G, T mean 10^3 to 10^15, except when applied to bytes, where these mean consecutive powers of 1024.

The numbers, left to right are the count of random row lookups, sequential row lookups, disk page reads, cluster inter-node traffic in bytes and cluster inter-node message count as an integer number of messages. If the configuration is a single server, the two last are 0.

The random and sequential lookup counts are incremented regardless of whether the row was found or not or whether it matched search conditions.

If the information is retrieved as an array, the array contains integer numbers representing these plus some more metrics.

Index - Meaning

- 0 - Random lookups
- 1 - sequential lookups
- 3 - lock waits
- 4 - total msec spent in lock wait on some thread. In a cluster situation, this may be more than elapsed real time.
- 5 - Disk reads
- 6 - Speculative disk reads. These are also counted in disk reads. A speculative read is a prefetch made on the basis of a read history of a disk extent.
- 7 - Cluster inter node message count
- 8 - Total bytes sent in cluster inter node traffic. A message is counted once, when sent.

If the thread calling db_activity is a web server thread, the totals are automatically reset when beginning the processing of the current web request.

6.2. HTML based Administration Console (Conductor) Guide

Abstract

This section describes how to administer the Virtuoso server from the Conductor interface. It primarily allow users to administer the server while giving access to many of the features that Virtuoso has to offer providing many conceptual demonstrations and introductions.

Most of the pages from the administration interface are provided to help administrators quickly and easily tune the Virtuoso server or navigate the various interfaces and features that Virtuoso has to offer.

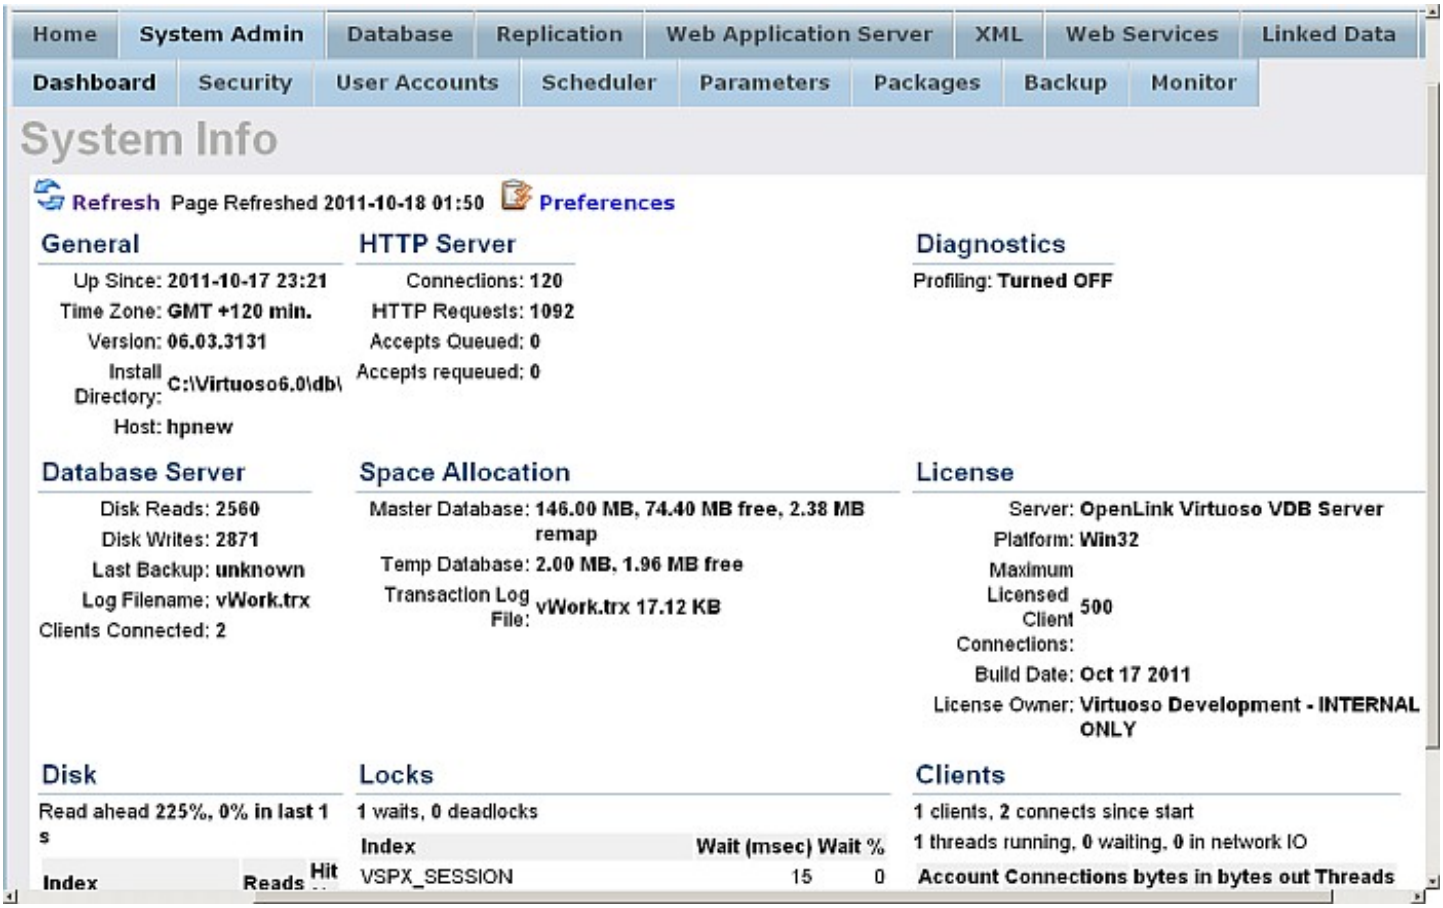
6.2.1. Virtuoso Conductor Administration

The Main Navigation Bar provides different tabs that allow you to administrate your Virtuoso server or use one of the provided samples.

Figure 6.1. Navigation

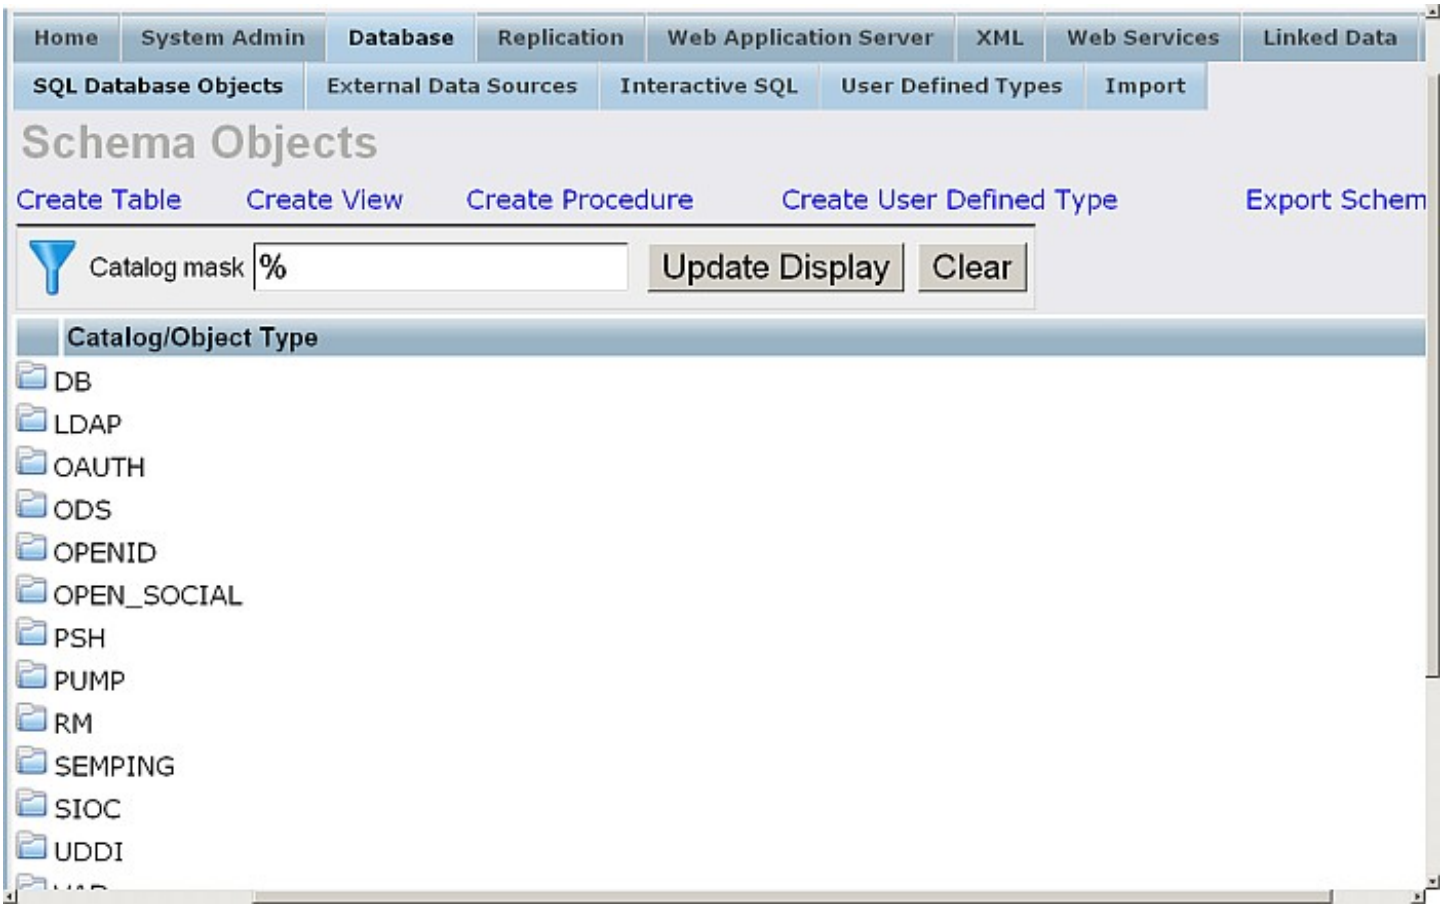
From "System Admin" you can view and change the Conductor Dashboard, manage user accounts; scheduler; Virtuoso Server parameter and Access Control Settings. You can also install /upgrade /uninstall Virtuoso packages and Monitor Virtuoso Server Statistics.

Figure 6.2. System Administration



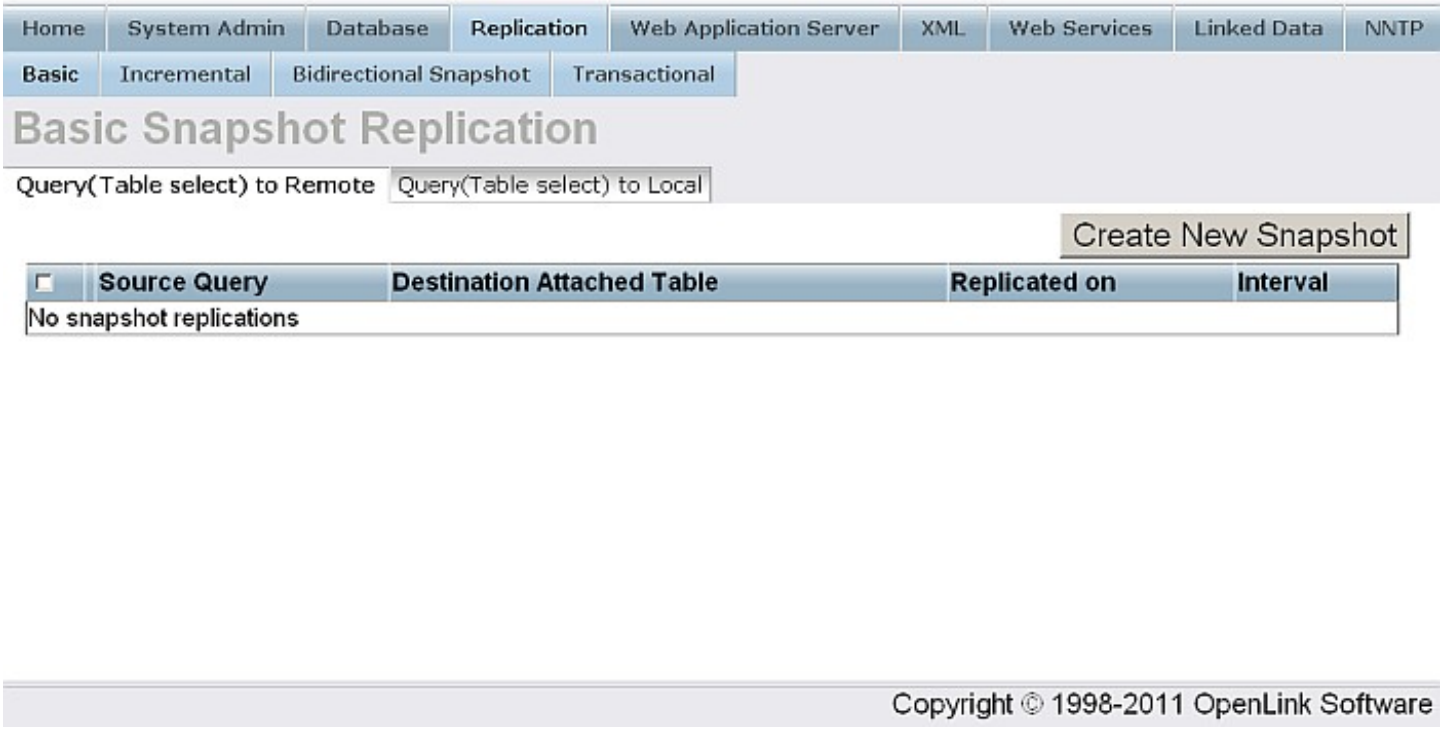
From "Database" you can administrate your database, manage the Virtuoso Relational Database System, administrate views, tables, stored procedures, trigger definitions, user define types, backups.

Figure 6.3. Database Administration



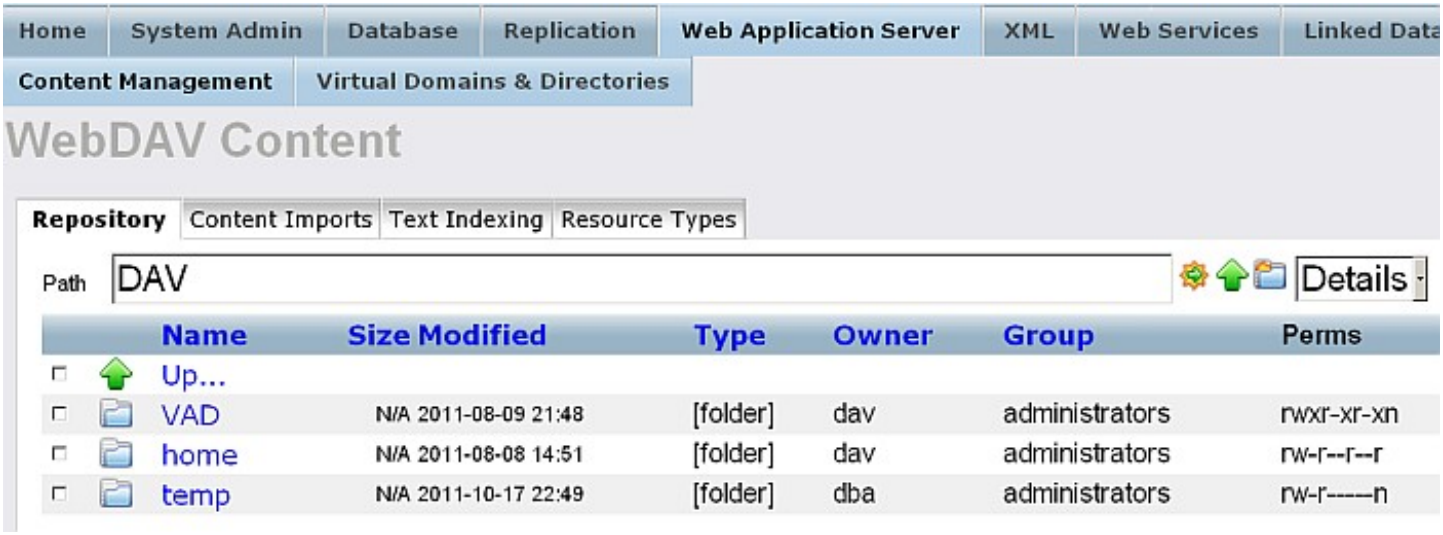
From "Replication" you can create Snapshot Replications to copy sections of the Database to remote locations or use Transactional Replication to keep Virtuoso Servers in sync over a definable interval.

Figure 6.4. Replication



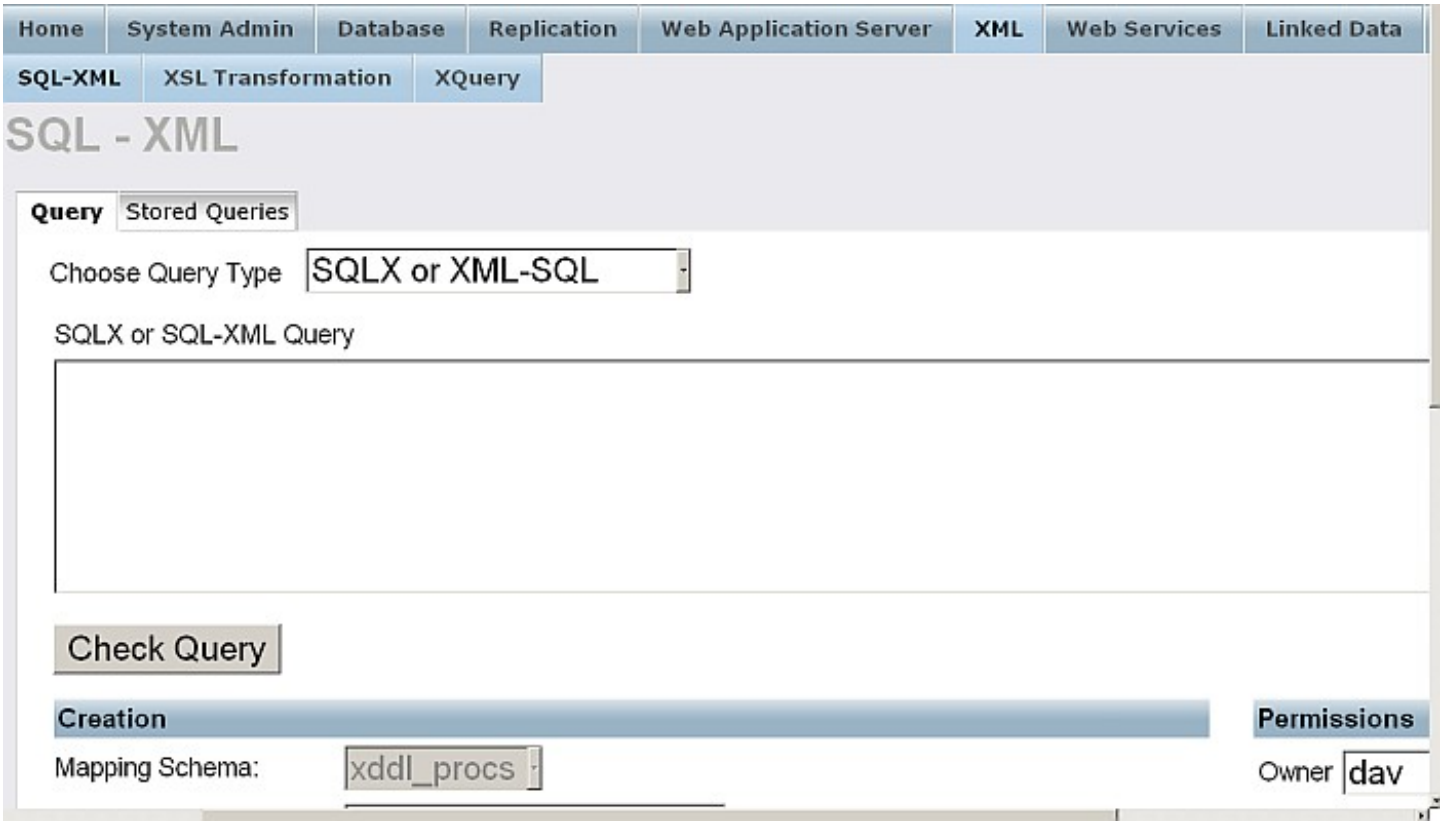
From "Web Application Server" you can configure Virtuoso's WebDAV, and HTTP Server functionality, which includes management of Virtual Domains & Directories.

Figure 6.5. Web Application Server Administration



From "XML" you can query Relational and XML Data using SQL, XQUERY, XPATH, and FREE TEXT.

Figure 6.6. Query Tools

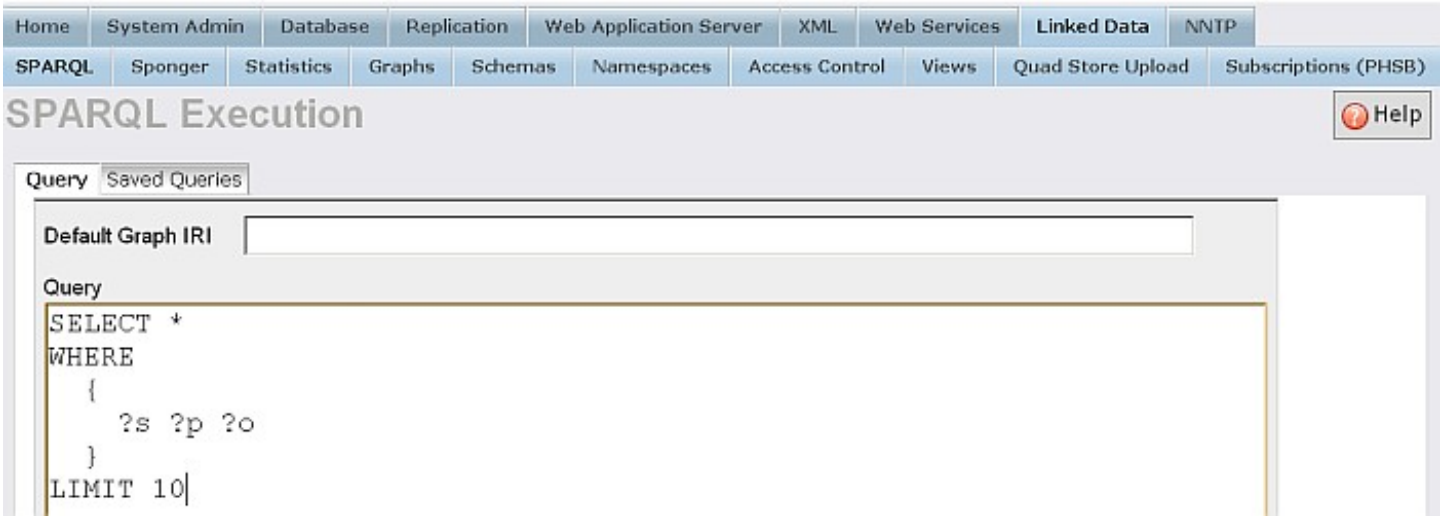


From "Web Services" you can add/ edit/ remove Web Services Endpoints, perform WSDL Import/Export, manage your BPEL processes.

Figure 6.7. Web Services

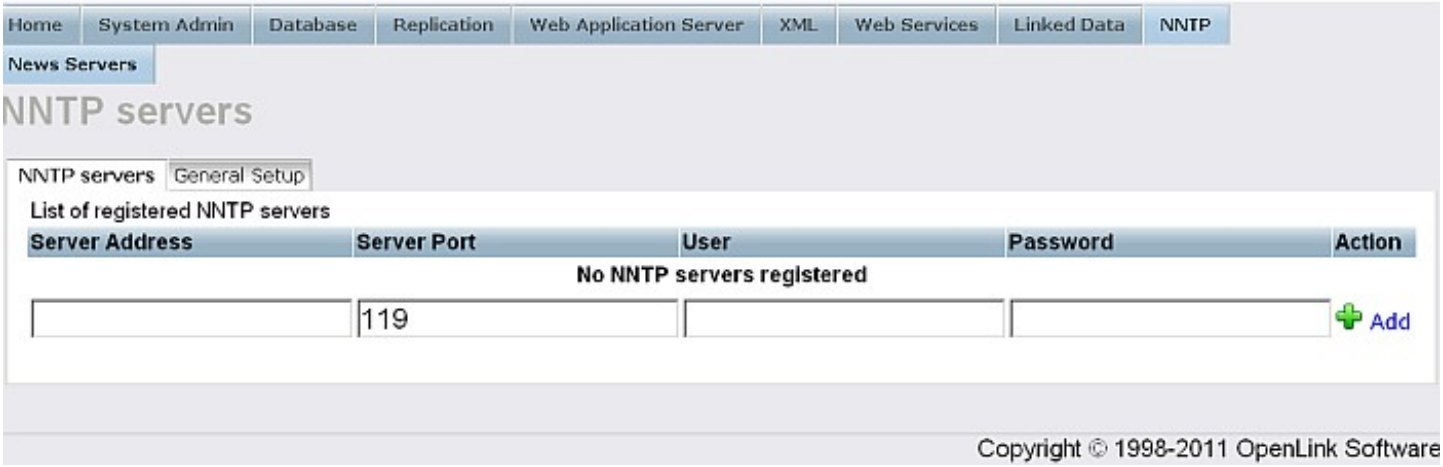
From "Linked Data" tab you can execute/save/load SPARQL queries, add/edit RDF Mapping, make statistics, manage graphs, import schemas and define namespaces, generated Linked Data Views, upload to the Quad Store:

Figure 6.8. RDF



Virtuoso's NNTP support which includes linking third-party NNTP servers into Virtuoso and controlling access to these servers.

Figure 6.9. NNTP Administration



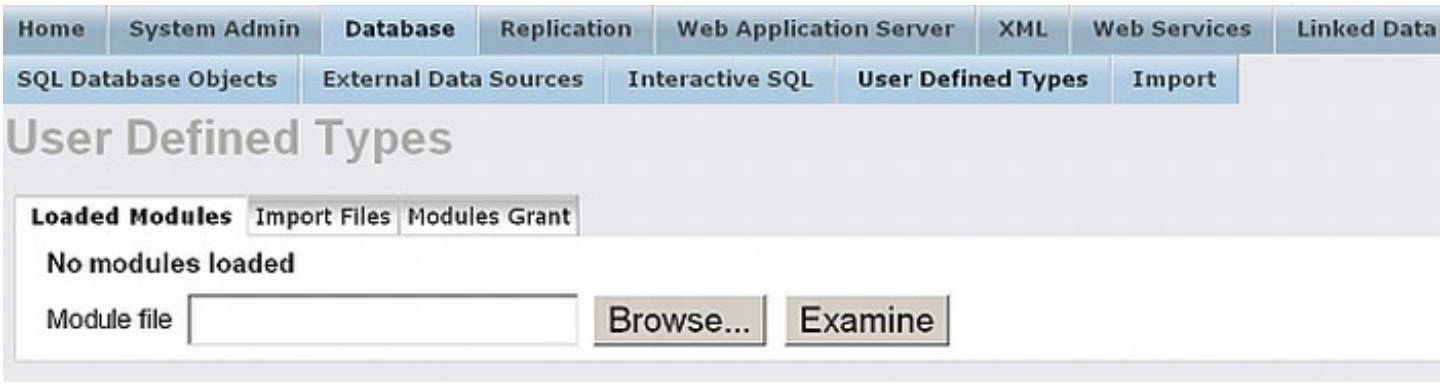
6.2.2. Runtime Hosting

The runtime hosting interfaces require Mono/CLR and Java extension servers.

Loaded Modules

You can view Loaded Modules list and each Module you can "Unload". Also you can browse for Module and examine its content.

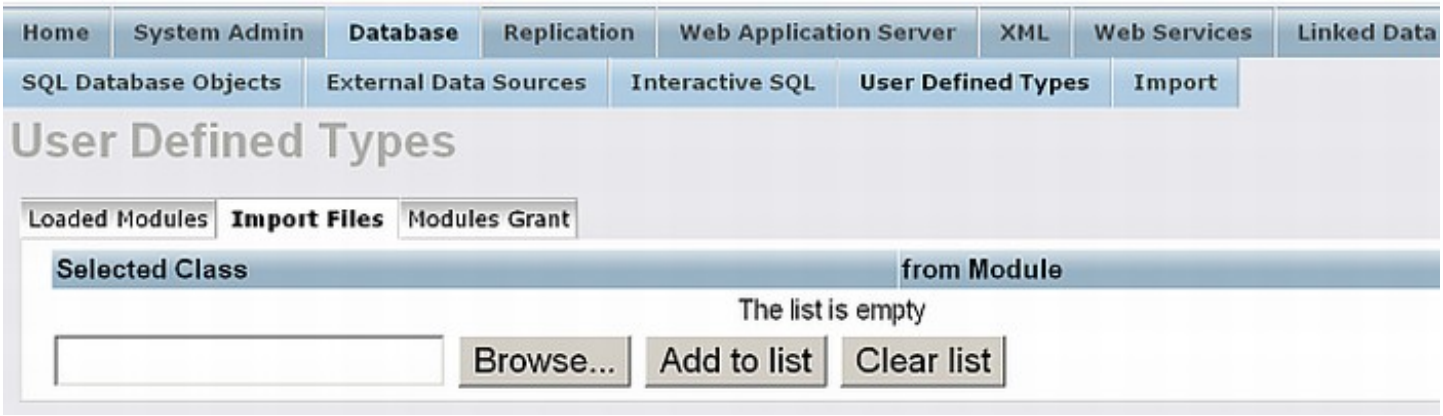
Figure 6.10. Loaded Modules



Import Files

To import files click the "Browse" button and select the class you want to import. Then click the "Add to list" button.

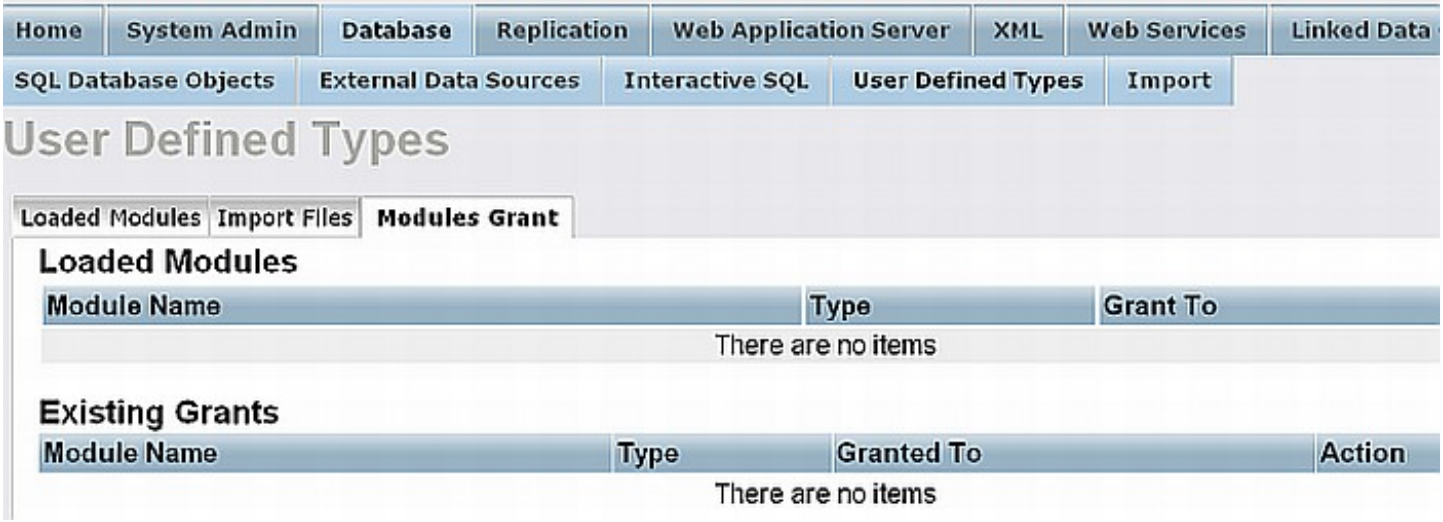
Figure 6.11. Import Files



Modules Grants

In order to change grants to a particular Module, select the desired grant value from the "Grant to" list and click the "Add" button.

Figure 6.12. Modules Grants



6.2.3. Web Services

Content Crawler

Some of the supported features are:

- *Import Targets* : Virtuoso can be set up to retrieve content from external web sites and host it in its own WebDAV repository via this page.

Figure 6.13. Web Robot - Crawl Job

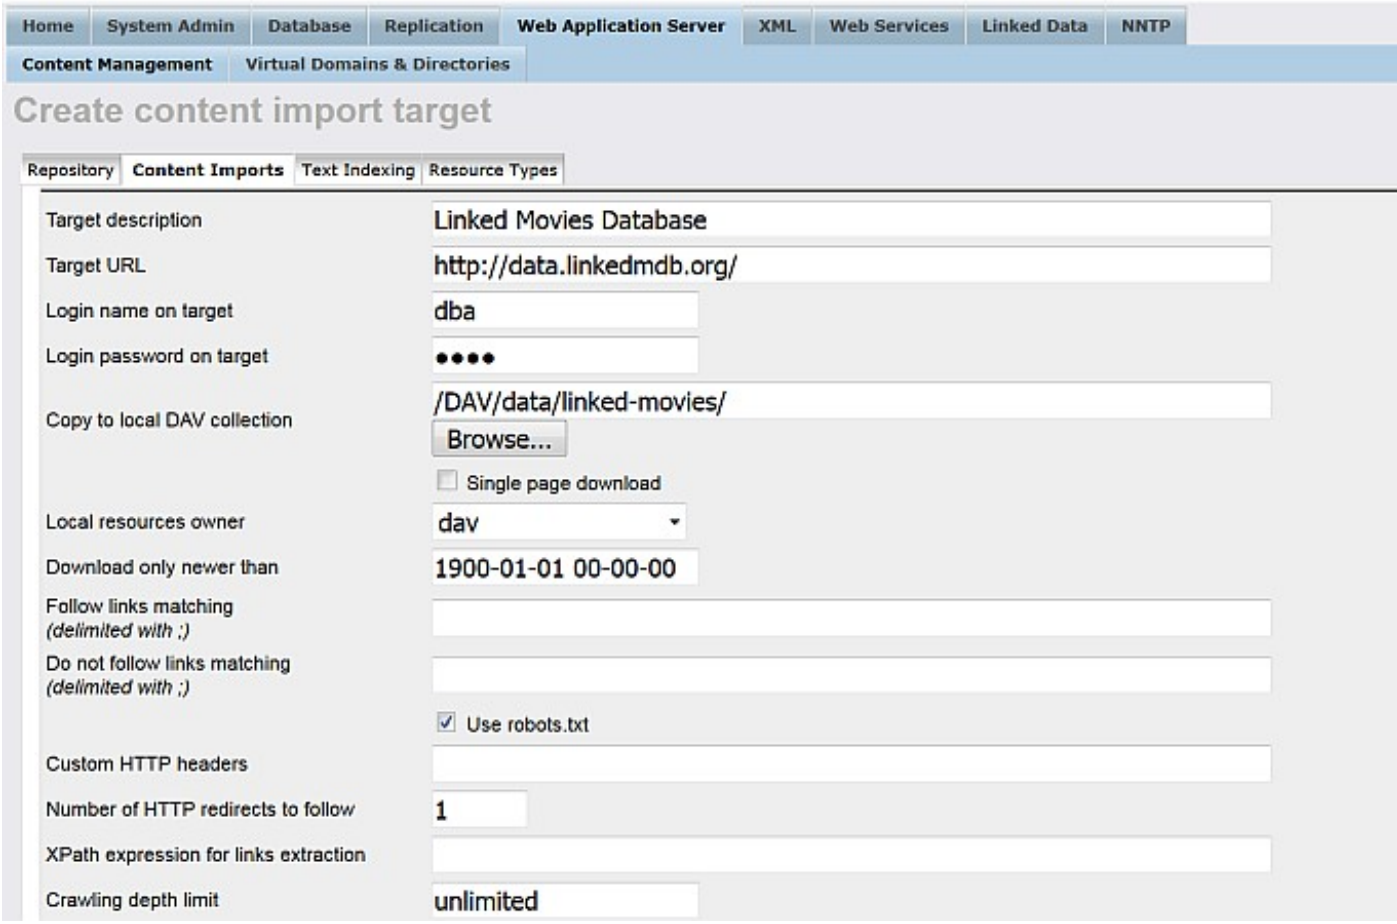


Figure 6.14. Web Robot - Crawl Job

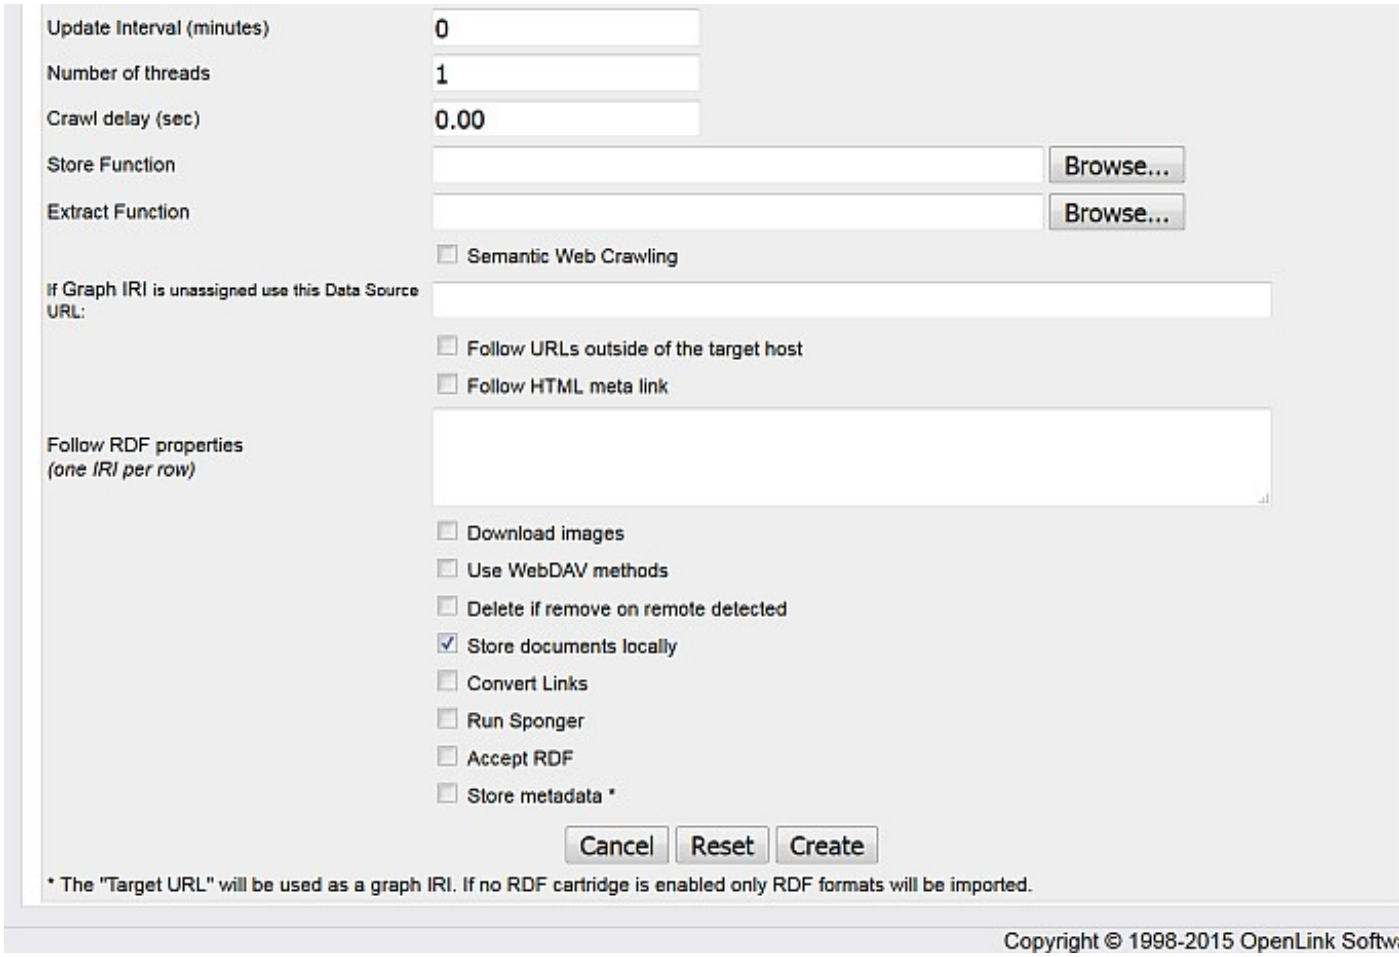


- *Target description* lets you provide a friendly name for the target that you are defining.
- *Target URL* is the url of the web site that you are trying to retrieve content from. Only the hostname should be provided here, along with the protocol. For example http://www.myhost.com.
- *Login name on target* is the username for accessing the remote server, if required.
- *Login password on target* is the password for the login name above.
- *Copy to local DAV collection* this *mandatory* value will serve as the DAV root location if content is stored locally.
- *Single page download* radio button specifies whether Virtuoso will retrieved linked content also.
- *Local Resources Owner* The DAV user that will be the owner of the content that will copied to DAV.
- The *Download only newer than* field allows you to specify a datetime value to prevent Virtuoso downloading files that are older than that datetime.
- Use the *Follow links matching (delimited with ;)* field to limit the content that is downloaded by specify pattern matching criteria.
- *Do not follow links matching (delimited with ;)* allows you limit content by specifying what files not to download.

- *Use robots.txt* check-box is checked by default.
- *Custom HTTP headers* can be used to specigy custom HTTP headers.
- *Number of HTTP redirects to follow* is set by default to 1.
- *XPath expression for links extraction* allows to be entered custom XPath expression.
- *Crawling depth limit* allows to limit crawling depth. By default is set to "unlimited".
- *Update Interval (minutes)* is on what interval the updated of the crawled data should be performed.
- *Number of threads* allows setting crawling threads.
- *Crawl delay (sec)* allows to be specified a delay. By default is set to "0.00".
- *Store Function* allows to be used a specific stored function for ex. in Semantic Sitemaps crawling.

See Also:

Example of Stored Functions.

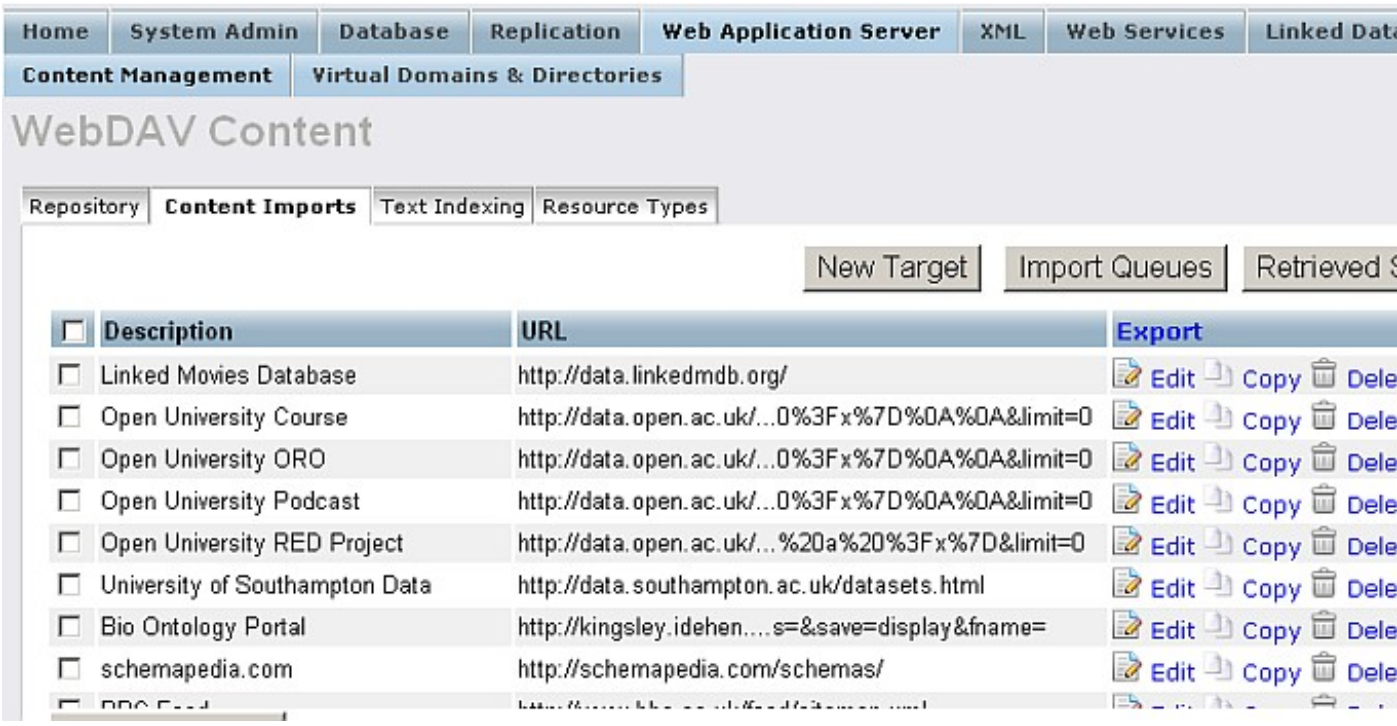
- *Extract Function* allows to be used a specific extract function for ex. in Semantic Sitemaps crawling. If left empty, will be used a system Store function.

See Also:

Example of Stored Functions.

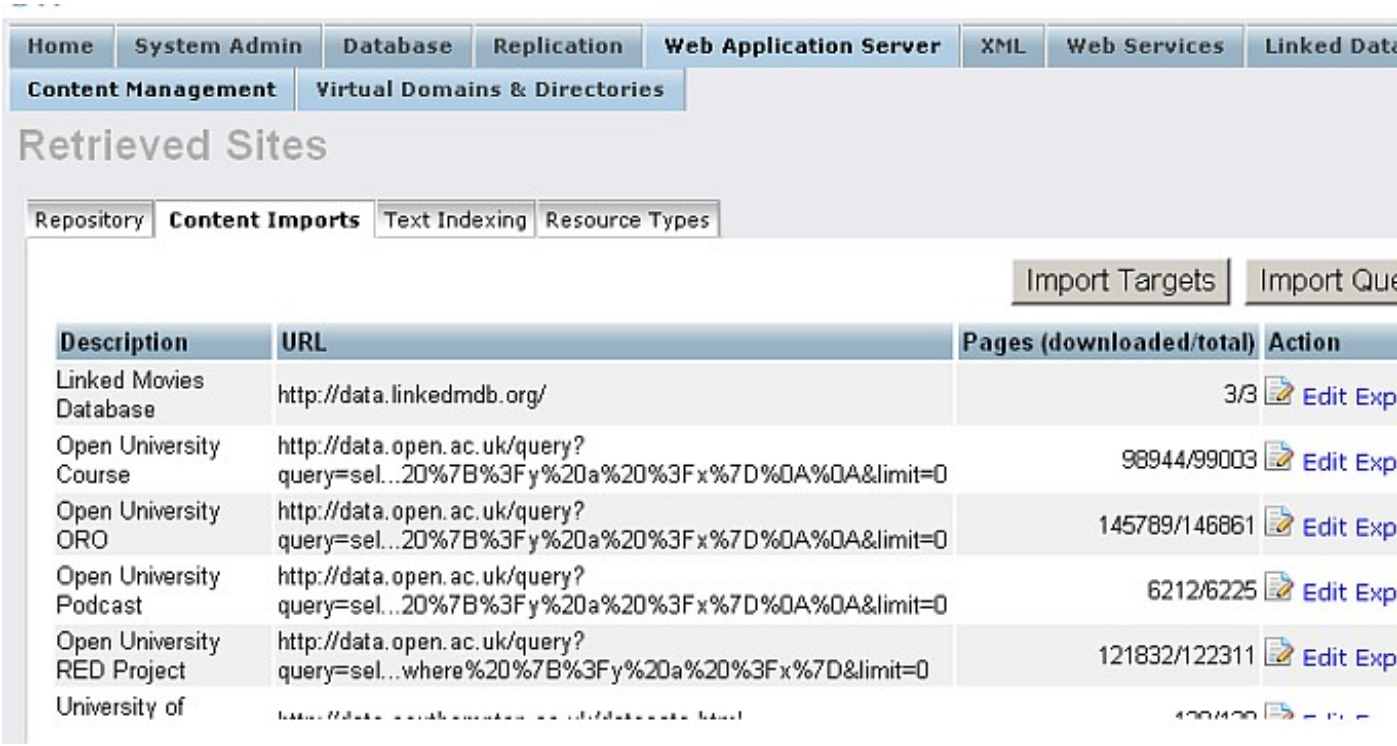
- *Semantic Web Crawling* : hatch to retrieve Semantic Sitemaps. If left empty, will be used a system Store function.
- *If Graph IRI is unassigned use this Data Source URL:* use to specify a custom graph URI for data storage.
- *Follow URLs outside of the target host* is check-box to specify either to follow URIS outside of the target host.
- *Follow HTML meta link* is check-box to specifiy either to follow HTML meta links.
- *Follow RDF properties (one IRI per row)* .
- *Download Images* radio buttons to allow Virtuoso to pull down image type also. You may want to prevent this if you are more interested in the textual content rather than bandwidth draining images.
- *Use WebDAV methods* can be checked if the host is known to support WebDAV methods. This would enable better copying of sites that support DAV.
- *Delete if remove on remote detected* can be switched on so that when Virtuoso synchronizes its content with that on the remote host it will check for files that have been removed on the remote and remove them from the local copy also.
- *Store metadata** when checked offers to be stored respectively metadata from FOAF, RDF, RSS/RDF and GRDLL data depending on which check-box is checked.
- When all details have been completed press the *Add* (or Update if updating) button to submit the web robot task to the queue.
- *Import Queues* : This page shows you a list of web copy targets that have been enlisted with the Virtuoso Server, and a list of web robot update schedules. Several options are available for each item listed: Start, Update, Schedule, Reset, and Stop. You can configure the scheduled update interval by pressing the Schedule link and entering a value in minutes. Once that is done you can start the schedule by pressing the Start link. You make a manual update of the content by pressing the Update link. You can stop the scheduled updates taking place by pressing the Stop link. To reset the details of the web copy item press the Reset link.

Figure 6.15. Web Robot - Queues



- *Retrieved Sites* : You can view a list of the links retrieved from the web copy from this page. You are also able to remove some of the content from this page by following the Edit link.

Figure 6.16. Web Robot - Retrieved Links



- *Export* : You can export content from the WebDAV repository. Note that you can only export content that has been retrieved using Virtuoso's Web Robot.

  When you click the "Export" link for a retrieved collection, you will be presented with a form for selecting the export target location. Choose the export method: either File System or DAV by clicking the "External WebDAV Server URL" check-box. This lets you indicate to the remote target where to store the exported content. Then type the target URL to an existing location on the server. Finally press the *Export* button to export. A confirmation will be supplied once the operation is complete.

Figure 6.17. Web Robot - Exporting Content

Note:

If is not checked the "External WebDAV Server URL" check-box, i.e. you are selecting the filesystem method, then you are restricted to Virtuoso targets. However WebDAV methods can be applied to any WebDAV server. WebDAV methods assume that the target is publicly available for writing.

- *Populate the RDF Quad Store* : Virtuoso's built-in Content Crawler to can be used to populate its RDF Quad Store, as a one-time run or on a scheduled basis.

  Transforming data sources into RDF "on the fly" is sufficient for many use cases, but there are times when the volume or sheer nature of a data source makes batch-loading necessary.

For example, Freebase offers RDF representations of its data, but it doesn't publish RDF dumps; even if it did, such dumps would usually be outdated by the time they were loaded.

One practical solution takes the form of a scheduled crawl of specific resources of interest.

Set Up the Content Crawler to Gather RDF

The Virtuoso Conductor can be used to set up various Content Crawler Jobs:

Setting up a Content Crawler Job to Add RDF Data to the Quad Store

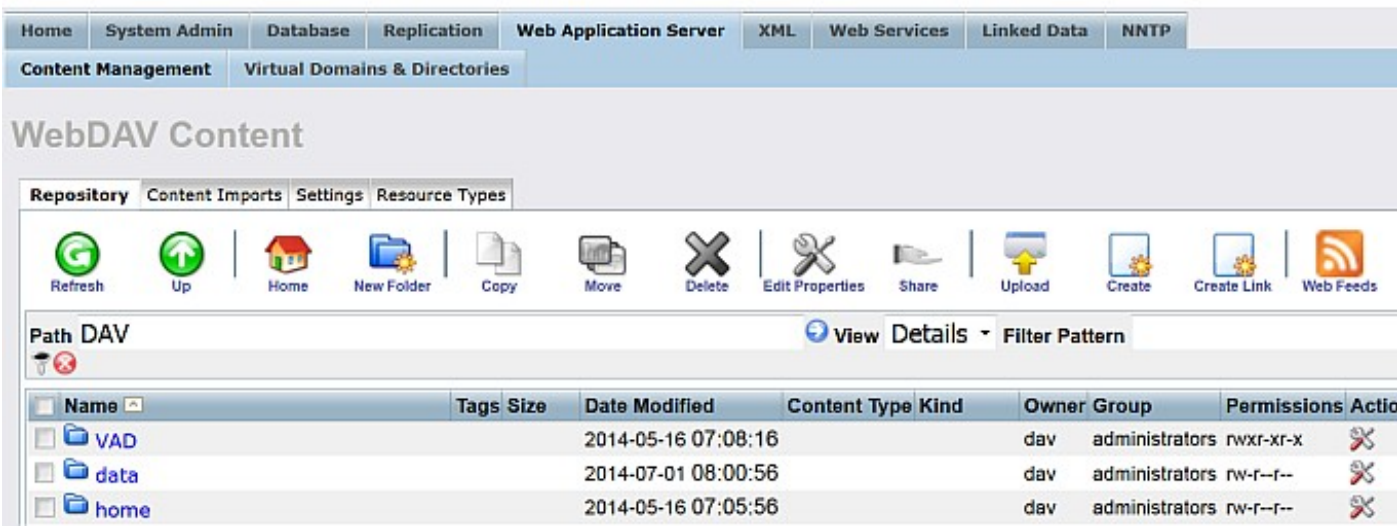
See details how to use Virtuoso Crawler for including the Sponger options so you crawl non-RDF but get RDF and this to the Quad Store.

Setting up a Content Crawler Job to Retrieve Sitemaps (when the source includes RDFa)

The following section describes how to set up a crawler job for getting content of a basic Sitemap where the source includes RDFa.

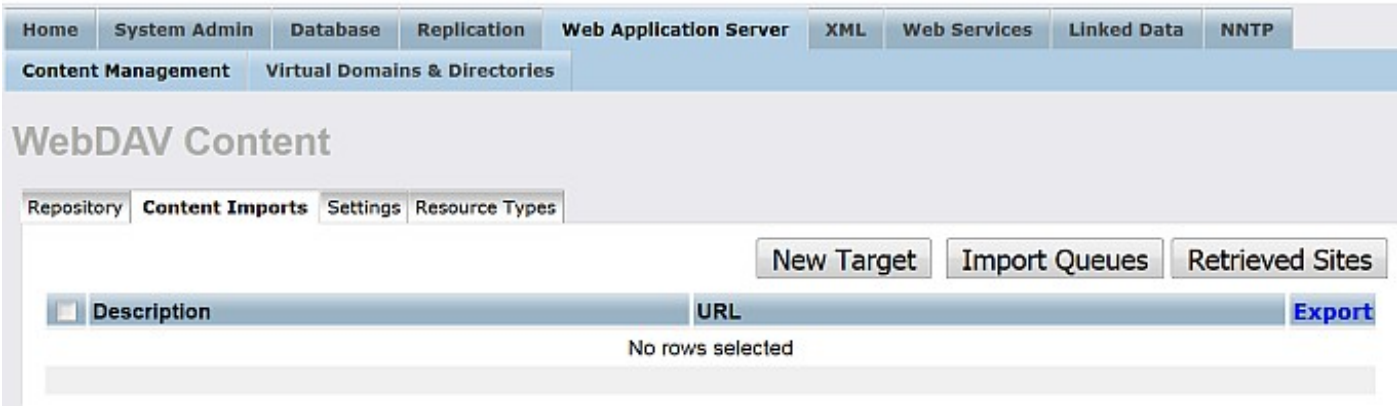
1. From the Virtuoso Conductor User Interface i.e. http://cname:port/conductor, login as the "dba" user.
2. Go to the "Web Application Server" tab.

Figure 6.18. Setting up a Content Crawler Job to Retrieve Sitemaps



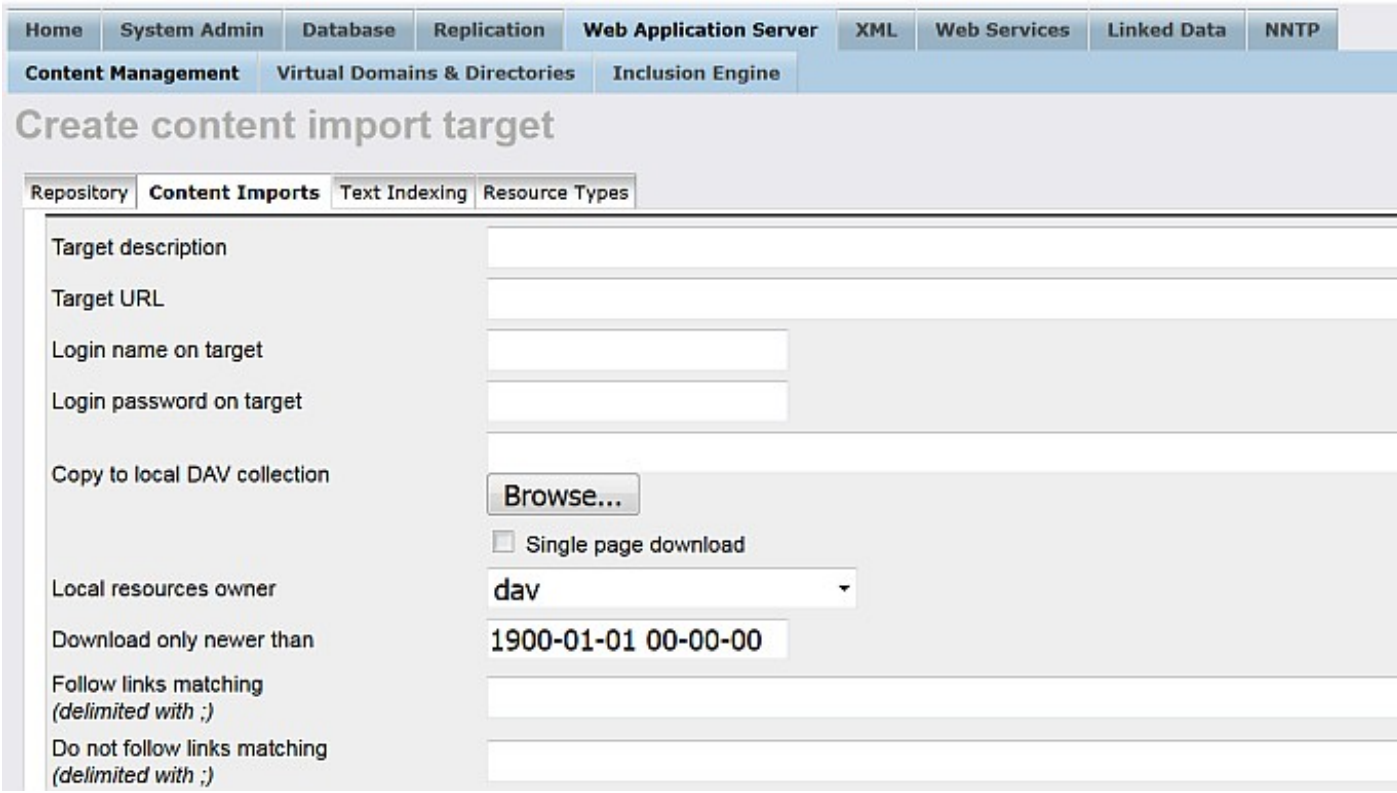
3. Go to the "Content Imports" tab.

Figure 6.19. Setting up a Content Crawler Job to Retrieve Sitemaps



4. Click on the "New Target" button.

Figure 6.20. Setting up a Content Crawler Job to Retrieve Sitemaps



5. In the form displayed:

   - Enter a name of choice in the "Target description" text box:

     ```
     Virtuoso Sample Example
     ```

   - Enter the URL of the site to be crawled in the "Target URL" text box:

     ```
     http://virtuoso.openlinksw.com/sitemap.xml
     ```

   - Enter the location in the Virtuoso WebDAV repository the crawled should stored, in the "Copy to local DAV collection" text box, for example, if user demo is available, then:

     ```
     /DAV/home/demo/VirtSample/
     ```

   - Choose the "Local resources owner" for the collection from the list box available, for ex: user demo.
   - Select the "Accept RDF" check box.
   - Optionally you can select "Convert Links" to make all HREFs in the local stored content relative.

Figure 6.21. Setting up a Content Crawler Job to Retrieve Sitemaps

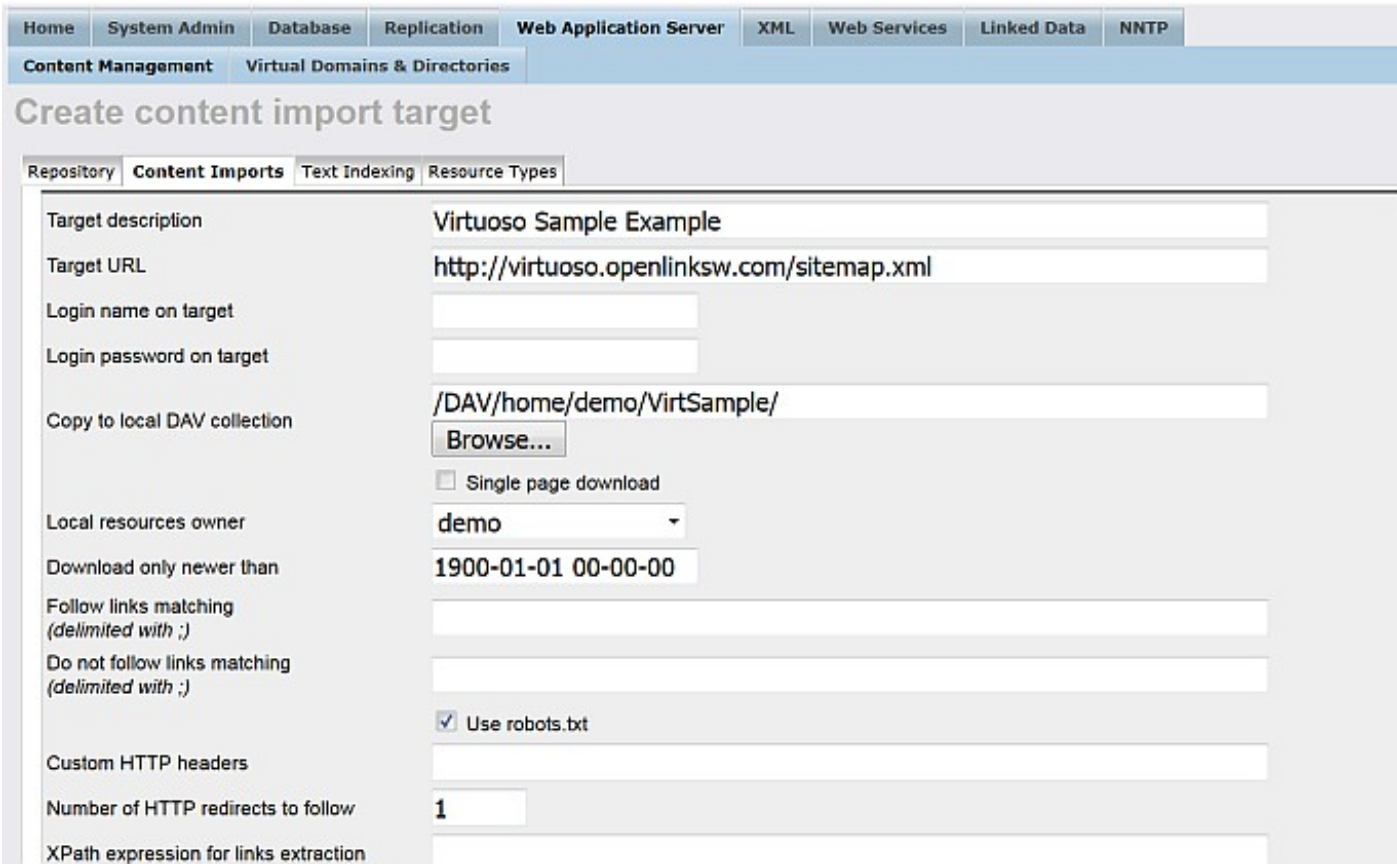


Figure 6.22. Setting up a Content Crawler Job to Retrieve Sitemaps

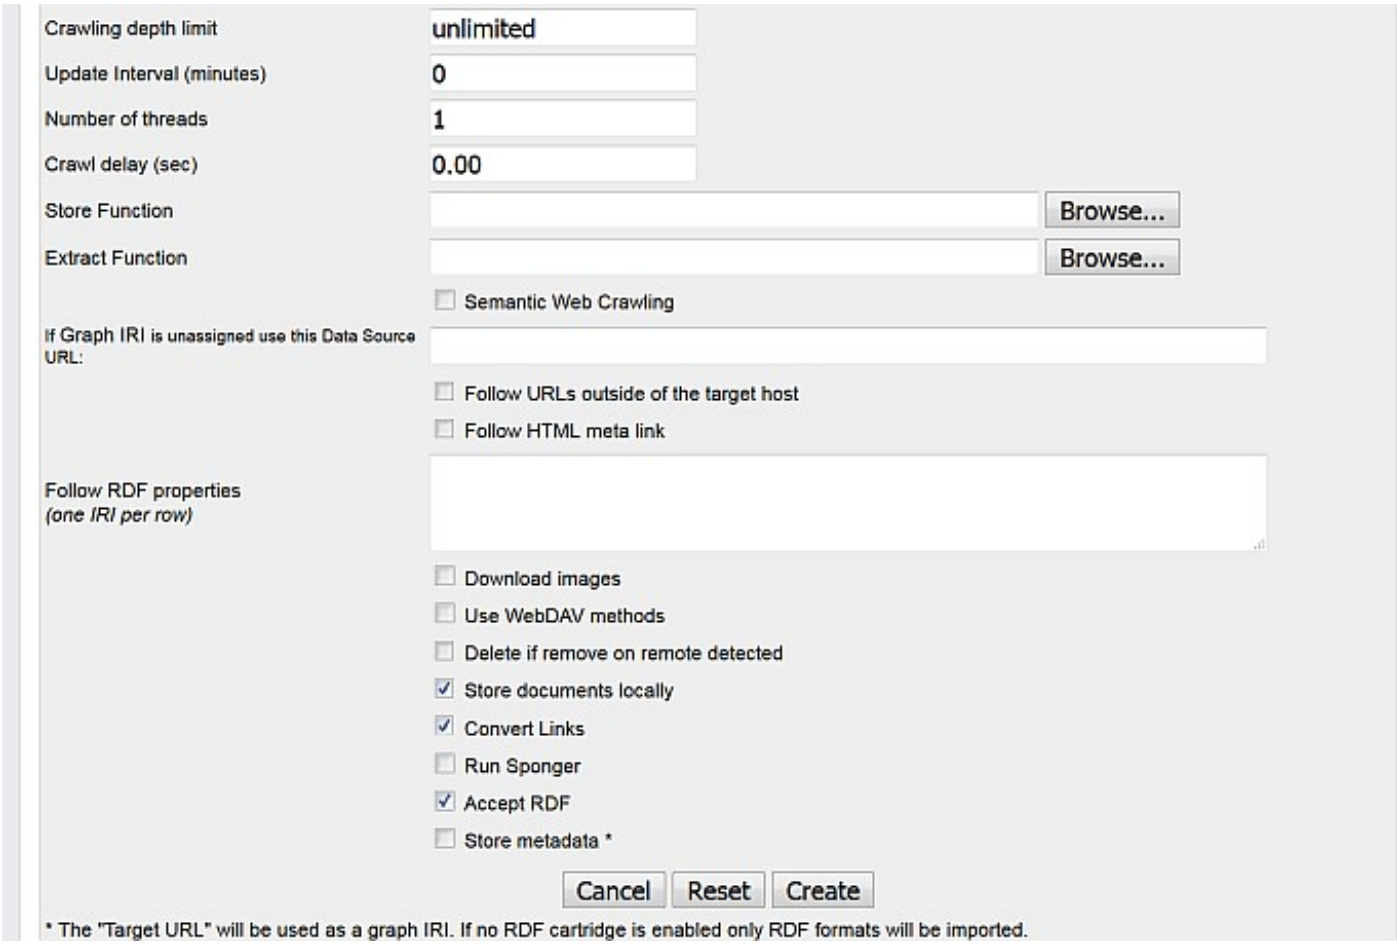
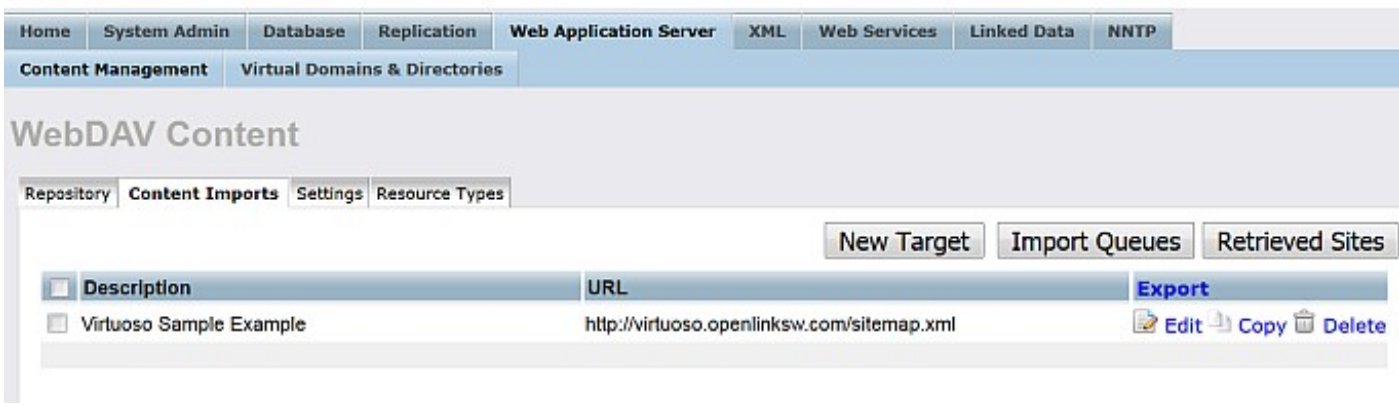


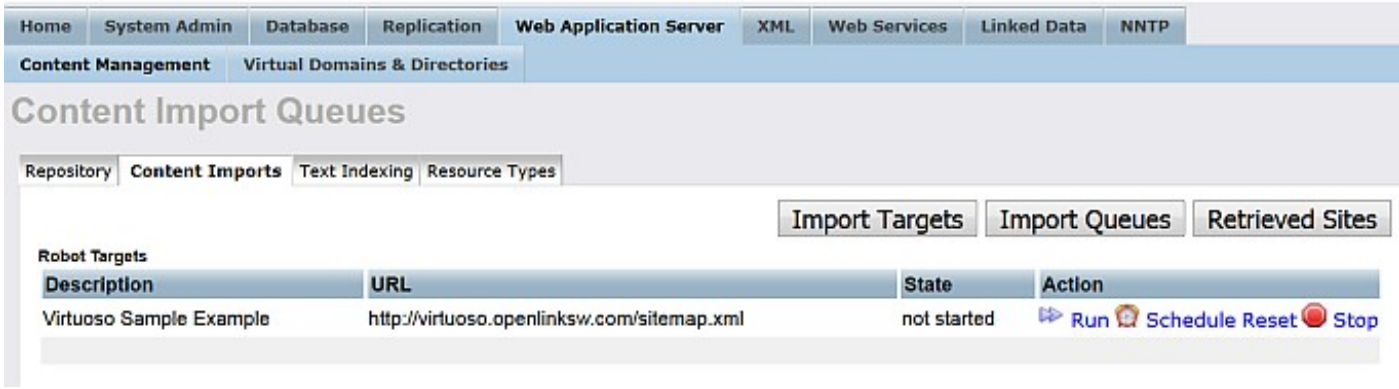
6. Click the "Create" button to create the import.

Figure 6.23. Setting up a Content Crawler Job to Retrieve Sitemaps



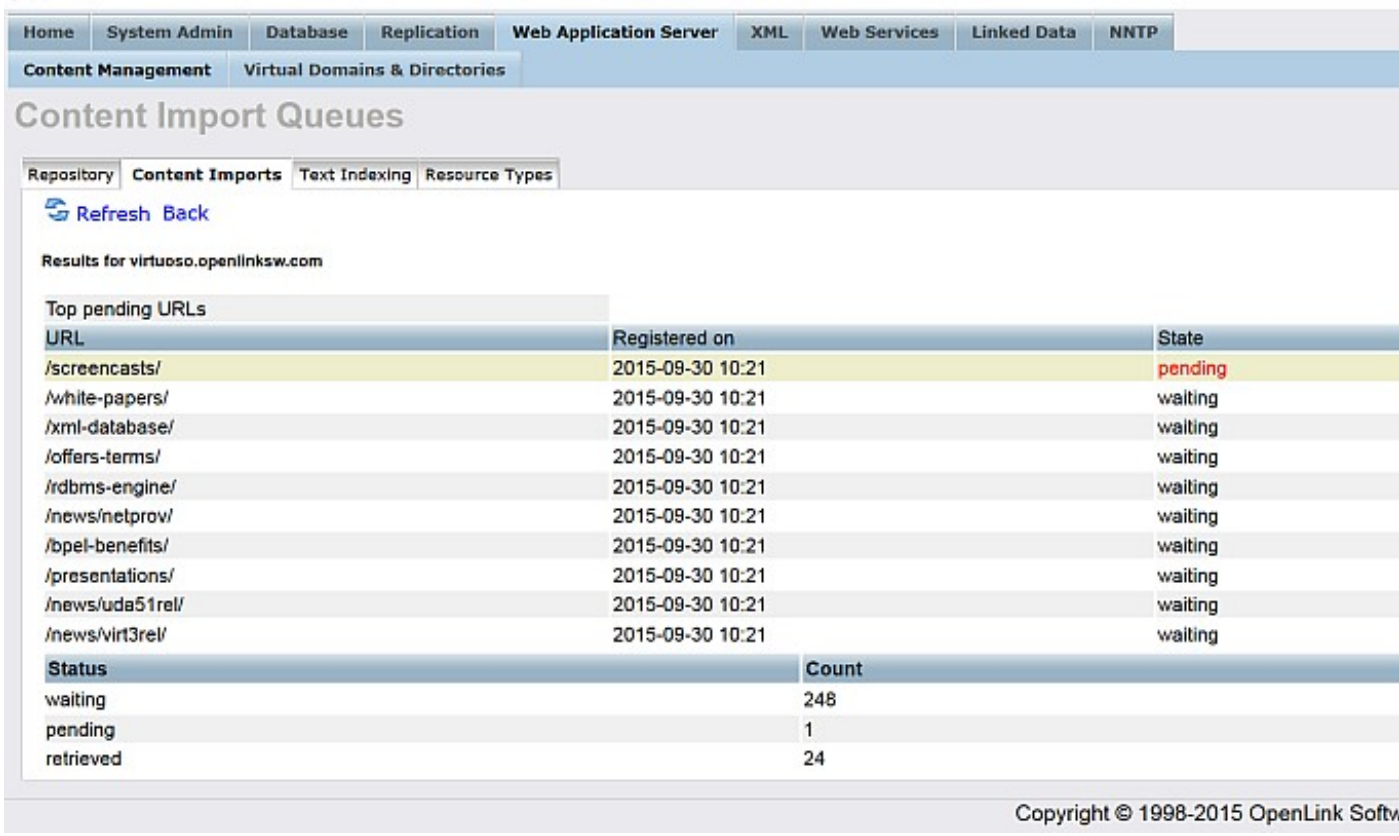
7. Click the "Import Queues" button.

Figure 6.24. Setting up a Content Crawler Job to Retrieve Sitemaps



8. For the "Robot targets" with label "Virtuoso Sample Example" click the "Run" button.
9. This will result in the Target site being crawled and the retrieved pages stored locally in DAV and any network resource triples being fetched in the RDF Quad store.

Figure 6.25. Setting up a Content Crawler Job to Retrieve Sitemaps

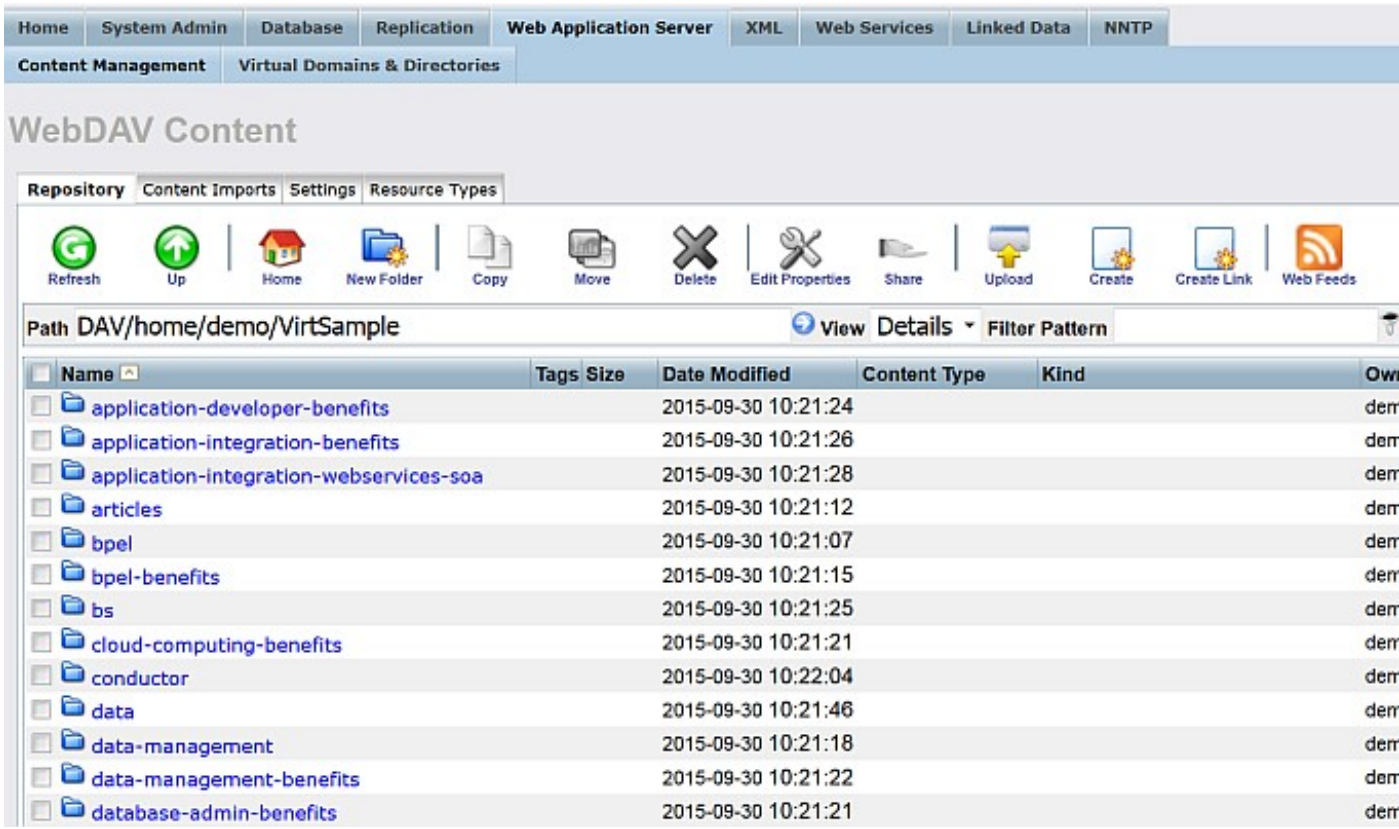


10. Go to the "Web Application Server" -> "Content Management" tab and navigate to the location of newly created DAV collection:

    ```
    /DAV/home/demo/VirtSample/
    ```

11. The retrieved content will be shown:

Figure 6.26. Setting up a Content Crawler Job to Retrieve Sitemaps

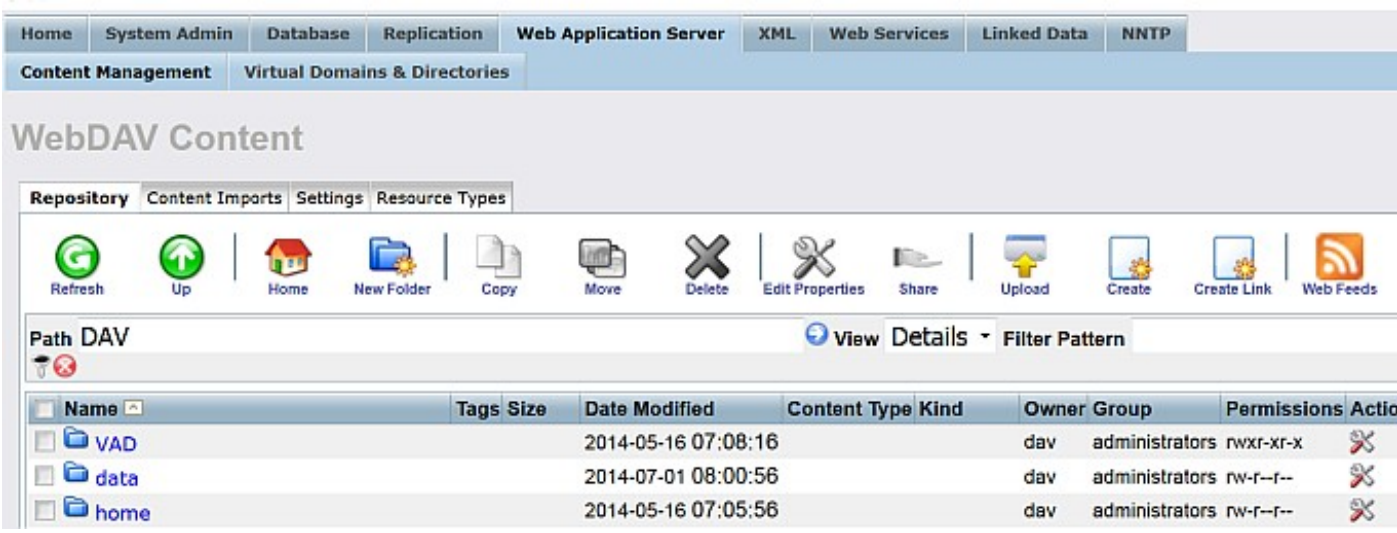


Setting up a Content Crawler Job to Retrieve Semantic Sitemaps (a variation of the standard sitemap)

The following section describes how to set up crawler job for getting Semantic Sitemap's content: a variation of standard sitemap:

1. From the Virtuoso Conductor User Interface i.e. http://cname:port/conductor, login as the "dba" user.
2. Go to "Web Application Server".

Figure 6.27. Setting up a Content Crawler Job to Retrieve Semantic Sitemap content

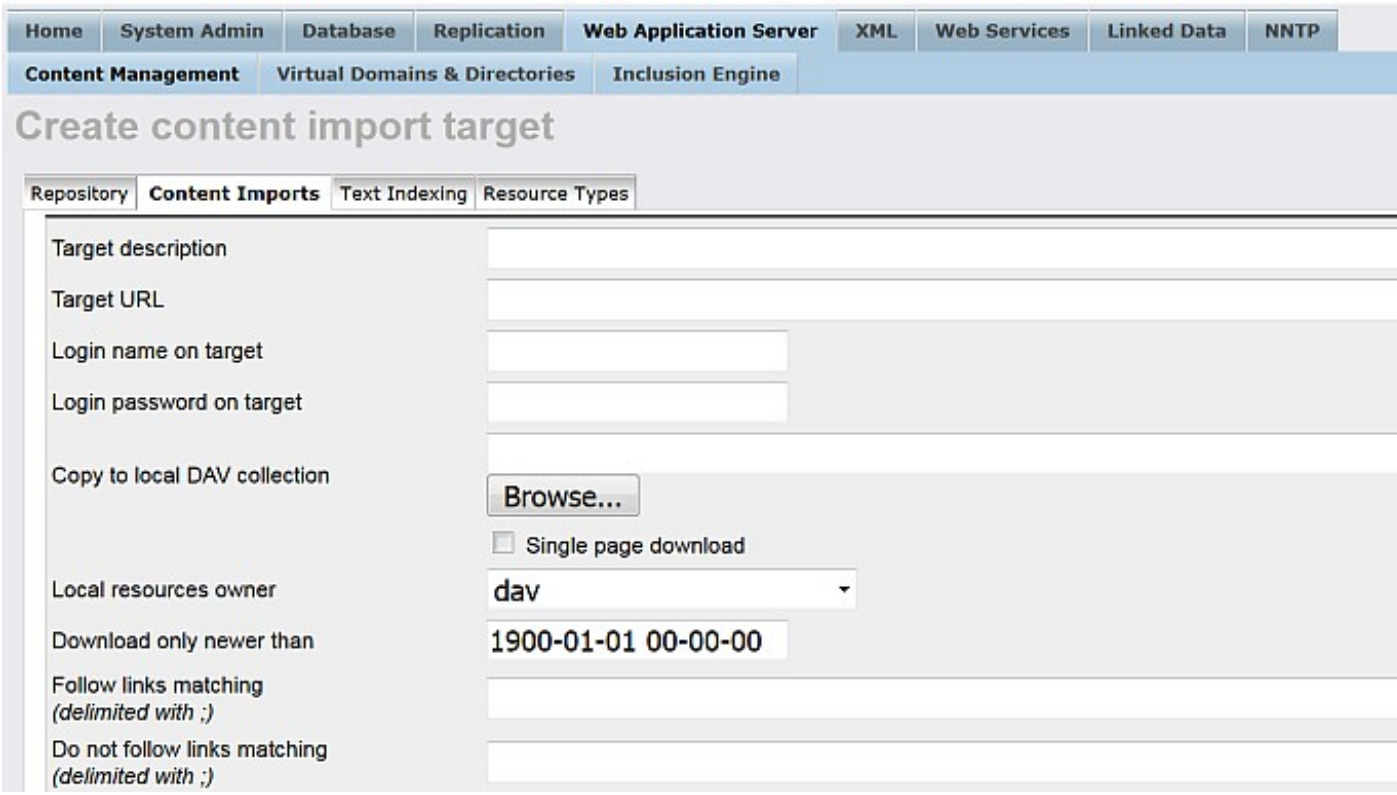


3. Go to "Content Imports".

Figure 6.28. Setting up a Content Crawler Job to Retrieve Semantic Sitemap content

4. Click "New Target".

Figure 6.29. Setting up a Content Crawler Job to Retrieve Semantic Sitemap content



5. In the shown form:

   - Enter for "Target description":

     ```
     Semantic Web Sitemap Example
     ```

   - Enter for "Target URL":

     ```
     http://virtuoso.openlinksw.com/sitemap-semantic.xml
     ```

   - Enter the location in the Virtuoso WebDAV repository the crawled should stored in the "Copy to local DAV collection" text box, for example, if user demo is available, then:

     ```
     /DAV/home/demo/semantic_sitemap/
     ```

   - Choose the "Local resources owner" for the collection from the list box available, for ex: user demo.
   - Hatch "Semantic Web Crawling"

     - Note: when you select this option, you can either:

       a. Leave the Store Function and Extract Function empty - in this case the system Store and Extract functions will be used for the Semantic Web Crawling Process, or:
       b. You can select your own Store and Extract Functions, for ex:

```
-- Example of Extract Function
use WS;

create procedure WS.WS.SITEMAP_BB_PARSE (
  in _host varchar,
  in _url varchar,
  in _root varchar,
  inout _content varchar,
  in _c_type varchar := null,
  in lev int := 0))
{
  --pl_debug+
  declare xt, xp, graph any;
  declare inx int;

--  dbg_obj_print ('WS.WS.GET_URLS_SITEMAP', _url);

  declare exit handler for sqlstate '*'
```

```
    {
--      dbg_obj_print (__SQL_MESSAGE);
      return;
    };

  if (_url like '%.xml.gz')
    {
      _content := gzip_uncompress (_content);
    }

  if (_url like '%.xml' or _url like '%.xml.gz' or _url like '%.rdf')
    {
      xt := xtree_doc (_content);
      if (xpath_eval ('/urlset/dataset', xt) is not null)
        {
          xp := xpath_eval ('/urlset/dataset/dataDumpLocation/text()', xt, 0
          graph := cast (xpath_eval ('/urlset/dataset/datasetURI/text()', xt
          if (length (graph))
            update VFS_SITE set VS_UDATA = serialize (vector ('graph', graph
          inx := 0;
          foreach (any u in xp) do
            {
              declare hf, host, url varchar;

              u := cast (u as varchar);
              hf := WS.WS.PARSE_URI (u);
              host := hf[1];
              --dbg_obj_print ('WS.WS.GET_URLS_SITEMAP PARSE', u);
              url := hf[2];
              insert soft VFS_QUEUE (VQ_HOST, VQ_TS, VQ_URL, VQ_STAT, VQ_ROO
                  values (host, now (), url, 'waiting', _root, NULL);
              if (row_count () = 0)
                update VFS_QUEUE set VQ_STAT = 'waiting', VQ_TS = now () whe
              inx := inx + 1;
            }
        }
      if (xpath_eval ('/sitemapindex/sitemap/loc', xt) is not null)
        {
          xp := xpath_eval ('/sitemapindex/sitemap/loc/text()', xt, 0);
          inx := 0;
          foreach (any u in xp) do
            {
              declare hf, host, url varchar;

              u := trim (cast (u as varchar));
              hf := WS.WS.PARSE_URI (u);
              host := hf[1];
--            dbg_obj_print ('WS.WS.GET_URLS_SITEMAP', host, _host);
              url := hf[2];
              if (url <> '')
                {
                  insert soft VFS_QUEUE (VQ_HOST, VQ_TS, VQ_URL, VQ_STAT, VQ
                      values (host, now (), url, 'waiting', _root, NULL);
                  if (row_count () = 0)
                    update VFS_QUEUE set VQ_STAT = 'waiting', VQ_TS = now ()
                  inx := inx + 1;
                }
            }
        }
    }
  commit work;
}
;

-- Example of Store Function
use WS;

create procedure WS.WS.SITEMAP_BB_STORE (
  in _host varchar,
  in _url varchar,
  in _root varchar,
  inout _content varchar,
  in _s_etag varchar,
```

```
    in _c_type varchar,
    in store_flag int := 1,
    in udata any := null,
    in lev int := 0)
{
  --pl_debug+
  declare graph varchar;

--  dbg_obj_print ('WS.WS.SITEMAP_BB_STORE', _url, udata);
  if (isarray (udata))
    graph := get_keyword ('graph', udata);
  else
    graph := null;

  if (graph is not null and _url like '%.rdf')
    {
      DB.DBA.RDF_LOAD_RDFXML (_content, graph, graph);
      DB.DBA.VT_INC_INDEX_DB_DBA_RDF_OBJ ();
    }
  insert soft VFS_URL (VU_HOST, VU_URL, VU_CHKSUM, VU_CPTIME, VU_ETAG, VU_RO
      values (_host, _url, md5 (_content), now (), _s_etag, _root);
  if (row_count () = 0)
    update VFS_URL set VU_CHKSUM = md5 (_content), VU_CPTIME = now (), VU_ET
        VU_HOST = _host and VU_URL = _url and VU_ROOT = _root;
  commit work;
}
;
```

6. Optionally you can select "Convert Link" to make all HREFs in the local stored content relative.
7. Hatch "Accept RDF"

Figure 6.30. Setting up a Content Crawler Job to Retrieve Semantic Sitemap content

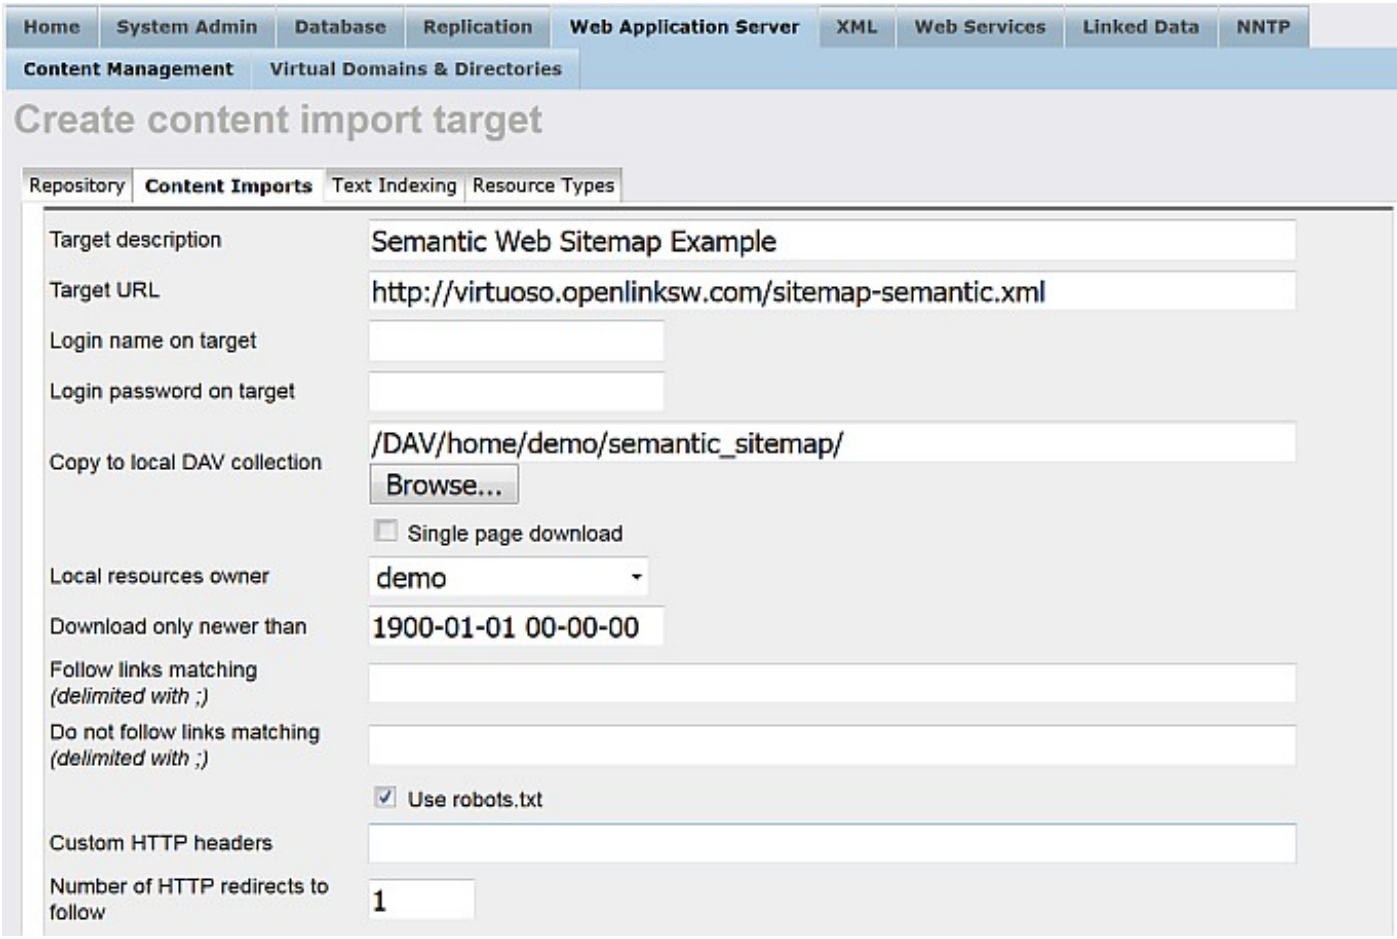


Figure 6.31. Setting up a Content Crawler Job to Retrieve Semantic Sitemap content

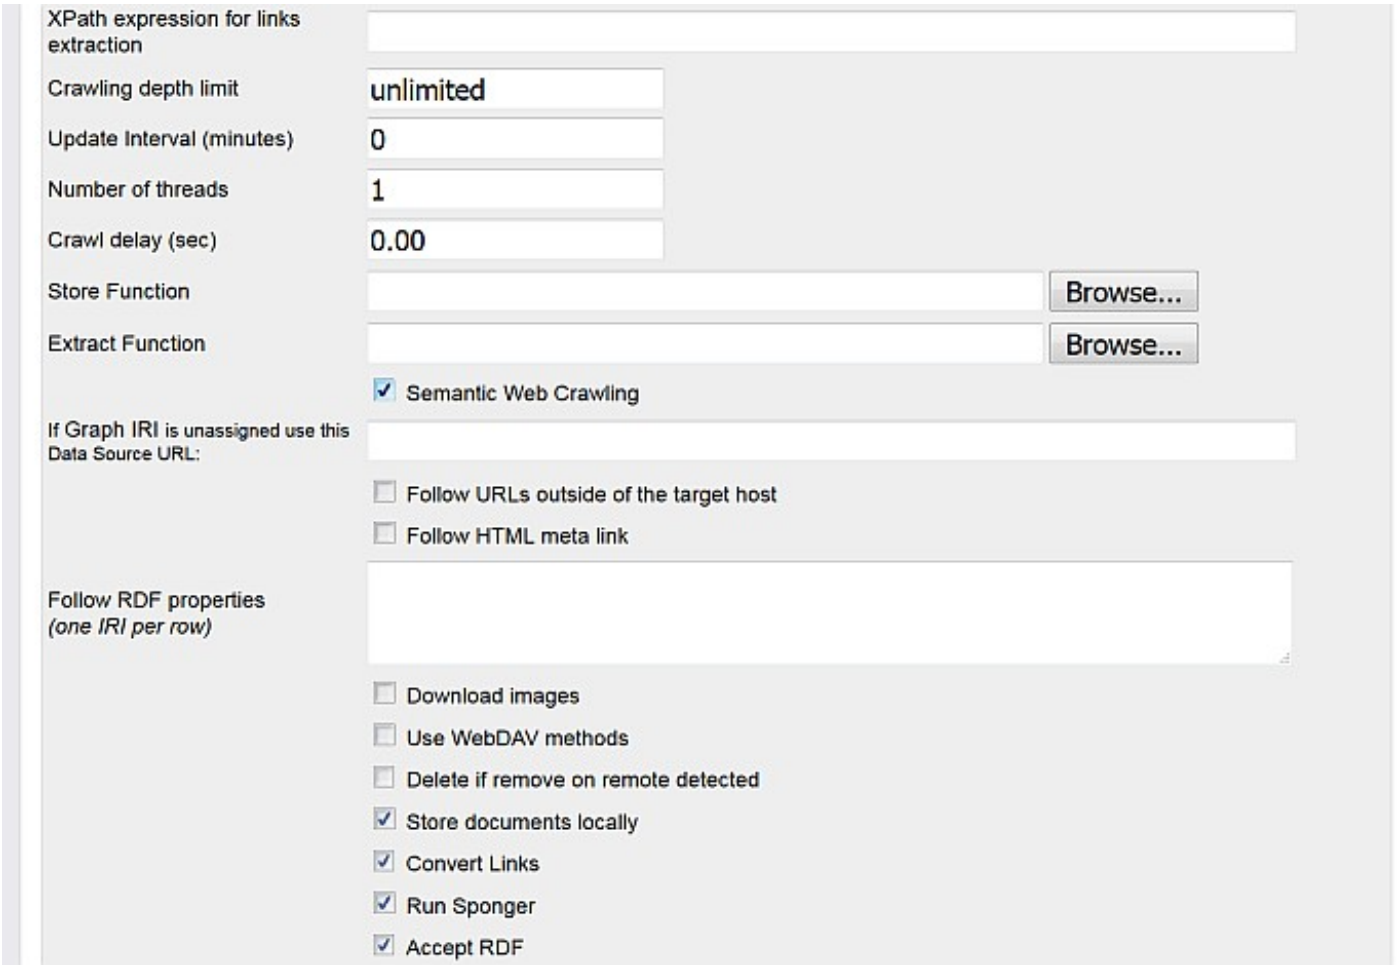

Figure 6.32. Setting up a Content Crawler Job to Retrieve Semantic Sitemap content

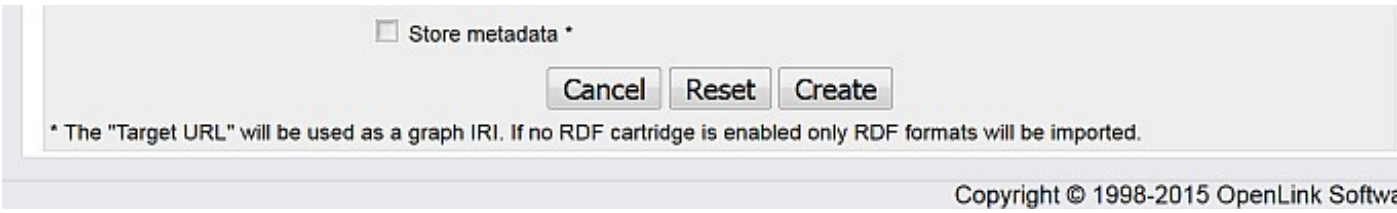
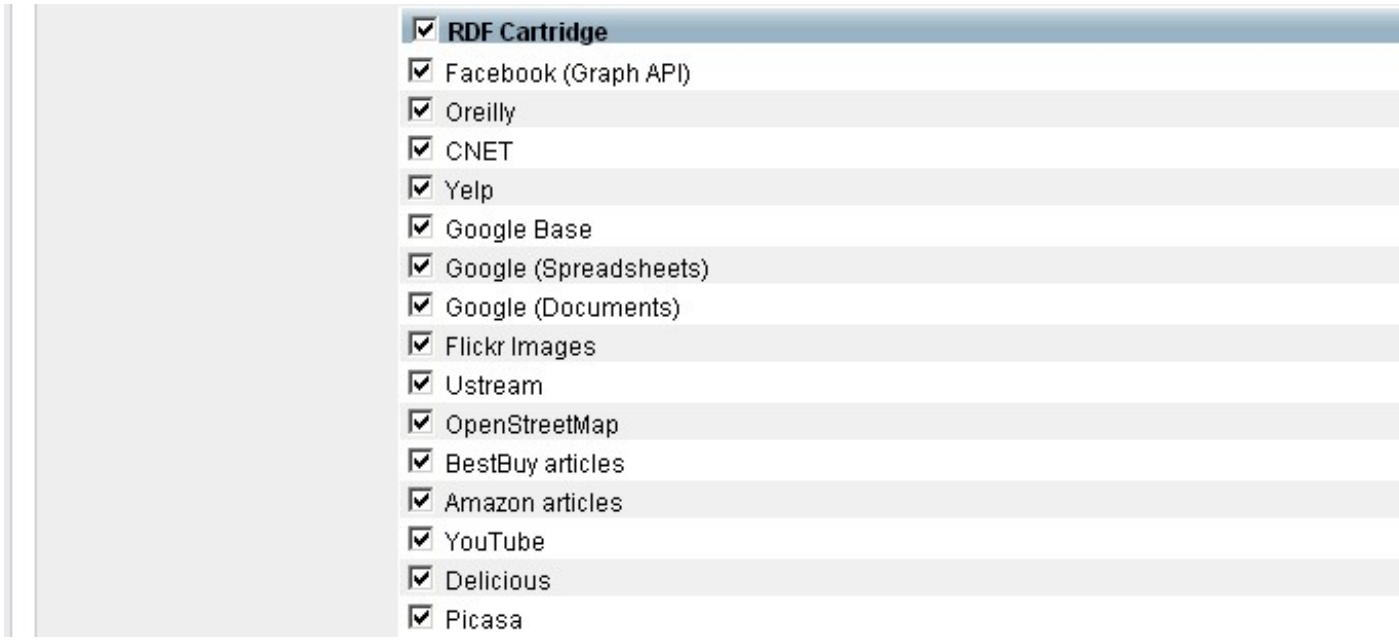


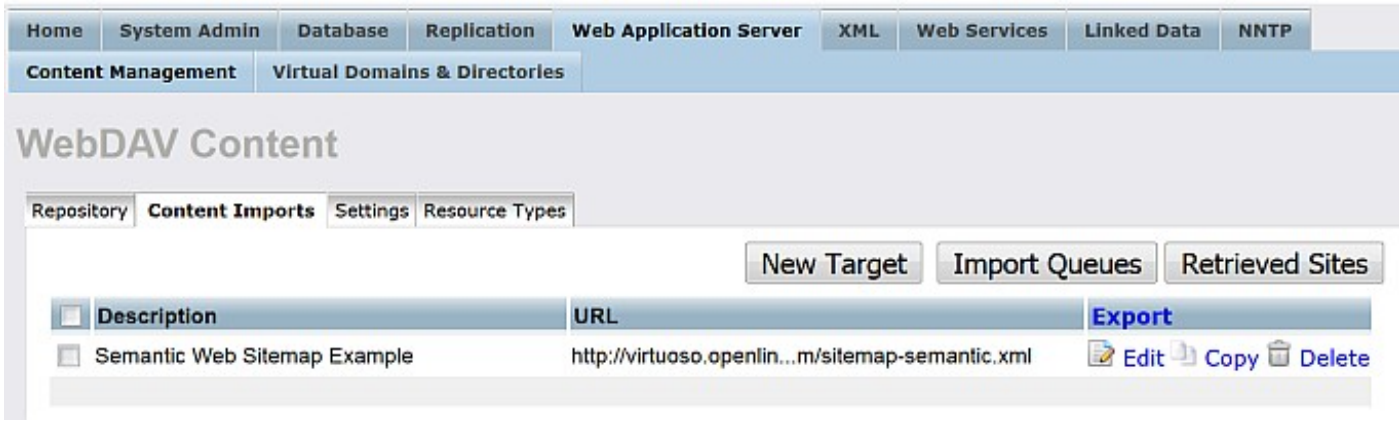
8. Optionally you can hatch "Store metadata *" and specify which RDF Cartridges to be included from the Sponger:

Figure 6.33. Setting up a Content Crawler Job to Retrieve Semantic Sitemap content



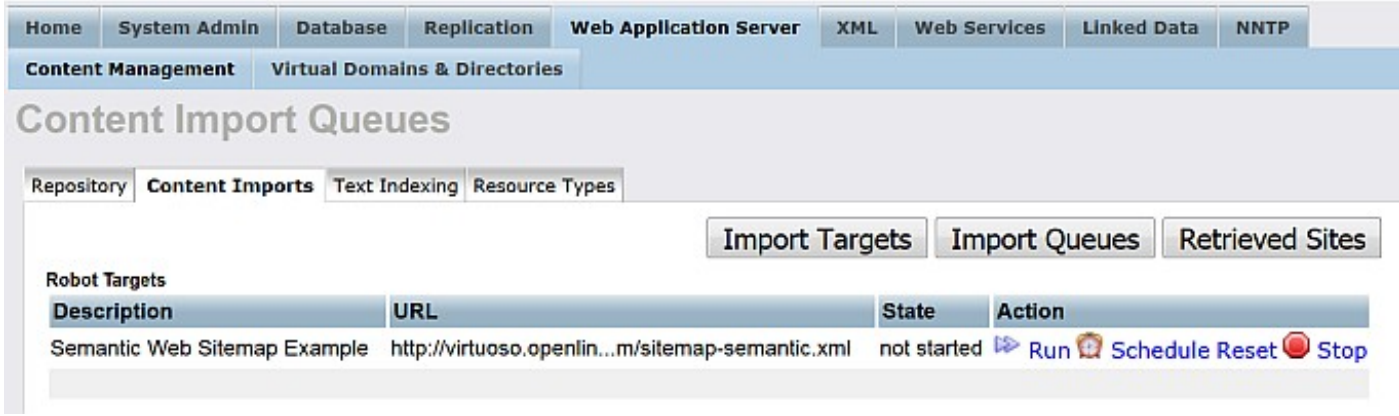
9. Click the button "Create".

Figure 6.34. Setting up a Content Crawler Job to Retrieve Semantic Sitemap content



10. Click "Import Queues".

Figure 6.35. Setting up a Content Crawler Job to Retrieve Semantic Sitemap content



11. For "Robot target" with label "Semantic Web Sitemap Example" click "Run".
12. As result should be shown the number of the pages retrieved.

Figure 6.36. Setting up a Content Crawler Job to Retrieve Semantic Sitemap content

13. Check the retrieved RDF data from your Virtuoso instance sparql endpoint http://cname:port/sparql with the following query selecting all the retrieved graphs for ex:

```
SELECT ?g
FROM <http://host:port/>
WHERE
  {
    graph ?g { ?s ?p ?o } .
    FILTER ( ?g LIKE <http://virtuoso.openlinksw.com/%> )
  }
```

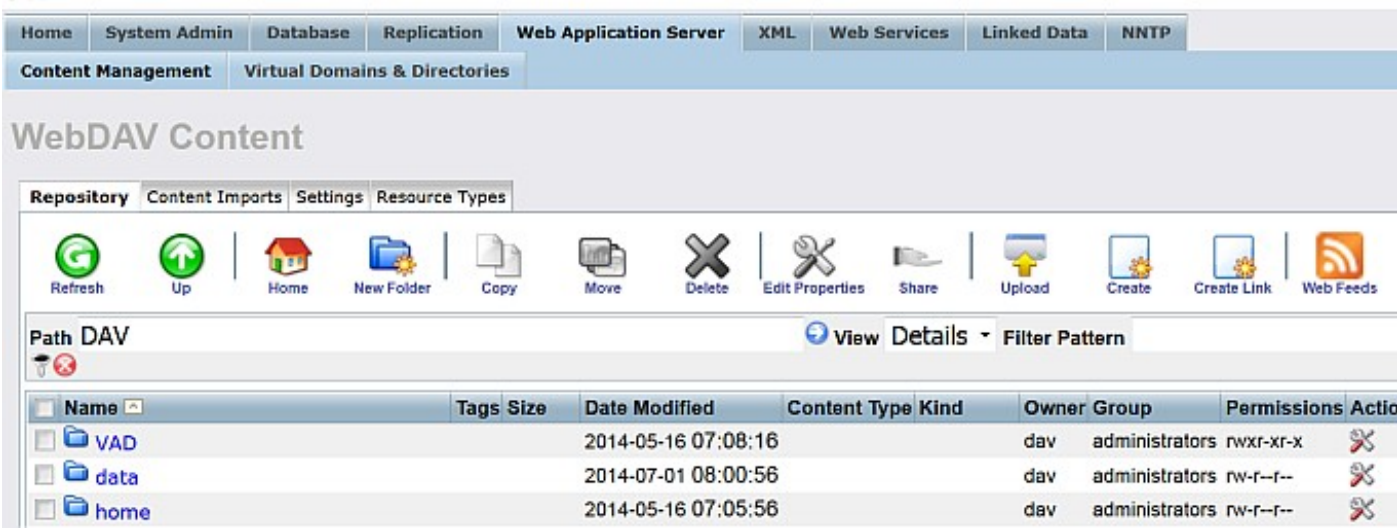
Figure 6.37. Setting up a Content Crawler Job to Retrieve Semantic Sitemap content

Figure 6.38. Setting up a Content Crawler Job to Retrieve Semantic Sitemap content

The following section describes how to set up crawler job for getting directories using Conductor.

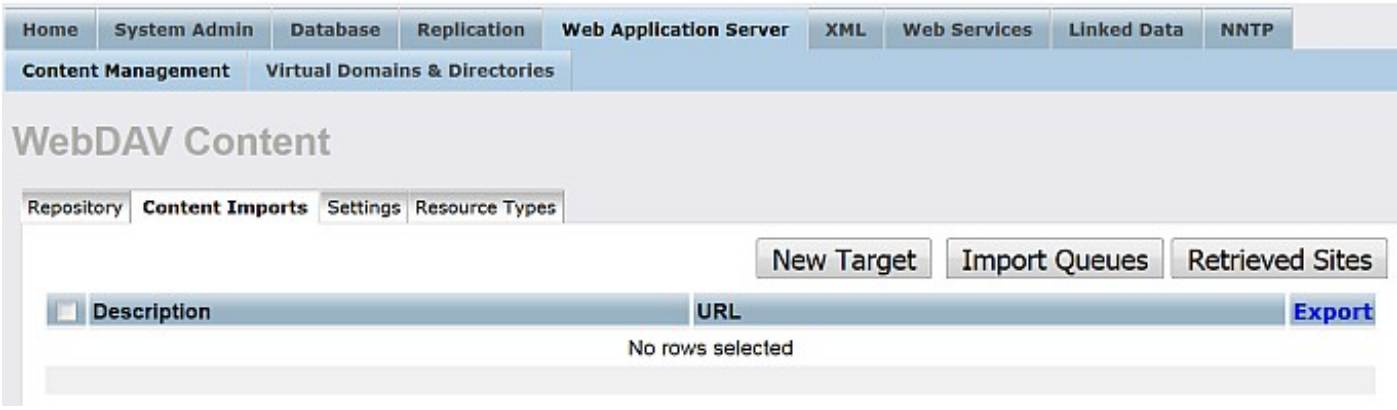
1. From the Virtuoso Conductor User Interface i.e. http://cname:port/conductor, login as the "dba" user.
2. Go to "Web Application Server".

Figure 6.39. Setting up a Content Crawler Job to Retrieve Content from Specific Directories



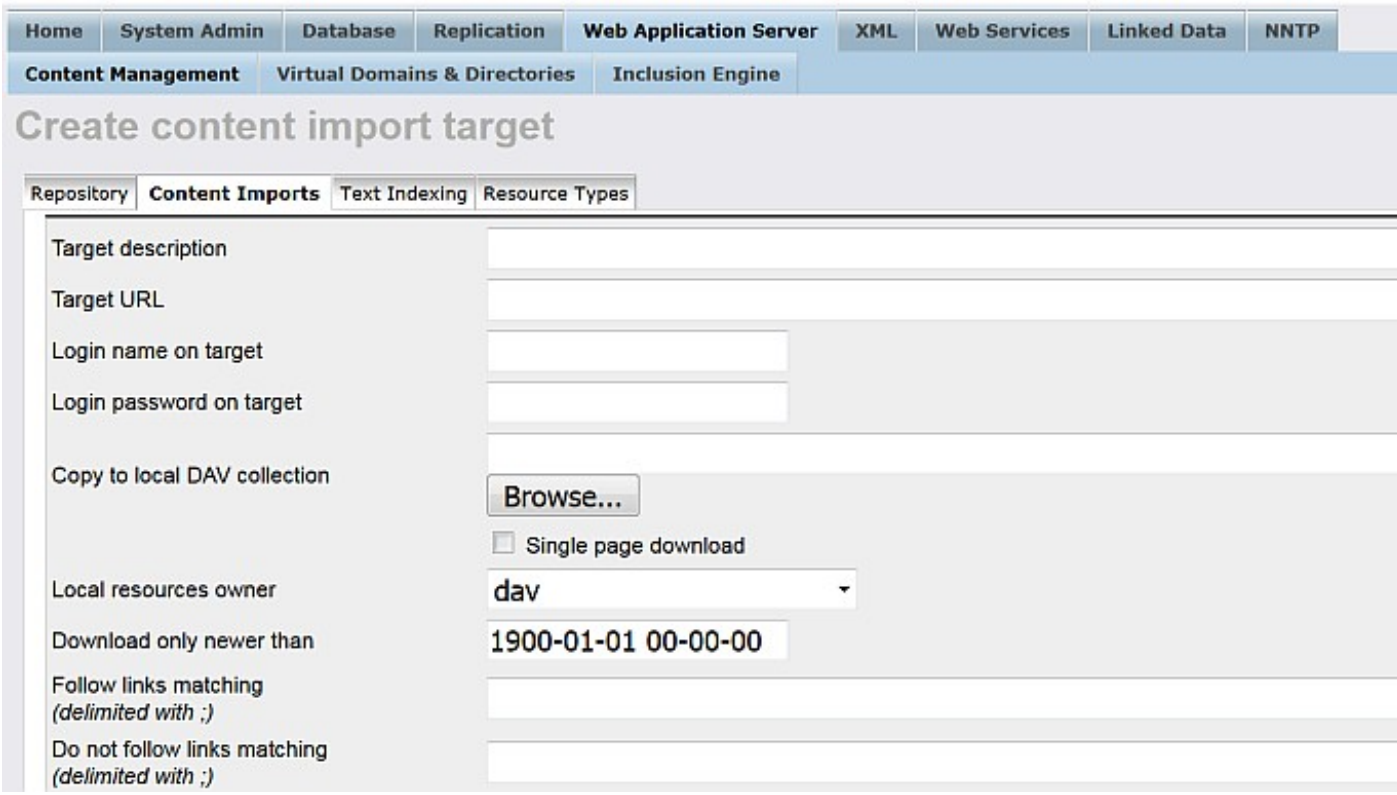
3. Go to "Content Imports".

Figure 6.40. Setting up a Content Crawler Job to Retrieve Content from Specific Directories



4. Click "New Target".

Figure 6.41. Setting up a Content Crawler Job to Retrieve Content from Specific Directories



5. In the shown form:

   - Enter for "Target description":

     ```
     UDA WebSite
     ```

   - Enter for "Target URL":

     ```
     http://uda.openlinksw.com/
     ```

   - Enter for "Copy to local DAV collection" for available user, for ex. demo:

     ```
     /DAV/home/demo/uda/
     ```

   - Choose from the available list "Local resources owner" an user, for ex. demo.

Figure 6.42. Setting up a Content Crawler Job to Retrieve Content from Specific Directories

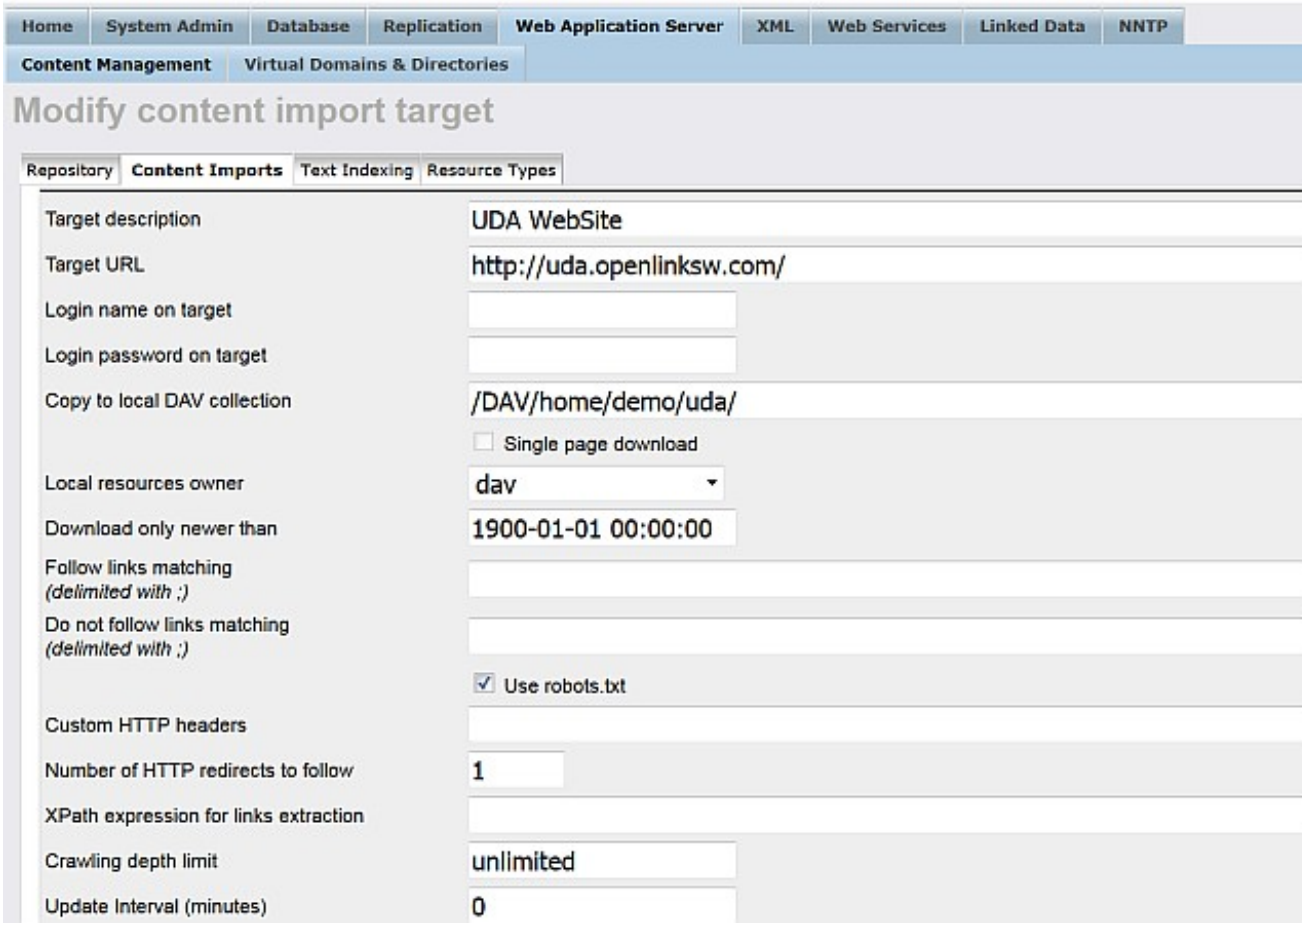


Figure 6.43. Setting up a Content Crawler Job to Retrieve Content from Specific Directories

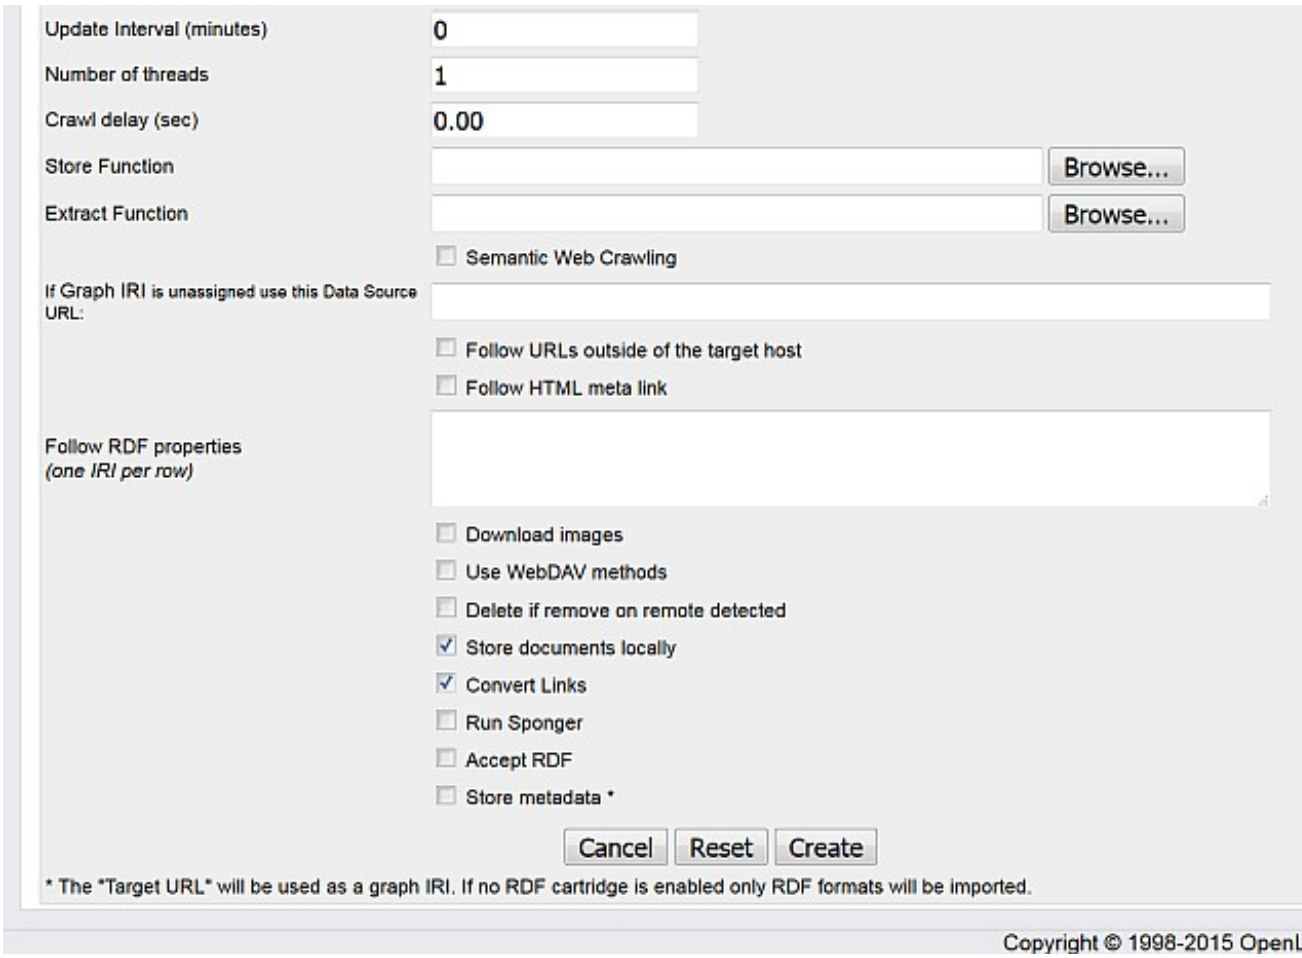


- Optionally you can select "Convert Link" to make all HREFs in the local stored content relative.
- Click the button "Create".

6. As result the Robot target will be created:

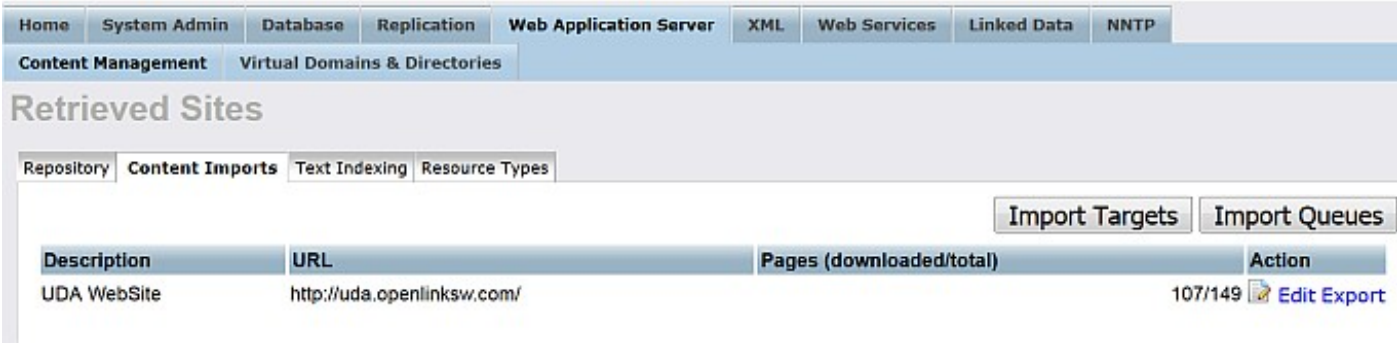
Figure 6.44. Setting up a Content Crawler Job to Retrieve Content from Specific Directories

7. Click "Import Queues".

Figure 6.45. Setting up a Content Crawler Job to Retrieve Content from Specific Directories

8. Click "Run" and go to "Retrieved Sites".
9. As result should be shown the number of the total pages retrieved.

Figure 6.46. Setting up a Content Crawler Job to Retrieve Content from Specific Directories

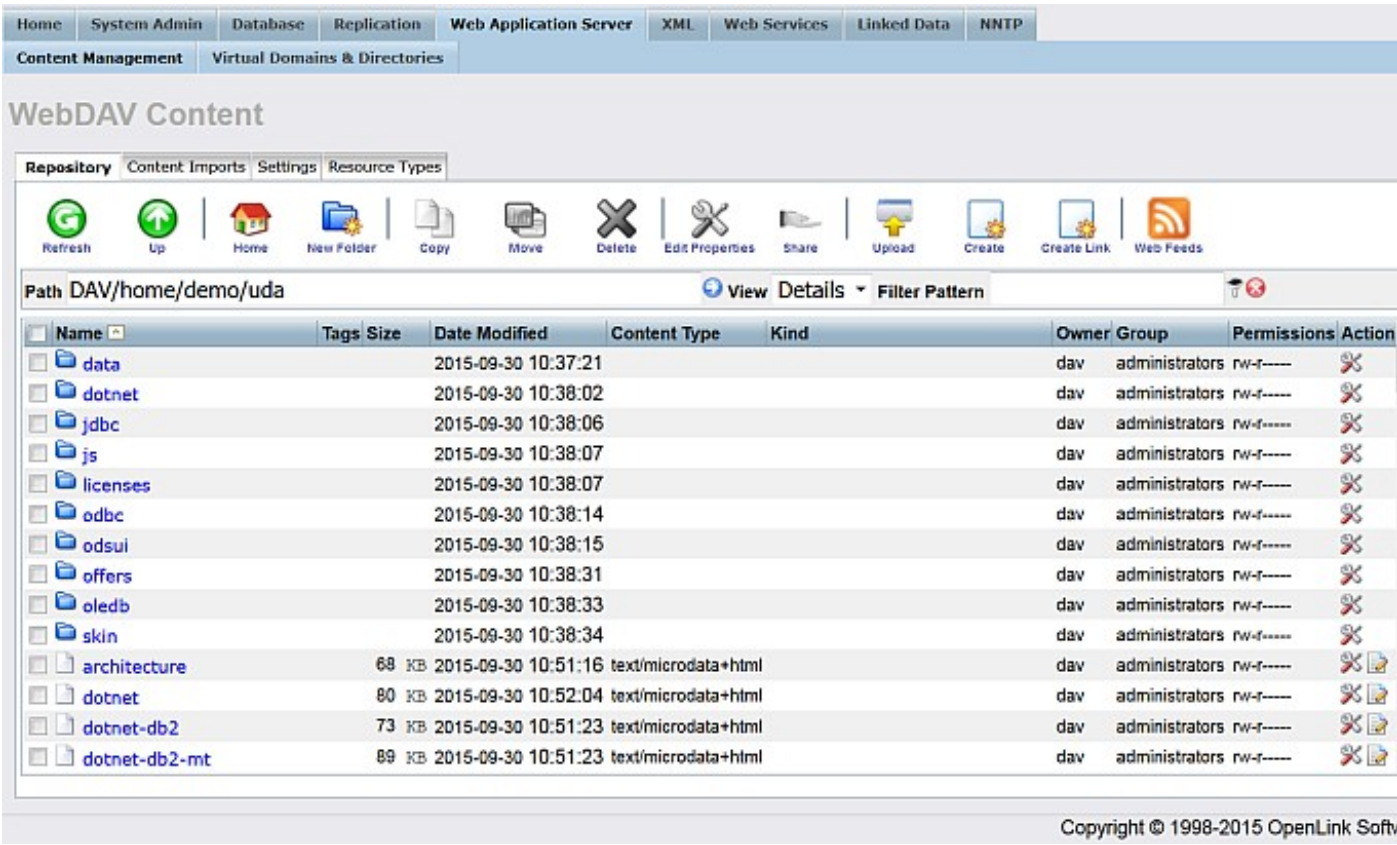


10. Go to "Web Application Server" -> "Content Management" and go to path:

```
DAV/home/demo/uda/
```

11. As result the retrieved content will be shown:

Figure 6.47. Setting up a Content Crawler Job to Retrieve Content from Specific Directories



Setting up a Content Crawler Job to Retrieve Content from ATOM feed

This section demonstrates populating the Virtuoso Quad Store using ATOM feed.

Populating the Virtuoso Quad Store can be done in different ways Virtuoso supports. The Conductor -> Content Import UI offers plenty of options, one of which is the XPath expression for crawling RDF resources URLs and this feature is a powerful and easy-to-use for managing the Quad Store.

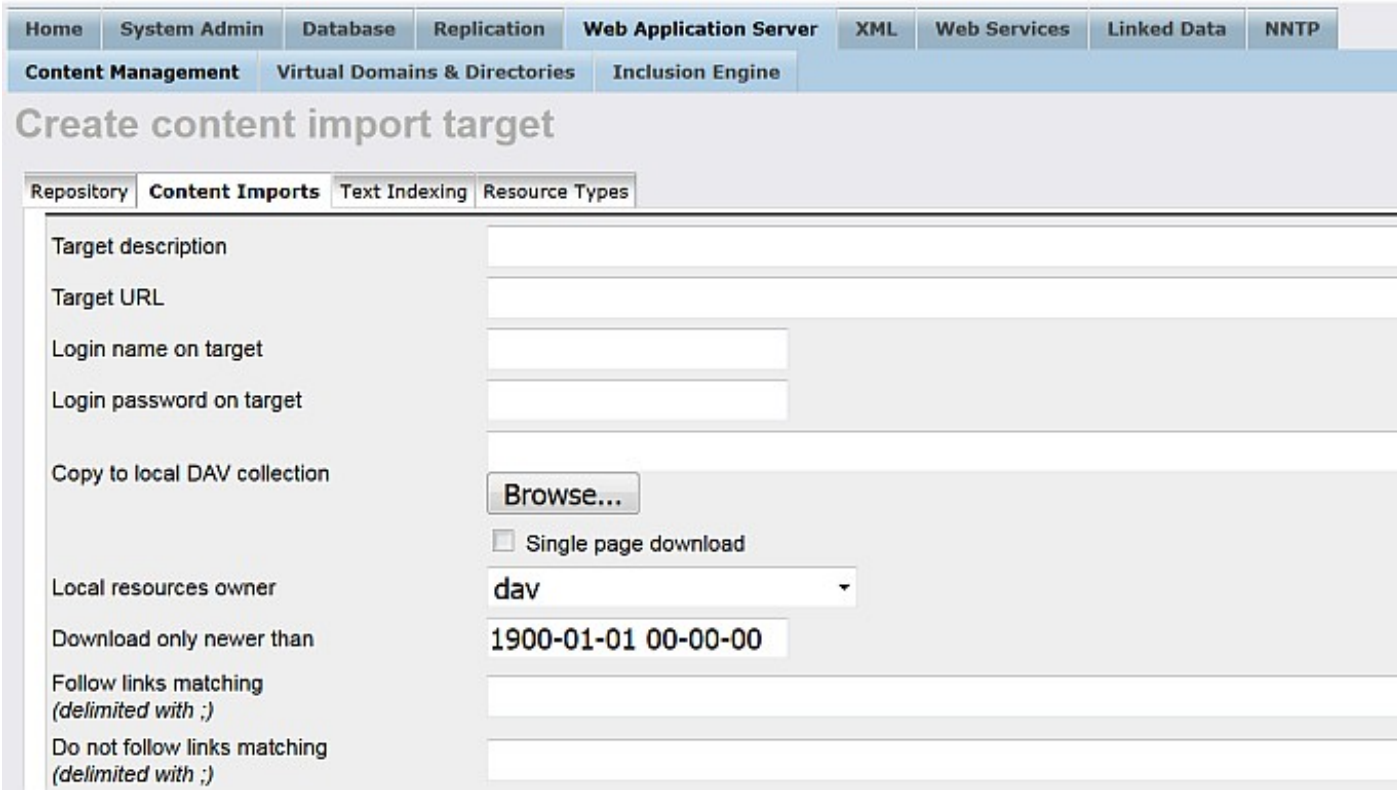
To populate the Virtuoso Quad Store, in this Guide we will use a XPAth expression for the URLs of the RDF resources references in a given ATOM feed. For ex. this one of the "National Bibliography" Store.

1. Go to http://cname/conductor
2. Enter dba credentials
3. Go to Web Application Server -> Content Management -> Content Imports:

Figure 6.48. Crawling ATOM feed

4. Click "New Target":

Figure 6.49. Crawling ATOM feed



5. In the presented form specify respectively:

   - "Target description": for ex. National Bibliography ;
   - "Target URL": for ex. http://data.libris.kb.se/nationalbibliography/feed/ ;

     Note: the entered URL will be the graph URI for storing the imported RDF data. You can also set it explicitly by entering another graph URI in the "If Graph IRI is unassigned use this Data Source URL:" shown as option in this form.
   - "Copy to local DAV collection": for ex.

     ```
     /DAV/temp/nbio/
     ```
   - "XPath expression for links extraction:":

     ```
     //entry/link/@href
     ```
   - "Update Interval (minutes)": for ex. 10 ;
   - "Run Sponger": hatch this check-box ;
   - "Accept RDF": hatch this check-box ;
   - Optionally you can hatch "Store metadata" ;
   - "RDF Cartridge": hatch this check-box and specify what cartridges will be used.

Figure 6.50. Crawling ATOM feed

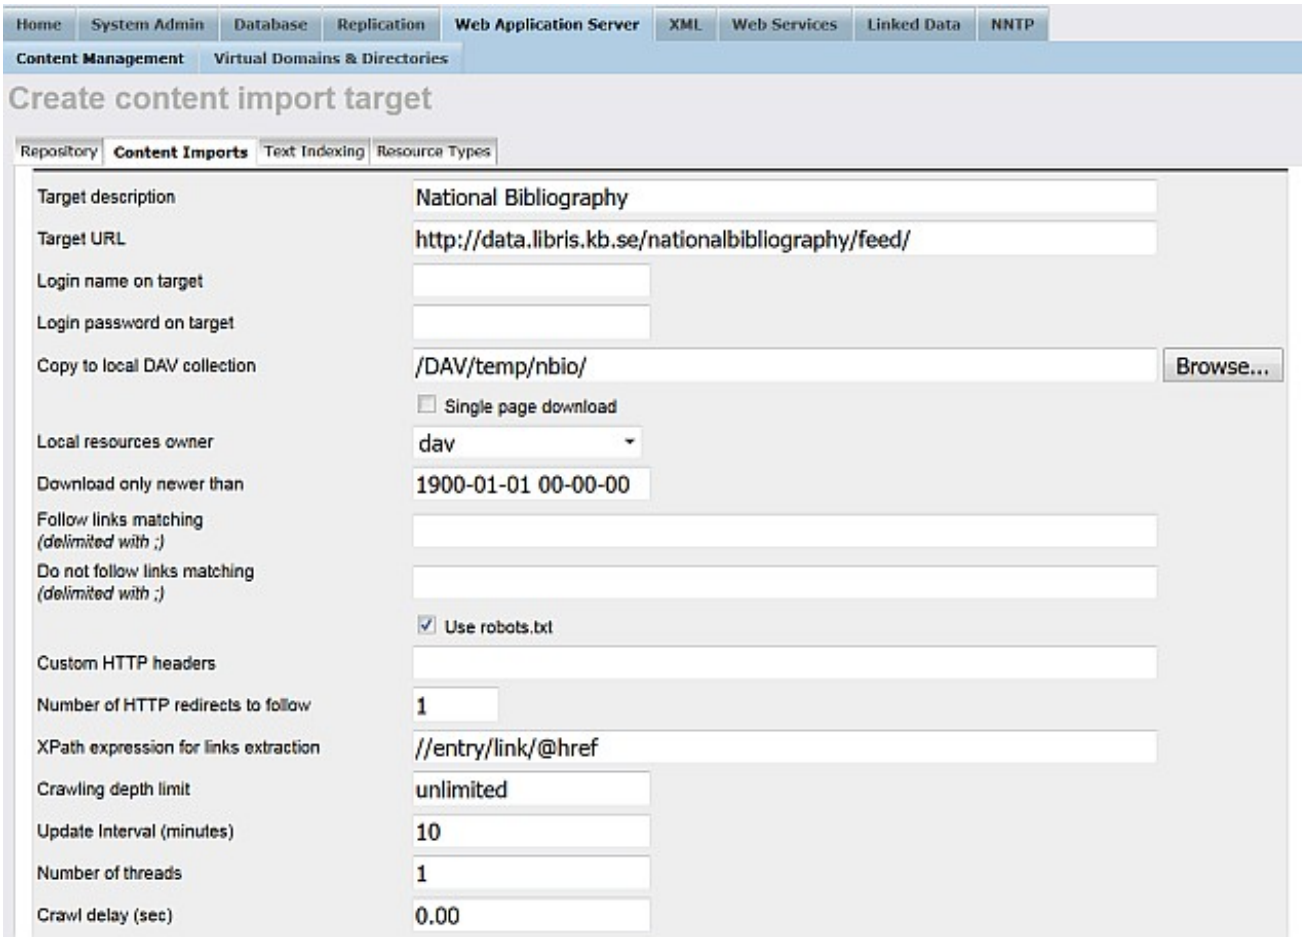


Figure 6.51. Crawling ATOM feed

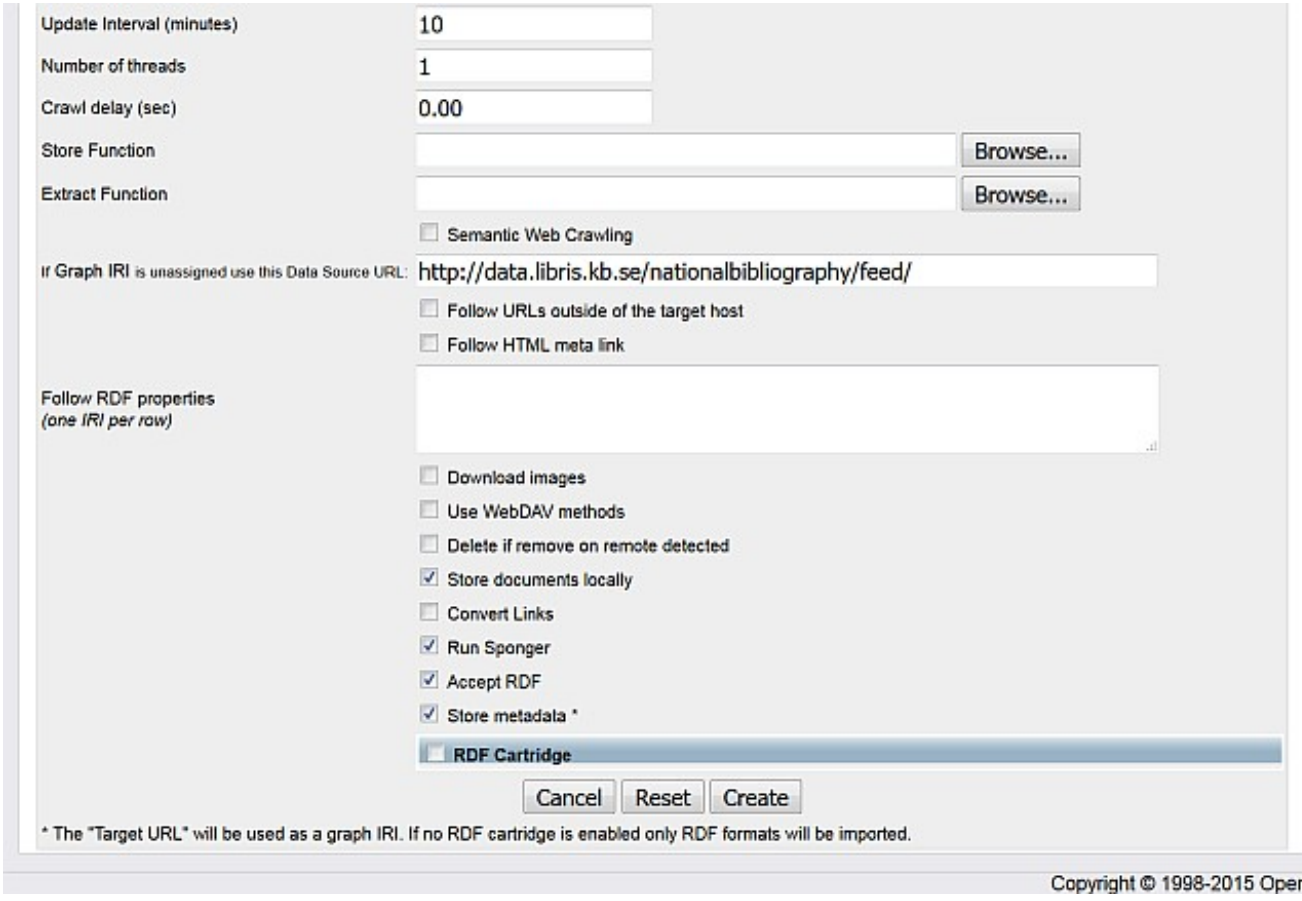
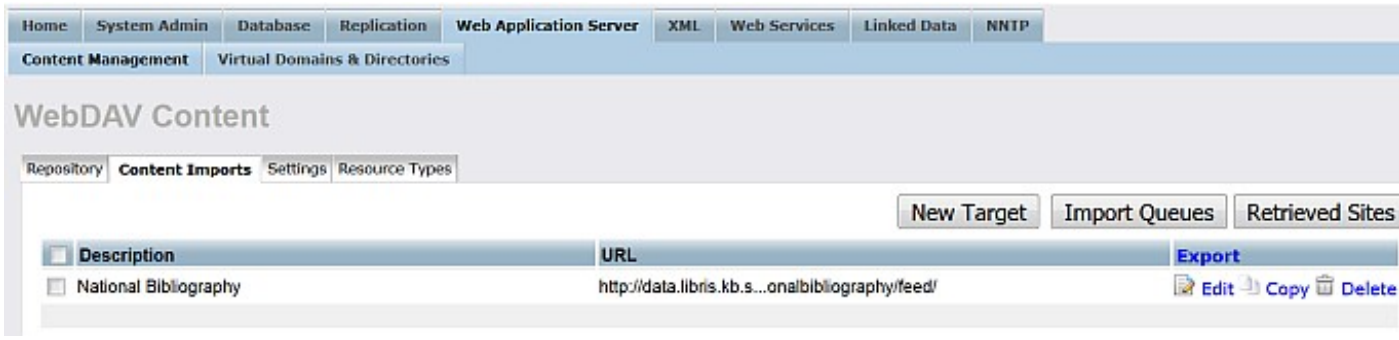


6. Click "Create".
7. The new created target should be displayed in the list of available Targets:

Figure 6.52. Crawling ATOM feed

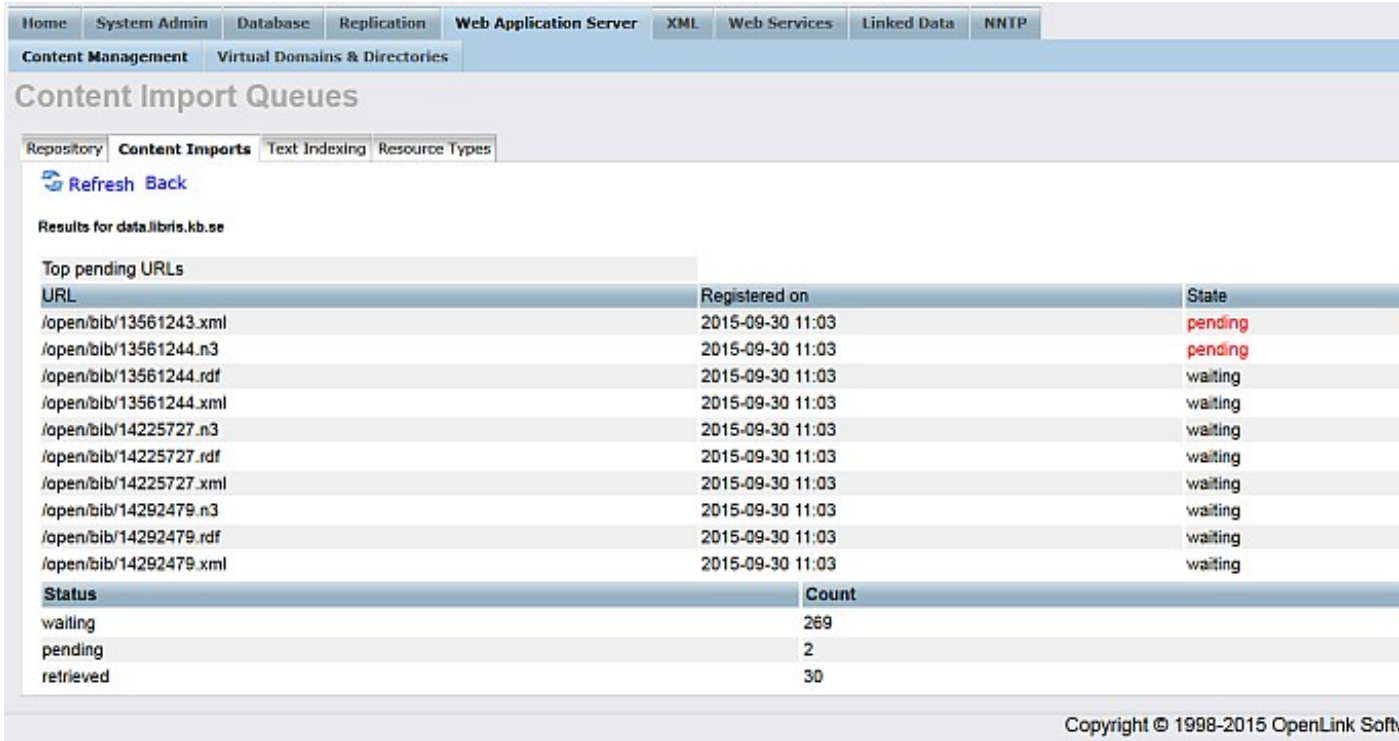


8. Click "Import Queues":

Figure 6.53. Crawling ATOM feed

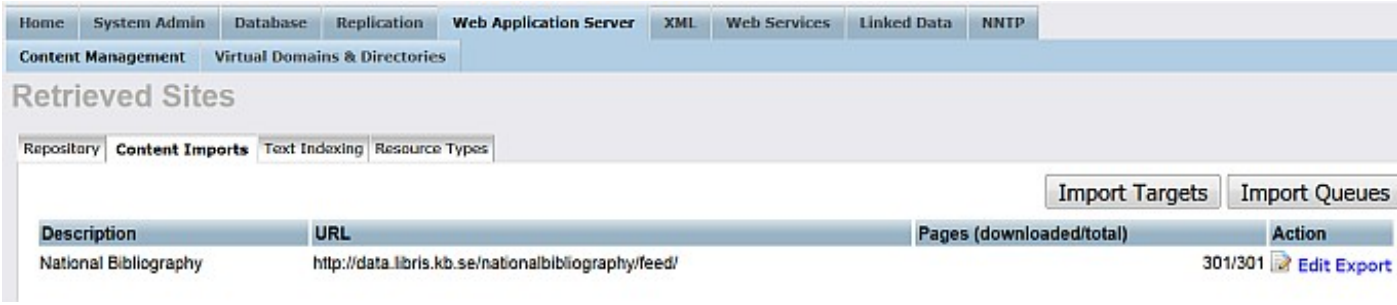
9. Click for "National Bibliography" target the "Run" link from the very-right "Action" column.
10. Should be presented list of Top pending URLs:

Figure 6.54. Crawling ATOM feed



11. Go to "Retrieved Sites" to check the total URLs that were processed:

Figure 6.55. Crawling ATOM feed



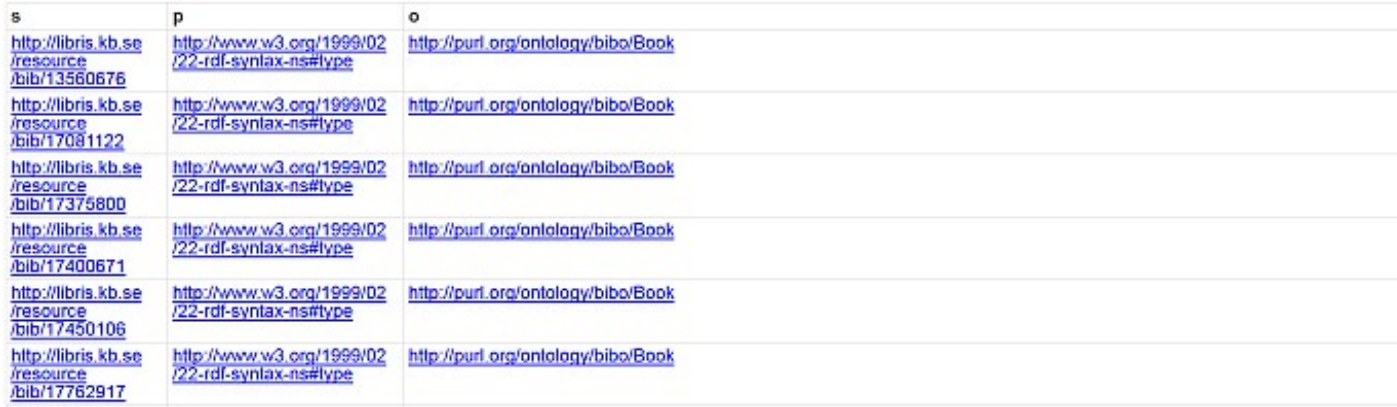
12. To view the imported RDF data, go to http://example.com/sparql and enter a simple query for ex.:

```
SELECT *
FROM <http://data.libris.kb.se/nationalbibliography/feed/>
WHERE
  {
    ?s ?p ?o
  }
```

Figure 6.56. Crawling ATOM feed

13. Click "Run Query".
14. The imported RDF data triples should be shown:

Figure 6.57. Crawling ATOM feed



Setting up a Content Crawler Job to Retrieve Content from SPARQL endpoint

The following step-by section walks you through the process of:

- Populating a Virtuoso Quad Store with data from a 3rd party SPARQL endpoint
- Generating RDF dumps that are accessible to basic HTTP or WebDAV user agents.

1. Sample SPARQL query producing a list SPARQL endpoints:

```
PREFIX rdf:      <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
PREFIX rdfs:     <http://www.w3.org/2000/01/rdf-schema#>
PREFIX owl:      <http://www.w3.org/2002/07/owl#>
PREFIX xsd:      <http://www.w3.org/2001/XMLSchema#>
PREFIX foaf:     <http://xmlns.com/foaf/0.1/>
PREFIX dcterms:  <http://purl.org/dc/terms/>
PREFIX scovo:    <http://purl.org/NET/scovo#>
PREFIX void:     <http://rdfs.org/ns/void#>
PREFIX akt:      <http://www.aktors.org/ontology/portal#>

SELECT DISTINCT ?endpoint
WHERE
  {
    ?ds a void:Dataset .
    ?ds void:sparqlEndpoint ?endpoint
  }
```

2. Here is a sample SPARQL protocol URL constructed from one of the sparql endpoints in the result from the query above:

```
http://void.rkbexplorer.com/sparql/?query=PREFIX+foaf%3A+%3Chttp%3A%2F%2Fxmlns.com%2Ffoaf%2F0.1%2F
```

3. Here is the cURL output showing a Virtuoso SPARQL URL that executes against a 3rd party SPARQL Endpoint URL:

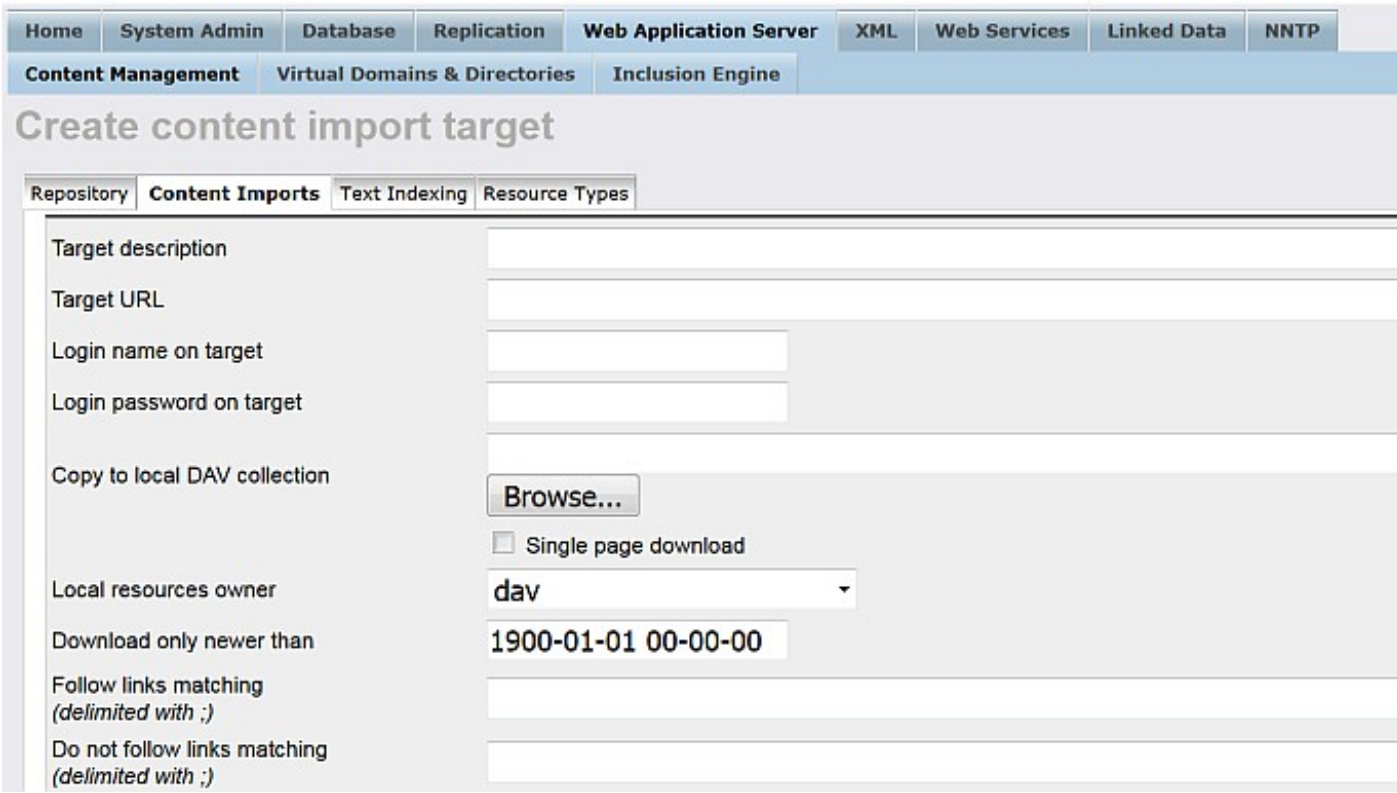
```
$ curl "http://void.rkbexplorer.com/sparql/?query=PREFIX+foaf%3A+%3Chttp%3A%2F%2Fxmlns.com%2Ffoaf%
%3A+++++%3Chttp%3A%2F%2Frdfs.org%2Fns%2Fvoid%23%3E++%0D%0ASELECT+distinct+%3Furl++WHERE+%7B+%3Fds+
omepage+%3Furl+%7D%0D%0A&format=sparql"
<?xml version="1.0" ?>
<sparql xmlns="http://www.w3.org/2005/sparql-results#">
  <head>
    <variable name="url"/>
  </head>
  <results ordered="false" distinct="true">
    <result>
      <binding name="url"><uri>http://kisti.rkbexplorer.com/</uri></binding>
    </result>
    <result>
      <binding name="url"><uri>http://epsrc.rkbexplorer.com/</uri></binding>
    </result>
    <result>
      <binding name="url"><uri>http://test2.rkbexplorer.com/</uri></binding>
    </result>
    <result>
      <binding name="url"><uri>http://test.rkbexplorer.com/</uri></binding>
    </result>
    ...
    ...
    ...
  </results>
</sparql>
```

4. Go to Conductor UI -- http://example.com/conductor and provide dba credentials;
5. Go to "Web Application Server"-> "Content Management" -> "Content Imports"

Figure 6.58. Crawling SPARQL Endpoints

6. Click "New Target":

Figure 6.59. Crawling SPARQL Endpoints



7. In the presented form enter for ex.:

   a. "Target description": voiD store
   b. "Target URL": the url from above i.e.:

      ```
      http://void.rkbexplorer.com/sparql/?query=PREFIX+foaf%3A+%3Chttp%3A%2F%2Fxmlns.com%2Ffoaf%2
      ```

   c. "Copy to local DAV collection":

      ```
      /DAV/void.rkbexplorer.com/content
      ```

   d. "Follow links matching (delimited with ;)":

      ```
      %
      ```

   e. Un-hatch "Use robots.txt" ;
   f. "XPath expression for links extraction":

      ```
      //binding[@name="url"]/uri/text()
      ```

   g. Hatch "Semantic Web Crawling";
   h. "If Graph IRI is unassigned use this Data Source URL:": enter for ex:

      ```
      http://void.collection
      ```

i. Hatch "Follow URLs outside of the target host";
j. Hatch "Run "Sponger" and "Accept RDF"

Figure 6.60. Crawling SPARQL Endpoints

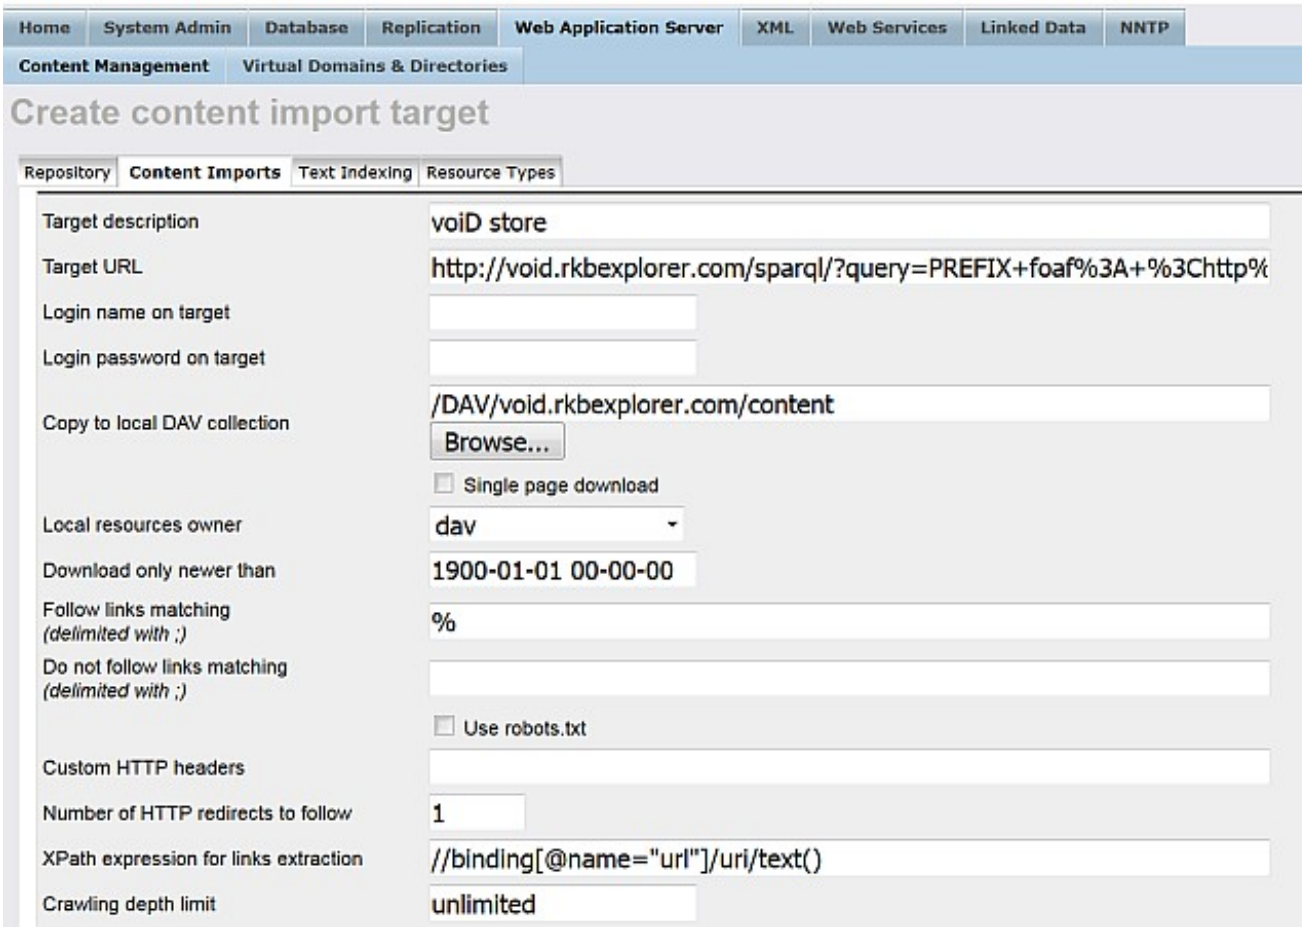


Figure 6.61. Crawling SPARQL Endpoints

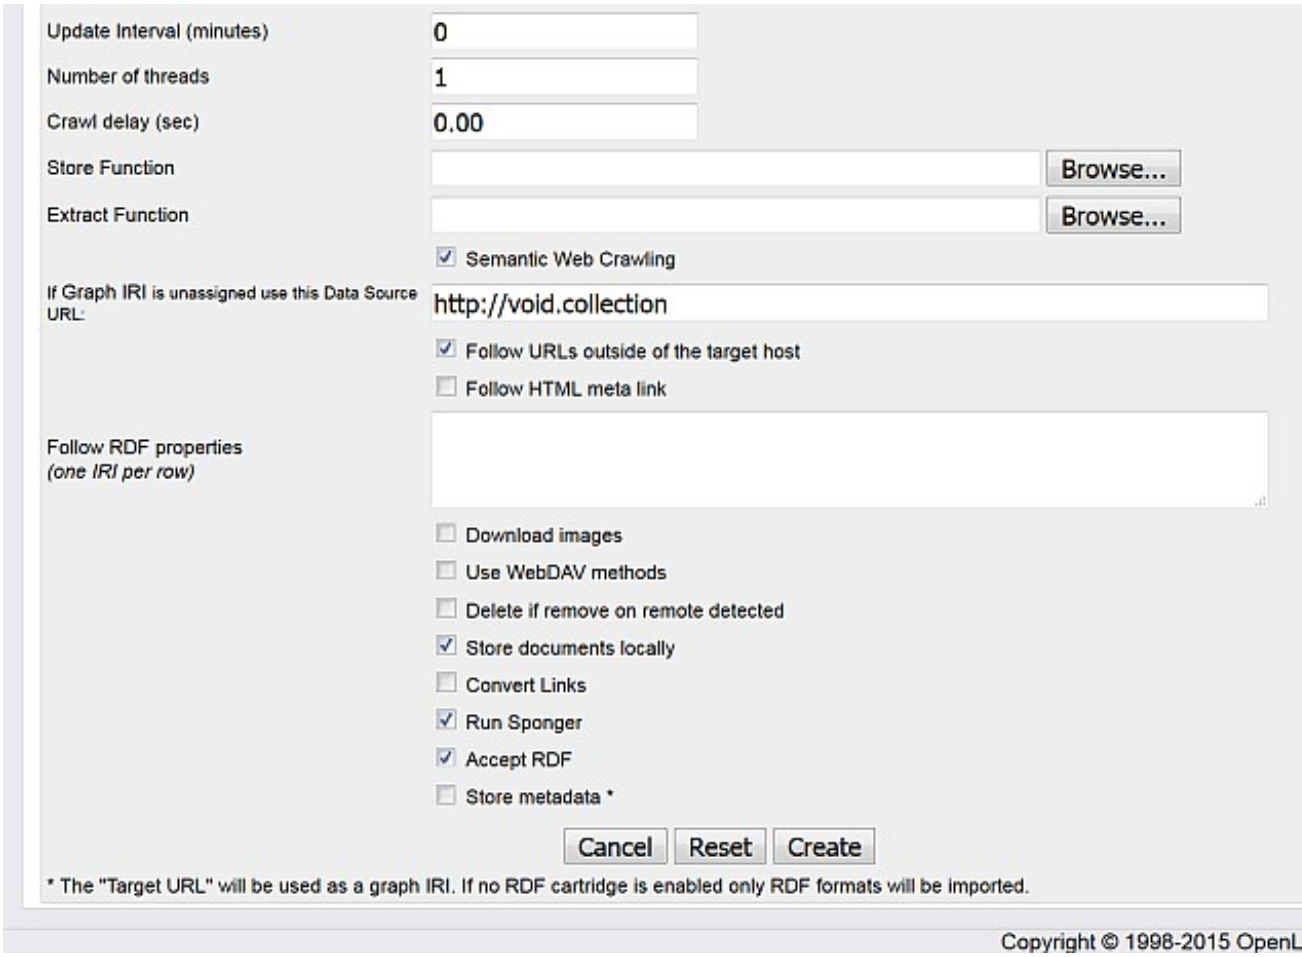
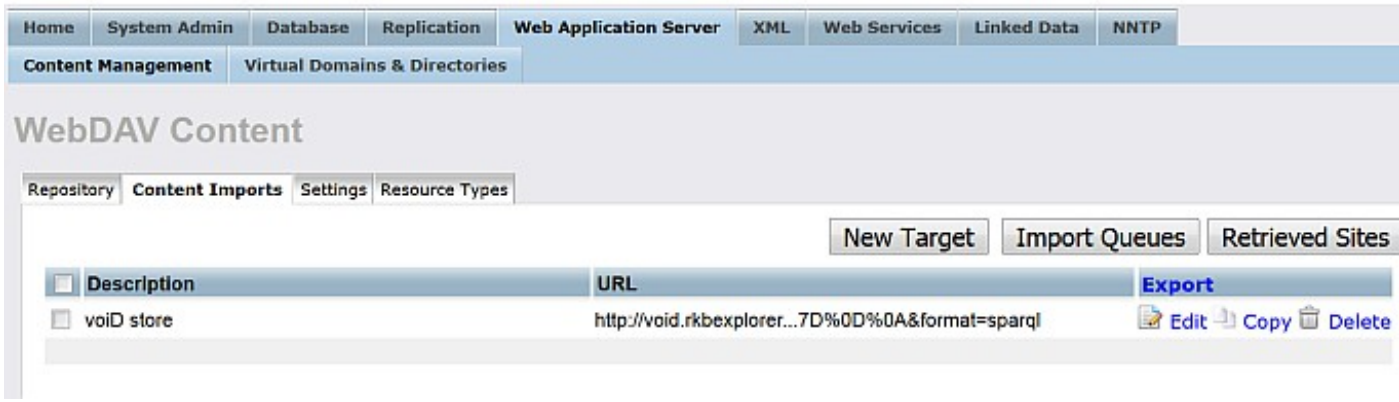


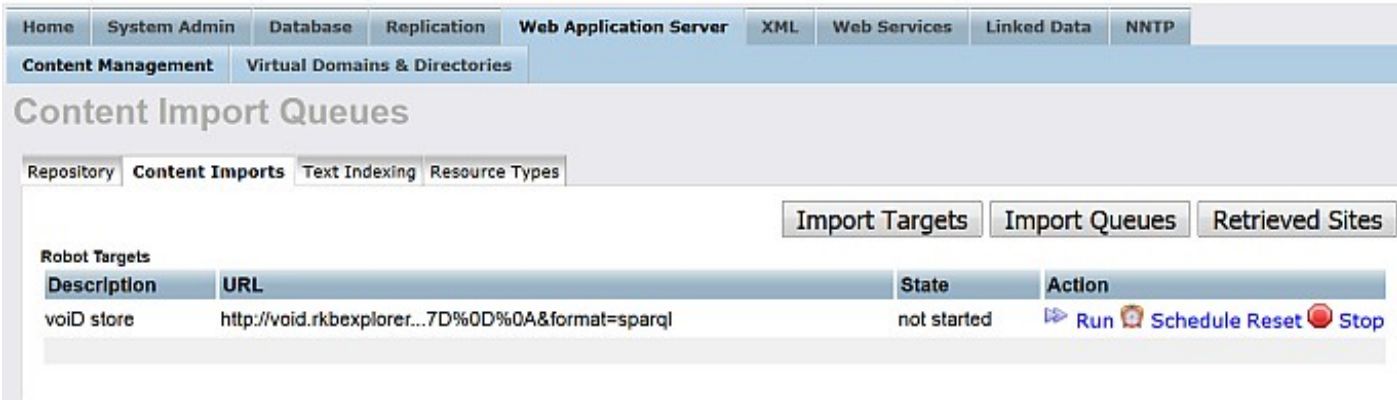
8. Click "Create";
9. The target should be created and presented in the list of available targets:

Figure 6.62. Crawling SPARQL Endpoints



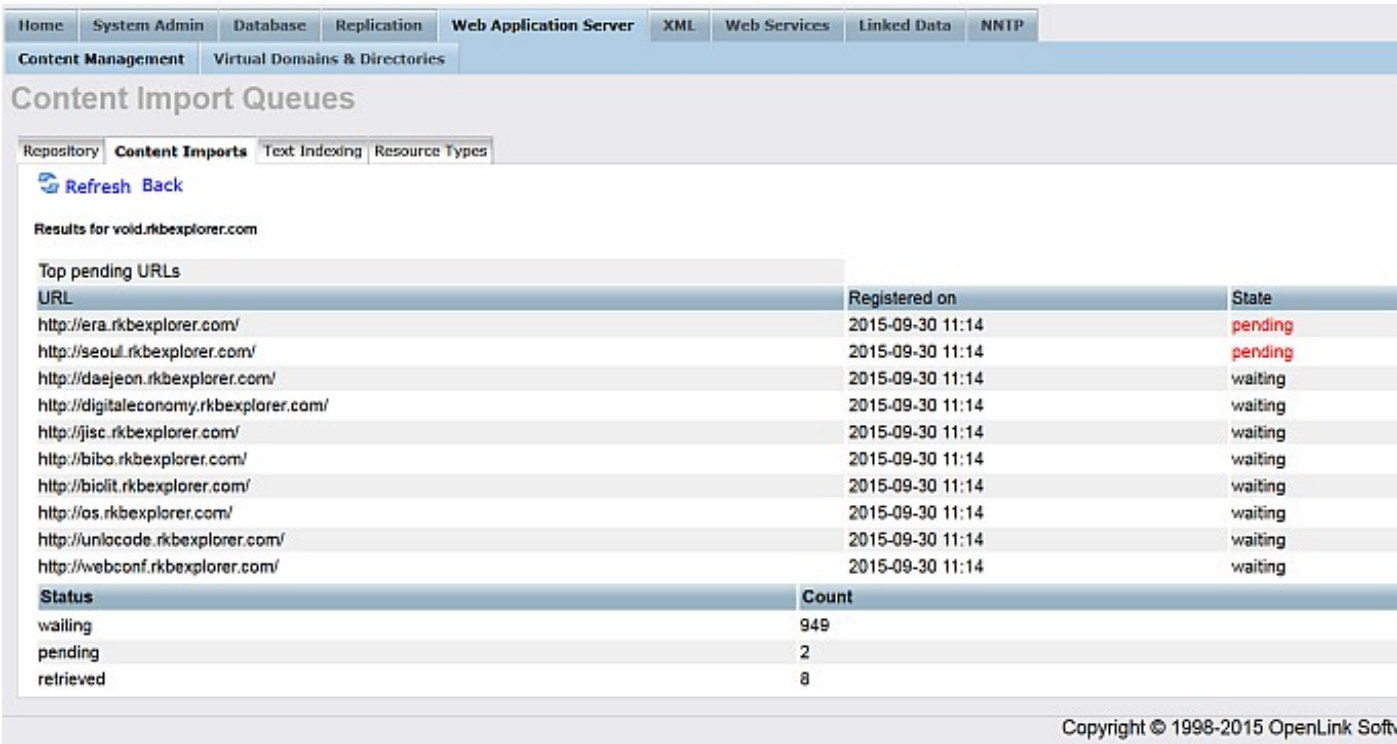
10. Click "Import Queues":

Figure 6.63. Crawling SPARQL Endpoints



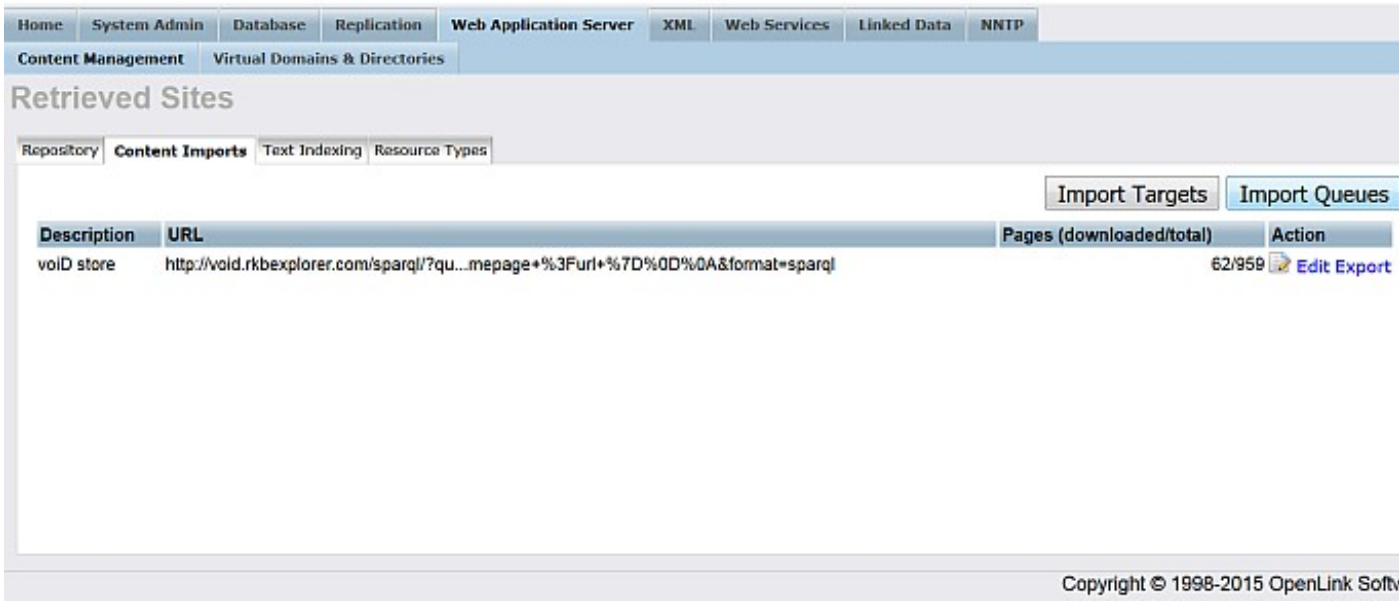
11. Click "Run" for the imported target:

Figure 6.64. Crawling SPARQL Endpoints



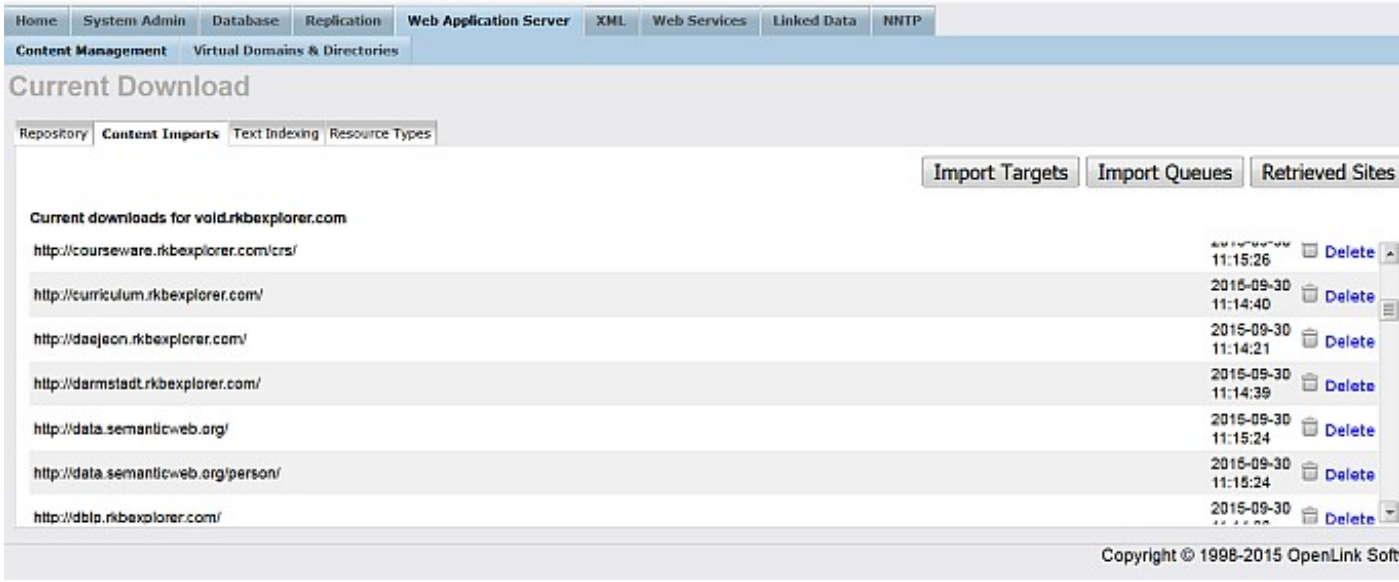
12. To check the retrieved content go to "Web Application Server"-> "Content Management" -> "Content Imports" -> "Retrieved Sites":

Figure 6.65. Crawling SPARQL Endpoints



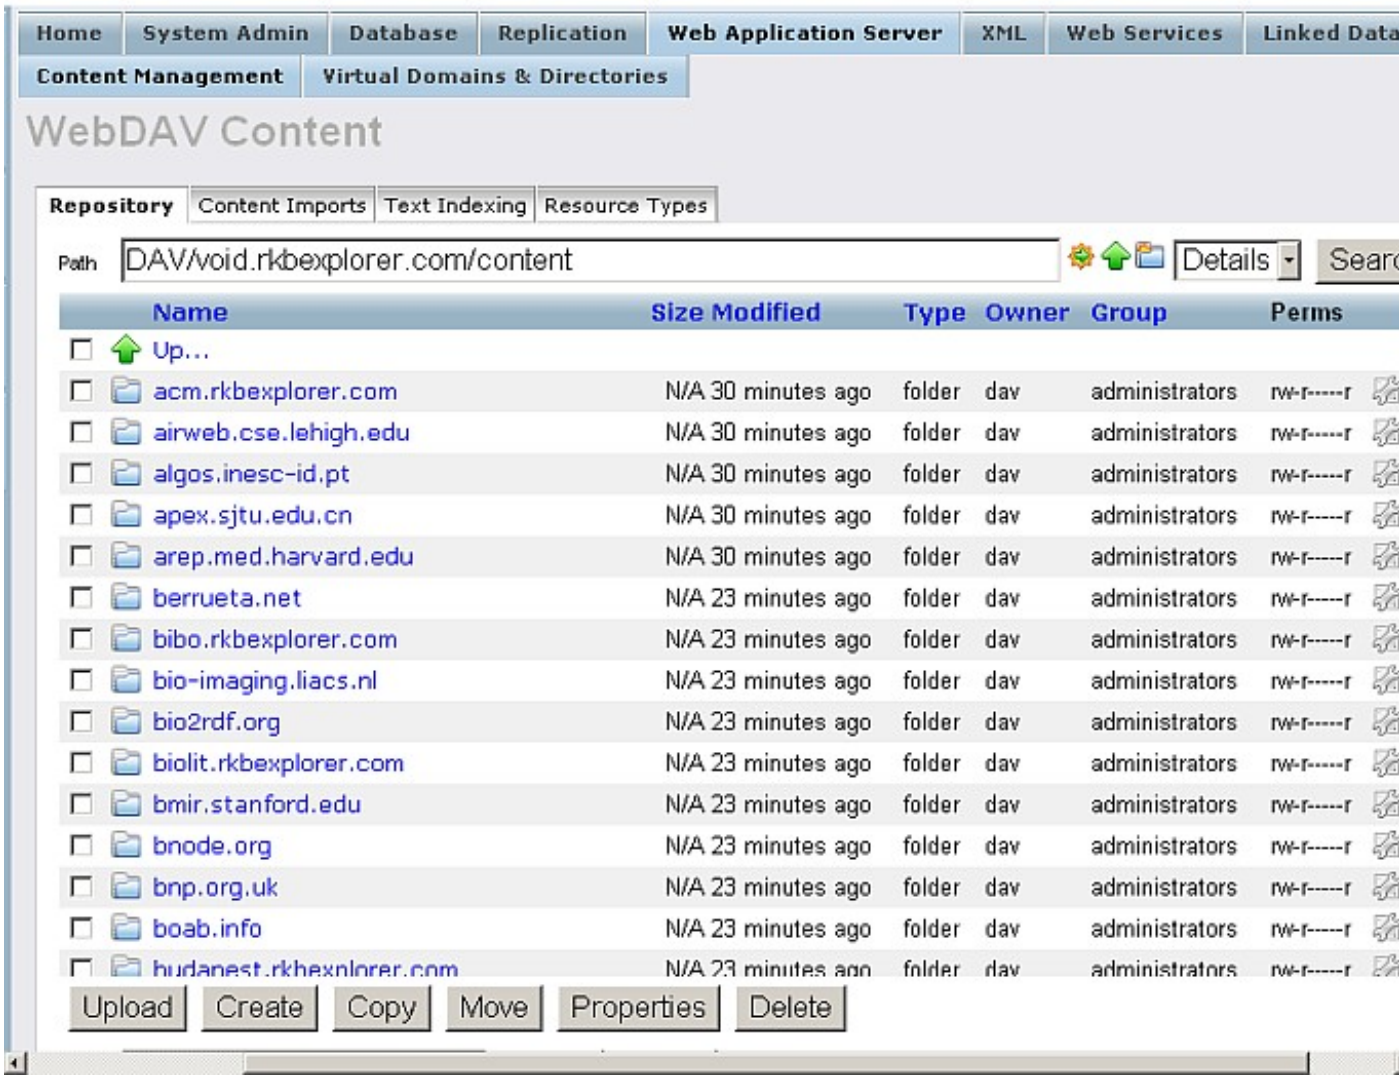
13. Click "voiD store" -> "Edit":

Figure 6.66. Crawling SPARQL Endpoints



14. To check the imported URLs go to "Web Application Server"-> "Content Management" -> "Repository" path DAV/void.rkbexplorer.com/content/:

Figure 6.67. Crawling SPARQL Endpoints



15. To check the inserted into the RDF QUAD data go to http://cname/sparql and execute the following query:

```
SELECT *
FROM <http://void.collection>
WHERE
  {
    ?s ?p ?o
  }
```

Figure 6.68. Crawling SPARQL Endpoints

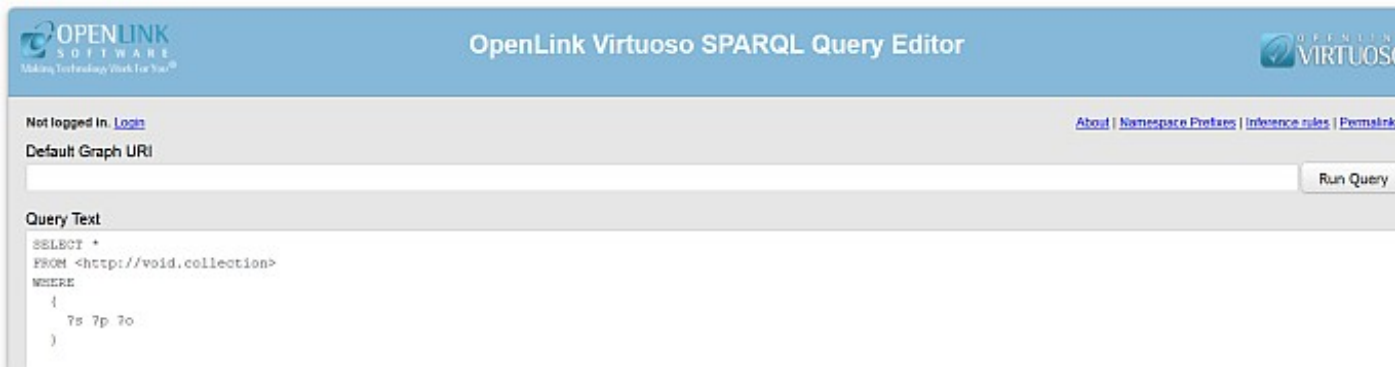


Figure 6.69. Crawling SPARQL Endpoints

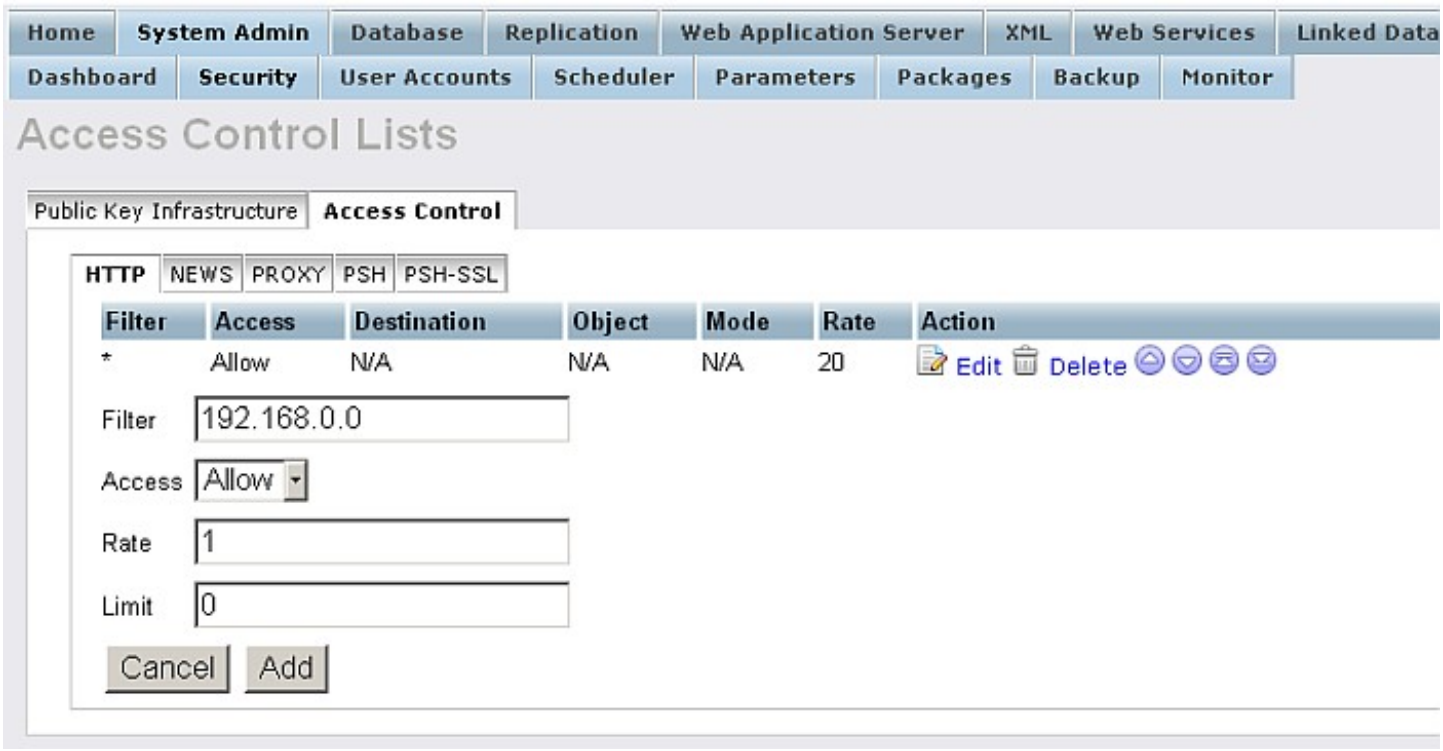
Access Control

From "System Admin" -> Security -> "Access Controls" you can manage Rules and ACL respectively for HTTP, News, Proxy. The tabs PSH and PSH-SSL are available only when the pubsubhub_dav.vad is installed.

Figure 6.70. Access Control Lists

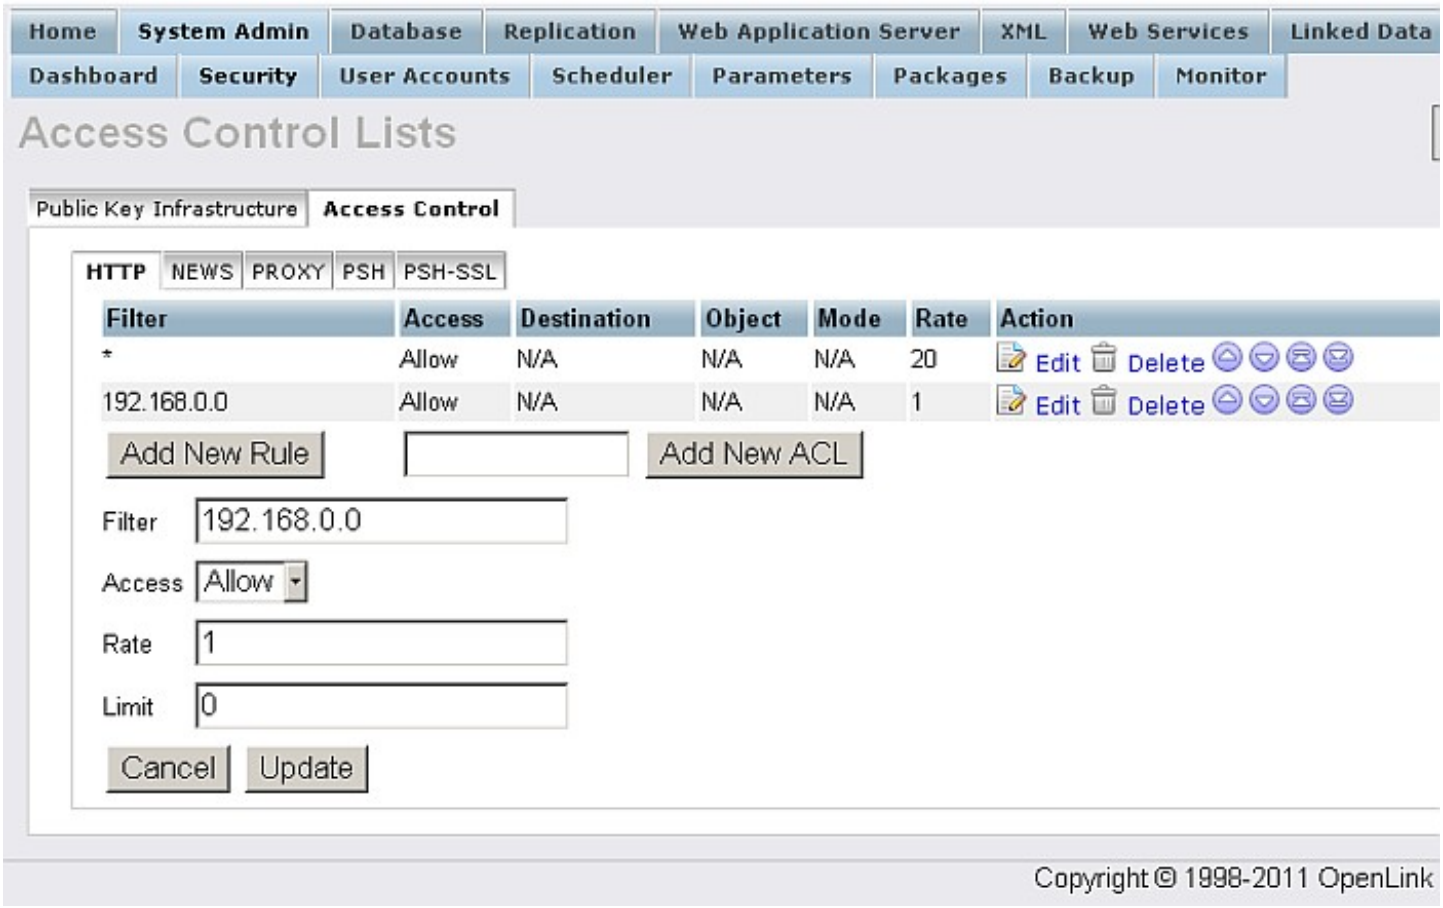
For each of the tabs "HTTP", "NEWS", "PROXY" the created rules will be shown in a list with Filter, Access, Destination, Object, Mode, Rate values. You can also add/delete rules, re-arrange rules order.

Figure 6.71. Access Control List for HTTP



Click the link "Edit" for a rule. Then specify the filter and access values.

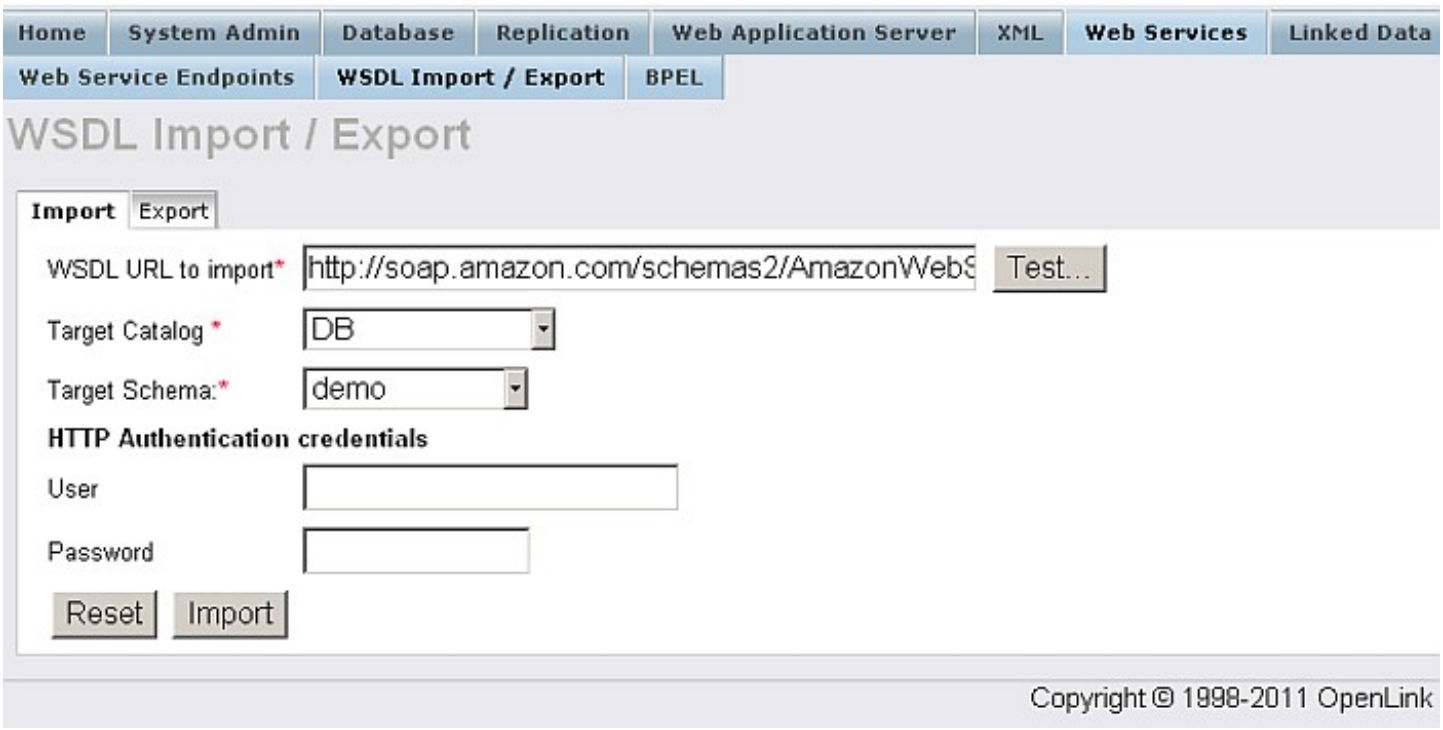
Figure 6.72. Access Control Lists



Import WSDL

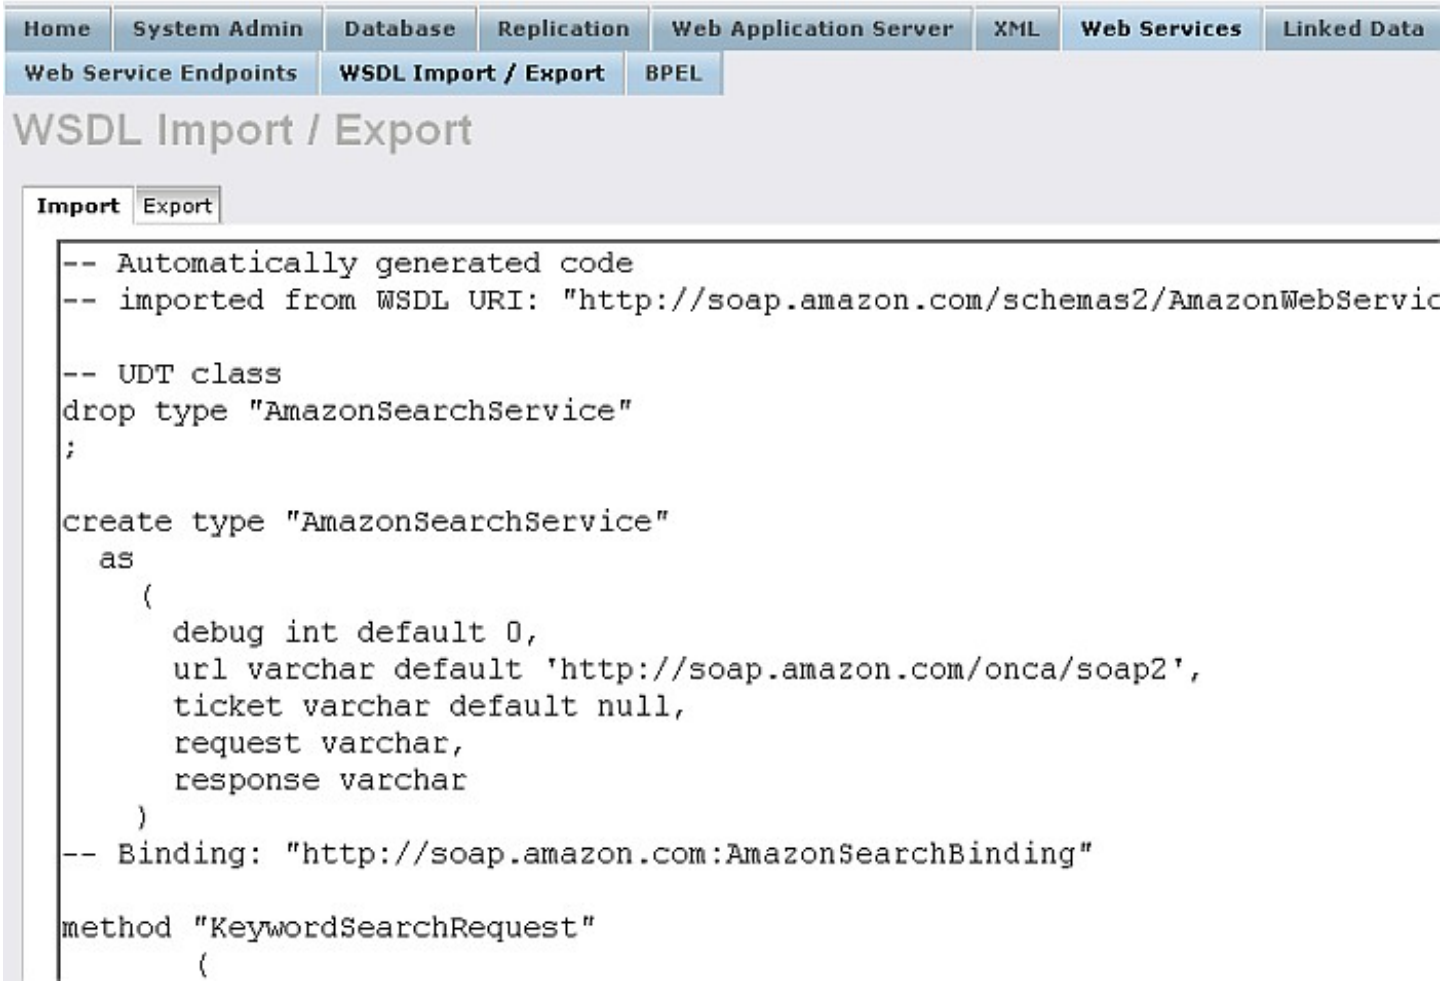
From "Web Services" / "WSDL Import/Export" you can provide a URL to a WSDL description. In return Virtuoso will automatically provide a wrapper for the services available, hence stored procedures and user-defined types that are callable within Virtuoso while the processing and mechanics of the services are actually handled at the source.

Figure 6.73. WSDL Import



After Virtuoso examines the supplied URL to a WSDL you are presented with the source code for the PL wrappers and Virtuoso user-defined types to be created. You have the chance to edit the code for more specific needs and then you can either save this to a file for later work, or execute it in Virtuoso to create the procedures and types.

Figure 6.74. WSDL Import



Any errors in the code will be highlighted if you try and execute it.

If you wish to save the file the appropriate file system ACLs must be in place for the destination.

6.2.4. WebDAV Administration

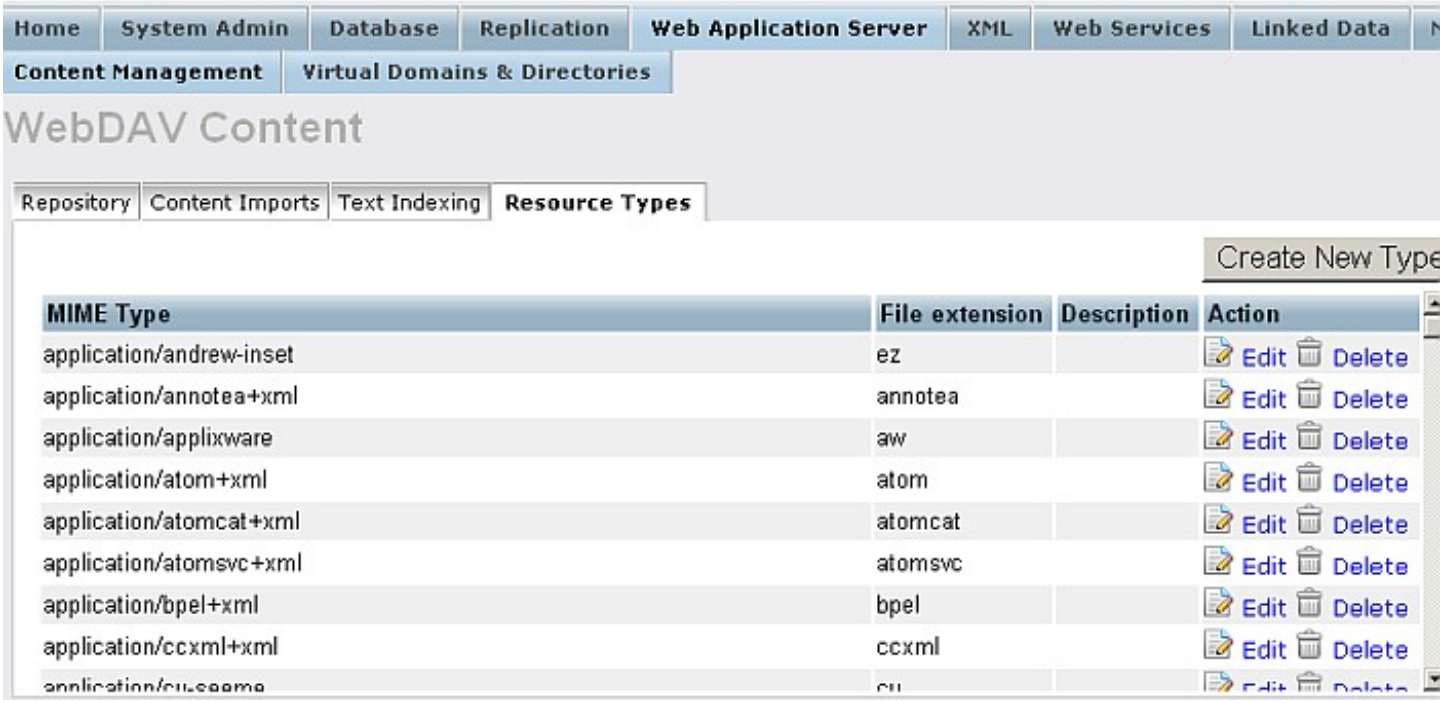
DAV, or WebDAV, is a protocol for Web-based Distributed Authoring and Versioning. The location where content items are placed is called the *repository* . Content elements are called *documents* , corresponding to files, and *folders/collections* , corresponding to directories. Collectively these documents and folders (collections) are known as *resources* .

Virtuoso implements the DAV protocol, allowing you to create and manage resources either directly through repository manipulations or indirectly, through a variety of WebDAV services.

DAV Resource Types

To make sure that when Virtuoso serves files to client user agents the type of file is conveyed properly so that the right application can be used with that file a list or file types are maintained in the server. This list is used when sending any content via the HTTP server which include content in DAV and under VSP.

Figure 6.75. DAV Resource Types



The Web Application Server/Content Management/Resource Types page shows the list of currently defined resource types in the Virtuoso server. You can edit or remove these types by using the action links on the right most column of the list next to the type applicable.

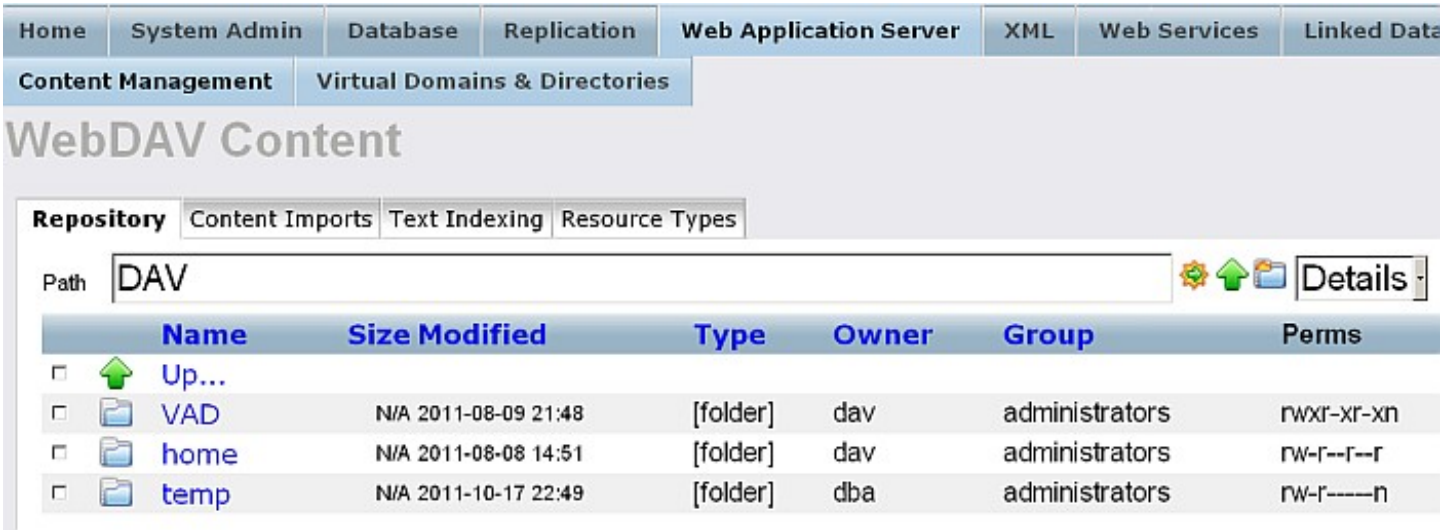
Add new types by typing the details into the fields provided and pressing the *Save* button.

Content Management

The content management page gives you an interface to the WebDAV repository resources. From here you can navigate or create directories, commonly referred to as collections or folders in DAV, alter properties, upload or remove files, or edit documents.

The Repository tab lists the current location within the tree and the current login name. The root of the repository is usually `/DAV/` .

Figure 6.76. Content Management



Resource Names

Resource names are given with collection (folder) names listed first, then individual documents. Permissions on resources are presented in a style similar to Unix, with (r)ead, (w)rite, and e(x)ecute permissions listed for the resource owner (the user), the resource's group, and for the general public. If a permission is present, the letter is shown; if not, it is replaced with a dash.

Resource Permissions

Unlike Unix, the Repository does not use the designation 'd' for directories, which in DAV are more commonly referred to as collections. Collections are distinguished by a different icon - a folder-like icon - and by having the type named "collection".

In addition, the permissions string has a trailing letter designating the indexing status of the resource. This letter is 'n' to designate that indexing is off, 'r' for recursive indexing, and 't' for direct indexing.

Resource User and Group

By default, the user and group of a DAV resource are those set by the service that created the resource, or they are the ID and primary group of the user who was logged in when the resource was created.

Resource Size

The size of a document resource is its size in disk bytes. Note that this does not necessarily correspond to characters displayed on the screen because of encodings. For example, the HTML token &-a-m-p-semicolon is five bytes on disk but displays as a single screen character.

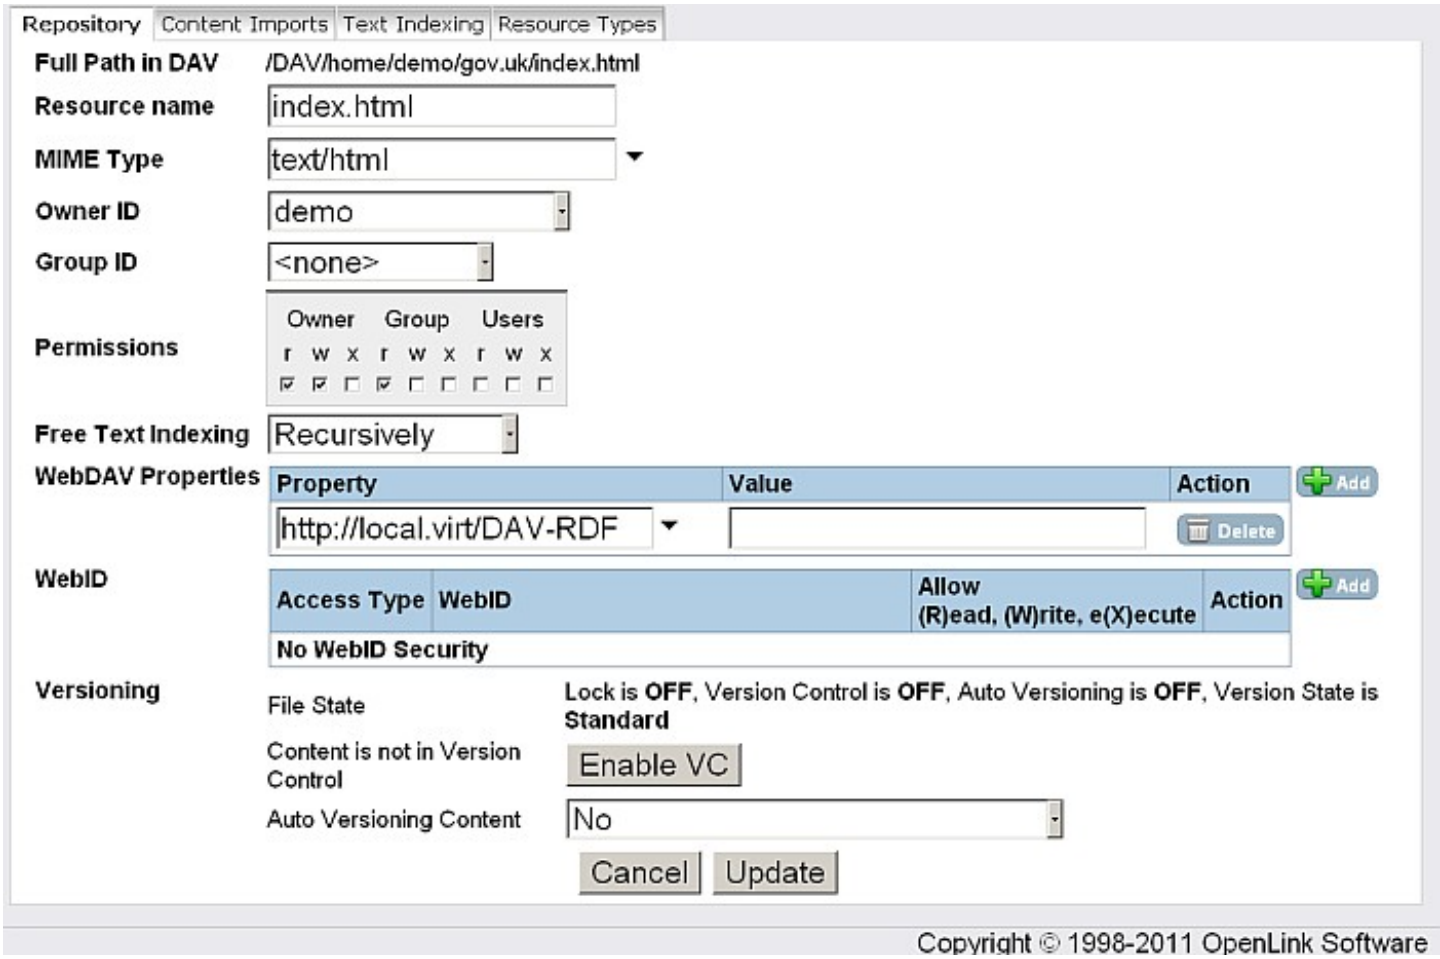
Resource Type

The type of a resource is always "collection" for collections (folder). For documents it can be any of the known resource types (see Resource Types below). The resource type is usually based on the resource's extension; for example, .xml files are usually assumed to be `text/xml` . If Virtuoso does not recognize the extension of a resource, it assigns the default type of `application/octet-stream` .

Editing Properties

Within the Content Management screen, you can change any of the properties of a resource, other than its name, by selecting the resource via the checkbox to the left of the icon, and pressing the "Properties" button.

Figure 6.77. Edit Resource Properties



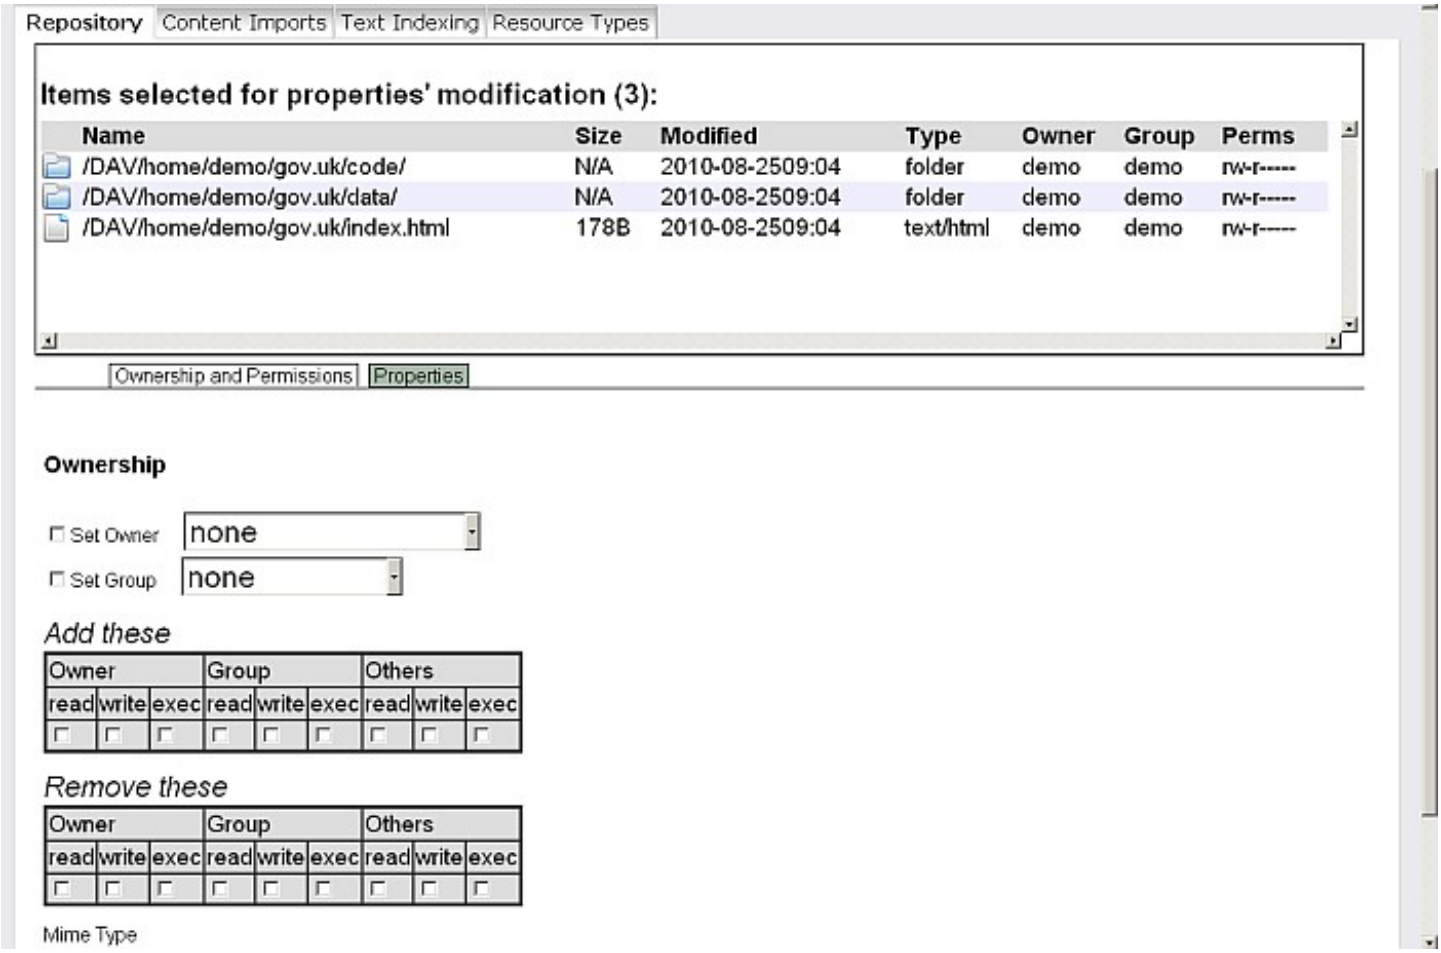
XML documents also permit you to edit their XML properties specifically. This can be done on any document of type text/xml by clicking on the icon for the document.

Properties

When clicked this button from the bottom of the page, you can edit the properties for one or a group of resources which should be selected. The name of a resource cannot be changed.

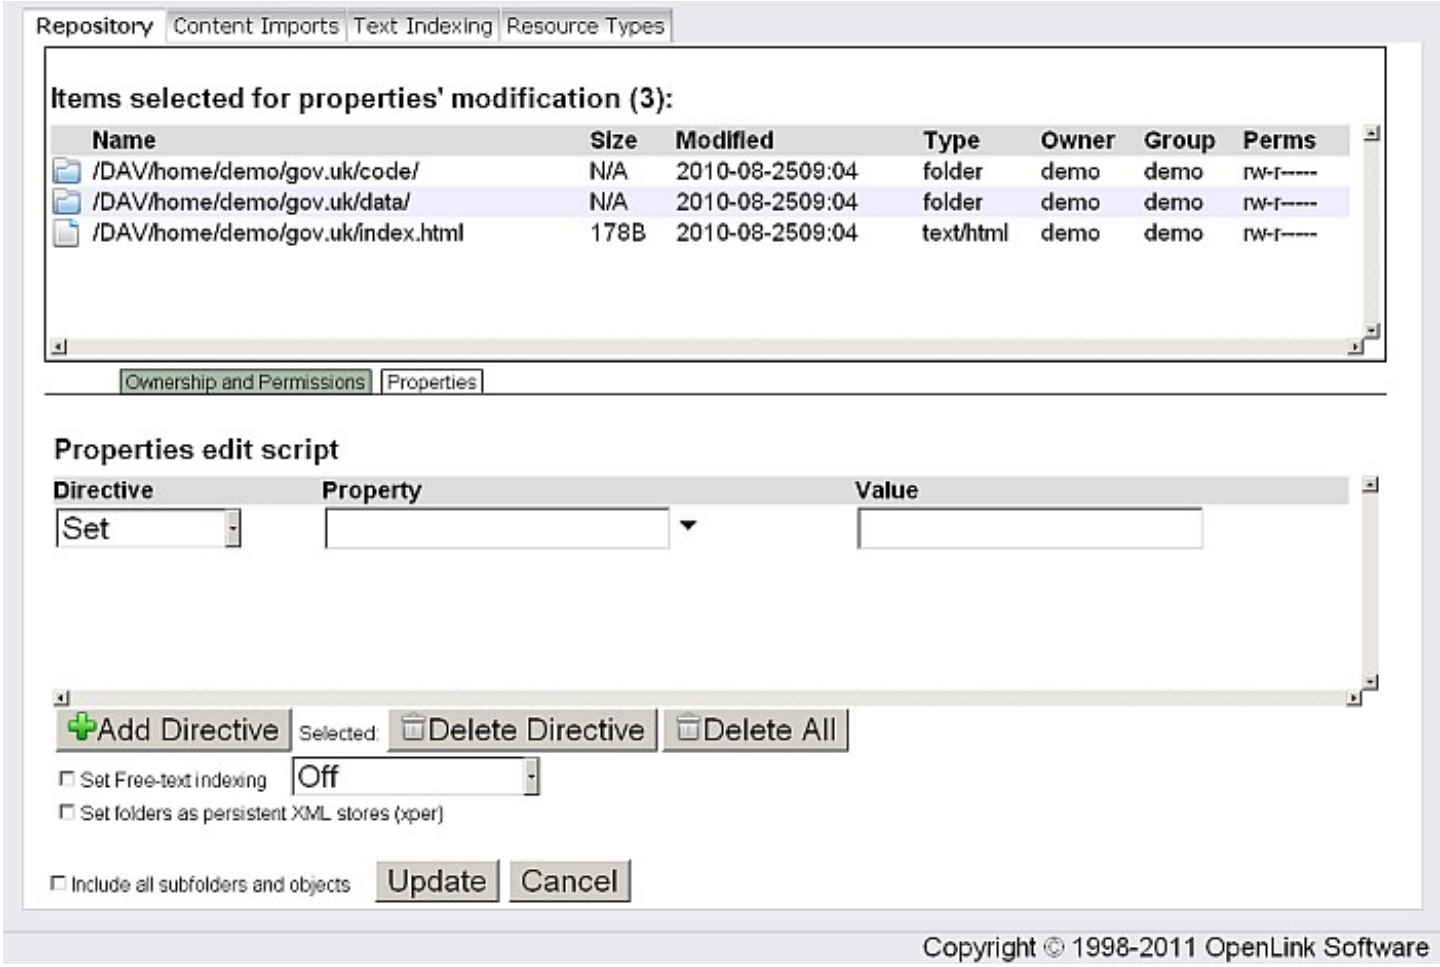
The owner, group, permissions, and indexing controls on this form apply to the appropriate properties of resources, as documented above. Changes to the type of a collection (folder) are ignored.

Figure 6.78. Multiple Resources Edit Properties



The "Property" control permits you to change or add additional properties. There is a pulldown of predefined XML-related properties, or you may create your own property.

Figure 6.79. Multiple Resources Edit Properties



WebDAV Properties

This control permits you to manipulate the specific properties of XML documents. Existing properties are shown with their values, and can be removed. New properties can be added.

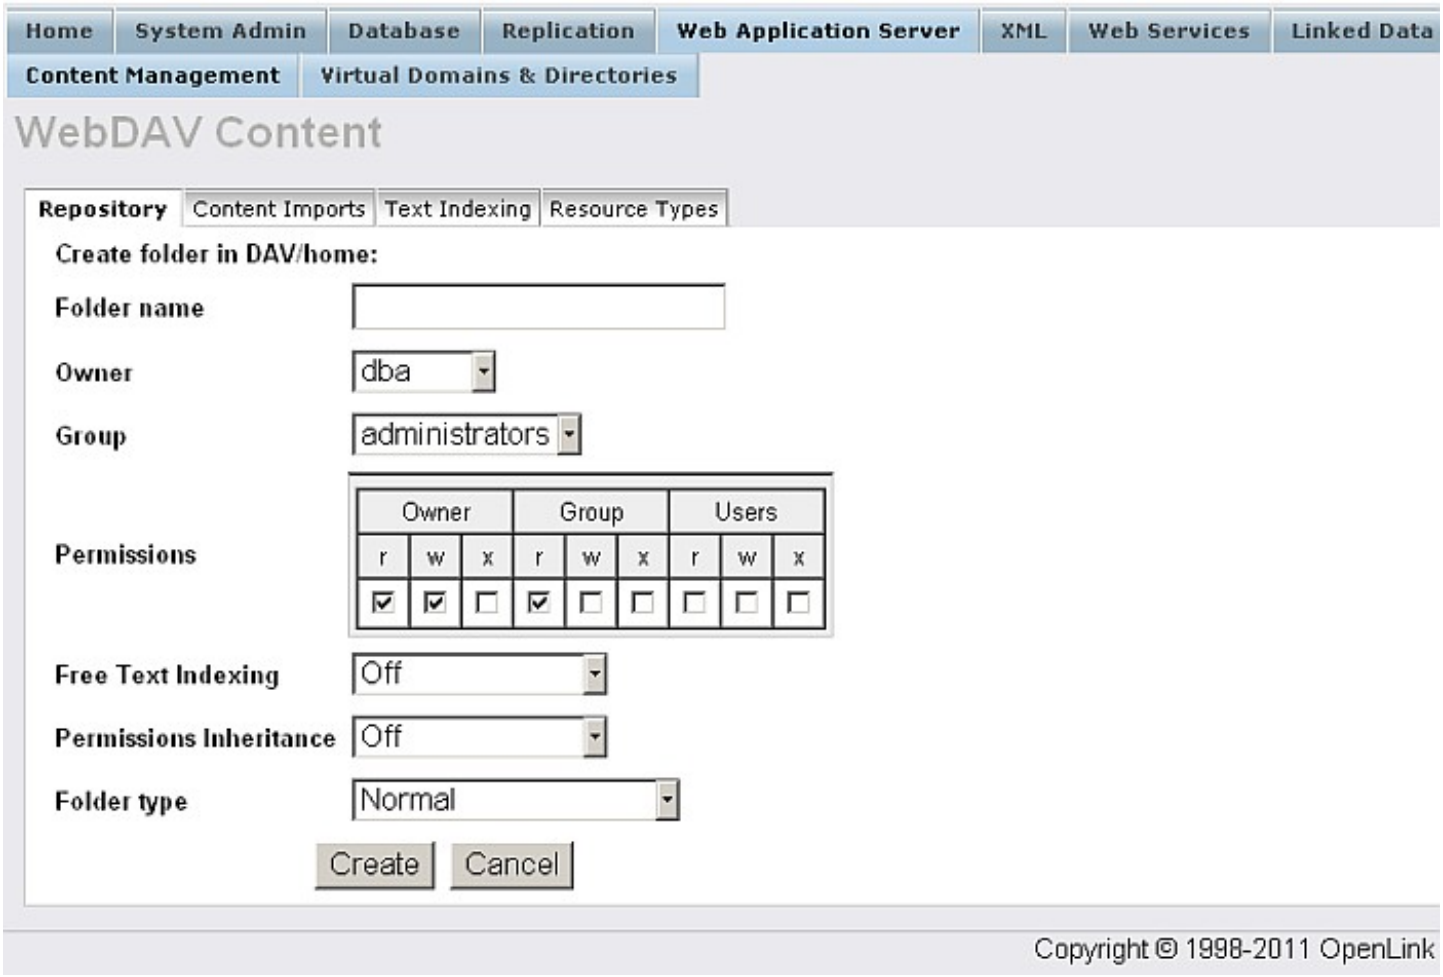
XML-related properties are generally set by specific XML-related services and do not need to be edited directly by users; however, this interface provides a quick means to correct a minor typo or other change without re-running the entire service. For example, you can change the `xml-sql-root` property, which controls the name of the root XML element for the document.

Adding New Resources

Resources may be added to the repository in two ways: by uploading files or by creating new collections (folders). Buttons for both these methods are on the page.

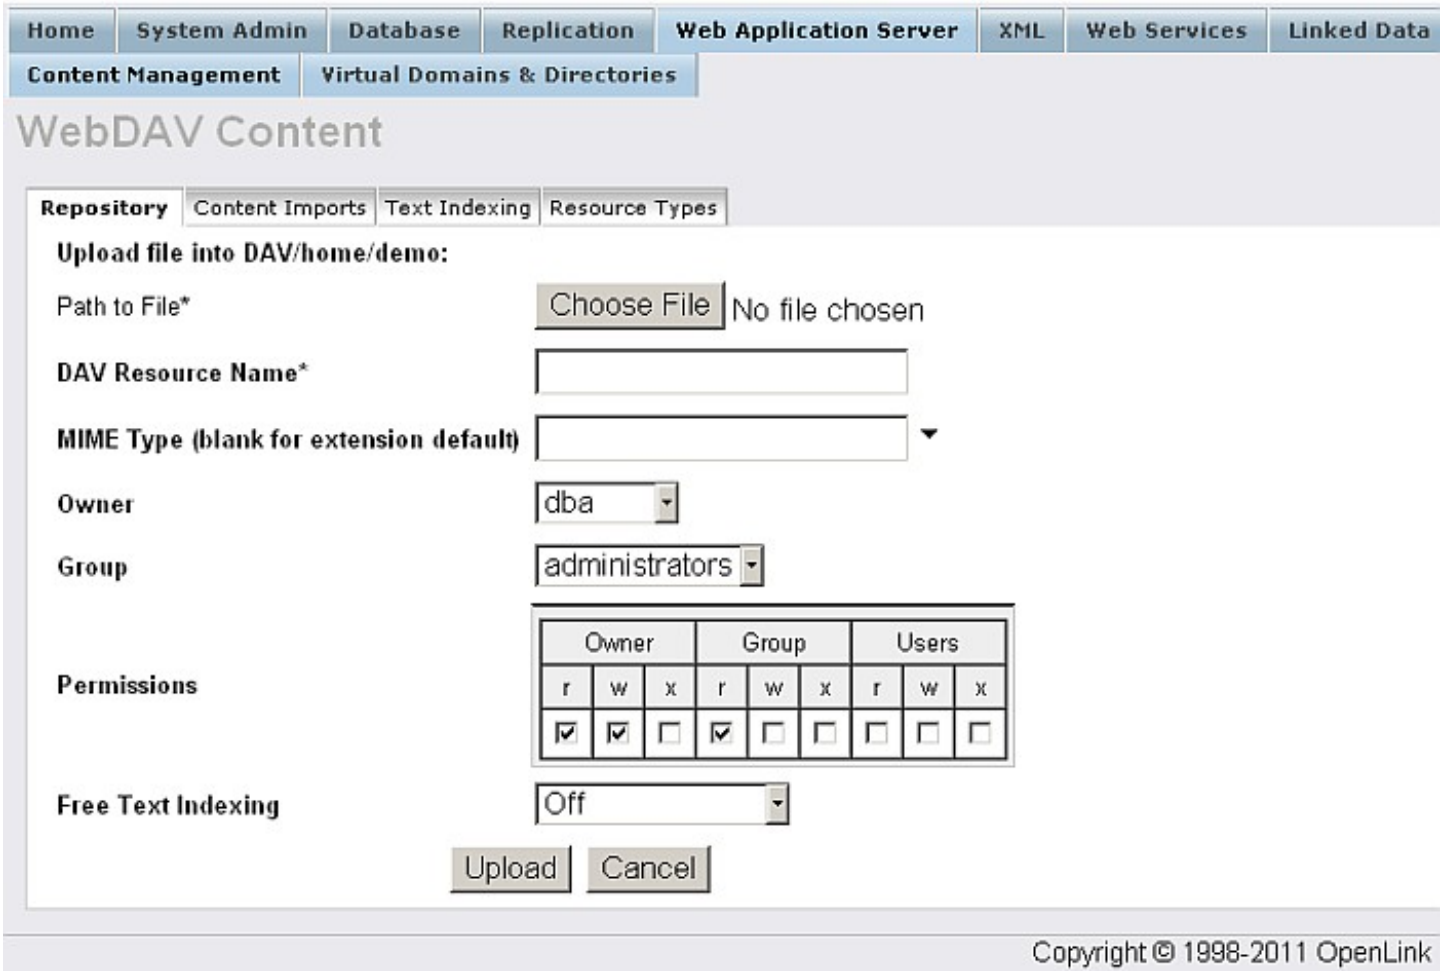
The "Create Folder" button brings up a form in which you can specify the name of the collection (folder), its owner and group, and the initial permissions. You may also turn on indexing for the folder's contents at this point.

Figure 6.80. Create Folder



The "Upload File" button brings up a form in which you can specify the name and location of a file on your local computer that is to be copied into the DAV repository. You need to specify the name of the resource in the repository and give it a type. You can also set the basic repository properties here.

Figure 6.81. Upload File



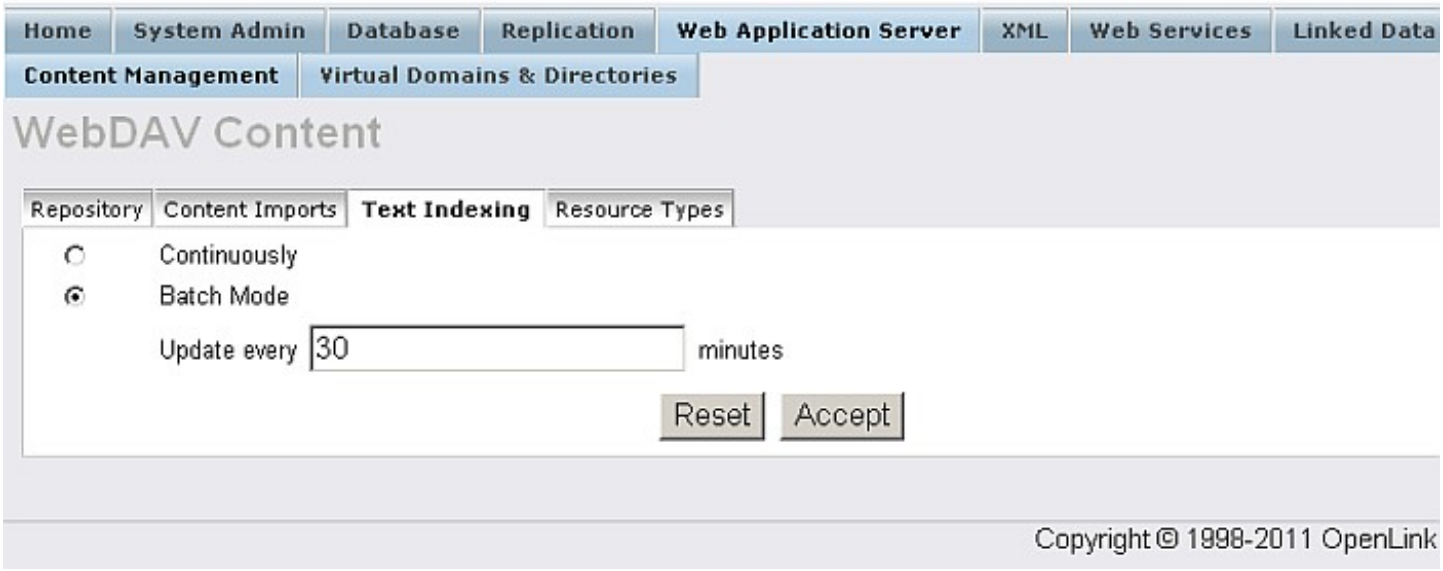
Free Text

Indexing Mode

When files are inserted into Virtuoso's WebDAV repository, if their type is a type of text file such as plain text TXT, XML, or HTML, then they may be automatically free text indexed.

By default files are automatically free text indexed as they are inserted into Virtuoso. This is very convenient but can be time consuming if you frequently insert or update text files. For this reason Virtuoso can be set to index in batch mode at a particular interval in minutes.

Figure 6.82. DAV Free Text Index Configuration



To change the free-text index mode to batch mode check the check-box and provide a non-zero time interval (in minutes). Press the *Accept* button to save the changes into the server.

6.2.5. Internet Domains

HTTP Virtual Directories

From Virtual Domains & Directories you can define Virtual HTTP directories. Virtual Directories let you define multiple HTTP server listeners in Virtuoso for either the same network interface or another one. Virtual directories can respond logically to a name or directly by IP address. Both types as well as default responses can be defined here.

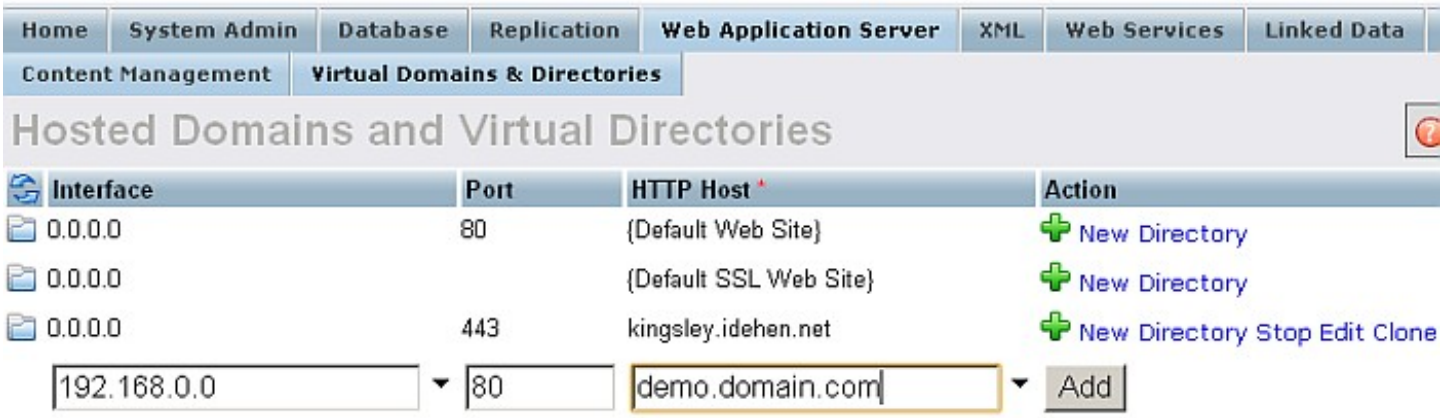
Each virtual directory can also have HTTP maps defined for it. This allow you to set logical paths on an HTTP directory to point to specific directories available to Virtuoso through the file system or DAV.

You can also publish stored procedures to a SOAP defined directory during the virtual directory definition.

Figure 6.83. Virtual Directories

Click on the *Add New Site* button to start adding a new Virtual Web Site and its directories.

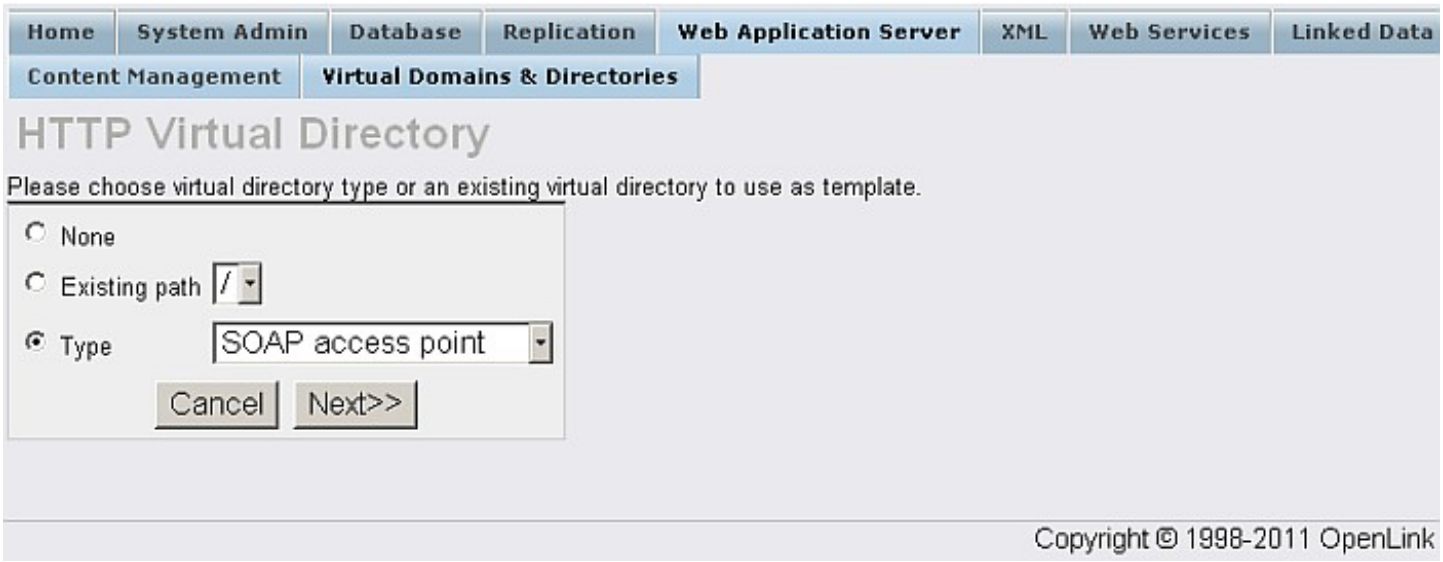
Figure 6.84. Virtual Directories: Site Details



When adding or editing a web site you must supply a host.domain name, which will be used to match again incoming requests to produce the correct response, the IP address of the network interface, to set-up the listener on, and the TCP port number that will be used to listen for incoming requests. Although Virtuoso will be listening on the specified interface you can set up multiple sites on this interface. The site required by client web browsers will be determined by the host name specified in the request. This provides the virtual site.

Click on "New Directory" to continue.

Figure 6.85. Virtual Directories Mappings



Before the directory settings are configured you can select from a few types to help configure the details to follow quicker and easier. For SOAP virtual directories this step is particular useful.

Select "Type" and then click "Next" to continue.

Figure 6.86. Virtual Directories

The "Virtual Directory Information" tab lets you configure most aspects of the virtual directory.

The default directory checkbox can be checked if you want the site being defined to act as the default site for the interface. This means that if a request is made to the interface that does not match a hostname defined for the interface, the default will be returned.

Logical Path will be the path that Virtuoso will respond to for this virtual directory mapping. This is what will be placed on the URL. Physical Path or URL is what Virtuoso will actually supply the content from. In either case you can use the Browse buttons to traverse the file systems graphically. Use the WebDAV Source Checkbox to instruct Virtuoso to use the WebDAV store for the physical location. "Default Page" will be returned if no page is specified in the incoming URL.

Note:
Virtual directories for SOAP must always use a physical path of /SOAP/.

The physical path of /SOAP/ does not need to exist in the filesystem under the VSP-root directory for normal SOAP operation. If it does existing it can be used to answer non-SOAP requests. Thus, configuring the virtual directory for SOAP with a "Default Page" can be used to avoid SOAP clients receiving HTTP 404 errors when testing the SOAP endpoint using standard HTTP only. Some SOAP applications assume the SOAP endpoint is down if they received HTTP 404 without checking the SOAP endpoint itself.

The permissions panel lets you choose whether to enable various abilities in the directory.

In the SOAP Options section you can publish or unpublish procedures and/or templates, both native and remote to the virtual directory using the Publish/Unpublish buttons respectively. The SOAP Options text-area allows you to specify other SOAP options such as DIME encapsulations and WS-security settings. These options are supplied as name=value pairs terminated with a semi-colon and a carriage-return. Here is an example of the options used for the default Interop test based demo virtual directory:

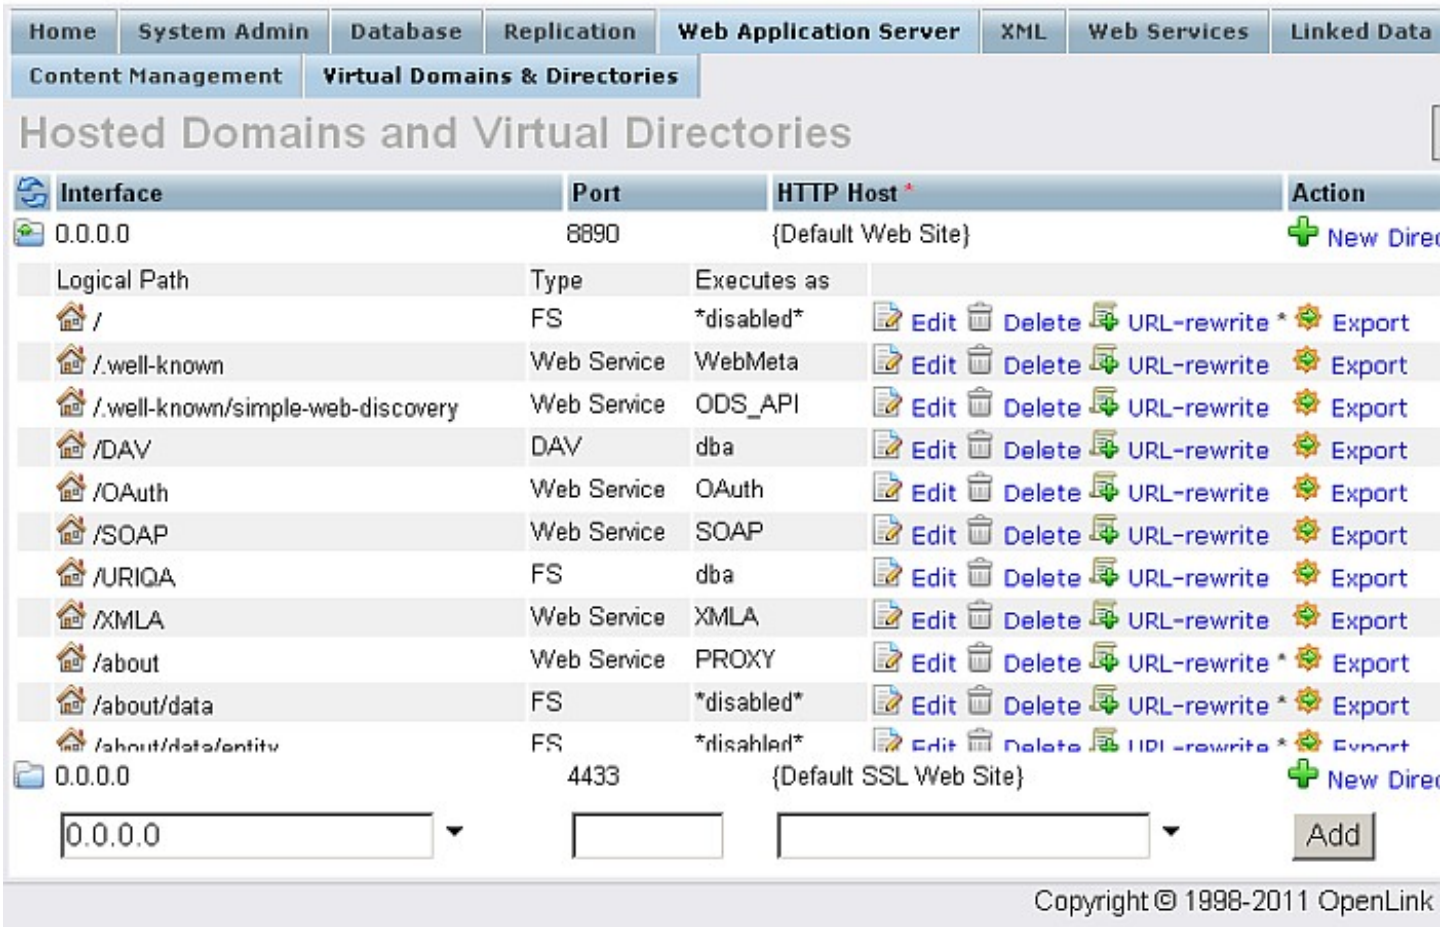
```
Namespace=http://soapinterop.org/;
MethodInSoapAction=no;
ServiceName=InteropTests;
HeaderNS=http://soapinterop.org/echoheader/;
CR-escape=yes;
```

See Also:
For a list of available SOAP Options review the end section of the SOAP chapter: Optional Parameters to the SOAP Endpoint .

The Authentication Options panel lets you define the authentication rules for the Virtual Directory.

Once the form details have been completed press on the Add button to save the them and proceed to configure mappings for the directory.

Figure 6.87. Virtual Directories Mappings



This screen lists mappings that have been defined for the virtual site. If you have just created a fresh site then only one line will be displayed. The "Add Virtual Directory" button will let you define more. Back returns you to the start page, Edit and Delete allow you to edit or remove existing mappings as their link suggests.

See Also:
Virtual Directories

For example, here are the basic steps to be performed, in order to mount FS folder to DAV:

1. Suppose there is a folder with name "test" in your FS and it is under the root of the ServerRoot defined in your virtuoso ini file.
2. Also suppose in the folder "test" there is a file index.html with simple content:

```
<!DOCTYPE HTML PUBLIC "-//IETF//DTD HTML//EN">
<html>
  <head>
    <title>OpenLink Virtuoso Conductor Simple Test</title>
  </head>
  <body>
    <table cellspacing="0" cellpadding="0" border="1" width="50%">
      <tr>
       <td><b>Name</b></td><td></b>State</b></td>
      </tr>
      <tr>
       <td>Simple test for mounting FS to DAV</td><td>Successful.</td>
      </tr>
    </table>
  </body>
</html>
```

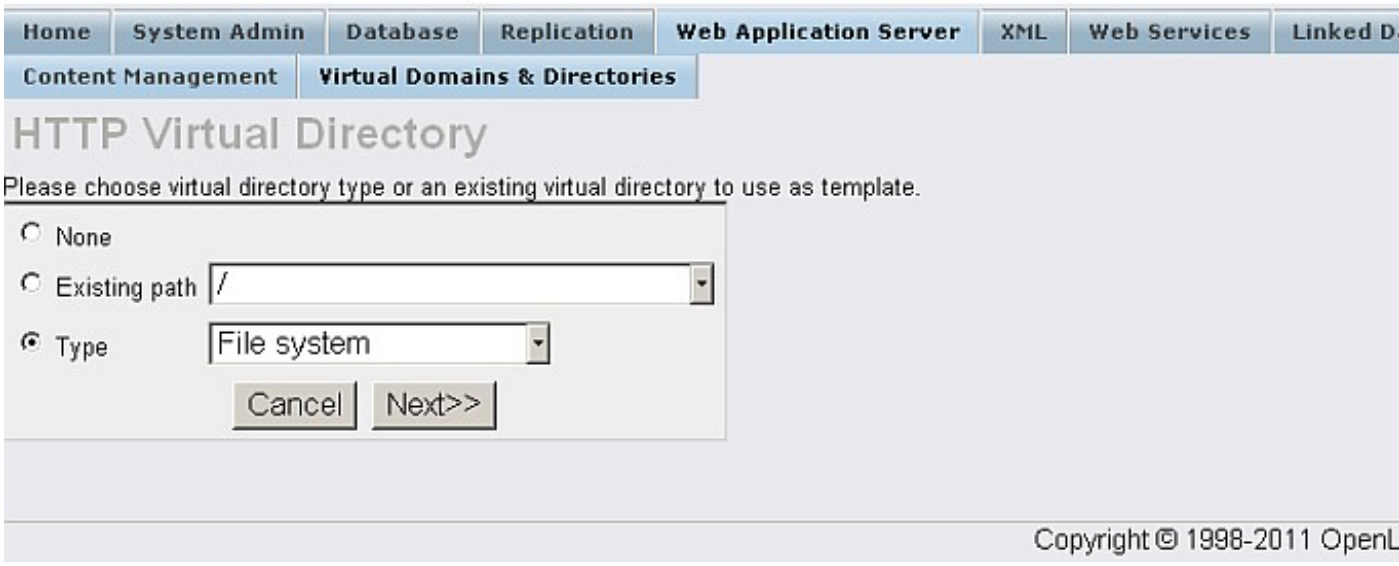
3. Install the Conductor package
4. Go to http://host:port/conductor and login as dba user.

5. Go to Web Application Server -> Virtual Domains & Directories.

Figure 6.88. Mount FS to DAV

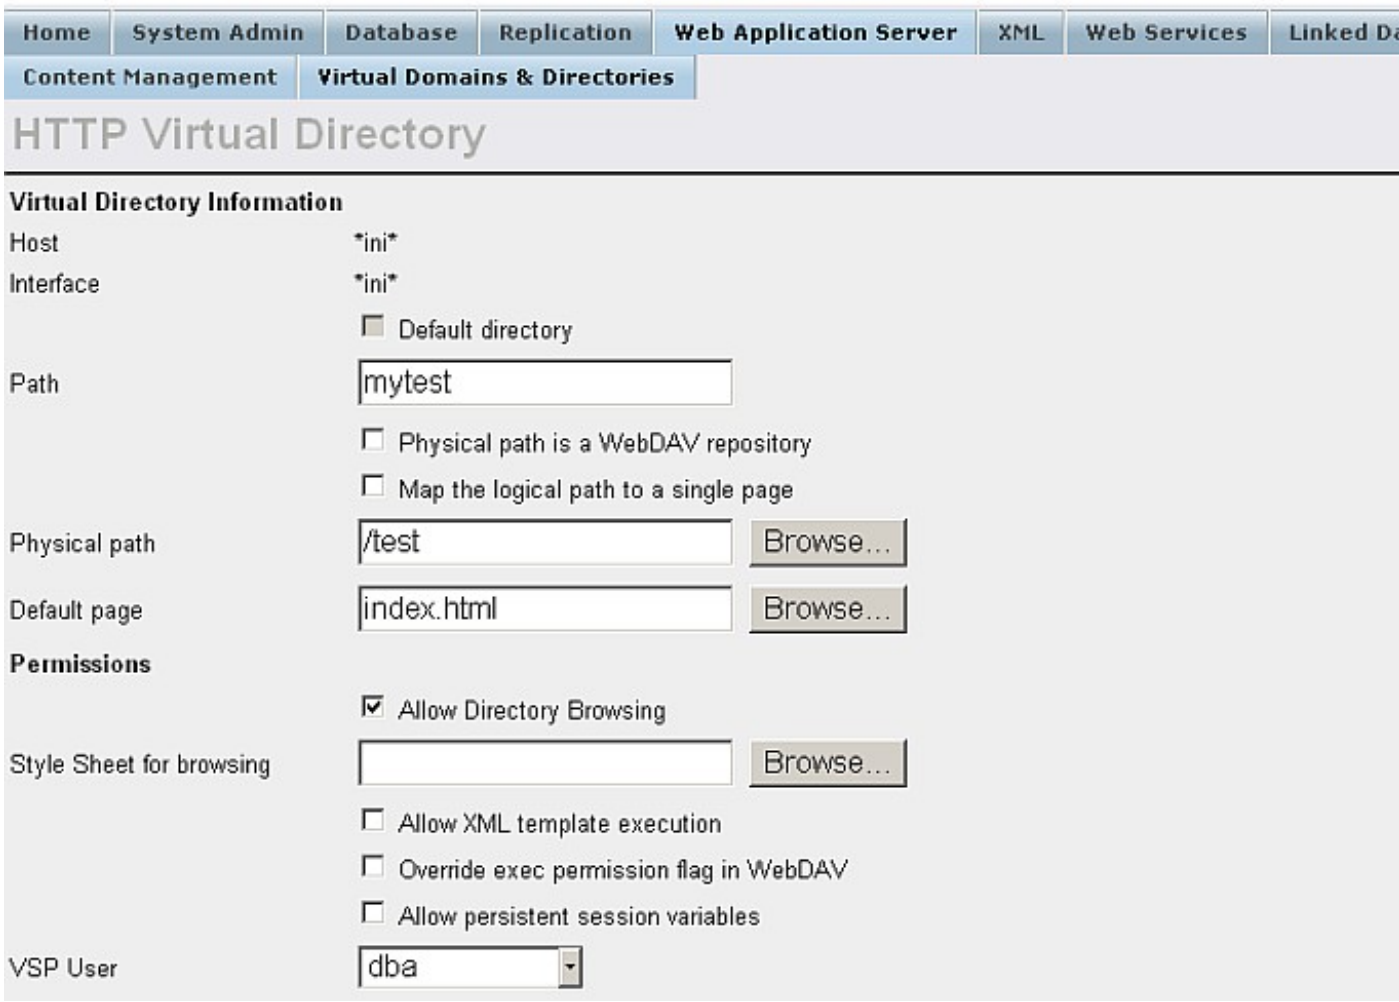
6. For your {Default Web Site} click the link "New Directory".
7. Check the check-box "Type" and select from the drop-down list "Filesystem".

Figure 6.89. Mount FS to DAV



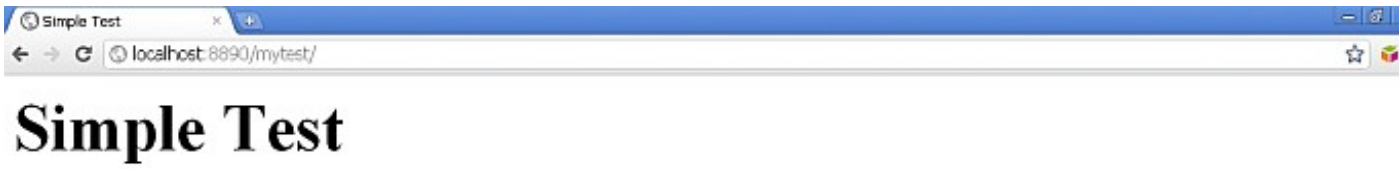
8. Click "Next"
9. In the shown form: Enter for the field "Path": mytest; Enter for the field "Physical path": /test; Enter for the field "Default page": index.html; Check the check-box "Allow Directory Browsing"; Leave the rest of the fields with their default values.
10. Click "Save Changes"

Figure 6.90. Mount FS to DAV



11. From your browser access the url: http://host:port/mytest/
12. As result the content of the index.html file will be shown:

Figure 6.91. Mount FS to DAV



6.2.6. XML Services

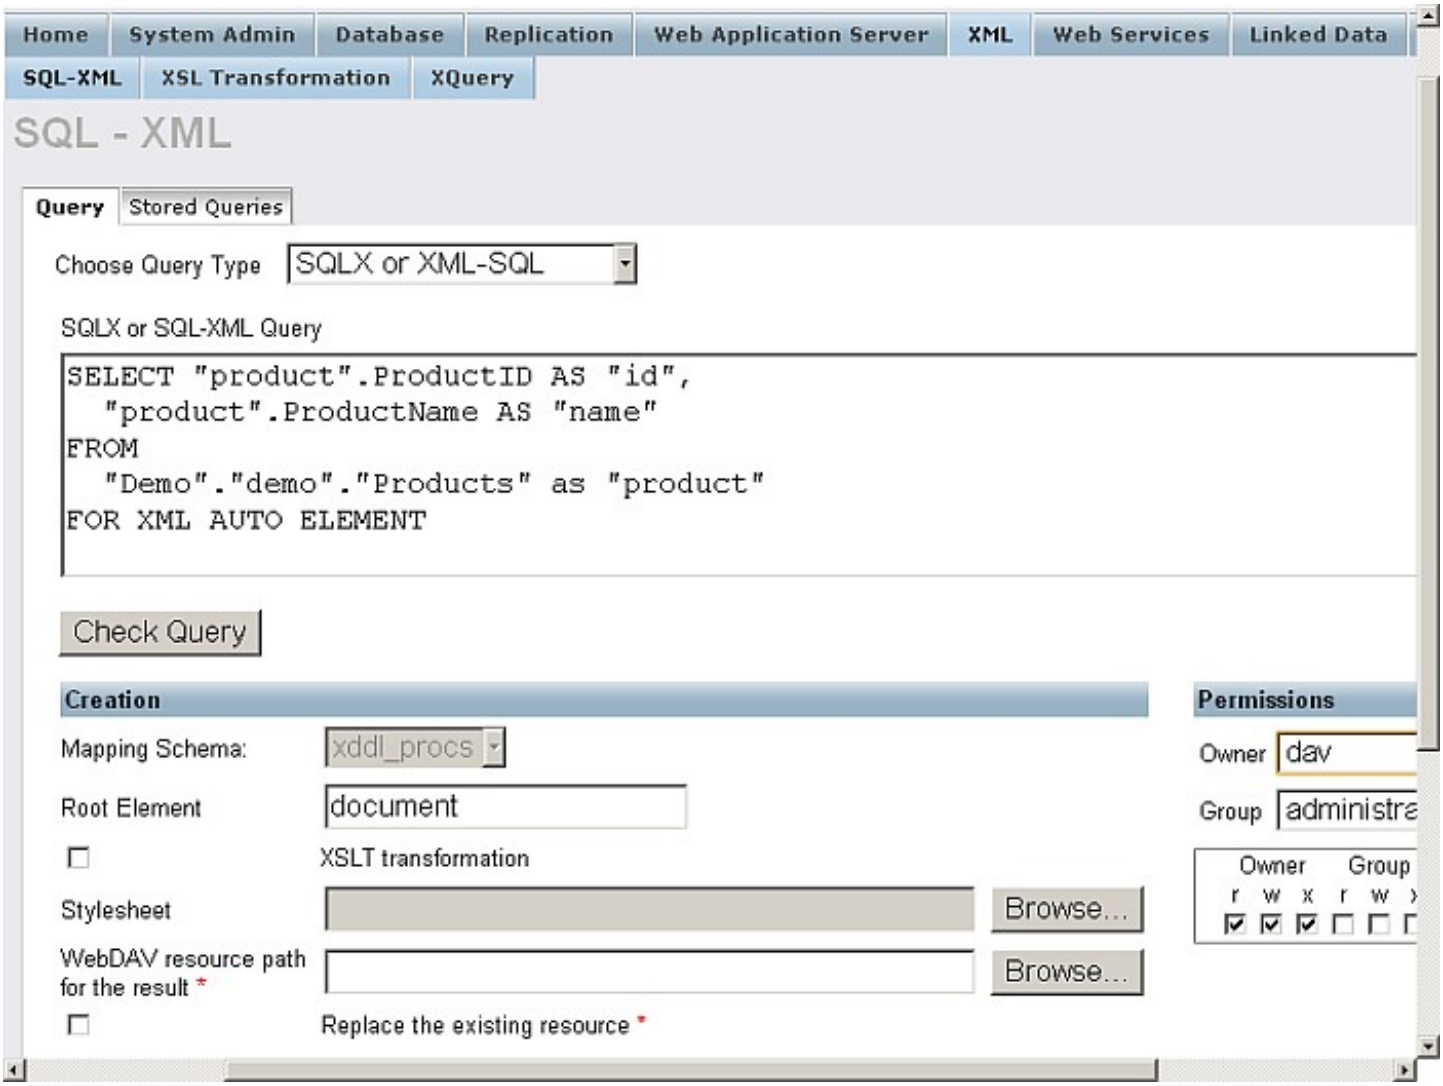
SQL-XML Statements

Go to XML/SQL-XML and enter a SQL to XML statement in the *SQLX or SQL-XML Query* text-area:

Example 6.15. For example:

```
SELECT "product".ProductID AS "id",
  "product".ProductName AS "name"
FROM
  "Demo"."demo"."Products" as "product"
FOR XML AUTO ELEMENT
```

Figure 6.92. SQL-XML Statements



Type the root XML element name into the *Root Element* field. The results of the query will be contained within this root element.

Type the full path and resource name where you want your XML resource to reside under WebDAV in the *WebDAV Resource path for the result* field. Collection(s) described in the full path must already exist.

You may use the *Browse* button next to the *WebDAV Resource path for the result* field to navigate existing WebDAV collections (folders) or resources to store the result of query.

From the "Stored Queries" tab if you choose a resource that already exists as a query in WebDAV resource, after click the "Edit" link, the form will automatically acquire the details from the query.

If an XSLT transformation should be performed on retrieval time then you may either type the location of the stylesheet in the *Stylesheet* field or press the *Browse* button next to it to search for a valid XSLT stylesheet from the WebDAV repository.

Provide the appropriate *WebDAV owner* and *group* of stored result using the drop downs provided.

Select appropriate *permissions* for the stored result.

The query can be set to update itself at specific intervals of time or execute every time the resource is retrieved. If *Persist XML* is checked the query will be executed on *Update every* 10 minutes by default.

Press the *Execute* button to execute the statement and store as a WebDAV resource. Use *Reset* to clear the form

If you want to build a schema definition for the result then press the *Create XML Schema* radio-button.

Virtuoso can provide the generated XML output with a full DTD for the data. Press *Create External DTD* to enable this option for

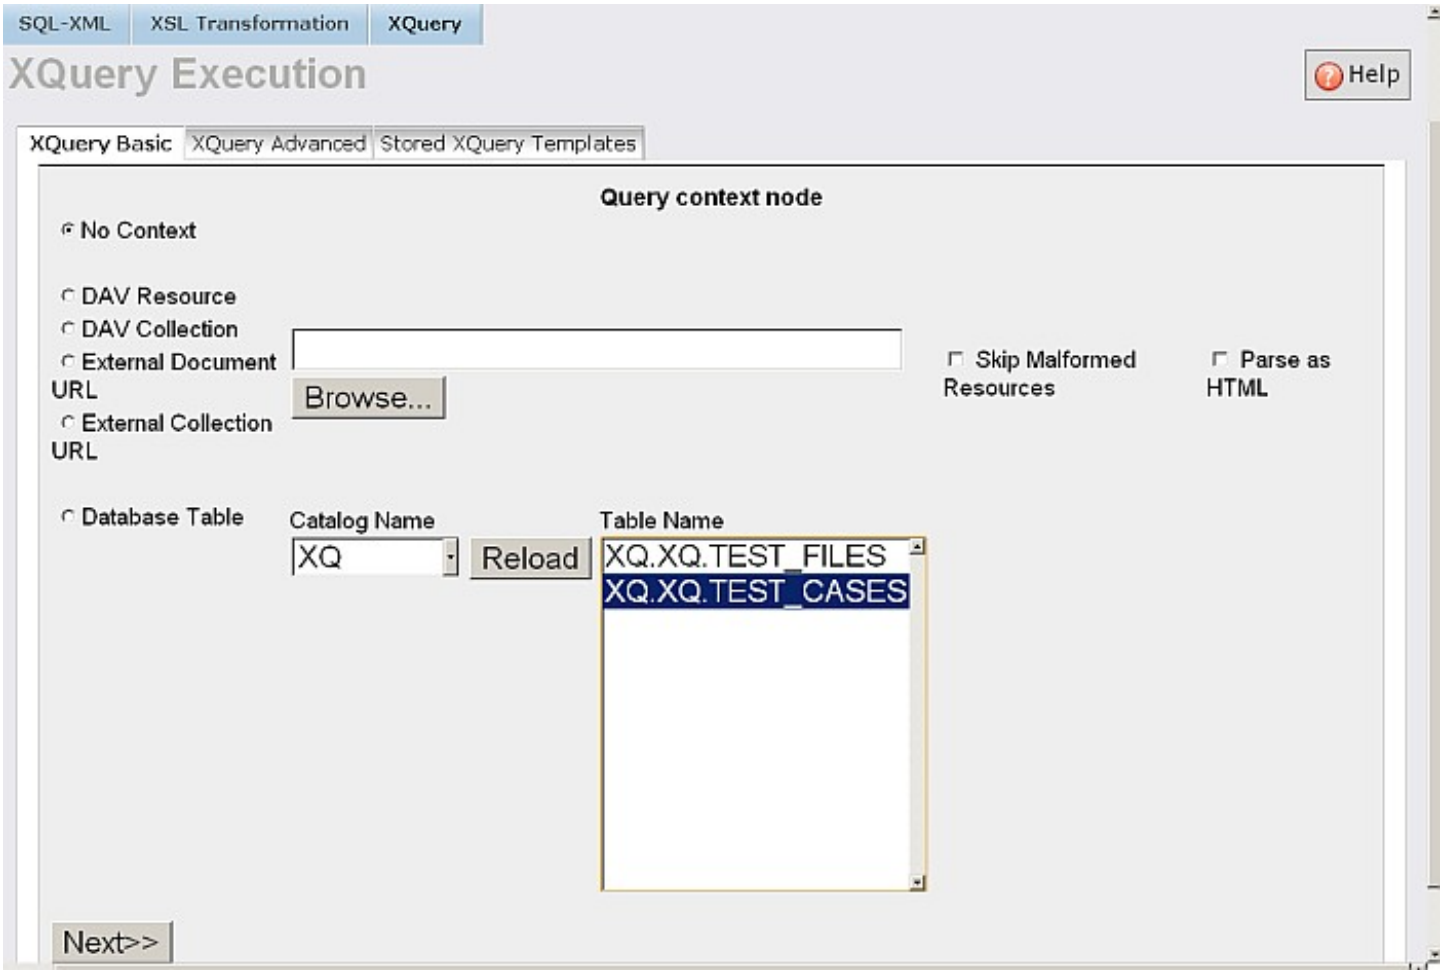
the query.

XQuery Search

Go to XML / XQuery /Xquery Basic.

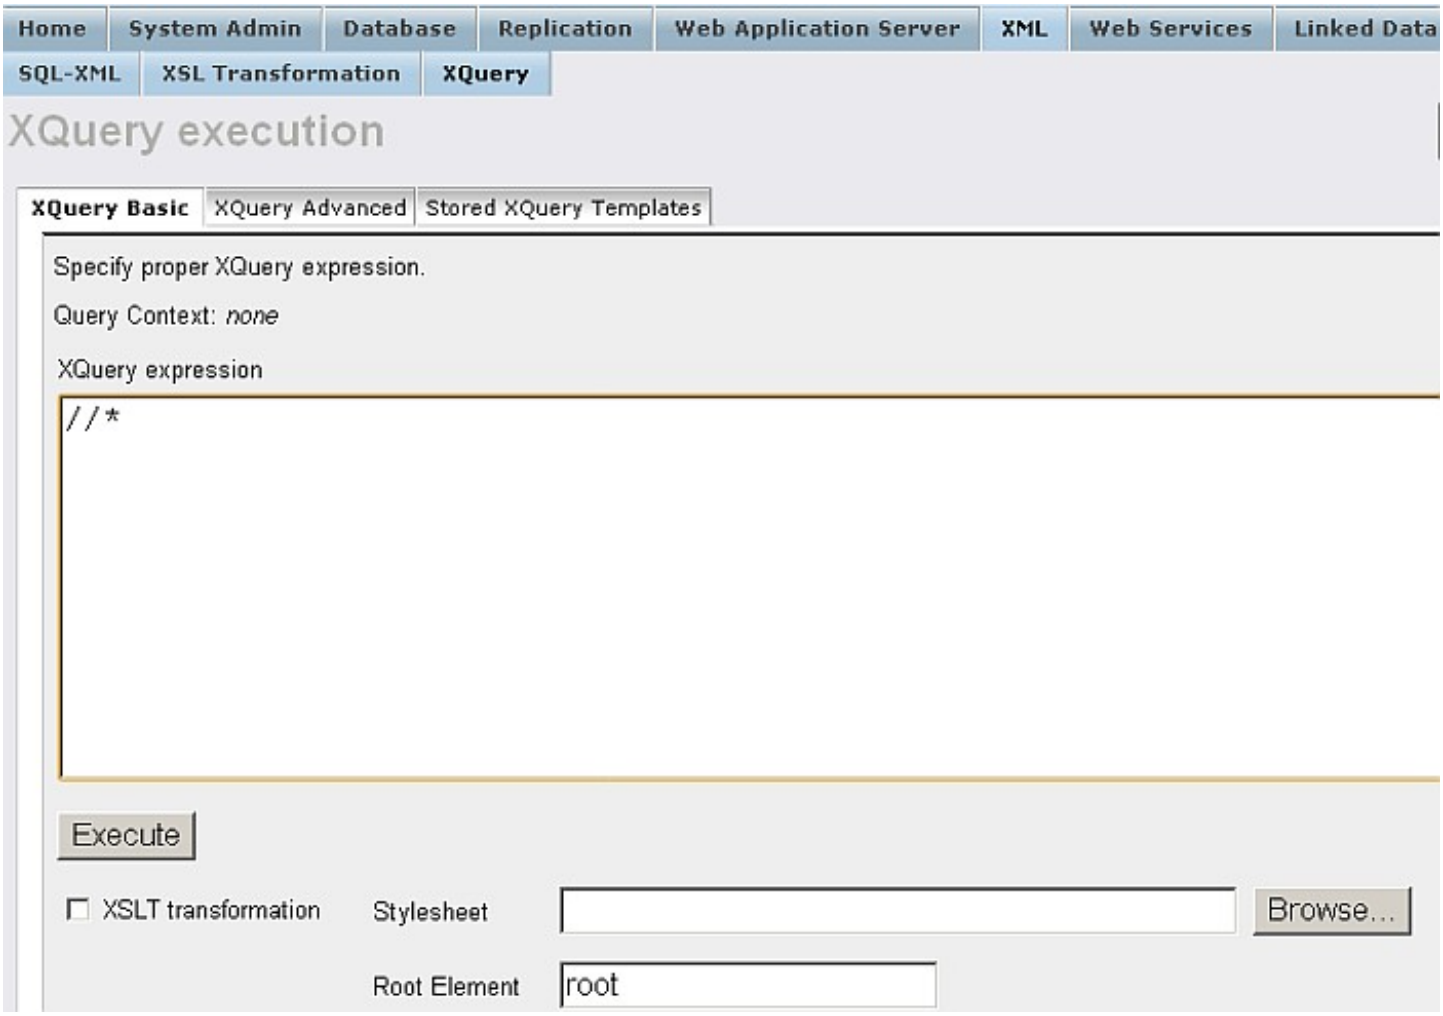
XQuery Document Search applies the XPATH expression to every realized XML contained within the Query Scope to qualify search hit results. Note that this does not include XML Views unless persistent.

Figure 6.93. XPATH Query of DAV



Choose the *Scope of Query* from within the WebDAV repository. You may define the scope as either No Context, DAV Resource (file), DAV Collection (folder), External Document URL, External Collection URL or Database Table. Use the *Browse* button to browse the contents of WebDAV to make a selection. The query will then be confined to the selected resource or collection and its children. Then Click the button "Next" in order to continue.

Figure 6.94. XPATH Query of DAV



Enter that XPATH query expression into the text area that you wish to interrogate your WebDAV XML documents with. e.g. *//** or *//title*

The *Root Element* field allows you specify the name of the root element to contain document element matches for each document found. This aids stylesheet design.

Choose an *Output Style Sheet* by either typing its URL or using *Browse* to select an XSL resource from WebDAV. You only need to specify a style sheet if you want to transform your XML results using XSLT.

Click the button "Next" in order to continue.

Choose an *Store into* location by either typing its URL or using *Browse* to select a DAV resource from WebDAV

Set *Permissions* for the output result. Check "r" for read rights for Group and Users in order to view later the saved xml file.

You may want to *Replace the existing resource* by checking the shown check-box with this label.

Choose *Output Type* that you wish to obtain. *Persist XML* should be selected with Update interval im minutes or if you want to be created as XML Template, fill in the "Create as XML Template Description" field.

Click the button "Save".

Figure 6.95. XPATH Query of DAV

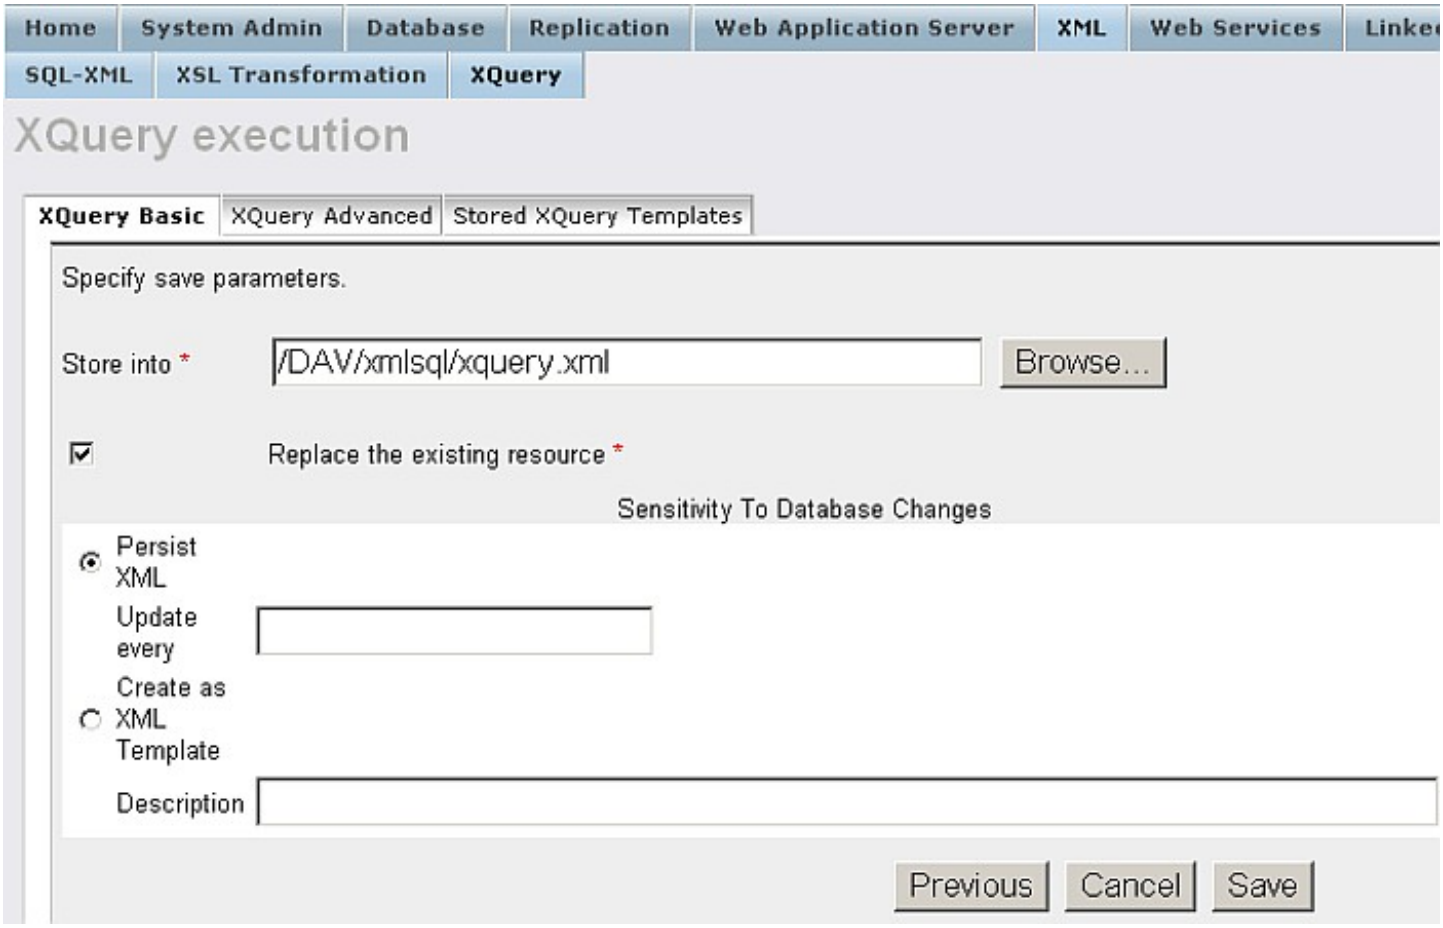


Figure 6.96. XPATH Query of DAV

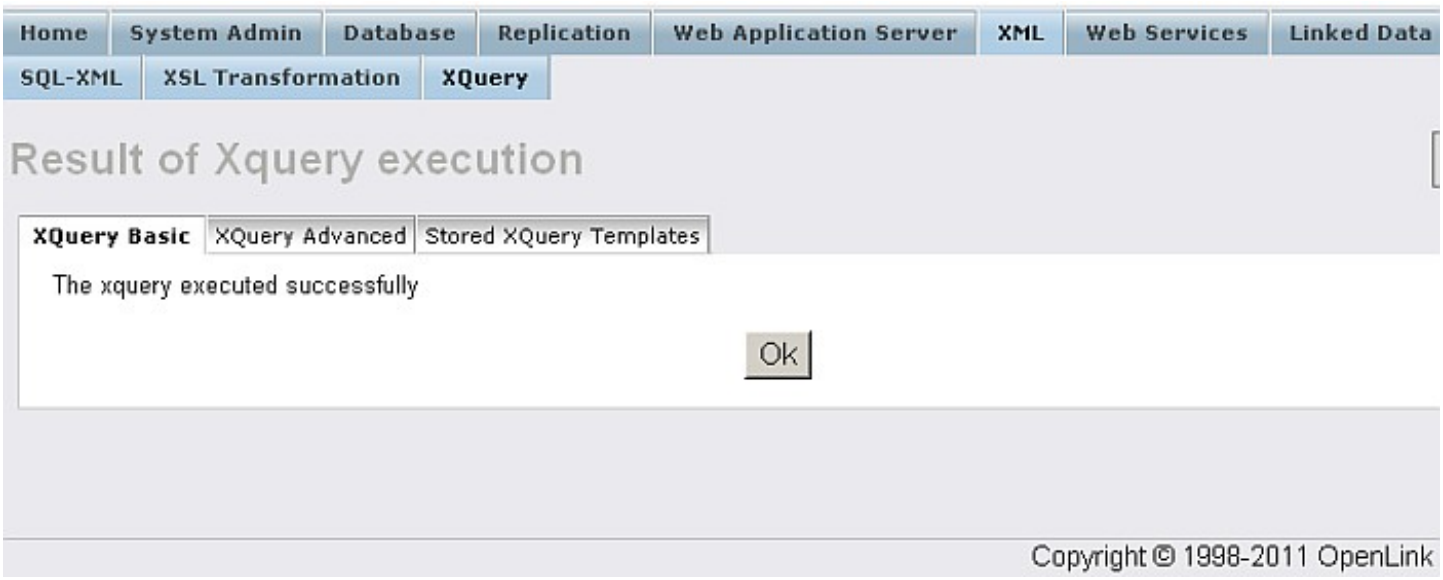

If for location you have chosen /DAV/xmlsql/xquery.xml, you can view the saved file accessing the url: http://host:port/DAV/xmlsql/xquery.xml

Figure 6.97. XPATH Query of DAV

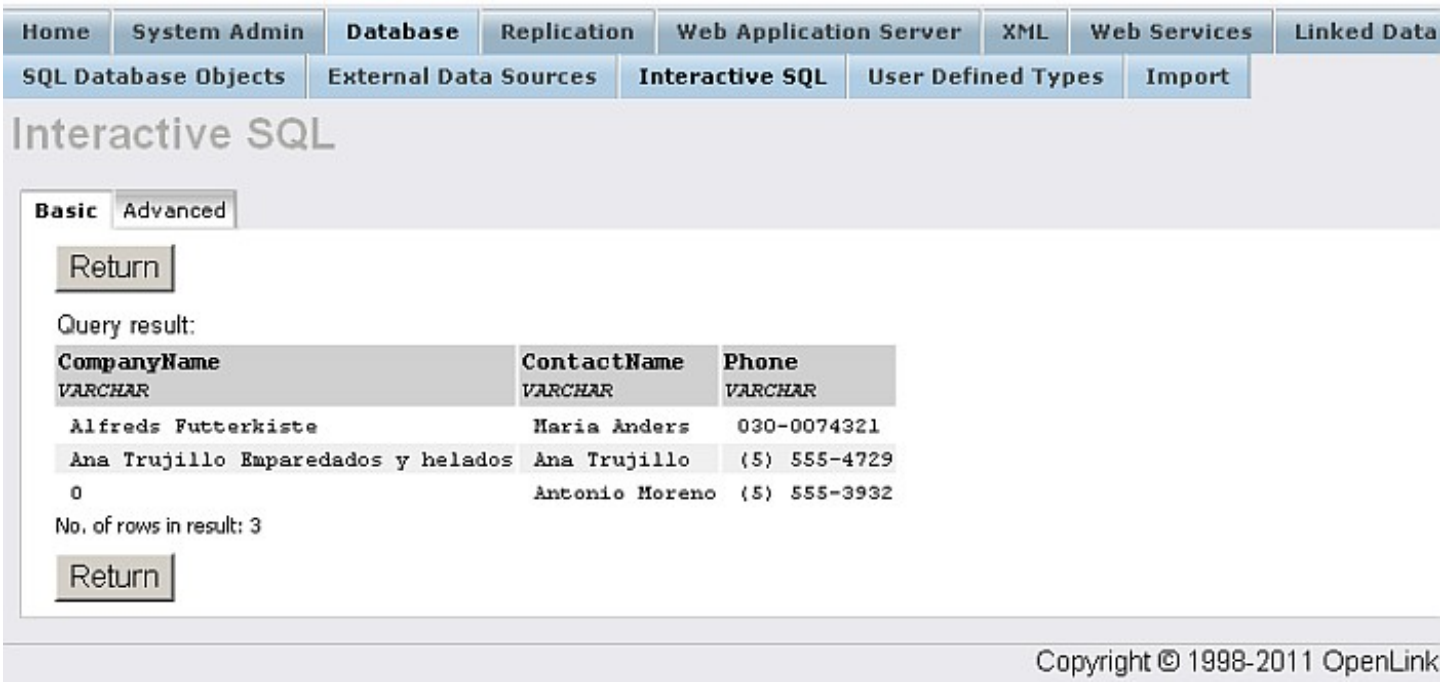
6.2.7. Query Tools

Relational Data using SQL

Conductor Interactive SQL allows you to quickly and directly query Virtuoso using SQL. It offers *Save* and *Load* facilities which allow SQL queries to be saved as an XML template, and read back later. With a query in the SQL Statement box click on the *Execute* for the results which will in the "Base" tab with option to return back to the query area. The *Clear* clears the SQL Statement text box.

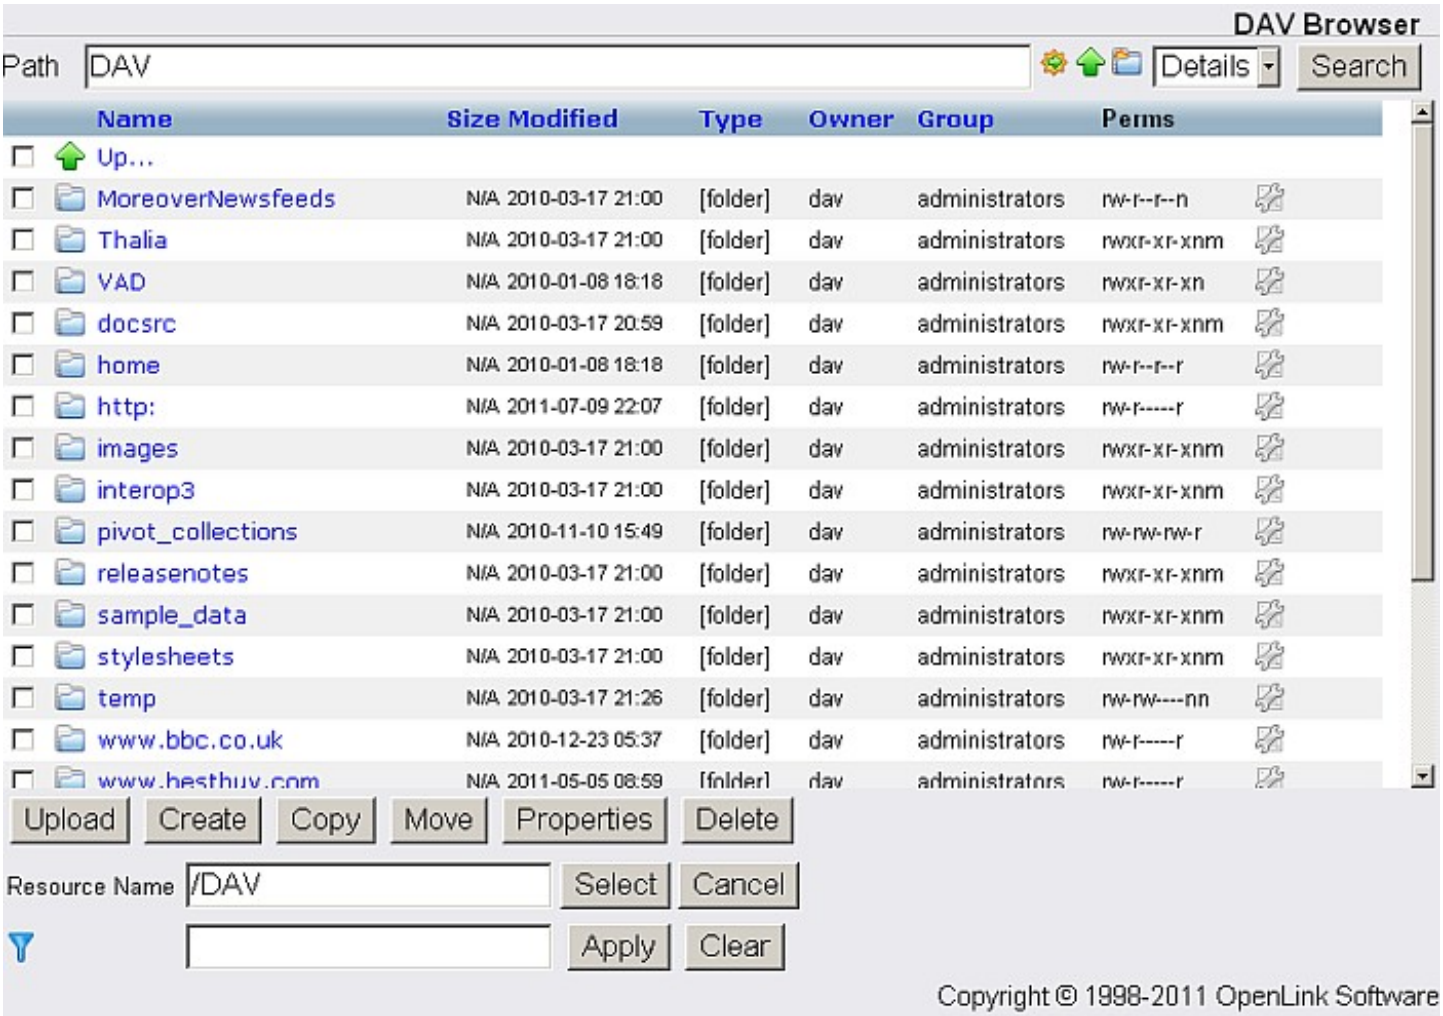
Figure 6.98. Querying Relational Database Using SQL

Figure 6.99. Results



Specify the location for the file to be saved to by selecting the "WebDAV source" or "Local file" check-box.

Figure 6.100. Saving SQL in an XML Template



Click the "Browse" button. As result will be opened the Virtuoso WebDAV/File Browser where you should define the XML template based on the SQL Query. Specify a *Root Element* that will contain the resulting XML tree. Specify the file name and location of the XML Template.

XML Data Using XQuery

The Conductor Interactive XQuery facility allows you to create, execute, save and reload queries using the evolving W3C XML Query (XQuery) Language . Virtuoso currently supports the 1.0 version of this language.

This language uses XPath-like expressions, as well as a set of functions and operators, to permit effective parallel searching of a set of XML documents. Where XPath works with one XML "tree", XQuery searches a "forest". The result is an XML document.

In order to create an XQuery you must both create the query statement - by typing or pasting it into the text box - and specify the document context. Since Virtuoso's XQuery implementation operates over XML data in relational tables, this means the tables and columns that are to be searched.

Note that the XQuery language also allows a query to specify all or part of the document context for the query. In the example below we will see how these can interact. The user interface form permits you to select a table - either one of the XQuery test data tables that come with Virtuoso, or the WS.WS.SYS_DAV_RES table, which stores Virtuoso's WebDAV Repository content.

The form specifies a *`Key Column`* and a *`Data Column`* . For the sample tables, the values for these are filled in for you. The *`Path`* is prepended to any `document()` function specified in the query text to find Key column values of XML trees against which the query is to be run.

Once a query has been written and debugged, it can be saved by pressing the Save button. This brings you to the form for saving a query as an XML Template in the DAV repository.

Pressing the Execute button causes the query result (an XML tree) to be shown on the page below the Statement type-in box.

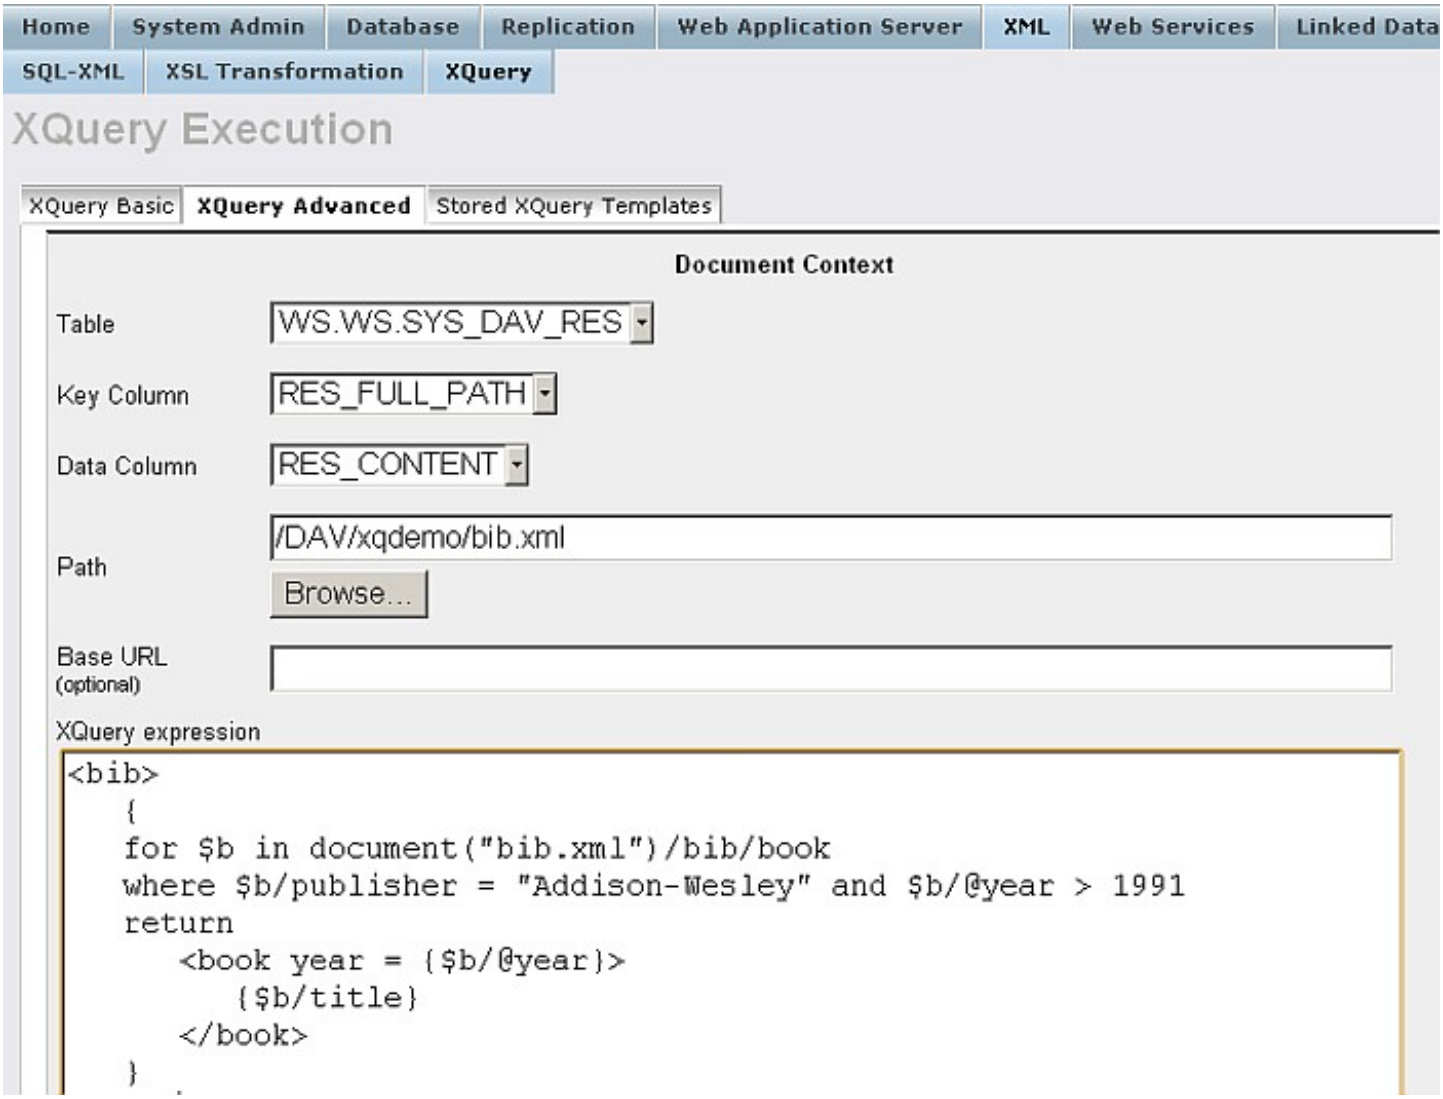
Example 6.16. XQuery Test File Example

In this example, we will query the table XQuery test files table, with "name" as the key column and "text" as the data column.

The query text, shown below, is a sample query from the W3C's XML Query Use Cases document (http://www.w3.org/TR/xmlquery-use-cases). This query contains a document() call specifying a document named "bib.xml". In order to have the query run properly, we first set the Path form value to "xqdemo/". This causes the query to find all rows in the table XQ.XQ.TEST_FILES that have the value "xqdemo/bib.xml" in their Name column.

```
<bib>
   {
   for $b in document("bib.xml")/bib/book
   where $b/publisher = "Addison-Wesley" and $b/@year > 1991
   return
      <book year = {$b/@year}>
         {$b/title}
      </book>
   }
</bib>
```

Figure 6.101. XQuery Test File Results



6.2.8. Replication & Synchronization

Snapshot Replication

Conductor "Replication" offers manage Virtuoso Replication. You are offered with "Basic", "Incremental", "Bidirectional Snapshot" and "Transactional" sub-tabs.

- From

  Replication/Basic/Query(Table select)to local

  to replicate local table(s) to another data source click

  Create New Snapshot

  and follow the wizard.
- To copy the changes from the local table to the remote select some replications and press

  Synchronize
- To drop the replication definition without dropping the destination table select some replications and press

  Remove
- To drop the replication definition and the destination table select some replications and press

  Remove & Drop Remote
- To copy the changes from the local table to the remote automatically select some replications, enter minutes in

Scheduled Interval

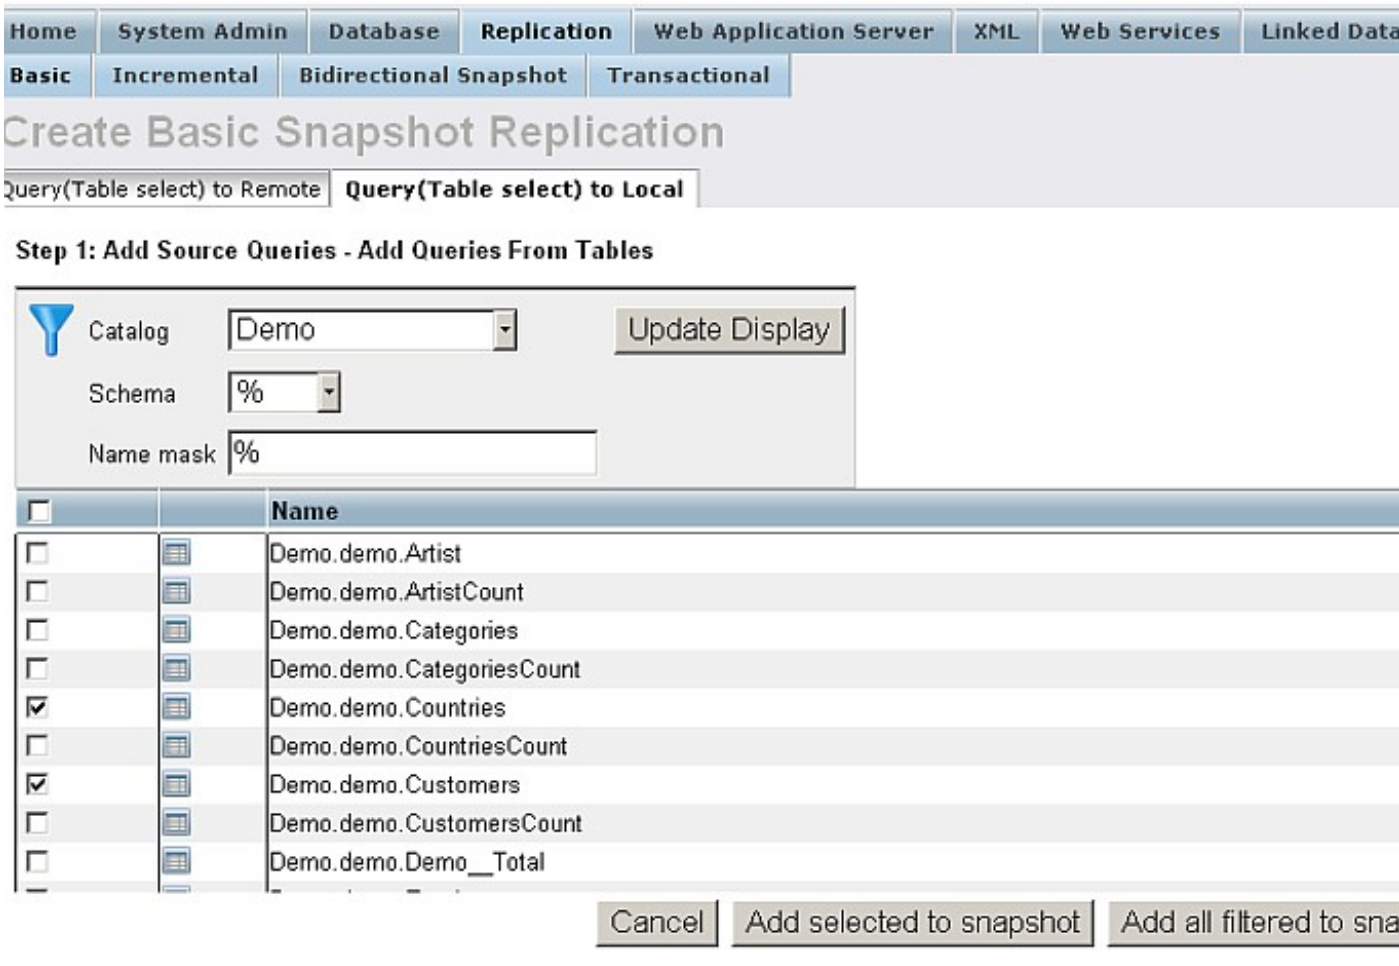
and press

Schedule

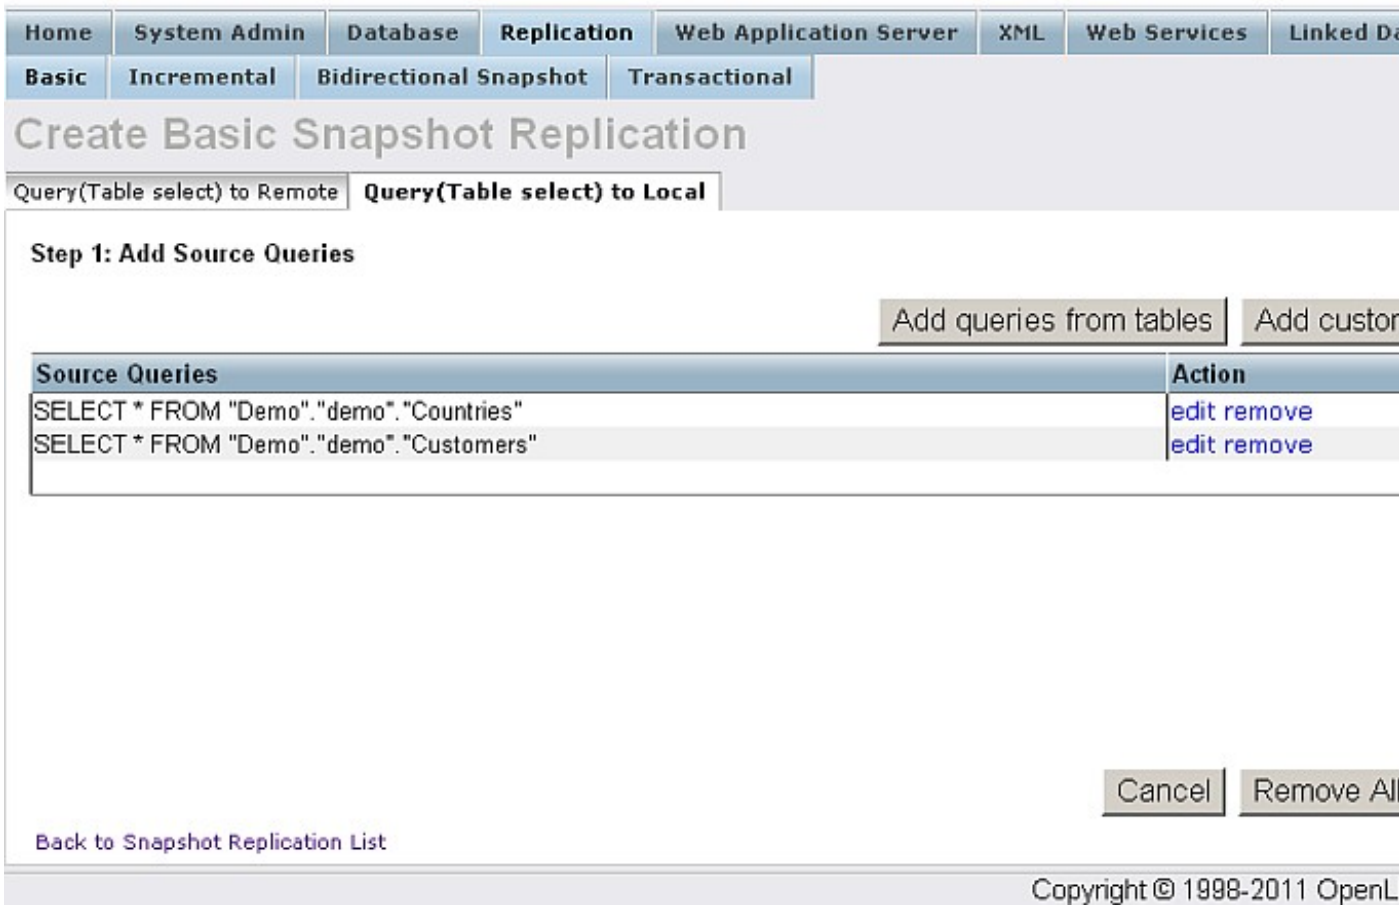
- To remove scheduled update select the replications enter 0 in "Scheduled Interval" and press Schedule

- **Figure 6.102. Snapshot Replication**

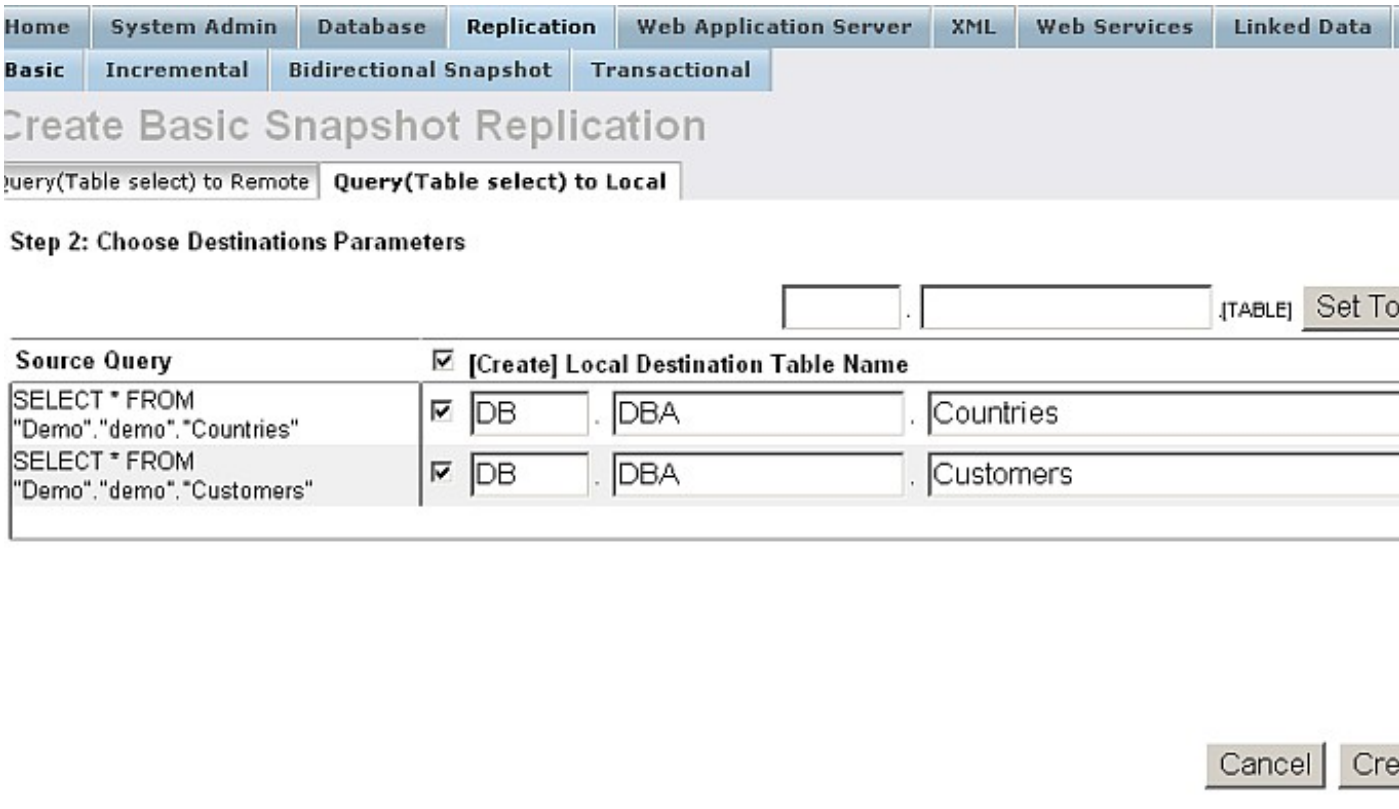
- **Figure 6.103. Snapshot Replication**



- **Figure 6.104. Snapshot Replication**

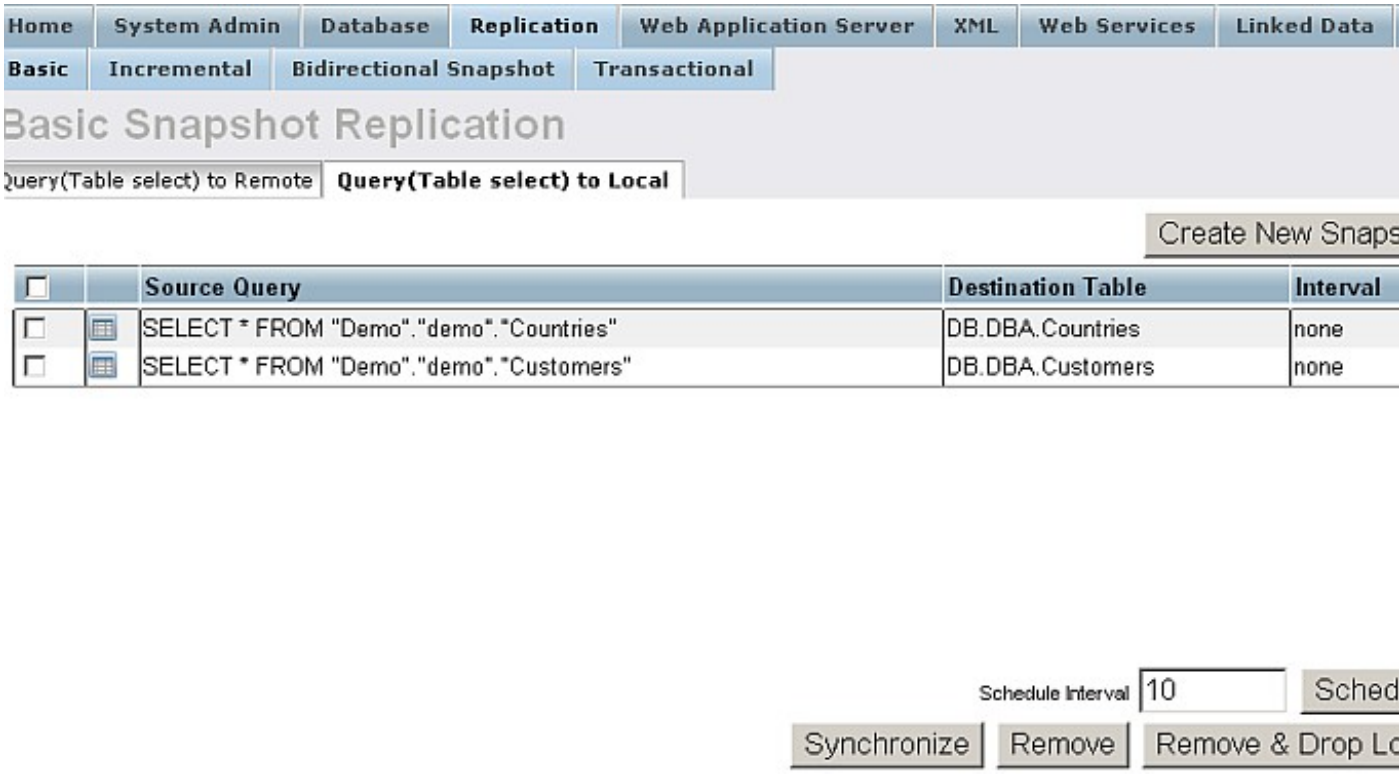


♦ **Figure 6.105. Snapshot Replication**



♦ **Figure 6.106. Snapshot Replication**

♦ **Figure 6.107. Snapshot Replication**



Transactional Replication

Publications

The Transaction Publication screen lists publications. You can add, edit or remove publications as necessary, each time using the guide-lines of the wizard.

Figure 6.108. Transaction Replication - Publications

Add a new publication by clicking on the *Create* button.

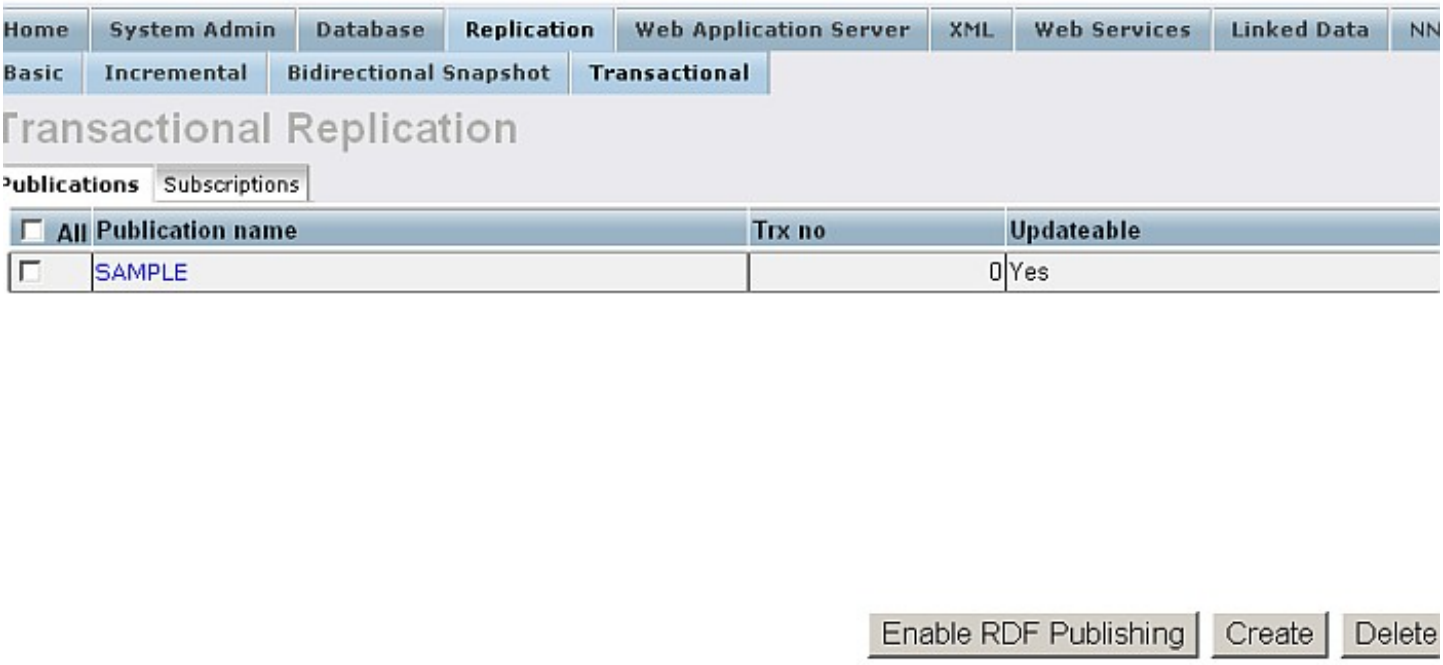
Edit an existing publication by clicking on publication name.

Remove publications by selecting their checkbox and clicking on the *Delete* button. Use caution, as this action cannot be reverted.

When creating a new publication you must supply a name. At this point you have the option to create an updateable publication - see the Bi-Directional Transactional Replication section for more details - which allows updates to come from subscribers rather than being limited to originating from the publisher only.

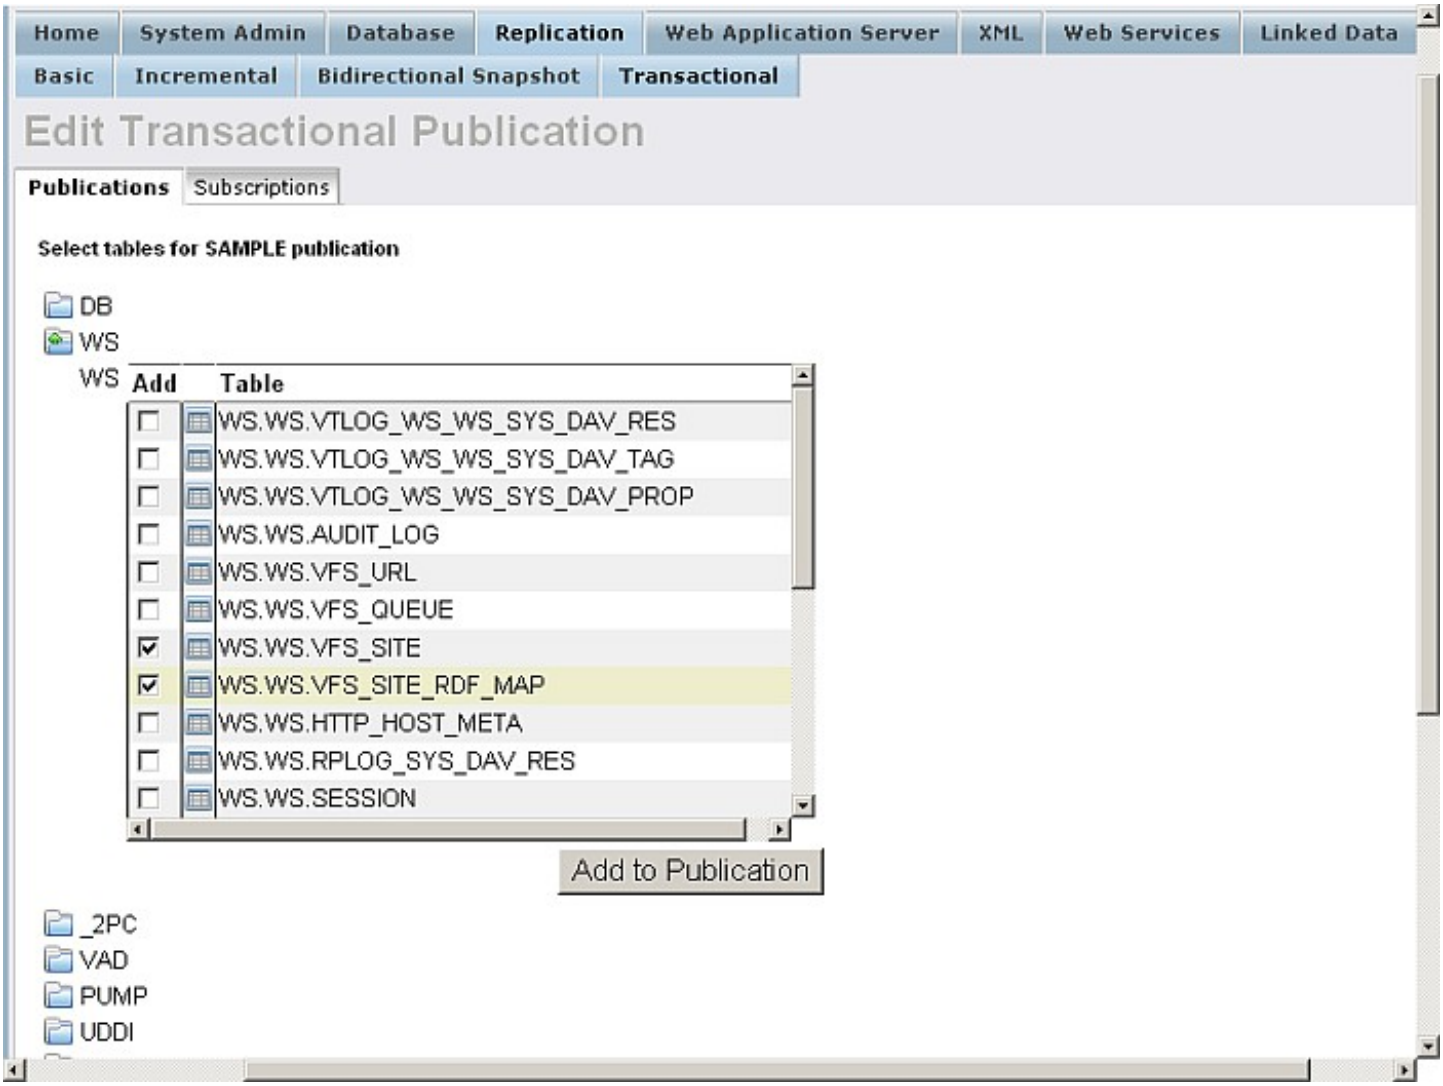
Figure 6.109. Transaction Replication - New Publication

Figure 6.110. Transaction Replication - List of Publications



Once a new publication has been made you can add database objects to it using the *Add ...* buttons, or remove them by selecting their checkbox and using the *Remove* button. To add a new table to the publication click on *Add Table/Procedure* . Follow the wizard by choosing the appropriate database/catalog by clicking on its name, you will then be presented with the tables within it.

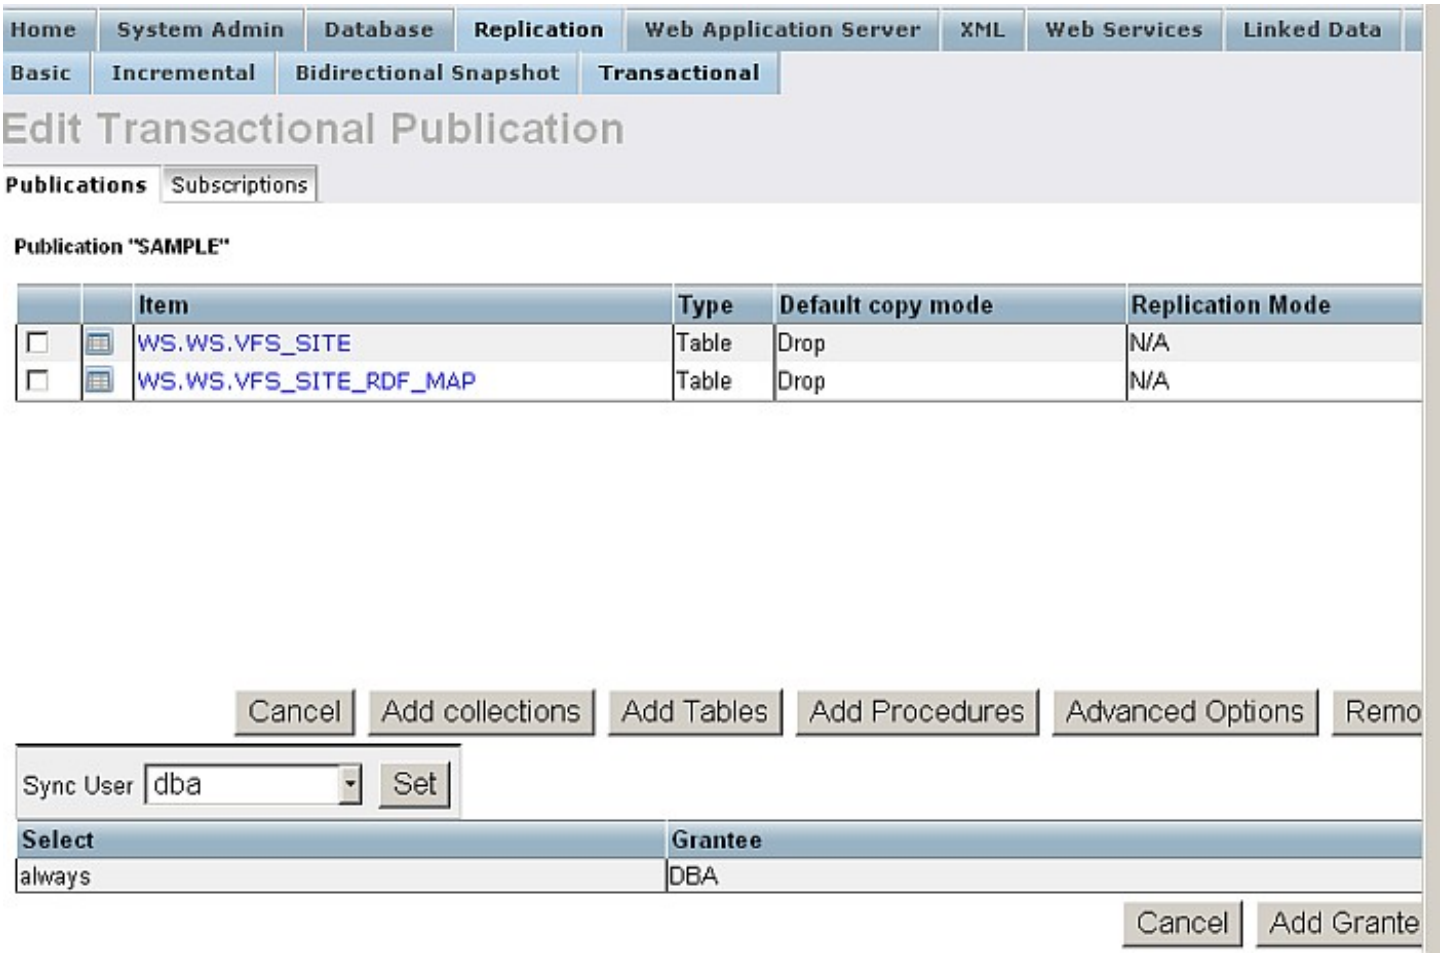
Figure 6.111. Transaction Replication - Publish Tables and Procedures



Select the tables to publish using the checkboxes and press *Add to Publication* to add the tables and continue.

Once returned the publication screen, the published tables will be listed. Updatable publication will need conflict resolvers in case of conflicting data arriving from a subscriber. Click on the table name to manage the resolvers list.

Figure 6.112. Transaction Replication - Published Items



Use the *Add /Remove* to add or remove selected resolvers.

Click on Publication Item -> *New Resolver* to add a new resolver. You have the following details to contend with:

- *Name Suffix*

  Conflict resolver name suffix.
- *Order*

  Resolver order number.
- *Type*

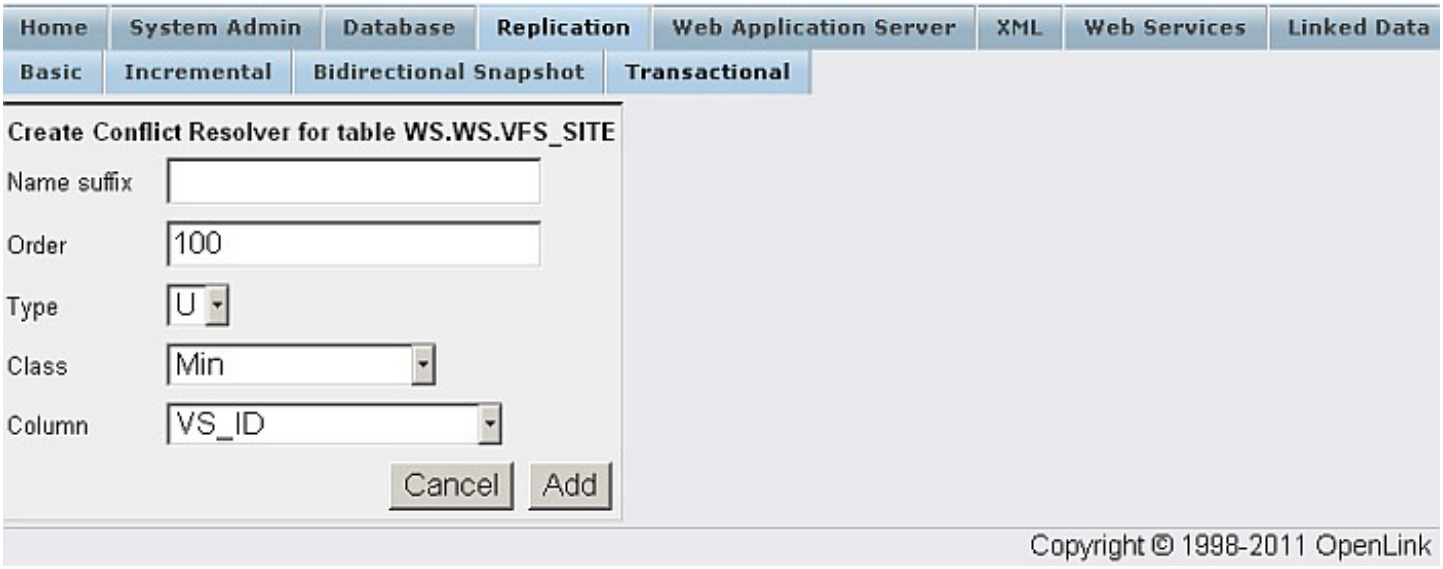
  The resolver type, one of: Insert, Update, or Delete for resolving such SQL queries.
- *Class*

  The kind of resolver. Class can be one of the following:

  'max' row with maximum value of specified column wins
  'min' row with minimum value of specified column wins
  'ave' new value of specified column is calculated as: `current_val = (current_val + new_val) / 2`
  'add' new value of specified column is calculated as: `current_val = current_val + (new_val - old_val)`
  'pub_wins'
  'custom' publisher always wins
  'sub_wins' subscriber always wins
- *Column*

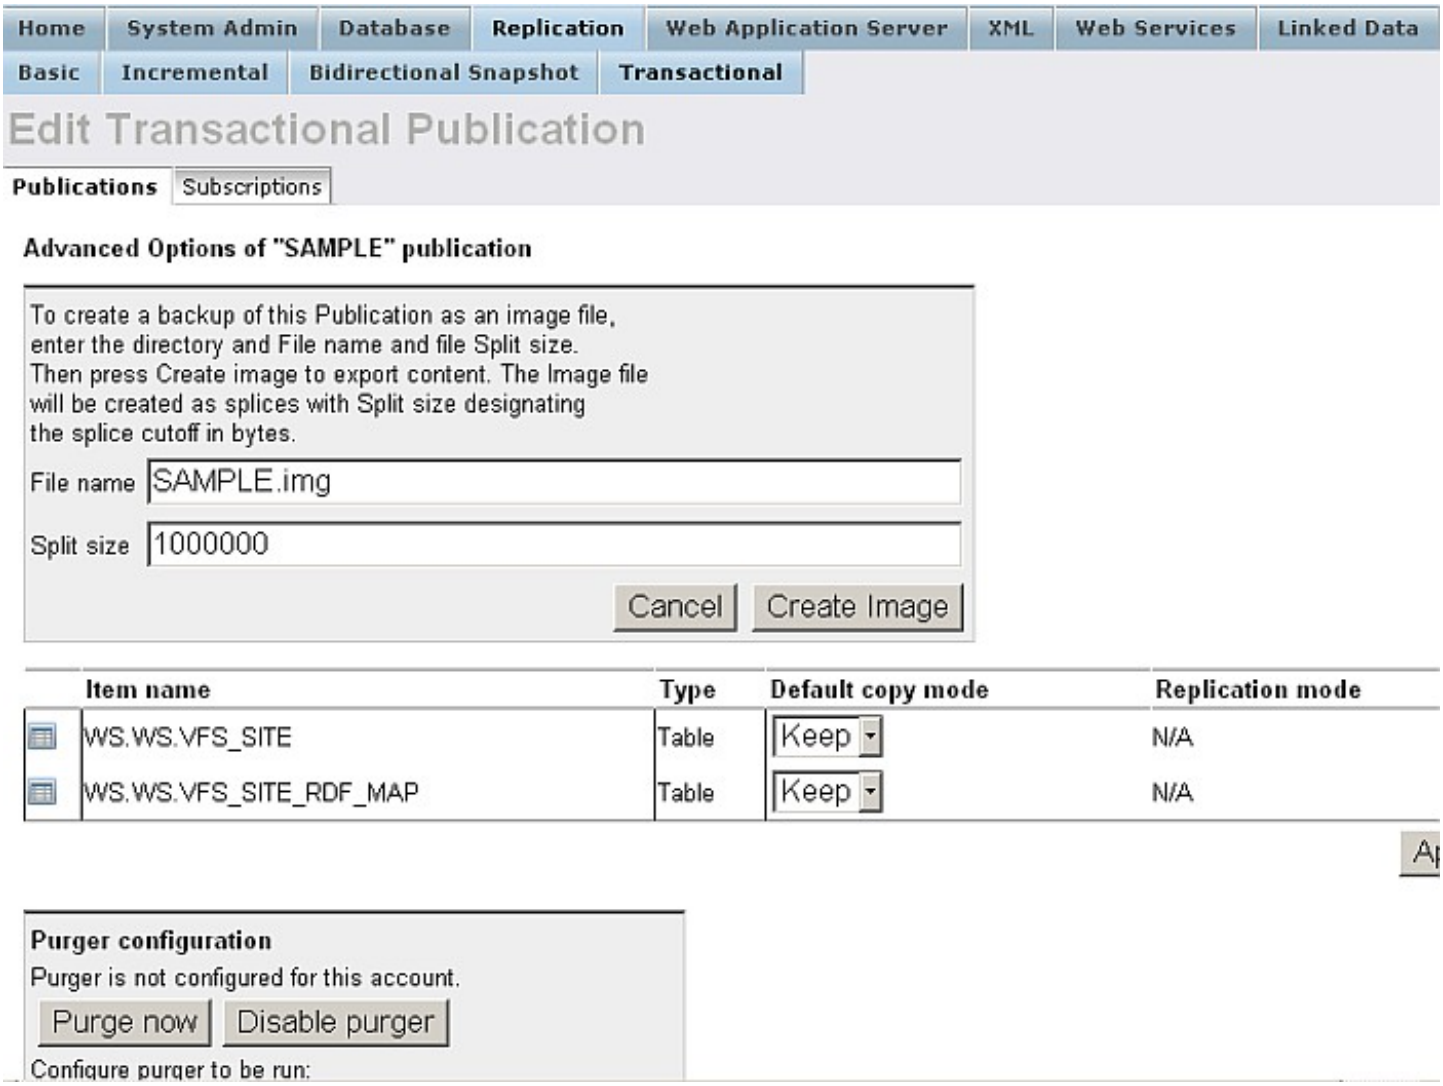
  This should specify the column name if `class` is not one of 'pub_wins', 'sub_wins' or 'custom'.

Figure 6.113. Transaction Replication - Resolvers



Click on Publication -> *Advanced Options* to set additional settings such as split size, default copy mode of publication item, etc.

Figure 6.114. Transaction Replication - Advanced

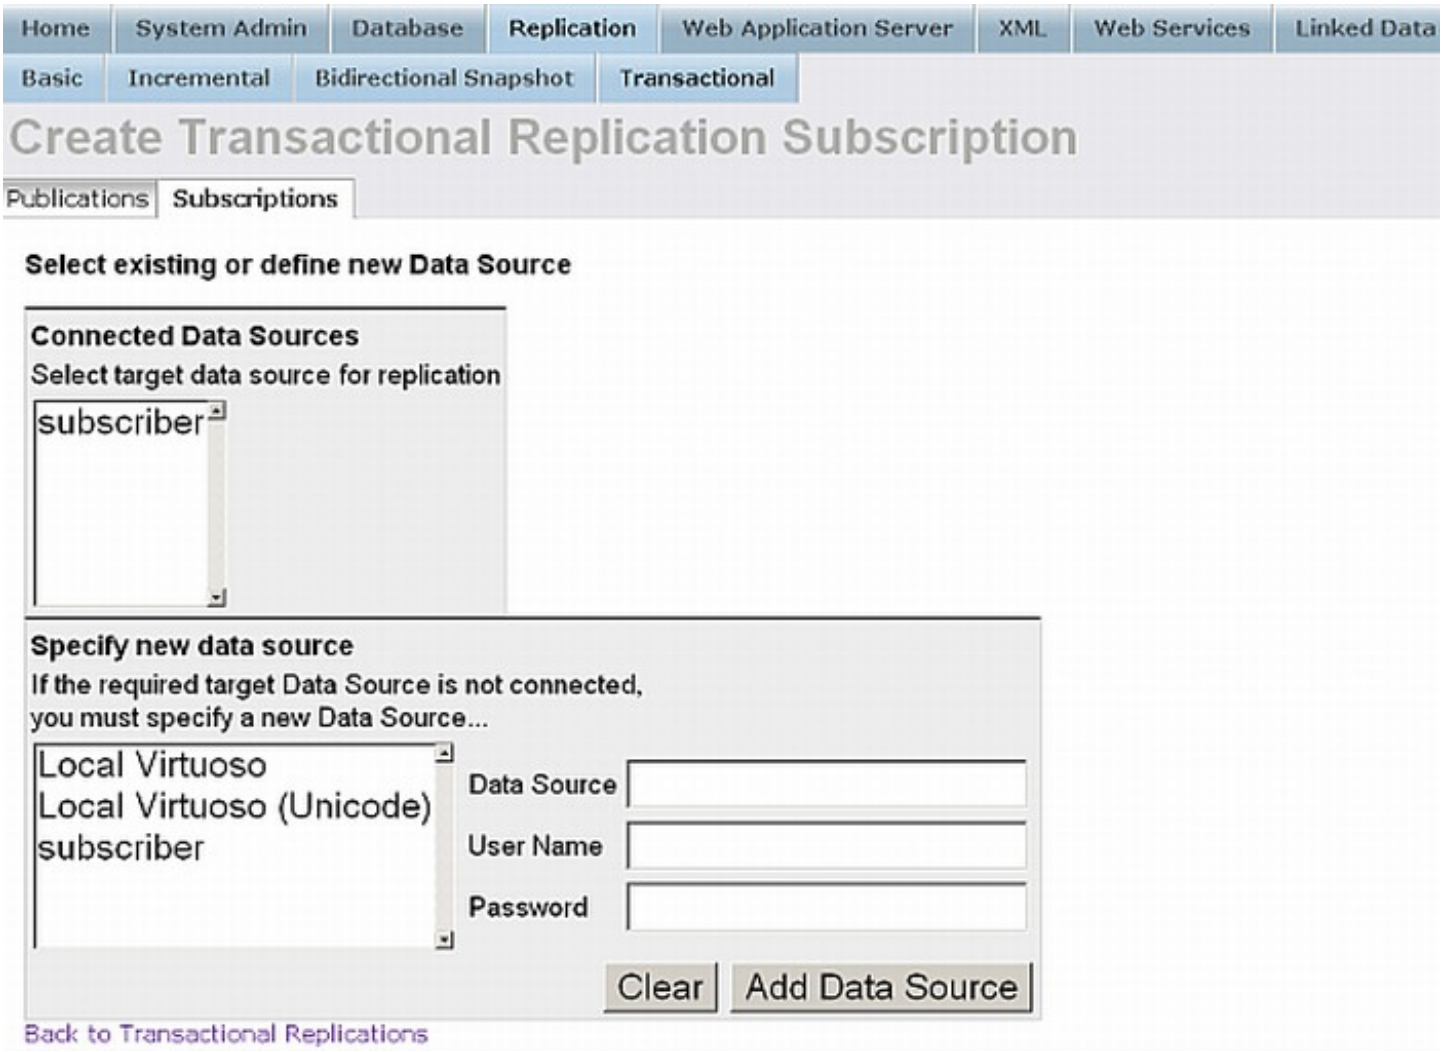


Subscriptions

- To add new subscription click at New Subscription and follow the wizard.
- Click Edit to change properties.
- To drop subscription click at link Drop.
- To synchronize subscription click the Sync button.
- To disconnect all subscriptions click at Disconnect all button.
- To load image file click at Load image button and follow the wizard.

Figure 6.115. Transaction Replication - Subscription

Figure 6.116. Transaction Replication - Subscription



6.2.9. Database Administration

Users & Group Accounts

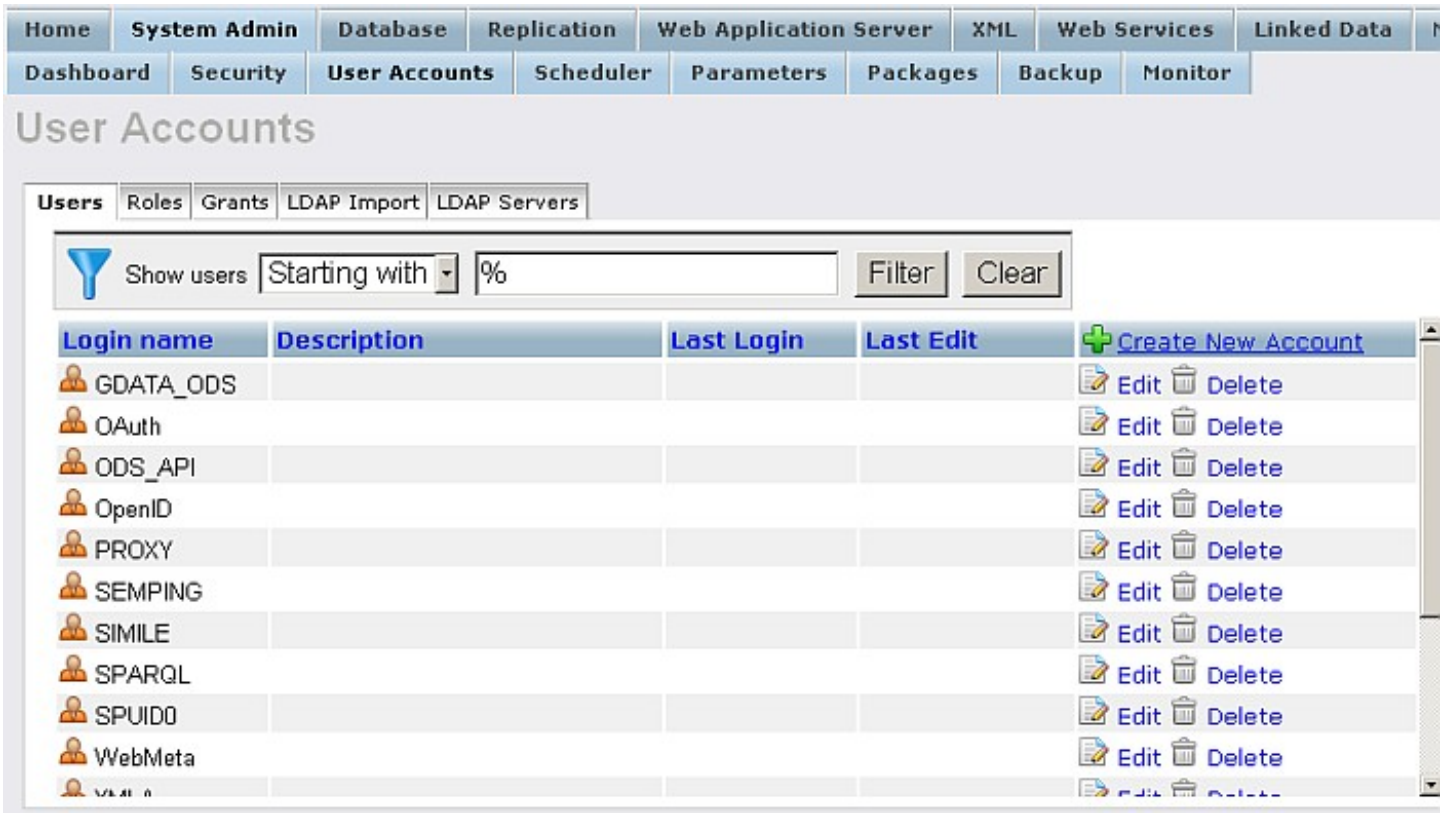
From System Admin / user Accounts you can alter the users that can access the Virtuoso database. You may add a new user by clicking the "Create New Account" link, edit an existing user, or delete users. You can associate users with groups or make new groups.

Groups are created and function like normal user accounts. To define a group you simply create a new user, and then to make use of the group you assign users to that group from the drop down which will contain available groups.

To create a new user or group you must enter a username, password and confirm the password by retyping it in the fields provided. You may optionally specify a group and default qualifier. You can use groups to control access to a set of users by maintaining the permissions granted to the group for which they are members. Specifying a default qualifier allows you to specify the catalog or database for which queries will be run against that do not explicitly refer to a particular catalog or database.

You can import users by adding LDAP Servers(s) from the "LDAP Servers" tab, and then from the "LDAP Import" to specify from which LDAP server the import should be done:

Figure 6.117. Users Accounts

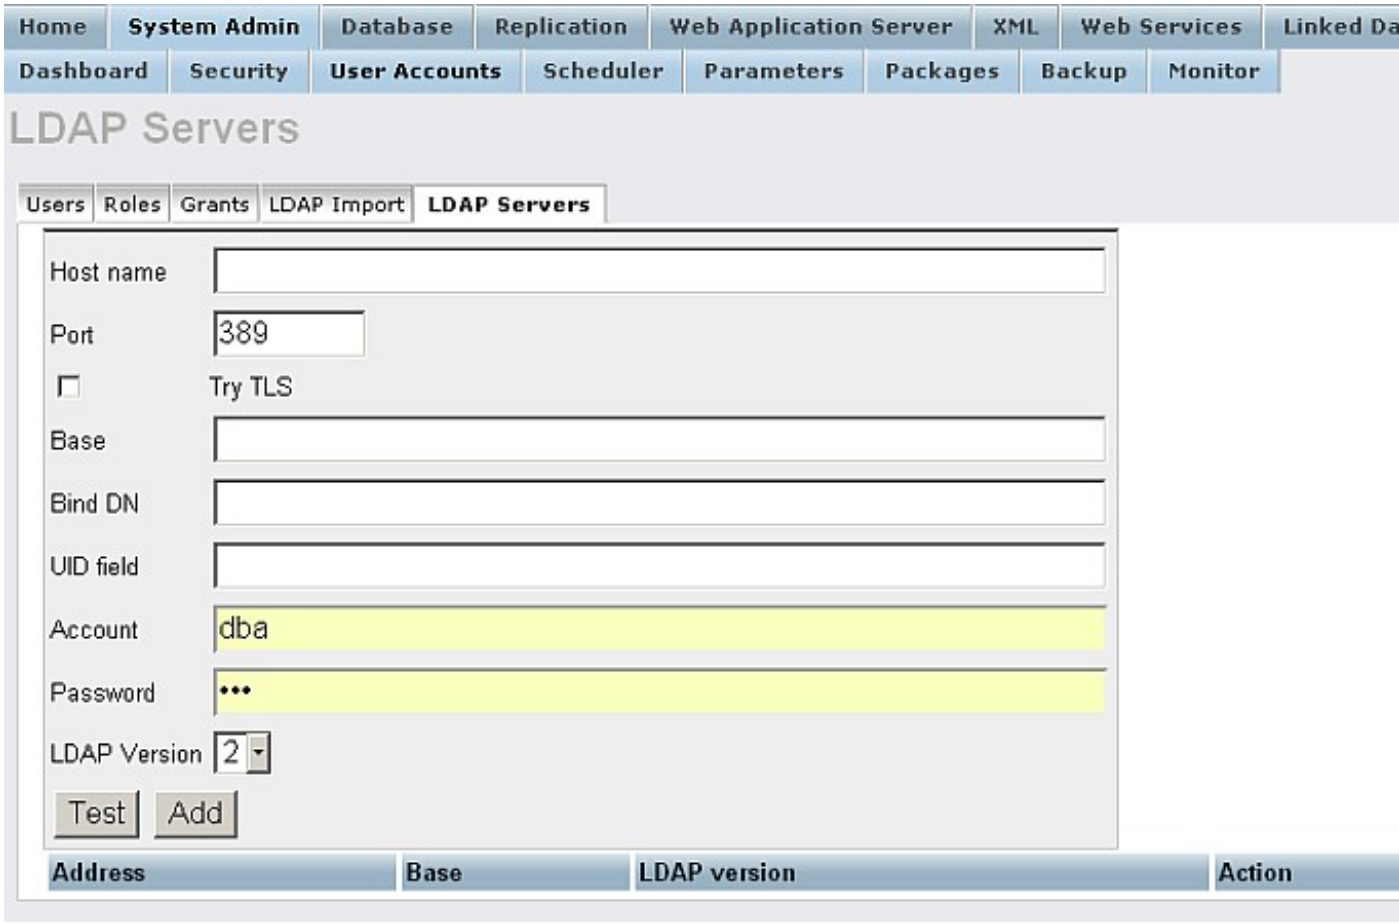


Configuring and import from LDAP server

The following steps describe how to configure LDAP server and then import user(s) using the Conducor UI:

1. Go to http://cname:port/conductor
2. Enter user dba credentials
3. Go to System Admin -> User Accounts -> LDAP Servers

Figure 6.118. LDAP Servers Configure and Import

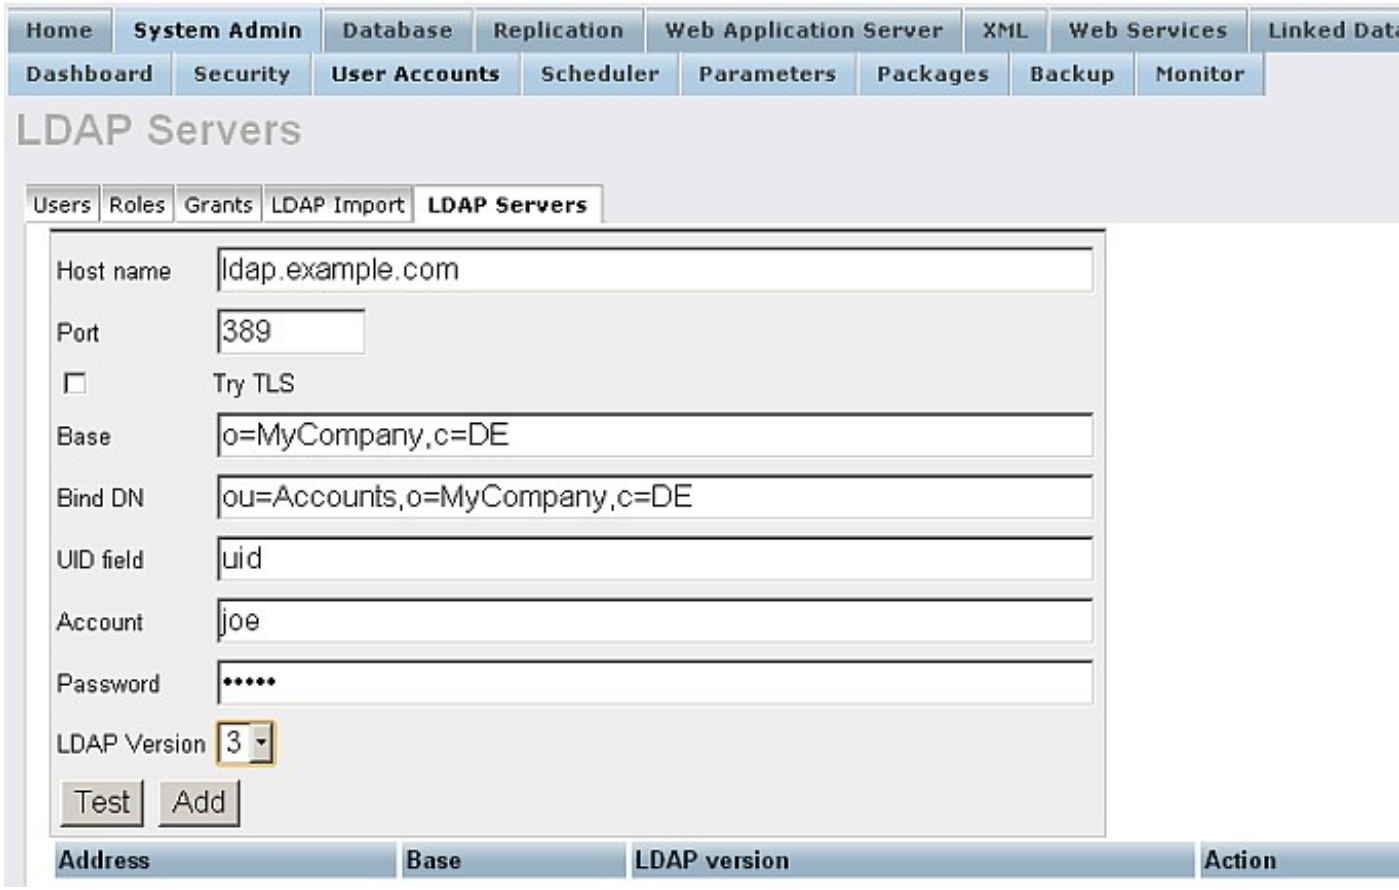


4. Enter in the LDAP servers form respectively:

    a. Host Name: for ex.: ldap.example.com

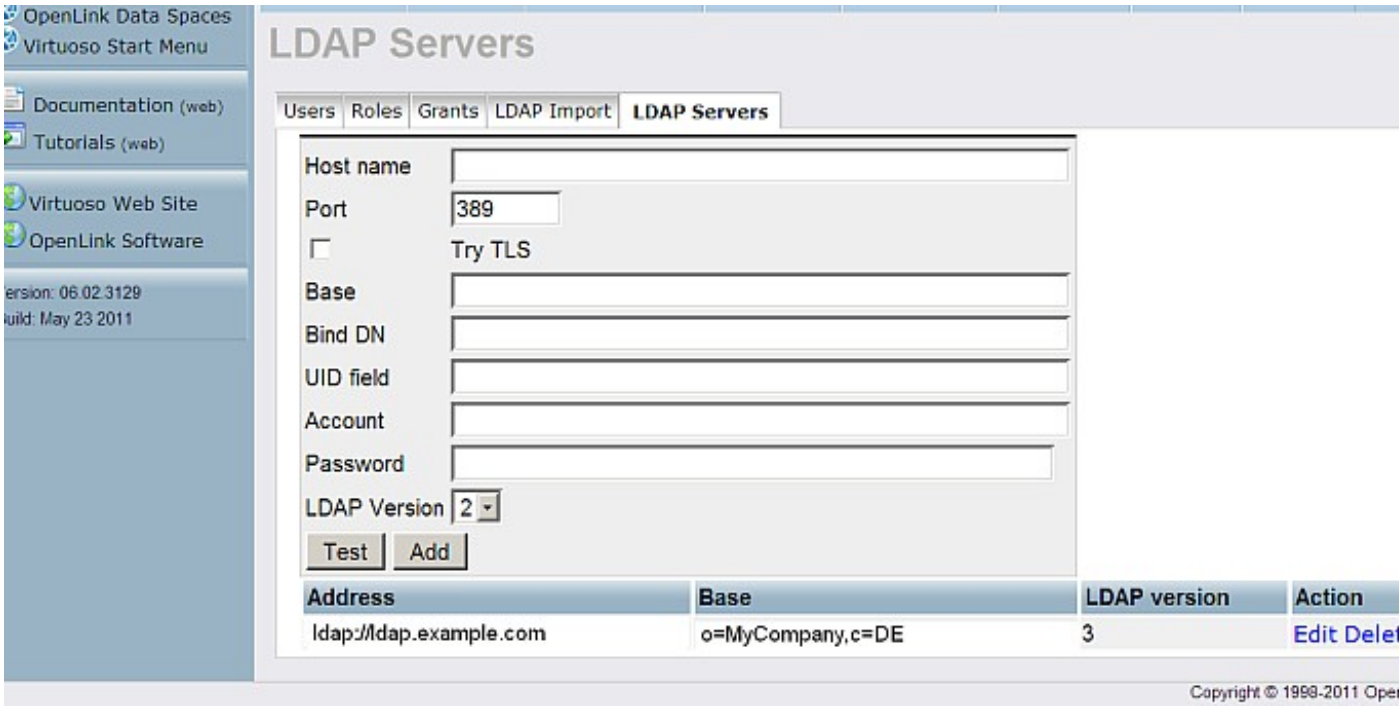
    Note: you can also use ldap:// or ldaps:// in front of Host name
    b. Base: for ex.: o=MyCompany,c=DE
    c. Base DN: for ex: ou=Accounts,o=MyCompany,c=DE
    d. UID field: uid
    e. Account: for ex: joe
    f. Password: *******
    g. LDAP version: choose for ex. 3
5. Check the connection by pressing "Test":

Figure 6.119. LDAP Servers Configure and Import



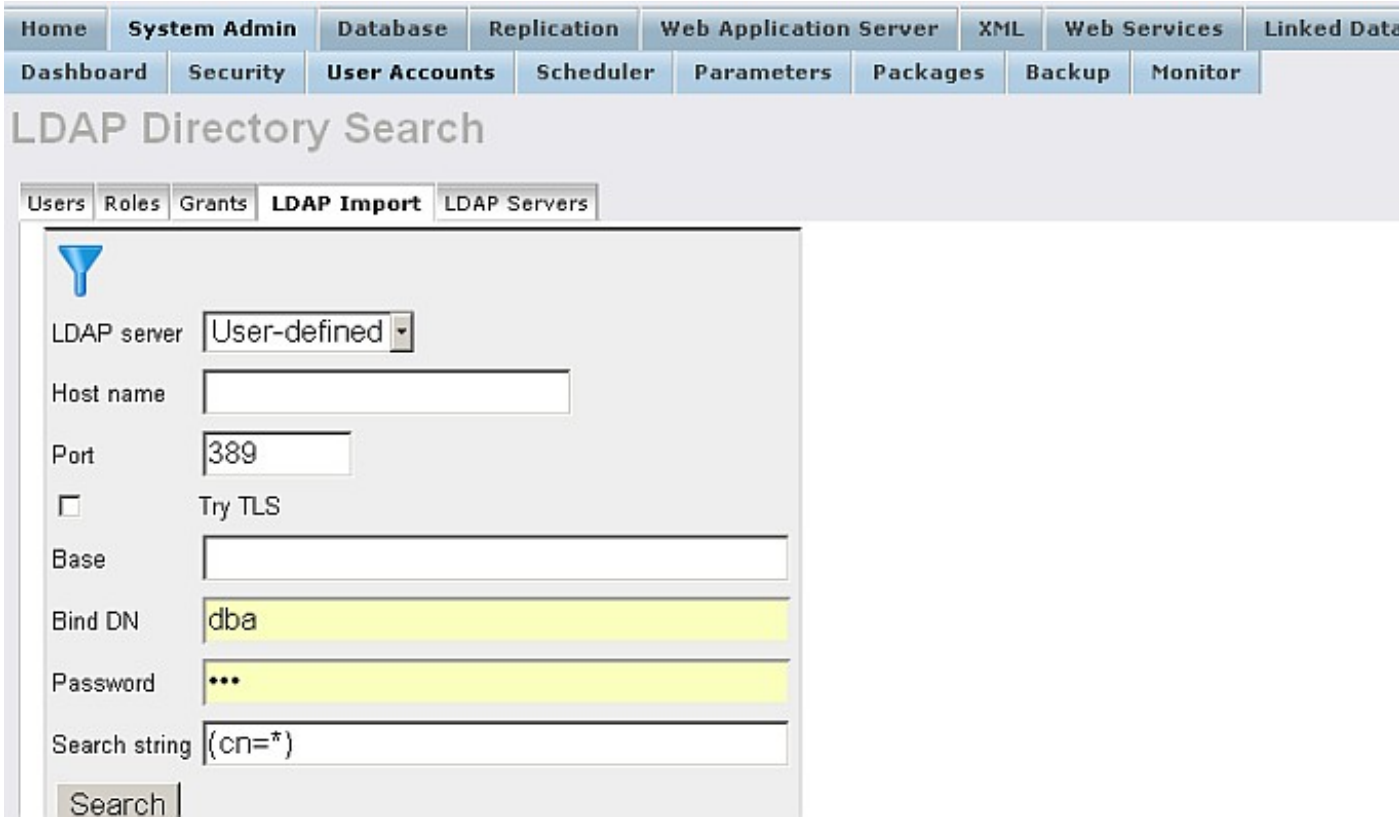
6. If the test connection is successful, click "Add".

Figure 6.120. LDAP Servers Configure and Import



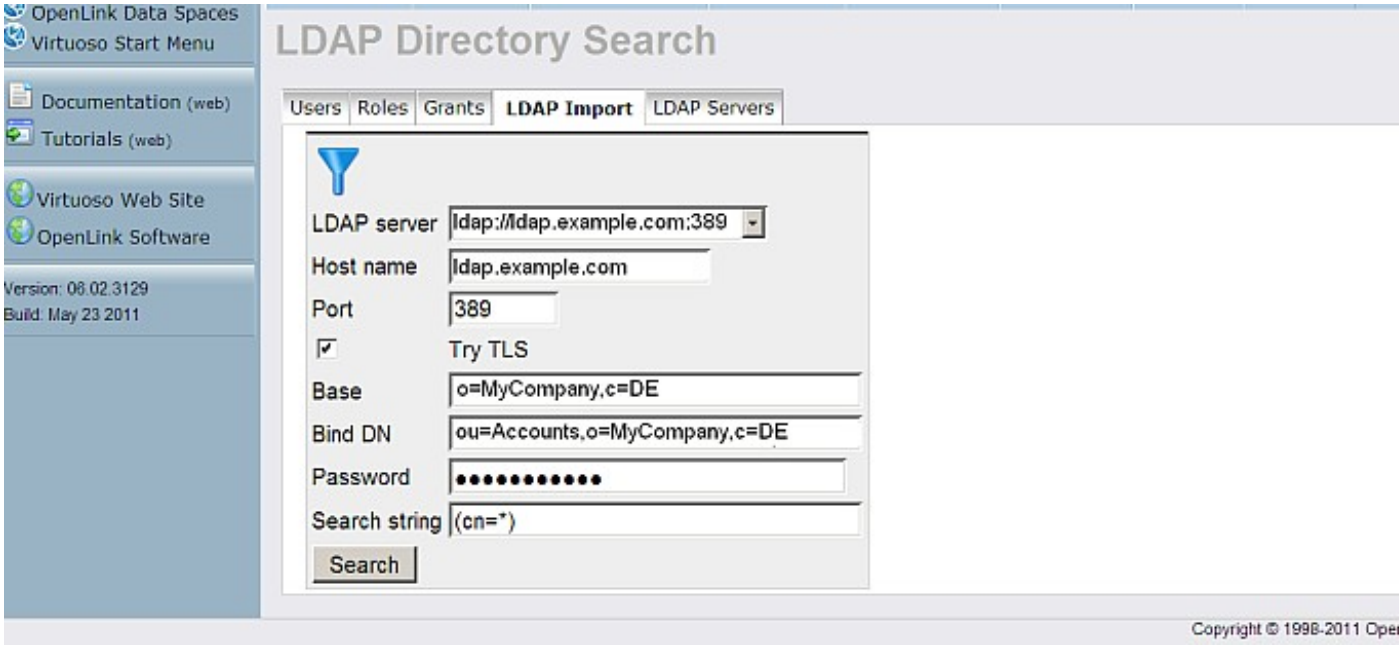
7. Next you can import various data from your LDAP server.
8. Go to System Admin -> User Accounts -> LDAP Import

Figure 6.121. LDAP Servers Configure and Import



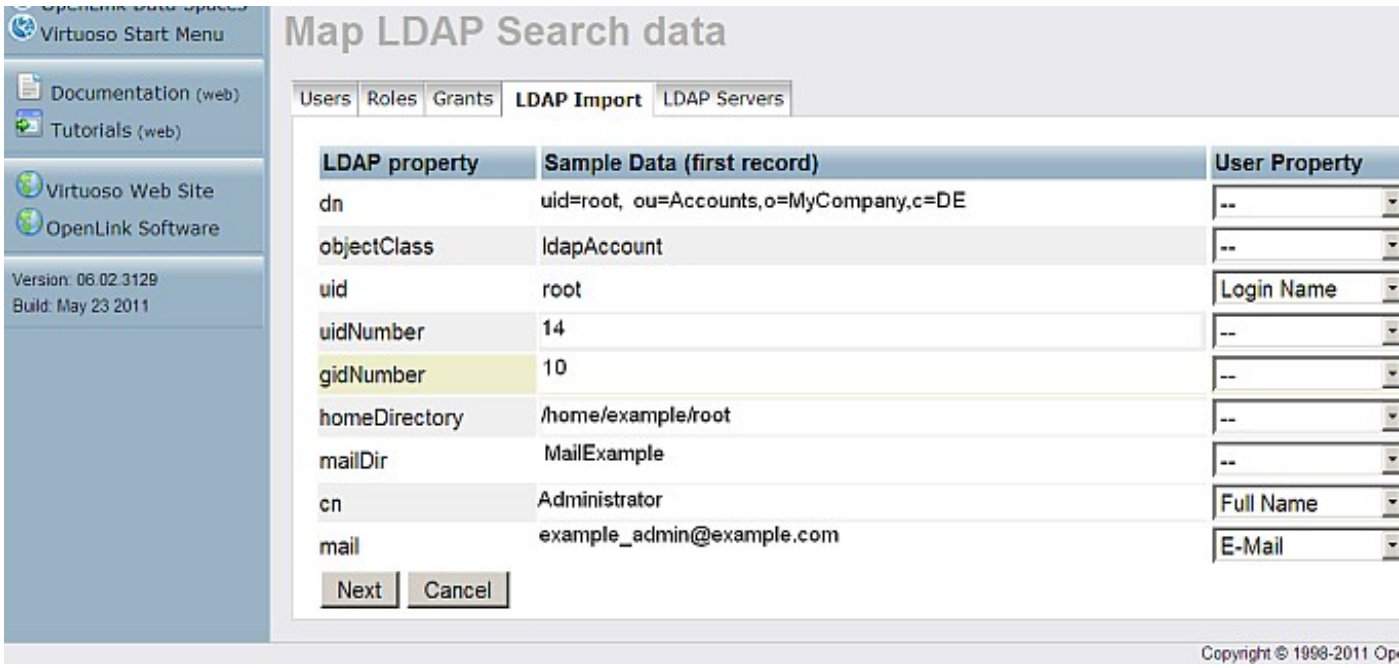
9. Select the LDAP server added from above:

Figure 6.122. LDAP Servers Configure and Import



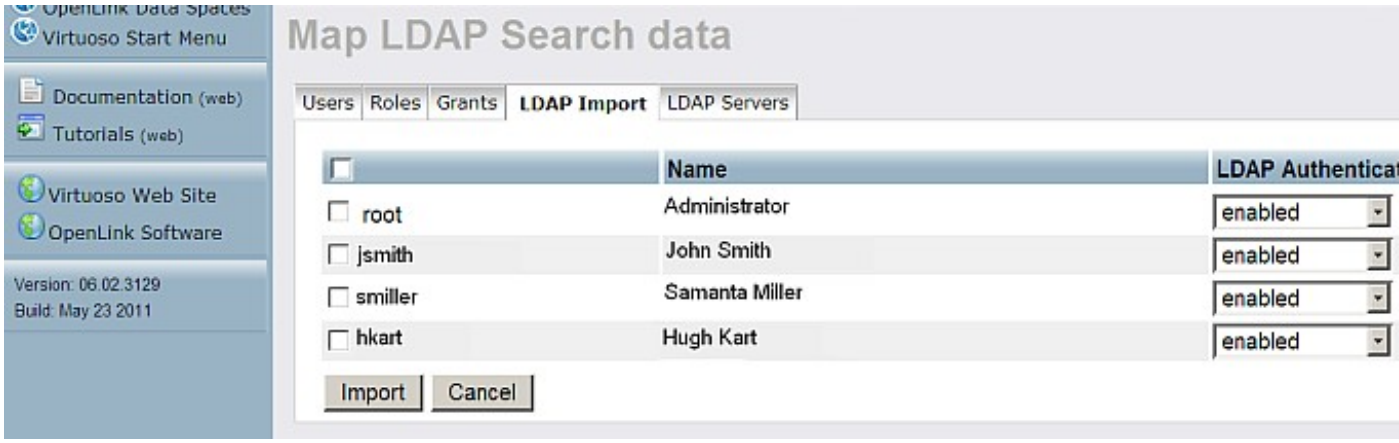
10. Click "Search".

Figure 6.123. LDAP Servers Configure and Import



11. Click "Next".

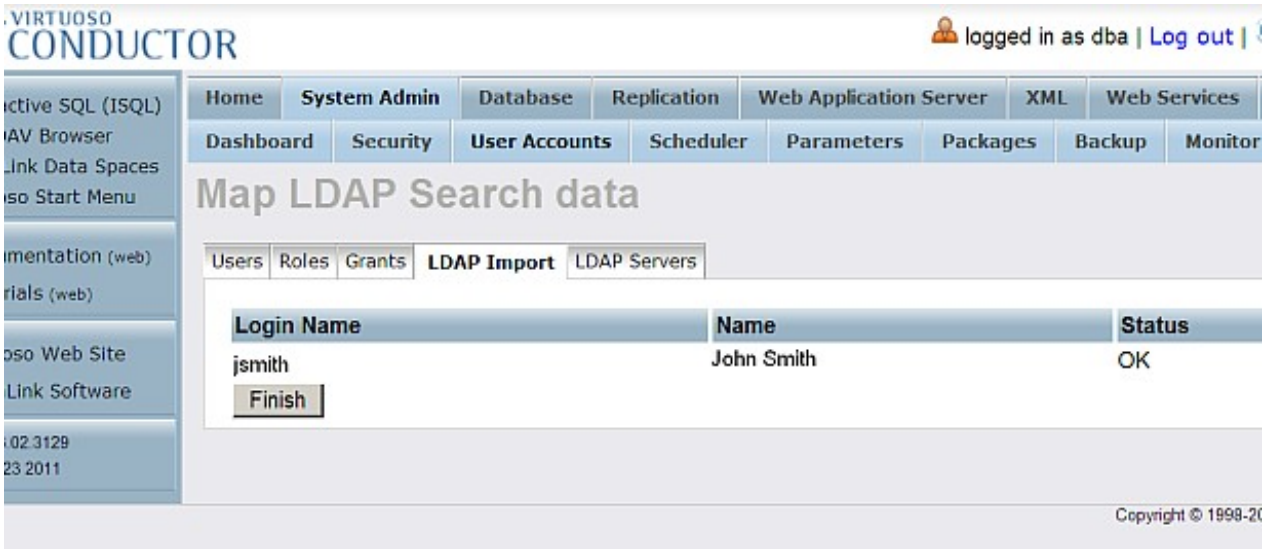
Figure 6.124. LDAP Servers Configure and Import



12. Select the desired profiles to be imported and set prefered "LDAP Authentication" for selected user:

    - If set to "enabled", then on an attempt to log in into Virtuoso, the system tries to log in into the LDAP server with the given username and password. If this succeeds, then the user logs in successfully in Virtuoso.
    - If set to "account check", then on an attempt to log in into Virtuoso, the system performs a check if there is such an user on the LDAP server. If yes, then the user logs in successfully in Virtuoso.

Figure 6.125. LDAP Servers Configure and Import



13. Click "Import".

    Note: By default an importing LDAP user has "User type" set to "WebDAV". To log in into iSQL with an imported LDAP user credentials you should:

    a. Make sure you have set in Virtuoso ini the SQL_ENCRYPTION_ON_PASSWORD parameter to 1 in the [Client] section, i.e.:

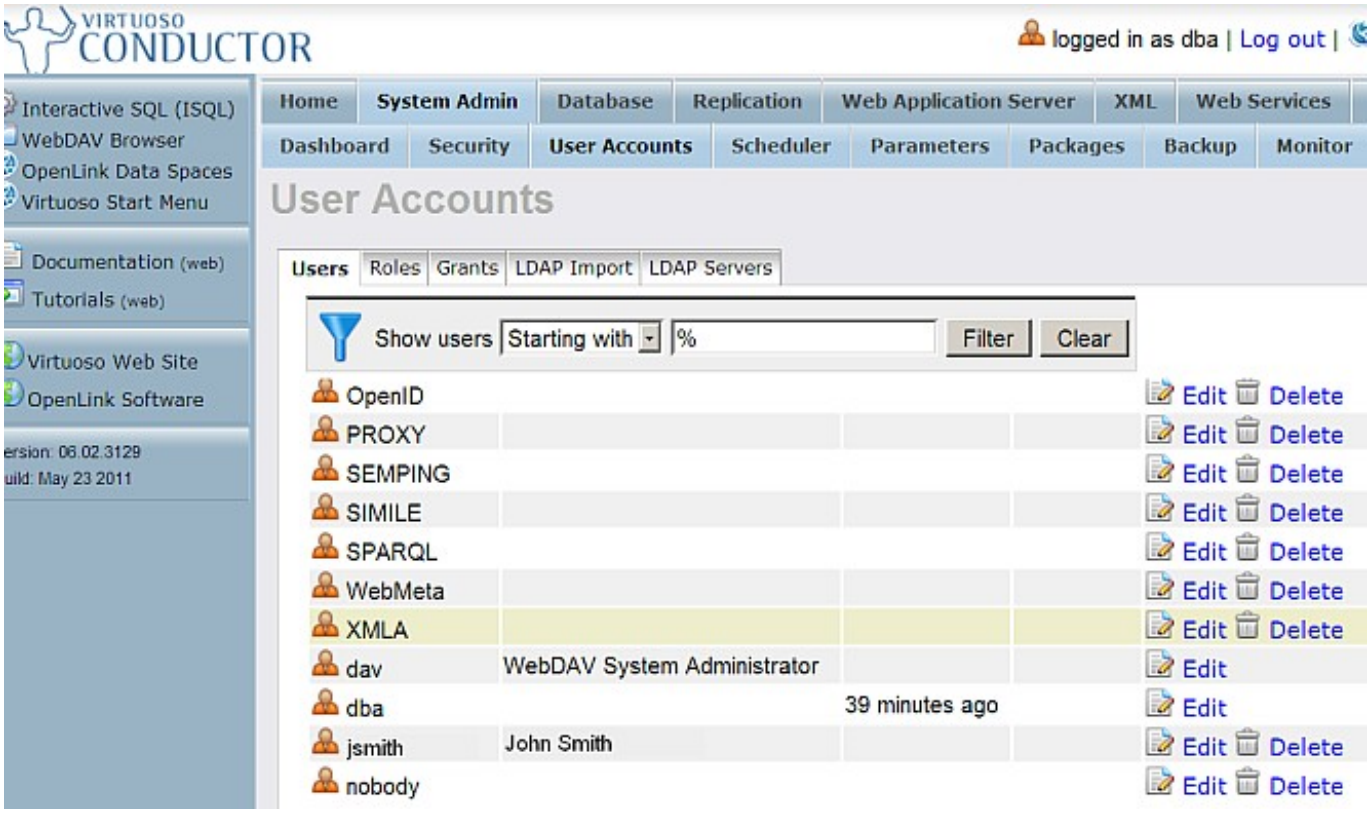
    ```
    ;virtuoso.ini
    ....
    [Client]
    SQL_ENCRYPTION_ON_PASSWORD  = 1
    ...
    ```

    b. Set the "User type" of the imported LDAP user to be "SQL/ODBC" by going to Virtuoso Conductor -> System Admin -> User Accounts -> user -> Edit -> field "User type".
    c. Log in into iSQL:

    ```
    isql host:port ldap-user-name ldap-user-password
    ```

14. Click "Finish".
15. The imported profile(s) should be displayed in the Users tab:

Figure 6.126. LDAP Servers Configure and Import



Databases

Each catalog (database) within Virtuoso will be listed under the Databases /Schema Objects. For each catalog you will be able to view and in some cases edit details about the tables, views, triggers, and store procedures stored within that catalog.

Figure 6.127. Viewing Tables details for the Demo catalogue in the Demo Database

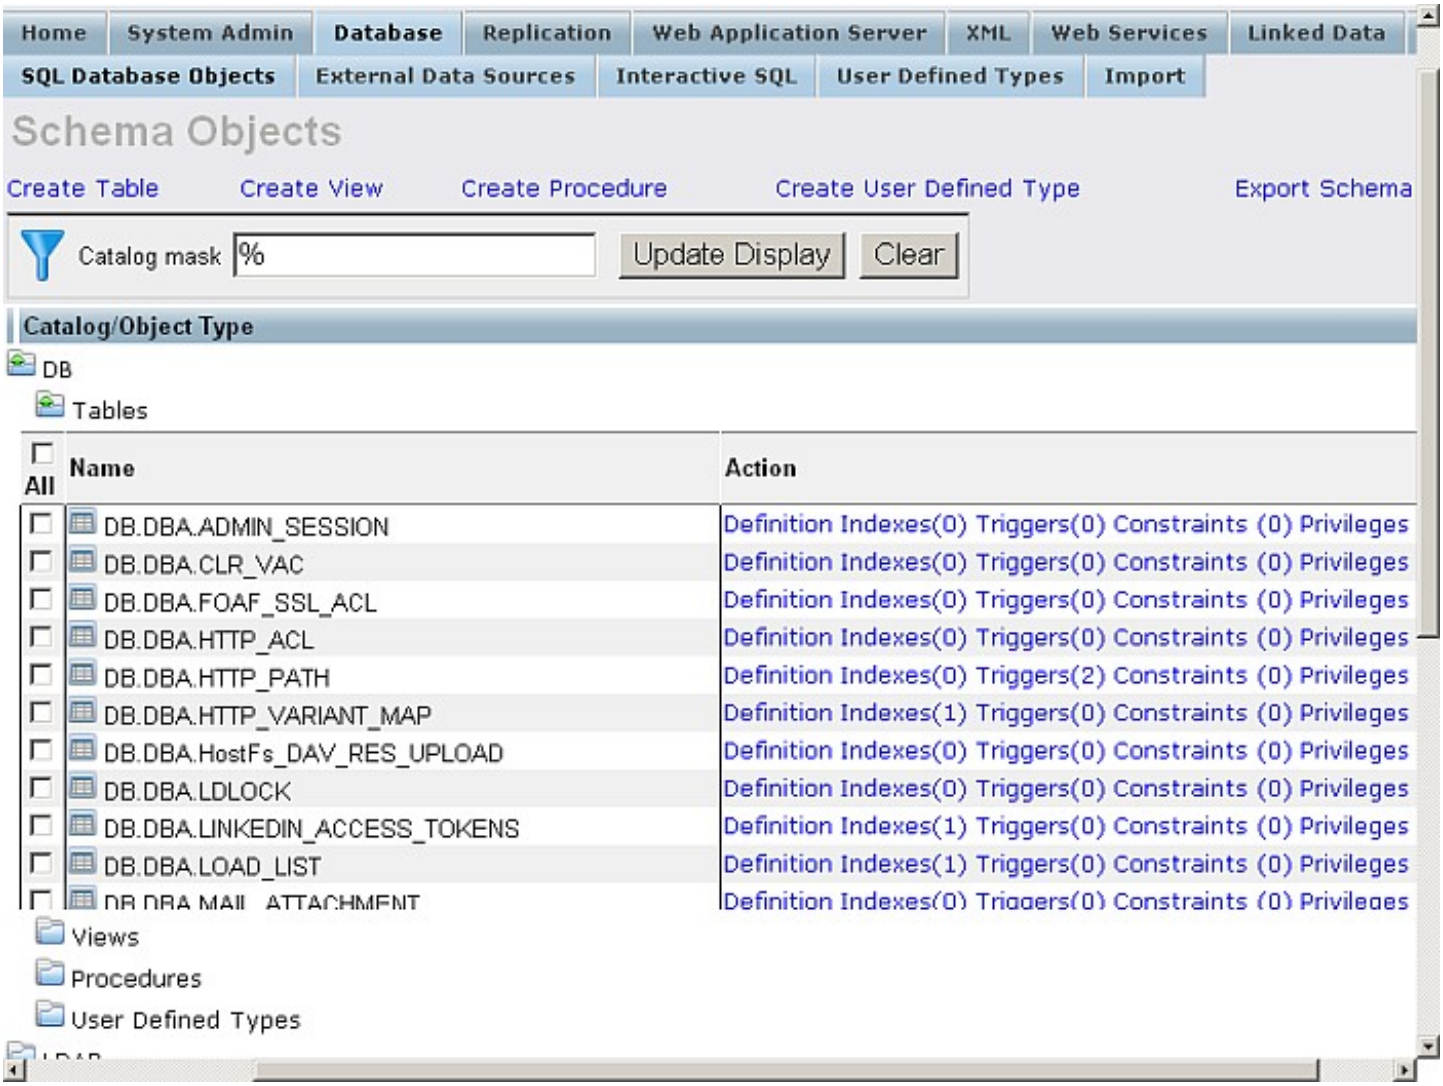


Figure 6.128. Viewing Views details for the Demo catalogue in the Demo Database

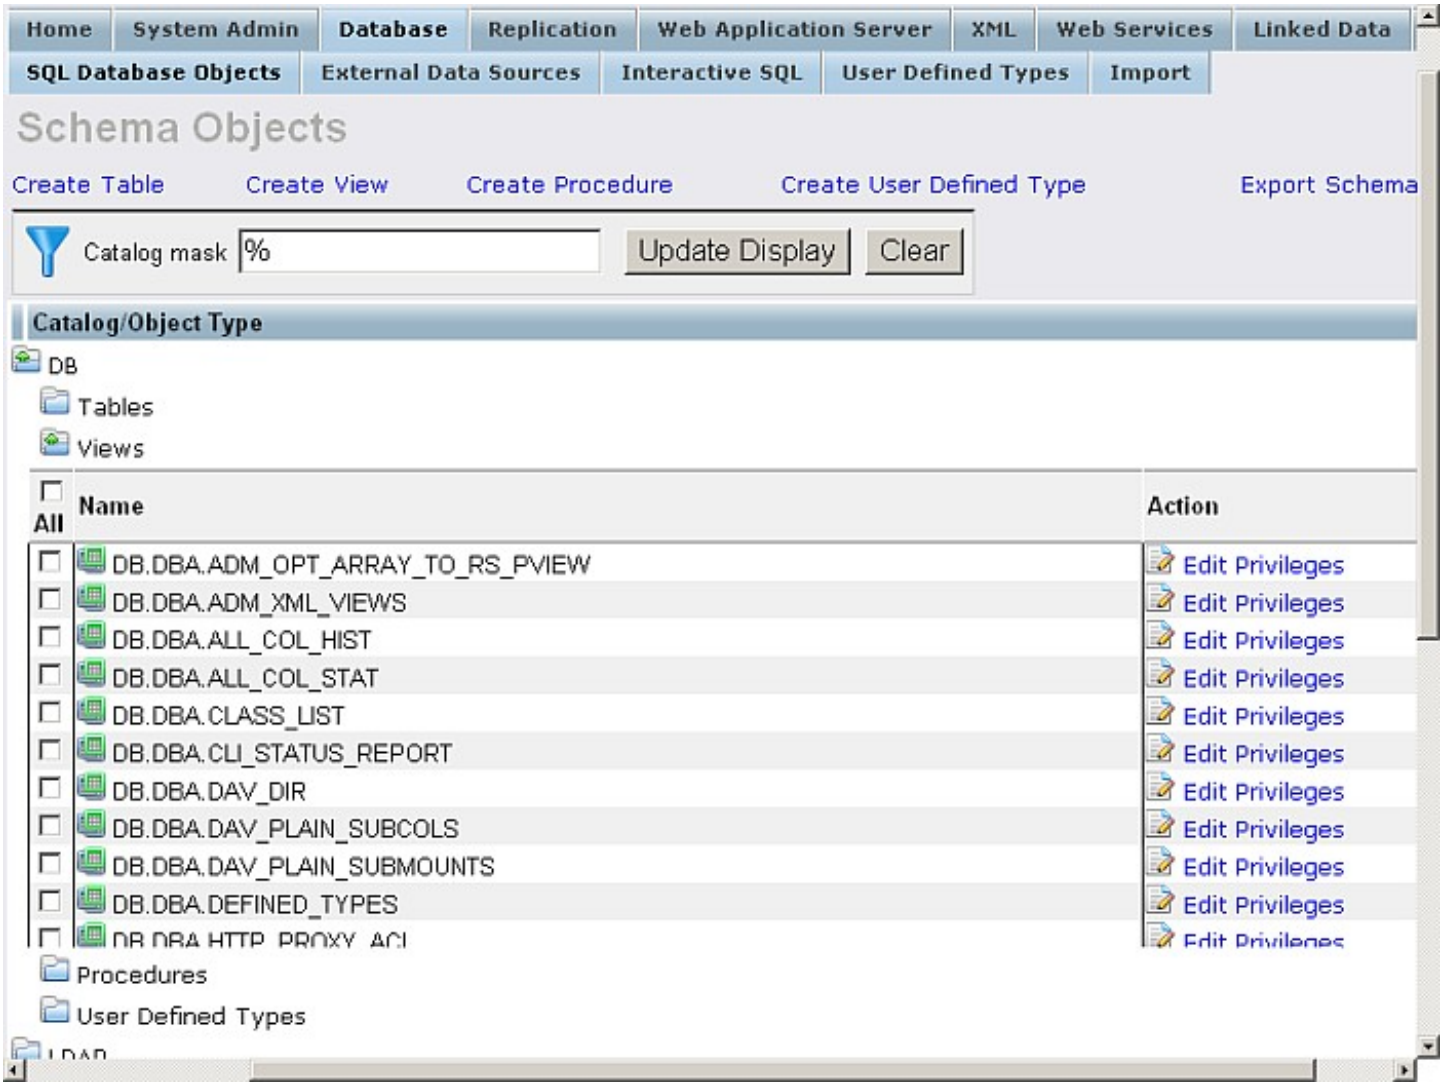
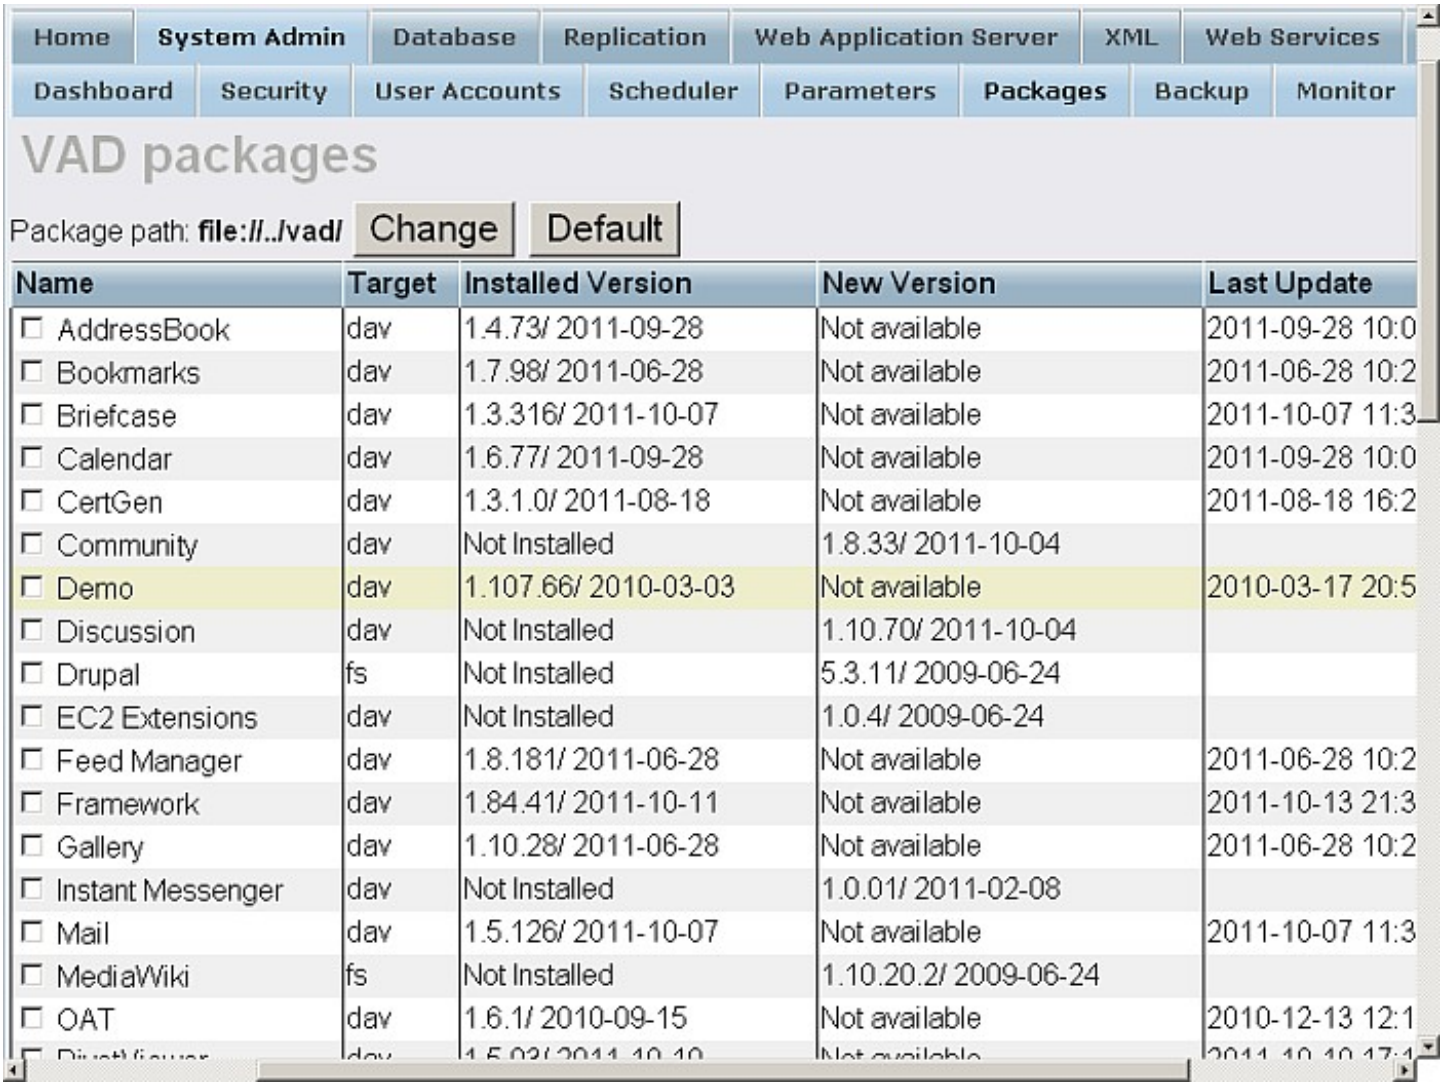


Demo Database Installation

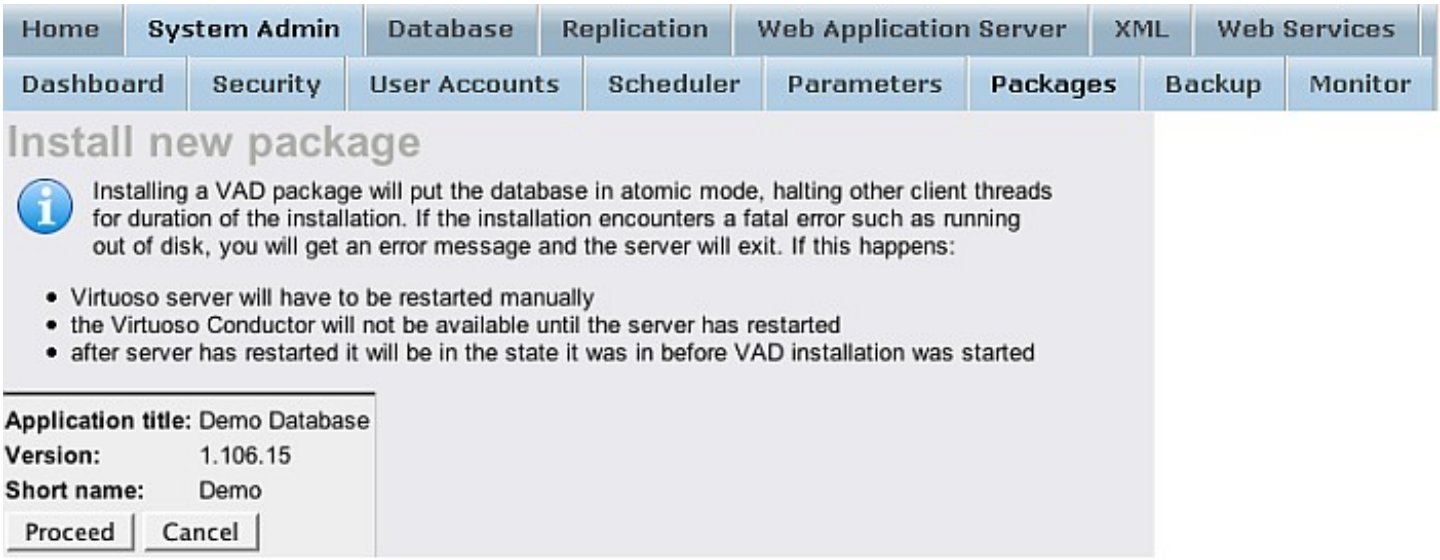
The Virtuoso Demonstration database can be installed with the Conductor by navigating to the "System Admin" -> "Packages" tab where a list of available Virtuoso applications are displayed, one of which is for the "Demo" database package as shown below:

Figure 6.129. Install Demo db using Conductor UI: "System Admin" -> "Packages"



Select the "Demo" package and click on the "Install" button to commence the installation process:

Figure 6.130. Install Demo db: confirmation

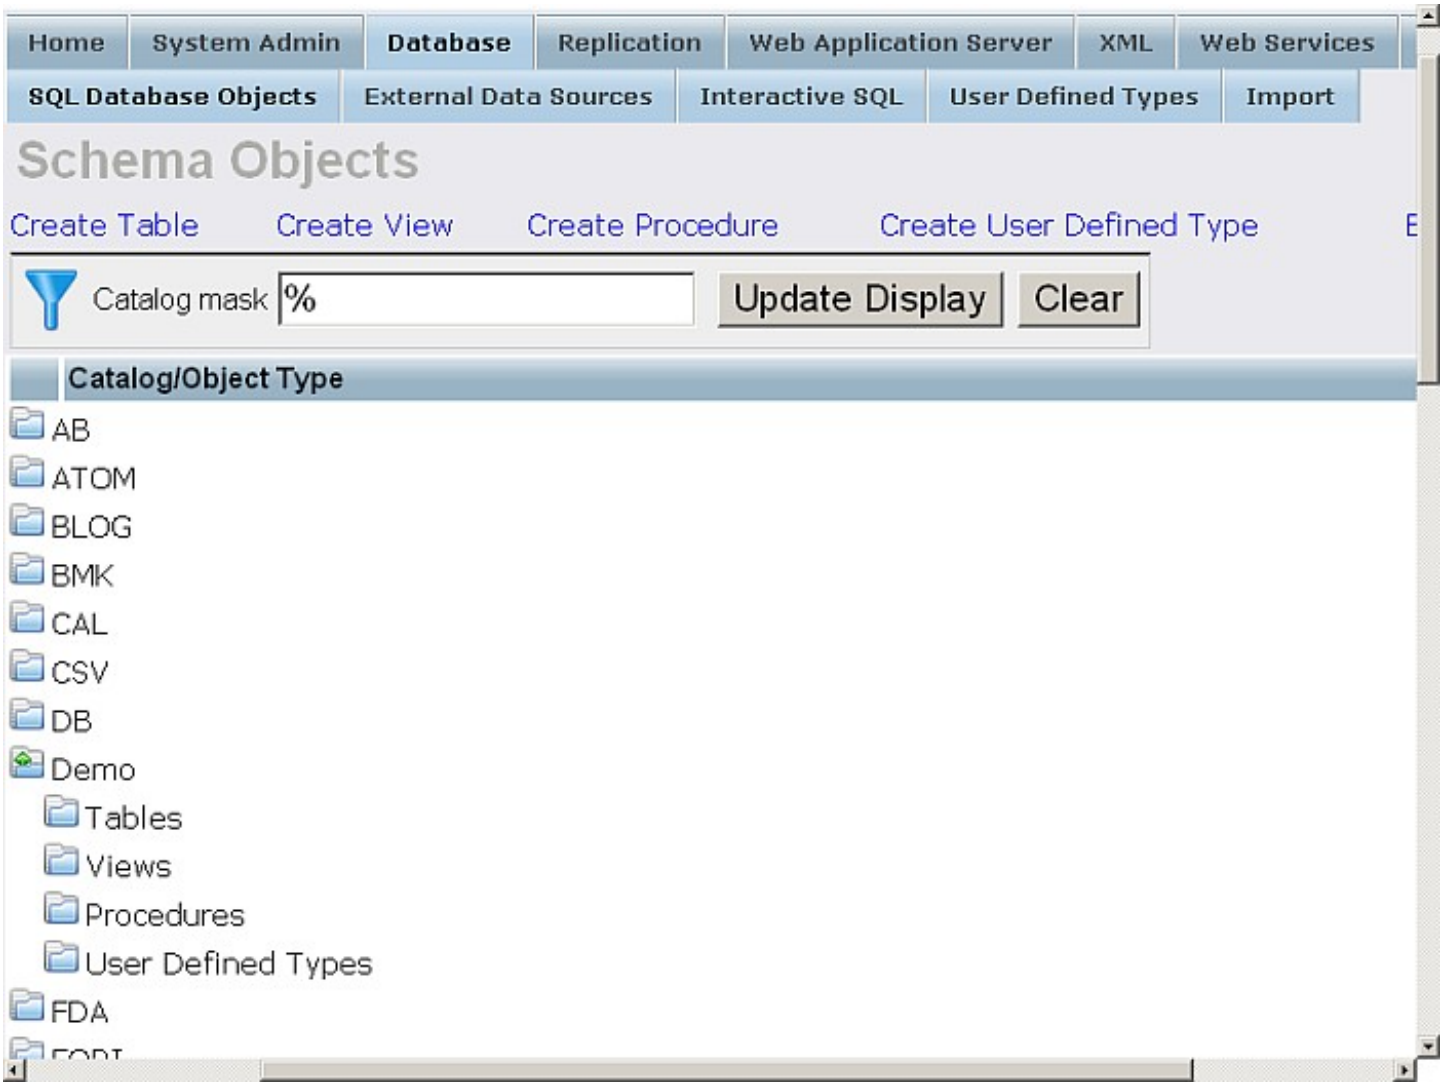


Click on the "proceed" button to install the indicated "Demo Database" application package:

Figure 6.131. Install Demo db: proceed

Once installed the demo database schema can be viewed from the "Database" -> "Schema Objects" tab of the Conductor:

Figure 6.132. Install Demo db: view schema objects



Editing Triggers

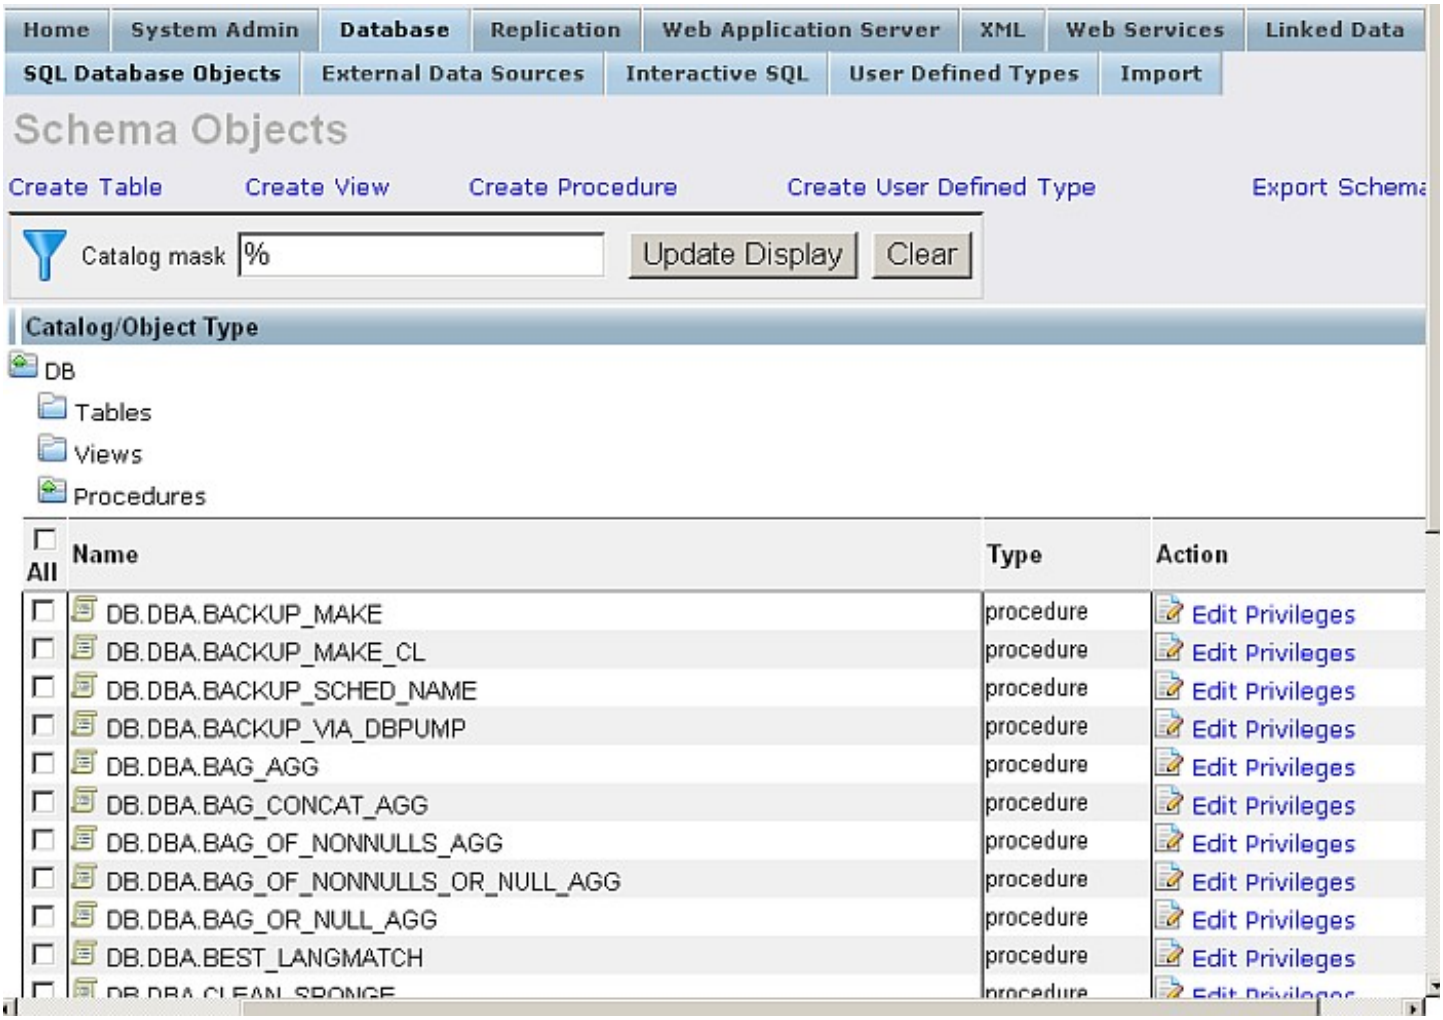
For each table, Virtuoso gives you the ability to edit the triggers linked to that table, as well as adding new triggers. The link text "Triggers" is followed by a number in parentheses that tells you how many triggers exist associated with that table. If no number is shown, there are no triggers. Clicking on the text takes you to the trigger edit page.

The triggers page shows you the name of each trigger, an excerpt from the text of the trigger, and permits you to edit or drop the triggers. In the last column of the shown form there is a "New Trigger" link for creation of a new trigger.

Editing Stored Procedures

The stored procedures link shows a page of information about existing stored procedures for the database you are viewing. If there are stored procedures, you can see their names and text excerpts, and you may edit or drop them. Adding new stored procedures can be done via the ISQL command-line interface or from the "Create Procedure" link shown above the list of objects for the relevant database.

Figure 6.133. Viewing Stored Procedures details for the DB catalogue



Stored procedures may also refer to modules that contain a group of related stored procedures. These are created and edited as a group, rather than individually. An example of this is the module DB.DBA.AmazonSearchService, which contains procedures such as KeywordSearchRequest() and BrowseNodeSearchRequest().

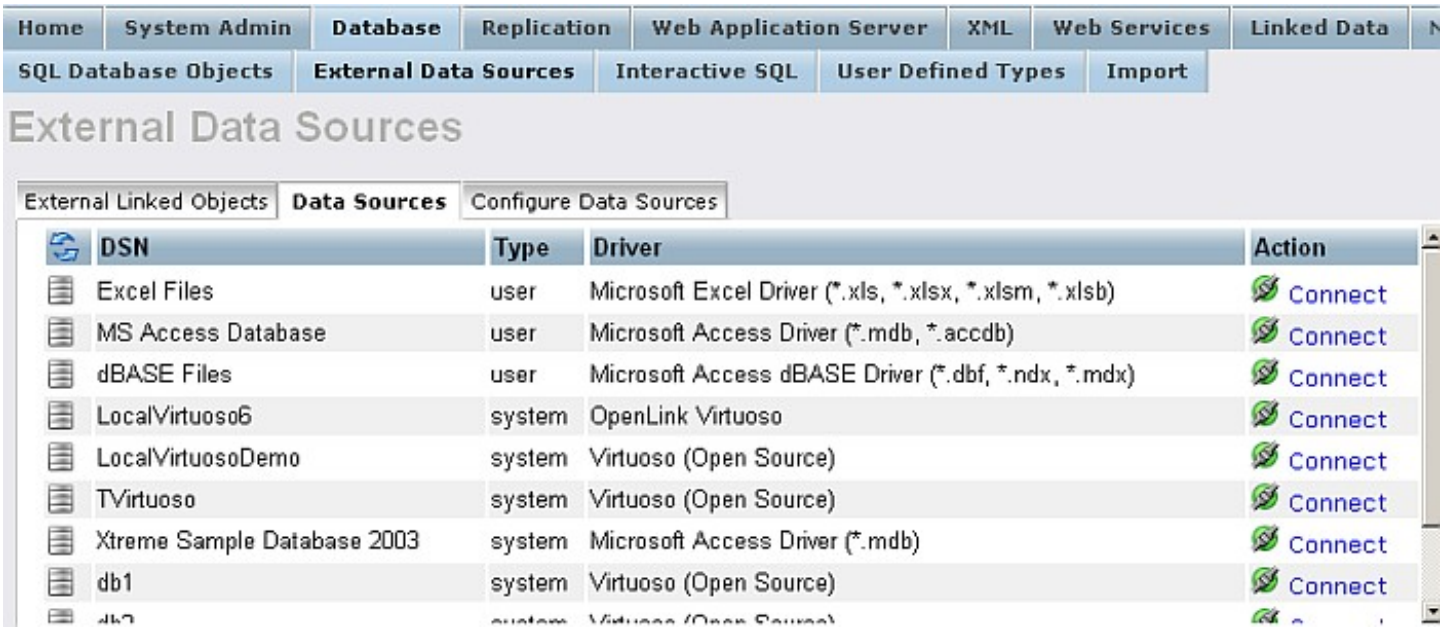
External Data Sources

From Database / External Data Sources you will be able to manage the Virtual Database feature of Virtuoso. You are able to administer ODBC Data Sources, how to link remote tables and view, and already linked remote connections.

Data Sources

This tab shows you the available Data Sources. For these one, to which there is no connection, will be shown the link"Connect". For the datasource for which there is already established connection, will be shown the links "Link objects", "Change Credentials" and "Disconnect".

Figure 6.134. Remote Datasources connected to Virtuoso

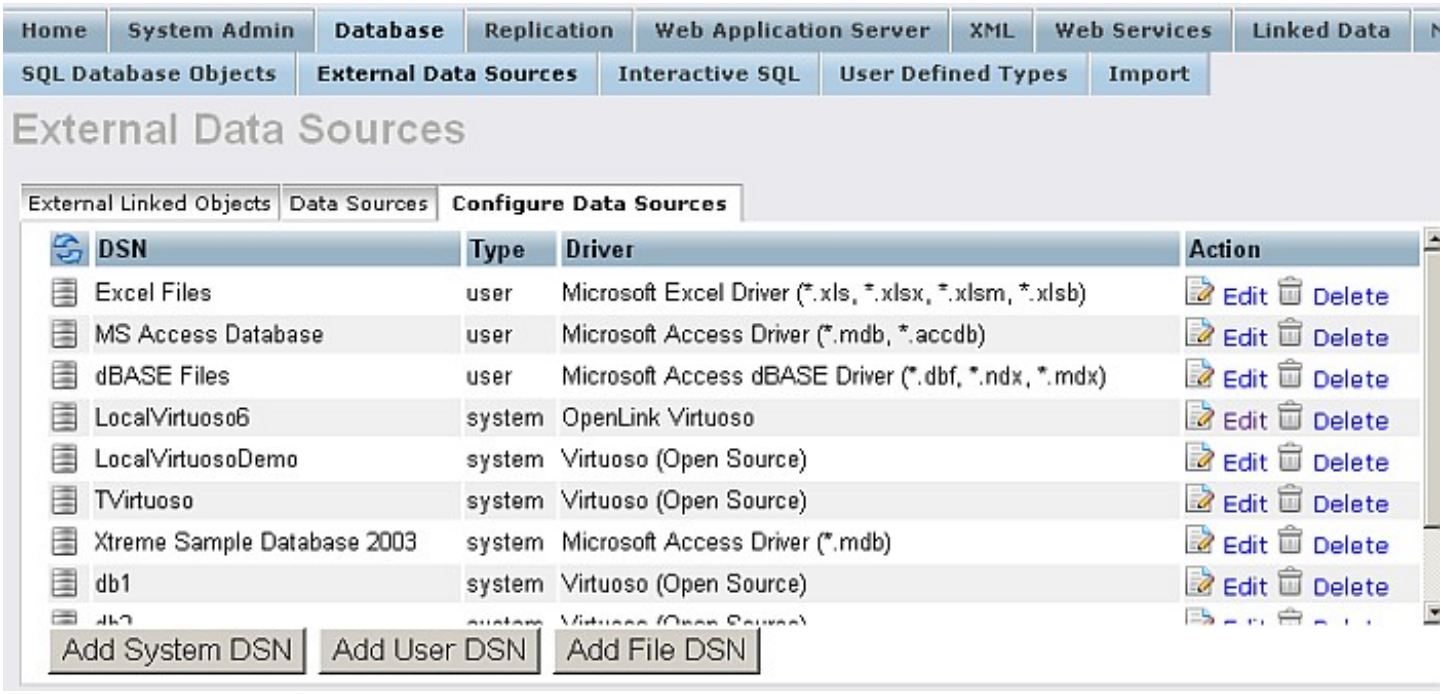


If you need to alter the authentication details of a particular Data Source then select the "Change Credentials" link. If you want to link new objects, select the "Link objects" link.

Configure Data Sources

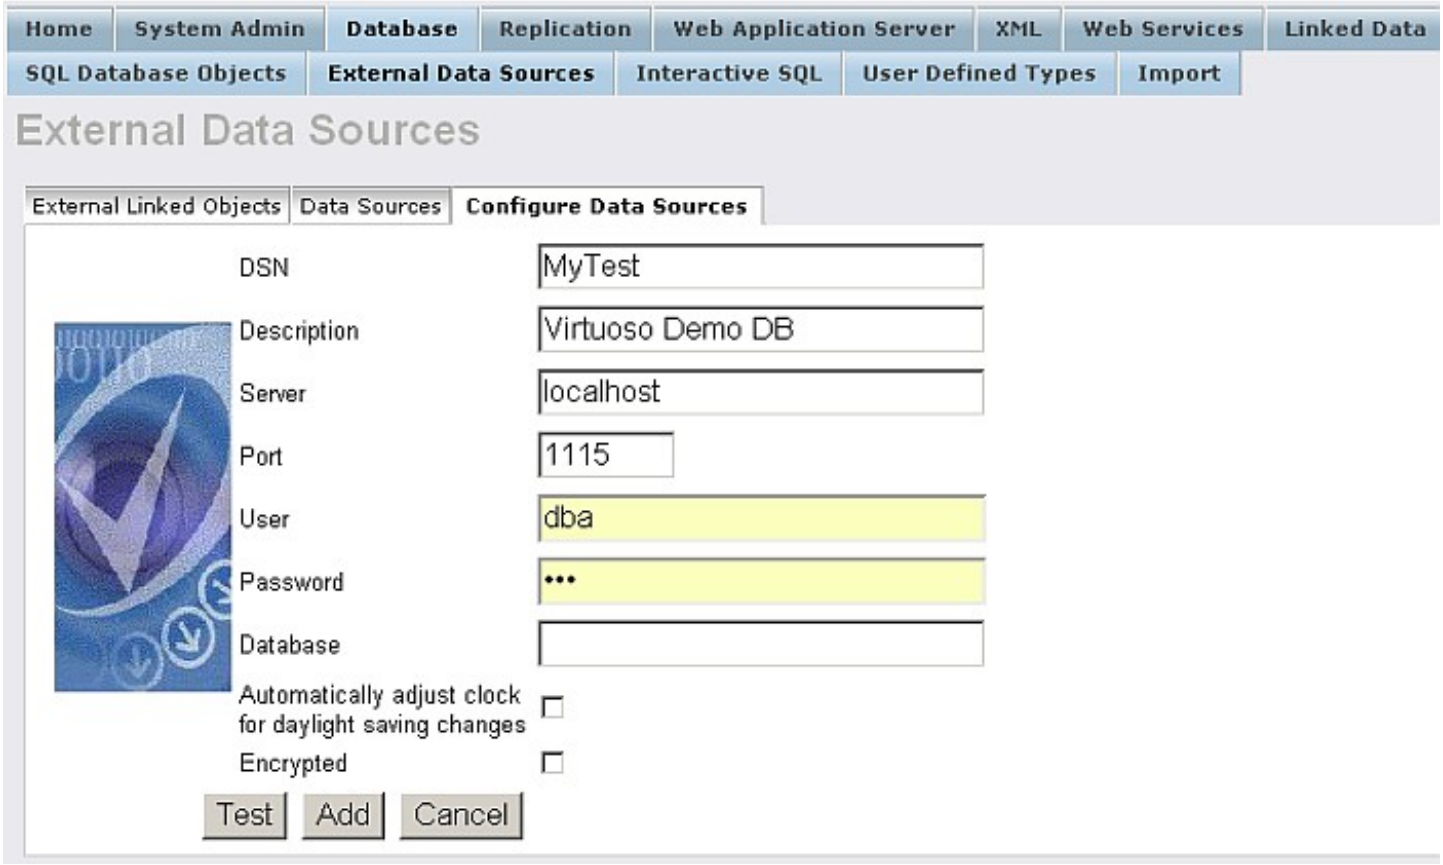
This section will allow you to configure the data sources themselves on the remote machine. The table that will be presented to you will contain both User and System data sources. You will be able to edit and create either User or System data sources, however, Virtuoso will only be able to use the User data sources that belong to the user that started the Virtuoso Server.

Figure 6.135. Configuring ODBC Datasources



Follow the buttons on the screen as to how you want to manage a data source. You can create new, edit or remove existing data sources.

Figure 6.136. Configuring A Virtuoso ODBC Datasources



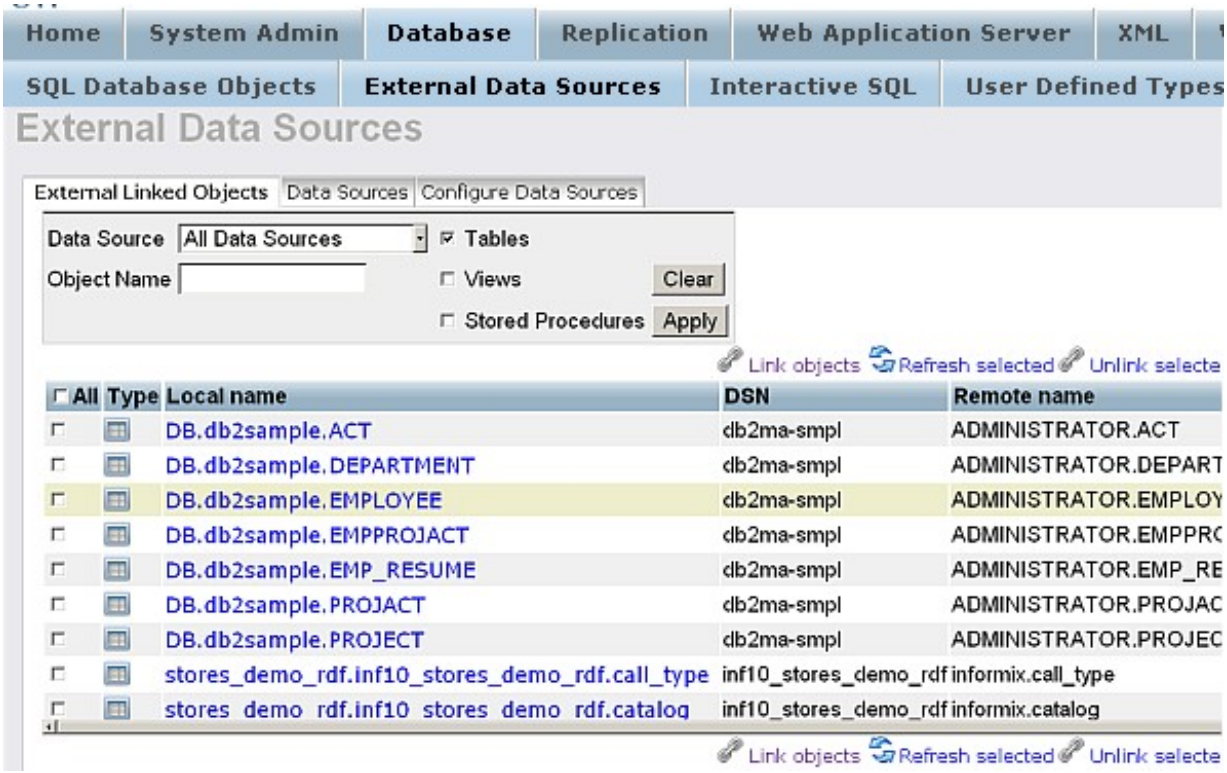
The Virtuoso Server can make use of File Data Sources too. This provides the usual associated conveniences. These enable you to migrate a Virtuoso database to another machine hosting the same ODBC Driver, Virtuoso then has enough information to connect using the installed driver to a remote data source, the tables would not need to be relinked. File DSN's are read from server's root directory. File DSN's can only be read if this directory is contained in the Virtuoso INI file parameter DirsAllows.

Note:
Windows NT or 2000 services by default start as the LocalSystem special user account. This account will not contain the same User DSNs as your own user. The Virtuoso service can be started with other users but you must be aware of any possible system permission problems. It is recommended that Virtuoso make use of System or File DSNs wherever possible.

External Linked Objects

This page will allow you to manage the remote objects that are linked into Virtuoso. You can unlink objects by selecting them and pressing the "Unlink selected" button.

Figure 6.137. Linking Tables from Remote Datasources



To link new tables into Virtuoso select "Link objects" link or go to the "Data Sources" tab. Click the "Connect" link for a data source. If this data source has been used before then the existing authentication details will automatically be provided. Otherwise you will have to provide these details in the username and password fields provided. When you are ready press the "Link objects" link.

As results you should be presented with list of available remote tables and optionally views and procedures. If the connection fails then an error will be returned to the top of the page instead. You should be able to link any of the listed tables or views into Virtuoso. In order for Virtuoso to be able to correctly query the underlying table it needs to be able to uniquely identify each row (record) within the table or view. Tables should always be created with a primary key, and details of which should be available from the data source. With a primary key available Virtuoso will be able to link the table in to the server easily. In some cases and certainly in the case of views Virtuoso may not be able to determine a primary key or what constitutes uniqueness in the table. On the right most column will be an action link to a page that allows you to alter the primary key information about the table or view that is to be linked. Some primary key information is italized to indicate the explicit definition of a primary key.

You will be required to enter primary key information for views before they can be linked.

Select the tables that you want to link into the Virtuoso Server by checking the check box on the left most column of the list for table or view in question. When you are ready press the *Link* ... button at the bottom of the page.

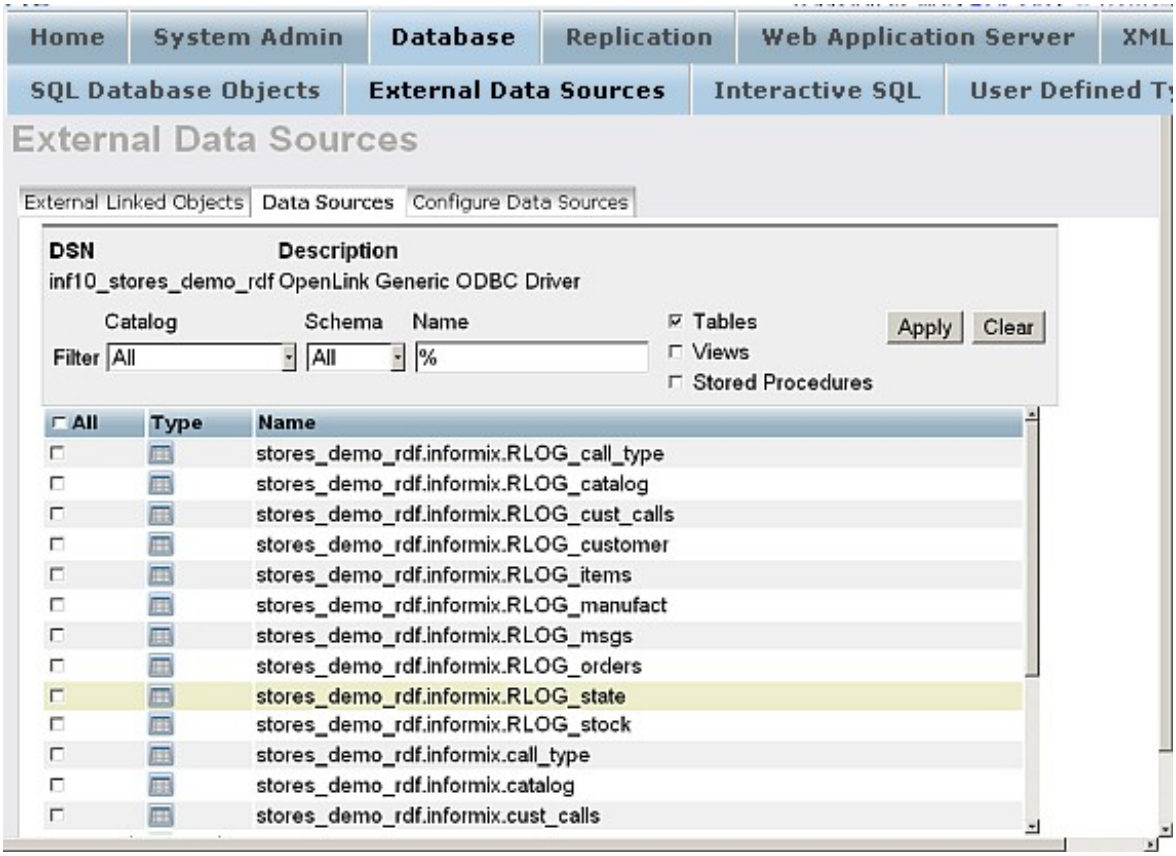
As result the selected tables will be linked and listed in the first list as Currently Linked.

Remote Procedures

In order to view the list of remote procedures, you should check the "Stored Procedures" check-box and click the button "Apply". As result the procedures that are already connected to Virtuoso will be shown with checked check-box. You can unlink these by selecting them and pressing the *Unlink* button.

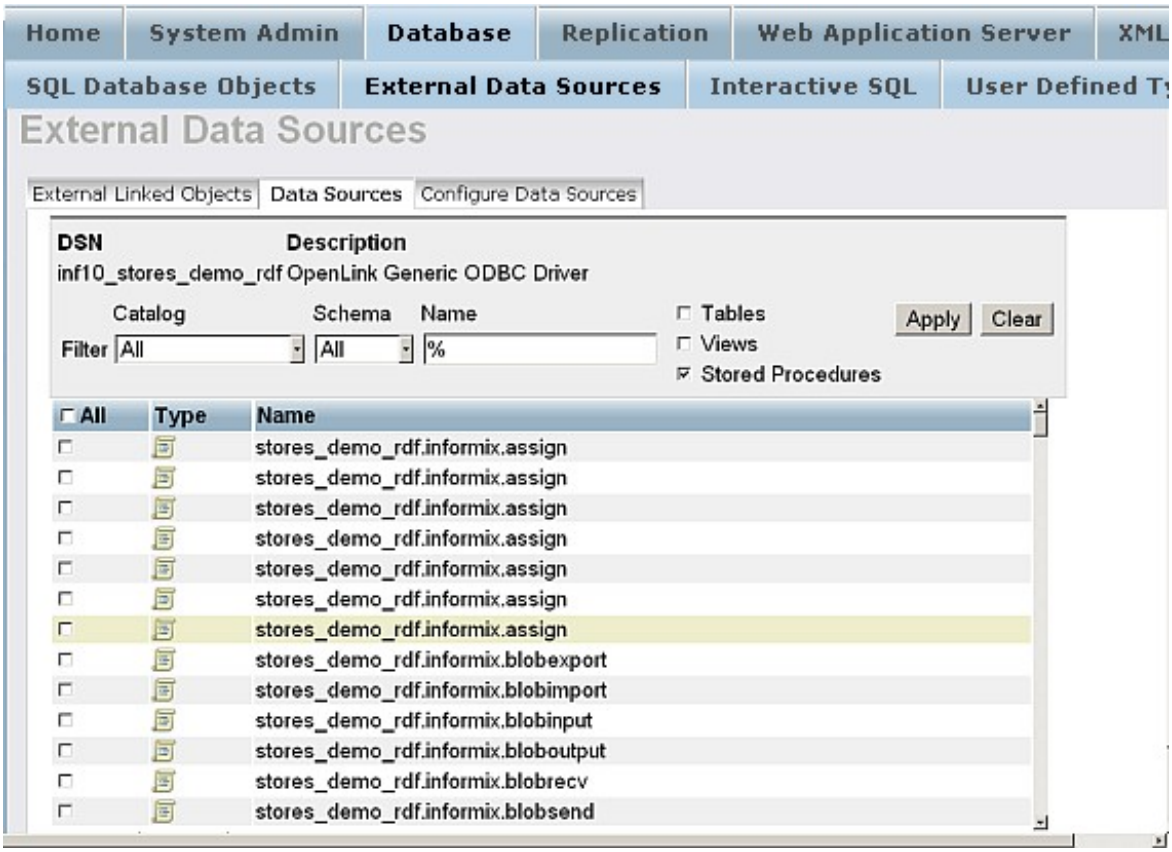
To link new procedures into Virtuoso select the Data Source from the list of available n t ab "Data Sources". If this data source has been used before then the existing authentication details will automatically be provided. Otherwise you will have to provide these details in the username and password fields provided. When you are ready press the *Link Objects* link. The page will next require you to select the catalog/owner combination to refine the search list of procedures on the remote datasource. Check the check-box "Stored procedures" and click the "Apply" button to list the available stored procedures.

Figure 6.138. Linking Procedures from Remote Datasources



When the page returns you will be presented with a list of available remote procedures. You should be able to link any of the listed procedures into Virtuoso.

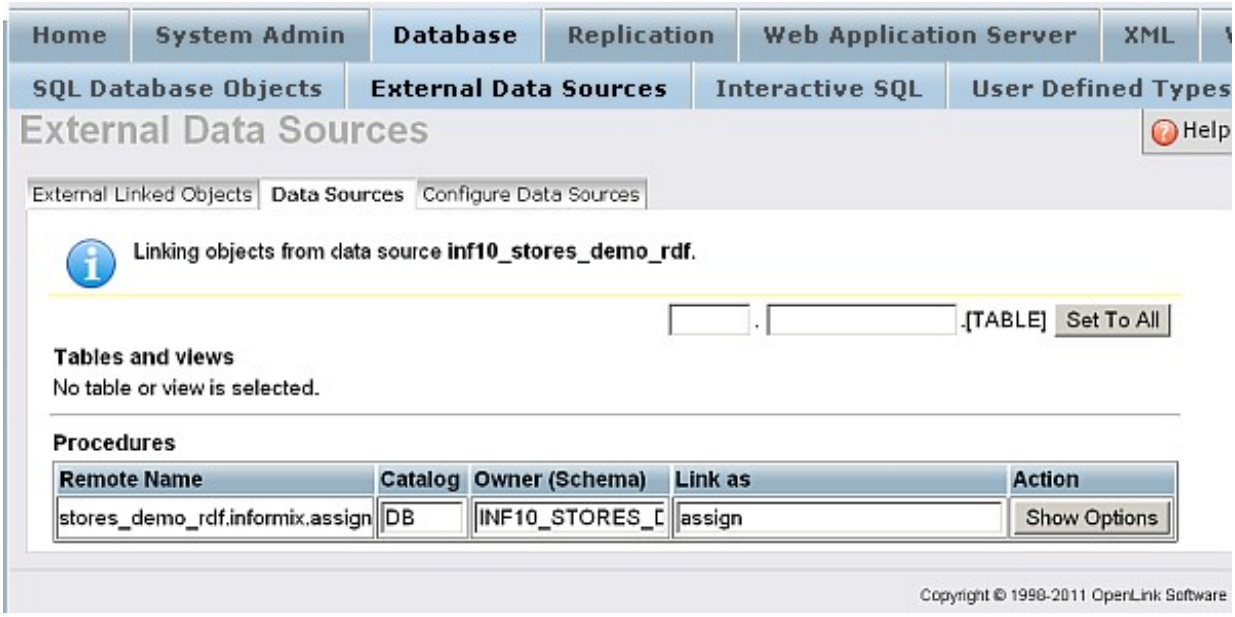
Figure 6.139. Linking Procedures from Remote Datasources



Select the procedures that you want to link into the Virtuoso Server by checking the check box on the left most column of the list for the procedure in question. When you are ready press the *Link ...* button at the bottom of the page.

You will be presented with a new page that lists the procedures chosen and the data type information regarding them. This gives you an opportunity to alter the data type mappings that Virtuoso will use both internally and for any future interactions with the SOAP server. If you do not want to specify any special type information the details can be left as default.

Figure 6.140. Linking Procedures from Remote Datasources



For each remote procedure you have the option to change how they will be referenced within Virtuoso by making changes to the fields for *Local Name* , *Database* , and *Schema* . These fields define how you will find the linked procedure locally to Virtuoso only and do not affect the remote data source.

For each procedure there are radio buttons for selecting the *PL Wrapper Requirements* . This option is of particular importance for remote procedures capable of returning a resultset. Remote procedures can be linked using a Virtuoso PL wrapper meaning that Virtuoso procedure language code provides a mechanism for negotiating the result set. The available options are:

Soap Execution - Generates a PL wrapper that can be published to Web Services.

SQL Execution - Generates a PL Wrapper that is more suitable for general SQL use.

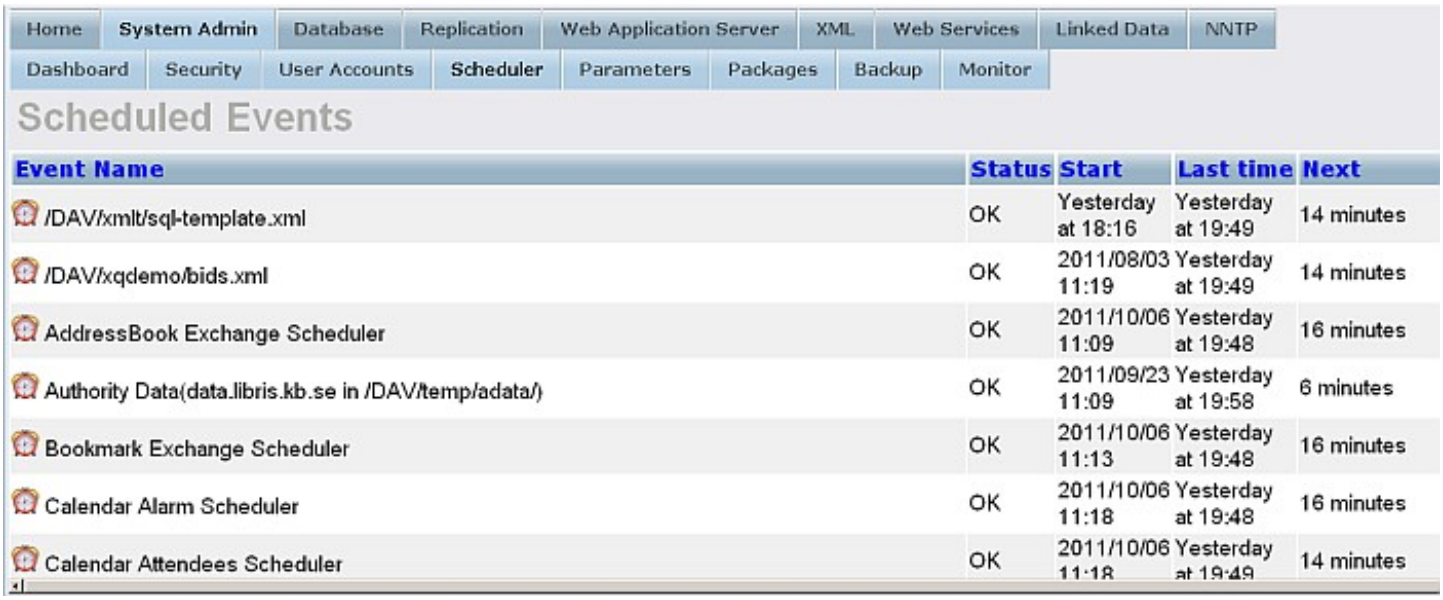
None - Does not generate and PL Wrapper code and simply links the procedure by reference.

There is a description input box for you to write a description or comment for the linked procedure. This comment will only be applicable to procedures that are linked using a PL Wrapper, and is only directly applicable for PL Wrappers for SOAP execution.

Event Scheduler

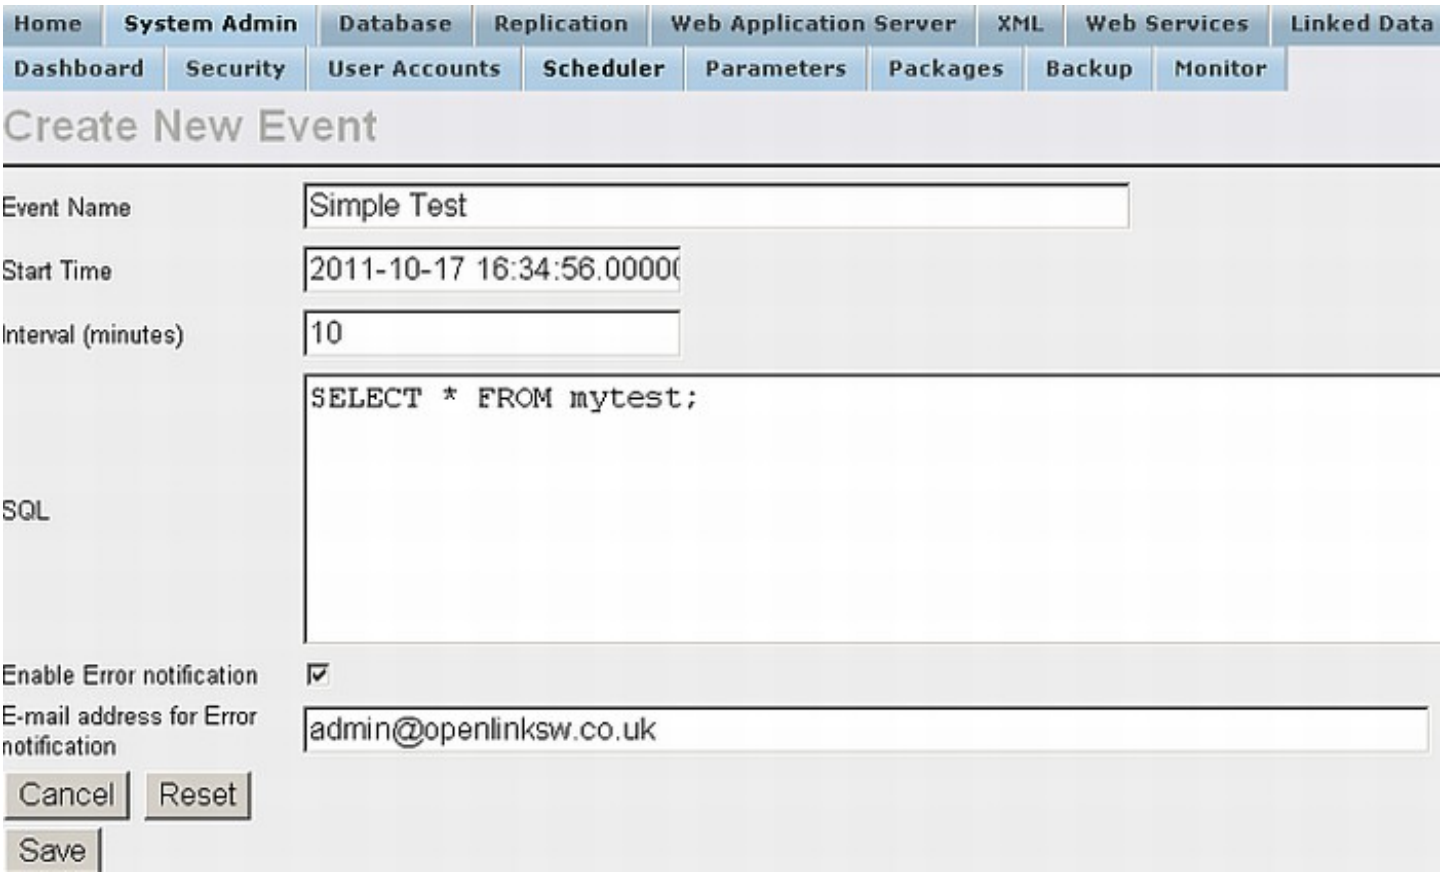
The System Admin / Scheduler tab allows you to view, edit and remove events that can be scheduled to run from a particular time at a defined interval.

Figure 6.141. Event Scheduler



To add a new scheduled event click the "Create New Event" link in tha last column of the shown form. The Event Name is a unique name required to uniquely identify each event. Start Time is when the event will be run for the first time and takes the form of a normal SQL timestamp value. Interval(minutes) is the length of time in minutes to wait to run the event again. SQL is a valid piece of SQL that you want to schedule to run. You can also check for "Enable Error Notification" and enter E-Mail for error notification.

Figure 6.142. Event Scheduler



Events write possible error messages into the Virtuoso log file.

Virtuoso Configuration Editor

From System Admin/Parameters you can change the Virtuoso Configuration settings:

Figure 6.143. Virtuoso (virtuoso.ini) Configuration File Editor

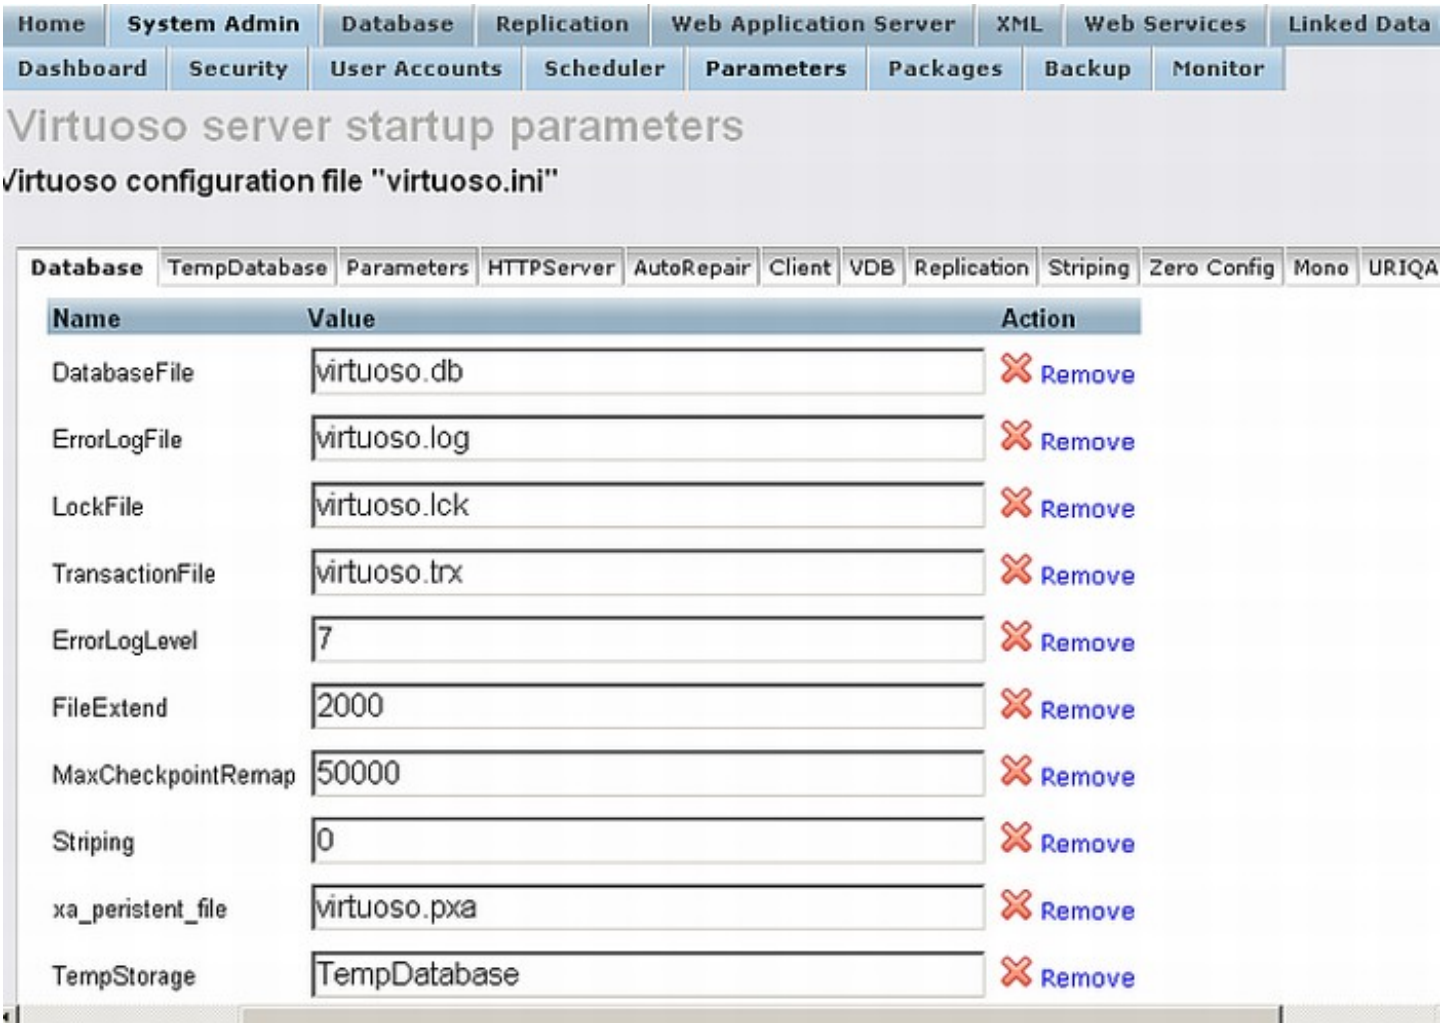


Figure 6.144. Virtuoso (virtuoso.ini) Configuration File Editor

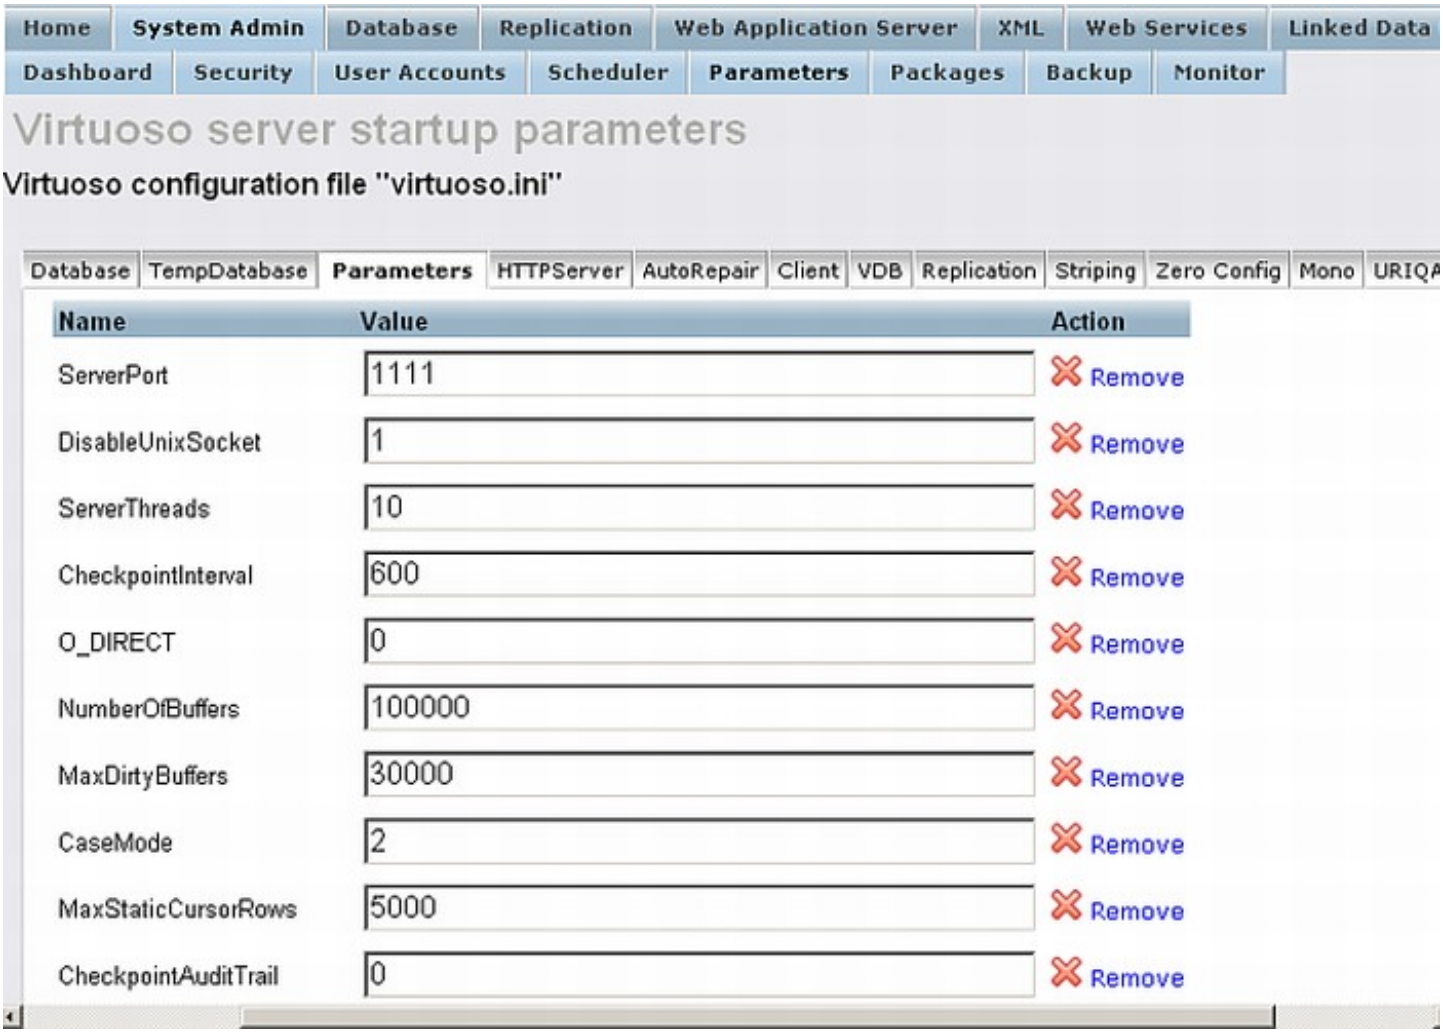

Figure 6.145. Virtuoso (virtuoso.ini) Configuration File Editor

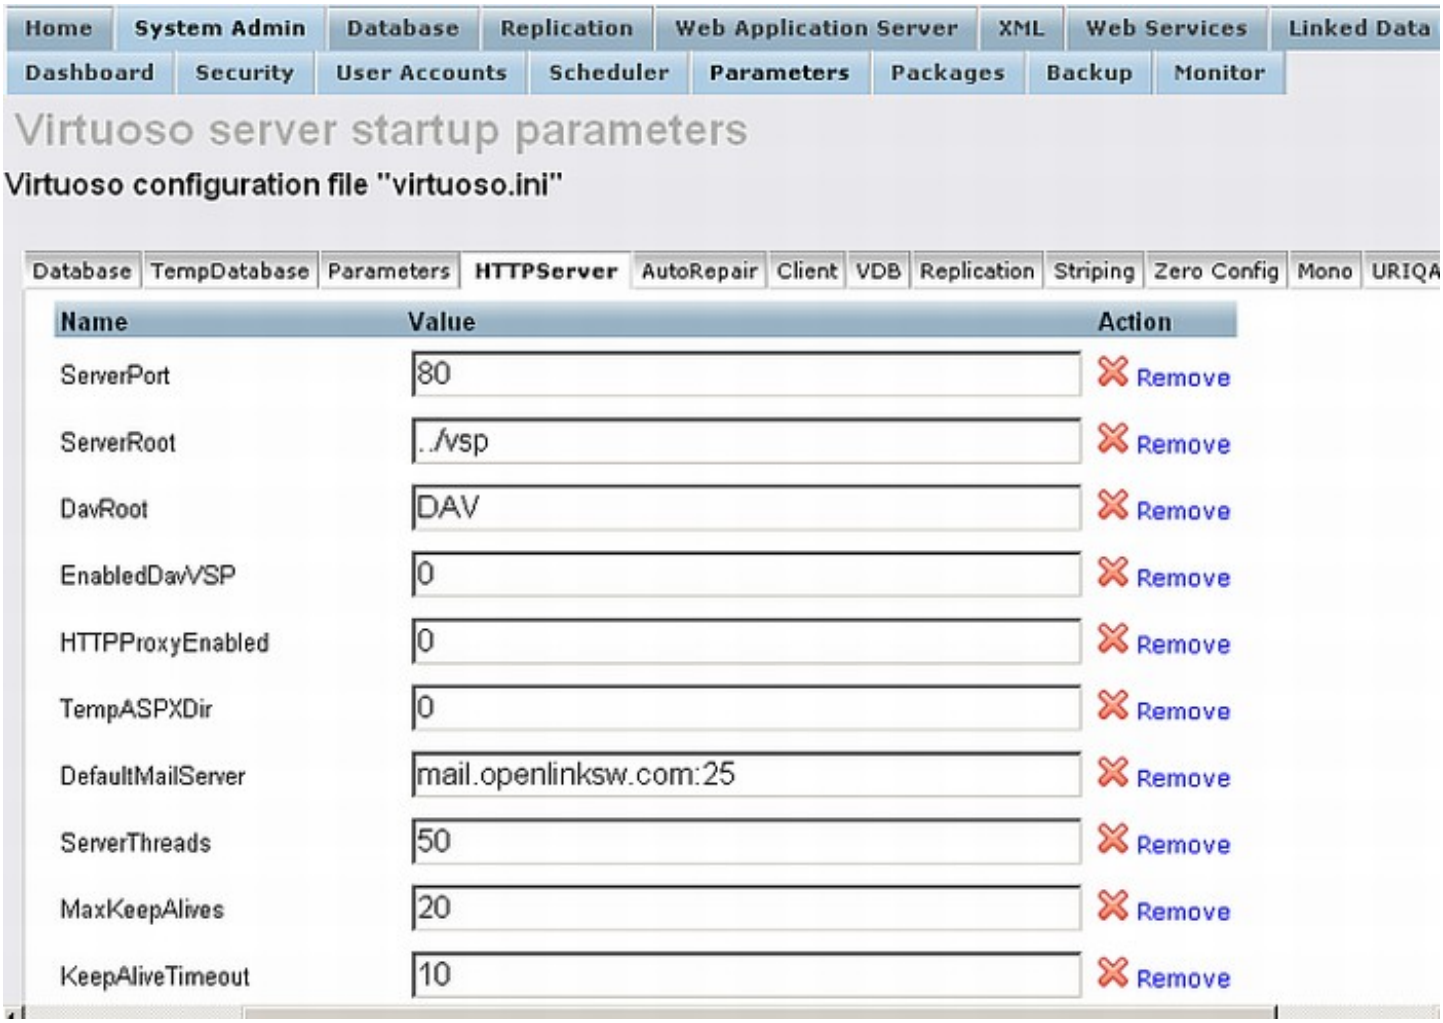

Figure 6.146. Virtuoso (virtuoso.ini) Configuration File Editor

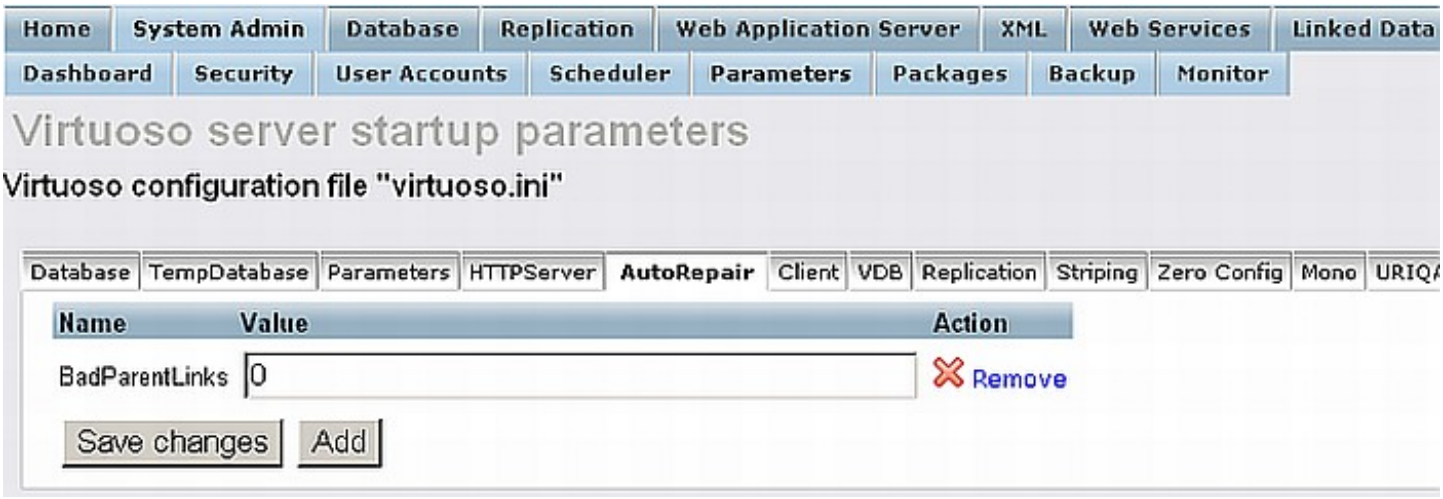

Figure 6.147. Virtuoso (virtuoso.ini) Configuration File Editor

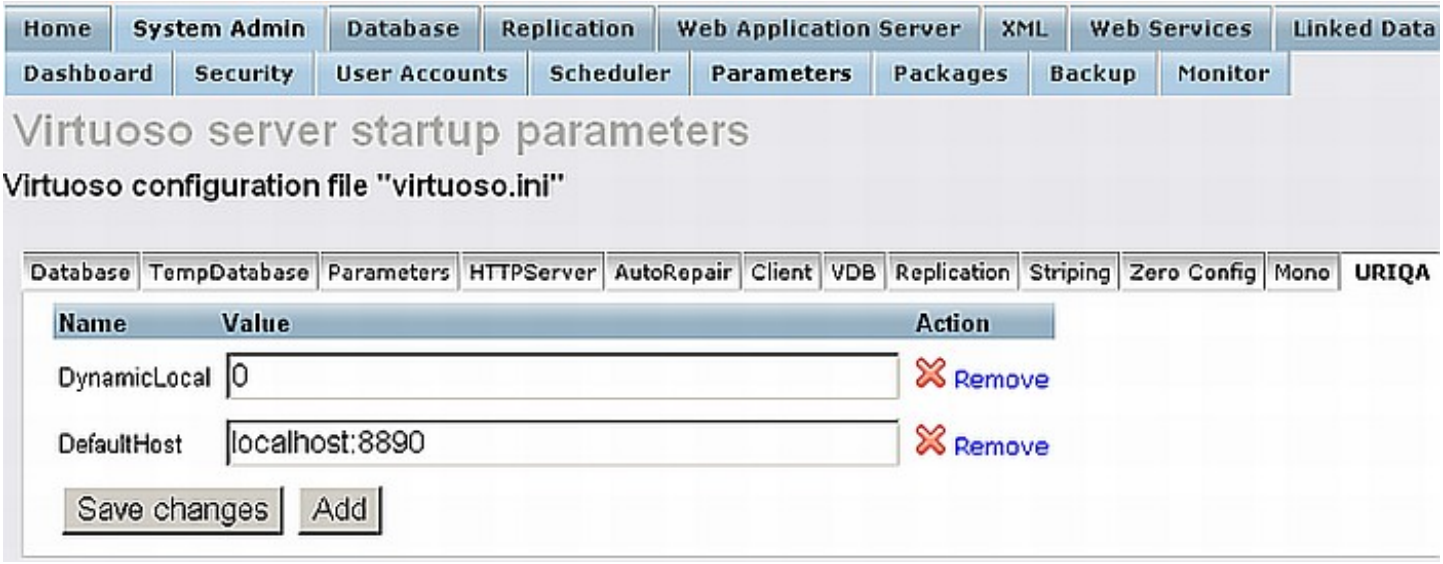

Figure 6.148. Virtuoso (virtuoso.ini) Configuration File Editor

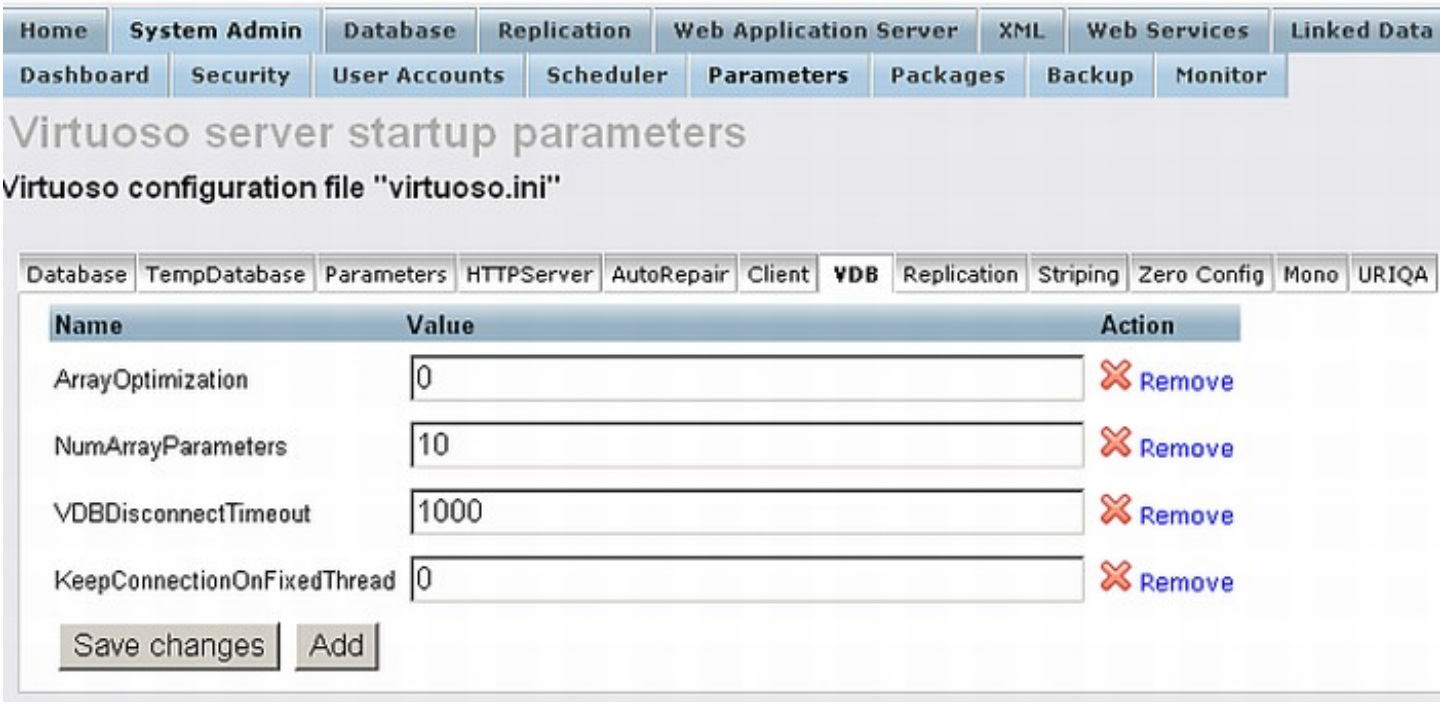

Figure 6.149. Virtuoso (virtuoso.ini) Configuration File Editor

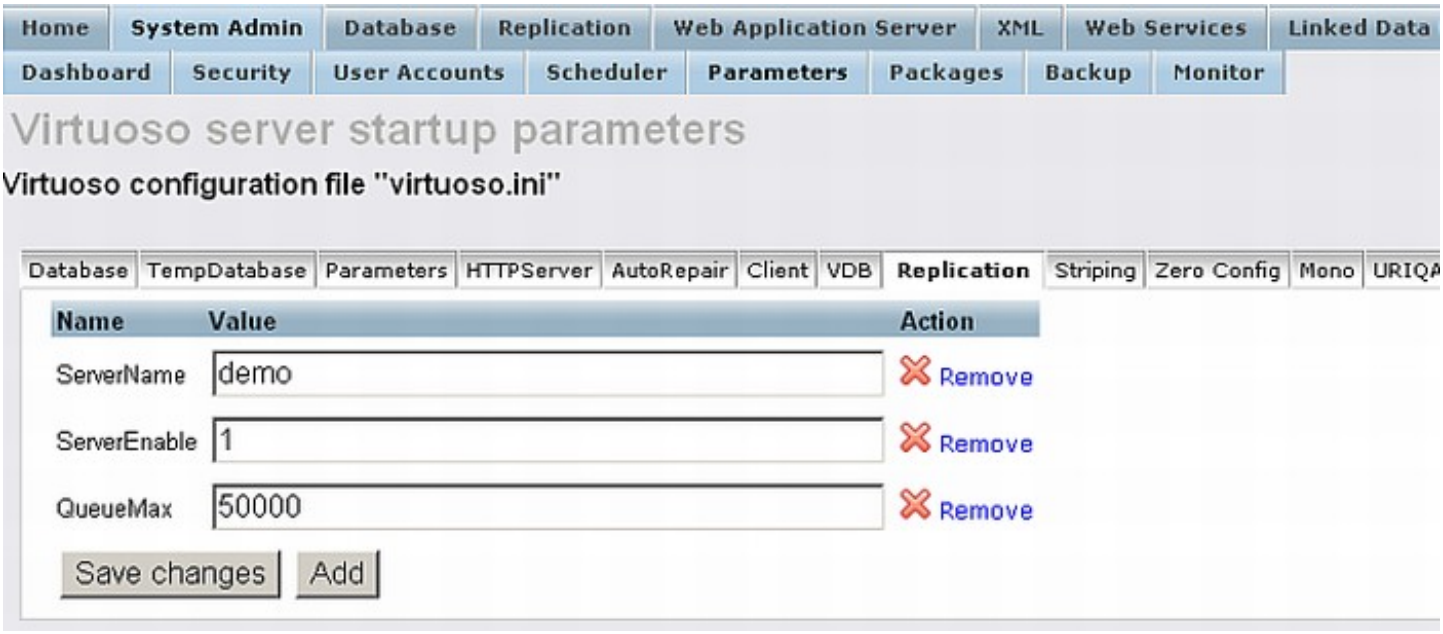
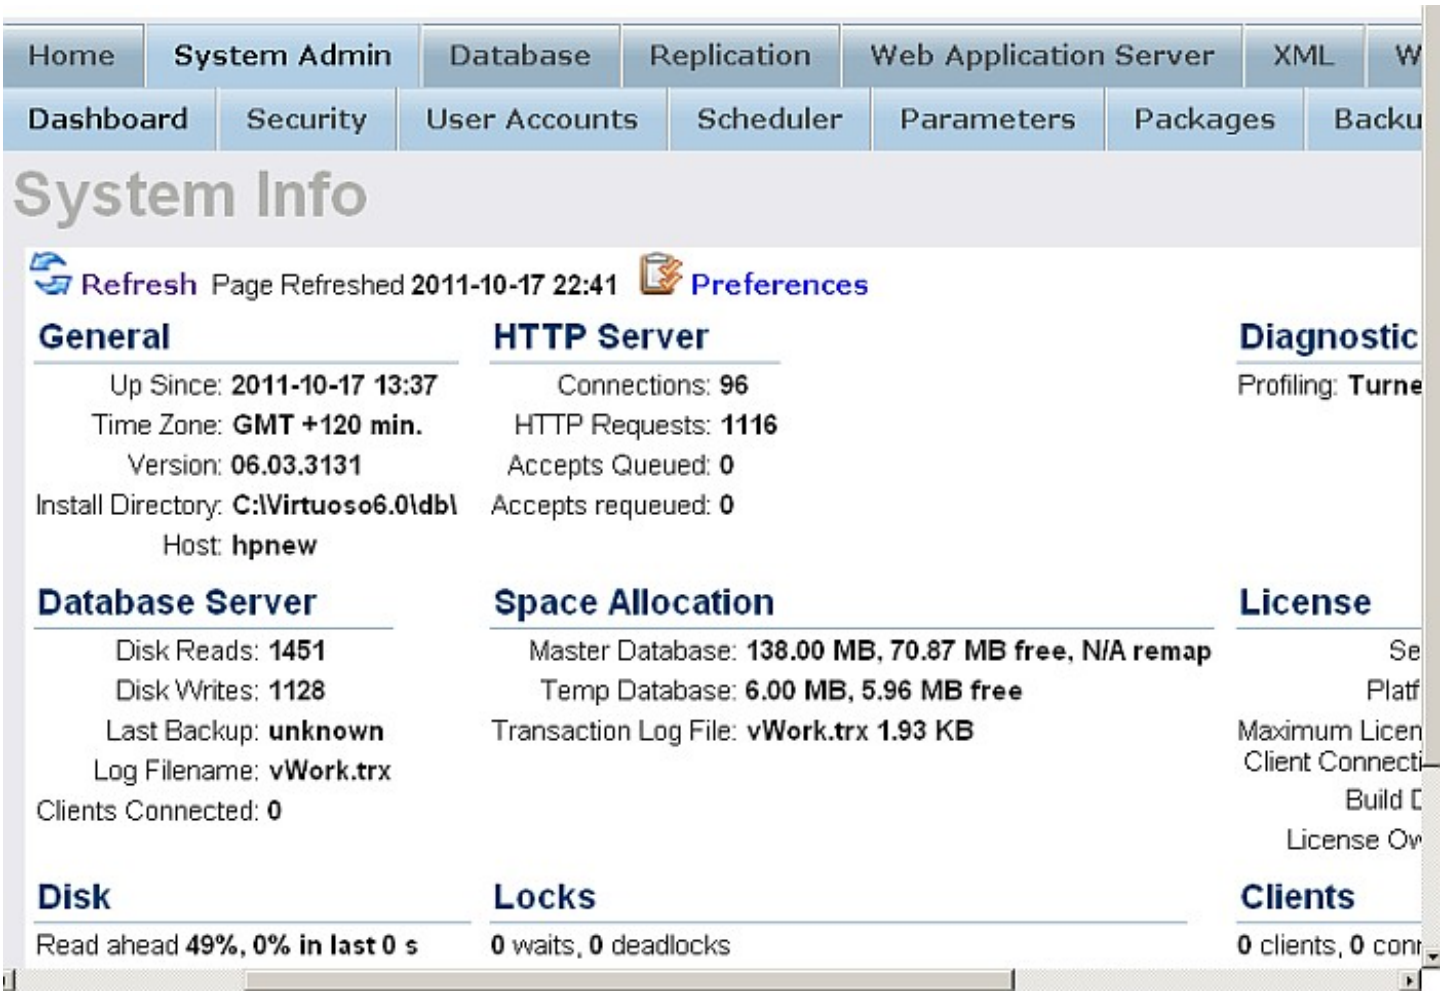


Dashboard and Monitor

The System Admin/Dashboard consists of a collection of statistical information about your Virtuoso server. This includes general licensing information, locking, webserver hits statistics and more.

Figure 6.150. Dashboard



The System Admin/Monitor shows in details statistical information about your server.

Figure 6.151. Monitor - General Information

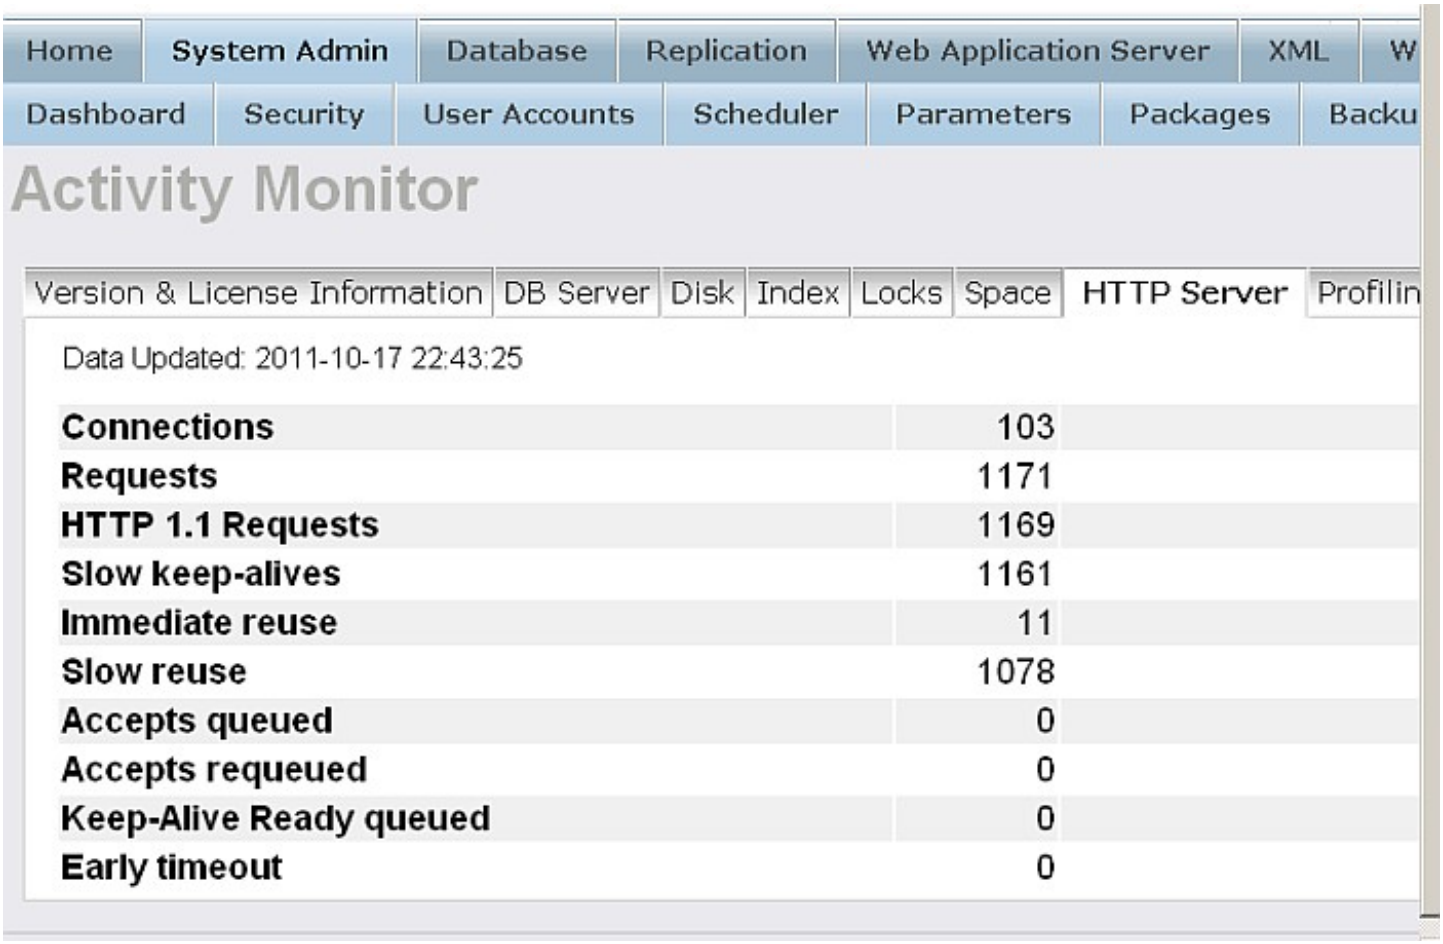

Figure 6.153. Monitor - Index Usage

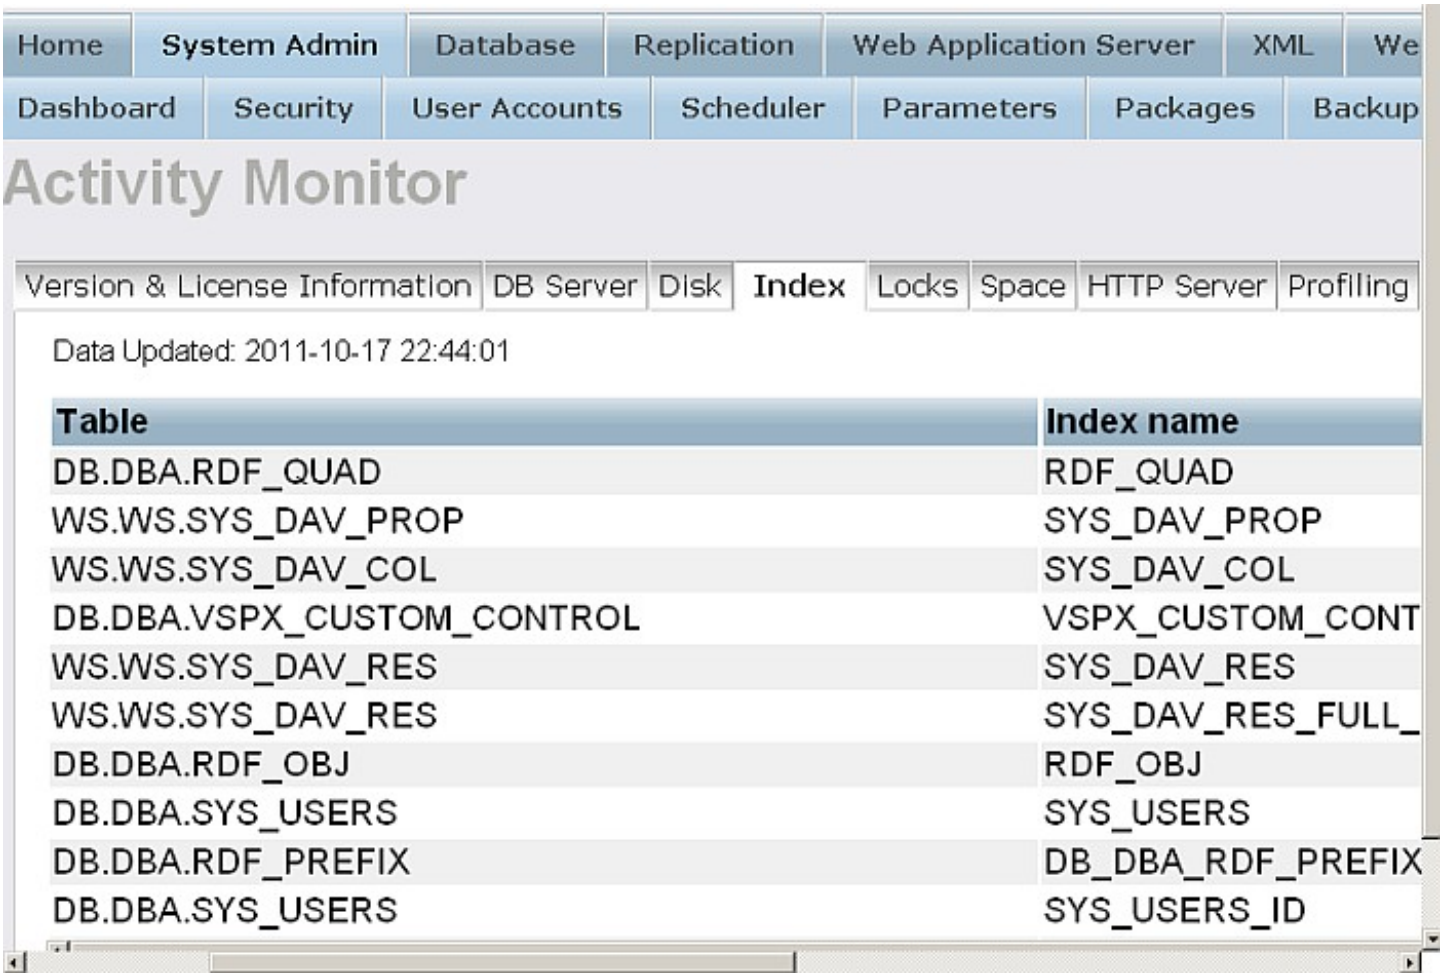

Figure 6.154. Monitor - Profiling

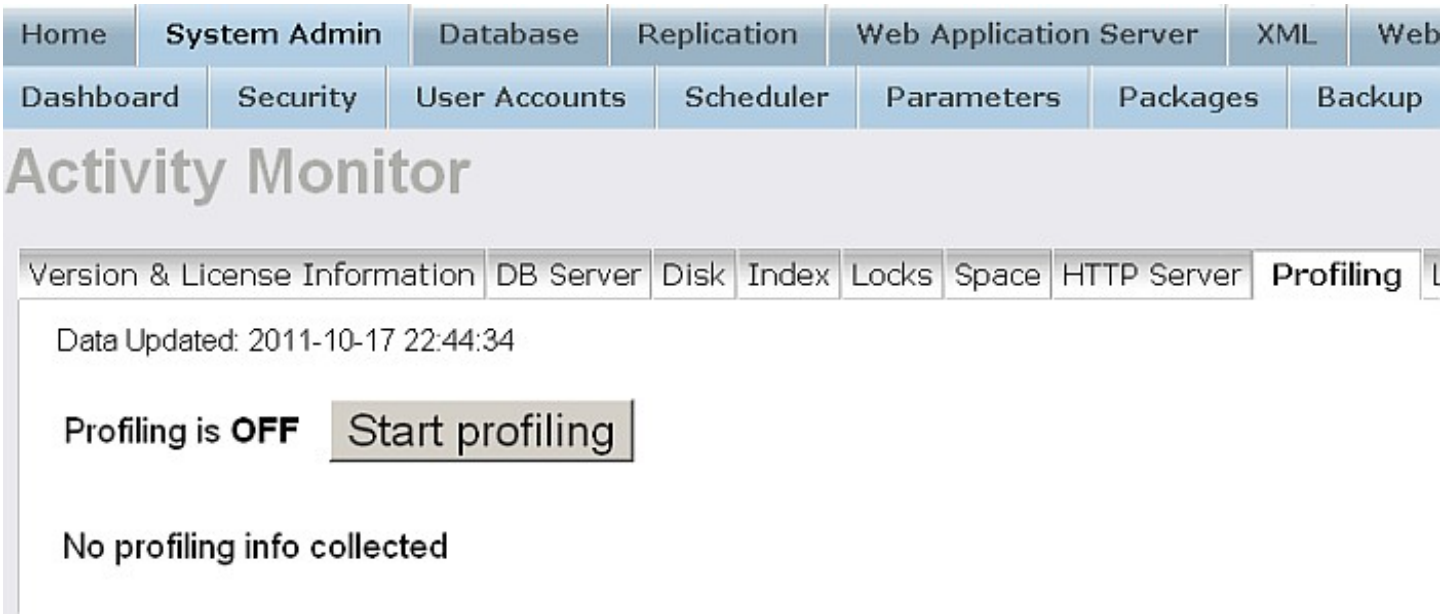


6.2.10. Conductor Linked Data Administration

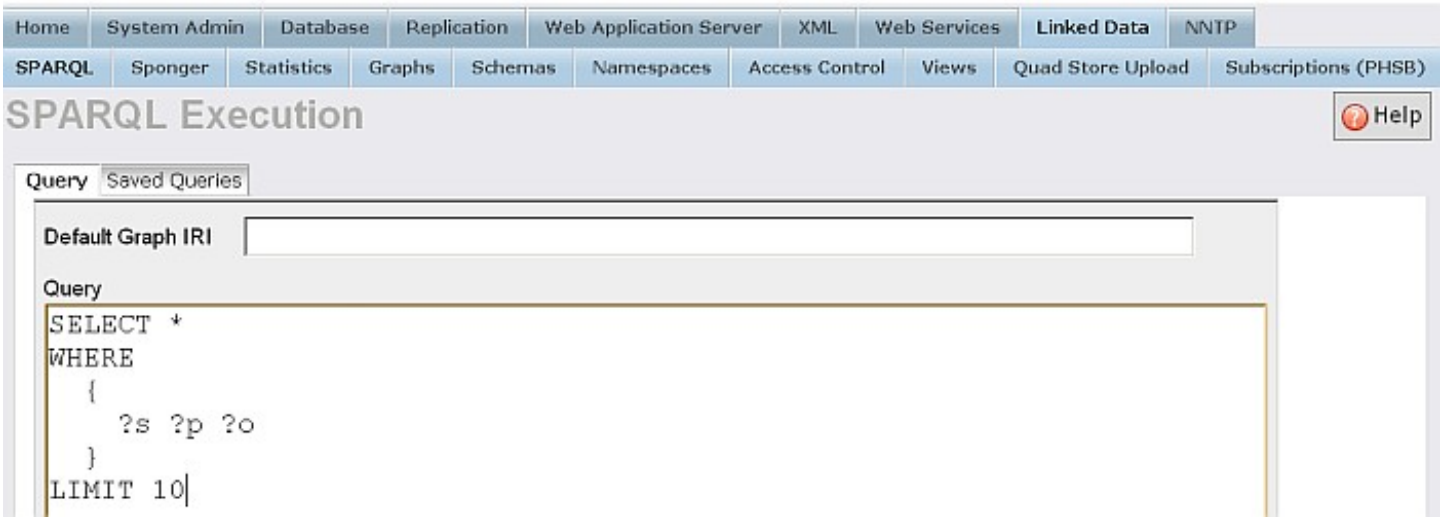
From Conductor the "Linked Data" tab allows you to execute/save/load SPARQL queries, to add/edit RDF Mapping, to perform statistics and manage graphs, to import schemas and define namespaces, to generated Linked Data Views and to upload to the Quad Store.

SPARQL

Query

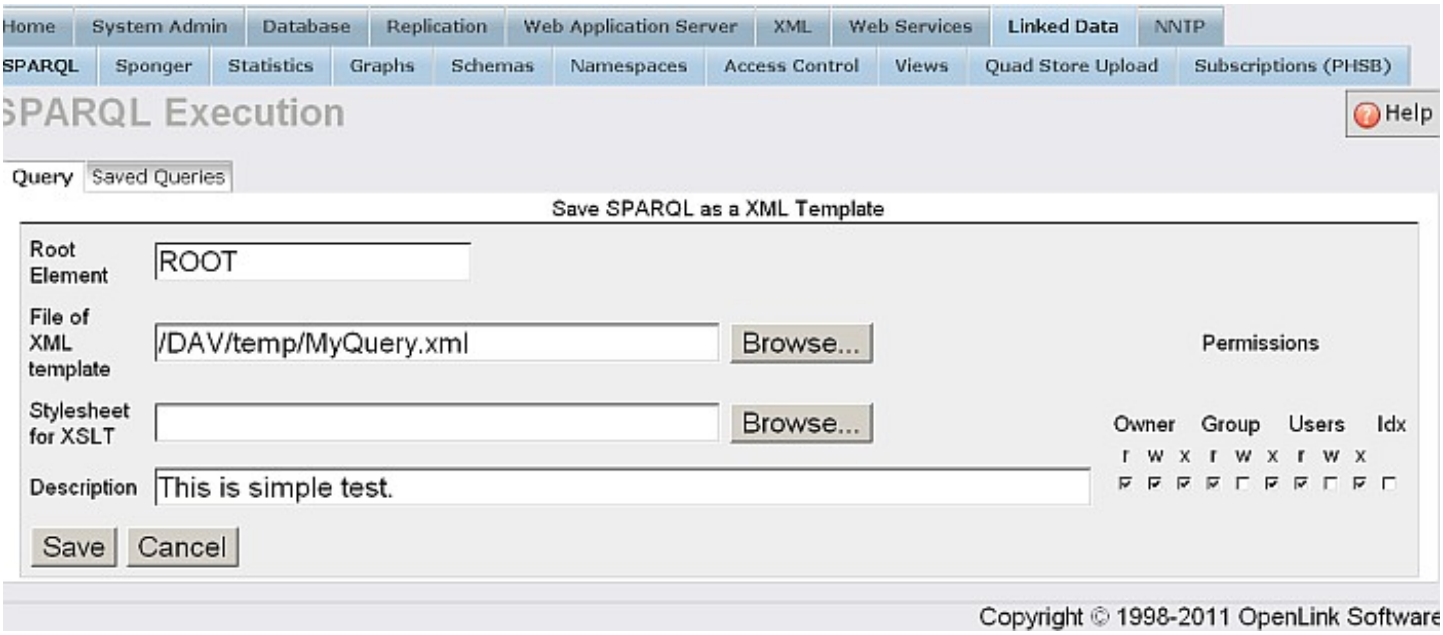
"SPARQL -> Query" offers form form SPARQL query execution:

Figure 6.155. RDF



Also you can save the results in a query or load such:

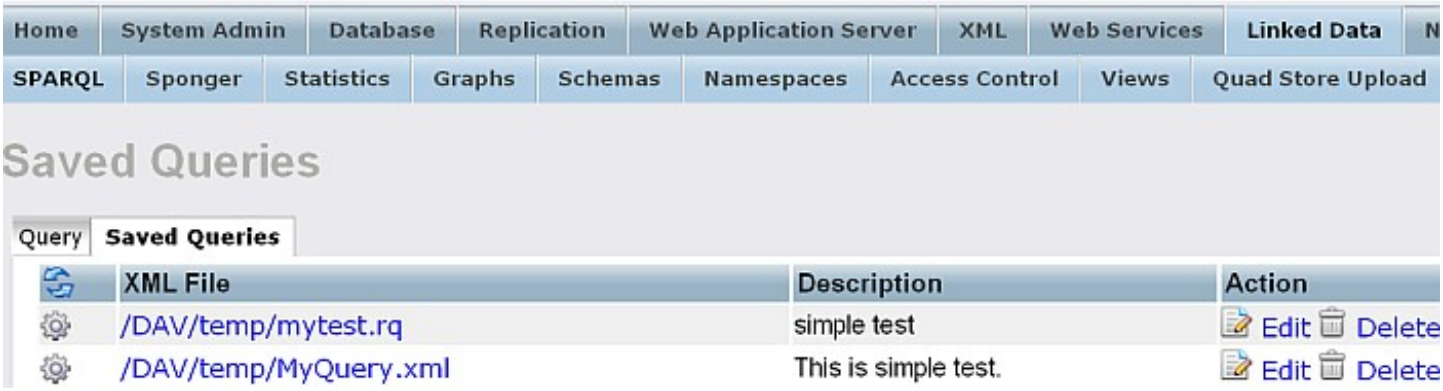
Figure 6.156. RDF



Saved Queries

"SPARQL -> Saved Queries" offers list of saved queries, which can be opened in the "Query" tab in order to be executed:

Figure 6.157. RDF

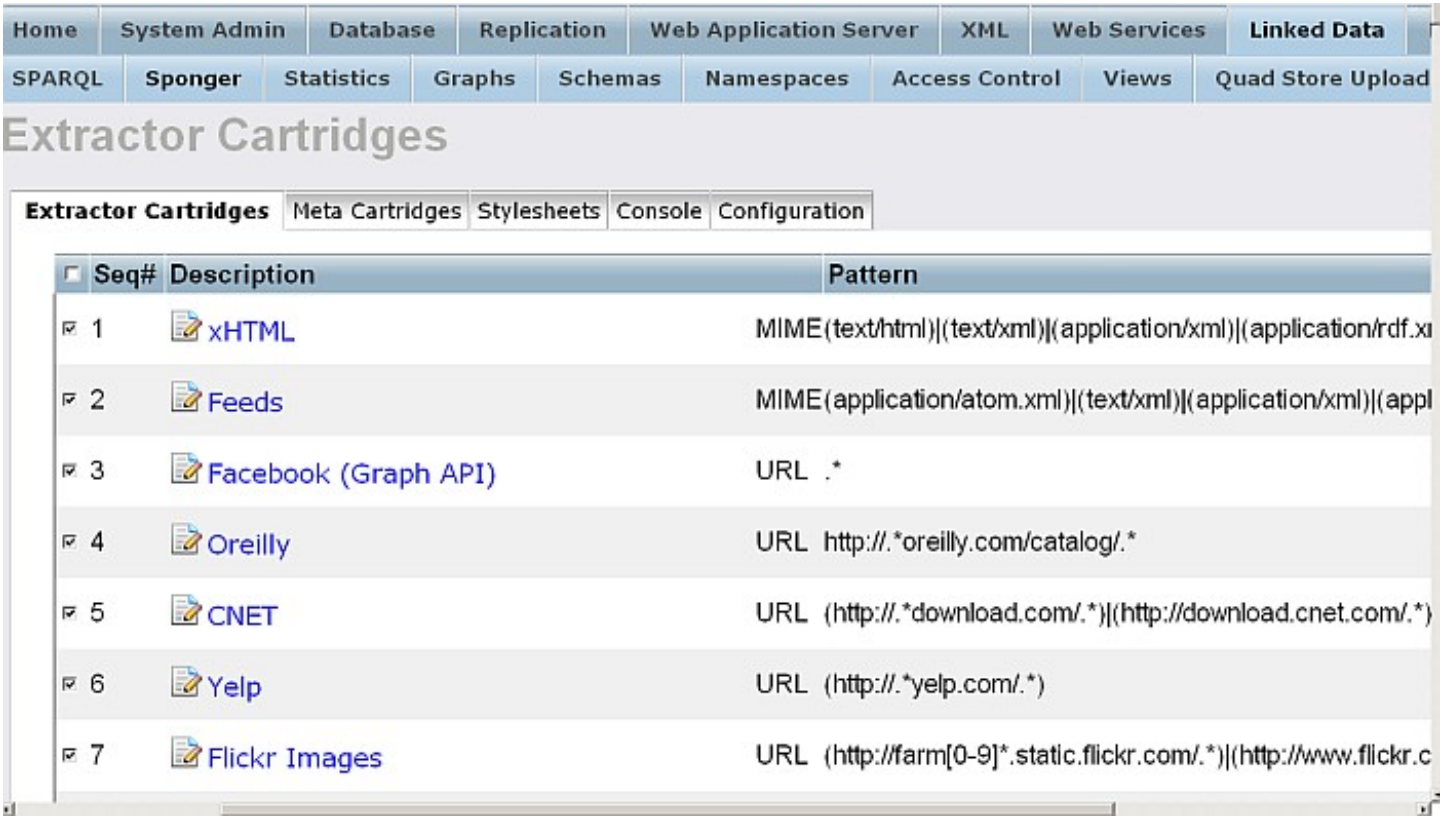


Sponger

Extractor Cartridges

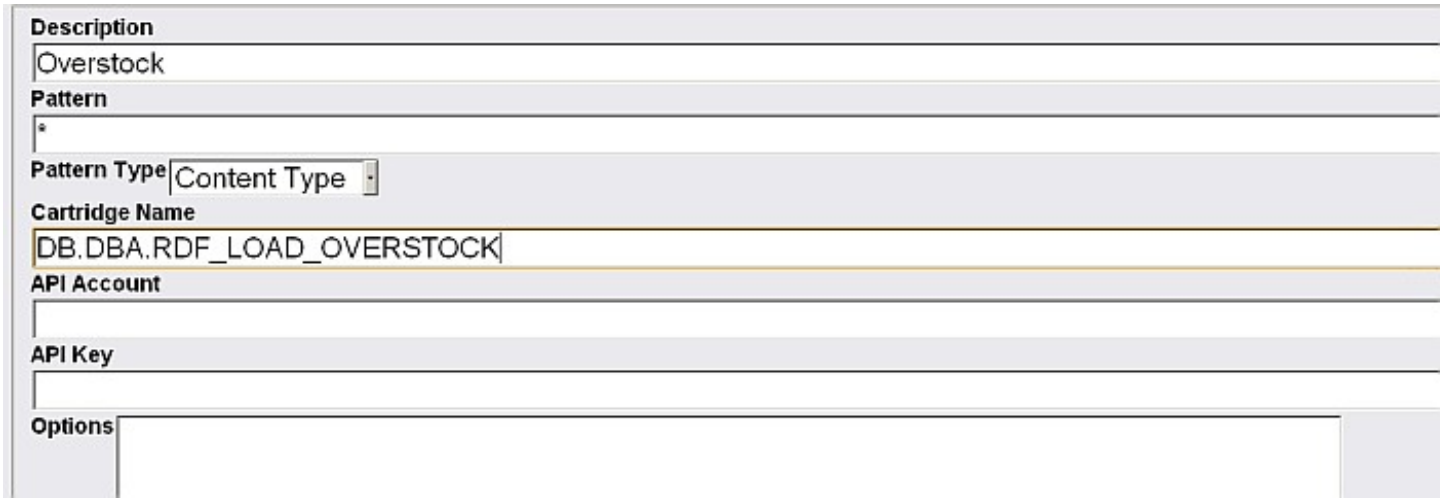
Shows list of available extractor cartridges. They can be re-ordered by place of appearance, edit or deleted:

Figure 6.158. RDF



You can also add a new extractor cartridge:

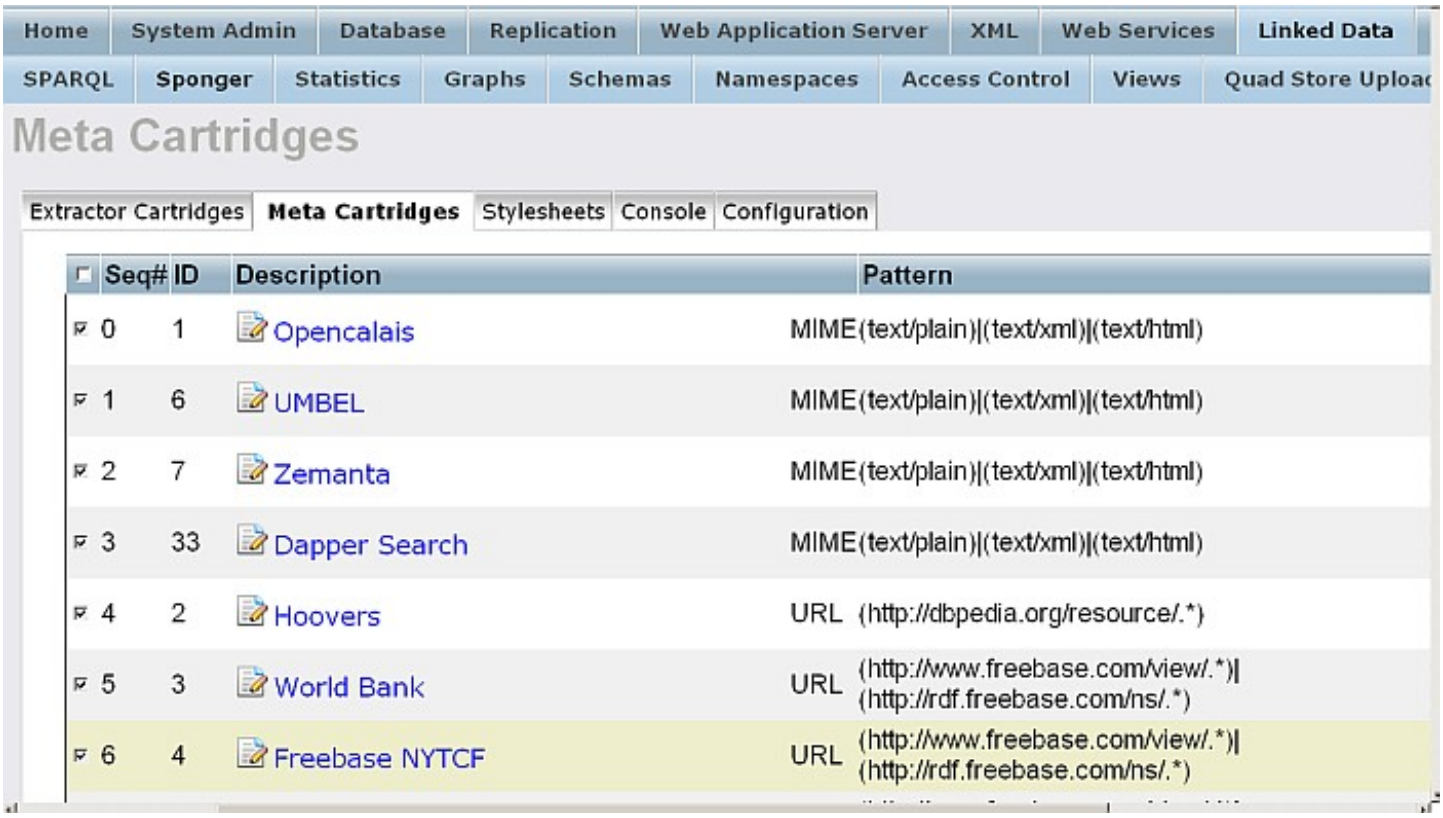
Figure 6.159. RDF



Meta Cartridges

Shows list of available meta cartridges. They can be re-ordered by place of appearance, edit or deleted:

Figure 6.160. RDF



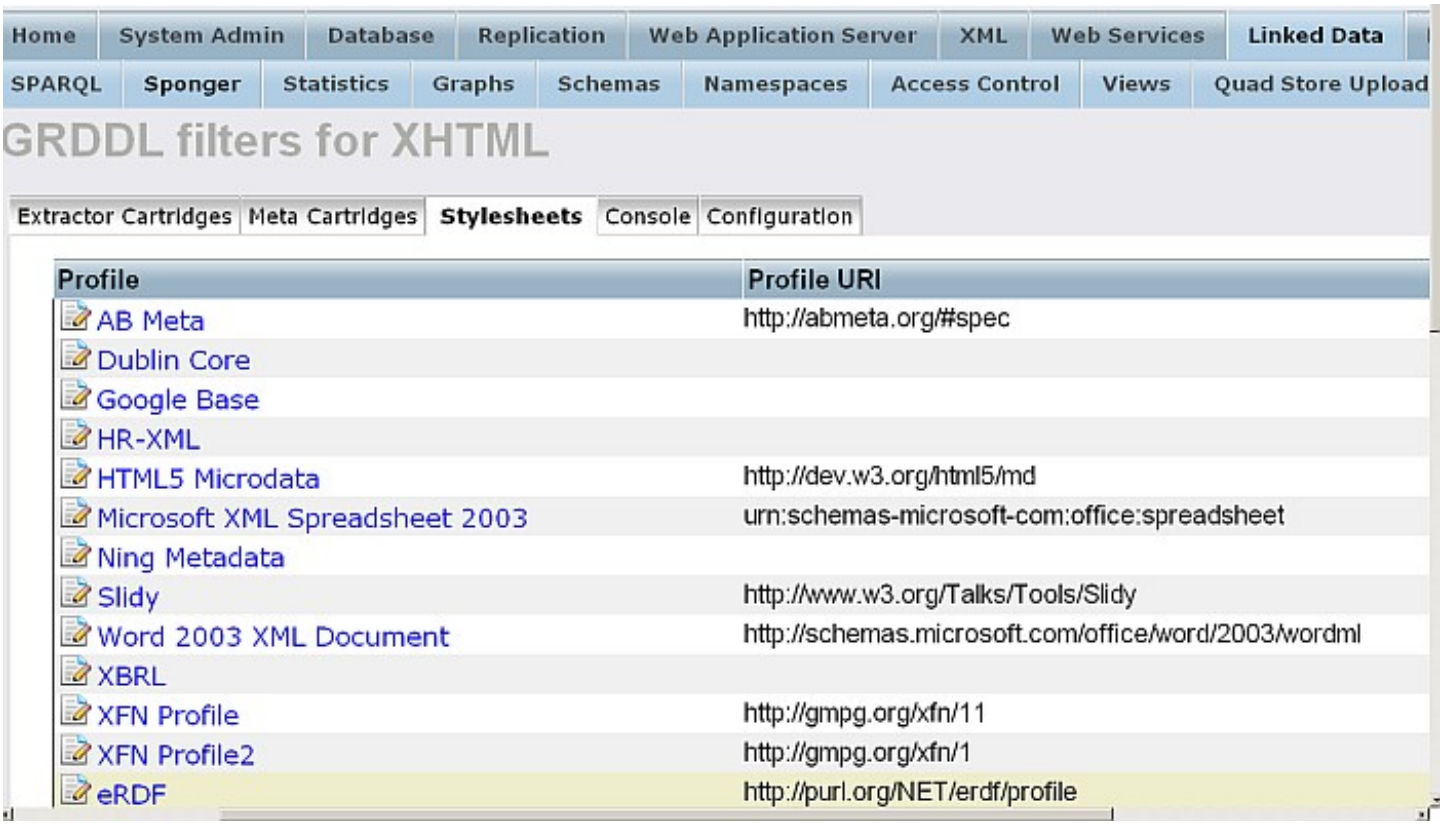
You can also add a new meta cartridge:

Figure 6.161. RDF

Stylesheets

Shows list of available stylesheets for processing cartridges. From here you can manage these stylesheets by adding new, editing existing ones or deleting them:

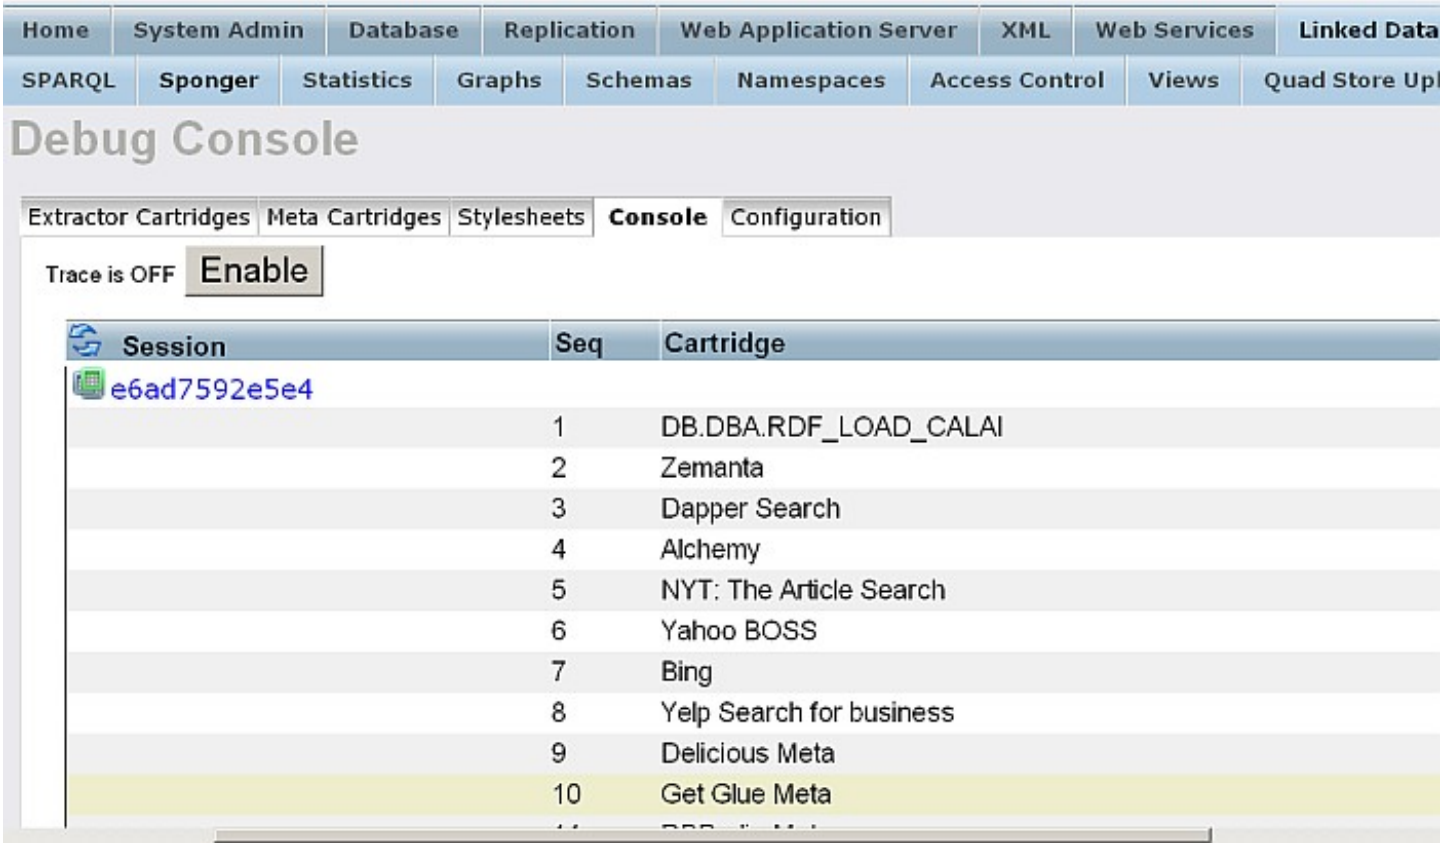
Figure 6.162. RDF



Console

Offers tracking cartridges exection. By default is off. When enabled, shows list of sessions per cartridge:

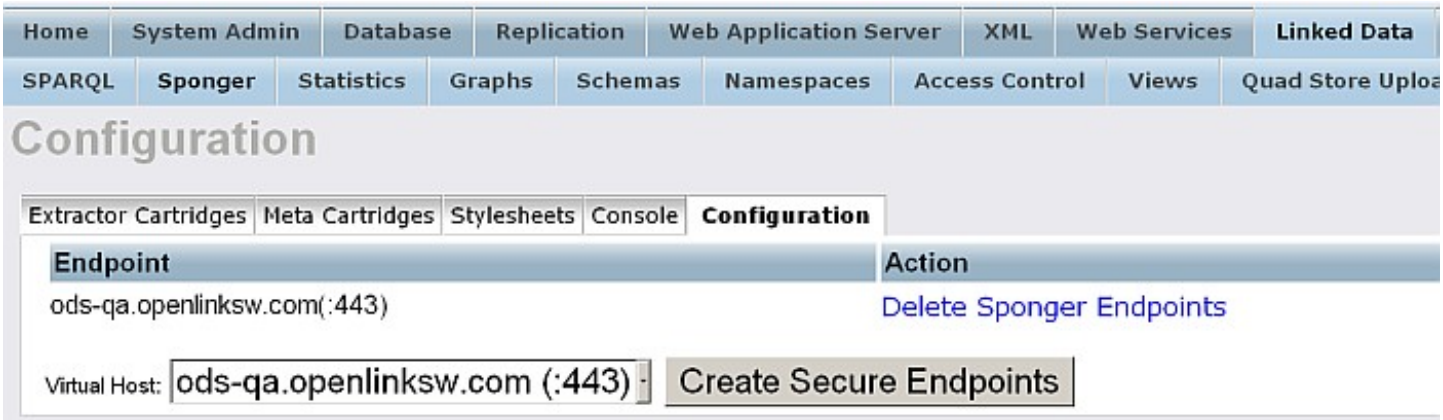
Figure 6.163. RDF



Configuration

Offers creation of secure endpoints for pre-defiend vitual host:

Figure 6.164. RDF



Statistics

Offers interface for `DB.DBA.RDF_VOID_STORE(graph, to_graph)` . In the new graph (field "Publish to") will be saved the VoID statistics data when generated:

Figure 6.165. RDF

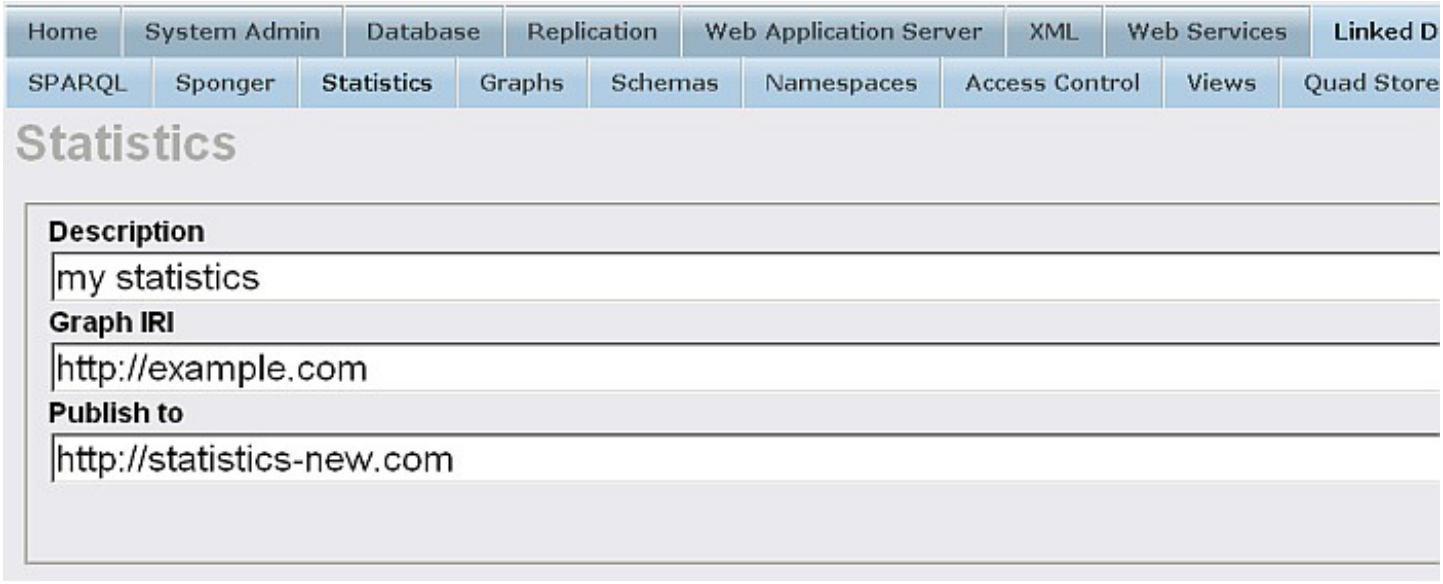


Figure 6.166. RDF

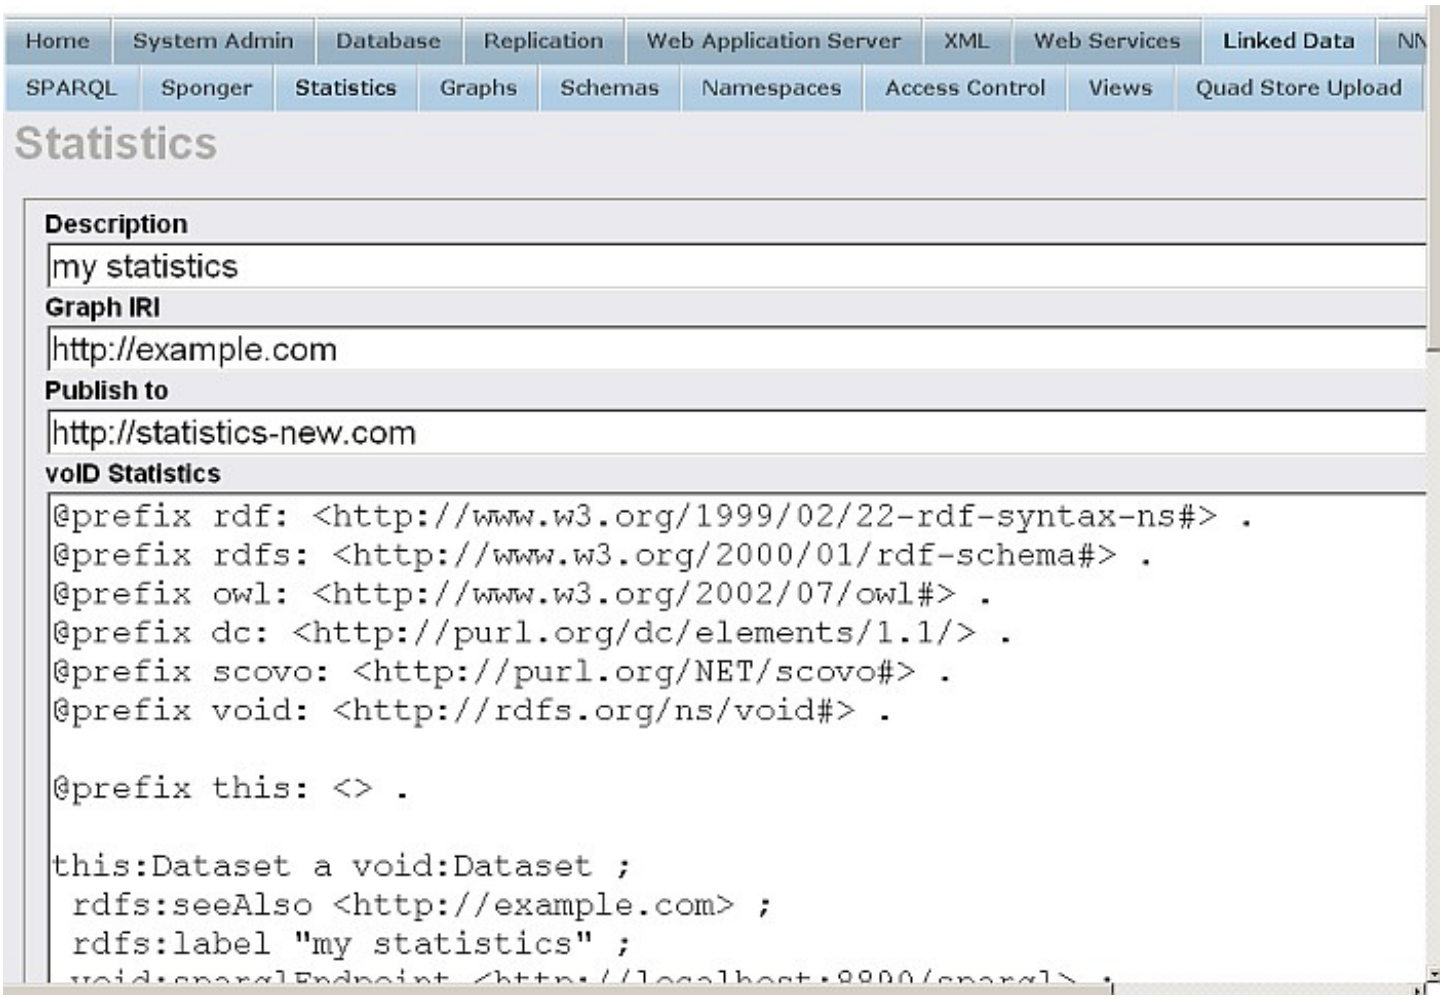
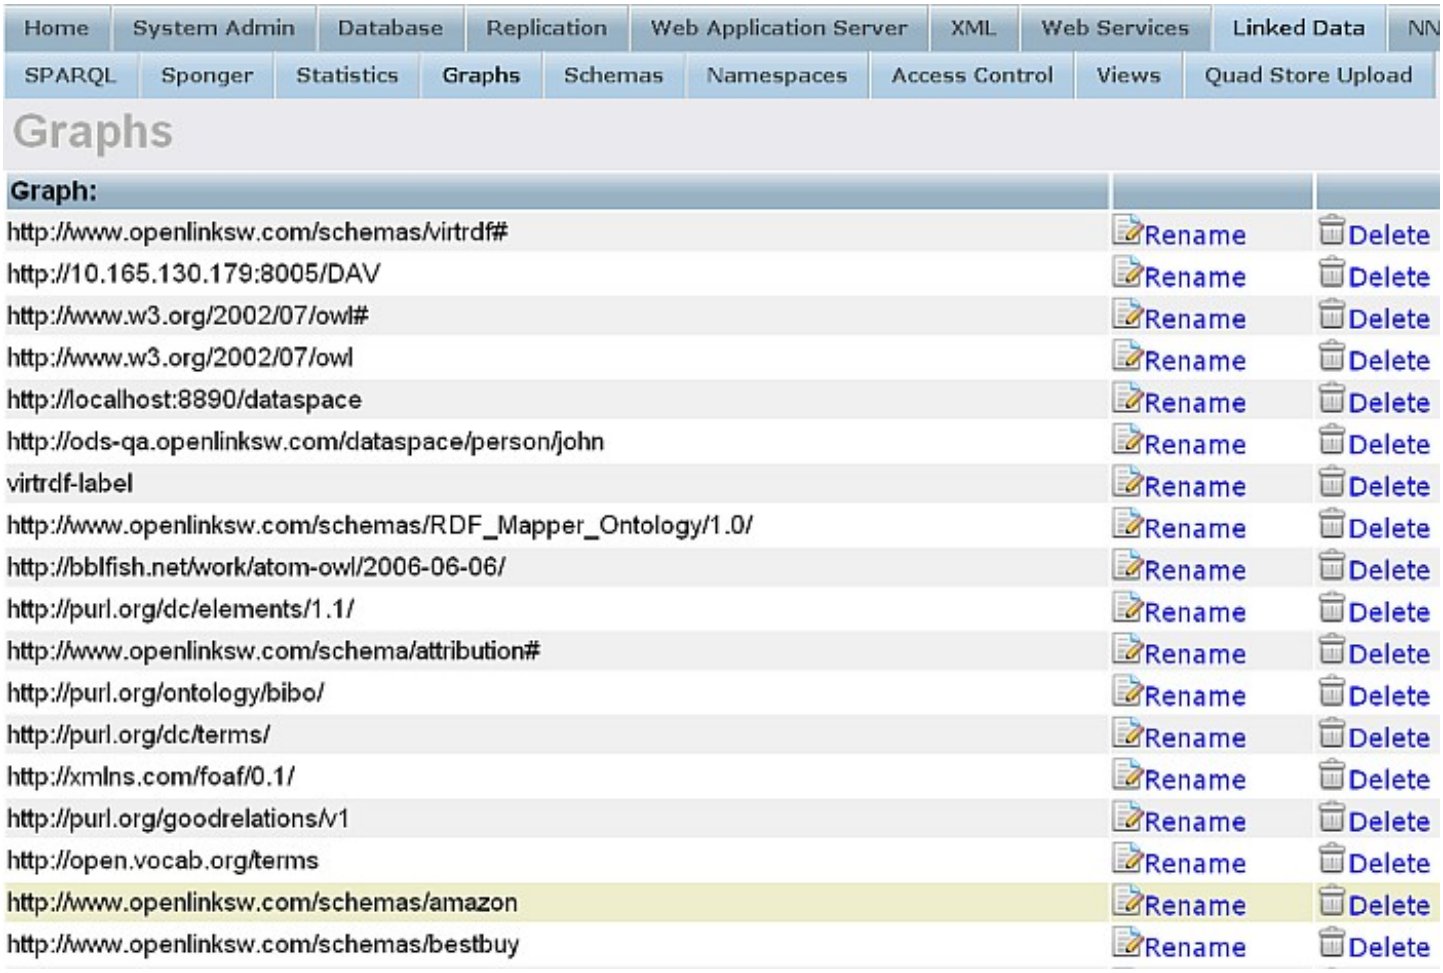


Graphs

"Graphs" tab shows list of current graphs in the RDF Quad Store. From here day can be renamed or deleted:

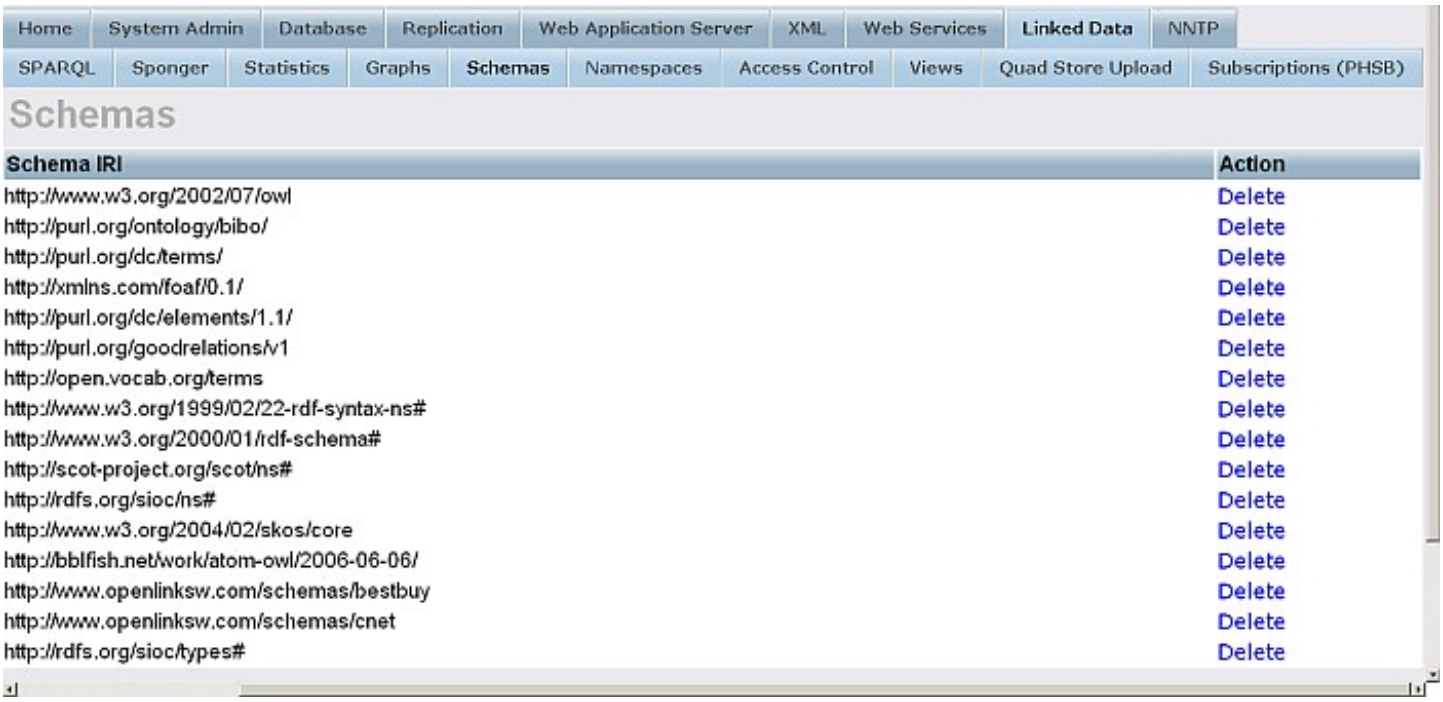
Figure 6.167. RDF



Schemas

Shows list of available schemas IRI-s and offers a new schema IRI to be imported:

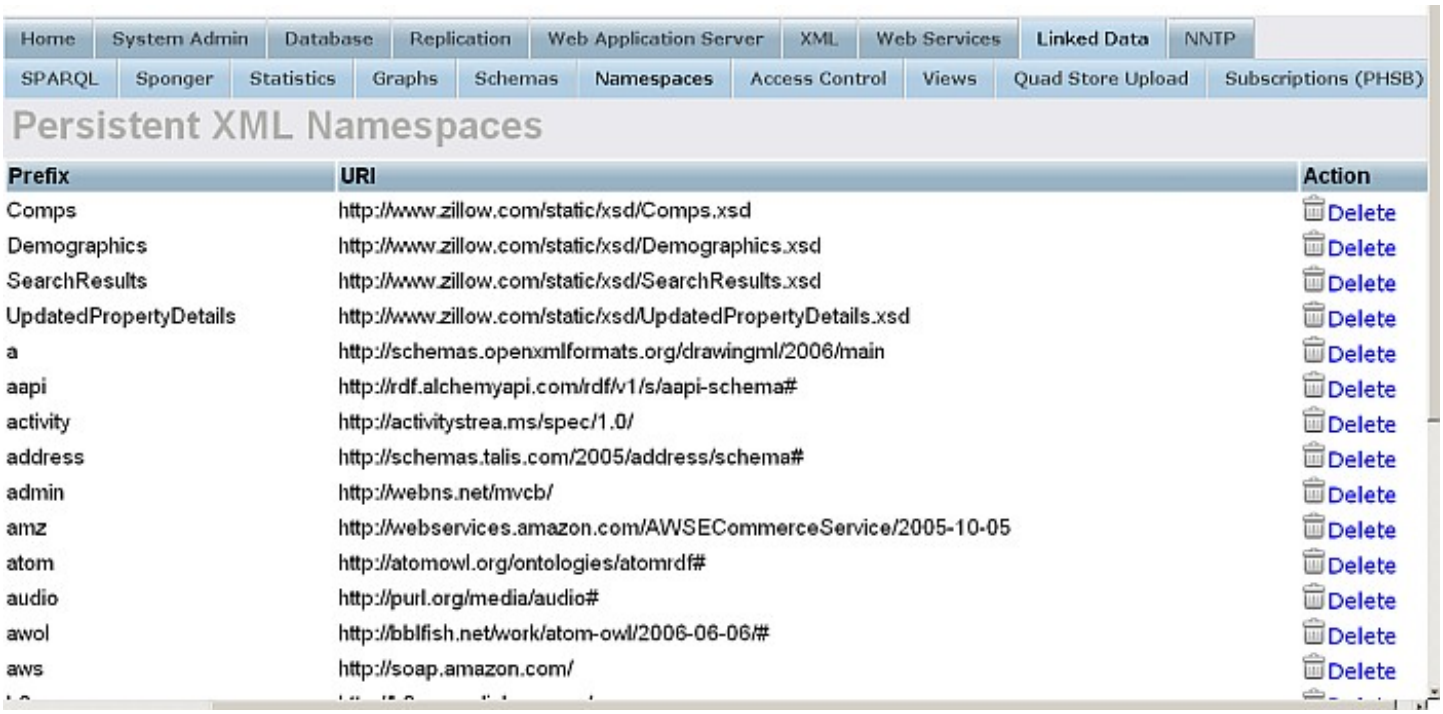
Figure 6.168. RDF



Namespaces

Shows list of namespace prefixes and offers a new namespace prefix to be imported:

Figure 6.169. RDF



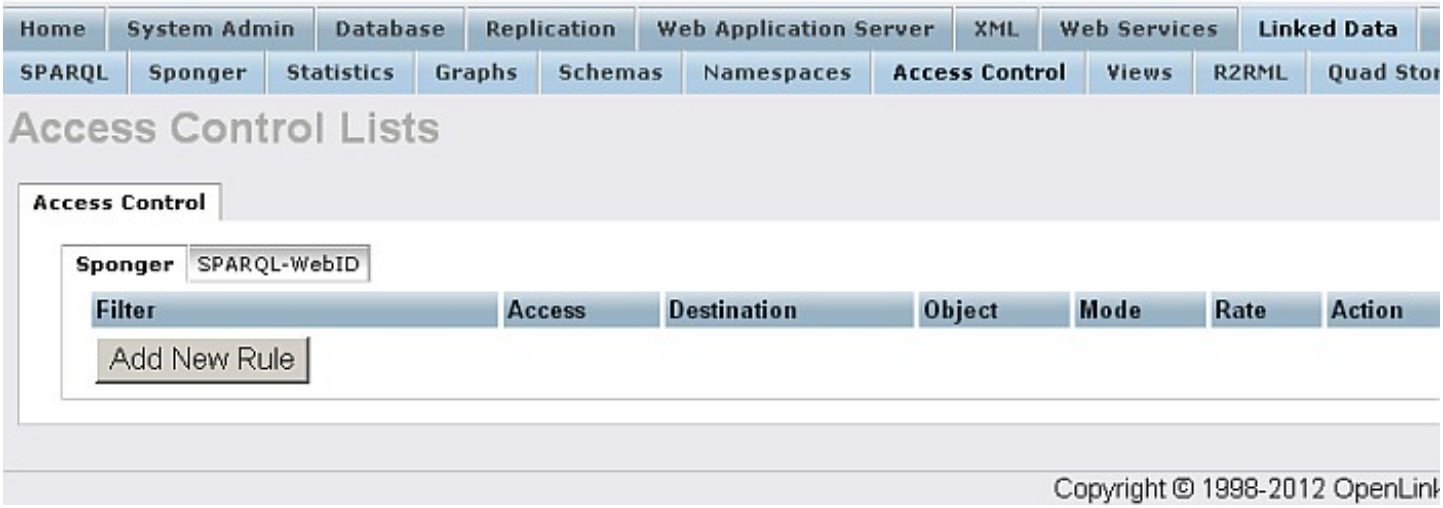
Access Control

Sponger

Manage Sponger rules by adding new ones, deleting, re-ordering, etc.

This tab is available only when the cartridges_dav.vad is installed.

Figure 6.170. RDF



SPARQL-WebID

Here you can manage different WebID Protocol ACLs WebID ACL by granting SPARQL Roles such as "SELECT", "UPDATE", "SPONGE":

This tab is available only when the policy__manager_dav.vad is installed.

Views

Virtuoso uses a SPARQL-based Meta Schema Language to provide RDBMS-to-RDF mapping functionality (also described as, Linked Data Views of SQL data). The language is an extension of the SPARQL query language meshed with Virtuoso's SPASQL (SPARQL-inside-SQL) functionality. The language enables you to declaratively map relational database schema tables, columns, rows, and foreign key relationships to Classes, Attributes, Relationships, and Instances (Objects/Entities/Individuals) defined by RDF Schemas or OWL Ontologies. The mapping process uses a special built-in Virtuoso function to generate IRIs / URIs in "Subject" or "Object" position of a SPARQL graph pattern, en route to building a set of SQL compiler rules and optimizations for translating SPARQL queries into SQL on the fly.

6.2.11. Conductor News Server Administration

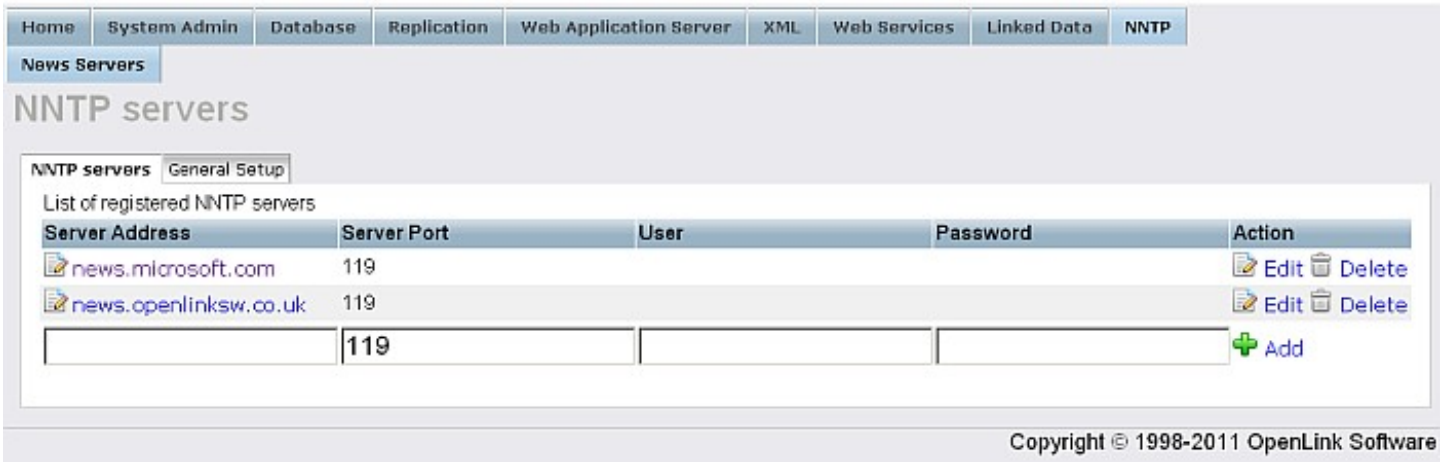
Conductor Newsgroups Administration

From Conductor the NNTP tab allows you to view and configure Newsgroups associated with the Virtuoso News Server. Like Virtuoso's virtual database, Virtuoso can "link" in newsgroups from remote news servers. This interface allows you to view the configuration and control the newsgroups both local and remote.

The Virtuoso News server component will need to be enabled in the Virtuoso.ini file by specifying the NewsServerPort number.

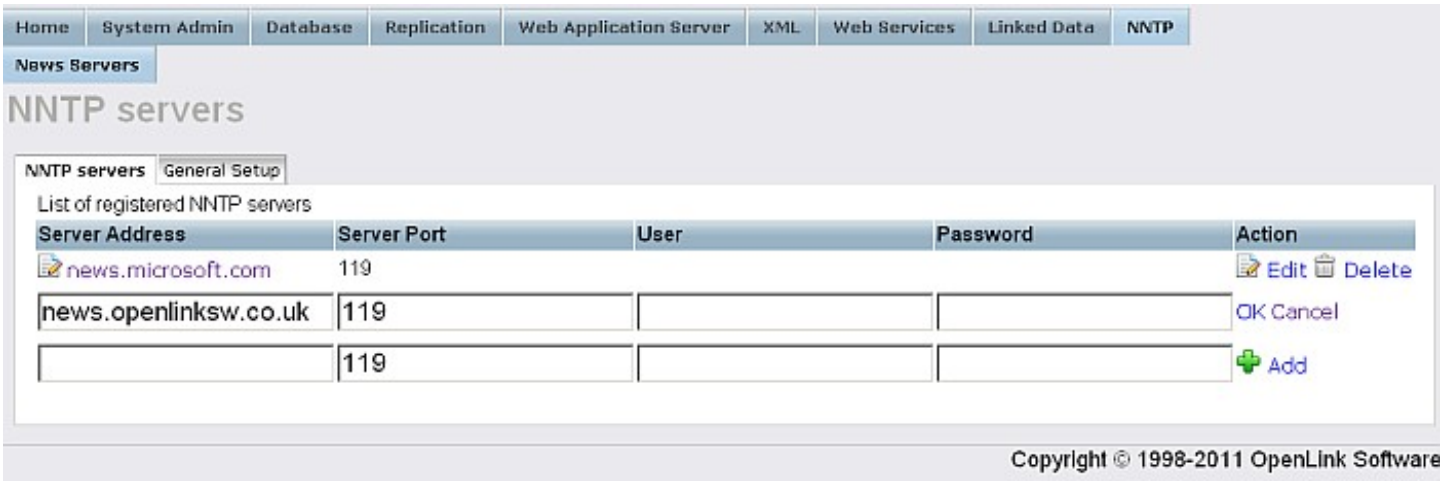
The tab "NNTP Servers" shows list of the registered News servers.

Figure 6.175. News Server Administration



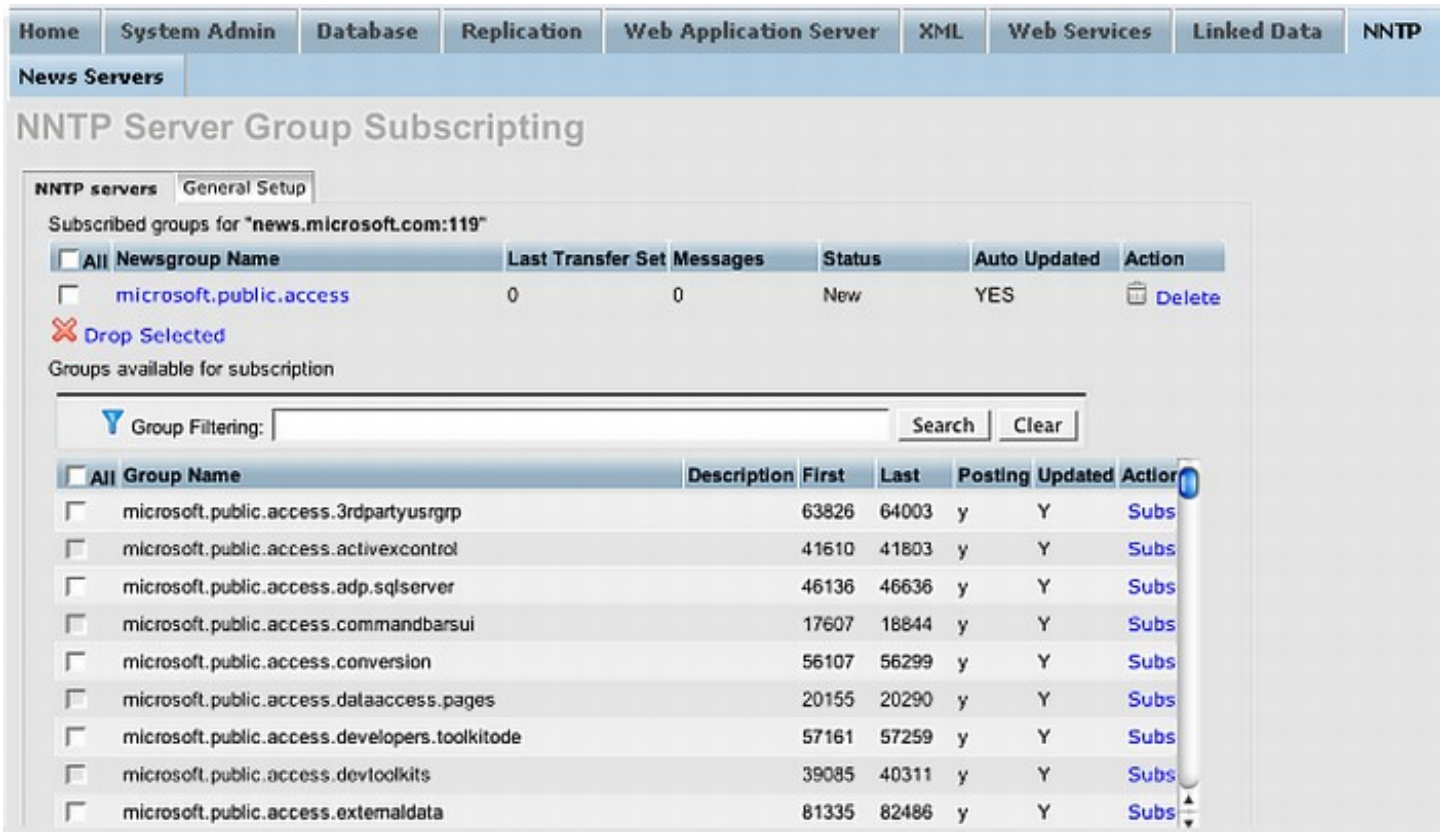
Click the "Edit" link to change the news server settings, or click the "Delete" link to remove the news server.

Figure 6.176. Edit News Server Properties



Click the "Edit Groups" link for a current News Server in order to manage the list of available newsgroups.

Figure 6.177. News Groups List



You can also *update* the cache list of newsgroups. Newsgroup names are (re)fetched in a batch background scheduled task. This is because the list can be very long or the connection to the news server could be slow. The status of the fetch is indicated in the grey bar at the foot of the newsgroup list table.

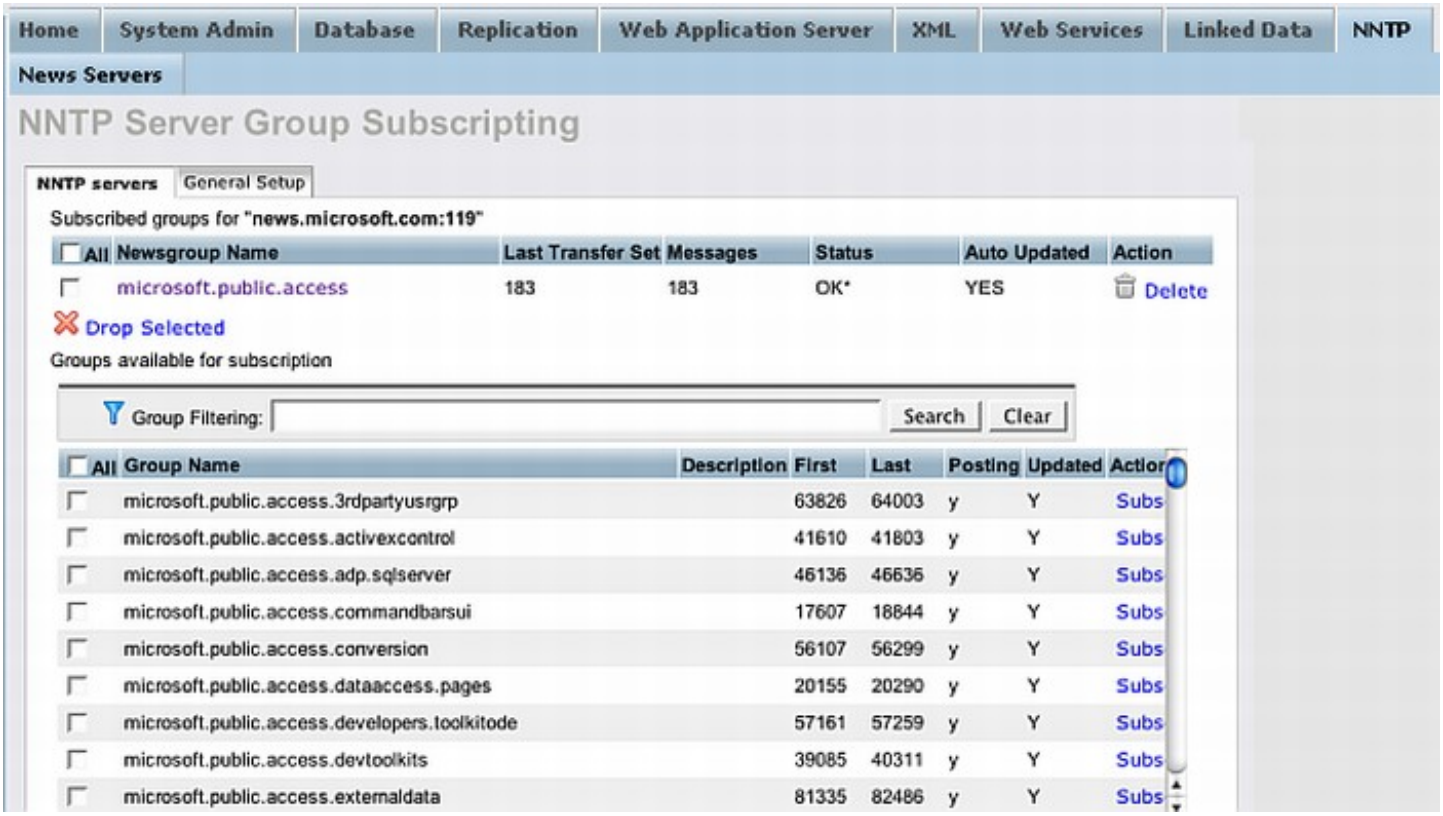
For each newsgroup listed for a news server you can *update* the messages fetched, view and edit the *Properties* of the group, or *Remove* the group from the list. Also you can get previous 500 messages or to get new messages by clicking the links at the bottom of the form shown below.

Figure 6.178. Manage subscribed for Newsgroup

Add Newsgroup

From the "NNTP Servers" tab click on the "Edit Groups" link for a registered News Server. Then click the *Subscribe to newsgroups* link to subscribe to newsgroups on the server.

Figure 6.179. Add Newsgroup



Once groups are selected you can use the *Subscribe Selected* button to add the groups.

Use the *Back to servers list* link to return to the News Servers List page.

Adding New News Server

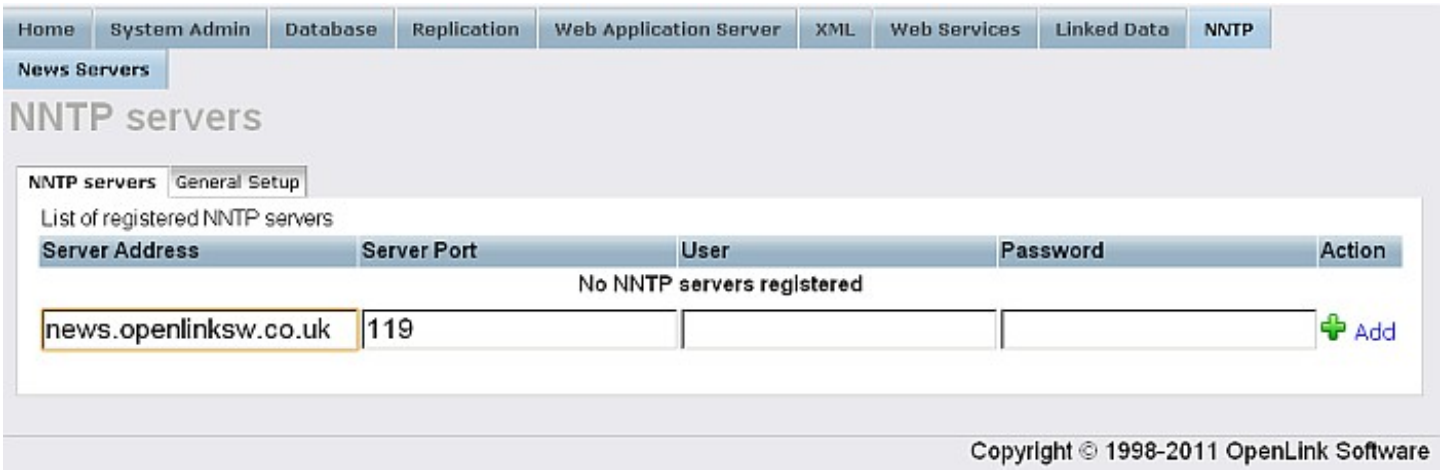
From Conductor NNTP/NNTP Servers you can add remote servers. The values you need to provide in the form are as follows:

Server Address is the IP address or hostname of the external news server.

Server Port is the port number that the news server is listening on. By default news servers listen on port 119.

Username and *Password* allow you to provide login credentials if the server requires them.

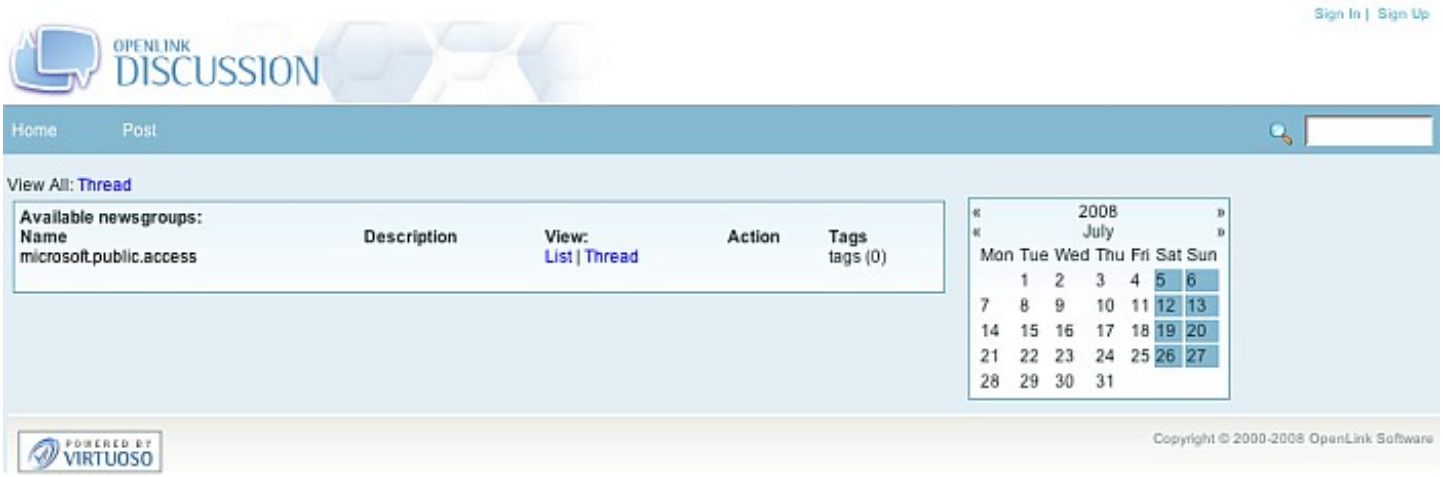
Figure 6.180. News Server Administration



Viewing Newsgroups

You can view the messages of a newsgroup either using the Conductor UI going to NNTP/NNTP Servers/News Server/News Group, or using the ODS Framework UI. In the second case you need to have the ods_framework_dav.vad package and the ods_discussion_dav.vad package installed. Then you can go from ODS to tab "Discussions" where will be shown the list of available newsgroups. Each one has shown as link its name, which leads to page where are listed its messages.

Figure 6.181. View of messages in a newsgroup in ODS Discussions.



News Message Free Text Search

You can perform Free Text Search using the ODS search option.

6.3. Virtuoso Cluster Operation

Abstract

This chapter describes setting up and operating Virtuoso on a cluster of computers. The section on Virtuoso cluster programming documents the SQL extensions specific to cluster application development.

These sections apply to Virtuoso as of version 6.0.

Clustering primarily offers greatly increased scalability for large databases without requiring application changes. The database is divided over a number of servers, of which all provide transparent access to the same data.

6.3.1. General

Virtuoso can be run in cluster mode where one logical database is served by a collection of server processes spread over a cluster of machines.

The cluster's composition is declared in a cluster.ini file which is to be in the starting directory of each of the servers composing the cluster. This file declares the hosts and listening ports of all processes composing the cluster and which of these processes is the local process and which the master.

A cluster has a single master process which is the only one allowed to run DDL operations and which is responsible for distributed deadlock resolution. In all other respects, all server processes of the cluster are interchangeable.

The set of processes declared in the cluster.ini files is called the physical cluster.

Each cluster server process has its own database and log files and is solely responsible for these. All configuration fields in virtuoso.ini and related files apply to the process whose ini file this is and their meaning is not modified by clustering.

Specifically, the SQL client and HTTP and other listening ports of each process are declared as usual and are used as usual. A cluster server process has additionally a cluster listening port that is used for cluster communications. This may not be connected to by anything except other processes of the same physical cluster. The cluster listener ports of all processes are declared in cluster.ini and all processes must specify the same information.

cluster.ini fields

The below is a sample cluster.ini file declaring a physical cluster of 4 processes.

```
[Cluster]
Threads = 100
ThisHost = Host1
Master = Host1
ReqBatchSize = 100
BatchesPerRPC = 4
BatchBufferBytes = 20000
LocalOnly = 2

Host1 = box1:2222
Host2 = box2:2223
Host3 = box3:2224
Host4 = box4:2225

Host1-1 = box1-1:12222
Host2-1 = box2-1:12223
Host3-1 = box3-1:12224
Host4-1 = box4-1:12225
```

The lines Host1 ... Host4 declare the listening ports of each process. The line ThisHost = 1 declares that this process is Host1, hence cluster listener at box1:2222 box1 - box4 and box1-1 - box4-1 are machine names that must be resolvable in the local context. IP numbers can also be used. Mentioning a host several times declares additional interfaces for the host. Any of these interfaces may be used for cluster connection to the Virtuoso server at the host. Thus Host1 = gives the first interface, Host1-1 the second and so on. This is useful since servers most often have multiple network interfaces and Virtuoso balances the traffic among these interfaces if multiple interfaces are provided. Each host will listen at all the host:port numbers mentioned and other hosts will decide which interface to use based on load.

The Threads line gives the maximum number of threads that will be made for serving requests from other hosts of the cluster. This is in addition to any other threads reserved in any other ini files.

The Threads line gives the maximum number of threads that will be made for serving requests from other hosts of the cluster. This is in addition to any other threads reserved in any other ini files.

The other fields should be left at the values shown.

6.3.2. Setting up a Cluster

To make a new empty clustered Virtuoso database, set up the individual instances. The processes must be of exactly the same version, the operating systems, byte orders or word lengths of the participating machines do not have to match.

Each individual database is assigned its database files and other configuration by editing its virtuoso.ini file. No installation besides having the Virtuoso executable and the virtuoso.ini file is needed.

If there is a Virtuoso installation on the machine, use the executable from that and set up an empty directory with the virtuoso.ini file.

Once the individual database directories are set up, write the cluster.ini file as shown above. Copy this into each running directory beside the virtuoso.ini file. Edit each to specify which host the file belongs to. Set ThisHost to point to the host which the this file belongs. Set Master to point to one of the hosts and make sure each file has the same master and a distinct ThisHost.

Start the server processes. This will initialize the empty databases.

Connect to the master host's SQL port with a SQL client to continue. The initial default user and password is dba. To verify that the cluster nodes can connect to each other, do status (''); twice. The second status should have a line beginning with Cluster xx nodes.

6.3.3. Using Clustering with an Existing Database

The procedure for converting a single server database into a clustered one will be specified later. For 6.0, there is no automatic way of doing this.

One can take an existing database and convert it to clustered operation by copying the initial database to each node of the cluster. Set up the database so that each node would run an identical copy. Then make the cluster.ini files.

Start the servers. Connect to the master and run the partitioning statements for all keys of all tables that are to be managed by the cluster.

At this point, each database will also hold rows that are not its responsibility, unless of course all tables are declared as replicated. The rows that are present and do not fall in the partition managed by the host should be deleted.

This can be done with a stored procedure to be supplied later

6.3.4. Partitioning

All databases in a cluster share precisely the same schema. Any DDL operations take effect on all nodes simultaneously.

The tables can be of one of three types:

- Partitioned: A row of a partitioned table resides in exactly one partition, according to the values of its partitioning columns. Each partition is stored at least once in the cluster but may be kept in multiple replicas if so configured. All indices of a partitioned table must specify partitioning but need not be partitioned in the same way. The data tables of an application will typically be partitioned.
- Replicated: The table and its contents exist in identical form on all nodes. Queries are answered from local data and updates go to all nodes. This is the case with schema tables, for example but can be used for application tables also.
- Local: The table exists on all nodes but each node has purely local content and all queries and updates to the table refer only to local content. This is the case for some configuration tables with only local scope, such as specifying web service end points.

Partitioning an index means that different hosts store different parts of the index. For each partitioned index one or more partitioning columns must be declared. Also each partitioned index is always held in its totality in a logical cluster. A logical

cluster is a subset of the machines composing the physical cluster declared in cluster.ini. Usually the logical and physical cluster are the same.

The logical cluster additionally declares how partitions are to be replicated. It is namely possible to declare that a specific partition be stored in multiple identical copies.

There are two predefined logical clusters: REPLICATED and __ALL. If a table's indices specify the REPLICATED cluster in their partitioning declaration, the data will be maintained in identical copies on all nodes.

The __ALL cluster is the default logical cluster for any partitioned table. Using this, each row will go to exactly one place, balanced over the set of nodes declared in the cluster.ini file.

Basic applications do not need to declare their own cluster since the default one is most often applicable.

CREATE CLUSTER Statement

```
CREATE CLUSTER <name> DEFAULT <group>[ [,...]

group: GROUP (<host>[,...])
```

A logical cluster has a single global name and it consists of one or more host groups. Each host group is given a partition of whatever object that is stored in the logical cluster. Each host of a host group replicates the partition assigned to this host group.

One logical cluster is predefined. It is called replicated and it consists of one group which has all the hosts of the physical cluster. The replicated logical cluster is used for storing any schema tables. This causes all schema information to be identically stored on all nodes of the physical cluster.

If a table is created on a clustered Virtuoso and no partitioning is declared, the table exists on all nodes with independent content on each. This is generally not desirable since the same query will return different data depending on which host runs it.

For performance, it is best to replicate any short, seldom changing lookup tables on all hosts.

Example

```
create cluster C2 default group ("Host1"), group ("Host2"), group ("Host3"), group ("Host4") ;
```

This would declare a logical cluster identical to the default __ALL cluster if the cluster.ini specified hosts 1 - 4.

The REPLICATED cluster could be declared as follows:

```
create cluster C3 default group ("Host1", "Host2", "Host3", Host4");
```

ALTER INDEX and CREATE INDEX Statements and Partitioning

The ALTER INDEX statement is used for declaring the partitioning of an index. For a non-primary key index, the corresponding CREATE INDEX can also declare the partitioning. If one index of a table is partitioned, all indices of the table must be partitioned. If no partitioning is declared, the table will exist on all nodes but will have independent content on each. Partitioning of a key must be set when the key is empty. Thus, to create a partitioned table, first create the table and declare partitioning for its primary key.

The name of the primary key index is the same as that of the table. If the table has no explicit primary key, it has an implicit one, named after the table and having the invisible _IDN column as single key part. This may be used as a partitioning key.

If clustering is not enabled, partitioning can still be declared but it will have no effect. Thus a single application DDL file can be used for clustered and single process versions of the application schema.

```
ALTER INDEX <index-name> ON <table-name> PARTITION [CLUSTER <cluster-name>] (<col-spec>[,...])

col-spec : <column-name> <type> [<options>]

type: INT | VARCHAR

options: (<mask>) | (<length>, <mask>)
```

The PARTITION declaration may occur at the end of a create index statement. This causes the index to be created, partitioned and then filled. Otherwise it would not be possible to add indices to non-empty tables.

All or part of a partitioning column's value can be used for calculating a index entry hash which then determines which host group of the logical cluster gets to store the index entry. There are two types of hashing, integer and varchar. Integer applies to integer like types such as integer and bigint and iri id and varchar applies to anything else. Floating point columns or decimals should not be used for partitioning. Large objects or UDT's cannot be used for partitioning.

For an integer partitioning, the mask is a bitmask applied to the number before extracting the part that is used for the hash. A mask of 0hexffff00 will use the second and third least significant bytes for hashing, thus values 0-255 will hash to the same, values 256-512 to the same and so on. The value 0hex1000000 will again hash to the same as 0.

Having consecutive integers hash to the same will cause them to go to the same host group and become physically adjacently which is good for key compression. If no mask is specified 0hexffff is used, meaning that each consecutive number gets a different hash, based on the low 16 bits of the number.

For a varchar partitioned column, the default is to calculate a hash based on all bytes of the string. For purposes of key compression, it may be good to put strings with a common prefix in the same partition.

The option consists of two integers, the length and the mask. If the length is positive, the length first characters are used for the hash. If the string is shorter than length, all characters are used. If the length is negative, we take the absolute value of the length and use all bytes of the string except the length last ones. If the string is shorter than -length, all the bytes are used. A length of -1 means to use all bytes except the last one, a length of 2 means to use the 2 first characters only.

The string's hash value is a large integer. The mask controls how many bits of this hash are used for the hash of the index entry.

Example

```
create table part (id int, code int, str varchar);
alter index part on part partition (id int (0hexffff00));

create index str on part (str) partition (str varchar (-1));
-- for the primary key, hash all values differing in the low byte together.
-- for str, hash all values differing only in the last character together.

create table part_code (code int primary key, description varchar);
alter index part_code on part_code cluster replicated;
```

This declares a lookup table for describing the values of the code column of the part table. This is replicated on all nodes of the cluster. Note that no partitioning columns need be specified since no matter the partition key the row would end up on all nodes regardless.

6.3.5. Transactions

A Virtuoso cluster is fully transactional and supports the 4 isolation levels identically with a single server Virtuoso. Transactions are committed using single to two phase commit as may be appropriate and this is transparent to the application program.

Distributed deadlocks are detected and one of the deadlocking transactions is killed, just as with a single process.

Transactions are logged on the cluster nodes which perform updates pertaining to the transaction.

A transaction has a single owner connection. Each client connection has a distinct transaction. From the application program's viewpoint there is a single thread per transaction. Any parallelization of queries is transparent.

For roll forward recovery, each node is independent. If a transaction is found in the log for which a prepare was received but no final commit or rollback, the recovering node will ask the owner of the transaction whether the transaction did commit. Virtuoso server processes can provide this information during roll forward, hence a simultaneous restart of cluster nodes will not deadlock.

Performance Considerations

A lock wait in a clustered database requires an asynchronous notification to a monitor node. This is done so that a distributed deadlock can be detected. Thus the overhead of waiting is slightly larger than with a single process.

We recommend that read committed be set as the default isolation since this avoids most waiting. A read committed transaction will show the last committed state of rows that have exclusive locks and uncommitted state. This is set as DefaultIsolation = 2.

In the parameters section of each virtuoso.ini file.

Row Autocommit Mode

Virtuoso has a mode where insert/update/delete statements commit after each row. This is called row autocommit mode and is useful for bulk operations that need no transactional semantic.

The row autocommit mode is set by executing log_enable (2) or log_enable (3), for no logging and logging respectively. The setting stays in effect until set again or for the duration of the connection. Do not confuse this with the autocommit mode of SQL client connection.

In a clustered database the row autocommit mode is supported but it will commit at longer intervals in order to save on message latency. Statements are guaranteed to commit at least once, at the end of the statement.

A searched update or delete statement in row autocommit mode processes a few thousand keys between commits, all in a distributed transaction with 2PC. These are liable to deadlock. Since the transaction boundary is not precisely defined for the application, a row autocommit batch update must be such that one can distinguish between updated and non-updated if one must restart after a deadlock. This is of course not an issue if updating several times makes no difference to the application.

Naturally, since a row can be deleted only once, the problem does not occur with deletes. Both updates and deletes in row autocommit mode are guaranteed to keep row integrity, i.e. all index entries of one row will be in the same transaction.

Naturally, since a row can be deleted only once, the problem does not occur with deletes. Both updates and deletes in row autocommit mode are guaranteed to keep row integrity, i.e. all index entries of one row will be in the same transaction.

A row autocommit insert sends all keys of the row at once and each commit independently. Hence, a checkpoint may for example cause a situation where one index of a row is in the checkpoint state and the other is not.

Thus, a row autocommit insert on a non-empty application table with transactional semantic is not recommended. This will be useful for bulk loads into empty tables and the like, though.

6.3.6. Administration

The cl_exec function

All administrative operations other than data definition take effect on the node to which they are issued.

```
cl_exec (in cmd varchar, in params any := NULL, in is_txn := 0)
```

The cl_exec() SQL function can be used for executing things on all nodes of a cluster.

The cmd is a SQL string. If it contains parameter markers (?), the params array is used for assigning values, left to right. If is_txn is 1, the cl_exec makes a distributed transaction and does not automatically commit on locally on each node. Thus cl_exec() can be used as part of a containing distributed transaction.

Example

```
cl_exec ('shutdown')
--will shut all nodes.

cl_exec ('dbg_obj_print (?)', vector ('hello'));
--will print hello to the standard output of all the processes of the cluster.
```

Any recovery, integrity checking, crash dump or similar can be done node by node as with single processes.

See Also:

- Cluster Installation and Config
- Backup and Restore Example

Status Display

The status () function has a cluster line right below the database version information. This line shows cluster event counts and statistics between the present and previous calls to status. Calling status ('cluster') will show this line only. Calling status ('cluster_d') shows this line and below it the same line with data on each individual host in the cluster.

If cluster nodes are off-line, the nodes concerned are mentioned above the cluster status line.

The line consists of the following fields.

```
Cluster 4 nodes, 4 s. 9360 m/s 536 KB/s 117% cpu 0% read 44% clw threads 2r 0w 1i buffers 1939 766 d 0 w
Cluster 4 nodes, 4 s. 9360 m/s 536 KB/s
```

This first group gives the network status. The count of nodes online (4), the measurement interval, number of seconds since the last status command (4 seconds). The m/s is the messages per second, i.e. 9360 single messages sent for intra-cluster purposes per second over the last 4s. The KB/s is the aggregate throughput, i.e. the count of bytes sent divided by the length of the measure,measurement interval. This allows calculating an average message length. Only intra-cluster traffic is counted, SQL client server and HTTP connections are not included.

```
117% cpu 0% read 44% clw threads 2r 0w 1i
```

This group gives the process status. The CPU% is at 100% if one thread is running at one full CPU. The maximum CPU% is 100 times the number of CPU's in the cluster. Differences between CPU's are not considered. The read % is the sum of real time spent waiting for disk divided by the time elapsed. The maximum number is 100 times the peak number of threads running during the interval. 500% would mean an average of five threads waiting for disk times during the interval. The clw% is the sum of real time a thread has waited for cluster request responses during the period. The maximum is 100% times the peak number of threads running.

The threads section (2r 0w 1i) is a snapshot of thread state and means that 2 threads are involved with processing, 0 of these is waiting for a lock and 1 is waiting for network I/O.

```
buffers 1939 766 d 0 w 0 pfs
```

This is a snapshot of the database buffers summed over all nodes. 1939 used for disk caching, 766 dirty 0 wired down.

The pfs number is the total number of page faults during the interval summed over the cluster. This provides a warning about swapping and should be 0 or close at ll times.

6.3.7. Cluster Network Diagnostics and Metrics

Proper cluster operation requires that each process in the cluster be capable of initiating a connection to any other process. This may be prevented by firewall settings or the like. If a connection can be initiated from host 1 to host 2, it does not follow that host 2 can initiate a connection to host 1. These situations can lead to intermittent errors. These errors can be difficult to pinpoint since operations from host 2 to host 1 can work for most of the time if there is a connection available that was already established by the other host.

To check point to point connectivity, do the following on each host in turn, with no other activity on the cluster:

Log in to the SQL port of the host.

```
SQL> cl_reset ();
SQL status ('cluster');
SQL status ('cluster');
```

The first status ('cluster') may show no samples if this is the first time it is called. At the second call you should see a status line that does not contain mentions of any host being down.

The cl_reset function disconnects any connections to other cluster hosts from this host. This makes sure that a fresh connection will be started for the status command.

net_meter utility

The net_meter utility is a SQL stored procedure that measures the aggregate throughput of a cluster network with different types of workload.

First load the netmeter.sql file on the master node of the cluster.

```
SQL> load netmeter.sql;
```

Then run

```
SQL> net_meter (1, 1000, 1000, 1);
```

This returns a single result row with two numbers: The count of round trips per second and the throughput in megabytes per second.

```
net_meter ( in n_threads int,
            in n_batches int,
            in bytes int,
            in ops_per_batch int)
```

This SQL procedure runs a network test procedure on every host of the cluster. The network test procedure sends a message to every other host of the cluster and waits for the replies from each host. After the last reply is received the action is repeated. This results in a symmetrical load of the network, all points acting as both clients and servers to all other points.

The parameters have the following meaning:

- *n_threads*

  - The number of network test instances started on each host. A value of 4 on a cluster of 4 hosts would result in a total of 16 network test procedures spread over 4 processes.
- *n_batches*

  - The number of message exchanges done by each network test procedure. A message exchange consists of sending one request to every other host of the cluster and of waiting for all to have replied.
- *bytes*

  - The number of bytes sent to each host in each message exchange. The reply from each host has the same number of bytes.
- *ops_per_batch*

  - This causes each message batch to contain several operations. In practice this is a multiplier on the number of bytes.

cl_ping

```
cl_ping ( in target_host int,
          in n_pings int,
          in bytes_per_ping int)
```

This built-in function measures raw point to point network throughput. Whereas net_meter includes a more complex n to n point traffic pattern and scheduling of functions on multiple threads, cl_ping does not involve anything except a process to process connection and no thread switching, transaction contexts or other overhead.

cl_io_report

This built in function prints out a summary of the cluster connections of the host on which it is run. The output goes to the server process' standard output. This lists the bytes in and out as well as the file descriptor numbers of any connections this host has with any other host.

6.3.8. Elastic Cluster Operations

Initializing

When a set of Virtuoso servers configured as a cluster is first started, the elastic cluster setup is automatically performed if the cluster.ini of each host contains the [ELASTIC] section as described below. This is the normal way in which an elastic cluster is initialized.

The *__elastic* option of the create cluster statement is used for creating an elastic logical cluster.

```
create cluster ELASTIC __elastic 2048 4 group (Host1), group (Host2), group (Host3), group (Host4);
```

or:

```
create cluster ELASTIC __elastic 2048 4 ALL;
```

This creates an elastic cluster called ELASTIC which initially consists of 4 host groups. Each host group has a single copy of the data allocated to the host group. The data is partitioned among the host groups so that each host group has a separate fraction of the data. The second variant defaults the host groups from the cluster.ini, so that each host mentioned is in a host group of its own. The first number after the *__elastic* clause is the maximum number of physical slices in the cluster. The second number is the number of physical slices initially created per host group. In general each host group should have as many slices as there are hardware threads on the CPU (s) running the host(s) in the host group.

The name ELASTIC is specially known. If a logical cluster of this name exists, it is the default logical cluster instead of the non-elastic *__ALL* cluster in create or alter statements that specify partitioning.

Database files for an elastic cluster are created in a directory and striping set that is specified in the cluster.ini file of each host. The cluster.ini file of each participating host must have this section at the time of executing the create cluster statement. The section of the ini file has the name as in the create cluster statement, e.g.:

```
[ELASTIC]
Slices = 16
Segment1 = 1024, /data6/dbs/btc1-el.db = q1
Segment2 = 1024, /data2/dbs/btc1-el.db = q2
Segment3 = 1024, /data8/btc1-1/btc1-el.db = q3

[ELASTIC_1]
Segment1 = 1024, /data2/dbs/btc1-d-el.db = q2
```

Note that an elastic cluster may specify multiple segments. Each segment has an independent striping, as in other segments. When initialized, one segment is created for each of the slices hostted by the host in question. The segment may consist of multiple files if striping is specified. The database files for the segments are named as per the path and file name in the segment clause, with the slice number appended at the end, prefixed with a '.'. The files are initially created in the first segment of the logical cluster. If one wishes to move the files, one can do so between the segments declared for the cluster when the server is not running. At the next startup, it will look in all the segments for slices matching the path name plus .[0-9]*.

Specifying distinct IO queues for distinct devices is useful, as with other file system layouts.

To move slices between servers, more steps are necessary, see following sections.

In the example at hand, we specify two sets of files, one labeled ELASTIC_1. This is useful if one wishes to divide objects among different types of storage, e.g. disk and ssd. If two cluster names differ only by having _[0-9]* tagged at the end or having _[0-9]* with different numbers at the end while the rest of the name is the same, the system will manage these as twins so as to keep the slices belonging to either collocated. So slice movement and splitting will be mirrored between the two. If an If two objects share a partitioning key between such twin clusters operations are assumed to be colocatable.

The Slices setting specifies how many physical slices are initially created per host group. For example if a server has 2 CPU sockets with a 8 core 16 thread CPU on each, and two Virtuoso processes are run on each server, one per NUMA node (CPU socket), it is practical to specify 16 slices per host group. In this way there will be up to 32 threads per query on the machine, leading to full platform utilization.

After creation, the cluster can be used in the cluster clause of create index and alter index for specifying that the object in question

is to be created in the elastic cluster.

```
create table TE ( row_no int,
                  string1 varchar,
                  string2 varchar,
                  primary key (row_no));
alter index TE on TE partition cluster ELASTIC (row_no int (0hexffff00));
```

The table TE is now allocated in the cluster ELASTIC. Due to default behavior, the cluster ELASTIC is redundant since objects preferentially get created in it if it exists. The table is now ready for use. Note that the bit mask in the partitioning clause of the partitioning key row_no must specify enough bits to cover the number of logical slices in the cluster, 2048 in the present case. If this is not the case, some logical slices will never be used, as there will be less distinct partitioning hash values than logical slices.

Adding and Removing Hosts

The number of server processes (hosts) used for managing an elastic cluster may vary during the cluster's lifetime. If the elastic cluster keeps partitions in multiple copies, i.e. host groups in the initial create cluster statement have more than one host, any new host groups that are added must have the same number of hosts. Each new host of a new host group must be identically initialized to contain a copy of the REPLICATED logical cluster of the cluster into which the hosts are added. This is done by simply copying the non-elastic database file(s) of any host of the existing cluster. The copy can be made while the cluster is running.

```
cl_add_host_group (in cl_name varchar, in hosts any array) returns int
```

This function adds a host group to an elastic cluster. The host group must contain the same number of hosts as all the other host groups and the hosts must not be part of any other host group in this cluster.

The new hosts must be assigned IP addresses in the cluster.ini file of all presently running hosts. At the time of being added, the hosts in the new host group must be running and must be initialized to share a copy of the REPLICATED cluster shared by all hosts of the physical cluster.

After successful addition:

```
cl_remove_host_group (in cl_name varchar, in host varchar)
```

6.3.9. Setting CPU Affinity

If one runs multiple Virtuoso processes on a physical machine it may be advantageous to bind the processes to a physical CPU. In this way one may be certain that memory allocated for the processes is local to the CPU on which the process runs. This is specially important for servers with more than 2 CPU sockets, as there can be high variability in memory access latency Even with dual-socket Intel servers there caan be performance gains of up to 20% from setting CPU affinity if the workload is well balanced. On the other hand if the workload is not balanced, binding a process to a CPU may lead to less platform utilization than not specifying affinity.

There are two settings in the virtuoso.ini for affinity:

1. *Affinity*

   is the overall affinity for threads of the server process and is specified by comma-separated CPU numbers or ranges of numbers.
2. *ListenerAffinity*

   is the affinity of the thread handling incoming cluster traffic. In the interest of low latency, it may be advantageous to bind the listener thread to a core of its own, so that it will never be preempted. This can decrease the incidence of blocking on write for other processes since incoming messages will be read at full interface speed all the time.

For example:

```
...
Affinity = 1-7, 16-23
ListenerAffinity = 0
...
```

specifies that the process is bound to CPU 0 of a dual socket 16 core 32 thread system.

See numactl -- hardware for the actual numbers of the cores on each CPU. CPU 0, i.e. first thread of first core is here exclusively allocated to network traffic and canbnot be preempted by any other thread running for the server process.

6.4. Virtuoso Cluster Fault Tolerance

Abstract

This chapter discusses fault tolerance and how to configure it. The following aspects are covered:

- Setting up a fault tolerant logical cluster inside a physical cluster. Creating tables and indices for fault tolerance.
- Interpreting status and error messages and managing failures and recovery.
- Optimizing a schema for fault tolerance: For read-intensive workloads, the work can be profitably split among many copies of the same partition.
- RDF specifics relating to fault tolerance.
- Splitting a cluster so that one copy of the partitions does bulk load while another serves online queries.

6.4.1. Introduction

Virtuoso Cluster supports optional fault tolerance by storing partitions in more than one copy if desired. This is a cluster-only feature, providing for transparent fail-over with fully transactional semantics. This feature is in no way related to the other forms of replication discussed in the Virtuoso documentation. This feature can be used for load balancing of read-intensive workloads and for fault tolerance of arbitrary workloads in a tightly coupled cluster. This feature is not suited for synchronizing geographically distributed copies.

Fault tolerance is enabled at the level of logical cluster. Making the logical cluster __ALL fault tolerant has the effect of making all the normally non fault tolerant database objects into fault tolerant ones.

6.4.2. Sample Configuration

We will take a minimal example of a fault tolerant setup with 4 server processes, grouped in two groups of two mutually mirroring servers. The word host here refers to a single server process. How these are distributed over physical hardware is a separate question. Each host (i.e. server process) has exclusive control over its database files. Two processes may not share files.

```
create cluster DUP default group ("Host1", "Host2"), group ("Host3", "Host4");
```

Each group clause in the statement defines a set of mutually replicating, interchangeable processes. The cluster is operational as long as at least one process for each group is available. If all the processes in one group are down, the tables created in the cluster will not be available in their entirety. Even if some fragment of a table were unavailable, the remaining fragments are still available for transactions that concern only them.

For all tables or indices created in a cluster with fault tolerance, partitioning is applied for determining which group of the groups listed in the create cluster statement gets which individual entry. After this, all the hosts that make up the group are guaranteed to hold a copy of said entry at the commit of each transaction.

Regardless of the definition of logical clusters, there are global functions at the level of the physical cluster which need to be replicated for fault tolerance. For these functions include resolving distributed deadlocks and allocating sequence ranges. See the discussion of sequences in the cluster programming guide for more on this. These global functions are handled by a single process called the master. To keep a standby master that is synchronously kept in sync with the first master, one can define multiple master processes, as follows:

```
Master = Host1
Master2 = Host2
```

These lines in the cluster.ini files of the servers constituting the cluster mean that if Host1 is available, it will perform the functions of the master and if it is not available, these functions go to Host2. If both are available, then Host1 does the work and synchronously updates Host2 before returning the results to the requesting host.

To create a table or index in a specific logical cluster, one uses the cluster option in alter index or create index. For example:

```
create table T1 (row_no int primary key, string1 varchar);
alter index  t1 on t1 partition cluster DUP (row_no int (0hexffff00));
```

```
create index string1 on t1 partition cluster DUP (string1 varchar (5));
```

These statements define that t1 will be kept in duplicate copies spread as declared for logical cluster DUP. Partitioning can be altered only when the table concerned is empty. To make an existing non-replicated table into a replicated one, use alter table rename, as follows:

```
create table T1 (row_no int primary key, string1 varchar);
alter index  t1 on t1 partition (row_no int (0hexffff00));
create index string1 on t1 partition  (string1 varchar (5));
```

The table is created in the default logical cluster, which by default is not replicated. Now fill the table with a large amount of data. Then do the move over to replicated storage with minimum effect on overall server availability, follow the below steps:

```
drop index string2;
alter table t1 rename t1_old;

create table T1 (row_no int primary key, string1 varchar);
alter index  t1 on t1 partition cluster DUP (row_no int (0hexffff00));
create index string1 on t1 partition cluster DUP (string1 varchar (5));

log_enable (2);
```

This turns on row autocommit and disables logging for the session. This is necessary, as otherwise the statements below will abort due to running out of rollback space if the table is large. Disabling logging also saves some extra time.

```
insert into t1 select * from t1_old;
delete from t1_old;
drop table t1_old;
```

First deleting the contents and then dropping the table shortens the global atomic section that corresponds to dropping the table. Otherwise all servers would be unavailable also for the time of deleting the content, which might take long.

Finally:

```
cl_exec (checkpoint');
```

Makes the operation permanent. All the above work would be lost in the event of any failure since it was done without logging.

```
log_enable (1);
```

Restores default transaction and logging behavior to the session.

If T1 were very large, e.g. 100's of G or more, then one could do checkpoint after each step so as not to keep a full copy of all indices of t1 in the old and new versions simultaneously. Dropping an index or deleting rows actually frees the space at the next checkpoint. One could also write a procedure for copying the table in parts and run many such copies in parallel for different parts of the table. This would have obvious advantages for moving terabytes of data.

6.4.3. Transactions

Replication of partitions is entirely synchronous and transactional, with two phase commit. Replicated partitions show serializable semantics insofar the transactions dealing with replicated partitions are in serializable isolation.

These processes are transparent to the developer and administrator. One can program as one would in the case of a non-clustered database. The below has bearing mostly on optimization.

A read with read committed isolation can be done in any copy of a partition. Read committed reads make no locks nor do they wait for locks. For uncommitted updated rows, they show the pre-update state. Thus read committed can be freely load balanced over all copies of a partition.

A read with repeatable or serializable isolation will always be done on the first copy of a partition. This is done so as to have proper serialization of locking. If a row is locked for repeatable read and another transaction wishes to lock it for update, the latter will wait. Thus, transactions with locking resolve locking issues on the first copy of each partition. The first copy is the copy of the partition held by the first process mentioned in the partition's group clause of a create cluster. If the process is not available, the role of the first copy falls on the second, third and so on. If no host of the hosts mentioned in the group clause is available, the

operation cannot be performed. We will later define what we mean by available.

Updates to replicated partitions are performed concurrently on all the copies of the partition. Updates are replicated as they are made, not at time of commit, hence there is almost no added latency arising from keeping replicated partitions: When one is ready to commit, all are.

Distributed deadlock detection is handled by the master host. In the event of its failure, the function is taken over by the first node to be available in the sequence of master succession, as indicated above.

6.4.4. Dividing Virtuoso Hosts Over Physical Machines

This section describes how Virtuoso hosts should be placed on actual machines for optimal balance and fault tolerance.

All hosts (Virtuoso processes) constituting a cluster should be of the same size. This means that most importantly they should have an equal amount of memory allocated in virtuoso.ini.

The situation is simplest if all physical machines are of the same spec. This is not necessary though since a larger machine can host more Virtuoso hosts (processes). For balanced resource use, the machines should however have an equal amount of memory per core.

Naturally, all hosts mentioned in the same group clause in a create cluster statement must reside on different physical hardware. This is also true of the master host list in the cluster.ini file. Putting them on the same machine or a different virtual machine on the same machine defeats the whole point of fault tolerance. If VM's are automatically balanced on a data center network, one should keep the above in mind. It is recommended to use real machines with real network interfaces for database.

In each host group, the first host gets some more load than the other hosts. This is because serializable reading always must go to the first in the group. Thus, the first hosts should be evenly spread over the hardware, so do not put all the group firsts on the same machine.

Supposing 2 machines with 8 cores each, one would have hosts 1-16, 1-8 on the first, and 9-16 on the second. For analytics, have one core per host, for OLTP, one can have two or four cores per host.

In this case, one would write the create cluster as follows:

```
create cluster XX group ("Host1", "Host9"), group ("Host10", "Host2"), group ("Host3", "Host11"), group (
  group ("Host5", "Host13"), group ("Host14", "Host6"), group ("Host7", "Host15"), group ("Host16", "Host
```

Both machines have 4 firsts and four seconds. One could vary the memory allocation per process so as to have maybe 20% more RAM per host for a first of group than for the others in the group. This may optimize the situation when all are online and will not excessively penalize the fallback position.

Varying the amount of memory depending on whether a host is first or second makes sense only for read intensive workloads. Dividing firsts and seconds evenly over the hardware makes sense for all workloads.

6.4.5. Managing Availability

This section concerns prerelease 3117 amd onwards and is not final. Later versions have higher level management features but the primitives discussed here continue to apply.

In its normal state, a cluster has all the constituent processes up and all state is kept synchronous.

When a host unexpectedly disconnects, the following takes place:

- All transactions which have a write affecting this host become uncommittable. The application will see this immediately, as soon as it does anything within the transaction.
- All work proceeding at the request of the failed host on other hosts is aborted.
- All remaining network connections to the failed host are disconnected.

If a query was proceeding and it had state on the failing host, the failure will be reported to the client of the query and the query will be aborted. A subsequent query, if in read committed isolation, will automatically avoid the failed host and use surviving ones. Thus, the application sees a failure as a retryable abort of a transaction or query.

For update transactions, if all copies of a partition are not online, the update cannot be made. In order to allow proceeding with updates even after a failure, the failed host must be declared removed. This means that if it were to come back on, it would not get any updates or queries from the other hosts until it was explicitly admitted back into the cluster.

In version 6.00,3116, enabling updates when all hosts are not online must be done manually. In other words, read only work will proceed uninterrupted but updates will be prohibited if all hosts are not online. Read balancing and re-enabling updates when all hosts have rejoined the cluster is done automatically.

In order to declare that a host has for the time being left the cluster or has returned to the cluster after having left it, one uses the function cl_host_enable ().

For example, suppose a hardware failure that takes multiple processes (hosts) offline. As long as for each there is at least one surviving host of the same group (as per create cluster), read operations proceed normally. But to re-enable writes for the time the failed hardware is replaced, the operator must inform the cluster that the failed hosts are not expected to return immediately and that no further reference to them should be made, specifically, the rest should not attempt to keep them up to date.

This is done with cl_host_enable. This is a SQL stored procedure. Log in as dba on a surviving master host and do:

```
SQL> cl_host_enable (1, 0);
```

This will abort all the transactions pending at the time and declare host 1 to be off limits to the rest of the cluster. If Host1 was playing the role of the master, the master role is automatically transferred to the next one in the succession.

The succession of master hosts is declared in the cluster.ini with the settings of Master, Master2, Master3 and so on. All cluster.ini files must agree.

After this, even though Host1 is now acknowledged offline, updates can proceed.

To rejoin a recovered host into a cluster, so as to again have an additional copy of the formerly incompletely replicated partition, one can do

```
SQL>cl_host_enable (1, 1);
```

This states that Host1 is again part of the cluster. This statement must be executed on an online master node of the cluster, thus not on Host1 itself.

Supposing that the database files of Host1 have been lost in the failure and that Host1 and Host2 were in the same group. The restore would go by taking the cluster offline, copying the database files of Host1 to Host1 and starting the database again. Then the dba would issue cl_host_enable (1) and Host1 would again be available.

To do this without downtime, one may do the following:

- Disable checkpoints on Host2: checkpoint_interval (0); Operations continue. Copy the database files of host2 to host1.
- Start host1.
- Put host2 and all hosts with which host2 occurs in the same group in read-only mode: cl_read_only (2, 1)
- copy the transaction file of host2 to host1 and replay it with replay ().
- rejoin host1 to the cluster with cl_host_enable (1, 1);
- Re-enable updates with cl_read_only (2, 0);
- re-enable checkpoint on host2 with checkpoint_interval (), setting it to its previous value. See virtuoso.ini.

Further versions perform these operations automatically. The above procedure is error prone. Do not try it unless you understand exactly why each step is made and what its effects are supposed to be.

6.4.6. Optimizing Schema for Fault Tolerance

Having the working set in memory is the single most important factor of database performance. When storing partitions in duplicate, one in principle also requires double the memory to keep adequate working set during write operations.

However, most web and data warehouse workloads are read-intensive. In this situation, the reading load can be balanced over the replicated copies. If this balancing were done at random or round robin, all copies would eventually maintain the same working set. In other words, 64G of RAM spread over two machines would behave like 32G. If the data volune is larger than memory, it

makes sense to have the different replicas cache different parts of the partition they share.

Consider, using the example of cluster DUP mentioned above:

```
create table customer (c_id int primary key, c_name varchar, c_state varchar);
alter index customer on customer partition cluster DUP (c_id int (0hexffff0000));

create table orders (o_id int primary key, o_c_id  int, o_date datetime, o_value numeric);
alter index orders on orders partition cluster DUP (o_id int (0hexffff0000));
create index o_c_id on orders (o_c_id) partition cluster DUP (o_c_id (0hexffff0000));
```

This has the effect of saying that the 16 low bits of c_id or o_id do not participate in the partition hash. The hash is made from bits 32-16. Thus c_id 0-64K will be in one partition, 64K-128K in another, 128K-192K in a third and so on, these partitions are then spread by hash over the host groups listed in the create cluster.

Now, doing the join

```
select sum (o_value) from customer, orders where c_state = 'MA' and c_id = o_c_id;
```

will take o_c_id's 0-32K from the first copy of the first partition, id's 32K-64K from the second copy of the first partition, c_o_id's 64K-96K from the first copy of the second partition and so forth.

The load is split by applying range partition on the low bits of id's, so that a system with 64G split over two replicas behaves like 64G RAM for read committed reading but as 32G of RAM for writing. This is enabled by leaving low bits of id's outside of the partition hash by specifying a mask, as shown above.

6.4.7. Interpreting Status Messages

There are special error codes and status reports dealing with cluster failures.

The status function with an argument of 'cluster_d' shows a host by host report of the cluster:

```
SQL> status ('cluster_d');
```

If all is normal, the message is as described in the cluster administration section. If some hosts are down, meaning that they do not accept network connections at the cluster port, these are first listed as being down. Then follows the summary status line and a status line for all the hosts that can be connected to.

A host being contactable over the cluster protocol does not mean that it is online or in sync with the rest.

If a physical cluster has no logical clusters that are in duplicate, there is no redundancy, except for the built in redundancy of schema.

If a host is not in the online state, an extra line in the cluster status report describes the state in more detail. The state can be one of:

- roll forward - The host is recovering from log. The count of transactions replayed to date is shown after this.
- removed - The host is considered down and no attempt is made to contact it until it explicitly rejoins the cluster. This is controlled with the cl_host_enable function.

It is possible that the host considers itself in one state and the host showing the report thinks that it is in some other state. If this is so, the status report mentions it.

Applications see cluster failures through the following SQL states:

- 08C01 - A host cannot be contacted or can be contacted but is not in the online state
- 08C02 - An operation that previously had a connection to a host finds that it no longer has the connection.
- 08C03 - A master only operation was tried on a non-master. Indicates possibility of divergent understanding of master succession. This is expected to reset itself.
- 08C04 - A write was attempted on a partition that is flagged read only, as per cl_read_only.
- 08C05 - A request was refused because the host serving the request thinks the requesting host is not admitted to cluster as per cl_host_enable, i.e. was removed and not reintroduced.

- 08C06 - A cluster operation was not made because the host thinks it is not joined to the cluster either because it has not finished roll forward or because it is marked removed by ch_host_enable.

6.4.8. Administration API

This section documents the SQL procedures used for managing failures and setting hosts on and off line. These are stored procedures for DBA group users only, all in the DB.DBA. qualifier/owner. The dba will typically not call these directly. These are intended for use by management scripts and internal functions.

```
cl_host_enable (in host_no int, in flag int)
```

The host_no is the number as in the cluster.ini Host<nn> entries. The flag is 1 for joined and 0 for removed.

This controls whether a host is excluded from operations. Only a previously excluded host can be rejoined to the cluster with this function. This is not for adding new hosts. A host will be excluded from operations if it is long term unavailable,e.g. is running on failed hardware. If the unavailability is only for the time of a restart, removing the host is not generally practical.

If a host is rejoined to its cluster, then the caller of this function asserts that the joining host is up to date. If it were not up to date one could get discrepancy between copies of partitions, which is a loss of integrity and can be hard to detect. Being up to date means, for all objects of all replicated logical clusters where this host participates, having the exact same logical content in the host's (i.e. server process') database files as in the databases of the hosts which are in the same group as the rejoining host.

This function must be called on a master host that is itself in the online state. The setting is recorded on all master hosts. All non-master hosts update their copy of this setting from the first available master in the master succession. There is always at least one master node that is in the online state. If they all are offline, then the cluster in general is unavailable and the last one cannot be removed from online state with cl_host_enable.

This function aborts all pending transactions, so that the whole cluster has no uncommitted state. This puts all the hosts that can be reached into an atomic state where they only accept operations from the master who initiated the atomic state. If the atomic state cannot be obtained within a timeout, the operation fails and can be retried. This is possible if two hosts attempt to get an atomic state and deadlock or if rollback of pending state takes longer than the timeout. Once in atomic state, all masters record the change in cluster join status and all non-masters get a notification of the change. Once all these are acknowledge and logged, the atomic section ends.

An application whose transaction was aborted in this manner will see this as a deadlock, with the 40001 SQL state and a message mentioning global atomic state.

```
cl_read_only (in host_no int, in flag int)
```

This sets the partitions of which host host_no has a copy into read only state. A flag of 1 means read only, 0 means read write. This does not abort transactions but will prevent any new updates touching the partition. Transactions with existing uncommitted state in the partition can commit. To abort all transactions first, use this with __atomic (1) first and then __atomic (0) to finish the atomic state. This is a volatile state and does not survive server restart. This is intended for use in bringing copies of partitions up to date, which is a process that would have to be retried anyway if interrupted by failure.

```
__atomic (in flag int)
```

This places the cluster in global atomic mode. A flag of 1 starts this and a flag of 0 finishes this. Row autocommit is also implicitly enabled. During such time, no host of the cluster accepts connection through web or SQL ports and only serves requests made by the transaction which started the atomic section with __atomic (1). When an atomic section starts, all transactions are aborted and are guaranteed to all be rolled back upon successful completion of __atomic (1). New transactions will also not start until __atomic (0) is called. Starting an atomic section may fail by timeout if rollback takes too long or if two competing __atomic(1) requests deadlock with each other.

```
cl_control (in host_no int, in op varchar, in new_value any := null)
```

This returns the value associated with cluster related settings. If a new value is specified the old value is returned and the new value is set.

The op specifies the setting. It is one of:

- cl_master_list - succession of master hosts as an array of host numbers. Read only.
- cl_host_list- Array of all host numbers. Read only.
- ch_group_list - List of host numbers of hosts which occur in the same group with host no. These are the hosts which share a partition with host no according to at least one create cluster statement. Read only.
- cl_host_map - String with a character per each host number up to the maximum existing host number. The character is represents the status as known by the host on which thus function is called. The new_value argument can be specified for changing this setting.
- ch_status - Returns/sets the status of host no as known by this host.
- cl_master_host - Return/set the host number used by this host for master only requests.

The status of a host is one of:

- 0 - online
- 1 - removed
- 2 - temporarily offline
- 4 - pending roll forward
- 7 - host number is not used

Cluster Control Utility

A Virtuoso cluster does not per se require a separate administration utility. It will be online and usable when all the constituent servers are online. In the event of using fault tolerance, the *clctl utility* should however be used for managing servers going offline and rejoining the cluster. This is needed in order to ensure that the operation sequences for marking a server process as failed and for bringing a failed server process back online are correctly carried out. In the following section, we use the word host to mean an individual database server process. Several of these may exist on a single computer.

clctl has a configuration file named *cl.cfg* , which it reads from its working directory. This file describes the layout of the Virtuoso cluster being managed.

This file can be filled in manually after the cluster has been set up. It is only used by *clctl* .

Before using clctl, the cl.cfg file must be created, see the cl.cfg Configuration File section below. Note that ssh is used for executing commands on remote machines. This requires ssh to be set up so as not to require manual login.

The database file names for the database files of two hosts that are each others' online replicas must be the same and there must be an equal number of stripes.

Note : *clctl* can presently be used only if the database consists of a single file plus transaction log file in the same directory. These must be named *virtuoso.db* and *virtuoso.trx* . The hostname and directory is given separately for each host in *cl.cfg* .

clctl has the following subcommands:

```
clctl start
```

Starts all the hosts of the cluster.

```
clctl start <host>
```

Starts all a given node of the cluster.

```
clctl stop
```

Shuts down all the hosts of the cluster.

```
clctl stop <host>
```

Shuts down a given node of the cluster.

```
clctl status
```

Displays a one line status summary for each host.

```
clctl ro <host>
```

Sets a node of the cluster in a read-only mode

```
clctl rw <host>
```

Sets a node of the cluster in a read-write mode

```
clctl disable <host>
```

This notifies the cluster that <host> identified by its number in the cl.cfg file has failed and that the cluster will continue normal operation without this host.

The host will have to be rebuilt based on the state of its replica before it can rejoin the cluster. This is done with the clctl rebuild command.

If there is a transient failure like an unplugged network cable or a reboot, disabling the temporarily failed host does not always make sense because rebuilding it may involve copying hundreds of GB of data which can take significant time.

After the failure, the cluster is available for reading but is not available for writing until the failed host is either back online or disabled with this command.

Example:

```
clctl disable 3
```

Means that Host3 as defined in cl.cfg is removed and will have to be rejoined to the cluster with:

```
clctl rebuild 3

clctl rebuild <host>
```

Once a host has been removed from the cluster with clctl disable, it can be brought back online with this command. The host is identified by its number in the cl.cfg file. This command automates the following operations:

- Make a log checkpoint on the online replica of the host being rebuilt. This allows the database files to be copied to serve as a basis of the database of the recovering host. During this copy the replica will not do log checkpoints, so that the database file copy is clean. During this time the cluster is available for writing.
- After the database files are copied, the recovering host is started. At this point, there is a read only window while the recovering host replays the transactions its online replica has accumulated while its database was being copied. When the replay of the replica's transaction log is complete, the recovering host is marked to be a part of the cluster and writing is re-enabled.
- To ensure integrity of the recovered cluster, these operations have to be performed in this exact sequence, hence the clctl utility should be used for this.

```
clctl enable <host>
```

Enable a node of the cluster.

The cl.cfg Configuration File

The *cl.cfg* file contains a description of the layout of the cluster. It specifies a remote exec command for starting servers and gives the locations of database files used by these servers. The database file locations are needed for copying the database for restoring a failed host.

```
[Global]
Exec     = ssh
# command for remote execution. ssh must be set up so that the machine
# from which clctl is run can connect without login prompt to the
# machines hosting the databases.

Copy     = rsync -zvP
# command for copying files between the hosts. This is executed on the
# host receiving the copy.
```

```
BinDir   = /usr/bin
# Directory for the isql and other Virtuoso commands on the host
# running clctl

Password = dba
# The Virtuoso password for the dba account. All hosts of the cluster
# have the same dba password since all login and user account information
# is replicated on all hosts. This is a Virtuoso account and no operating
# system account corresponds to it.

Master   = Host1
# The cluster master information as given in each cluster.ini file

Master2  = Host2
# Fallback master as given in each cluster.ini file.
```

For each host the following fields are given:

```
[Host1]
Host      = localhost
# DNS Name of the machine hosting  the Virtuoso host in question

DBDir     = /home/v6/binsrc/tests/suite/clflt/cl1
# The absolute path of the directory containing the database files
# of this host

BinDir    = /home/v6/bin
# Absolute path of the Virtuoso binaries

SpareHost = 2
# Online replica of this host. The rebuild command uses this
# information to decide which database files to copy when
# rebuilding this host after failure.

SqlPort   = 1111
# Port for SQL listener of this host. Corresponds to the
# ServrPort setting in this host's virtuoso.ini file.
```

Below is a sample of a full cl.cfg file for a cluster of 4 hosts all on the same machine (localhost):

Example:

```
[Global]
Exec     = ssh
Copy     = rsync -zvP
BinDir   = /usr/bin
Password = dba
Master   = Host1
Master2  = Host2

[Host1]
Host      = localhost
DBDir     = /home/v6/binsrc/tests/suite/clflt/cl1
BinDir    = /home/v6/bin
SpareHost = 2
SqlPort   = 1111

[Host2]
Host      = localhost
DBDir     = /home/v6/binsrc/tests/suite/clflt/cl2
BinDir    = /home/v6/bin
SpareHost = 1
SqlPort   = 1311

[Host3]
Host      = localhost
DBDir     = /home/v6/binsrc/tests/suite/clflt/cl3
BinDir    = /home/v6/bin
SpareHost = 4
SqlPort   = 1312
```

```
[Host4]
Host      = localhost
DBDir     = /home/v6/binsrc/tests/suite/clflt/cl4
BinDir    = /home/v6/bin
SpareHost = 3
SqlPort   = 1313
```

6.4.9. RDF Specifics

To set up fault tolerant RDF storage, one can use the template provided in the clrdfdup.sql file in the distribution.

The below applies to testing with prerelease 06.00.3116.The fault tolerance function in 6.00.3116 is provided as a demonstration of concept exclusively and is not intended for production use and has not been tested in production. The below steps will demonstrate the basic capability but one should not try things not explicitly mentioned.

The test starts with an empty database. Edit the create cluster statement in the clrdfdup.sql file to correspond to the setup at hand. Then load the file:

```
SQL> load clrdfdup.sql;
SQL> cl_exec ('checkpoint');
```

Now load data. The load will be non-transactional but now will keep two copies of each partition. Use log_enable (2) and ttlp or rdf_load_db..rdfxml as described in the relevant documentation.

After some data is loaded, do another checkpoint.

```
SQL> cl_exec ('checkpoint');
```

You may query the data. Now shut down one of the servers. Querying should remain possible as long as one host in each group is online. Start the previously stopped host and stop of another from the same group. Querying remains possible.

Do not try non-transactional loading when all hosts are not online. This produces incorrect results. Do not stop hosts during non-transactional loading. This also produces inconsistent results.

Transactional loading is safe for stopping servers during loading but will stop the loading with an error. The removed host must be either brought back online or removed with cl_host_enable for the loading to proceed.

Do not test transactional RDF loading with 6.00.3116. This version is tested for duplicate partitions with SQL data but incompletely with RDF.

6.4.10. Fault Tolerance Programming

This section describes aspects of fault tolerance in writing cluster aware SQL applications. Specifically, partitioned functions, which are a way of explicitly dividing procedural execution among hosts of a cluster, have issues and features that are specific to fault tolerance and must be treated separately.

In using a daq or dpipe, one can specify whether the function is to be partitioned like:

1. Read committed read - low bits not used for partition can be used for intra partition balancing, as described in the schema optimization section.
2. The function is called on all replicas, as an update.
3. The function is called on the first replica, like a read for update
4. The function is called on all but the first copy of the partition.

Combinations of 3 and 4 can be used if the function, for example, allocates sequence numbers which must be then replicated over the remaining copies. Thus the function that allocates the new sequence number is called with in mode 3 and another function that uses this number is called in mode 4.

For a daq_call call, these options are specified in the 5th argument, flags.

- 0 - read committed

- 1 - write all
- 2 - write first
- 3 - write all but first

For dpipes, this is stated in the dpipe_define call's flags argument. The values to be or'ed over the flags are:

- 0 - read committed
- 1 - update all
- 4 - update first copy
- 8 - update all but first copy.

Chapter 7. Data Access Interfaces

Abstract

This chapter covers installation, configuration, and utilization of the data access drivers / providers (ODBC, JDBC, OLE-DB, and ADO.NET) that comprise the Virtuoso Client Connectivity kit.

7.1. ADO.Net Data Provider

7.1.1. Introduction

Virtuoso includes an ADO.NET 2.x & 3.x data providers compatible with Visual Studio 2008 and Entity Frameworks, that provides access to native Virtuoso data (SQL, XML, and RDF) in addition to any Virtuoso Linked Tables from external ODBC

and JDBC accessible data sources. Known-compatible external data sources include Oracle (versions 7.x to 11.x) , Microsoft SQL Server (6.x to 2005) , IBM DB2 , Sybase (4.2 to 15.x) , IBM Informix (5.x to 11.x) , Ingres (6.4 to 9.x) , Progress (7.x to 10.x) , MySQL , PostgreSQL and Firebird .

Benefits

This provider equips Microsoft .NET based applications, development environments, and programming languages with conceptual entity-based access to native and heterogeneous data sources.

Features

- ADO.NET 3.5 compliance
- .NET Entity Frameworks compatibility
- Full integration with Visual Studio 2008
- ADO.NET Data Services compatibility
- LINQ to Entities compatibility
- High-Performance & Scalability
- High Security
- Support for Native and 3rd party ODBC and JDBC accessible RDBMS engines and Web Services
- Tested against all major .NET applications and development environments
- Support for Microsoft Siliverlight versions 2 and 3
- Support for .Net RIA Services

7.1.2. Installation & Configuration

There are two installation types to consider:

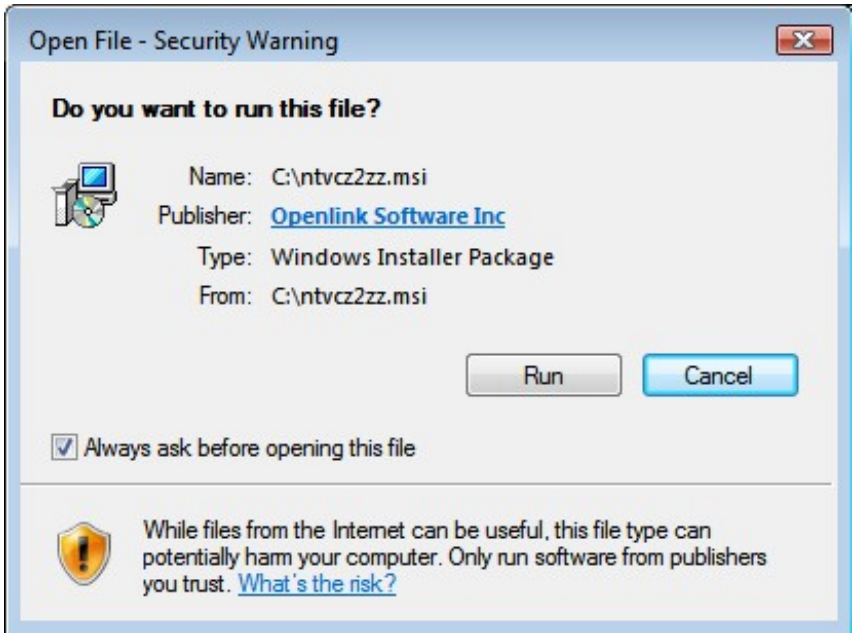
- If you have an existing Virtuoso instance, or will install Virtuoso on a different host, you only need to install of the ADO.Net Provider Client on the Visual Studio host.
- If you have no existing Virtuoso instance, you can install both the ADO.Net Provider Client and the Virtuoso Universal Server on the Visual Studio host.

Installation of the ADO.Net Provider Client on Windows

The Virtuoso ADO.Net Provider is part of the Virtuoso Client Connectivity Kit installer, and if the target Virtuoso Server installation already exists on the network this is the only component that needs to be installed.

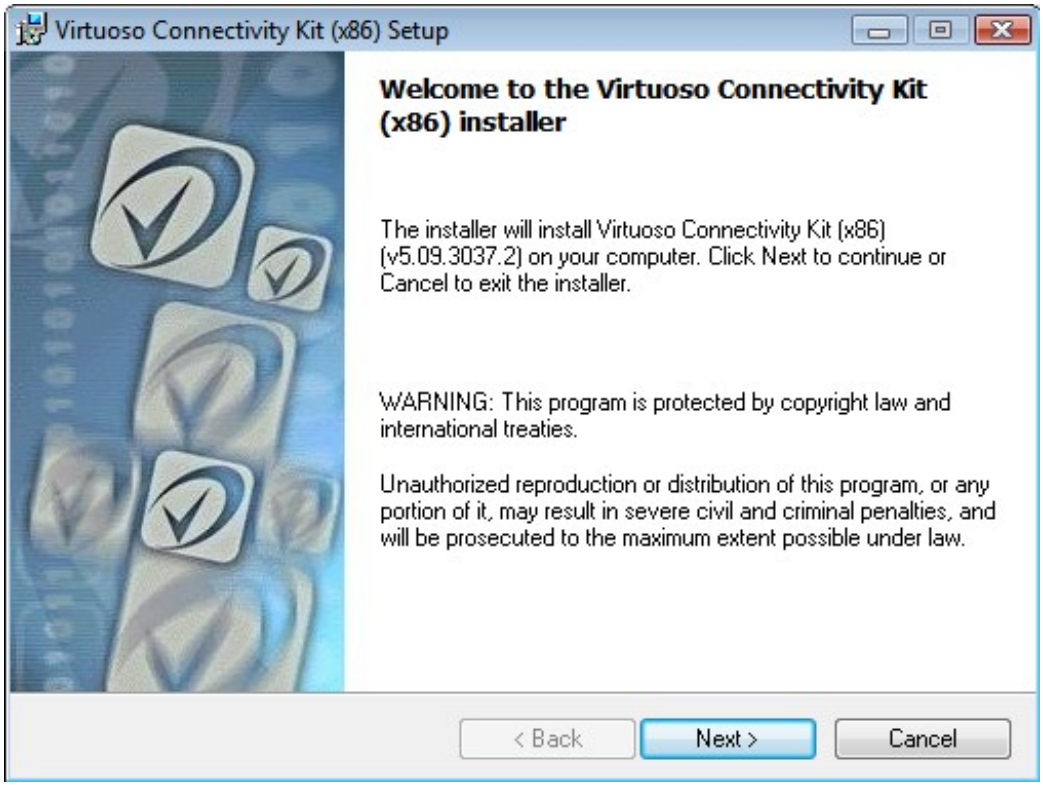
1. Download and run the Virtuoso Client Connectivity Kit installer for your target Windows OS:
   - Windows 98/NT/2000/XP/2003/Vista/2008 (32 Bit) (x86)
   - Windows XP/2003/Vista/2008 (64 Bit) (x86_64)
2. Choose the "run" button to allow the signed "Virtuoso Client Connectivity kit" installer to start.

   Figure 7.1. Run



3. Choose the "Next" button to begin the installation process.

Figure 7.2. Installation: Next

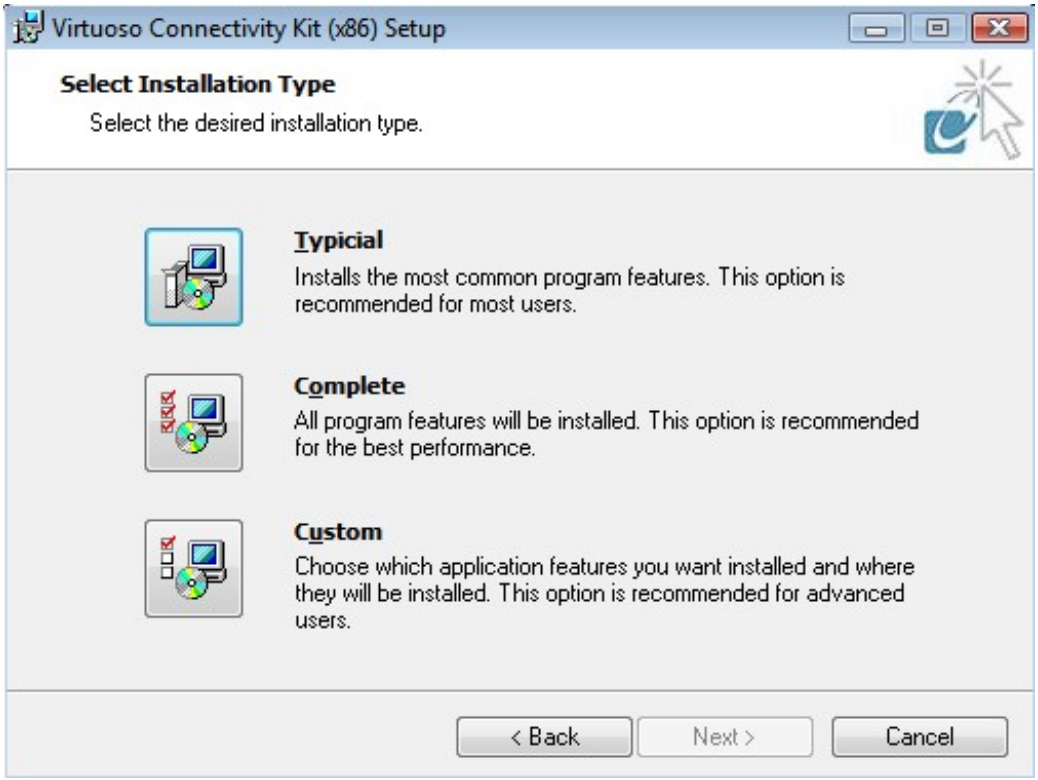


4. Check the "I agree with license agreement" checkbox and choose the "Next" button.

Figure 7.3. Installation: Agree license

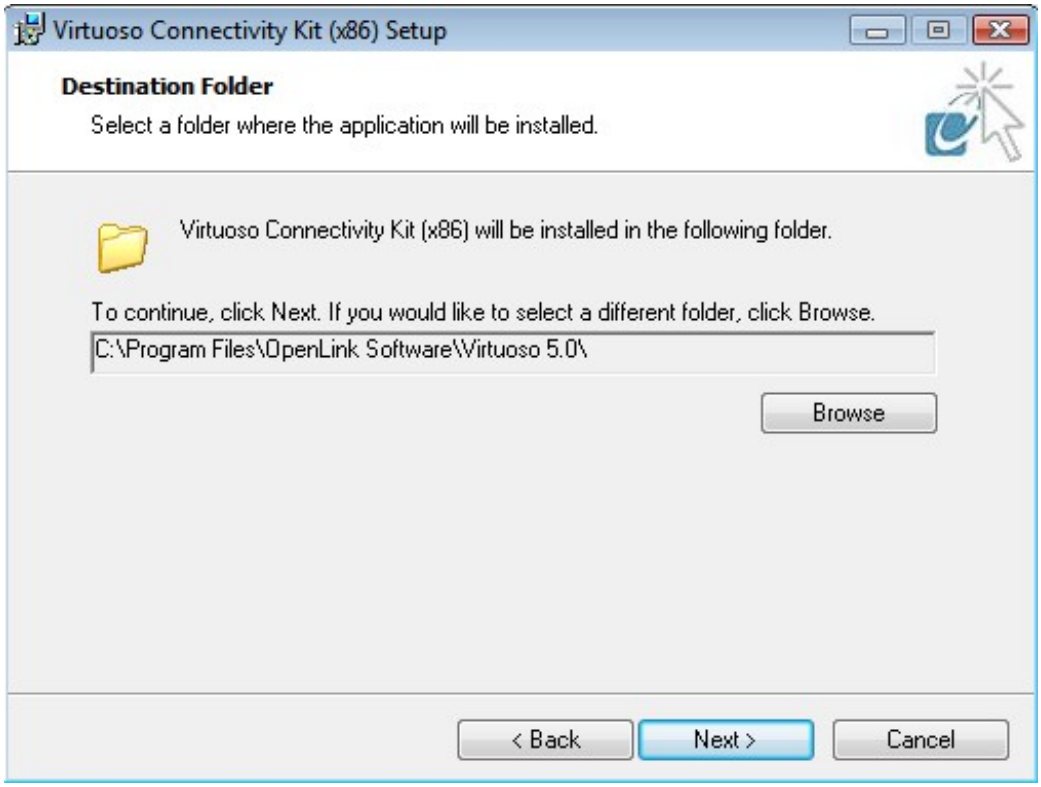
5. Choose the "Custom" option to manually select what components are installed and in which location, or choose the "Typical" or "Complete" options as recommended and skip to step 7.

Figure 7.4. Custom Install



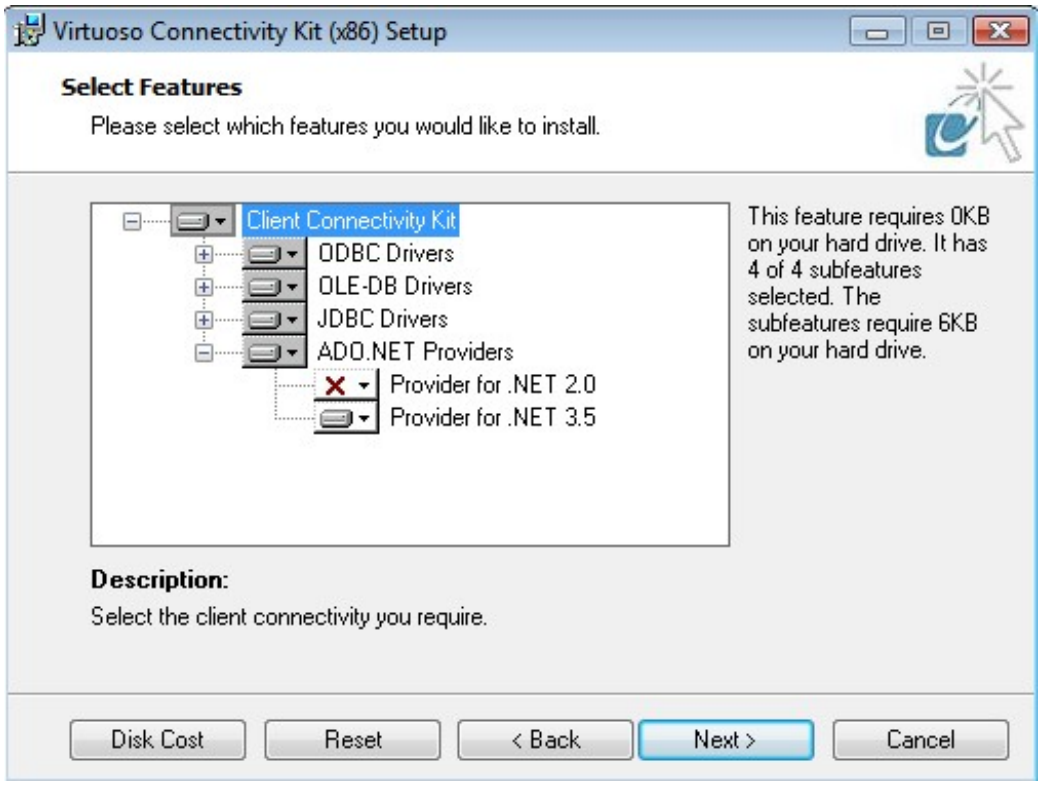
6. If the "Custom" option what chosen, select the installation directory or leave default and choose the "Next" button to continue.

Figure 7.5. Installation



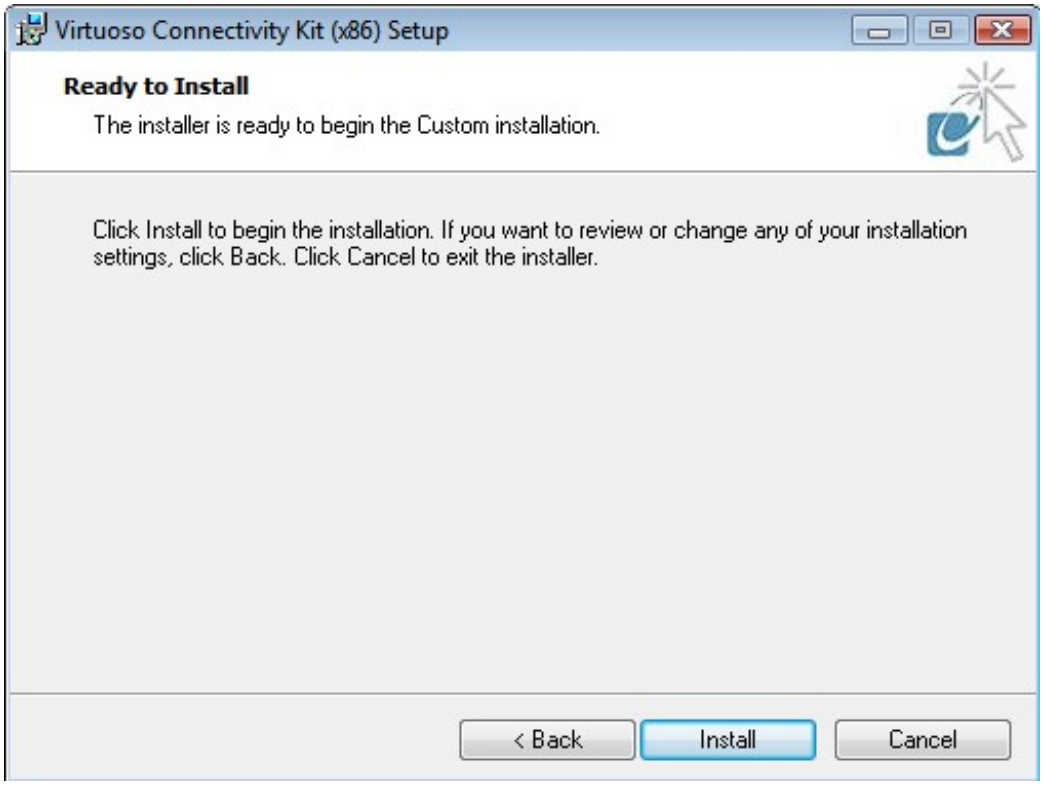
7. Select which of the ADO.NET Providers are to be installed and choose "Next" to continue.

Figure 7.6. ADO.NET Providers



8. The installer is now ready to begin the installation, choose the "Install" button to commence the process.

Figure 7.7. Install

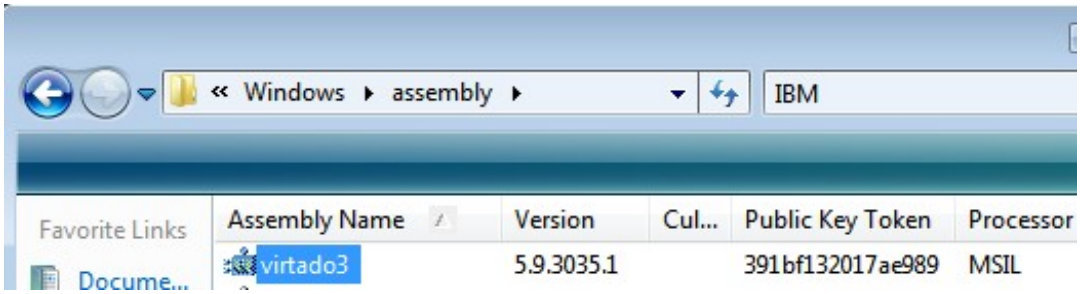


9. The installation was successfully completed.

Figure 7.8. Completed installation

10. The installation of the Provider can be verified by checking the %WINDOWS%\assembly folder and checking that the Provider(s) chosen for installation is(are) listed - "virtado3" and/or "virtado2".

Figure 7.9. Provider

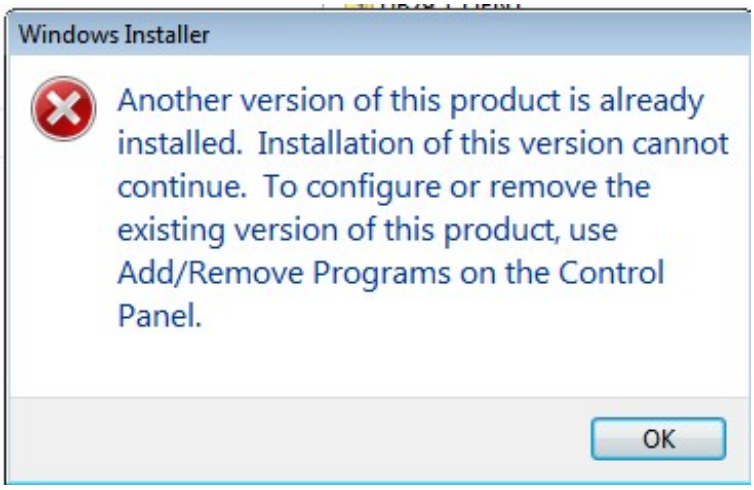


The installation of the ADO.Net Provider Client is complete.

Uninstallation

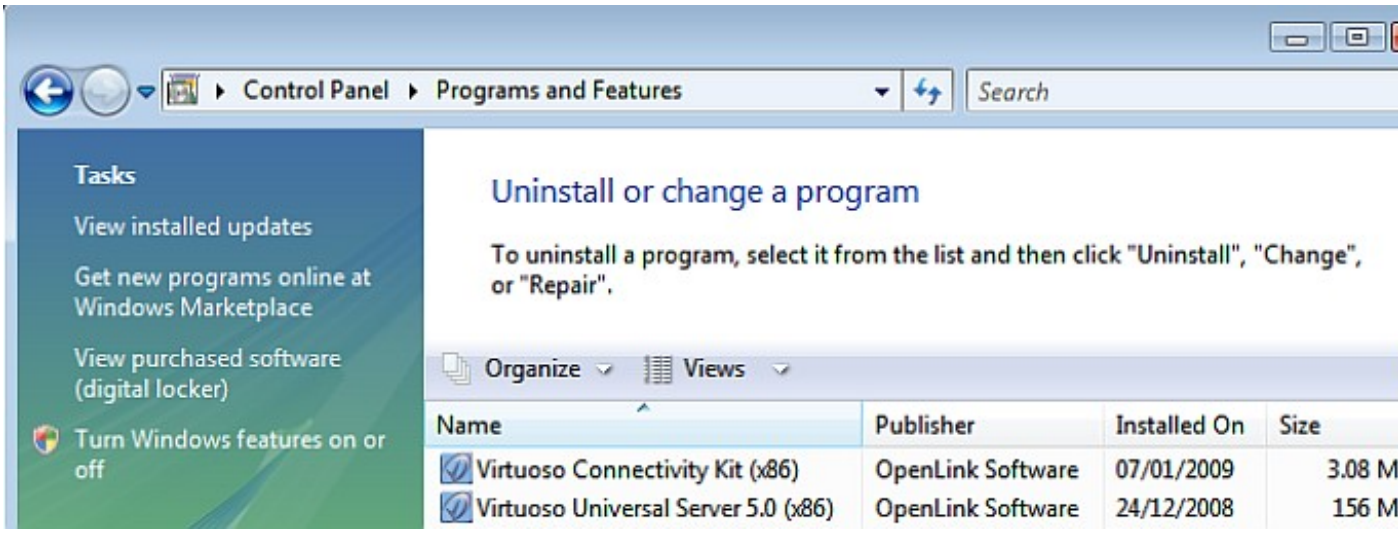
1. If you attempt to run the installer again, the following message will be displayed.

   Figure 7.10. Installer message

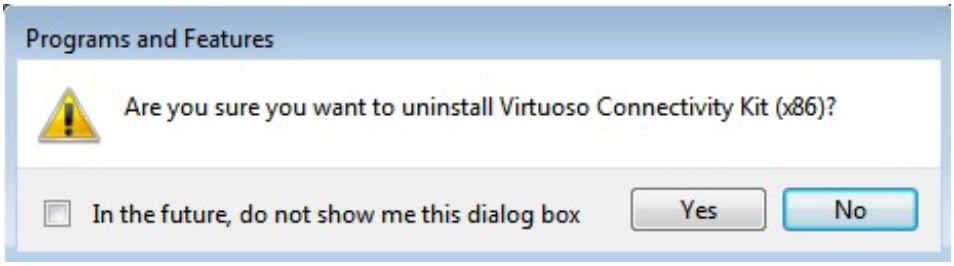
2. The Provider can be uninstalled from the "Control Panel" -> "Programs and Features" menu, by selecting the "Virtuoso Client Connectivity kit" from the list of installed components and clicking the "unistall" option presented.

   Figure 7.11. Uninstall

3. Choose "Yes" to uninstall the Virtuoso ADO.Net Provider.

   Figure 7.12. Uninstall



Installation of the ADO.Net Provider Client and Virtuoso Universal Server on Windows

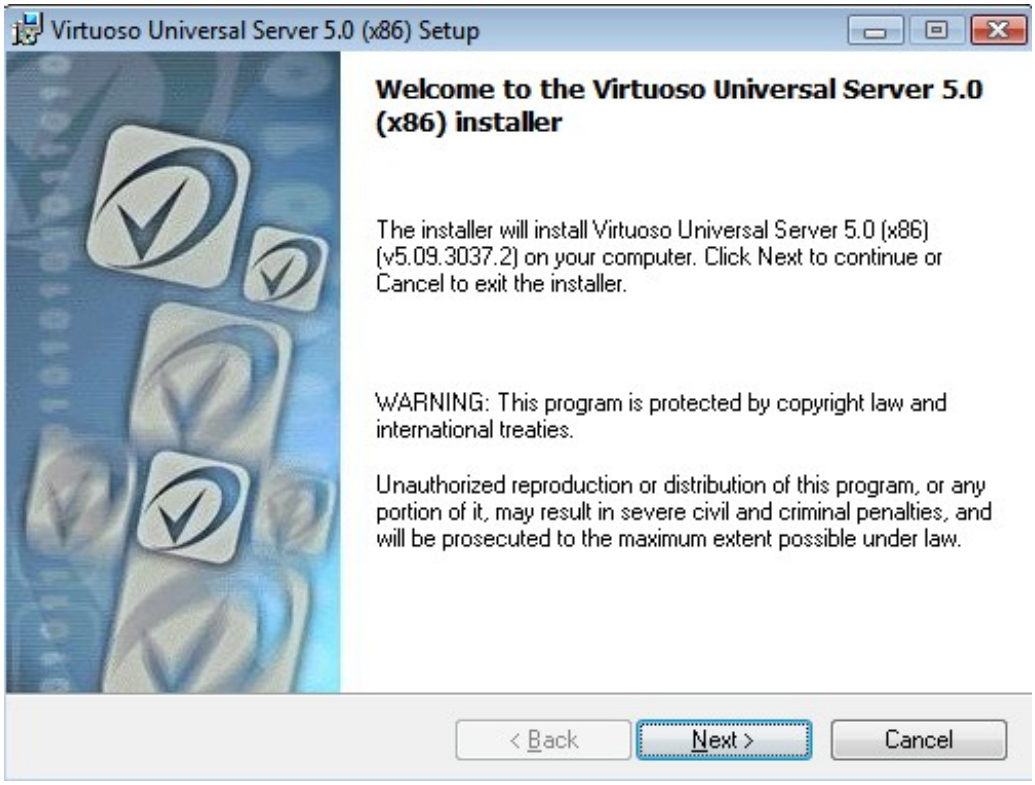
If both the ADO.Net Provider client and Virtuoso Server are to be installed on the same Windows machine, then the Virtuoso Universal Server installer can be used as it includes all the Virtuoso client and server components available in a single installer. An instance in which this particular installation type is require would be when using the Provider to provide Entity Framework connectivity to the remote database schema objects.

1. Download and run the Virtuoso Universal Server installer for your target Windows OS:
   - Windows 98/NT/2000/XP/2003/Vista/2008 (32 Bit) (x86)
   - Windows XP/2003/Vista/2008 (64 Bit) (x86_64)
2. Choose the "run" button to allow the signed "Virtuoso Universal Server" installer to start.

Figure 7.13. Run

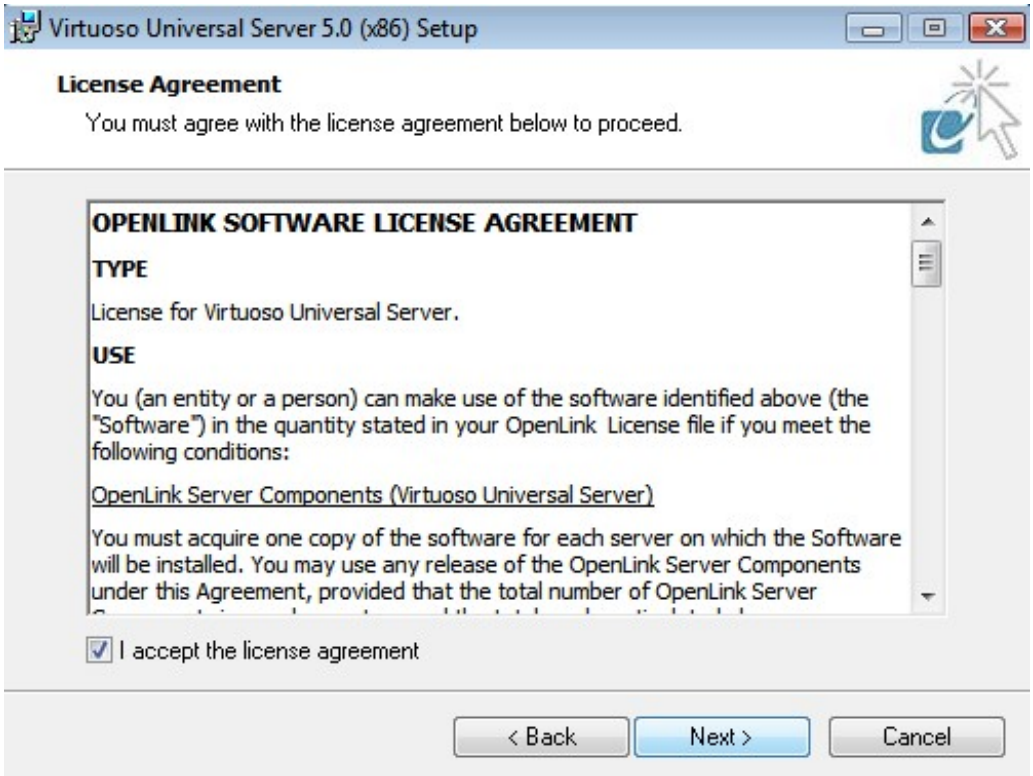
3. Choose the "Next" button to begin the installation process.

Figure 7.14. Next



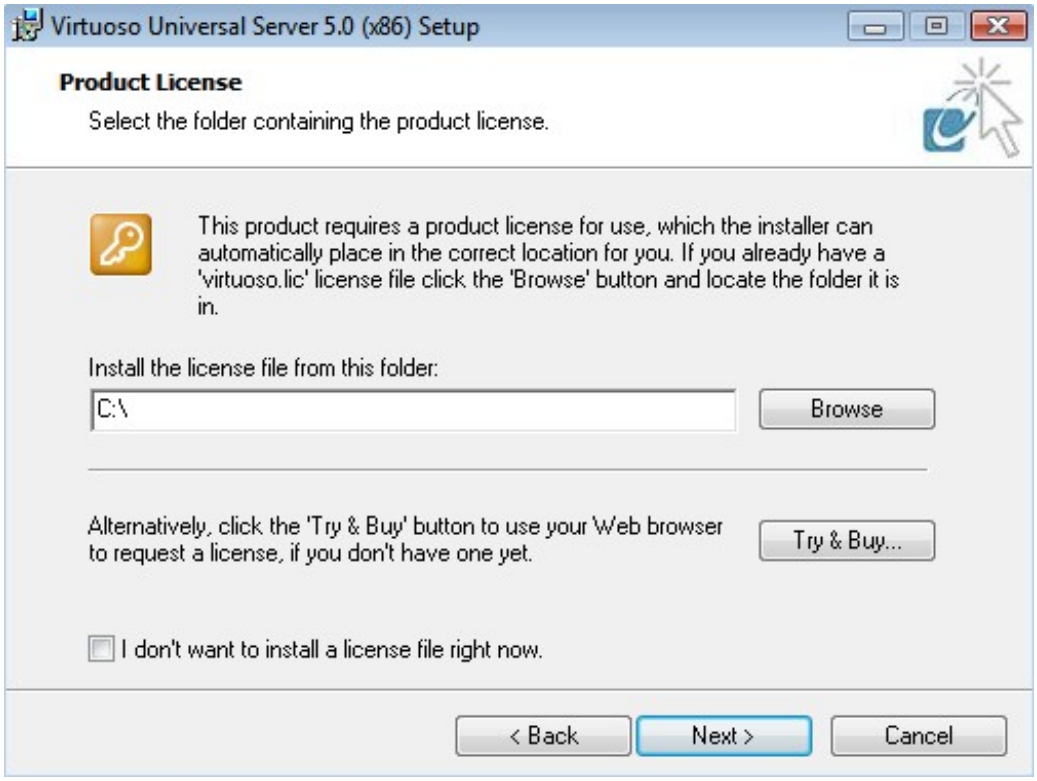
4. Check the "I agree with license agreement" checkbox and choose the "Next" button.

Figure 7.15. Agree license



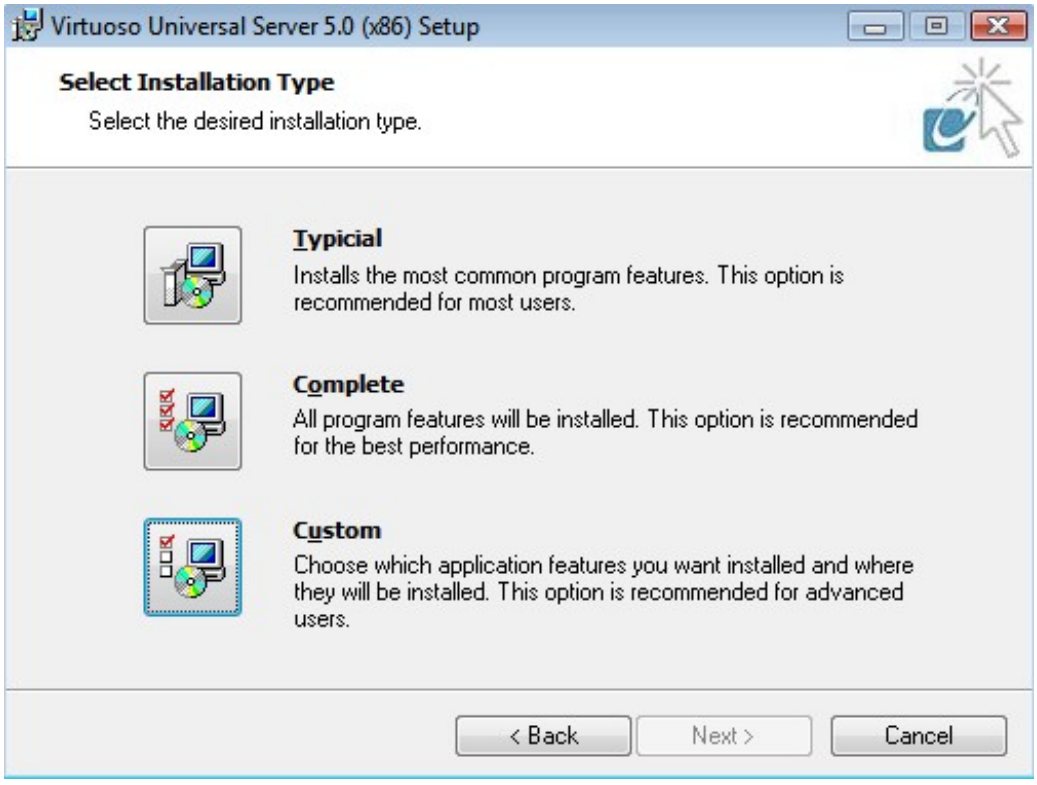
5. Choose the "Custom" option to manually select what components are installed and in which location, or choose the "Typical" or "Complete" options as recommended and skip to step 7.

Figure 7.16. Custom option



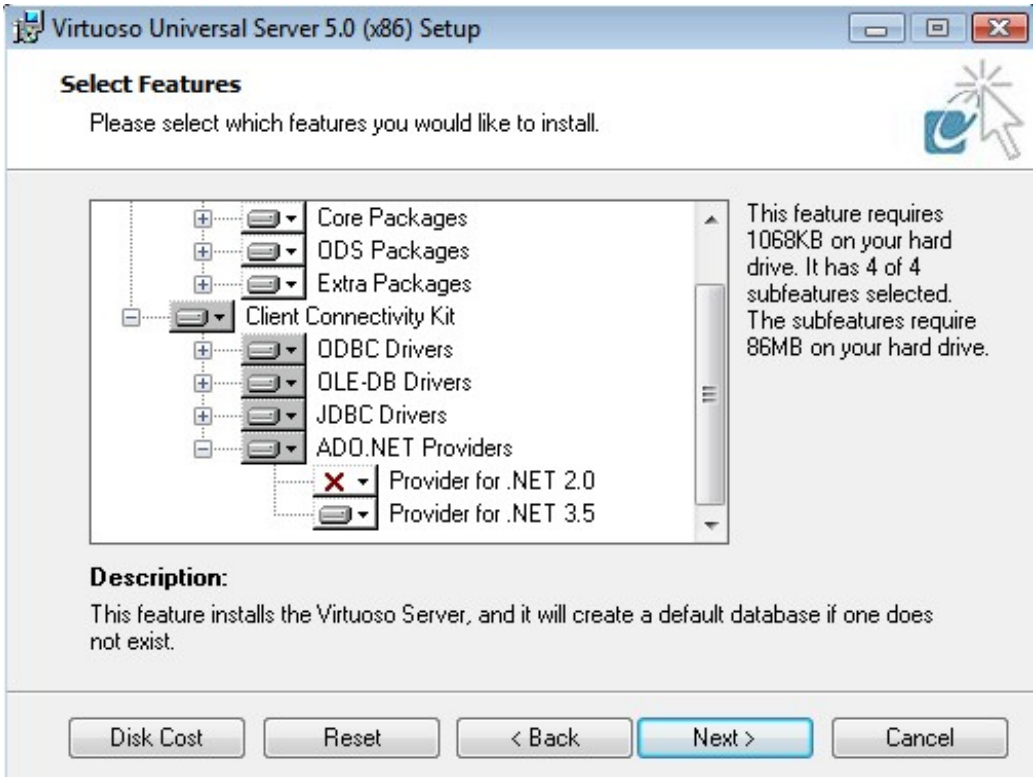
6. If the "Custom" option what chosen, select the installation directory or leave default and choose the "Next" button to continue.

Figure 7.17. Installation directory



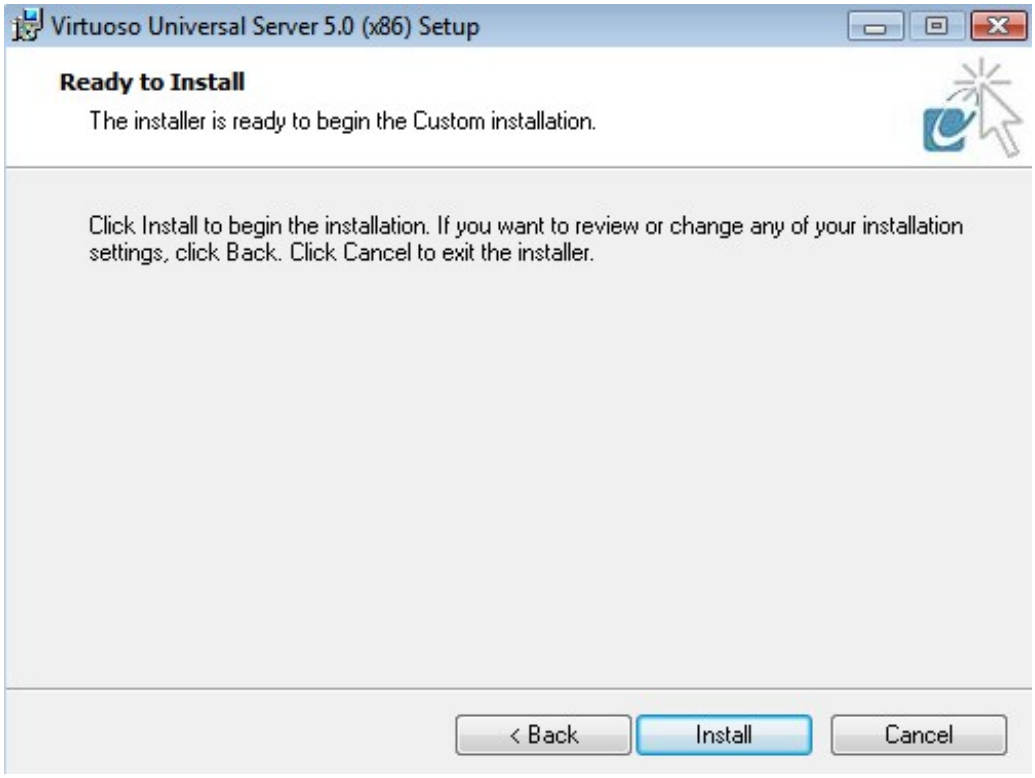
7. Select which of the ADO.NET Providers are to be installed and choose "Next" to continue.

Figure 7.18. ADO.NET Providers



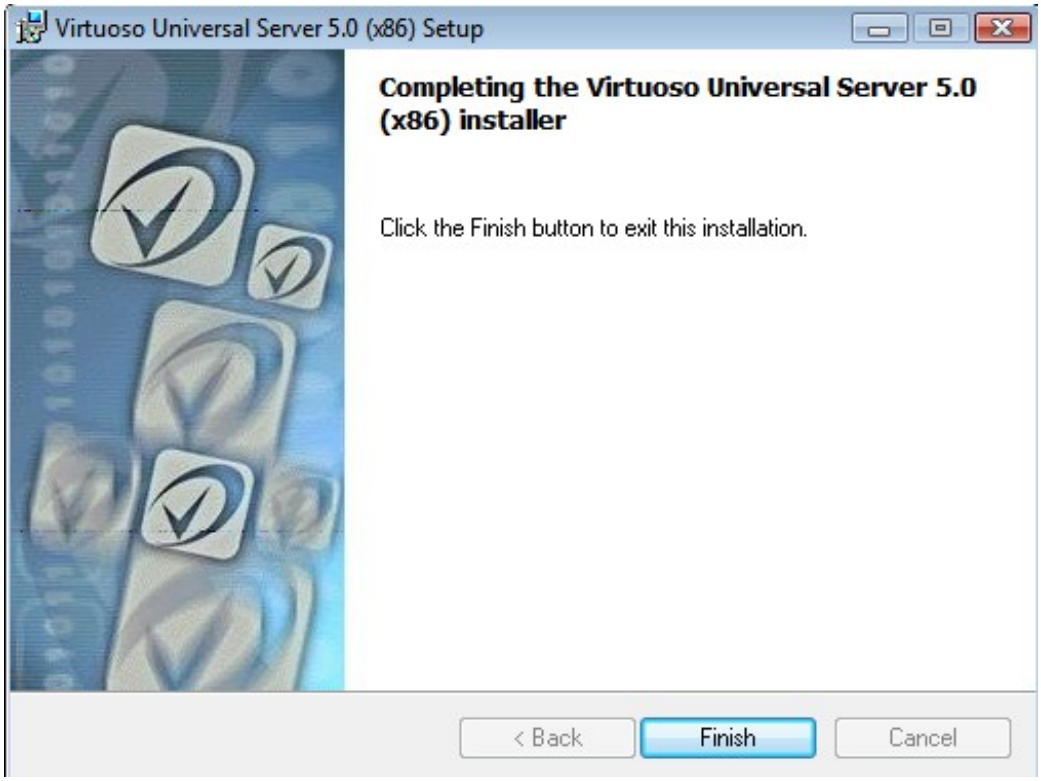
8. The installer is now ready to begin the installation, choose the "Install" button to commence the process.

Figure 7.19. Begin installation



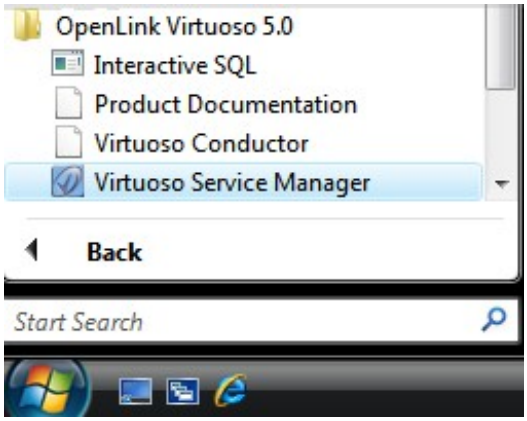
9. The installation was successfully completed.

Figure 7.20. Installation completed



10. Post installation the Virtuoso Server can be started by running the "Virtuoso Service Manager" which gets added to the Windows "Icons Tray" in the status bar.

Figure 7.21. Post installation



11. Double click on the "Virtuoso Service Manager" icon in the "Icons Tray" to load the application, select the "OpenLink Virtuoso Server" instance and press the "Start" button to run the Service.

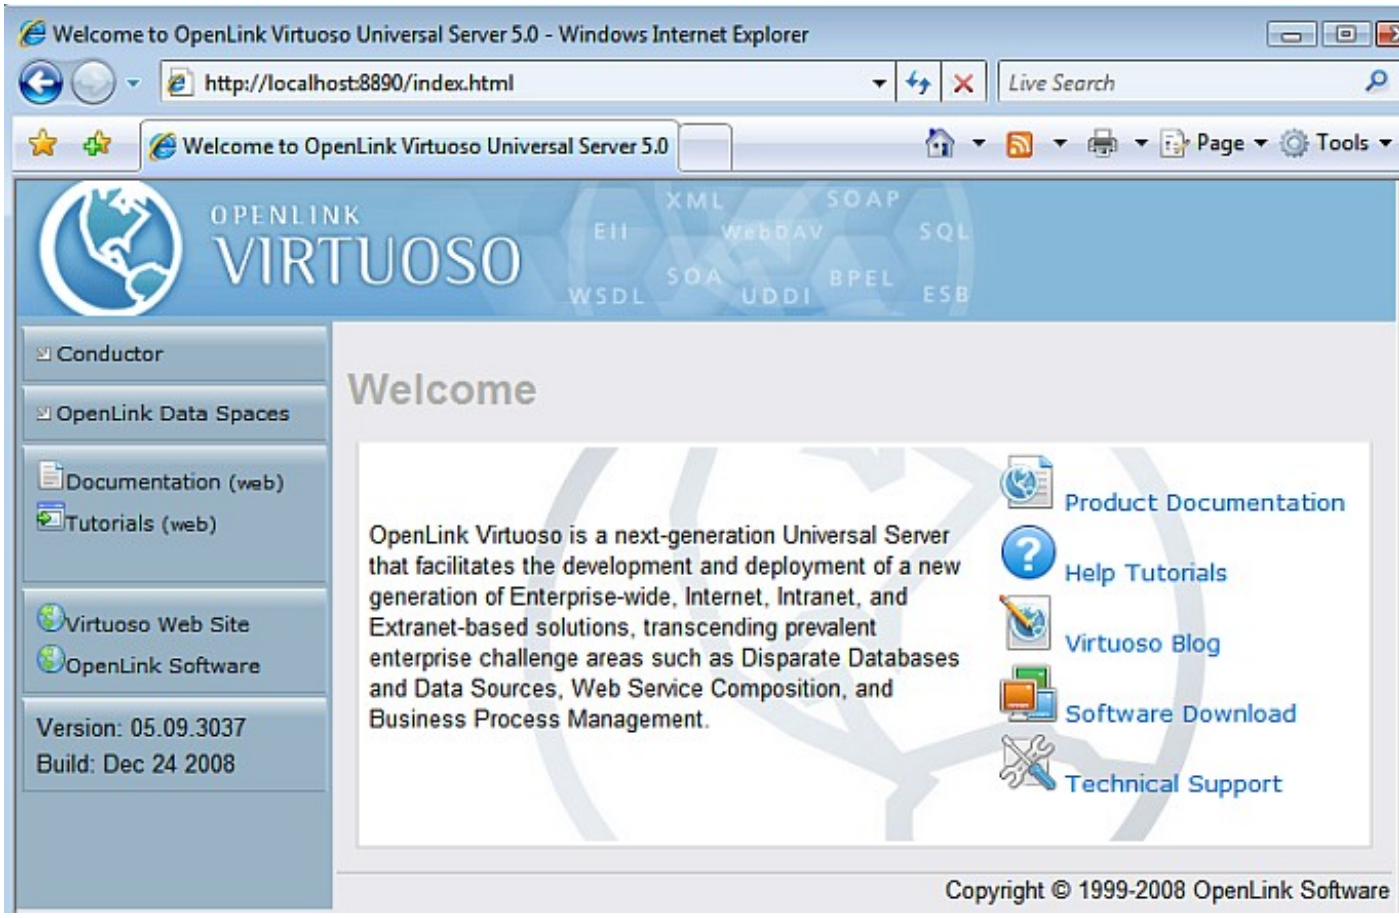
Figure 7.22. Virtuoso Service Manager

12. Once the Virtuoso service has successfully started, it is *recommended* that the default "dba" and "dav" passwords be changed to secure values by loading the URL "http://example.com/install" in a Web Browser which loads the following page for making these changes.

Figure 7.23. Defaults

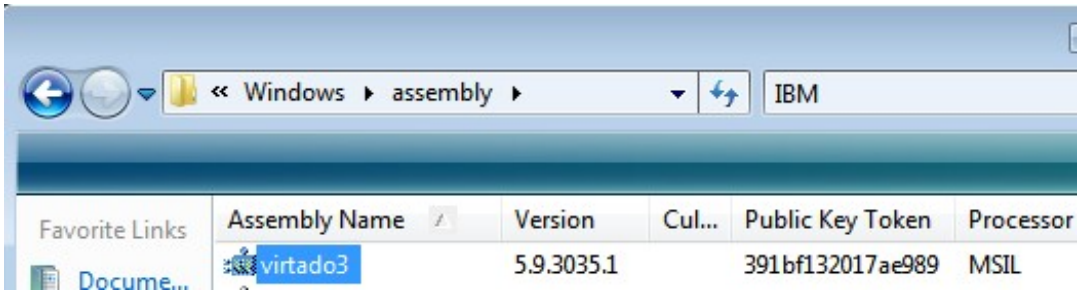
13. The Virtuoso Server is now available for use.

Figure 7.24. Virtuoso Server



14. The installation of the ADO.Net Provider can be verified by checking the %WINDOWS%\assembly folder and checking that the Provider(s) chosen for installation is(are) listed - "virtado3" and/or "virtado2".

Figure 7.25. Installation verification

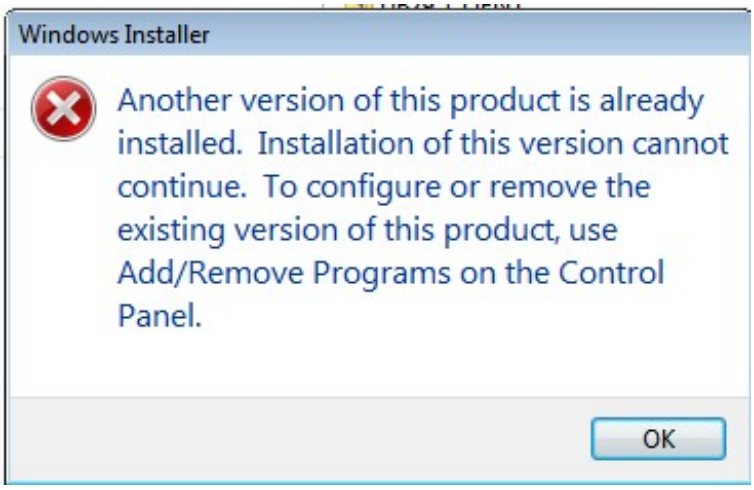


The installation of the ADO.Net Provider Client and Virtuoso Universal Server is complete.

Uninstallation

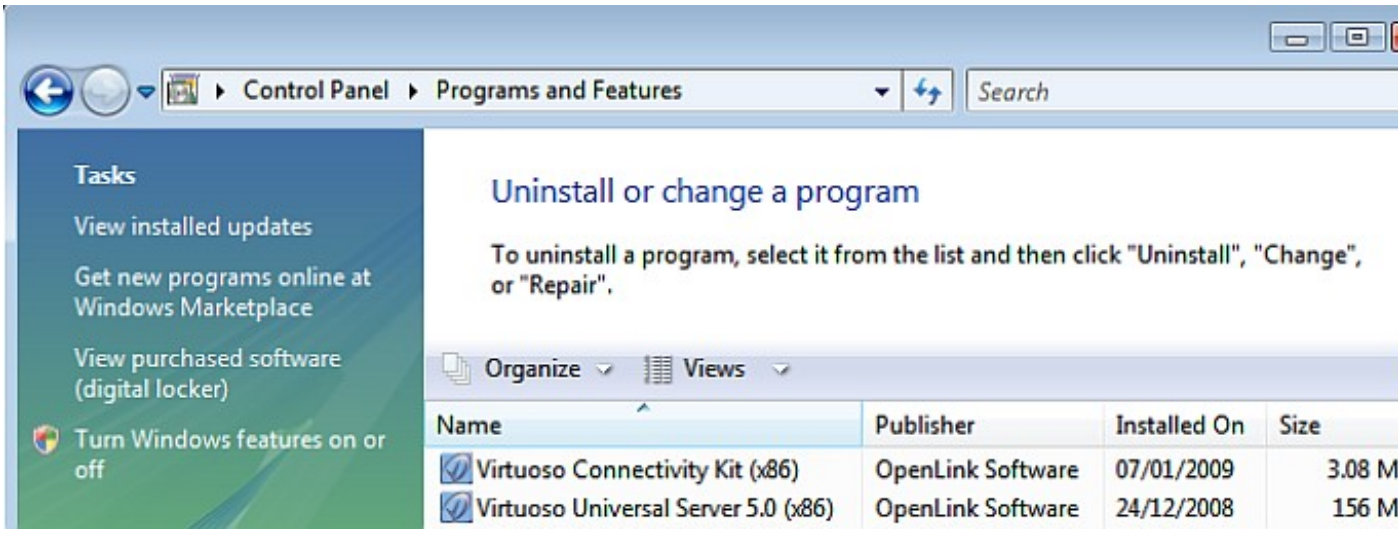
1. If you attempt to run the installer again, the following message will be displayed.

Figure 7.26. Installer message



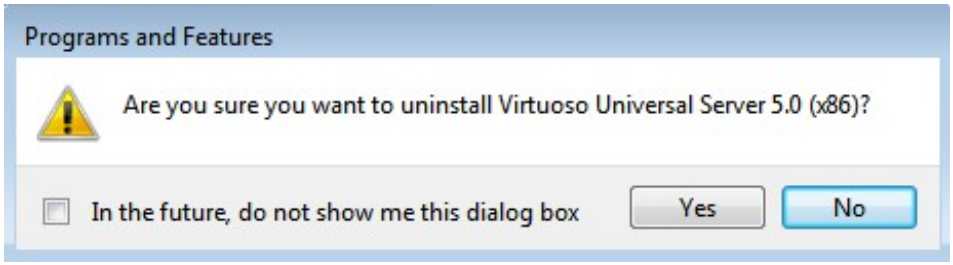
2. The Provider can be uninstalled from the "Control Panel" -> "Programs and Features" menu, by selecting the "Virtuoso Client Connectivity kit" from the list of installed components and clicking the "unistall" option presented.

Figure 7.27. Uninstall



3. Choose "Yes" to uninstall the Virtuoso ADO.Net Provider.

Figure 7.28. Uninstall



7.1.3. Programmers Guide

Sample Walk through Applications

- Using Visual Studio 2008 to Build a Data Grid Form Application
- Using Visual Studio 2008 to Build an Entity Frameworks based Windows Form Application
- Using Visual Studio 2008 to Build an ADO.NET Data Services based Application
- Windows Form Application for accessing Virtuoso RDF data via SPASQL using the Virtuoso ADO.Net Provider
- Web Data Service Application for accessing Virtuoso RDF data via SPASQL using the Virtuoso ADO.Net Provider
- Creating a Silverlight Application to consume the service
- Creating A Simple .NET RIA Services Application to Display Data from Virtuoso
- Creating a .Net RIA Services Application that will Update Virtuoso Data

Using Entity Frameworks, ADO.NET, the Virtuoso Virtual Database Engine

Virtuoso's in-built virtual database engine for ODBC and JDBC accessible databases enables it to act as bridge between Entity Frameworks & ADO.NET based client applications. Thus, you simply link external databases into Virtuoso using the browser based Conductor UI or programmatically using SQL extensions. Once the external tables a linked/attached, they inherit the functionality prowess of Virtuoso, and this particular use case scenario, complete compatibility with Entity Frameworks and ADO.NET 3.5.

- Using Microsoft Entity Frameworks to Access Oracle Schema Objects with Virtuoso
- Using Microsoft Entity Frameworks to Access Progress Schema Objects with Virtuoso
- Using Microsoft Entity Frameworks to Access Ingres Schema Objects with Virtuoso
- Using Microsoft Entity Frameworks to Access Informix Schema Objects with Virtuoso
- Using Microsoft Entity Frameworks to Access DB2 Schema Objects with Virtuoso
- Using Microsoft Entity Frameworks to Access Sybase Schema Objects with Virtuoso
- Using Microsoft Entity Frameworks to Access MySQL Schema Objects with Virtuoso
- Using Microsoft Entity Frameworks to Access PostgreSQL Schema Objects with Virtuoso
- Using Microsoft Entity Frameworks to Access JDBC Schema Objects with Virtuoso
- Using Microsoft Entity Frameworks to Access ODBC Schema Objects with Virtuoso
- Using Microsoft Entity Frameworks to Access Firebird Schema Objects with Virtuoso
- Using Microsoft Entity Frameworks to Access Microsoft SQL Server Schema Objects with Virtuoso

VirtDbType Enumeration

Specifies Virtuoso data types.

Members

Table 7.1.

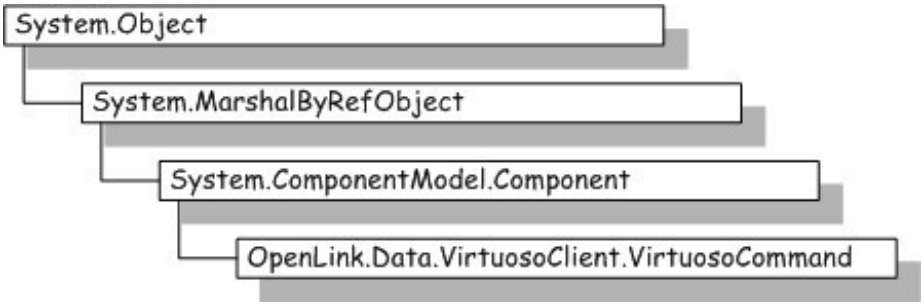
Member name	Description
`Binary`	BINARY data. This maps to an Array of type Byte .
`Char`	CHAR data. This maps to String .

Member name	Description
Date	DATE data. This maps to DateTime .
DateTime	DATETIME data. This maps to DateTime .
Decimal	This is equal to Numeric .
Double	DOUBLE PRECISION data. This maps to Double .
Float	This is equal to Double.
Integer	INTEGER data. This maps to Int32
LongBinary	LONG BINARY data. This maps to an Array of type Byte .
LongNVarChar	LONG NVARCHAR data. This maps to String .
LongVarChar	LONG VARCHAR data. This maps to String .
NChar	NChar data. This maps to String .
Numeric	NUMERIC data. This maps to Decimal
NVarChar	NVARCHAR data. This maps to String .
Real	REAL data, This maps to Single .
SmallInt	SMALLINT data. This maps to Int16
Time	TIME data. This maps to TimeSpan
TimeStamp	TIMESTAMP data. This maps to an Array of type Byte .
VarBinary	VARBINARY data. This maps to an Array of type Byte .
VarChar	VARCHAR data. This maps to String .

VirtuosoCommand Class

Represents an SQL statement or stored procedure to execute against a Virtuoso database. This class cannot be inherited.

Figure 7.29. Virtuoso .Net Provider VirtuosoCommand Class



```
                public
                sealed
                class
                VirtuosoCommand
               extends,
                Component

    implements,
                ICloneable
              ,
                IDbCommand
               {
}
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

The VirtuosoCommand class provides the following methods for executing commands against a Virtuoso database:

Table 7.2.

Item	Description
ExecuteReader	Executes commands that return rows.
ExecuteNonQuery	Executes commands such as SQL INSERT, DELETE, UPDATE, and SET statements.
ExecuteScalar	Retrieves a single value (for example, an aggregate value) from a database.

VirtuosoCommand Constructor

Initializes a new instance of the VirtuosoCommand class.

VirtuosoCommand Constructor ()

Initializes a new instance of the VirtuosoCommand class.

```
public VirtuosoCommand();
```

Remarks

The base constructor initializes all fields to their default values. The following table shows initial property values for an instance of VirtuosoCommand.

Table 7.3.

Properties	Initial Value
CommandText	empty string ("")
CommandTimeout	30
CommandType	CommandType.Text
Connection	null

You can change the value for any of these properties through a separate call to the property.

VirtuosoCommand Constructor (string)

Initializes a new instance of the VirtuosoCommand class with the text of the query.

```
public VirtuosoCommand( string  cmdText );
```

Parameters

cmdText
: The text of the query.

VirtuosoCommand Constructor (string, VirtuosoConnection)

Initializes a new instance of the VirtuosoCommand class with the text of the query and an VirtuosoConnection object.

```
public VirtuosoCommand( string  cmdText ,
                        VirtuosoConnection  connection );
```

Parameters

cmdText
: The text of the query.

connection
: A VirtuosoConnection object that represents the connection to a Virtuoso database.

ConnectionString Property

The Virtuoso ADO.NET Provider ConnectionString property implements the IDbConnection.ConnectionString property to get or set the string used to open a Virtuoso database connection, and includes the source database name and other parameters needed to establish the initial connection. The default value is an empty string.

```
public  string  ConnectionString  ;
```

Property Value

Includes the source database name and other parameters needed to establish the initial connection. The default value is an empty string.

ConnectionString has the following syntax: Each connection string is a sequence of settings Individual settings are separated by semicolons. Each setting is a pair of name and value delimited by the equal sign. Whitespace is ignored on either side of both names and values. Names are case insensitive. The value part can be quoted by either single or double quote characters or remain unquoted at all. However if it includes a semicolon, single quote, or double quote characters, it must be enclosed in either type of quotes. To embed the same character that is used for enclosing the value the character within the value must be doubled.

The following table lists the valid names for values within the ConnectionString:

Table 7.4.

Name	Default	Description
Connect Timeout or Connection Timeout	15	The number of seconds to wait for a connection to the server before terminating the attempt and generating an error.
Connection Lifetime	0	When a connection is returned to the pool, its creation time is compared with the current time, and the connection is destroyed if that time span (in seconds) exceeds the value specified by connection lifetime. Useful in clustered configurations to force load balancing between a running server and a server just brought on-line.
Charset	utf-16	Specifies the character set to be used by the provider when passing string values to and from the database. Must be set to utf-8 to handle Unicode strings passed in SPARQL/SPASQL queries of RDF data.
Data Source or Server or Address or Network Address or Host		The name or network address of the instance of Virtuoso server to which to connect. Can take comma delimited list of instances for connection fail over.
Encrypt	false	Specifies if the connection must be SSL encrypted. Currently encryption only works with an ODBC-based provider.
Enlist	true	When true, the pooler automatically enlists the connection in the creation thread's current transaction context.
Initial Catalog or Database		The name of the database.
Max Pool Size	100	The maximum number of connections allowed in the pool.
Min Pool Size	0	The minimum number of connections allowed in the pool.
Password or Pwd		The password for the Virtuoso account logging on.
Persist Security Info	false	When set to 'false', security-sensitive information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open State. Resetting the connection string resets all connection string values including the password.
Pooling	true	When true, the VirtuosoConnection object is drawn from the appropriate pool, or if necessary, is created and added to the appropriate pool.
RoundRobin	false	Enables load balancing in which case the server for the connection is chosen at random from the comma delimited provided as for a Failover connection.
User ID or Uid		The Virtuoso login name.

Implements

IDbCommand.ConnectionString

Remarks

The *ConnectionString* is similar to an OLE DB connection string, but is not identical. Unlike OLE DB or ADO, the connection string that is returned is the same as the user set *ConnectionString* minus security information if the *Persist Security Info* value is set to *false* (default). The Virtuoso ADO.NET Data Provider neither persists nor returns the password in a connection string unless you set *Persist Security Info* to true.

The *ConnectionString* property can be set only when the connection is closed. Many of the connection string values have corresponding read-only properties. When the connection string is set, all of these properties are updated, except when an error is detected; in this case, none of the properties are updated. *VirtuosoConnection* properties return only those settings contained in the *ConnectionString* .

Resetting the *ConnectionString* on a closed connection resets all connection string values (and related properties) including the password. For example, if you set a connection string that includes "*Database=Demo* ", and then reset the connection string to "*Data Source=myserver;User ID=dba;Password=dba* ", the Database property is no longer set to *Demo* .

The connection string is parsed immediately after being set. If errors in syntax are found when parsing, a runtime exception (e.g., *ArgumentException*) is generated. Other errors can be found only when an attempt is made to open the connection.

VirtuosoCommand Constructor (string, VirtuosoConnection, VirtuosoTransaction)

Initializes a new instance of the VirtuosoCommand class with the text of the query, an VirtuosoConnection object, and the VirtuosoTransaction.

```
public VirtuosoCommand( string  cmdText ,
                        VirtuosoConnection  connection ,
                        VirtuosoTransaction  transaction );
```

Parameters

cmdText
: The text of the query.

connection
: A VirtuosoConnection object that represents the connection to a Virtuoso database.

transaction
: The VirtuosoTransaction in which the VirtuosoCommand executes.

Properties

CommandText Property

Gets or sets the SQL statement or stored procedure to execute against the Virtuoso database.

```
public  string  CommandText  ;
```

Property Value

The SQL statement or stored procedure to execute. The default value is an empty string ("").

Implements

IDbCommand.CommandText

Remarks

When the CommandType property is set to StoredProcedure, the CommandText property should be set using standard ODBC stored procedure escape sequences. Setting the CommandText to the name of the stored procedure does not function as it does for some other .NET data providers.

The Virtuoso .NET Data Provider does not support named parameters for passing parameters to a SQL statement or a stored procedure called by an OleDbCommand when CommandType is set to Text. In this case, the question mark (?) placeholder must be used. For example:

```
SELECT * FROM Customers WHERE CustomerID = ?
```

As a result, the order in which VirtuosoParameter objects are added to the VirtuosoParameterCollection must directly correspond to the position of the question mark placeholder for the parameter.

CommandTimeout Property

Gets or sets the wait time before terminating an attempt to execute a command and generating an error.

```
public int CommandTimeout ;
```

Property Value

The time (in seconds) to wait for the command to execute. The default is 30 seconds.

Implements

IDbCommand.CommandTimeout

Remarks

A value of zero (0) specifies no limit to the wait time, rather than no wait time, and therefore should be avoided.

CommandType Property

Gets or sets a value indicating how the CommandText property is interpreted.

```
public CommandType CommandType ;
```

Property Value

One of the System.Data.CommandType values. The default is Text.

Implements

IDbCommand.CommandType

Remarks

When the CommandType property is set to StoredProcedure, you should set the CommandText property to the full ODBC call syntax. The command then executes this stored procedure when you call one of the Execute methods (for example, ExecuteReader or ExecuteNonQuery).

The Connection, CommandType and CommandText properties cannot be set if the current connection is performing an execute or fetch operation.

The Virtuoso .NET Data Provider does not support passing named parameters to an SQL statement or to a stored procedure called by a VirtuosoCommand. In either of these cases, use the question mark (?) placeholder. For example:

```
SELECT * FROM Customers WHERE CustomerID = ?
```

The order in which VirtuosoParameter objects are added to the VirtuosoParameterCollection must directly correspond to the position of the question mark placeholder for the parameter.

Connection Property

Gets or sets the VirtuosoConnection used by this instance of the VirtuosoCommand.

```
public VirtuosoConnection Connection ;
```

Property Value

The connection to a Virtuoso database. The default is a null value.

Parameters Property

Gets the VirtuosoParameterCollection.

```
public  VirtuosoParameterCollection  Connection  ;
```

Property Value

The parameters of the SQL statement or stored procedure. The default is an empty collection.

Remarks

When CommandType is set to Text, the Virtuoso .NET Data Provider does not support passing named parameters to an SQL statement or to a stored procedure called by an VirtuosoCommand. In either of these cases, use the question mark (?) placeholder. For example:

```
SELECT * FROM Customers WHERE CustomerID = ?
```

The order in which VirtuosoParameter objects are added to the VirtuosoParameterCollection must directly correspond to the position of the question mark placeholder for the parameter in the command text.

Note:
If the parameters in the collection do not match the requirements of the query to be executed, an error may result.

Transaction Property

Gets or sets the VirtuosoTransaction within which the VirtuosoCommand executes.

```
public  VirtuosoTransaction  Transaction  ;
```

Property Value

A VirtuosoTransaction. The default is a null value.

Remarks

You cannot set the Transaction property if it is already set to a specific value, and the command is in the process of executing. If you set the transaction property to an VirtuosoTransaction object that is not connected to the same VirtuosoConnection as the VirtuosoCommand object, an exception will be thrown the next time you attempt to execute a statement.

UpdatedRowSource Property

Gets or sets how command results are applied to the DataRow when used by the Update method of the DbDataAdapter.

```
public  UpdateRowSource  UpdatedRowSource  ;
```

Property Value

One of the System.Data.UpdateRowSource values.

Implements

IDbCommand.UpdatedRowSource

Methods

Cancel Method

Attempts to cancel the execution of an VirtuosoCommand.

```
public void Cancel();
```

Implements

IDbCommand.Cancel

Remarks

If there is nothing to cancel, nothing happens. However, if there is a command in process, and the attempt to cancel fails, no exception is generated.

CreateParameter Method

Creates a new instance of a VirtuosoParameter object.

```
public VirtuosoParameter CreateParameter();
```

Return Value

A VirtuosoParameter object.

Remarks

The CreateParameter method is a strongly-typed version of IDbCommand.CreateParameter.

ExecuteNonQuery Method

Executes an SQL statement against the Connection and returns the number of rows affected.

```
public int ExecuteNonQuery();
```

Return Value

For UPDATE, INSERT, and DELETE statements, the return value is the number of rows affected by the command. For all other types of statements, the return value is -1.

Implements

IDbCommand.ExecuteNonQuery

Remarks

You can use ExecuteNonQuery to perform catalog operations (for example, querying the structure of a database or creating database objects such as tables); or to change the data in a database, without using a DataSet, by executing UPDATE, INSERT, or DELETE statements.

Although ExecuteNonQuery does not return any rows, any output parameters or return values mapped to parameters are populated with data.

ExecuteReader Method

Sends the CommandText to the Connection and builds a VirtuosoDataReader.

ExecuteReader Method ()

Sends the CommandText to the Connection and builds a VirtuosoDataReader.

```
public VirtuosoDataReader ExecuteReader();
```

Return Value

A VirtuosoDataReader object.

ExecuteReader Method (CommandBehavior)

Sends the CommandText to the Connection and builds a VirtuosoDataReader using one of the CommandBehavior values.

```
public VirtuosoDataReader ExecuteReader( CommandBehavior  behavior );
```

Parameters

behavior
: One of the System.Data.CommandBehavior values.

Return Value

A VirtuosoDataReader object.

ExecuteScalar Method

Executes the query, and returns the first column of the first row in the resultset returned by the query. Extra columns or rows are ignored.

```
public object ExecuteScalar();
```

Return Value

The first column of the first row in the resultset.

Implements

IDbCommand.ExecuteScalar

Remarks

Use the ExecuteScalar method to retrieve a single value (for example, an aggregate value) from a database. This requires less code than using the ExecuteReader method, and then performing the operations necessary to generate the single value using the data returned by a VirtuosoDataReader.

A typical ExecuteScalar query can be formatted as in the following C# example:

```
command.CommandText = "select count(*) from foobar";
int count = (int) command.ExecuteScalar();
```

ICloneable.Clone Method

This member supports the .NET Framework infrastructure and is not intended to be used directly from your code.

```
object ICloneable.Clone();
```

IDbCommand.CreateParameter Method

This member supports the .NET Framework infrastructure and is not intended to be used directly from your code.

```
IDbDataParameter IDbCommand.CreateParameter();
```

IDbCommand.ExecuteReader Method

This member supports the .NET Framework infrastructure and is not intended to be used directly from your code.

IDbCommand.ExecuteReader Method ()

This member supports the .NET Framework infrastructure and is not intended to be used directly from your code.

```
IDataReader IDbCommand.ExecuteReader();
```

IDbCommand.ExecuteReader Method (CommandBehavior)

This member supports the .NET Framework infrastructure and is not intended to be used directly from your code.

```
IDataReader IDbCommand.ExecuteReader( CommandBehavior  behavior );
```

Prepare Method

Creates a prepared (or compiled) version of the command at the Virtuoso server.

```
public void Prepare();
```

Implements

IDbCommand.Prepare

VirtuosoCommandBuilder Class

Provides a means of automatically generating single-table commands used to reconcile changes made to a DataSet with the associated Virtuoso database. This class cannot be inherited.

System.Object
System.MarshalByRefObject
System.ComponentModel.Component
VirtuosoCommandBuilder

```
                    public
                    sealed
                    class
                    VirtuosoCommandBuilder
                   extends,
                    Component
                   {
      }
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

The VirtuosoDataAdapter does not automatically generate the SQL statements required to reconcile changes made to a DataSet associated with the data source. However, you can create a VirtuosoCommandBuilder object that generates SQL statements for single-table updates if you set the SelectCommand property of the VirtuosoDataAdapter. Then, the VirtuosoCommandBuilder generates any additional SQL statements that you do not set.

The relationship between a VirtuosoDataAdapter and its corresponding VirtuosoCommandBuilder is always one-to-one. To create this correspondence, you set the DataAdapter property of the VirtuosoCommandBuilder object. This causes the VirtuosoCommandBuilder to register itself as a listener for RowUpdating events on the specified VirtuosoDataAdapter object.

To generate INSERT, UPDATE, or DELETE statements, the VirtuosoCommandBuilder uses the SelectCommand property to retrieve a required set of metadata. If you change the value of SelectCommand after the metadata has been retrieved (for example, after the first update), you then should call the RefreshSchema method to update the metadata.

The VirtuosoCommandBuilder also uses the Connection, CommandTimeout, and Transaction properties referenced by the SelectCommand. The user should call RefreshSchema if any of these properties are modified, or if the value of the SelectCommand property itself is changed. Otherwise the InsertCommand, UpdateCommand, and DeleteCommand properties retain their previous values.

If you call Dispose, the VirtuosoCommandBuilder is disassociated from the VirtuosoDataAdapter, and the generated commands are no longer used.

VirtuosoCommandBuilder Constructor

VirtuosoCommandBuilder Constructor ()

Initializes a new instance of the VirtuosoCommandBuilder class.

```
public VirtuosoCommandBuilder();
```

VirtuosoCommandBuilder Constructor (VirtuosoDataAdapter)

Initializes a new instance of the VirtuosoCommandBuilder class with the associated VirtuosoDataAdapter object.

```
public VirtuosoCommandBuilder( VirtuosoDataAdapter  adapter );
```

Parameters

adapter
: A VirtuosoDataAdapter object to associate with this VirtuosoCommandBuilder.

Remarks

The VirtuosoCommandBuilder registers itself as a listener for RowUpdating events that are generated by the VirtuosoDataAdapter specified in this property.

Properties

DataAdapter Property

Gets or sets a VirtuosoDataAdapter object for which SQL statements are automatically generated.

```
public  VirtuosoDataAdapter  DataAdapter  ;
```

Property Value

A VirtuosoDataAdapter object.

Remarks

The VirtuosoCommandBuilder registers itself as a listener for RowUpdating events that are generated by the VirtuosoDataAdapter specified in this property.

QuotePrefix Property

Gets or sets the beginning character or characters to use when working with database objects (for example, tables or columns) whose names contain characters such as spaces.

```
public  string  QuotePrefix  ;
```

Property Value

The beginning character or characters to use. The default is an empty string.

Remarks

Database objects in Virtuoso servers can contain any valid characters, including spaces, commas, and semicolons. To accommodate this capability, use the QuotePrefix and QuoteSuffix properties to specify delimiters such as a left bracket and a right bracket to encapsulate the object name.

QuoteSuffix Property

Gets or sets the ending character or characters to use when working with database objects (for example, tables or columns) whose names contain characters such as spaces.

```
public  string  QuotePrefix  ;
```

Property Value

The ending character or characters to use. The default is an empty string.

Remarks

Database objects in Virtuoso servers can contain any valid characters, including spaces, commas, and semicolons. To accommodate this capability, use the QuotePrefix and QuoteSuffix properties to specify delimiters such as a left bracket and a right bracket to encapsulate the object name.

Methods

DeriveParameters Method

Retrieves parameter information from the stored procedure specified in the VirtuosoCommand and populates the Parameters collection of the specified VirtuosoCommand object.

```
public static void DeriveParameters( VirtuosoCommand  command );
```

Parameters

command
: The VirtuosoCommand referencing the stored procedure from which the parameter information is to be derived. The derived parameters are added to the Parameters collection of the VirtuosoCommand.

Remarks

`DeriveParameters` overwrites any existing parameter information for the VirtuosoCommand. `DeriveParameters` requires an extra call to the data server to obtain the information. If the parameter information is known in advance, it is more efficient to populate the parameters collection by setting the information explicitly.

For more information, see "Using Stored Procedures with a Command" in the Microsoft® .NET Framework SDK documentation.

Dispose Method

Releases the unmanaged and, optionally, the managed resources used by the VirtuosoCommandBuilder.

```
protected override void Dispose( bool  disposing );
```

Parameters

disposing
: `true` to release both managed and unmanaged resources; `false` to release only unmanaged resources.

Remarks

This method is called by the public Dispose method and the Finalize method. Dispose() invokes the protected Dispose(Boolean) method with the disposing parameter set to true. Finalize invokes Dispose with disposing set to false.

When the disposing parameter is true, the method releases all resources held by any managed objects that this VirtuosoCommand references. It does this by invoking the Dispose() method of each referenced object.

For more information about Dispose and Finalize, see "Cleaning Up Unmanaged Resources," and "Overriding the Finalize Method," in the .NET Framework SDK documentation.

GetDeleteCommand Method

Gets the automatically generated VirtuosoCommand object required to perform deletions on the Virtuoso database.

```
public VirtuosoCommand GetDeleteCommand();
```

Return Value

The automatically generated VirtuosoCommand object required to perform deletions.

Remarks

You can use the GetDeleteCommand method for informational or troubleshooting purposes because it returns the VirtuosoCommand object to be executed.

You can also use GetDeleteCommand as the basis of a modified command. For example, you might call GetDeleteCommand and modify the CommandTimeout value, and then explicitly set that on the VirtuosoDataAdapter.

After the SQL statement is first generated, you must explicitly call RefreshSchema if you change the statement in any way. Otherwise, the GetDeleteCommand still will be using information from the previous statement, which might not be correct. The SQL statements are first generated when the application calls either Update or GetDeleteCommand.

GetInsertCommand Method

Gets the automatically generated VirtuosoCommand object required to perform insertions on the Virtuoso database.

```
public VirtuosoCommand GetInsertCommand();
```

Return Value

The automatically generated VirtuosoCommand object required to perform insertions.

Remarks

You can use the GetInsertCommand method for informational or troubleshooting purposes because it returns the VirtuosoCommand object to be executed.

You can also use GetInsertCommand as the basis of a modified command. For example, you might call GetInsertCommand and modify the CommandTimeout value, and then explicitly set that on the VirtuosoDataAdapter.

After the SQL statement is first generated, you must explicitly call RefreshSchema if you change the statement in any way. Otherwise, the GetInsertCommand still will be using information from the previous statement, which might not be correct. The SQL statements are first generated when the application calls either Update or GetInsertCommand.

GetUpdateCommand Method

Gets the automatically generated VirtuosoCommand object required to perform updates on the Virtuoso database.

```
public VirtuosoCommand GetUpdateCommand();
```

Return Value

The automatically generated VirtuosoCommand object required to perform updates.

Remarks

You can use the GetUpdateCommand method for informational or troubleshooting purposes because it returns the VirtuosoCommand object to be executed.

You can also use GetUpdateCommand as the basis of a modified command. For example, you might call GetUpdateCommand and modify the CommandTimeout value, and then explicitly set that on the VirtuosoDataAdapter.

After the SQL statement is first generated, you must explicitly call RefreshSchema if you change the statement in any way. Otherwise, the GetUpdateCommand still will be using information from the previous statement, which might not be correct. The SQL statements are first generated when the application calls either Update or GetUpdateCommand.

RefreshSchema Method

Refreshes the database schema information used to generate INSERT, UPDATE, or DELETE statements.

```
public void RefreshSchema();
```

Remarks

You should call RefreshSchema whenever the SelectCommand value of the VirtuosoDataAdapter changes.

VirtuosoConnection Class

Represents an open connection to a Virtuoso database. This class cannot be inherited.

System.Object
System.MarshalByRefObject
System.ComponentModel.Component
VirtuosoConnection

```
                    public
                    sealed
                    class
                    VirtuosoConnection
                   extends,
                    Component

          implements,
                    ICloneable
                  ,
                    IDbConnection
                   {
       }
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

A VirtuosoConnection object represents a unique session to a Virtuoso database server.

The VirtuosoConnection object uses native resources such as network connection handles. You should always explicitly close any open VirtuosoConnection objects by calling Close or Dispose before the VirtuosoConnection object goes out of scope. Not doing so leaves the freeing of these native resources to garbage collection, which may not free them immediately. This, in turn, may eventually cause the underlying driver to run out of resources or reach a maximum limit, resulting in sporadic failures. For example, you might encounter Maximum Connections-related errors while a number of connections are waiting to be deleted by the garbage collector. Explicitly closing the connections by calling Close or Dispose allows a more efficient use of native resources, enhancing scalability and improving overall application performance.

VirtuosoConnection Constructor

Initializes a new instance of the VirtuosoConnection class.

VirtuosoConnection Constructor ()

Initializes a new instance of the VirtuosoConnection class.

```
public VirtuosoConnection();
```

Remarks

When a new instance of VirtuosoConnection is created, the read/write properties are set to the following initial values unless they are specifically set using their associated keywords in the ConnectionString property.

Table 7.5.

Properties	Initial Value
ConnectionString	empty string ("")

Properties	Initial Value
ConnectionTimeout	15
Database	empty string ("")

You can change the value for these properties only by using the ConnectionString property

VirtuosoConnection Constructor (string)

Initializes a new instance of the VirtuosoConnection class with the specified connection string.

```
public VirtuosoConnection( string  connectionString );
```

Parameters

connectionString
: The connection used to open the Virtuoso database.

Remarks

When a new instance of VirtuosoConnection is created, the read/write properties are set to the following initial values unless they are specifically set using their associated keywords in the ConnectionString property.

Table 7.6.

Properties	Initial Value
ConnectionString	connectionString
ConnectionTimeout	15
Database	empty string ("")

You can change the value for these properties only by using the ConnectionString property

Properties

ConnectionString Property

Gets or sets the string used to open a Virtuoso database.

```
public  string  ConnectionString  ;
```

Property Value

The connection string that includes the source database name, and other parameters needed to establish the initial connection. The default value is an empty string.

Implements

IDbConnection.ConnectionString

Remarks

The ConnectionString is similar to an OLE DB connection string, but is not identical. Unlike OLE DB or ADO, the connection string that is returned is the same as the user-set ConnectionString minus security information if the `Persist Security` Info value is set to `false` (default). The Virtuoso .NET Data Provider does not persist or return the password in a connection string unless you set `Persist Security Info` to true.

The ConnectionString property can be set only when the connection is closed. Many of the connection string values have corresponding read-only properties. When the connection string is set, all of these properties are updated, except when an error is detected. In this case, none of the properties are updated. VirtuosoConnection properties return only those settings contained in the ConnectionString.

Resetting the ConnectionString on a closed connection resets all connection string values (and related properties) including the password. For example, if you set a connection string that includes "Database=Demo", and then reset the connection string to "Data Source=myserver;User ID=dba;Password=dba", the Database property is no longer set to northwind.

The connection string is parsed immediately after being set. If errors in syntax are found when parsing, a runtime exception, such as ArgumentException, is generated. Other errors can be found only when an attempt is made to Open the connection.

Connection string has the following syntax. Each connection string is a sequence of settings Individual settings are separated by semicolons. Each setting is a pair of name and value delimited by the equal sign. Whitespace is ignored on either side of both names and values. Names are case insensitive. The value part can be quoted by either single or double quote characters or remain unquoted at all. However if it includes a semicolon, single quote, or double quote characters, it must be enclosed in either type of quotes. To embed the same character that is used for enclosing the value the character within the value must be doubled.

The following table lists the valid names for values within the ConnectionString.

Table 7.7.

Name	Default	Description
Connect Timeout -or- Connection Timeout	15	The length of time (in seconds) to wait for a connection to the server before terminating the attempt and generating an error.
Connection Lifetime	0	When a connection is returned to the pool, its creation time is compared with the current time, and the connection is destroyed if that time span (in seconds) exceeds the value specified by connection lifetime. Useful in clustered configurations to force load balancing between a running server and a server just brought on-line.
Data Source -or- Server -or- Address -or- Network Address		The name or network address of the instance of Virtuoso server to which to connect.
Encrypt	false	Specifies if the connection must be SSL encrypted. Currently encryption only works with an ODBC-based provider.
Enlist	true	When true, the pooler automatically enlists the connection in the creation thread's current transaction context.
Initial Catalog -or- Database		The name of the database.
Max Pool Size	100	The maximum number of connections allowed in the pool.
Min Pool Size	0	The minimum number of connections allowed in the pool.
Password		The password for the Virtuoso account logging on.

Name	Default	Description
-or- Pwd		
Persist Security Info	false	When set to 'false', security-sensitive information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open State. Resetting the connection string resets all connection string values including the password
Pooling	true	When true, the VirtuosoConnection object is drawn from the appropriate pool, or if necessary, is created and added to the appropriate pool.
User ID -or- Uid		The Virtuoso login name.

ConnectionTimeout Property

Gets or sets the time to wait while trying to establish a connection before terminating the attempt and generating an error.

```
public  int  ConnectionTimeout  ;
```

Property Value

The time (in seconds) to wait for a connection to open. The default value is 15 seconds.

Implements

IDbConnection.ConnectionTimeout

Remarks

A value of 0 indicates no limit, and should be avoided in a ConnectionString because an attempt to connect will wait indefinitely.

Database Property

Gets the name of the current database or the database to be used after a connection is opened.

```
public  string  Database  ;
```

Property Value

The name of the current database or the name of the database to be used once a connection is open. The default value is an empty string.

Implements

IDbConnection.Database

Remarks

Initially, the Database property is set in the connection string. The Database property can be updated by using the ChangeDatabase method.

State Property

Gets the current state of the connection.

```
public  ConnectionState  State  ;
```

Property Value

A bitwise combination of the ConnectionState values. The default is Closed.

Remarks

The allowed state changes are:

- From Closed to Open, using the Open method of the connection object.
- From Open to Closed, using either the Close method or the Dispose method of the connection object.

Methods

BeginTransaction Method

Begins a database transaction.

BeginTransaction Method ()

Begins a database transaction.

```
public VirtuosoTransaction BeginTransaction();
```

Return Value

An object representing the new transaction.

Remarks

To commit or roll back the transaction, you must explicitly use the Commit or Rollback methods.

To ensure that the Virtuoso .NET Data Provider transaction management model performs correctly, avoid using other transaction management models, such as those provided by the data source.

BeginTransaction Method (IsolationLevel)

Begins a database transaction with the specified isolation level.

```
public VirtuosoTransaction BeginTransaction( IsolationLevel  isoLevel );
```

Parameters

isoLevel
: The isolation level under which the transaction should run.

Return Value

An object representing the new transaction.

Remarks

To commit or roll back the transaction, you must explicitly use the Commit or Rollback methods.

To ensure that the Virtuoso .NET Data Provider transaction management model performs correctly, avoid using other transaction management models, such as those provided by the data source.

ChangeDatabase Method

Changes the current database for an open VirtuosoConnection.

```
public void ChangeDatabase( string  database );
```

Parameters

database
: The name of the database to use in place of the current database.

Implements

IDbConnection.ChangeDatabase

Remarks

The value parameter must contain a valid database name, and cannot contain a null value, an empty string (""), or a string with only blank characters.

Close Method

Closes the connection to the database. This is the preferred method of closing any open connection.

```
public void Close();
```

Implements

IDbConnection.Close

Remarks

The Close method rolls back any pending transactions. It then releases the connection to the connection pool, or closes the connection if connection pooling is disabled.

An application can call Close more than one time. No exception is generated.

CreateCommand Method

Creates and returns a VirtuosoCommand object associated with the VirtuosoConnection.

```
public VirtuosoCommand CreateCommand();
```

Return Value

A VirtuosoCommand object.

EnlistDistributedTransaction Method

Enlists in the specified transaction as a distributed transaction.

```
public void EnlistDistributedTransaction( ITransaction  transaction );
```

Parameters

transaction
: A reference to an existing transaction in which to enlist or null to unenlist.

Remarks

You can enlist in an existing distributed transaction using the EnlistDistributedTransaction method if auto-enlistment is disabled. Enlisting in an existing distributed transaction ensures that, if the transaction is committed or rolled back, modifications made by the code at the data source are also committed or rolled back.

ICloneable.Clone Method

This member supports the Microsoft® .NET Framework infrastructure and is not intended to be used directly from your code.

```
object ICloneable.Clone();
```

IDbConnection.BeginTransaction Method

This member supports the Microsoft® .NET Framework infrastructure and is not intended to be used directly from your code.

IDbConnection.BeginTransaction Method ()

This member supports the Microsoft® .NET Framework infrastructure and is not intended to be used directly from your code.

```
IDbTransaction IDbConnection.BeginTransaction();
```

IDbConnection.BeginTransaction Method (IsolationLevel)

This member supports the Microsoft® .NET Framework infrastructure and is not intended to be used directly from your code.

```
IDbTransaction IDbConnection.BeginTransaction( IsolationLevel  isoLevel );
```

IDbConnection.CreateCommand Method

This member supports the Microsoft® .NET Framework infrastructure and is not intended to be used directly from your code.

```
IDbCommand IDbConnection.CreateCommand();
```

Open Method

Opens a database connection with the property settings specified by the ConnectionString.

```
public void Open();
```

Implements

IDbConnection.Open

Remarks

The VirtuosoConnection draws an open connection from the connection pool if one is available. Otherwise, it establishes a new connection to an instance of Virtuoso server.

Note:
If the VirtuosoConnection goes out of scope, it is not closed. Therefore, you must explicitly close the connection by calling Close or Dispose.

VirtuosoDataAdapter Class

Represents a set of data commands and a connection to a data source that are used to fill the DataSet and update the data source. This class cannot be inherited.

System.Object
System.MarshalByRefObject
System.ComponentModel.Component
System.Data.Common.DataAdapter
System.Data.Common.DbDataAdapter
VirtuosoDataAdapter

```
                    public
                    sealed
                    class
                    VirtuosoDataAdapter
                   extends,
                    DbDataAdapter

        implements,
                    IDbDataAdapter
                   {
    }
```

Thread Safety

Any public static (Shared in Microsoft® Visual Basic®) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

The VirtuosoDataAdapter serves as a bridge between a DataSet and data source for retrieving and saving data. The VirtuosoDataAdapter provides this bridge by using Fill to load data from the data source into the DataSet, and using Update to send changes made in the DataSet back to the data source.

The VirtuosoDataAdapter also includes the SelectCommand, InsertCommand, DeleteCommand, UpdateCommand, and TableMappings properties to facilitate loading and updating of data.

VirtuosoDataAdapter Constructor

VirtuosoDataAdapter Constructor ()

Initializes a new instance of the VirtuosoDataAdapter class.

```
public VirtuosoDataAdapter();
```

Remarks

When you create an instance of VirtuosoDataAdapter, the following read/write properties are set to their default values, as shown in the table.

Table 7.8.

Properties	Default Value
MissingMappingAction	MissingMappingAction.Passthrough
MissingSchemaAction	MissingSchemaAction.Add

You can change the value of any of these properties through a separate call to the property.

VirtuosoDataAdapter Constructor (VirtuosoCommand)

Initializes a new instance of the VirtuosoDataAdapter class with the specified VirtuosoCommand as the SelectCommand property.

```
public VirtuosoDataAdapter( VirtuosoCommand  selectCommand );
```

Parameters

selectCommand
: A VirtuosoCommand that is an SQL SELECT statement or stored procedure, and is set as the SelectCommand property of the VirtuosoDataAdapter.

Remarks

This implementation of the VirtuosoDataAdapter constructor sets the SelectCommand property to the value specified in the selectCommand parameter.

When you create an instance of VirtuosoDataAdapter, the following read/write properties are set to their default values, as shown in the table.

Table 7.9.

Properties	Default Value
MissingMappingAction	MissingMappingAction.Passthrough
MissingSchemaAction	MissingSchemaAction.Add

You can change the value of any of these properties through a separate call to the property.

VirtuosoDataAdapter Constructor (string, VirtuosoConnection)

Initializes a new instance of the VirtuosoDataAdapter class with an SQL SELECT statement and a VirtuosoConnection.

```
public VirtuosoDataAdapter( string  selectCommandText ,
                            VirtuosoConnection  selectConnection );
```

Parameters

selectCommandText
: A string that is a SQL SELECT statement or stored procedure to be used by the SelectCommand property of the VirtuosoDataAdapter.

selectConnection
: A VirtuosoConnection that represents the connection.

VirtuosoDataAdapter Constructor (string, string)

Initializes a new instance of the VirtuosoDataAdapter class with an SQL SELECT statement and a connection string.

```
public VirtuosoDataAdapter( string  selectCommandText ,
                            string  selectConnectionString );
```

Parameters

selectCommandText
: A string that is a SQL SELECT statement or stored procedure to be used by the SelectCommand property of the VirtuosoDataAdapter.

selectConnectionString
: The connection string.

Properties

DeleteCommand

Gets or sets an SQL statement or stored procedure used to delete records in the data source.

```
public  VirtuosoCommand  DeleteCommand  ;
```

Property Value

A VirtuosoCommand used during an update operation to delete records in the database that correspond to deleted rows in the DataSet.

Remarks

When DeleteCommand is assigned to a previously created VirtuosoCommand, the VirtuosoCommand is not cloned. The DeleteCommand maintains a reference to the previously created VirtuosoCommand object.

InsertCommand

Gets or sets an SQL statement or stored procedure used to insert new records in the data source.

```
public  VirtuosoCommand  InsertCommand  ;
```

Property Value

A VirtuosoCommand used during an update operation to insert records in the database that correspond to new rows in the DataSet.

Remarks

When InsertCommand is assigned to a previously created VirtuosoCommand, the VirtuosoCommand is not cloned. The InsertCommand maintains a reference to the previously created VirtuosoCommand object.

SelectCommand

Gets or sets an SQL statement or stored procedure used to select records in the data source.

```
public  VirtuosoCommand  SelectCommand  ;
```

Property Value

A VirtuosoCommand used during Fill to select records from the database for placement in the DataSet.

Remarks

When SelectCommand is assigned to a previously created VirtuosoCommand, the VirtuosoCommand is not cloned. The SelectCommand maintains a reference to the previously created VirtuosoCommand object.

If the SelectCommand does not return any rows, no tables are added to the DataSet, and no exception is raised.

UpdateCommand

Gets or sets an SQL statement or stored procedure used to update records in the data source.

```
public  VirtuosoCommand  UpdateCommand  ;
```

Property Value

A VirtuosoCommand used during an update operation to update records in the database that correspond to modified rows in the DataSet.

Remarks

When UpdateCommand is assigned to a previously created VirtuosoCommand, the VirtuosoCommand is not cloned. The UpdateCommand maintains a reference to the previously created VirtuosoCommand object.

Methods

CreateRowUpdatedEvent

This member overrides DbDataAdapter.CreateRowUpdatedEvent.

```
protected override RowUpdatedEventArgs CreateRowUpdatedEvent( DataRow  dataRow ,
                                                              IDbCommand  command ,
                                                              StatementType
statementType ,
                                                              DataTableMapping
tableMapping );
```

CreateRowUpdatingEvent

This member overrides DbDataAdapter.CreateRowUpdatingEvent.

```
protected override RowUpdatedEventArgs CreateRowUpdatingEvent( DataRow  dataRow ,
                                                               IDbCommand  command ,
                                                               StatementType
statementType ,
                                                               DataTableMapping
tableMapping );
```

OnRowUpdated

Raises the RowUpdated event.

```
protected override void OnRowUpdated( RowUpdatedEventArgs  value );
```

Parameters

value
: A System.Data.Common.RowUpdatedEventArgs object that contains the event data.

Remarks

Raising an event invokes the event handler through a delegate. For an overview, see "Raising an Event" in the Microsoft® .NET Framework SDK documentation.

OnRowUpdating

Raises the RowUpdating event.

```
protected override void OnRowUpdating( RowUpdatingEventArgs  value );
```

Parameters

value
: A System.Data.Common.RowUpdatingEventArgs object that contains the event data.

Remarks

Raising an event invokes the event handler through a delegate. For an overview, see "Raising an Event" in the Microsoft® .NET Framework SDK documentation.

Events

RowUpdated

Occurs during an Update operation after a command is executed against the data source.

```
public  event  VirtuosoRowUpdatedEventHandler  RowUpdated  ;
```

Event Data

The event handler receives an argument of type VirtuosoRowUpdatedEventArgs containing data related to this event. The following VirtuosoRowUpdatedEventArgs properties provide information specific to this event.

Table 7.10.

Property	Description
Command	Gets the VirtuosoCommand executed when Update is called.
Errors (inherited from RowUpdatedEventArgs)	Gets any errors generated by the .NET data provider when the Command was executed.
RecordsAffected (inherited from RowUpdatedEventArgs)	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.
Row (inherited from RowUpdatedEventArgs)	Gets the DataRow sent through an Update.
StatementType (inherited from RowUpdatedEventArgs)	Gets the type of SQL statement executed.
Status (inherited from RowUpdatedEventArgs)	Gets the UpdateStatus of the Command.
TableMapping (inherited from RowUpdatedEventArgs)	Gets the DataTableMapping sent through an Update.

Remarks

When using the Update method, there are two events that occur per data row updated. The order of execution is as follows:

1. The values in the DataRow are moved to the parameter values.
2. The OnRowUpdating event is raised.
3. The command executes.
4. If the UpdateRowSource enumeration is set to FirstReturnedRecord, the first returned result is placed in the DataRow.
5. If there are output parameters, they are placed in the DataRow.
6. The OnRowUpdated event is raised.
7. AcceptChanges is called.

RowUpdating

Occurs during an Update operation before a command is executed against the data source.

```
public event VirtuosoRowUpdatingEventHandler RowUpdating ;
```

Event Data

The event handler receives an argument of type VirtuosoRowUpdatingEventArgs containing data related to this event. The following VirtuosoRowUpdatingEventArgs properties provide information specific to this event.

Table 7.11.

Property	Description
Command	Gets or sets the VirtuosoCommand to execute when Update is called.
Errors (inherited from RowUpdatingEventArgs)	Gets any errors generated by the .NET data provider when the Command executes.
Row (inherited from RowUpdatingEventArgs)	Gets the DataRow to send through an Update.
StatementType (inherited from RowUpdatingEventArgs)	Gets the type of SQL statement to execute.
Status (inherited from RowUpdatingEventArgs)	Gets the UpdateStatus of the Command.
TableMapping (inherited from RowUpdatingEventArgs)	Gets the DataTableMapping to send through the Update.

Remarks

When using the Update method, there are two events that occur per data row updated. The order of execution is as follows:

1. The values in the DataRow are moved to the parameter values.
2. The OnRowUpdating event is raised.
3. The command executes.
4. If the UpdateRowSource enumeration is set to FirstReturnedRecord, the first returned result is placed in the DataRow.
5. If there are output parameters, they are placed in the DataRow.
6. The OnRowUpdated event is raised.
7. AcceptChanges is called.

VirtuosoDataReader Class

Provides a means of reading a forward-only stream of rows from a Virtuoso database. This class cannot be inherited.

System.Object

System.MarshalByRefObject

VirtuosoDataReader

```
public
sealed
class
VirtuosoDataReader
extends,
```

```
                MarshalByRefObject

        implements,
                IDataReader
              ,
                IDataRecord
              ,
                IDisposable
              ,
                IEnumerable
               {
    }
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

To create a VirtuosoDataReader, you must call the ExecuteReader method of the VirtuosoCommand object, rather than directly using a constructor.

Changes made to a resultset by another process or thread while data is being read may be visible to the user of the VirtuosoDataReader. However, the precise behavior is both driver and timing dependent.

IsClosed and RecordsAffected are the only properties that you can call after the VirtuosoDataReader is closed. In some cases, you must call Close before you can call RecordsAffected.

Properties

Depth Property

Gets a value indicating the depth of nesting for the current row.

```
public  int  Depth  ;
```

Property Value

The depth of nesting for the current row.

Implements

IDataReader.Depth

Remarks

The outermost table has a depth of zero. The Virtuoso .NET Data Provider does not support nesting and always returns zero.

FieldCount Property

Gets the number of columns in the current row.

```
public  int  FieldCount  ;
```

Property Value

When not positioned in a valid record set, 0; otherwise the number of columns in the current record. The default is -1.

Implements

IDataRecord.FieldCount

Remarks

After executing a query that does not return rows, FieldCount returns 0.

IsClosed Property

Gets a value indicating whether the data reader is closed.

```
public  bool  IsClosed  ;
```

Property Value

`true` if the VirtuosoDataReader is closed; otherwise, `false` .

Implements

IDataReader.IsClosed

Remarks

IsClosed and RecordsAffected are the only properties that you can call after the VirtuosoDataReader is closed.

Item Property

Item Property (int)

Gets the value of the specified column in its native format given the column ordinal.

```
public  object  this[int i]  ;
```

Parameters

i
: The zero-based column ordinal.

Property Value

The value of the specified column in its native format.

Implements

IDataRecord.Item

Item Property (string)

Gets the value of the specified column in its native format given the column name.

```
public  object  this[string name]  ;
```

Parameters

name
: The column name.

Property Value

The value of the specified column in its native format.

Implements

IDataRecord.Item

RecordsAffected Property

Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

```
public  int  RecordsAffected  ;
```

Property Value

The number of rows changed, inserted, or deleted; 0 if no rows were affected or the statement failed; and -1 for SELECT statements.

Implements

IDataReader.RecordsAffected

Remarks

IsClosed and RecordsAffected are the only properties that you can call after the VirtuosoDataReader is closed.

Methods

Close Method

Closes the VirtuosoDataReader object.

```
public void Close();
```

Implements

IDataReader.Close

Remarks

You must explicitly call the Close method when you are through using the VirtuosoDataReader to use the associated VirtuosoConnection for any other purpose.

The Close method fills in the values for output parameters, return values and RecordsAffected.

GetBoolean Method

Gets the value of the specified column as a Boolean.

```
public bool GetBoolean( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

A Boolean that is the value of the column.

Implements

IDataRecord.GetBoolean

Remarks

Call IsDBNull to check for null values before calling this method.

GetByte Method

```
public byte GetByte( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

The value of the specified column as a byte.

Implements

IDataRecord.GetByte

Remarks

Call IsDBNull to check for null values before calling this method.

GetBytes Method

Reads a stream of bytes from the specified column offset into the buffer as an array, starting at the given buffer offset.

```
public long GetBytes( int  i ,
                      long  fieldOffset ,
                      byte[]  buffer ,
                      int  bufferOffset ,
                      int  length );
```

Parameters

i
: The zero-based column ordinal.

fieldOffset
: The index within the field from which to begin the read operation.

buffer
: The buffer into which to read the stream of bytes.

bufferOffset
: The index for buffer to begin the read operation.

length
: The number of bytes to read.

Return Value

The actual number of bytes read.

Implements

IDataRecord.GetBytes

Remarks

GetBytes returns the number of available bytes in the field. In most cases this is the exact length of the field. However, the number returned may be less than the true length of the field if GetBytes has already been used to obtain bytes from the field. This may be the case, for example, if the VirtuosoDataReader is reading a large data structure into a buffer. For more information, see the SequentialAccess setting of System.Data.CommandBehavior in the Microsoft® .NET Framework SDK documentation.

If you pass a buffer that is a null value, GetBytes returns the length of the field in bytes.

GetChar Method

```
public char GetChar( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

The value of the specified column as a character.

Implements

IDataRecord.GetChar

Remarks

Call IsDBNull to check for null values before calling this method.

GetChars Method

Reads a stream of characters from the specified column offset into the buffer as an array, starting at the given buffer offset.

```
public long GetChars( int  i ,
                      long  fieldOffset ,
                      char[]  buffer ,
                      int  bufferOffset ,
                      int  length );
```

Parameters

i
: The zero-based column ordinal.

fieldOffset
: The index within the field from which to begin the read operation.

buffer
: The buffer into which to copy data..

bufferOffset
: The index for buffer to begin the read operation.

length
: The number of characters to read.

Return Value

The actual number of characters read.

Implements

IDataRecord.GetChars

Remarks

GetChars returns the number of available characters in the field. In most cases this is the exact length of the field. However, the number returned may be less than the true length of the field if GetChars has already been used to obtain characters from the field. This may be the case, for example, if the VirtuosoDataReader is reading a large data structure into a buffer. For more information, see the SequentialAccess setting of System.Data.CommandBehavior in the Microsoft® .NET Framework SDK documentation.

If you pass a buffer that is a null value. GetChars returns the length of the field in characters.

GetData Method

Not currently supported.

```
public IDataReader GetData( int  i );
```

Implements

IDataRecord.GetData

GetDataTypeName Method

Gets the name of the source data type.

```
public string GetDataTypeName( int  i );
```

Parameters

i
The zero-based column ordinal.

Return Value

The name of the source data type.

Implements

IDataRecord.GetDataTypeName

GetDateTime Method

Gets the value of the specified column as a DateTime object.

```
public DateTime GetDateTime( int  i );
```

Parameters

i
The zero-based column ordinal.

Return Value

The value of the specified column as a DateTime object.

Implements

IDataRecord.GetDateTime

Remarks

Call IsDBNull to check for null values before calling this method.

GetDecimal Method

Gets the value of the specified column as a Decimal object.

```
public decimal GetDecimal( int  i );
```

Parameters

i
The zero-based column ordinal.

Return Value

The value of the specified column as a Decimal object.

Implements

IDataRecord.GetDecimal

Remarks

Call IsDBNull to check for null values before calling this method.

GetDouble Method

```
public double GetDouble( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

The value of the specified column as a double-precision floating point number.

Implements

IDataRecord.GetDouble

Remarks

Call IsDBNull to check for null values before calling this method.

GetFieldType Method

Gets the Type that is the data type of the object.

```
public Type GetFieldType( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

The Type that is the data type of the object.

Implements

IDataRecord.GetFieldType

GetFloat Method

```
public float GetFloat( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

The value of the specified column as a single-precision floating-point number.

Implements

IDataRecord.GetFloat

Remarks

Call IsDBNull to check for null values before calling this method.

GetGuid Method

Gets the value of the specified column as a globally-unique identifier (GUID).

```
public Guid GetGuid( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

The value of the specified column as a GUID.

Implements

IDataRecord.GetGuid

Remarks

Call IsDBNull to check for null values before calling this method.

GetInt16 Method

Gets the value of the specified column as a 16-bit signed integer.

```
public short GetInt16( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

The value of the specified column as a 16-bit signed integer.

Implements

IDataRecord.GetInt16

Remarks

Call IsDBNull to check for null values before calling this method.

GetInt32 Method

Gets the value of the specified column as a 32-bit signed integer

```
public int GetInt32( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

The value of the specified column as a 32-bit signed integer.

Implements

IDataRecord.GetInt32

Remarks

Call IsDBNull to check for null values before calling this method.

GetInt64 Method

Gets the value of the specified column as a 64-bit signed integer.

```
public long GetInt64( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

The value of the specified column as a 64-bit signed integer.

Implements

IDataRecord.GetInt64

Remarks

Call IsDBNull to check for null values before calling this method.

GetName Method

Gets the name of the specified column.

```
public string GetName( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

A string that is the name of the specified column.

Implements

IDataRecord.GetName

GetOrdinal Method

Gets the column ordinal, given the name of the column.

```
public int GetOrdinal( string  name );
```

Parameters

name
: The name of the column.

Return Value

The zero-based column ordinal.

Implements

IDataRecord.GetOrdinal

GetSchemaTable Method

Returns a DataTable that describes the column metadata of the VirtuosoDataReader.

```
public DataTable GetSchemaTable();
```

Return Value

A DataTable that describes the column metadata.

Implements

IDataReader.GetSchemaTable

Remarks

For the GetSchemaTable method returns metadata about each column in the following order:

Table 7.12.

DataReader Column	Description
ColumnName	The name of the column; this might not be unique. If the column name cannot be determined, a null value is returned. This name always reflects the most recent naming of the column in the current view or command text.
ColumnOrdinal	The ordinal of the column. This is zero for the bookmark column of the row, if any. Other columns are numbered starting with one. This column cannot contain a null value.
ColumnSize	The maximum possible length of a value in the column. For columns that use a fixed-length data type, this is the size of the data type.
NumericPrecision	If ProviderType is a numeric data type, this is the maximum precision of the column. The precision depends on the definition of the column. If ProviderType is not a numeric data type, this is a null value.
NumericScale	If ProviderType is decimal, the number of digits to the right of the decimal point. Otherwise, this is a null value.
DataType	Maps to the .Net Framework type of the column.
ProviderType	The indicator of the column's data type. If the data type of the column varies from row to row, this must be Object. This column cannot contain a null value.
IsLong	Set if the column contains a Binary Long Object (BLOB) that contains very long data.
AllowDBNull	Set if the consumer can set the column to a null value or if the provider cannot determine whether or not the consumer can set the column to a null value. Otherwise, not set. A column may contain null values, even if it cannot be set to a null value.
IsReadOnly	`true` if the column can be modified; otherwise `false` .
IsRowVersion	
IsUnique	`true` : No two rows in the base table-the table returned in BaseTableName-can have the same value in this column. IsUnique is guaranteed to be true if the column constitutes a key by itself or if there is a constraint of type UNIQUE that applies only to this column. `false` : The column can contain duplicate values in the base table. The default of this column is `false` .
IsKey	`true` : The column is one of a set of columns in the rowset that, taken together, uniquely identify the row. The set of columns with IsKey set to `true` must uniquely identify a row in the rowset. There is no requirement that this set of columns is a minimal set of columns. This set of columns may be generated from a base table primary key, a unique constraint or a unique index. `false` : The column is not required to uniquely identify the row.
IsAutoIncrement	`true` : The column assigns values to new rows in fixed increments. `false` : The column does not assign values to new rows in fixed increments. The default of this column is `false` .
BaseSchemaName	The name of the schema in the data store that contains the column. A null value if the base schema name cannot be determined. The default of this column is a null value.
BaseCatalogName	The name of the catalog in the data store that contains the column. NULL if the base catalog name cannot be determined. The default of this column is a null value.
BaseTableName	

DataReader Column	Description
	The name of the table or view in the data store that contains the column. A null value if the base table name cannot be determined. The default of this column is a null value.
BaseColumnName	The name of the column in the data store. This might be different than the column name returned in the ColumnName column if an alias was used. A null value if the base column name cannot be determined or if the rowset column is derived, but not identical to, a column in the data store. The default of this column is a null value.

GetString Method

Gets the value of the specified column as a string.

```
public string GetString( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

The value of the specified column as a string.

Implements

IDataRecord.GetString

Remarks

Call IsDBNull to check for null values before calling this method.

GetValue Method

Gets the value of the column at the specified ordinal in its native format.

```
public object GetValue( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

The value to return.

Implements

IDataRecord.GetValue

Remarks

This method returns DBNull for null database columns.

GetValues Method

Gets all the attribute columns in the current row.

```
public int GetValues( object[]  values );
```

Parameters

values
: An array of type Object into which to copy the attribute columns.

Return Value

The number of instances of Object in the array.

Implements

IDataRecord.GetValues

Remarks

For most applications, the GetValues method provides an efficient means for retrieving all columns, rather than retrieving each column individually.

You can pass an Object array that contains fewer than the number of columns contained in the resulting row. Only the amount of data the Object array holds is copied to the array. You can also pass an Object array whose length is more than the number of columns contained in the resulting row.

This method returns DBNull for null database columns.

IDisposable.Dispose Method

This member supports the Microsoft® .NET Framework infrastructure and is not intended to be used directly from your code.

```
void IDisposable.Dispose();
```

IEnumerable.GetEnumerator Method

This member supports the Microsoft® .NET Framework infrastructure and is not intended to be used directly from your code.

```
IEnumerable IEnumerable.GetEnumerator();
```

IsDBNull Method

Gets a value indicating whether the column contains non-existent or missing values.

```
public bool IsDBNull( int  i );
```

Parameters

i
: The zero-based column ordinal.

Return Value

`true` if the specified column value is equivalent to DBNull; otherwise, `false` .

Implements

IDataRecord.IsDBNull

Remarks

To avoid raising an error, call this method to check for null column values before calling the typed Get methods (for example, GetByte, GetChar, and so on).

NextResult Method

Advances the VirtuosoDataReader to the next result, when reading the results of batch SQL statements.

```
public bool NextResult();
```

Return Value

`true` if there are more result sets; otherwise, `false` .

Implements

IDataReader.NextResult

Remarks

Used to process multiple results, which can be generated by executing batch SQL statements.

By default, the VirtuosoDataReader is positioned on the first result.

Read Method

Advances the VirtuosoDataReader to the next record.

```
public bool Read();
```

Return Value

`true` if there are more rows; otherwise, `false` .

Implements

IDataReader.Read

Remarks

The default position of the VirtuosoDataReader is prior to the first record. Therefore, you must call Read to begin accessing any data.

VirtuosoError Class

Collects information relevant to a warning or error returned by Virtuoso server. This class cannot be inherited.

System.Object
VirtuosoError

```
                    public
                    sealed
                    class
                    VirtuosoError
                   {
        }
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

This class is created by the Virtuoso .NET Data Provider when an error occurs. An instance of VirtuosoError is created and managed by the VirtuosoErrorCollection, which in turn is created by the VirtuosoException class.

Properties

Message

Gets a short description of the error.

```
public  string  Message  ;
```

Property Value

A description of the error.

SQLState

Gets the five-character error code that follows the ANSI SQL standard for the database.

```
public  string  SQLState  ;
```

Property Value

The five-character error code, which identifies the source of the error.

VirtuosoErrorCollection Class

Collects all errors generated by the Virtuoso .NET Data Provider. This class cannot be inherited.

System.Object
VirtuosoErrorCollection

```
                  public
                  sealed
                  class
                  VirtuosoErrorCollection
                implements,
                  ICollection
                 {
      }
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

This class is created by VirtuosoException to collect instances of the VirtuosoError class. VirtuosoErrorCollection always contains at least one instance of the VirtuosoError class.

Properties

Count Property

Gets the number of errors in the collection.

```
public  int  Count  ;
```

Property Value

The total number of errors in the collection.

Implements

ICollection.Count

Item Property

Gets the error at the specified index.

```
public  VirtuosoError  this[int i]  ;
```

Parameters

i
: The zero-based index of the error to retrieve.

Property Value

A VirtuosoError that contains the error at the specified index.

Methods

CopyTo Method

Copies the elements of the VirtuosoErrorCollection into an array, starting at the given index within the array.

```
public void CopyTo( Array  array ,
                    int  i );
```

Parameters

array
: The array into which to copy the elements.

i
: The starting index of array.

Implements

ICollection.CopyTo

GetEnumerator Method

This member supports the Microsoft® .NET Framework infrastructure and is not intended to be used directly from your code.

```
IEnumerable IEnumerable.GetEnumerator();
```

VirtuosoException Class

The exception that is thrown when Virtuoso server returns a warning or error. This class cannot be inherited.

System.Object
System.Exception
System.SystemException
VirtuosoException

```
                    public
                    sealed
                    class
                    VirtuosoException
                   extends,
                    SystemException
                   {
}
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

This class is created whenever the Virtuoso .NET Data Provider encounters an error generated by the server (Client-side errors are raised as standard common language runtime exceptions.). It always contains at least one instance of VirtuosoError.

Properties

Errors Property

Gets a collection of one or more VirtuosoError objects that give detailed information about exceptions generated by the Virtuoso .NET Data Provider.

```
public  VirtuosoErrorCollection  Errors  ;
```

Property Value

The collected instances of the VirtuosoError class.

Remarks

This property is a wrapper for the VirtuosoErrorCollection.

Message Property

Gets the text describing the error.

```
public  string  Message  ;
```

Property Value

The text describing the error.

Remarks

This is a wrapper for the Message property of the first VirtuosoError in the Errors property.

VirtuosoInfoMessageEventArgs Class

Provides data for the InfoMessage event. This class cannot be inherited.

System.Object
System.EventArgs
VirtuosoInfoMessageEventArgs

```
                    public
                    sealed
                    class
                    VirtuosoInfoMessageEventArgs
                   extends,
                    EventArgs
                   {
      }
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

The InfoMessage event contains a VirtuosoErrorCollection collection with warnings sent from the Virtuoso srver.

Properties

Errors Property

Gets the collection of warnings sent from the Virtuoso server.

```
public  VirtuosoErrorCollection  Errors  ;
```

Property Value

The collection of warnings sent from the server.

VirtuosoInfoMessageEventHandler Delegate

Represents the method that will handle the InfoMessage event of a VirtuosoConnection.

```
public delegate void VirtuosoInfoMessageEventHandler( object  sender ,
                                                      VirtuosoInfoMessageEventArgs  e
);
```

Parameters

The declaration of your event handler must have the same parameters as the VirtuosoInfoMessageEventHandler delegate declaration.

sender
: The source of the event.

e
: A VirtuosoInfoMessageEventArgs object that contains the event data.

Remarks

When you create a VirtuosoInfoMessageEventArgs delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, unless you remove the delegate. For more information about event handler delegates, see "Events and Delegates" in the .NET Framework SDK documentation.

VirtuosoParameter Class

Represents a parameter to an VirtuosoCommand and optionally, its mapping to a DataColumn. This class cannot be inherited.

System.Object
System.MarshalByRefObject
VirtuosoParameter

```
                  public
                  sealed
                  class
                  VirtuosoParameter
                 extends,
                  MarshalByRefObject

        implements,
                  IDbDataParameter
                ,
                  IDataParameter
                ,
                  ICloneable
                 {
    }
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

VirtuosoParameter Constructor

VirtuosoParameter Constructor ()

Initializes a new instance of the VirtuosoParameter class.

```
public VirtuosoParameter();
```

VirtuosoParameter Constructor (string, object)

Initializes a new instance of the VirtuosoParameter class with the parameter name and value.

```
public VirtuosoParameter( string  parameterName ,
                          object  object );
```

Parameters

parameterName
: The name of the parameter to map.

value
: An Object that is the value of the VirtuosoParameter.

Remarks

When you specify an Object in the value parameter, the VirtDbType is inferred from the .NET Framework type of the Object.

VirtuosoParameter Constructor (string, VirtDbType)

Initializes a new instance of the VirtuosoParameter class with the parameter name and the data type.

```
public VirtuosoParameter( string  parameterName ,
                          VirtDbType  dbType );
```

Parameters

parameterName
: The name of the parameter to map.

dbType
: One of the VirtDbType values.

Remarks

The data type, and if appropriate, Size and Precision are inferred from the value of the dbType parameter.

VirtuosoParameter Constructor (string, VirtDbType, int)

Initializes a new instance of the VirtuosoParameter class with the parameter name, the VirtDbType, and the size.

```
public VirtuosoParameter( string  parameterName ,
                          VirtDbType  dbType ,
                          int  size );
```

Parameters

parameterName
: The name of the parameter to map.

dbType
: One of the VirtDbType values.

size
: The width of the parameter.

Remarks

The Size is inferred from the value of the dbType parameter if it is not explicitly set in the size parameter.

VirtuosoParameter Constructor (string, VirtDbType, int, string)

Initializes a new instance of the VirtuosoParameter class with the parameter name, VirtDbType, size, and source column name.

```
public VirtuosoParameter( string  parameterName ,
                          VirtDbType  dbType ,
```

```
                        int  size ,
                        string  sourceColumn );
```

Parameters

parameterName
: The name of the parameter to map.

dbType
: One of the VirtDbType values.

size
: The width of the parameter.

sourceColumn
: The name of the source column.

Remarks

The Size is inferred from the value of the dbType parameter if it is not explicitly set in the size parameter.

VirtuosoParameter Constructor (string, VirtDbType, int, ParameterDirection, Boolean, Byte, Byte, String, DataRowVersion, Object)

Initializes a new instance of the VirtuosoParameter class with the parameter name, the type of the parameter, the size of the parameter, a ParameterDirection, the precision of the parameter, the scale of the parameter, the source column, a DataRowVersion to use, and the value of the parameter.

```
public VirtuosoParameter( string  parameterName ,
                          VirtDbType  dbType ,
                          int  size ,
                          ParameterDirection  direction ,
                          bool  isNullable ,
                          byte  precision ,
                          byte  scale ,
                          string  sourceColumn ,
                          DataRowVersion  sourceVersion ,
                          object  value );
```

Parameters

parameterName
: The name of the parameter to map.

dbType
: One of the VirtDbType values.

size
: The width of the parameter.

direction
: One of the System.Data.ParameterDirection values.

isNullable
: `true` if the value of the field can be null, otherwise `false` .

precision
: The total number of digits to the left and right of the decimal point to which Value is resolved.

scale
: The total number of decimal places to which Value is resolved.

sourceColumn
: The name of the source column.

sourceVersion
: One of the System.Data.DataRowVersion values.

value
: An Object that is the value of the VirtuosoParameter.

Remarks

The Size and Precision are inferred from the value of the dbType parameter if they are not explicitly set in the size and precision parameters.

Properties

DbType Property

Gets or sets the DbType of the parameter.

```
public  DbType  DbType  ;
```

Property Value

One of the System.Data.DbType values. The default is String.

Implements

IDataParameter.DbType

Remarks

The VirtDbType and DbType are linked. Therefore, setting the DbType changes the VirtDbType to a supporting VirtDbType.

For a list of the supported data types, see the appropriate VirtDbType member.

Direction Property

Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter.

```
public  ParameterDirection  Direction  ;
```

Property Value

One of the System.Data.ParameterDirection values. The default is Input.

Implements

IDataParameter.Direction

Remarks

If the ParameterDirection is Output, and execution of the associated VirtuosoCommand does not return a value, the VirtuosoParameter will contain a null value. Null values are handled using the DBNull class. After the last row from the last resultset is read, the Output, InputOut, and ReturnValue parameters are updated.

IsNullable Property

Gets or sets a value indicating whether the parameter accepts null values.

```
public  bool  IsNullable  ;
```

Property Value

`true` if null values are accepted; otherwise, `false` . The default is `false` .

Implements

IDataParameter.IsNullable

Remarks

Null values are handled using the System.DBNull class.

ParameterName Property

Gets or sets the name of the VirtuosoParameter.

```
public  string  ParameterName  ;
```

Property Value

The name of the VirtuosoParameter. The default is an empty string ("").

Implements

IDataParameter.ParameterName

Remarks

Instead of named parameters, the Virtuoso .NET Data Provider uses positional parameters that are marked with a question mark (?) in the syntax of the command text. Parameter objects in the VirtuosoParameterCollection and the actual parameters accepted by the stored procedure or parameterized SQL statement correspond to each other based on the order in which the VirtuosoParameter objects are inserted into the collection rather than by parameter name. Parameter names can be supplied, but will be ignored during parameter object binding.

Precision Property

Gets or sets the maximum number of digits used to represent the Value property.

```
public  byte  Precision  ;
```

Property Value

The maximum number of digits used to represent the Value property. The default value is 0.

Implements

IDbDataParameter.Precision

Remarks

The Precision property is used only for decimal and numeric input parameters.

Scale Property

Gets or sets the number of decimal places to which Value is resolved.

```
public  byte  Scale  ;
```

Property Value

The number of decimal places to which Value is resolved. The default is 0.

Implements

IDbDataParameter.Scale

Remarks

The Scale property is used only for decimal and numeric input parameters.

Size Property

Gets or sets the maximum size, in bytes, of the data within the column.

```
public  int  Size  ;
```

Property Value

The maximum size, in bytes, of the data within the column. The default value is inferred from the parameter value.

Implements

IDbDataParameter.Size

Remarks

The Size property is used for binary and string types.

For variable-length data types, the Size property describes the maximum amount of data to transmit to the server. For example, for a string value, the Size property could be used to limit the amount of data sent to the server to the first one hundred bytes.

For nonstring data types and ANSI string data, the Size property refers to the number of bytes. For Unicode string data, the Size property refers to the number of characters. The count for strings does not include the terminating character.

If not explicitly set, the value of Size is inferred from the actual size of the specified parameter value.

For fixed-width data types, the value of Size is ignored. It can be retrieved for informational purposes, and returns the maximum amount of bytes the provider uses when transmitting the value of the parameter to the server.

SourceColumn Property

Gets or sets the name of the source column mapped to the DataSet and used for loading or returning the Value.

```
public  string  SourceColumn  ;
```

Property Value

The name of the source column that will be used to set the value of this parameter. The default is an empty string ("").

Implements

IDataParameter.SourceColumn

Remarks

When SourceColumn is set to anything other than an empty string, the value of the parameter is retrieved from the column with the SourceColumn name. If Direction is set to Input, the value is taken from the DataSet. If Direction is set to Output, the value is taken from the data source. A Direction of InputOutput is a combination of both.

SourceVersion Property

Gets or sets the DataRowVersion to use when loading Value.

```
public  DataRowVersion  DataRowVersion  ;
```

Property Value

One of the System.Data.DataRowVersion values. The default is Current.

Implements

IDataParameter.SourceVersion

Remarks

The SourceVersion is used by UpdateCommand during an Update operation to determine whether the parameter value is set to Current or Original. This allows primary keys to be updated. This property is ignored by InsertCommand and DeleteCommand.

This property is set to the version of the DataRow used by either the Item property (DataRow indexer), or the GetChildRows method of the DataRow object.

Value Property

Gets or sets the value of the parameter.

```
public  object  Value  ;
```

Property Value

An Object that is the value of the parameter. The default value is null.

Implements

IDataParameter.Value

Remarks

For input parameters, the value is bound to the VirtuosoCommand that is sent to the server. For output and return-value parameters, the value is set on completion of the VirtuosoCommand and after the VirtuosoDataReader is closed.

When sending a null parameter value to the server, the user must specify DBNull, not null. A null value in the system is an empty object that has no value. DBNull is used to represent null values.

If the application specifies the database type, the bound value is converted to that type when the provider sends the data to the server. The provider attempts to convert any type of value if it supports the IConvertible interface. Conversion errors may result if the specified type is not compatible with the value.

Both the DbType and VirtDbType properties can be inferred by setting Value. If applicable, the size, precision and scale will also be inferred from Value.

The Value property is overwritten by the Update method.

VirtDbType Property

Gets or sets the VirtDbType of the parameter.

```
public  VirtDbType  VirtDbType  ;
```

Property Value

One of the VirtDbType values. The default is NVarChar.

Remarks

The VirtDbType and DbType are linked. Therefore, setting the DbType changes the VirtDbType to a supporting VirtDbType.

For a list of the supported data types, see the appropriate VirtDbType member. For more information, see "Using Parameters with a DataAdapter" in the Microsoft® .NET Framework SDK documentation.

Methods

ICloneable.Clone Method

This member supports the Microsoft® .NET Framework infrastructure and is not intended to be used directly from your code.

```
object ICloneable.Clone();
```

ToString Method

Gets a string containing the ParameterName.

```
public override string ToString();
```

Return Value

A string containing the ParameterName.

VirtuosoParameterCollection Class

Represents a collection of parameters relevant to a VirtuosoCommand as well as their respective mappings to columns in a DataSet. This class cannot be inherited.

System.Object
System.MarshalByRefObject
VirtuosoParameterCollection

```
                    public
                    sealed
                    class
                    VirtuosoParameterCollection
                   extends,
                    MarshalByRefObject

          implements,
                    IDataParameterCollection
                  ,
                    ICollection
                  ,
                    IEnumerable
                  ,
                    IList
                   {
       }
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Properties

Count Property

Gets the number of VirtuosoParameter objects in the collection.

```
public  int  Count  ;
```

Property Value

The number of VirtuosoParameter objects in the collection.

Implements

ICollection.Count

Item Property

Item Property (int)

Gets or sets the VirtuosoParameter at the specified index.

```
public  object  this[int i]  ;
```

Parameters

index
: The zero-based index of the parameter to retrieve.

Property Value

The VirtuosoParameter at the specified index.

Item Property (string)

Gets or sets the VirtuosoParameter with the specified name.

```
public  object  this[string parameterName]  ;
```

Parameters

parameterName
: The name of the parameter to retrieve.

Property Value

The VirtuosoParameter with the specified name.

Methods

Add Method

Add Method (object)

Adds the specified VirtuosoParameter object to the VirtuosoParameterCollection.

```
public int Add( object  value );
```

Parameters

value
: The VirtuosoParameter to add to the collection.

Return Value

The index in the collection of the new VirtuosoParameter object.

Implements

IList.Add

Add Method (VirtuosoParameter)

Adds the specified VirtuosoParameter object to the VirtuosoParameterCollection.

```
public VirtuosoParameter Add( VirtuosoParameter  value );
```

Parameters

value
: The VirtuosoParameter to add to the collection.

Return Value

A reference to the new VirtuosoParameter object.

Add Method (string, object)

Adds a VirtuosoParameter to the VirtuosoParameterCollection with the specified parameter name and value.

```
public VirtuosoParameter Add( string  parameterName ,
                              object  value );
```

Parameters

parameterName
: The name of the parameter.

value
: The Value of the VirtuosoParameter to add to the collection.

Return Value

The new VirtuosoParameter object.

Add Method (string, VirtDbType)

Adds a VirtuosoParameter to the VirtuosoParameterCollection with the specified parameter name and data type.

```
public VirtuosoParameter Add( string  parameterName ,
                              VirtDbType  dbType );
```

Parameters

parameterName
: The name of the parameter.

value
: One of the VirtDbType values.

Return Value

The new VirtuosoParameter object.

Add Method (string, VirtDbType, int)

Adds a VirtuosoParameter to the VirtuosoParameterCollection with the specified parameter name, data type, and parameter size.

```
public VirtuosoParameter Add( string  parameterName ,
                              VirtDbType  dbType ,
                              int  size );
```

Parameters

parameterName
: The name of the parameter.

value
: One of the VirtDbType values.

size
: The size of the parameter (width of the column).

Return Value

The new VirtuosoParameter object.

Add Method (string, VirtDbType, int, string)

Adds a VirtuosoParameter to the VirtuosoParameterCollection with the specified parameter name, data type, parameter size, and source column name.

```
public VirtuosoParameter Add( string  parameterName ,
                              VirtDbType  dbType ,
                              int  size ,
                              string  sourceColumn );
```

Parameters

parameterName
: The name of the parameter.

value
: One of the VirtDbType values.

size
: The size of the parameter (width of the column).

sourceColumn
: The name of the source column.

Return Value

The new VirtuosoParameter object.

Clear Method

Removes all items from the collection.

```
public void Clear();
```

Implements

IList.Clear

Contains Method

Contains Method (object)

Gets a value indicating whether a VirtuosoParameter object exists in the collection.

```
public bool Contains( object  value );
```

Parameters

value
: The value of the VirtuosoParameter object to find.

Return Value

`true` if the collection contains the VirtuosoParameter; otherwise, `false` .

Implements

IList.Contains

Contains Method (string)

Gets a value indicating whether a VirtuosoParameter object with the specified parameter name exists in the collection.

```
public bool Contains( string  parameterName );
```

Parameters

parameterName
: The name of the VirtuosoParameter object to find.

Return Value

`true` if the collection contains the VirtuosoParameter; otherwise, `false` .

Implements

IDataParameterCollection.Contains

CopyTo Method

Copies VirtuosoParameter objects from the VirtuosoParameterCollection to the specified array.

```
public void CopyTo( Array  array ,
                    int  index );
```

Parameters

array
: The array into which to copy the VirtuosoParameter objects.

index
: The starting index of the array.

Implements

ICollection.CopyTo

GetEnumerator Method

This member supports the Microsoft® .NET Framework infrastructure and is not intended to be used directly from your code.

```
public IEnumerator GetEnumerator();
```

IndexOf Method

IndexOf Method (object)

Gets the location in the collection of a VirtuosoParameter object.

```
public int IndexOf( object  value );
```

Parameters

value
: The VirtuosoParameter object to find.

Return Value

The zero-based location of the VirtuosoParameter in the collection.

Implements

IList.IndexOf

IndexOf Method (string)

Gets the location in the collection of the VirtuosoParameter object with the specified parameter name.

```
public int IndexOf( string  parameterName );
```

Parameters

parameterName
: The name of the VirtuosoParameter object to find.

Return Value

The zero-based location of the VirtuosoParameter in the collection.

Implements

IDataParameterCollection.IndexOf

Insert Method

Inserts a VirtuosoParameter into the collection at the specified index.

```
public void Insert( int  index ,
                    object  value );
```

Parameters

index
: The zero-based index where the parameter is to be inserted within the collection.

value
: The VirtuosoParameter to add to the collection.

Implements

IList.Insert

Remove Method

Removes the specified VirtuosoParameter from the collection.

```
public void Remove( object  value );
```

Parameters

value
: The VirtuosoParameter object to remove from the collection.

Implements

IList.Remove

RemoveAt Method

RemoveAt Method (int)

Removes the VirtuosoParameter at the specified index from the collection.

```
public void RemoveAt( int  index );
```

Parameters

index
: The zero-based index of the parameter to remove.

Implements

IList.RemoveAt

RemoveAt Method (string)

Removes the VirtuosoParameter with the specified name from the collection.

```
public void RemoveAt( string  parameterName );
```

Parameters

parameterName
: The name of the parameter to remove.

Implements

IDataParameterCollection.RemoveAt

VirtuosoPermission Class

Provides the capability for the Virtuoso .NET Data Provider to ensure that a user has a security level adequate to access a data source. This class cannot be inherited.

System.Object

System.Security.CodeAccessPermission

VirtuosoPermission

```
                    public
                    sealed
                    class
                    VirtuosoPermission
                   extends,
                    CodeAccessPermission

          implements,
                    IUnrestrictedPermission
                   {
      }
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

VirtuosoPermission Constructor

VirtuosoPermission Constructor ()

Initializes a new instance of the VirtuosoPermission class.

```
public VirtuosoPermission();
```

VirtuosoPermission Constructor (PermissionState)

Initializes a new instance of the VirtuosoPermission class.

```
public VirtuosoPermission( PermissionState  state );
```

Parameters

state
: One of the System.Security.Permissions.PermissionState values.

Methods

Copy Method

Creates and returns an identical copy of the current permission object.

```
public override IPermission Copy();
```

Return Value

A copy of the current permission object.

Implements

IPermission.Copy

Remarks

A copy of a permission object represents the same access to resources as the original permission object.

FromXml Method

Reconstructs a security object with a specified state from an XML encoding.

```
public override void FromXml( SecurityElement  securityElement );
```

Parameters

securityElement
: The XML encoding to use to reconstruct the security object.

Implements

ISecurityEncodable.FromXml

Intersect Method

Returns a new permission object representing the intersection of the current permission object and the specified permission object.

```
public override IPermission Intersect( IPermission  target );
```

Parameters

target
: A permission object to intersect with the current permission object. It must be of the same type as the current permission object.

Return Value

A new permission object that represents the intersection of the current permission object and the specified permission object. This new permission object is a null reference (Nothing in Visual Basic) if the intersection is empty.

Implements

IPermission.Intersect

Remarks

The intersection of two permissions is a permission that describes the set of operations they both describe in common. Only a demand that passes both original permissions will pass the intersection.

IsSubsetOf Method

Returns a value indicating whether the current permission object is a subset of the specified permission object.

```
public override bool IsSubsetOf( IPermission  target );
```

Parameters

target
: A permission object that is to be tested for the subset relationship. This object must be of the same type as the current permission object.

Return Value

`true` if the current permission object is a subset of the specified permission object; otherwise `false` .

Implements

IPermission.IsSubsetOf

Remarks

The current permission object is a subset of the specified permission object if the current permission object specifies a set of operations that is wholly contained by the specified permission object. For example, a permission that represents access to C:\example.txt is a subset of a permission that represents access to C:\. If this method returns true, the current permission object represents no more access to the protected resource than does the specified permission object.

IsUnrestricted Method

Returns a value indicating whether the permission can be represented as unrestricted without any knowledge of the permission semantics.

```
public bool IsUnrestricted();
```

Return Value

`true` if the VirtuosoPermission instance was created with PermissionState.Unrestricted; otherwise, `false` .

Implements

IUnrestrictedPermission.IsUnrestricted

ToXml Method

Creates an XML encoding of the security object and its current state.

```
public override SecurityElement ToXml();
```

Return Value

An XML encoding of the security object, including any state information.

Implements

ISecurityEncodable.ToXml

Union Method

Creates a permission that is the union of the permission and the specified permission.

```
public override IPermission Union( IPermission  target );
```

Parameters

target
: A permission to combine with the current permission. It must be of the same type as the current permission.

Return Value

A new permission that represents the union of the current permission and the specified permission.

Remarks

The result of a call to Union is a permission that represents all the operations represented by both the current permission and the specified permission. Any demand that passes either permission passes their union.

VirtuosoPermissionAttribute

Allows security actions for VirtuosoPermission to be applied to code using declarative security. This class cannot be inherited.

System.Object
System.Attribute
System.Security.Permissions.SecurityAttribute
System.Security.Permissions.CodeAccessSecurityAttribute
VirtuosoPermissionAttribute

```
public
sealed
class
VirtuosoPermissionAttribute
extends,
```

```
                    CodeAccessSecurityAttribute
                   {
        }
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

VirtuosoPermissionAttribute Constructor

Initializes a new instance of the VirtuosoPermissionAttribute class.

```
public VirtuosoPermissionAttribute();
```

Parameters

action
: One of the SecurityAction values representing an action that can be performed using declarative security.

Methods

CreatePermission Method

Returns a VirtuosoPermission object that is configured according to the attribute properties.

```
public override IPermission CreatePermission();
```

Return Value

A VirtuosoPermission object.

VirtuosoRowUpdatedEventArgs Class

Provides data for the RowUpdated event. This class cannot be inherited.

System.Object
System.EventArgs
System.Data.Common.RowUpdatedEventArgs
VirtuosoRowUpdatedEventArgs

```
                    public
                    sealed
                    class
                    VirtuosoRowUpdatedEventArgs
                   extends,
                    RowUpdatedEventArgs
                   {
        }
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

VirtuosoRowUpdatedEventArgs Constructor

Initializes a new instance of the VirtuosoRowUpdatedEventArgs class.

```
public VirtuosoRowUpdatedEventArgs( DataRow  row ,
                                    IDbCommand  command ,
                                    StatementType  statementType ,
                                    DataTableMapping  tableMapping );
```

Parameters

row
: The DataRow sent through an Update.

command
: The IDbCommand executed when Update is called.

statementType
: One of the StatementType values that specifies the type of query executed.

tableMapping
: The DataTableMapping sent through an Update.

Properties

Command Property

Gets the VirtuosoCommand executed when Update is called.

```
public  new  VirtuosoCommand  Command  ;
```

Property Value

The VirtuosoCommand executed when Update is called.

VirtuosoRowUpdatedEventHandler Delegate

Represents the method that will handle the RowUpdated event of a VirtuosoDataAdapter.

```
public delegate void VirtuosoRowUpdatedEventHandler( object  sender ,
                                                     VirtuosoRowUpdatedEventArgs  e );
```

Parameters

The declaration of your event handler must have the same parameters as the VirtuosoRowUpdatedEventHandler delegate declaration.

sender
: The source of the event.

e
: A VirtuosoRowUpdatedEventArgs object that contains the event data.

Remarks

The handler is not required perform any action, and your code should avoid generating exceptions or allowing exceptions to propagate to the calling method. Any exceptions that do reach the caller are ignored. When you create a VirtuosoRowUpdatedEventHandler delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, unless you remove the delegate. For more information about event handler delegates, see "Events and Delegates" in the .NET Framework SDK documentation.

VirtuosoRowUpdatingEventArgs Class

Provides data for the RowUpdating event. This class cannot be inherited.

System.Object

System.EventArgs

System.Data.Common.RowUpdatingEventArgs

VirtuosoRowUpdatingEventArgs

```
public
sealed
class
VirtuosoRowUpdatingEventArgs
extends,
```

```
                    RowUpdatingEventArgs
                   {
        }
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

VirtuosoRowUpdatingEventArgs Constructor

Initializes a new instance of the VirtuosoRowUpdatingEventArgs class.

```
public VirtuosoRowUpdatingEventArgs( DataRow  row ,
                                     IDbCommand  command ,
                                     StatementType  statementType ,
                                     DataTableMapping  tableMapping );
```

Parameters

row
: The DataRow sent through an Update.

command
: The IDbCommand executed when Update is called.

statementType
: One of the StatementType values that specifies the type of query executed.

tableMapping
: The DataTableMapping sent through an Update.

Properties

Command Property

Gets or sets the VirtuosoCommand executed when Update is called.

```
public  new  VirtuosoCommand  Command  ;
```

Property Value

The VirtuosoCommand executed when Update is called.

VirtuosoRowUpdatingEventHandler Delegate

Represents the method that will handle the RowUpdating event of a VirtuosoDataAdapter.

```
public delegate void VirtuosoRowUpdatingEventHandler( object  sender ,
                                                      VirtuosoRowUpdatingEventArgs  e
);
```

Parameters

The declaration of your event handler must have the same parameters as the VirtuosoRowUpdatingEventHandler delegate declaration.

sender
: The source of the event.

e
: A VirtuosoRowUpdatingEventArgs object that contains the event data.

Remarks

The handler is not required perform any action, and your code should avoid generating exceptions or allowing exceptions to propagate to the calling method. Any exceptions that do reach the caller are ignored. When you create a

VirtuosoRowUpdatingEventHandler delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, unless you remove the delegate. For more information about event handler delegates, see "Events and Delegates" in the .NET Framework SDK documentation.

VirtuosoTransaction Class

Represents a transaction to be made at a Virtuoso database. This class cannot be inherited.

System.Object
System.MarshalByRefObject
VirtuosoTransaction

```
                    public
                    sealed
                    class
                    VirtuosoTransaction
                   extends,
                    MarshalByRefObject

          implements,
                    IDbTransaction
                  ,
                    IDisposable
                   {
       }
```

Thread Safety

Any public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

The application creates a VirtuosoTransaction object by calling BeginTransaction on the VirtuosoConnection object. All subsequent operations associated with the transaction (for example, committing or aborting the transaction), are performed on the VirtuosoTransaction object.

Properties

Connection

Gets the VirtuosoConnection object associated with the transaction.

```
public  VirtuosoConnection  Connection  ;
```

Property Value

The VirtuosoConnection object to associate with the transaction.

Remarks

A single application may have multiple database connections, each with zero or more transactions. This property enables you to determine the connection object associated with a particular transaction.

IsolationLevel

Specifies the IsolationLevel for this transaction

```
public  IsolationLevel  IsolationLevel  ;
```

Property Value

The IsolationLevel for this transaction.

Implements

IDbTransaction.IsolationLevel

Remarks

Parallel transactions are not supported. Therefore, the IsolationLevel applies to the entire transaction.

Methods

Commit Method

Commits the database transaction.

```
public void Commit();
```

Dispose Method

Releases the unmanaged resources used by the VirtuosoTransaction and optionally releases the managed resources.

```
public void Dispose();
```

Implements

IDisposable.Dispose

Rollback Method

Rolls back a transaction from a pending state.

```
public void Rollback();
```

Implements

IDbTransaction.Rollback

Remarks

The transaction can be rolled back only from a pending state (after BeginTransaction has been called, but before Commit is called).

7.2. Interactive SQL Utility

ISQL/ISQLO/ISQLU/isql-iodbc/isql-udbc

The Virtuoso ISQL utility allows users to execute queries & scripts against the Virtuoso or other SQL servers (depending on the suffix). It also supports a large number of options and it's own commands.

ISQL parses it's input for CREATE (PROCEDURE|TRIGGER|FUNCTION), '{', '}', ';', double and single quotes and comments to detect where the current command starts and finishes. If it's in a PROCEDURE|TRIGGER|FUNCTION declaration it changes it's command line prompt to '<procedure_name>(<curly_brace_nesting_level>)' to help the user enter the correct command. Otherwise it considers semicolon (;) as the statement end and executes the statement.

ISQL also has a form of script language by itself.

7.2.1. Invoking ISQL

ISQL is invoked from the command line of the operating system. It is a text-mode application with support of readline library (where available).

Specify the --help or the -? option to view the usage:

```
bash$ ./bin/isql --help
OpenLink Interactive SQL (Virtuoso), version 0.9849b.

   Usage :
isql <HOST>[:<PORT>] <UID> <PWD> file1 file2 ...

isql -H <server_IP> [-S <server_port>] [-U <UID>] [-P <PWD>]
     [-E] [-X <pkcs12_file>] [-K]
     [-u <name>=<val>]* [-i <param1> <param2>]

     isql -?
Connection options:

  -?                  - This help message
  -U username         - Specifies the login user ID
  -P password         - Specifies the login password
  -H server_addr      - Specifies the Server address (IP)
  -S server port      - Specifies the TCP port to connect to
  -E                  - Specifies that encryption will be used.
                        If no PK is specified, then anonymous connection is established.
  -C                  - Specifies that password will be sent in cleartext
  -X pkcs12_file      - Specifies that encryption & X509 certificates will
                        be used i.e the client PK <pksc12 file>
  -T server_cert      - Specifies the CA certificate(s) file to be used i.e. the list
                        of trusted issuers: a PEM (base64) file of all the X509 certificates
                        of the Certification Authorities (CA) which the client will use for
                        verifying the server's certificate. This is used on client side to
                        verify the server certificate.
  -b size             - Specifies the size of the command buffer to be used (in KBytes)
  -K                  - Shuts down the virtuoso on connecting to it

Parameter passing options:

  -u name1=val1... - Everything after -u is stored to associative array U,
                        until -i is encountered. If no equal sign then value
                        is NULL
  -i                  - Ignore everything after the -i option, after which
                        comes arbitrary input parameter(s) for isql procedure,
                        which can be referenced with $ARGV[$I] by the
                        ISQL-commands.
  <OPT>=<value>       - Sets the ISQL options

  Note that if none of the above matches then the non-options go as
  <HOST>[:<PORT>] <UID> <PWD> file1 file2 ...
```

If the command line option is not one of the above it is considered a "non-option" parameter. If the non-option parameter contains the equal sign ('=') then it's considered an ISQL option value assignment. For example 'MAXROWS=10' limits the number of rows returned for a resultset to 10 instead of the default 0.

Otherwise ISQL treats the "non-option" parameters (identified by their position) as follows :

Position 1 - <Host> or <port> or <Host:port> (native), DSN (ISQLO/ISQLU/isql-iodbc/isql-udbc)

Position 2 - <user_id>

Position 3 - <password>

Position 4 and later - script file name to load

Let us consider the following command line:

```
isql 1111 dba dba VERBOSE=OFF 'EXEC=status()' test.sql test2.sql -i arg1 arg2
```

The '1111' is the first "non-option", so it represents the connection host:port (This is all digits so the virtuoso CLI prepends this with 'localhost', i.e. this is an shortcut for 'localhost:1111').

The first 'dba' is the second "non-option", so it is used as User ID.

The second 'dba' is the third "non-option", so it is used as Password.

'VERBOSE=OFF' is a "non-option", but it has an equal sign in it, so this becomes an ISQL option SET statement. In this particular case this disables the output of "Done xxx msec" messages after each command.

'EXEC=status()' is a "non-option", but again has again an equal sign in it. EXEC is a special option. Setting it to a value means executing that value as an SQL command. The result of this is that status() gets executed and it's results shown.

'test.sql' is the fourth "non-option" and it specifies a file name to load a script from and execute.

'test2.sql' is the fifth "non-option" and it again specifies a file name to load a script from and execute.

'-i' specifies that the script argument list starts. So every option after the -i is filled in the ISQL $ARGV[] array.

The order of execution is:

1. Connect to 'localhost:1111' using UserID/Password dba/dba.
2. Set the VERBOSE ISQL flag to OFF.
3. Set the $ARGV[0]=arg1 and $ARGV[1]=arg2.
4. Execute status() and display the results.
5. Execute the script in test.sql and display the results.
6. Execute the script in test2.sql and display the results.
7. Disconnect and exit the ISQL

7.2.2. ISQL Commands

```
<SQL_command> &
```

Spawns a new copy of ISQL as a background OS process to execute the command. The new copy will make its own connection and will terminate after the command completes. The isql instance which received the command prompts for the next command without waiting for the spawned isql instance

```
! <command> (;|&)
```

Executes an OS command

```
SET <ISQL_OPTION>( |=)<VALUE>
```

sets the ISQL variable or associative array U value, if it is recognized as such. Otherwise passed to the server.

Example 7.1. Examples

```
SET U{test} 5; sets the associative array U's 'test' to have value of 5
```

```
SHOW [<ISQL_OPTION>]
```

shows the value of an ISQL option, if it is recognized as such. Otherwise passed to the server.

```
NOP
```

no-operation. Useful sometimes in an $IF command.

```
(ECHO|ECHOLN) [STDOUT|STDERR|ERROR_STREAM|BOTH] string1 string2 ...
```

echoes it's arguments into the specifies output stream (defaults to STDOUT if not specified) If ECHOLN is used it appends a new line after the last character printed.

```
WAIT_FOR_CHILDREN
```

Waits for background ISQL subcommands spawned by specifying an & instead of ; at the end of the statement.

```
LOAD <file_name>
```

Executes each statement of the specified file. Statements end in a semicolon or at the closing curly brace for procedure or trigger definitions.

```
HELP [<isql-command>]
```

Prints general or command specific help texts.

```
(EXIT|QUIT) [NOT]
```

Exits ISQL

EXIT NOT is a NO-OP, allowing statements like: EXIT $IF $EQU $ARGV[0] 10 $ARGV[0] NOT; which exits with exit code 10 if $ARGV[0] is ten (presumably keeping a some-kind of failure counter) but otherwise does nothing special, and continues from the next statement.

```
SLEEP [<seconds>]
```

sleeps for the specified number of seconds or until an OS signal arrives. If seconds is not specified it's considered 0 and the behavior is OS dependent (the OS sleep function on Unixes, Sleep() in the Windows API).

```
CONNECT [<conn_str>]
```

Without arguments forces the connection to be made with an ordinary way with SQLConnect and so-far specified connection details. With an argument uses SQLDriverConnect, giving that argument as a connection string (e.g. "DSN=Virtuoso;UID=DBA,PWD=DBA") If we are already connected, then is just NO-OP which is silently ignored.

```
TableQualifiers
```

Returns all defined table qualifiers.

```
TableOwners
```

Returns existing table owners list.

```
TableTypes
```

Returns list of current table types.

```
RECONNECT [<User_ID>]
```

If the ISQL is already connected then disconnects. After that it tries connecting to the same data source, but with using its argument as a user name. If none specified it gets the user name/password from the UID and PWD ISQL variables.

```
FOREACH [LINE|INTEGER|BLOB|TIMESTAMP|DATE|TIME]
        [FOLLOWING|IN (-|-b|<file_name>)|BETWEEN <n1> <n2>]
        <statement_with_params> <statement_with_params> ... [END]
```

This command executes the <statement_with_params> in a loop, after binding the parameters specified in it to values specified in the command.

Parameters are specified as follows :

? - an ordinary parameter bound to the foreach value

?C - the count of successful operations

LINE processes the input line by line

INTEGER converts the input into integer and then processes it.

BLOB reads the entire input and sets it as an blob parameter using SQLPutData

TIMESTAMP is the same as LINE, bit binds to a TIMESTAMP SQL Type

DATE is the same as LINE, but binds to a DATE SQL Type

TIME is the same as LINE, bit binds to a TIME SQL Type

IN specifies a set of items terminated by an END

BETWEEN specifies integer set starting from n1 and ending on n2

FOLLOWING as as IN but skips the input till the END keyword

Example 7.2. Examples:

```
foreach integer between 1 10 insert into num_tb values (?);
```

Inserts 10 rows from 1 to 10 into the num_tb

```
foreach line in my_text_file.txt insert into str_tb (line_no, data) values (?C, ?);
```

Inserts each line of the text file my_text_file.txt into str_tb's data column and puts line number in line_no column

```
foreach blob in my_text_file.txt insert into file_tb values (?);
```

inserts a row into the file_tb with the contents of the my_text_file.txt as a single blob value.

```
SHUTDOWN
```

Passes this through to the server as a command

```
CALL <SQL statement>
```

Tries to bind & print the SQL_RETURN_VALUE and display multiple resultsets (if any) after executing the statement.

```
COLUMNS [<table_mask>][/<column_mask>]
```

Calls SQLColumns ODBC

```
TABLES [<table_mask>]
```

Calls SQLTables ODBC

```
PRIMARYKEYS [<table_mask>]
```

Calls SQLPrimaryKeys ODBC

```
COLUMNPRIVILEGES [<table_mask>]/[<procedure_column_mask>]
```

Calls SQLColumnPrivileges ODBC

```
PROCEDURES [<procedure_mask>]
```

Calls SQLProcedures ODBC

```
PROCEDURECOLUMNS [<procedure_mask>]/[<procedure_column_mask>]
```

Calls SQLProcedureColumns ODBC

```
TABLEPRIVILEGES [<table_mask>]
```

Calls SQLTablePrivileges ODBC

```
GETTYPEINFO
```

Calls SQLGetTypeInfo (SQL_ALL_TYPES) ODBC

```
STATISTICS [<table_mask>] [/U]
```

Calls SQLStatistics ODBC. U means show only unique indexes otherwise all

```
SPECIALCOLUMNS [<table_mask>] [/(B?S?T?N?)]
```

Calls SQLSpecialColumns ODBC.

B means BEST_ROWID, otherwise ROWVER.

S means Session scope, T means transaction scope, otherwise current row.

N means No Nulls, otherwise Nullable.

7.2.3. ISQL Macro Substitution

Before executing commands ISQL expands macros in statement text. The following macros and macro related commands are available:

$LOADEXPR - the current script startup command

$LINENO - the current line number

$YYYYMMDD - the current date in the same format

$HHMMSS - the current time in the same format

```
$IF <cond> <THEN_RESULT> [<ELSE_RESULT>]
```

If the condition evaluates to non-empty and is not the literal 0 the value of the $IF is the <THEN_RESULT> else the <ELSE_RESULT>.

```
$(+|-) <arg1> <arg2>
```

result is the addition or substitution of the arg1 and arg2

```
$LAST[<n>]
```

an array of the last resultset row

```
$ARGV[<n>]
```

an array of the command line arguments

```
$U[<name>]
```

prints the user associative array U value for the name <name>

```
$<ISQL_Variable>
```

returns the value of that variable

```
$LT <v1> <v2>
```

returns 1 if the <v1> is lower that <v2>, empty otherwise

```
$GT <v1> <v2>
```

returns 1 if the <v1> is greater than <v2>, empty otherwise

```
$GTE <v1> <v2>
```

returns 1 if the <v1> is greater or equal than <v2>, empty otherwise

```
$LTE <v1> <v2>
```

returns 1 if the <v1> is lower or equal than <v2>, empty otherwise

```
$EQU <v1> <v2>
```

returns 1 if the <v1> is equal to <v2>, empty otherwise

```
$NEQ <v1> <v2>
```

returns 1 if the <v1> is not equal to <v2>, empty otherwise

Example 7.3. Examples:

```
ECHO $IF $EQU 1 2 "True" "False";
```

prints "False" to the standard output

```
EXIT $IF $NEQ 1 2 NOT;
```

never exits

```
ECHO $IF $EQU $ARGV[1] 1 "One" $IF $EQU $ARGV[1] "Two" "Unknown;
```

prints the "one" on 1 as arg 1, "two" on 2 as arg 1 otherwise "Unknown"

7.2.4. ISQL Variables

These variables are sometimes set as a side effect of executing statements, e.g. rowcnt and sometimes should be explicitly set by the user to control the operation of isql, e.g. maxrows.

The variable names are case insensitive. Like in UNIX shells, the variable name in an expression must be prefixed by a $ to return its value. Variables do not have an explicit data type. Like Unix shell variables they have string values which are sometimes interpreted as numbers and sometimes as booleans. Generally an on/off choice is represented by the values ON/OFF. The ON/OFF values are case insensitive.

Example 7.4. Example:

```
SQL> SET AUTOCOMMIT ON;
SQL> echo $autocommit;
ON
SQL> set U{var} foo;
SQL> echo $u{VAR};
foo
```

Note that the $u{<var>} notation is a general purpose text substitution macro without arguments. The expansion takes place regardless of SQL syntactic context.

Example 7.5. Example:

```
set u{table} SYS_KEYS;
select count (*) from $u{table};
```

Variable Reference

```
RETVAL
```

Function called return value

```
RETVALLEN
```

Function called return value length

```
ROWCNT
```

Number of rows in the last result set. If the statement was an insert, update or delete this is the number of rows affected.

```
COLCNT
```

Number of columns in the last resultset

```
ARGC
```

Number of ISQL command line arguments

```
I
```

Number of script arguments (after -i)

```
LIF
```

Result of the last $IF

```
INPUTLINE
```

Current executed line

```
STATE
```

SQL State (defaults to OK)

```
SQLSTATE
```

Same as state.

```
MESSAGE
```

the SQL error message from the last operation.

```
DRIVER
```

The Driver name

```
LWE
```

Last ECHO output

```
DSN
```

The DSN or host address used/to be used in connecting to the server. Use this with uid and pwd before the connect or reconnect command to change the connected server. This is useful for scripts which access multiple servers.

```
UID
```

The User ID used/to be used in connecting to the server

```
PWD
```

The Password used/to be used in connecting to the server

```
ERRORS
```

The current stream for errors (STDIN, STDOUT, STDERR or a file name)

```
PROMPT
```

Prints the PROMPT or not

```
EMPTY
```

The current empty string value

```
VERSION
```

ISQL version

```
BLOBS
```

When ON binds prints the BLOB resultset values when printing the resultset. Otherwise prints 'BLOB x chars'

```
ECHO
```

When ON prints the commands to the standard output before executing

```
BANNER
```

When ON prints the column names & types banner when printing the resultset

```
TYPES
```

When ON prints the Type information in the resultset's banner

```
VERBOSE
```

When ON Prints the Timing row after the resultset output

```
TIMESTOSTRINGS
```

When ON binds the SQL_DATE, SQL_TIME & SQL_TIMESTAMP columns to strings

```
TRAILING_NEWLINES
```

When ON prints new line after the row's end

```
DEADLOCK_RETRIES
```

How many times to retry the statement if deadlock occurred

```
MACRO_SUBSTITUTION
```

When ON ISQL does understand & process $ macros

```
IGNORE_PARAMS
```

When ON passes the ? through to the server instead of returning an error for unbound ?

```
BIND_RETURN_VALUES
```

When ON binds a buffer to SQL_RETURN_VALUE

```
AUTOCOMMIT
```

When ON ISQL executes statements in autocommit mode. By default isql executes statements in manual commit mode, following each execution with a SQLTransact call to commit. The difference is not visible most of the time.

```
ACCESSMODE
```

Sets the ODBC access mode (RW, RO)

```
TIMEOUT
```

ODBC Query timeout

```
MAXROWS
```

Print only the first so many rows. If 0 - unlimited.

```
CURRENT_QUALIFIER
```

Prints the current ODBC SQLGetInfo client Qualifier

```
INFO_DATABASE_NAME
```

Prints the current ODBC SQLGetInfo Database name

```
INFO_USER_NAME
```

Prints the current ODBC SQLGetInfo user name

```
INFO_GETDATA_EXTENSTIONS
```

Prints the current ODBC SQLGetInfo SQLGetData extensions flag

```
COMMAND_TEXT_ON_ERROR
```

When OFF ISQL does not print the text of the command in the error messages

7.2.5. Using isql as a General Purpose Test Driver

isql can be used to automatically run SQL scripts which execute statements, perform simple tests on the results and generate a report. This can be used to automate tests of stored procedures or to benchmark them.

Also note the use of & at the end of a command to spawn multiple isql instances on the background. This is useful for automatically creating concurrency situations for testing.

Consider the script:

```
drop table tt;
create table tt (id int identity not null primary key, ctr int);
create procedure tt_fill (in n int)
{
  declare ctr int;
  ctr := 0;
  while (ctr < n){
    insert into tt (ctr) values (ctr);
    ctr := ctr + 1;
  }
}

tt_fill (10000) &
tt_fill (10000) &
tt_fill (10000) &
tt_fill (10000) &

wait_for_children;
select count (*), count (distinct ctr)  from tt;

echo both $if $equ $last[1] 40000 "PASSED" "***FAILED";
echo both " Inserted " $last[1] " rows\n";
echo both $if $equ $last[2] 10000 "PASSED" "***FAILED";
echo both " Inserted " $last[2] " distinct ctr values\n";
```

Now suppose the above text were in the file test.sql. The command

```
isql 1111 errors=stdout <test.sql >test.out
```

would print the diagnostics to the standard error and the full trace to test.out. Note the errors=stdout would direct the error message for no table in the initial drop table to the text.out file, so the console would just print:

```
PASSED Inserted 40000 rows
PASSED Inserted 10000 distinct ctr values
```

7.3. Virtuoso Driver for ODBC

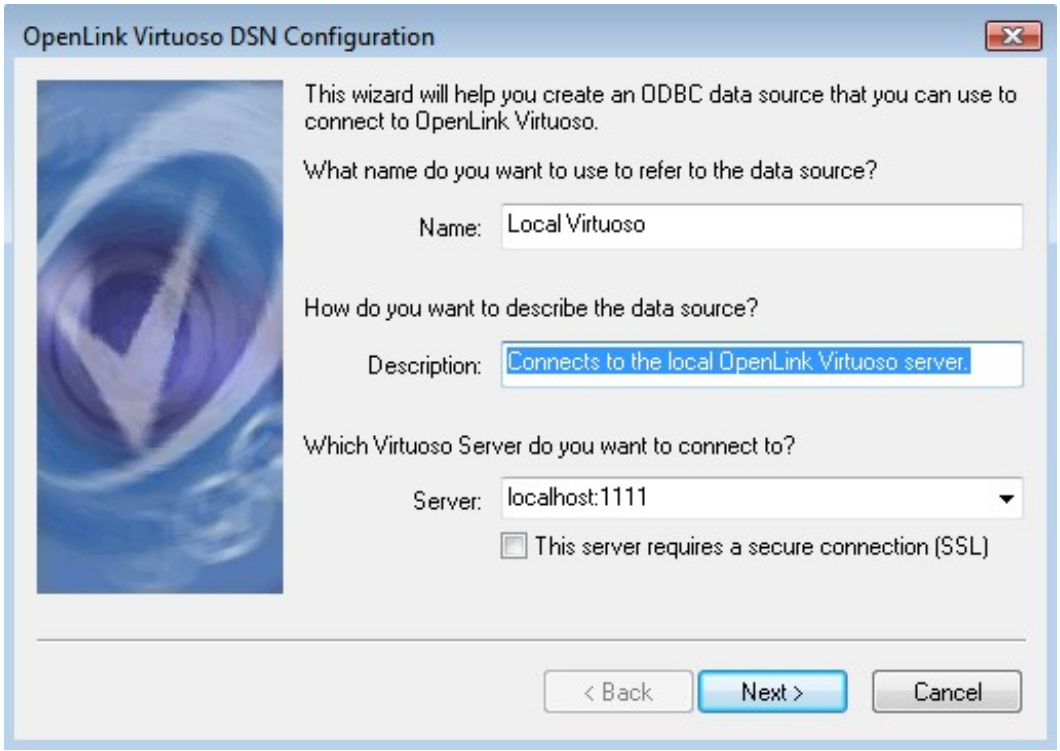
7.3.1. Windows ODBC Driver Configuration

At installation time two ODBC data source names (DSN's) are created with default values by the Virtuoso installer, the first DSN named "Local Virtuoso" provides a link to a local default Virtuoso database server instance, while the other named "Local Virtuoso Demo" provides a link to a local Virtuoso server for the Virtuoso demonstration database.

The process of creating additional ODBC DSN's for you Virtuoso drivers for ODBC is explained in the steps that follow:

1. Go to the Windows *Control panel* .
2. Double click on the *ODBC Administrator* applet. On Windows 2000 / XP the ODBC Administrator applet may be called *Data Source (ODBC)* and may be found under Administrative tools icon of the Control Panel.
3. Once the ODBC Administrator has been loaded choose by selecting the appropriate panel whether you want a new User or System Data Source. User Data Sources will only be available to the user that created them. System Data Sources will be available to all users and applications on the system.
4. Click on the *Add* Data Source Name button
5. Select the Driver named *OpenLink Virtuoso Driver*
6. Enter values into the fields presented by the Virtuoso Driver's DSN configuration dialog:

Figure 7.30. Virtuoso ODBC Driver Setup Dialogue for Windows



Name: provide a name that will act as a logical reference to the Virtuoso database server that you will be connecting to. Subsequent references to this database will be made to this value when ODBC compliant applications interact with your Virtuoso driver.

Description: allows you to provide a short description about the nature of the connection. This is optional.

Server: enter the hostname or IP address of the machine hosting your Virtuoso server and enter the port number that Virtuoso is listening at. This is configured in the Virtuoso ini file on the server.

7. Press the *Next* button to configure more details about the connection

Figure 7.31. Virtuoso ODBC Driver Setup Dialogue for Windows

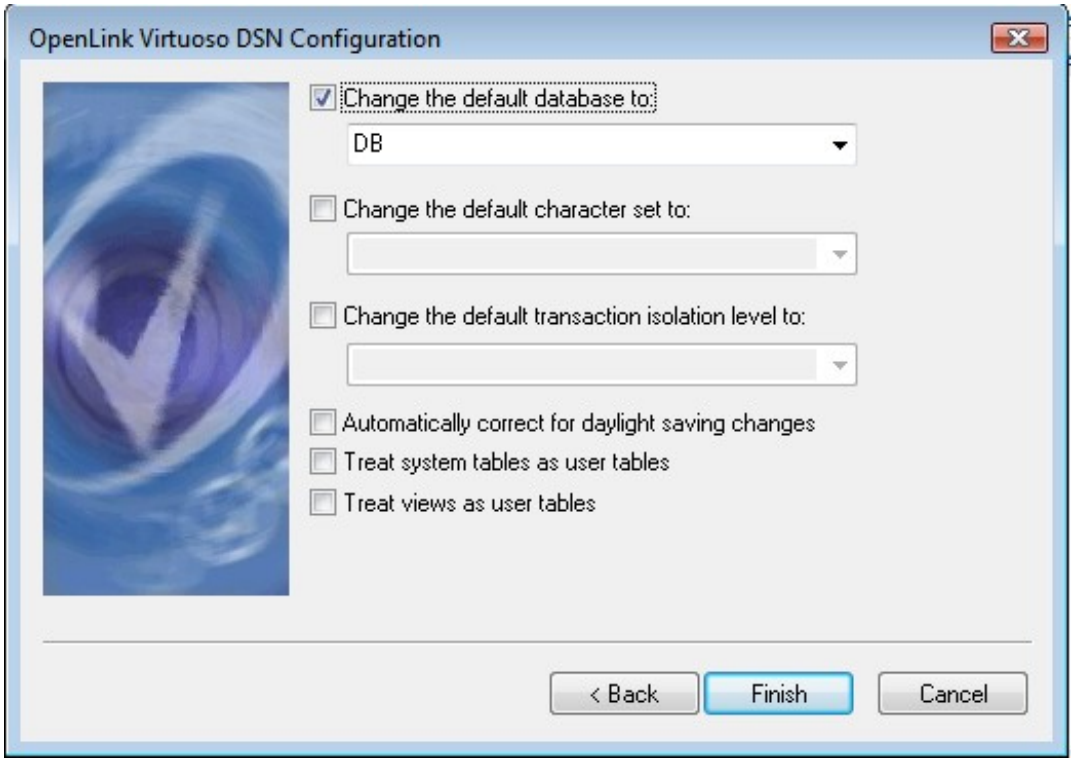
Connect to the Virtuoso Servet to obtain default settings for the additional configuration options: allows you to specify the default username and password for the connection.

Press the *Next* button

Database: allows you to select the default database for the connection. You will need to check the box above and supply a password to refresh this list. Objects created or selected without an explicit catalogue/database qualifier will automatically be sought from this select database.

Charset: lets you choose the default character set for the connection.

Figure 7.32. Virtuoso ODBC Driver Setup Dialogue for Windows



8. When the configuration is complete, and indeed at any time you are satisfied with the configuration press the *Finish* button to save the DSN.

7.3.2. Using X509 Certificates With ODBC Connection

Virtuoso can be configured to authenticate ODBC logins with a single X.509 certificate. The certificate must be registered server side for this purpose and may contain an additional custom attribute for the users SQL account name. In this way all login information is held in the possibly password protected certificate. The user specifies the certificate path in the place of the user name and the certificate encryption password as the password. This works with the login dialog of the ODBC driver or within a SQLDriverConnect login string.

It is also possible to set up the ODBC client to check for the server's X.509 certificate by specifying a client side CA (Certificate Authority) list.

The X509 certificate can be used for authentication with the Virtuoso server via SSL. In this case the ODBC client will use an X.509 certificate which contains a SQL username as an extension. This extension is added when the certificate is issued. Since an object ID (OID) of the username attribute can be used any valid object identifier that does not conflict with existing OIDs (for example 2.16.840.1.NNNNNN). It will be best to have one's own registered OID for that purpose.

WebID Protocol ODBC Login

Virtuoso supports WebID Protocol ODBC Login. Thus, the INI parameter X509ClientVerify can accept the following values:

- 0 - do not require
- 1 - ask for trusted certificates
- 2 - optionally ask, if certificate is given will be verified
- 3 - accept optionally any certificate even self-signed

If certificate contains WebID, the odbc login will use it. The WebID can be setup to particular account via Conductor's users interface.

A typical [Parameters] INI section should contain:

```
SSLServerPort         = 1113
SSLCertificate          = keys/server.crt
SSLPrivateKey         =  keys/server.key
X509ClientVerify      = 3
```

The client could connect in following way:

```
isql 1113 "" -X client.p12 -T server.crt
```

Note: The client certificate client.p12 contains WebID which is registered to some sql user account via Conductor.

ODBC Client Certificate Generation Using "openssl" Tool

To generate X509 certificates one can use the "openssl" tool obtained freely from www.openssl.org . The `openssl.cnf` configuration file must be edited to include the new extension for sqlUserName, but first we have to find the hexadecimal representation of the SQL Username. Then you can proceed the use the openssl to create and confirm the certificate. Follow the steps below:

1. *Find the HEX representation of the SQL Username*

   You can either work this out from ASCII codes or use a hexdump utility found on most Unix platforms. The following command would be sufficient, replacing <user_name> with the actual username:

   ```
   $ echo -n "<user_name>" | hexdump -e '":" 1/1 "%02X"'
   ```

   For example, the username `'dba'` would be `:64:62:61` .
2. *Edit the OpenSSL config file: openssl.cnf*

   Open the file in a text editor of your choosing and add the following:

   ```
   [ new_oids ]
   sqlUserName=2.16.840.1.NNNNNN.1

   ...
   [ usr_cert ]
   ...
   sqlUserName = DER:NN:NN:NN:NN:NN.....
   ```

   replacing `:NN:NN.....` with the hexadecimal representation of the username we discovered in the previous step.
3. *Make New Certificate Request*

   Make new certificate request using the command:

   ```
   $ openssl req -new
   ```

   The tool will ask for certain details. Once completed it will generate a private key also.
4. *Generate Certificate*

   Assuming the role of CA, generate a certificate using the request from the previous step, using the following command:

   ```
   $ openssl ca -in <req_file>
   ```

   The tool will print the details of request and will ask you to sign and commit the certificate into the CA repository.

5. *Verify New Certificate*

   Check that the certificate contains the right SQL account name; use the following command to obtain a text dump of the certificate:

   ```
   openssl x509 -in <certfile> -text -noout
   ```

   Now we can scan the contents of the output for the extension entries we added earlier:

   ```
   >>>>>
   X509v3 extensions:
   ....
   2.16.840.1.NNNNNNN.1:
   <SqlAccountName>
   ^^^^^^ this should match the new OID ^^^^^
   >>>>>
   ```

Virtuoso Server Configuration

The Virtuoso server can work in two modes based on an SSL connection:

basic - this is when only connection is secured, no certificate verification. The client is not required to have its own trusted certificate.

trusted - additional mechanisms are enabled to check client's certificate. in this case the client is required to have a trusted certificate.

To allow Virtuoso to check the client's certificates, the virtuoso.ini file must contain the following entries in [Parameters] section:

```
; Basic session encryption only parameters
SSLServerPort           = 1113
SSLCertificate          = ./srv.cert.pem ; server's certificate
SSLPrivateKey           = ./srv.key.pem  ; server's private key, must match the certificate
; Trusted operation parameters
X509ClientVerify        = 1
X509ClientVerifyCAFile  = ./ca.pem         ; CA list; file containing certificates of acceptable CA
X509ClientVerifyDepth   = 1                ; dependent of type of certificate checking can be &gt;1
X509ExtensionOID          = 2.16.840.1.NNNNNNN.1 ; the OID value, same as that used to make client's cert
```

All certificate/key files need to be in PEM format.

The server needs an "SSLCertificate" and "SSLPrivateKey" to begin listening on the "SSLServerPort". These are essential for the secure operations. Furthermore the certificate must match the private key; non-matching certificate and private keys will prevent server startup and an error will be logged. The private key is required to guarantee that the certificate's claim is true. The server certificate is used by the client to identify the server. The client can retrieve and verify this key and choose whether the server an be trusted depending on circumstances.

Note:

basic operation (SSL/TLS) encryption only cannot be used to identify a client with certificate.

The "X509ClientVerifyCAFile" is a file containing a CA's (Certificate Authority) certificates that the server can use to verify client certificates. The client certificate verification in general depends on the "X509ClientVerify" flag, which enables or disable this feature. The 'X509ClientVerifyDepth" parameter is used to verify to what degree server will trust the client's certificate. The lower the value, the higher the restriction levels, with a minimum value of 1. This means that the server will look in CA's certificates to find who has issued the client certificate. If there is no matching CA entry the connection will be rejected; If there is a matching entry then verify the issuer chain; If issuer chain is greater than "X509ClientVerifyDepth", the connection will be rejected.

All file paths above must be either absolute or relative to the server working directory.

Note:

If primary key file is encrypted then the server must be started in foreground mode so that a password can be supplied in order to open the file.

Virtuoso Client Configuration

The following connection options control the client's behavior regarding SSL:

Encrypt - specifies type of secure connection to be used.
ServerCert - (optional) to specify which certificate(s) are to be used to verify server certificates.
The *Encrypt* option can be set to '1' to specify a basic secure connection; no server identity verification will be performed. Note that this is only possible when the server is also set to make basic SSL connections.

To ensure server's identity the *Encrypt* option must be set to full or relative (to application working directory) path to the file containing client's certificate and private key. This file can be encoded in PKCS#12 or PEM format. The certificate and private key contained may be generated using the steps outlined above.

When the Encrypt option is set to point to a certificate file, the *ServerCert* option must be set to the full or relative path to file containing list of CA certificates in PEM format. The content of this file will be used to verify server's certificate.

When using these options the UID connection-option must be set to an empty string to enable certificate authorization. The PWD option will be used to open the private key.

Here is an example of an ODBC connect-string:

```
...
connectString =
"HOST=localhost:1113;UID=;PWD=keysecret;ENCRYPT=c:\certs\mycertwithkey.p12;SERVERCERT=c:\certs\ca.pem"
...
```

If client's certificate does not contains user name for SQL login then the server will try matching the certificate fingerprint against registered certificates. If any SQL account has such a certificate registered it will be used for login. Otherwise login will be rejected.

Registering Keys with Virtuoso

To enable a client certificate to be used for authorization, the DBA must register it's MD5 fingerprint (checksum) in the database. Registered certificates can be removed from system. Two functions exist for the purposes: `USER_CERT_REGISTER()` , and `USER_CERT_UNREGISTER()` . Both functions rely on the MD5 checksum of the certificates being registered or un-registered, therefor you have the option of supplying these functions with the certificate file or the MD5 checksum directly.

The functions are:

```
USER_CERT_REGISTER (user_name , certificate , password , type );

USER_CERT_UNREGISTER (user_name , certificate , password , type );
```

The registered certificate's fingerprints are kept in the DB.DBA.SYS_USERS table as vectors of strings under the 'LOGIN_CERTIFICATES' user option value (U_OPTS column). The data stored there can be retrieved using a third function:

```
USER_GET_OPTION()
```

For example, one might invoke:

```
USER_CERT_REGISTER ('DBA', 'file:/dba.pem', '', 'PEM');
```

Note that 'file:' URL is needed to designate certificate is in a file on file system.

The above action can be performed also without certificate supplied if the MD5 fingerprint is known:

```
USER_CERT_REGISTER ('DBA', 'D9:6D:47:D7:67:47:D7:3C:2C:E0:89:91:F3:BC:E7:59');
```

and

```
USER_CERT_UNREGISTER ('DBA', 'D9:6D:47:D7:67:47:D7:3C:2C:E0:89:91:F3:BC:E7:59');
```

7.3.3. Manually configuring a Virtuoso ODBC DSN on Unix

If you have iODBC installed, you can configure Virtuoso data sources by adding the following entry into the relevant .odbc.ini file. Usually it is the value of the ODBCINI environment variable or $HOME/.odbc.ini:

Sample DSN:

```
[LocalVirt]
Driver=/usr/local/lib/virtodbc_32.so
# absolute path to the shared object
Address=localhost:1111
# host and port of the Virtuoso server
```

If the application that will load the ODBC driver is multithreaded, use the virtodbc32_r.so driver instead.

Linking Client Applications

The isql and other utilities are linked directly with the Virtuoso client code. See the Makefiles for the libraries used. These are identical in function with the ODBC driver but accept a host:port in the place of a data-source name to be resolved from the odbc ini file.

Generally applications should pass via ODBC. Directly linking with the ODBC driver shared object is also possible.

JDBC

If you specified:

```
--with-jdbc3=<path of JDK>
```

to the configure in the installation root directory, running make will produce the files libsrc/JDBCDriverType4/virtjdbc3.jar and virtjdbc3ssl.jar. These can be placed on the Java class path. See Virtuoso JDBC Documentation for URL formats etc.

7.3.4. ODBC Compliance

The Virtuoso Driver for ODBC conforms to both the ODBC 1.x,2.x,and 3.x versions of the ODBC specification, it implements Core, Level 1, Level 2, and Extensions functionality. It also has a native support for the wide versions of the ODBC API (e.g. SQLColumnsW) in Windows. This driver enables you to communicate with local or remote Virtuoso servers across any combination of platforms supported by Virtuoso.

ODBC API implementation details

SQLAllocHandle

Virtuoso ODBC driver does not allow allocation and usage of explicitly allocated descriptor handles. That is why the SQLAllocHandle (SQL_HANDLE_DESC) will return an error.

SQLBulkOperations

Only the SQL_ADD operation is supported.

SQLColAttributes

The virtuoso ODBC driver does not return information for the following attributes:

- **SQL_COLUMN_TABLE_NAME.** Returns an empty string instead
- **SQL_COLUMN_OWNER_NAME.** Returns an empty string instead
- **SQL_COLUMN_QUALIFIER_NAME.** Returns an empty string instead
- **SQL_COLUMN_CASE_SENSITIVE.** Returns 1 instead
- **SQL_COLUMN_AUTO_INCREMENT.** Returns 0 instead
- **SQL_COLUMN_MONEY.** Returns 0 instead
- **SQL_COLUMN_UNSIGNED.** Returns 0 instead

SQLDriverConnect

The Virtuoso ODBC driver recognizes the following SQLDriverConnect connection string keywords:

- **DSN.** The data source name.
- **HOST.** The virtuoso server host specification (in the form : [<hostname>[:]][<portnumber>]
- **UID.** The virtuoso user ID used to connect
- **PWD.** The login password used to connect
- **DATABASE.** The qualifier to use when connected (overrides the user's default qualifier)
- **CHARSET.** The name of the character set to use for wide/narrow conversions
- **DAYLIGHT.** Boolean parameter (1/0). When ON (1) it takes into account the client OS daylight savings settings.
- **ENCRYPT.** String parameter (file name or "1"). Specifies how the ODBC connection will be encrypted. see the Using SSL For Secure ODBC connections for details.
- **PWDCLEAR.** Integer parameter (default to 0). Specifies how the password will be sent over the wire. 0 - send digest of the password, 1 - send password in cleartext, 2 - send password garbaled.
- **SERVERCERT.** String parameter (file name). Specifies the path for the CA list used to verify the server's certificate (in PEM format). see the Using SSL For Secure ODBC connections for details.
- **FORCE_DBMS_NAME.** String parameter (default "OpenLink Virtuoso"). When set it alters the result of SQLGetInfo (SQL_DBMS_NAME).
- **NoSystemTables.** Boolean parameter (1/0) (default 0). When set it alters the result of SQLTables () so that it won't find or return tables of type SYSTEM TABLE.
- **IsolationLevel.** String parameter ("Read Uncommitted"/"Read Committed"/"Repeatable Read"/"Serializable"). When set it specifies the initial transaction isolation mode for that connection.

SQLGetEnvAttr

The SQL_ATTR_OUTPUT_NTS does not have any effect on the Virtuoso driver. It allows the value to be set and retrieved but with no further effect.

SQLNativeSql

All ODBC syntax is parsed server side. The native SQL syntax for Virtuoso is the ODBC syntax.

Not Supported ODBC API functions

Virtuoso ODBC driver does not support the following ODBC API functions:

- SQLCopyDesc

7.3.5. Virtuoso Scrollable Cursor Engine

Virtuoso implements server side scrollable cursors. ODBC 2.0, ODBC 3.5 and JDBC 2.0 API's are supported.

Cursor types include:

- **Forward only.** This is the default, non-scrollable cursor.
- **Static.** The cursor's evaluation is computed when the cursor statement is first executed. Positioned operations are possible but their effect will not show nor will changes be detected.
- **Keyset.** When the cursor is opened a keyset is built. Rows within the keyset can be fetched and modified by positioned operations. Changes will show when refreshing data and changes by other transactions will be detected for update and delete. Inserts by the same or different transaction will not appear. A keyset cursor may have a finite keyset size. When scrolling outside of the given keyset the keyset will shift to cover the new rows.
- **Dynamic.** A dynamic cursor will reflect all changes by the same and different transactions. The dynamic cursor's evaluation is constructed as needed, hence it generally has less overhead than other types of cursors.
- **Mixed.** A mixed cursor is a combination of a keyset-driven cursor and a dynamic cursor. It is used when the result set is too large to reasonably generate a keyset for the entire result set. Mixed cursors use a keyset smaller than the entire result set but larger than the rowset.

  While the application is scrolling within the keyset, the behavior is keyset-driven. When the application scrolls beyond the keyset, the behavior becomes dynamic to fetch the requested rows and generate a new keyset. The behavior then reverts back to keyset-driven within that keyset, as before.

Forward Only Cursors

A forward only cursor is substantially more efficient than a scrollable cursor. It however does not allow positioned operations (the WHERE CURRENT OF SQL phrase), or SQLSetPos. The SQLExtendedFetch function is supported but only the SQL_FETCH_NEXT fetch type is then allowed.

Cursor Operations

Virtuoso supports all ODBC scrollable cursor operations. These include

SQLExtendedFetch / SQLScrollFetch fetch type.

- SQL_FETCH_FIRST
- SQL_FETCH_LAST
- SQL_FETCH_NEXT
- SQL_FETCH_PRIOR
- SQL_FETCH_RELATIVE
- SQL_FETCH_ABSOLUTE
- SQL_FETCH_BOOKMARK

SQLSetPos operations.

- SQL_POSITION
- SQL_REFRESH
- SQL_ADD
- SQL_UPDATE
- SQL_DELETE

Positioned SQL statements, i.e. the WHERE CURRENT OF clause, is supported for scrollable cursors.

Cursor Options

The cursor options

- SQL_CURSOR_TYPE
- SQL_CONCURRENCY
- SQL_KEYSET_SIZE
- Cursor name (SQLSetCursorName)

have to be set before a SQLPrepare or SQLExecDirect.

The SQL_ROWSET_SIZE can be varied while a cursor is open.

Cursors and Transactions

All forward only or scrollable cursors survive committing or rolling back transactions. A cursor maintains its position over a transaction's end. Hence the next fetch operation will resume from the correct place. If a dynamic cursor's current row / rowset is deleted, the cursor will continue from the next greater / lesser row in the order of the cursor's ordering columns. This also applies to mixed mode (keyset with finite keyset size) cursors scrolling outside of the keyset bounds. A forward only cursor will retain its logical position across commit/rollback.

The SQL_CONCURRENCY values of SQL_CONCUR_READ_ONLY and SQL_CONCUR_LOCK cause Virtuoso to lock the rows in the keyset / rowset in shared or exclusive mode, respectively.

Optimistic Concurrency Control

A scrollable cursor may have a SQL_CONCURRENCY setting of SQL_CONCUR_VALUES. This enables optimistic concurrency control. This is a mechanism which will reflect an update or delete of a row if the row has been modified by a third party after the time the application last read the row.

A 'updated meanwhile' condition detected in this manner will prevent the operation and return a SQL state of 01001 with SQL_SUCCESS_WITH_INFO from SQLSetPos.

The updates and deletes made through SQLSetPos are still subject to being committed or rolled back by normal transaction control. The 01001 state does not prevent the current transaction from committing.

The 01001 state is only detected if the update or delete is made by SQLSetPos and the row at hand has been changed by any statement of any transaction. If the update of updated operation is carried out by any other operation than SQLSetPos of the statement that last read the value the condition cannot be detected.

Note that the time between the last read and the SQLSetPos update can be long and can span multiple transactions.

Cursor Information

Table 7.13. Cursor Support

	Static	Keyset	Dynamic
SQLRowCount	x	x	
SQL_BOOKMARK	x	x	x
SQL_ROW_NUMBER	x	x	
reflect update		x	x
reflect delete			x
reflect inx			x
Notice update	x	x	x
Notice delete	x	x	x

SQLRowCount is set after the initial SQLExecute. This is the actual row count or the keyset size for a mixed mode cursor. A dynamic cursor does not know this since it builds the evaluation as needed.

All cursors support bookmarks.

The SQL_ROW_NUMBER is the ordinal number of the current row in the cursor's evaluation. A dynamic cursor cannot know this, as the scrolling may start from end and rows may appear on either side of the current row while the cursor is open.

'reflect' means that the new values or added / deleted rows appear when re-scrolling over the rows. A deletion is reflected by omitting the row.

'notice' means that the row is flagged by SQL_UPDATE, SQL_DELETED or SQL_ADDED in the SQLExtendedFetch status array when the cursor re-scrolls over the rows in question.

Cursors and Virtual Database

The cursor subsystem modifies the cursor's defining select statement to make various backward and forward read statements, update and delete statements etc. These transformations can be seen through the explain function.

Since cursors are implemented by generating SQL statements these work transparently against remote database, independently of their possible native cursor support.

Cursor Special Cases

SQL SELECT statements fall in two categories: Simple, which consist of one or more tables, an arbitrary WHERE clause and an optional ORDER BY, and Complex, which includes all other SELECT's, e.g. ones with GROUP BY, derived tables, full outer joins, UNION's etc.

A simple statement can easily be modified to read backwards or forwards from a given point. Also, each result row of a simple statement has a physical counterpart, or many physical counterparts for a join. Having a physical counterpart makes it possible to define the meaning of a positioned update or delete. A GROUP BY is a counter-example.

All complex SQL statements occurring as cursors are processed as static cursors regardless of the declared cursor type.

Cursors and Performance

If a cursor's ordering corresponds to an ordering in an index, dynamic cursors will generally perform best. This is understandable since the engine can quickly locate the current row based on an index and then just read backward or forward on that index. On the other hand, if the result set is very sparsely spread over the table or if there is no ordering index dynamic cursors will have a substantial penalty.

If used as a forward only cursor in a single transaction, a dynamic cursor is only some 30% slower than a forward only cursor.

A static or keyset cursor has a relatively long execute time since the initial execute will make the entire keyset. The initial execute of a dynamic cursor is instantaneous since the fetch operations will do the work as needed.

With most off the shelf applications, e.g. Microsoft ADO, static and keyset cursors are preferable because the applications may rely on row counts and row numbers which are not known for dynamic cursors.

Positioned operations are not affected by cursor type.

7.3.6. Effect of Connection & Statement Options

Connection Options

SQL_AUTOCOMMIT

The autocommit option is set at the connection level and affects every statement executed after it being set. Setting the option does not communicate itself with the server and is therefore fast.

Autocommit is on by default. Autocommitting SELECT statements are executed with read committed isolation. This is appropriate since any update based on the autocommitting read would be in a different transaction and hence would block to wait for access to the selected row. Also re-evaluating a select in autocommit mode would read the data in a different transaction. Hence there is no point in repeatable read isolation for autocommitting cursors. Cursors inside procedures have the normal repeatable read isolation regardless of whether the procedure was called in autocommit mode.

When an autocommitting statement starts it is executed in the transaction That is the connection's current transaction when it is received. Before starting the autocommitting statement sets the connection's current transaction to a new one. In this manner a client can issue multiple asynchronous autocommitting statements at the same time and the statements will execute concurrently, each in its own transaction.

If array parameters are used in a statement on an autocommitting connection each parameter row will be processed in its own transaction in sequential order. Multiple Asynchronous statements must be used to execute one client's statements in parallel.

To commit or roll back a transaction in manual-commit mode, an application should call SQLEndTran. Applications should not attempt to commit or roll back transactions by executing COMMIT or ROLLBACK statements with SQLExecute or SQLExecDirect. The effects of doing this are undefined.

SQL_TXN_ISOLATION

This option allows all the values defined in ODBC,

The isolation of an operation is the property of the operation rather than of the transaction within which it takes place. Once an operation has started, e.g. a cursor has been opened, its isolation cannot be changed.

The value of this option will affect any subsequently executed statement. Note that setting this option to different values during a transaction will work, thus a transaction can have cursors with different isolations although that is presumably not the intention of the ODBC specification.

See the transaction model for a definition of the different isolation levels.

A statement in autocommit mode executes in the same transaction as the previous statement. The transaction is committed when the statement successfully completes. The next statement in the connection will execute in the fresh transaction that was

associated to the connection at the start of the previous autocommitting statement.

As a consequence of this multiple concurrent autocommitting transactions may execute on the same connection at the same time.

Statements executed with array parameters execute each set of parameters as a separate transaction if the connection is in autocommit mode.

SQL_ACCESS_MODE

This has the effect of reversing any SQL_CONCUR_LOCK concurrency to SQL_CONCUR_READ_ONLY. The statement option's value is not changed though.

SQL_CURRENT_QUALIFIER

This sets or gets the current qualifier. The initial value is obtained from the server at connect time. The values reflect the effects of any USE statements.

SQL_NO_CHAR_C_ESCAPE (=5002)

This has the same effect as the NO_CHAR_C_ESCAPE option in the SET statement. It takes boolean int values (0/non-0)

SQL_CHARSET (=5003)

This has the same effect as the CHARSET option in SET statement. It takes string values (the name of the character set to use).

SQL_ENCRYPT_CONNECTION (=5004)

Usable only with the Virtuoso CLI (because the ODBC/iODBC driver manager does not pass-through the custom options to the driver on SQLConnect/SQLDriverConnect). When set to the string "1" means use SSL but no X509 certificates. Setting it to a NULL (default) means no encryption of the ODBC connection. Any other string is treated as a file name of one PKCS12 package to get the data from for establishing an encrypted SSL connection using X509 certificates (see the -E/-X ISQL options).

SQL_SHUTDOWN_ON_CONNECT (=5005)

Usable only with the Virtuoso CLI (because the ODBC/iODBC driver manager does not pass through the custom options to the driver on SQLConnect/SQLDriverConnect). Shuts down the server on connection after authenticating the DBA user (see the -K ISQL option).

SQLSetStmtOption Statement Options

Virtuoso supports all ODBC 2.x and ODBC 3.x statement options. The following options are mentioned below due to implementation specific details.

SQL_CONCURRENCY

The supported values are SQL_CONCUR_READ_ONLY, SQL_CONCUR_LOCK and SQL_CONCUR_VALUES, the last option is only available for scrollable cursors. A select statement with SQL_CONCUR_READ_ONLY will make shared locks when locking for repeatable read or serializable transactions. The SQL_CONCUR_LOCK for a select statement will cause it to make exclusive locks, as if it had the FOR UPDATE clause specified.

See the section on scrollable cursors for the effect of SQL_CONCUR_VALUES. For all statements except scrollable cursors this value reverts to SQL_CONCUR_READ_ONLY.

Any searched update or delete statements will make exclusive locks in all cases.

SQL_MAX_ROWS

This option only affects static cursors.

SQL_TXN_TIMEOUT

This is an extension that allows setting a time limit on the current transaction. The time limit starts at the execution of the statement specifying this option. The transaction will terminate the indicated number of seconds after the execute whether the statement has completed or not.

SQL_PREFETCH_SIZE

This is an extension option that controls how many rows of a forward only cursor are prefetched by the execute and fetch calls. A high value is advantageous for long consecutive reads since it cuts down on the number of client server messages exchanged. On the other hand a large value can result in unnecessary data transfer and locking if only the first few rows of a cursor are fetched. A value of -1 will cause the entire rowset to be fetched at the execute, so that no matter the select size, only one message is exchanged. The default value is 20. This can also be set in the virtuoso.ini file.

A select with array parameters will always work as with a SQL_PREFETCH_SIZE of -1, meaning that all the result sets are computed and sent to the client by the SQLExecute call that opens the cursor.

SQL_CURSOR_TYPE

SQL_KEYSET_SIZE
SQL_CONCURRENCY
The cursor type options should be set before preparing a statement. Other options may be set at any time. The rowset and prefetch options should not be modified after executing a SELECT.

SQL_GETLASTSERIAL

This is an extension that returns the last assigned identity column value. The return buffer pvParam is of type SQLINTEGER. For this to be meaningful, the statement in question must be an INSERT into a table that has an identity column. Note that if there are more than one identity columns or if triggers make inserts with identity columns the value will be undefined.

7.3.7. Efficient Use of API

DO NOT USE SQLExecDirect. If a statement is executed more than once it is much faster to prepare the statement with SQLPrepare and then use SQLExecute repeatedly. The system only compiles the statement once, therefore there is no parsing overhead for repeatedly compiling the same text.

Array parameters for insert, update or single row selects are about twice as fast as the same operations on a single parameter set.

The OR connective in SQL can result in slow queries with extensive locking.

Autocommit should be used when possible, i.e. make the last statement of a transaction autocommitting to avoid having to commit the transaction as a separate operation.

7.3.8. Executing SQL from Python script

In order to execute SQL from Python script, you need to add the following lines to the /etc/odbc.ini file:

```
[Local Virtuoso]
Driver  = /PREFIX/lib/virtodbc_r.so
Address = localhost:1111
```

where PREFIX is replaced by the full path where Virtuoso is installed and also assuming that is used let's say port 1111 in virtuoso.ini (which is set by default).

Then you should be able to connect with:

```
c = pyodbc.connect('DSN=Local Virtuoso;UID=dba;PWD=dba')
```

7.3.9. Extensions

Virtuoso ODBC RDF Extensions for SPASQL

The Virtuoso ODBC Driver adds a number of defines to the ODBC API to allow an ODBC compliant application to query meta information on SPASQL queries.

If the application uses the iODBC Driver Manager V3.52.7 or higher, it can simply include the iodbcext.h header file, which contains information on extensions of many ODBC drivers like DB2, SQL Server and Virtuoso.

If however the application is compiled against another Driver Manager, like the Microsoft Driver Manager on Windows, the following construction should to be used:

```
#ifdef WIN32
# include <windows.h>
#endif

#include <sql.h>
#include <sqlext.h>

#if defined (HAVE_IODBC)
#include <iodbcext.h>
#endif

/*
 *  Include Virtuoso ODBC extensions for SPASQL result set
 */
#if !defined (SQL_DESC_COL_DV_TYPE)

/*
 *  ODBC extensions for SQLGetDescField
 */
# define SQL_DESC_COL_DV_TYPE               1057L
# define SQL_DESC_COL_DT_DT_TYPE            1058L
# define SQL_DESC_COL_LITERAL_ATTR          1059L
# define SQL_DESC_COL_BOX_FLAGS             1060L
# define SQL_DESC_COL_LITERAL_LANG          1061L
# define SQL_DESC_COL_LITERAL_TYPE          1062L

/*
 *  Virtuoso - ODBC SQL_DESC_COL_DV_TYPE
 */
# define VIRTUOSO_DV_DATE                   129
# define VIRTUOSO_DV_DATETIME               211
# define VIRTUOSO_DV_DOUBLE_FLOAT           191
# define VIRTUOSO_DV_IRI_ID                 243
# define VIRTUOSO_DV_LONG_INT               189
# define VIRTUOSO_DV_NUMERIC                219
# define VIRTUOSO_DV_RDF                    246
# define VIRTUOSO_DV_SINGLE_FLOAT           190
# define VIRTUOSO_DV_STRING                 182
# define VIRTUOSO_DV_TIME                   210
# define VIRTUOSO_DV_TIMESTAMP              128
# define VIRTUOSO_DV_TIMESTAMP_OBJ          208

/*
 *  Virtuoso - ODBC SQL_DESC_COL_DT_DT_TYPE
 */
# define VIRTUOSO_DT_TYPE_DATETIME          1
# define VIRTUOSO_DT_TYPE_DATE              2
# define VIRTUOSO_DT_TYPE_TIME              3

/*
 *  Virtuoso - ODBC SQL_DESC_COL_BOX_FLAGS
 */
#define VIRTUOSO_BF_IRI                     0x1
#define VIRTUOSO_BF_UTF8                    0x2
#define VIRTUOSO_BF_DEFAULT_ENC             0x4

#endif
```

API

SQLGetDescField

Before the application can retrieve the column meta data using `SQLGetDescField`, it first needs to retrieve the correct descriptor handle attached to the statement handle:

```
SQLHDESC hdesc = NULL;
SQLRETURN rc;

rc = SQLGetStmtAttr (hstmt, SQL_ATTR_IMP_ROW_DESC, &hdesc, SQL_IS_POINTER, NULL);
if (!SQL_SUCCEEDED(rc))
  {
    /* Handle error */
  }
```

SQLGetDescField - SQL_DESC_COL_DV_TYPE. Retrieves the datatype of a field.

```
SQLINTEGER dvtype;
SQLRETURN rc;

rc = SQLGetDescField (hdesc, colNum, SQL_DESC_COL_DV_TYPE, &dvtype, SQL_IS_INTEGER, NULL);

#define VIRTUOSO_DV_DATE                    129
#define VIRTUOSO_DV_DATETIME                211
#define VIRTUOSO_DV_DOUBLE_FLOAT            191
#define VIRTUOSO_DV_IRI_ID                  243
#define VIRTUOSO_DV_LONG_INT                189
#define VIRTUOSO_DV_NUMERIC                 219
#define VIRTUOSO_DV_RDF                     246
#define VIRTUOSO_DV_SINGLE_FLOAT            190
#define VIRTUOSO_DV_STRING                  182
#define VIRTUOSO_DV_TIME                    210
#define VIRTUOSO_DV_TIMESTAMP               128
#define VIRTUOSO_DV_TIMESTAMP_OBJ           208
```

If this call returns `SQL_SUCCESS` or `SQL_SUCCESS_WITH_INFO`, the dvtype variable will contain the underlying Virtuoso datatype as indicated in the following table:

SQLGetDescField - SQL_DESC_COL_DT_DT_TYPE. Retrieves the date subtype of a field.

```
SQLINTEGER dv_dt_type;
SQLRETURN rc;

rc = SQLGetDescField (hdesc, colNum, SQL_DESC_COL_DT_DT_TYPE, &dv_dt_type, SQL_IS_INTEGER, NULL);

#define VIRTUOSO_DT_TYPE_DATETIME           1
#define VIRTUOSO_DT_TYPE_DATE               2
#define VIRTUOSO_DT_TYPE_TIME               3
```

If this call returns `SQL_SUCCESS` or `SQL_SUCCESS_WITH_INFO`, the dttype variable will contain the underlying Virtuoso date subtype as indicated in the following table:

SQLGetDescField - SQL_DESC_COL_LITERAL_ATTR. Retrieves the literal attributes associated with the field.

```
SQLINTEGER littype;
SQLINTEGER lang, type;
SQLRETURN rc;

rc = SQLGetDescField (hdesc, colNum, SQL_DESC_COL_DT_DT_TYPE, &littype, SQL_IS_INTEGER, NULL);

lang = (littype >> 16) & 0xFFFF;
type = littype & 0xFFFF;

select RL_ID from DB.DBA.RDF_LANGUAGE where RL_TWOBYTE = ?

select RDT_QNAME from DB.DBA.RDF_DATATYPE where RDT_TWOBYTE = ?
```

Note:
This call is deprecated in favor of using the SQL_DESC_COL_LITERAL_LANG and SQL_DESC_LITERAL_TYPE options of SQLGetDescField which caches these lookups to speed up describe operations.

If this call returns SQL_SUCCESS or SQL_SUCCESS_WITH_INFO , the littype variable will contain the encoded language and rdf type information of the field.

These numbers are uniq to the database the client has connected to, and correspond to information in the DB.DBA.RDF_LANGUAGE and DB.DBA.RDF_DATATYPE tables:

and

SQLGetDescField - SQL_DESC_COL_BOX_FLAGS. Retrieves the flags associated with the field:

```
SQLINTEGER flags;
SQLRETURN rc;

rc = SQLGetDescField (hdesc, colNum, SQL_DESC_COL_BOX_FLAGS, &flags, SQL_IS_INTEGER, NULL);

#define VIRTUOSO_BF_IRI                     0x1
#define VIRTUOSO_BF_UTF8                    0x2
#define VIRTUOSO_BF_DEFAULT_ENC             0x4

for example:

flags    description

0        field contains a Latin1 encoded literal string
1        field contains an IRI (always UTF-8 encoded)
2        field contains an UTF-8 encoded literal string
3        field contains an UTF-8 encoded IRI (should not happen)
```

If this call returns SQL_SUCCESS or SQL_SUCCESS_WITH_INFO , the following bitmasks can be used to determine the representation of the field:

SQLGetDescField - SQL_DESC_COL_LITERAL_LANG. Retrieves the language string for this field:

```
SQLCHAR langbuf[100];
SQLINTEGER len1;
SQLRETURN rc;

rc = SQLGetDescField (hdesc, colNum, SQL_DESC_COL_LITERAL_LANG, langbuf, sizeof (langbuf), &len1);
```

If this call returns SQL_SUCCESS or SQL_SUCCESS_WITH_INFO, , the langbuf variable will contain the language of the field.

SQLGetDescField - SQL_DESC_COL_LITERAL_TYPE. Retrieves the data type string for this field:

```
SQLCHAR typebuf[100];
SQLINTEGER len2;
SQLRETURN rc;

rc = SQLGetDescField (hdesc, colNum, SQL_DESC_COL_LITERAL_TYPE, typebuf, sizeof (typebuf), &len2);
```

If this call returns SQL_SUCCESS or SQL_SUCCESS_WITH_INFO , the typebuf variable will contain the rdf type of the field.

Evaluating Nodes

The following pseudo code evaluates the various type and flag information retrieved using the above API calls and shows what kind of node a field is.

```
switch (dvtype)
  {
  case VIRTUOSO_DV_STRING:
    {
      if (flag == 1)
```

```
      {
        if (strncmp ((char *) data, "_:", 2) == 0)
          {
            /* node is a Turtle style named BNode */
          }
        else
          {
            /* node is an URI string */
          }
      }
    else
      {
        if (strncmp ((char *) data, "nodeID://", 9) == 0)
          {
            /* node is a BNode */
          }
        else
          {
            /* node is a string literal */
          }
      }
    break;
  }

case VIRTUOSO_DV_RDF:
  /* node is a typed literal with possible lang and type */
  break;

case VIRTUOSO_DV_LONG_INT:
  /* node is a literal http://www.w3.org/2001/XMLSchema#integer */
  break;

case VIRTUOSO_DV_SINGLE_FLOAT:
  /* node is a literal http://www.w3.org/2001/XMLSchema#float */
  break;

case VIRTUOSO_DV_DOUBLE_FLOAT:
  /* node is a literal http://www.w3.org/2001/XMLSchema#double */
  break;

case VIRTUOSO_DV_NUMERIC:
  /* node is a literal http://www.w3.org/2001/XMLSchema#decimal */
  break;

case VIRTUOSO_DV_TIMESTAMP:
case VIRTUOSO_DV_DATE:
case VIRTUOSO_DV_TIME:
case VIRTUOSO_DV_DATETIME:
  switch (dv_dt_type)
    {
    case VIRTUOSO_DT_TYPE_DATE:
      /* node is a literal http://www.w3.org/2001/XMLSchema#date */
      break;
    case VIRTUOSO_DT_TYPE_TIME:
      /* node is a literal http://www.w3.org/2001/XMLSchema#time */
      break;
    default:
      /* node is a literal http://www.w3.org/2001/XMLSchema#dateTime */
      break;
    }
  break;

case VIRTUOSO_DV_IRI_ID:
  /*
   * node is an IRI ID
   *
   * This type is only returned in output:valmode "LONG"
   * It needs to be translated into a literal string using the
   * ID_TO_IRI() function as the value is database specific.
   */
  break;

default:
```

```
    /* unhandled type */
    return NULL;
  }
```

Examples

The following program performs a SPARQL query against a Virtuoso Database using SPASQL. Note that the connection parameters and the sparql query are compiled into the executable.

To compile it on Linux against iODBC the following command can be used:

```
gcc -o odbc_iri -I/usr/local/iODBC odbc_iri.c -L/usr/local/iODBC/lib -liodbc -ldl
```

It can then be called as:

```
./odbc_iri
```

which will print out the first 50 triples from the database in N3 format.

Here it is the source code:

7.4. Virtuoso Driver for JDBC

The Virtuoso Drivers for JDBC are available in "jar" file formats for JDBC 1.x, JDBC 2.x and JDBC 3.x specifications. These are Type 4 Drivers implying that utilization is simply a case of adding the relevant "jar" file to your CLASSPATH and then providing an appropriate JDBC URL format in order to establish a JDBC session with a local or remote Virtuoso server. It is important to note that when you make a JDBC connection to a Virtuoso Server, you do also have access to Native and External Virtuoso tables. Thus, you actually have a type 4 JDBC Driver for any number of different database types that have been linked into Virtuoso.

The JDBC 2 and JDBC 3 drivers also incorporate SSL encryption to enable very secure connections to the Virtuoso database.

7.4.1. Virtuoso Drivers for JDBC Packaging

These drivers are installed alongside the Virtuoso Server or as part of a Virtuoso Client components only installation. They are packaged as follows:

Table 7.14. Features Comparison

Driver Name	Java Package	"jar" File Archive	Default Location	Java Version
virtuoso.jdbc.Driver	virtuoso.jdbc	virtjdbc.jar	<virtuoso installation directory>\jdk11	Java 1.1.x
virtuoso.jdbc2.Driver	virtuoso.jdbc2	virtjdbc2.jar		Java 1.2/1.3

Driver Name	Java Package	"jar" File Archive	Default Location	Java Version
			<virtuoso installation directory>\jdk12	
virtuoso.jdbc3.Driver used for Java 1.4 and Java 1.5	virtuoso.jdbc3	virtjdbc3.jar	<virtuoso installation directory>\jdk13	Java 1.4
virtuoso.jdbc4.Driver used for Java 1.6	virtuoso.jdbc4	virtjdbc4.jar	<virtuoso installation directory>\jdk14	Java 1.6

7.4.2. Virtuoso Driver For JDBC URL Format

JDBC compliant applications and applets connect to JDBC Drivers using JDBC Uniform Resource Locators (URLs). Although there are two Virtuoso Drivers for JDBC, both share the same JDBC URL format.

The Virtuoso Driver for JDBC URL format takes the following form:

```
jdbc:virtuoso://<Hostname>:<Port#>/DATABASE=<dbname>/UID=<user name>/PWD=<password>/
  CERT=<certificate_alias>/KPATH=<keystore_path>/PASS=<keystore_password>/
  PROVIDER=<ssl_provider_classname>/SSL/CHARSET=<character set>/
  TIMEOUT=<timeout_secs>/PWDTYPE=<authentication_type>/log_enable=<integer>
```

Also is supported Host:Port list in connection string:

```
jdbc:virtuoso://<Hostname>:<Port#>,<Hostname1>:<Port1#>,<Hostname2>:<Port2#>/
```

If Port is omitted, the default port 1111 is used.

Each part of the URL is explained below:

Protocol Identifiers. this is a constant value of "jdbc" since JDBC is the protocol in question

Sub Protocol Identifier. this is a constant value that identifies "virtuoso" as a sub protocol of JDBC

Hostname. this identifies the machine hosting a server process that speaks the "virtuoso" sub dialect of the "jdbc" protocol

Port Number. this identifies the port number on the machine from which the server which speaks the "virtuoso" sub dialect of "jdbc" listening for incoming client connections The default port number for a Virtuoso server is "1111".

/DATABASE. this identifies the database (Qualifier or Catalog) that you are connecting to via a Virtuoso server

/UID. a valid user name for the Virtuoso database that you are connecting to via JDBC

/PWD. a valid password for the user name

/CERT=<certificate _alias>. name of the certificate to use for the SSL connection stored in the keystore. This is a required option for an SSL authenticated connection

/KPATH=<keystore_p ath>. This optional parameter lets you specify the keystore file name (default: $HOME/.keystore). The path separator is \, and which is then replaced during the connection by the right platform path separator.

/PASS=<keystore_pa ssword>. password required for accessing the keystore file. This is required for the SSL authenticated connection.

/PROVIDER=<ssl_pro vider_classname>. The class name of the SSL Provider (e.g. com.sun.ssl.net.internal.ssl.Provider) to use for the SSL cryptography. This parameter is required for SSL connections.

/SSL. The SSL option is used only for SSL connection without user authentication

/CHARSET=<characte r set>. This allows the client to specify a character set for data encoding. When this option is set then all Java strings, natively Unicode, are converted to the character set specified here.

/TIMEOUT=<timeout_ secs>. Specifies the maximum amount of time (in seconds) that the driver will wait for a response to a query. When this time is exceeded a time-out error will be reported and the network connection closed, assumed to be broken.

/PWDCLEAR=<authent ication_type>. Specifies the authentication mode; how the user credentials may be transmitted to the server. This option can be one of the following 3 types: cleartext, encrypt, digest. The default is digest.

"cleartext" will transfer the password to the server in cleartext

"encrypt" will transfer the password to the server using Virtuoso's symmetric encryption technique.

"digest" will calculate an MD5 digest of the password (and some additional session variables) that will be sent to the server to be compared with the value calculated server-side.

/log_enable=<integ er>. Set log_enable=2 in order to auto commit on every changed row. Out of memory cannot be caused as with this setting there is no image in the memory for rollback.

/roundrobin. boolean attribute 1 - for use RoundRobin; 0 - do not use . (used only if more than one host:post values are in connection string)

/fbs. integer attribute, prefetch buffer size (default is 100)

/sendbs. integer attribute, socket send buffer size (default is 32768 bytes)

/recvbs. integer attribute, socket receive buffer size (default is 32768 bytes)

/usepstmtpool. boolean attribute 1 - for use PreparedStatement pool; 0 - do not use (Only for Java 1.6 and above)

/pstmtpoolsize. integer attribute, PreparedStatement pool size (default is 25)

Note:
Since JSSE has only incorporated SSL support for JDK 1.2 and above, SSL has only been implemented for the JDBC 2.x, JDBC 3.x and JDBC 4.x drivers for Virtuoso.

7.4.3. Virtuoso Driver JDBC 3.0 features

Virtuoso Driver For JDBC 3.0 javax.sql.DataSource

JDBC 3.0 compliant applications and applets may connect to a JDBC data source using JDBC `javax.sql.DataSource` instances. The Virtuoso JDBC 3.0 driver provides an implementation of the `javax.sql.DataSource` interface in the `virtuoso.jdbc3.VirtuosoDataSource` class, supporting the following properties:

Table 7.15. JDBC 3.0 VirtuosoDataSource properties

Name	Type	URL Option Equivalent	Description	
dataSourceName	java.lang.String		used in connection pooling	
description	java.lang.String		string to describe the data source (free form)	
serverName	java.lang.String		The host name of the remote host to connect to	
portNumber	int		The port on the remote host to connect to	
user	java.lang.String	/UID	username to use for the session	
password	java.lang.String	/PWD	password to use for the session	
databaseName	java.lang.String	/DATABASE	Initial catalog qualifier for the session	
charset	java.lang.String	/CHARSET	Charset used in wide<->narrow translations	
pwdClear	java.lang.String	/PWDTYPE	authentication method	

Virtuoso Driver For JDBC 3.0 & Connection Pooling

The Virtuoso JDBC 3.0 driver supports connection pooling.

The virtuoso.jdbc3.VirtuosoDataSource implements the `javax.sql.ConnectionPoolDataSource` interface. In order to use the connection pooling the administrator must deploy one instance of the `virtuoso.jdbc3.VirtuosoDriver` in the JNDI repository and set all of it's properties except `dataSourceName` . This is the "main" connection pooling data source. Then the administrator should deploy a second instance of the `virtuoso.jdbc3.VirtuosoDataSource` class and set only it's `dataSourceName` property.

Applications will use the second `virtuoso.jdbc3.VirtuosoDataSource` instance to get a connection. It will in turn call the first one to obtain all connect info and return the `java.sql.Connection` instance.

Virtuoso Driver For JDBC 3.0 & Distributed Transactions

Virtuoso supports the industry standard XA specification for distributed transaction processing. The XA specification defines an interface between the transaction manager (TM) and resource manager (RM) in a distributed transaction system. This is a generic interface and it does not directly address the use of distributed transactions from Java. The Java mapping of the XA interface is defined in Sun Microsystems Java Transaction API (JTA) and JDBC 3.0 specifications. The Virtuoso JDBC 3.0 driver supports the JTA architecture by providing the implementation of JTA resource manager interfaces.

The Virtuoso JDBC 3.0 driver provides the `virtuoso.java3.VirtuosoXid` , `virtuoso.java3.VirtuosoXADataSource` , `virtuoso.java3.VirtuosoXAConnection` , and `virtuoso.java3.VirtuosoXAResource` classes which implement the interfaces `javax.transaction.xa.Xid` , `javax.transaction.xa.XADataSource` , `javax.sql.XAConnection` , and `javax.sql.XAResource` respectively. The use if these interfaces is usually transparent for applications and the application developer shouldn't bother with them. They are used only by the JTS transaction manager which normally runs as a part of the J2EE server.

The task of the J2EE server administrator is to setup the necessary Virtuoso XA datasources. The exact procedure of this depends on the J2EE server in use (such as BEA WebLogic, IBM WebSphere, etc). Generally, this includes two steps:

1. Include the JDBC driver's jar file into J2EE server's class path.
2. Deploy an instance of `javax.transaction.xa.XADataSource` with appropriately set properties into the J2EE server's JNDI repository.

The `virtuoso.java3.VirtuosoXADataSource` class is derived from `virtuoso.java3.VirtuosoDataSource` and inherits all of its properties. These properties has to be set as described in the section Virtuoso Driver For JDBC 3.0 javax.sql.DataSource .

For example, the following has to be done in case of Sun's J2EE Reference Implementation.

1. Add the path of virtjdbc3.jar to the J2EE_CLASSPATH variable in the file $(J2EE_HOME)/bin/userconfig.bat on Windows or $(J2EE_HOME)/bin/userconfig.sh on Unix/Linux:

   ```
   set J2EE_CLASSPATH=C:/Virtuoso/lib/virtjdbc3.jar
   ```

   or

   ```
   J2EE_CLASSPATH=/home/login/virtuoso/lib/virtjdbc3.jar
   export J2EE_CLASSPATH
   ```
2. Using the following command add the XA datasource with JNDI name "jdbc/Virtuoso" which refers to the Virtuoso server running on the same computer on port 1111:

   ```
   j2eeadmin -addJdbcXADatasource jdbc/Virtuoso virtuoso.jdbc3.VirtuosoXADataSource -props server
   ```

JDBC 3.0 javax.sql.RowSet Driver Implementation

The Virtuoso JDBC 3.0 driver has two implementations of the `javax.sql.RowSet` interface - `virtuoso.javax.OPLCachedRowSet` and `virtuoso.javax.OPLJdbcRowSet` .

The `virtuoso.javax.OPLCachedRowSet` class implements a totally disconnected, memory cached rowset and the `virtuoso.javax.OPLJdbcRowset` class spans the rest of the JDBC API to implement it's methods.

Extension datatype for RDF

The IRIs and RDF literals, kept in the Virtuoso RDF store are represented by a strings and structures. Thus accessing RDF objects needs special datatypes in order to distinguish strings from IRIs and to get language and datatype of the RDF literals.

Therefore Virtuoso JDBC driver provides following classes for accessing RDF store: `virtuoso.jdbc3.VirtuosoExtendedString` for IRIs and `virtuoso.jdbc3.VirtuosoRdfBox` for RDF literal objects.

The class `virtuoso.jdbc3.VirtuosoExtendedString` will be returned when a string representing an IRI is returned to the client. It has two members "str" and "iriType", the "str" member keeps string representation of the IRI, "iriType" denote regular IRI or blank node with enum values VirtuosoExtendedString.IRI and VirtuosoExtendedString.BNODE.

If the RDF literal object have language or datatype specified then `virtuoso.jdbc3.VirtuosoRdfBox` will be returned. The following methods could be used :

```
String toString () : returns string representation of the literal
String getType () : returns string containing the datatype  of the literal
String getLang () : returns language code for the literal
```

The following code snippet demonstrates how to use extension datatypes for RDF

```
... initialization etc. skipped for brevity
boolean more = stmt.execute("sparql select * from <gr> where { ?x ?y ?z }");
ResultSetMetaData data = stmt.getResultSet().getMetaData();
while(more)
{
    rs = stmt.getResultSet();
    while(rs.next())
    {
        for(int i = 1;i <= data.getColumnCount();i++)
        {
            String s = rs.getString(i);
            Object o = ((VirtuosoResultSet)rs).getObject(i);
            if (o instanceof VirtuosoExtendedString) // String representing an IRI
              {
                VirtuosoExtendedString vs = (VirtuosoExtendedString) o;
                if (vs.iriType == VirtuosoExtendedString.IRI && (vs.strType & 0x01) == 0x01)
                    System.out.println ("<" + vs.str +">");
                else if (vs.iriType == VirtuosoExtendedString.BNODE)
                    System.out.println ("<" + vs.str +">");
              }
            else if (o instanceof VirtuosoRdfBox) // Typed literal
              {
                VirtuosoRdfBox rb = (VirtuosoRdfBox) o;
                System.out.println (rb.rb_box + " lang=" + rb.getLang() + " type=" + rb.getType());

              }
            else if(stmt.getResultSet().wasNull())
                System.out.println("NULL");
            else //
            {
                System.out.println(s);
            }

        }
    }
    more = stmt.getMoreResults();
}
...
```

7.4.4. Virtuoso Driver JDBC 4.0 features

Virtuoso Driver For JDBC 4.0 javax.sql.DataSource

JDBC 4.0 compliant applications and applets may connect to a JDBC data source using JDBC `javax.sql.DataSource` instances. The Virtuoso JDBC 4.0 driver provides an implementation of the `javax.sql.DataSource` interface in the `virtuoso.jdbc4.VirtuosoDataSource` class, supporting the following properties:

Table 7.16. JDBC 4.0 VirtuosoDataSource properties

Name	Type	URL Option Equivalent	Description	
dataSourceName	java.lang.String		used in connection pooling	
description	java.lang.String		string to describe the data source (free form)	
serverName	java.lang.String		The host name of the remote host to connect to	
portNumber	int		The port on the remote host to connect to	
user	java.lang.String	/UID	username to use for the session	
password	java.lang.String	/PWD	password to use for the session	
databaseName	java.lang.String	/DATABASE	Initial catalog qualifier for the session	
charset	java.lang.String	/CHARSET	Charset used in wide<->narrow translations	
pwdClear	java.lang.String	/PWDTYPE	authentication method	

Additionally, the following attributres are supported:

```
--- for SSL enabled ---
   public void setCertificate (String value);
   public String getCertificate ();

   public void setKeystorepass (String value);
   public String getKeystorepass ();

   public void setKeystorepath (String value);
   public String getKeystorepath ();

   public void setProvider (String value);
   public String getProvider ();

----------------------

   public void setFbs (int value);
   public int getFbs ();

   public void setSendbs (int value);
   public int getSendbs ();

   public void setRecvbs (int value);
   public int getRecvbs ();

   public void setRoundrobin (boolean value);
   public boolean getRoundrobin ();

-- For Java 1.6 and above
   public void setUsepstmtpool (boolean value);
   public boolean getUsepstmtpool ();

   public void setPstmtpoolsize (int value);
   public int getPstmtpoolsize ();
```

Virtuoso Driver For JDBC 4.0 & Connection Pooling

The Virtuoso JDBC 4.0 driver supports connection pooling.

The virtuoso.jdbc4.VirtuosoDataSource implements the `javax.sql.ConnectionPoolDataSource` interface. In order to use the connection pooling the administrator must deploy one instance of the `virtuoso.jdbc4.VirtuosoDriver` in the

JNDI repository and set all of it's properties except `dataSourceName` . This is the "main" connection pooling data source. Then the administrator should deploy a second instance of the `virtuoso.jdbc4.VirtuosoDataSource` class and set only it's `dataSourceName` property.

Applications will use the second `virtuoso.jdbc4.VirtuosoDataSource` instance to get a connection. It will in turn call the first one to obtain all connect info and return the `java.sql.Connection` instance.

VirtuosoConnectionPoolDataSource.class has the following connection pooling attributes:

```
/**
 * Get the minimum number of physical connections
 * the pool will keep available at all times. Zero ( 0 ) indicates that
 * connections will be created as needed.
 *
 * @return   the minimum number of physical connections
 *
**/
public int getMinPoolSize();

/**
 * Set the number of physical connections the pool should keep available
 * at all times. Zero ( 0 ) indicates that connections should be created
 * as needed
 * The default value is 0 .
 *
 * @param   parm a minimum number of physical connections
 *
 * @exception  java.sql.SQLException if an error occurs
 *
**/

public void setMinPoolSize(int parm);

/**
 * Get the maximum number of physical connections
 * the pool will be able contain. Zero ( 0 ) indicates no maximum size.
 *
 * @return   the maximum number of physical connections
 *
**/
public int getMaxPoolSize();

/**
 * Set the maximum number of physical conections that the pool should contain.
 * Zero ( 0 ) indicates no maximum size.
 * The default value is 0 .
 *
 * @param   parm a maximum number of physical connections
 *
 * @exception  java.sql.SQLException if an error occurs
 *
**/
public void setMaxPoolSize(int parm);

/**
 * Get the number of physical connections the pool
 * will contain when it is created
 *
 * @return   the number of physical connections
 *
**/
public int getInitialPoolSize();

/**
 * Set the number of physical connections the pool
 * should contain when it is created
 *
 * @param   parm a number of physical connections
 *
 * @exception  java.sql.SQLException if an error occurs
 *
**/
```

```
public void setInitialPoolSize(int parm);

/**
 * Get the number of seconds that a physical connection
 * will remain unused in the pool before the
 * connection is closed. Zero ( 0 ) indicates no limit.
 *
 * @return   the number of seconds
**/
public int getMaxIdleTime();

/**
 * Set the number of seconds that a physical connection
 * should remain unused in the pool before the
 * connection is closed. Zero ( 0 ) indicates no limit.
 *
 * @param  parm a number of seconds
 *
 * @exception  java.sql.SQLException if an error occurs
 *
**/
public void setMaxIdleTime(int parm);

/**
 * Get the interval, in seconds, that the pool will wait
 * before enforcing the current policy defined by the
 * values of the above connection pool properties
 *
 * @return  the interval (in seconds)
**/
public int getPropertyCycle();

/**
 * Set the interval, in seconds, that the pool should wait
 * before enforcing the current policy defined by the
 * values of the above connection pool properties
 *
 * @param  parm an interval (in seconds)
**/
public void setPropertyCycle(int parm);

/**
 * Get the total number of statements that the pool will
 * keep open. Zero ( 0 ) indicates that caching of
 * statements is disabled.
 *
 * @return  the total number of statements
**/
public int getMaxStatements();

/**
 * Set the total number of statements that the pool should
 * keep open. Zero ( 0 ) indicates that caching of
 * statements is disabled.
 *
 * @param  parm a total number of statements
 *
 * @exception  java.sql.SQLException if an error occurs
 *
**/
public void setMaxStatements(int parm);
```

Virtuoso Driver For JDBC 4.0 & Distributed Transactions

Virtuoso supports the industry standard XA specification for distributed transaction processing. The XA specification defines an interface between the transaction manager (TM) and resource manager (RM) in a distributed transaction system. This is a generic interface and it does not directly address the use of distributed transactions from Java. The Java mapping of the XA interface is defined in Sun Microsystems Java Transaction API (JTA) and JDBC 4.0 specifications. The Virtuoso JDBC 4.0 driver supports the JTA architecture by providing the implementation of JTA resource manager interfaces.

The Virtuoso JDBC 4.0 driver provides the `virtuoso.java3.VirtuosoXid`, `virtuoso.java3.VirtuosoXADataSource`, `virtuoso.java3.VirtuosoXAConnection`, and `virtuoso.java3.VirtuosoXAResource` classes which implement the interfaces `javax.transaction.xa.Xid`, `javax.transaction.xa.XADataSource`, `javax.sql.XAConnection`, and `javax.sql.XAResource` respectively. The use if these interfaces is usually transparent for applications and the application developer shouldn't bother with them. They are used only by the JTS transaction manager which normally runs as a part of the J2EE server.

The task of the J2EE server administrator is to setup the necessary Virtuoso XA datasources. The exact procedure of this depends on the J2EE server in use (such as BEA WebLogic, IBM WebSphere, etc). Generally, this includes two steps:

1. Include the JDBC driver's jar file into J2EE server's class path.
2. Deploy an instance of `javax.transaction.xa.XADataSource` with appropriately set properties into the J2EE server's JNDI repository.

The `virtuoso.java3.VirtuosoXADataSource` class is derived from `virtuoso.java3.VirtuosoDataSource` and inherits all of its properties. These properties has to be set as described in the section Virtuoso Driver For JDBC 4.0 javax.sql.DataSource .

For example, the following has to be done in case of Sun's J2EE Reference Implementation.

1. Add the path of virtjdbc4.jar to the J2EE_CLASSPATH variable in the file $(J2EE_HOME)/bin/userconfig.bat on Windows or $(J2EE_HOME)/bin/userconfig.sh on Unix/Linux:

   ```
   set J2EE_CLASSPATH=C:/Virtuoso/lib/virtjdbc4.jar
   ```

   or

   ```
   J2EE_CLASSPATH=/home/login/virtuoso/lib/virtjdbc4.jar
   export J2EE_CLASSPATH
   ```
2. Using the following command add the XA datasource with JNDI name "jdbc/Virtuoso" which refers to the Virtuoso server running on the same computer on port 1111:

   ```
   j2eeadmin -addJdbcXADatasource jdbc/Virtuoso virtuoso.jdbc4.VirtuosoXADataSource -props server
   ```

JDBC 4.0 javax.sql.RowSet Driver Implementation

The Virtuoso JDBC 4.0 driver has two implementations of the `javax.sql.RowSet` interface - `virtuoso.javax.OPLCachedRowSet` and `virtuoso.javax.OPLJdbcRowSet` .

The `virtuoso.javax.OPLCachedRowSet` class implements a totally disconnected, memory cached rowset and the `virtuoso.javax.OPLJdbcRowset` class spans the rest of the JDBC API to implement it's methods.

Extension datatype for RDF

The IRIs and RDF literals, kept in the Virtuoso RDF store are represented by a strings and structures. Thus accessing RDF objects needs special datatypes in order to distinguish strings from IRIs and to get language and datatype of the RDF literals.

Therefore Virtuoso JDBC driver provides following classes for accessing RDF store: `virtuoso.jdbc4.VirtuosoExtendedString` for IRIs and `virtuoso.jdbc4.VirtuosoRdfBox` for RDF literal objects.

The class `virtuoso.jdbc4.VirtuosoExtendedString` will be returned when a string representing an IRI is returned to the client. It has two members "str" and "iriType", the "str" member keeps string representation of the IRI, "iriType" denote regular IRI or blank node with enum values VirtuosoExtendedString.IRI and VirtuosoExtendedString.BNODE.

If the RDF literal object have language or datatype specified then `virtuoso.jdbc4.VirtuosoRdfBox` will be returned. The following methods could be used :

```
String toString () : returns string representation of the literal
String getType () : returns string containing the datatype  of the literal
String getLang () : returns language code for the literal
```

The following code snippet demonstrates how to use extension datatypes for RDF

```
... initialization etc. skipped for brevity
boolean more = stmt.execute("sparql select * from <gr> where { ?x ?y ?z }");
ResultSetMetaData data = stmt.getResultSet().getMetaData();
while(more)
{
    rs = stmt.getResultSet();
    while(rs.next())
    {
        for(int i = 1;i <= data.getColumnCount();i++)
        {
            String s = rs.getString(i);
            Object o = ((VirtuosoResultSet)rs).getObject(i);
            if (o instanceof VirtuosoExtendedString) // String representing an IRI
              {
                VirtuosoExtendedString vs = (VirtuosoExtendedString) o;
                if (vs.iriType == VirtuosoExtendedString.IRI && (vs.strType & 0x01) == 0x01)
                    System.out.println ("<" + vs.str +">");
                else if (vs.iriType == VirtuosoExtendedString.BNODE)
                    System.out.println ("<" + vs.str +">");
              }
            else if (o instanceof VirtuosoRdfBox) // Typed literal
              {
                VirtuosoRdfBox rb = (VirtuosoRdfBox) o;
                System.out.println (rb.rb_box + " lang=" + rb.getLang() + " type=" + rb.getType());

              }
            else if(stmt.getResultSet().wasNull())
                System.out.println("NULL");
            else //
            {
                System.out.println(s);
            }

        }
    }
    more = stmt.getMoreResults();
}
...
```

7.4.5. Installation & Configuration Steps

Perform the following steps in order to make use of your Virtuoso Drivers for JDBC:

Note:
You only have to perform these steps if a first attempt to use the Virtuoso Drivers for JDBC fails, the Virtuoso installer will attempt to configure these settings for you at installation time.

1. Ensure your PATH environment variable is pointing to a version of the Java Virtual Machine (JVM) that is compatible with the version of the JDBC Driver Manager installed on your machine. Consult the section above to double check. You can also type the following command to verify Java versions:

   ```
   java -version
   ```
2. Add the appropriate Virtuoso for JDBC "jar" file to your CLASSPATH environment variable.
3. Attempt to make a connection using one of the sample JDBC Applications or Applets provided with your Virtuoso installation.

Note:
If you have problems using the virtuoso JDBC driver despite your CLASSPATH being defined correctly, you may force the Java Virtual Machine to load a specific JDBC driver using: `-D` on the java command line: e.g:

```
-Djdbc.drivers=virtuoso.jdbc.Driver.
```

You can check the Virtuoso JDBC driver version from the command line using: `java virtuoso.jdbc.Driver`

7.4.6. Virtuoso JDBC Driver Hibernate Support

Introduction

What

Hibernate is a powerful, open source, high performance object/relational persistence and query service. Hibernate lets you develop persistent classes following object-oriented idiom - including association, inheritance, polymorphism, composition, and collections. Hibernate allows you to express queries in its own portable SQL extension (HQL), as well as in native SQL, or with an object-oriented Criteria and Example API.

Why

Hibernate employs very aggressive, and very intelligent first and second level caching strategy, providing a high performance and scalable development framework for Java. Greater cross portability and productivity can also be achieve using hibernate as the same techniques can be employed across multiple databases.

How

Hibernate uses JDBC for accessing databases and may require a given database has a custom SQL dialect file that informs Hibernate what SQL dialects are to be use for performing certain operations against the target database. Although not strictly required, it should be used to ensure Hibernate Query Language (HQL) statements are correctly converted into the proper SQL dialect for the underlying database. Virtuoso includes a new jar file called virt_dialect.jar containing the SQL dialect mappings required between hibernate and Virtuoso and is used in conjunction to the Virtuoso JDBC Drivers (virtjdbc3.jar or virtjdbc4.jar).

Setup and Testing

Three sample programs are provided to test Virtuoso hibernate support. Extract the contents of the zip file to a location of choice.

Requirements

- Hibernate 3.3 or higher
- JDK 5.0 or higher on any operating system
- Ant 1.6
- Virtuoso SQL Dialect jar file (virt_dialect.jar)
- Virtuoso JDBC Driver (virtjdbc4.jar)

Building and running the example

The following Ant targets are available:

```
clean         Clean the build directory
compile       Build example
run           Build and run example
```

Hibernate connection string

Edit the file `hibernate.cfg.xml` in the "bin" and "src" directories of the hibernate application directory with the correct connection attributes for the Virtuoso Server instance:

```
$ more hibernate.cfg.xml
<?xml version='1.0' encoding='utf-8'?>
<!DOCTYPE hibernate-configuration PUBLIC
        "-//Hibernate/Hibernate Configuration DTD 3.0//EN"
        "http://hibernate.sourceforge.net/hibernate-configuration-3.0.dtd">

<hibernate-configuration>

    <session-factory>

        <!-- Database connection settings -->

        <property name="connection.driver_class">virtuoso.jdbc4.Driver</property>
        <property name="connection.url">jdbc:virtuoso://localhost:1111/</property>
```

```
        <property name="connection.username">dba</property>
        <property name="connection.password">dba</property>

        <!-- JDBC connection pool (use the built-in) -->

        <property name="connection.pool_size">1</property>

        <!-- SQL dialect -->

        <property name="dialect">virtuoso.hibernate.VirtuosoDialect</property>

        <!-- Enable Hibernate's current session context -->

        <property name="current_session_context_class">thread</property>

        <!-- Disable the second-level cache  -->

        <property name="cache.provider_class">org.hibernate.cache.NoCacheProvider</property>

        <!-- Echo all executed SQL to stdout -->

        <property name="show_sql">true</property>

        <!-- Drop and re-create the database schema on startup -->

        <property name="hbm2ddl.auto">create</property>

        <mapping resource="events/Event.hbm.xml"/>

    </session-factory>

</hibernate-configuration>
```

The key attributes being

- *connection.driver_class*

  - Virtuoso JDBC Driver class name, typically virtuoso.jdbc4.Driver
- *connection.url* - Virtuoso JDBC Driver connect string for target Virtuoso server instance, of the form `jdbc:virtuoso://hostname:portno`
- *connection.username*

  - Virtuoso Server username
- *connection.password*

  - Virtuoso Server password

7.4.7. Examples

To assist you further during your utilization or evaluation of OpenLink's Drivers for JDBC a number of demonstration JDBC compliant Applets and Applications are bundled with your OpenLink Driver for JDBC installation, our demo programs are provided in both binary and source code format for your free use.

Example 1

This sample performs a simple insert and retrieval of data against the Virtuoso database.

1. Open your command shell and change to the "ex1" directory
2. The following required files need to be placed in the ./lib directory:

```
antlr-2.7.6.jar
commons-collections-3.1.jar
commons-logging-1.0.4.jar
dom4j-1.6.1.jar
hibernate3.jar
javassist-3.4.GA.jar
jta-1.1.jar
lib.lst
```

```
log4j-1.2.15.jar
slf4j-api-1.5.10.jar
slf4j-api-1.5.2.jar
slf4j-jcl-1.5.10.jar
virtjdbc4.jar
virt_dialect.jar
```

3. Run the example with "ant run" and read the log output on the console:

```
$ ant run
Buildfile: build.xml

clean:
   [delete] Deleting directory /Users/hughwilliams/hibernate/ex1/bin
    [mkdir] Created dir: /Users/hughwilliams/hibernate/ex1/bin

copy-resources:
     [copy] Copying 3 files to /Users/hughwilliams/hibernate/ex1/bin
     [copy] Copied 2 empty directories to 1 empty directory under /Users/hughwilliams/hibernate/ex

compile:
    [javac] Compiling 3 source files to /Users/hughwilliams/hibernate/ex1/bin

run:
     [java] Hibernate: insert into Event (EVENT_DATE, title) values (?, ?)
     [java] Hibernate: select identity_value()
     [java] Hibernate: insert into Event (EVENT_DATE, title) values (?, ?)
     [java] Hibernate: select identity_value()
     [java] Hibernate: select event0_.EVENT_ID as EVENT1_0_, event0_.EVENT_DATE as EVENT2_0_, even
     [java] Event: My Event1 Time: 2010-03-14 03:27:51.0
     [java] Event: My Event2 Time: 2010-03-14 03:27:53.0

BUILD SUCCESSFUL
Total time: 3 seconds
```

4. Hibernate logging levels can be varied by changing the settings in the src/hibernate.cfg.xml and src/log4j.properties files.

Example 2

Hello World with Java Persistence

1. Open your command shell and change to the "ex2" directory
2. The following required files need to be placed in the ./lib directory:

```
antlr-2.7.6.jar
asm-attrs.jar
asm.jar
c3p0-0.9.0.jar
cglib-2.1.3.jar
commons-collections-2.1.1.jar
commons-logging-1.0.4.jar
dom4j-1.6.1.jar
ejb3-persistence.jar
freemarker.jar
hibernate-annotations.jar
hibernate-commons-annotations.jar
hibernate-entitymanager.jar
hibernate-tools.jar
hibernate3.jar
javassist.jar
jboss-archive-browsing.jar
jta.jar
log4j-1.2.13.jar
virtjdbc4.jar
virt_dialect.jar
```

3. Use "ant schemaexport" to export a database schema automatically to the database. Ignore any errors about failing ALTER TABLE statements, they are thrown because there are no tables when you run this for the first time.

```
$ ant schemaexport
Buildfile: build.xml

compile:
```

```
copymetafiles:

schemaexport:
[hibernatetool] Executing Hibernate Tool with a JPA Configuration
[hibernatetool] 1. task: hbm2ddl (Generates database schema)
[hibernatetool]
[hibernatetool]     drop table MESSAGES;
[hibernatetool]
[hibernatetool]     create table MESSAGES (
[hibernatetool]         MESSAGE_ID decimal(20,0)  identity,
[hibernatetool]         MESSAGE_TEXT varchar(255) null,
[hibernatetool]         NEXT_MESSAGE_ID decimal(20,0) null,
[hibernatetool]         primary key (MESSAGE_ID)
[hibernatetool]     );
[hibernatetool]
[hibernatetool]     alter table MESSAGES
[hibernatetool]         add
[hibernatetool]         foreign key (NEXT_MESSAGE_ID)
[hibernatetool]         references MESSAGES;

BUILD SUCCESSFUL
Total time: 2 seconds
```

4. Check the DDL that was also exported to the file helloworld-ddl.sql

```
$ more helloworld-ddl.sql

    drop table MESSAGES;

    create table MESSAGES (
        MESSAGE_ID decimal(20,0)  identity,
        MESSAGE_TEXT varchar(255) null,
        NEXT_MESSAGE_ID decimal(20,0) null,
        primary key (MESSAGE_ID)
    );

    alter table MESSAGES
        add
        foreign key (NEXT_MESSAGE_ID)
        references MESSAGES;
```

5. Run the example with "ant run" and read the log output on the console

```
$ ant run
Buildfile: build.xml

compile:

copymetafiles:

run:
     [java] 1 message(s) found:
     [java] Hello World with JPA

BUILD SUCCESSFUL
Total time: 2 seconds
```

6. Call ant run again

```
$ ant run
Buildfile: build.xml

compile:

copymetafiles:

run:
     [java] 2 message(s) found:
     [java] Hello World with JPA
     [java] Hello World with JPA

BUILD SUCCESSFUL
Total time: 2 seconds
```

7. If you call ant schemaexport again, all tables will be re-created

8. Hibernate logging levels can be varied by changing the settings in the src/etc/log4j.properties and src/etc/META-INF/persistence.xml files

Example 3

This sample performs more complex insert and retrieval of data against the Virtuoso database.

1. Open your command shell and change to the "ex3" directory
2. The following required files need to be placed in the ./lib directory:

   antlr-2.7.6.jar commons-collections-3.1.jar commons-logging-1.0.4.jar dom4j-1.6.1.jar hibernate3.jar javassist-3.4.GA.jar jta-1.1.jar libs.lst log4j-1.2.15.jar slf4j-api-1.5.10.jar slf4j-api-1.5.2.jar slf4j-jcl-1.5.10.jar virtjdbc4.jar virt_dialect.jar
3. Run the example with "ant run" and read the log output on the console:

```
$ ant run
Buildfile: build.xml

clean:
   [delete] Deleting directory /Users/hughwilliams/hibernate/ex3/bin
    [mkdir] Created dir: /Users/hughwilliams/hibernate/ex3/bin

copy-resources:
     [copy] Copying 4 files to /Users/hughwilliams/hibernate/ex3/bin
     [copy] Copied 2 empty directories to 1 empty directory under /Users/hughwilliams/hibernate/ex

compile:
    [javac] Compiling 4 source files to /Users/hughwilliams/hibernate/ex3/bin
    [javac] Note: Some input files use unchecked or unsafe operations.
    [javac] Note: Recompile with -Xlint:unchecked for details.

run:
     [java] Hibernate: insert into EVENTS (EVENT_DATE, title) values (?, ?)
     [java] Hibernate: select identity_value()
     [java] Hibernate: insert into EVENTS (EVENT_DATE, title) values (?, ?)
     [java] Hibernate: select identity_value()
     [java] Hibernate: insert into PERSON (age, firstname, lastname) values (?, ?, ?)
     [java] Hibernate: select identity_value()
     [java] Hibernate: select person0_.PERSON_ID as PERSON1_2_0_, event2_.EVENT_ID as EVENT1_0_1_,
     [java] Hibernate: select event0_.EVENT_ID as EVENT1_0_0_, event0_.EVENT_DATE as EVENT2_0_0_,
     [java] Hibernate: select participan0_.EVENT_ID as EVENT1_1_, participan0_.PERSON_ID as PERSON
     [java] Hibernate: insert into PERSON_EVENT (PERSON_ID, EVENT_ID) values (?, ?)
     [java] Hibernate: update PERSON set age=?, firstname=?, lastname=? where PERSON_ID=?
     [java] Added person 1 to event 2
     [java] Hibernate: insert into PERSON (age, firstname, lastname) values (?, ?, ?)
     [java] Hibernate: select identity_value()
     [java] Hibernate: select person0_.PERSON_ID as PERSON1_2_0_, person0_.age as age2_0_, person0
     [java] Hibernate: select emailaddre0_.PERSON_ID as PERSON1_0_, emailaddre0_.EMAIL_ADDR as EMA
     [java] Hibernate: insert into PERSON_EMAIL_ADDR (PERSON_ID, EMAIL_ADDR) values (?, ?)
     [java] Hibernate: select person0_.PERSON_ID as PERSON1_2_0_, person0_.age as age2_0_, person0
     [java] Hibernate: select emailaddre0_.PERSON_ID as PERSON1_0_, emailaddre0_.EMAIL_ADDR as EMA
     [java] Hibernate: insert into PERSON_EMAIL_ADDR (PERSON_ID, EMAIL_ADDR) values (?, ?)
     [java] Added two email addresses (value typed objects) to person entity : 1
     [java] Hibernate: select event0_.EVENT_ID as EVENT1_0_, event0_.EVENT_DATE as EVENT2_0_, even
     [java] Event: My Event Time: 2010-03-14 03:30:02.0
     [java] Event: My Event Time: 2010-03-14 03:30:06.0

BUILD SUCCESSFUL
Total time: 5 seconds
```

4. Hibernate logging levels can be varied by changing the settings in the src/hibernate.cfg.xml and src/log4j.properties files.

Example 4

This example demonstrates how to make Multi Thread Virtuoso connection using JDBC.

It starts 3 threads: one thread executes SPARQL select and two threads execute SPARQL inserts:

```
import java.util.*;
```

```
import java.sql.*;
import java.math.*;

public class MTtest extends Thread {

  int mode = 0;
  int startId = 0;

  static  String urlDB = "jdbc:virtuoso://localhost:1111";

 public MTtest(int _mode, int _init) {
   mode = _mode;
   startId = _init;
 }

 void prnRs(ResultSet rs)
 {
   try {
     ResultSetMetaData rsmd;

     System.out.println(">>>>>>>>>");
     rsmd = rs.getMetaData();
     int cnt = rsmd.getColumnCount();

       while(rs.next()) {
         Object o;

         System.out.print("Thread:"+Thread.currentThread().getId()+"  ");
         for (int i = 1; i <= cnt; i++) {
           o = rs.getObject(i);
           if (rs.wasNull())
             System.out.print("<NULL> ");
           else
             System.out.print("["+ o + "] ");
         }
         System.out.println();
       }

   } catch (Exception e) {
     System.out.println(e);
     e.printStackTrace();
   }
   System.out.println(">>>>>>>>>");
 }

 public static void main(String argv[])
 {
  try {

    Class.forName("virtuoso.jdbc3.Driver");

    Connection conn = DriverManager.getConnection(urlDB,"dba","dba");
    Statement st = conn.createStatement();

    st.execute("sparql clear graph <mttest>");
    st.execute("sparql insert into graph <mttest> { <xxx> <P01> \"test1\" }");
    st.execute("sparql insert into graph <mttest> { <xxx> <P01> \"test2\" }");
    st.execute("sparql insert into graph <mttest> { <xxx> <P01> \"test3\" }");
    st.execute("sparql insert into graph <mttest> { <xxx> <P01> \"test4\" }");
    st.execute("sparql insert into graph <mttest> { <xxx> <P01> \"test5\" }");
    conn.close();

    int init = 0;

    for(int i=0; i < 2; i++) {
      MTtest thr1 = new MTtest(1, init);
      init+=10;

      MTtest thr2 = new MTtest(0, init);
      init+=10;

      MTtest thr3 = new MTtest(0, init);
      init+=10;
```

```
      thr1.start();
      thr2.start();
      thr3.start();

      thr1.join();
      thr2.join();
      thr3.join();
    }

    System.out.println("===End===");

  } catch (Exception e) {
    System.out.print(e);
    e.printStackTrace();
  }
 }

 public void run( )
 {
  try {

    Connection conn = DriverManager.getConnection(urlDB,"dba","dba");
    Statement st;

    st = conn.createStatement();

    if (mode == 1)
    {
      String query = "sparql SELECT * from <mttest> WHERE {?s ?p ?o}";
      ResultSet rs = st.executeQuery(query);
      prnRs(rs);
    }
    else
    {
      long id = Thread.currentThread().getId();
      for (int i =0; i < 5; i++)
        st.execute("sparql insert into graph <mttest> { <xxx"+startId+"> <P"+id+"> \"test"+i+"\" }");

      System.out.println("\nThread:"+Thread.currentThread().getId()+"  ===Rows Inserted===");
    }

    conn.close();

  } catch (SQLException e) {
        System.out.println("============================================================");
        System.out.println(">>["+e.getMessage()+"]");
        System.out.println(">>["+e.getErrorCode()+"]");
        System.out.println(">>["+e.getSQLState()+"]");
        System.out.println(e);
        System.out.println("============================================================");
        e.printStackTrace();
        System.exit(-1);
  } catch (Exception e) {
        System.out.println("============================================================");
        System.out.println(e);
        System.out.println("============================================================");
        e.printStackTrace();
        System.exit(-1);
  }
 } // run( )

}
```

7.5. OLE DB Provider for Virtuoso

OLE DB is an open data access technology developed and promoted by Microsoft. It allows for uniform data access across diverse data sources including but not limited to conventional RDBMSes. Based on the COM architecture it provides very flexible and exhaustive set of interfaces any database application developer might ever need. At the same time, OLE DB is somewhat overcomplicated and therefore is rarely used directly. In the majority of cases people use ADO(+) instead, ADO is another, somewhat simpler, of Microsoft's data access technologies. However, ADO itself is based upon OLE DB, thus those who use

ADO make indirect use of OLE DB as well.

With the advent of ADO.NET, OLE DB is no longer as an much essential part of the overall Microsoft data access architecture as it used to be. However it still remains important and useful working together with the Microsoft OLE DB .NET Data Provider.

The OLE DB Provider for Virtuoso (VIRTOLEDB) gives OLE DB and ADO applications access to the Virtuoso databases. In principle, the same thing is possible through the conjunction of the Virtuoso ODBC driver and Microsoft OLE DB Provider for ODBC. However, VIRTOLEDB provides native OLE DB access which is more complete and more efficient. Therefore it is preferable for this purpose.

7.5.1. Using the OLE DB Provider for Virtuoso

Being a COM in-process server VIRTOLEDB has to be installed on the client computer. When VIRTOLEDB is properly installed it can be used by a host of existing applications thanks to the support of standard OLE DB interfaces.

System Requirements

VIRTOLEDB requires the following software:

- Windows 98, ME, NT4.0, 2000, or XP.
- Virtuoso Server running on the same or remote computer.
- Redistributable files provided with Microsoft Data Access Components (MDAC) 2.5 or higher. Note that this version of MDAC comes along with Windows 2000. It is also available (as well as other versions of MDAC) at the Microsoft Web site: http://www.microsoft.com/data/

Installing the Provider

VIRTOLEDB is installed as a part of Virtuoso installation on a Windows platform. The following files pertain to the OLE DB Provider for Virtuoso.

Table 7.17. OLE DB Provider for Virtuoso Files

File	Description
virtoledb.dll	DLL that implements the VIRTOLEDB provider.
virtoledb.h	Header file for development of VIRTOLEDB consumers.

The installation procedure, in addition to placing VIRTOLEDB files on a client computer, also registers VIRTOLEDB in the system to make it known as a COM server. This also makes it available through the OLE DB root enumerator object and the Data Links component.

Invoking the Provider

Applications that utilize OLE DB Data Links component can use VIRTOLEDB without any specific measures. Applications that need to directly invoke VIRTOLEDB should follow examples provided in this section.

Using Data Link User Interface

Data Links is a user interface component for connecting to OLE DB data sources and constructing ADO-style connection strings. It belongs to OLE DB core components and is a part of MDAC. It is used my many applications including development environments like MS Visual Studio.

VIRTOLEDB uses the extension mechanism of the Data Link API and provides a customized version of the Data Link connection page.

Figure 7.33. Data Link Provider Page

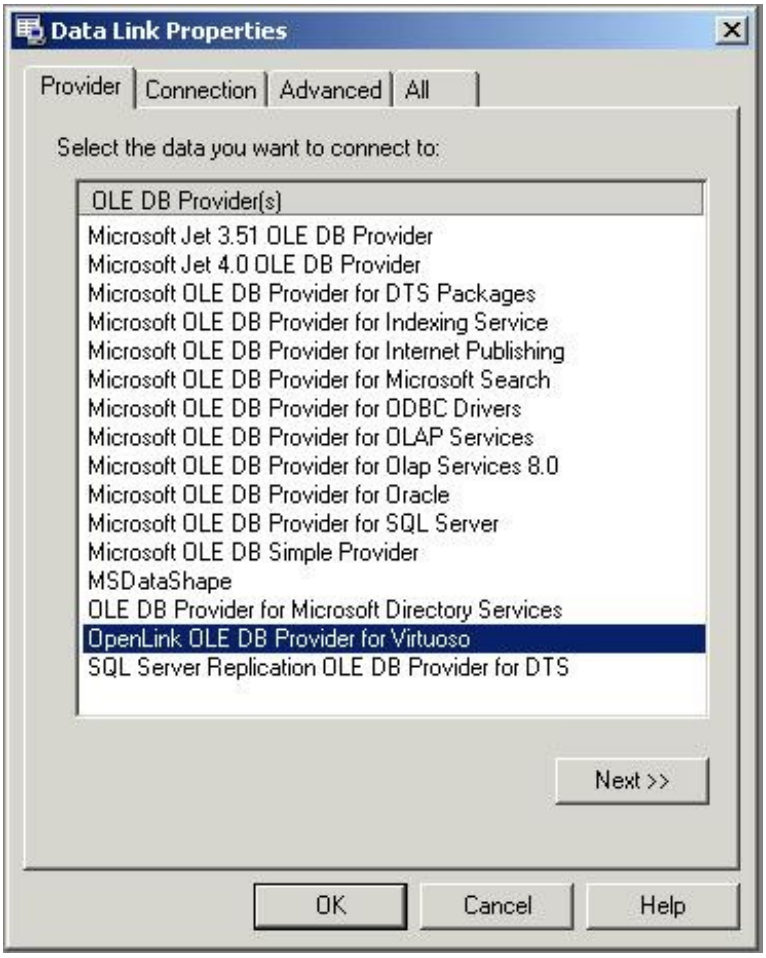

Figure 7.34. Data Link Connection Page

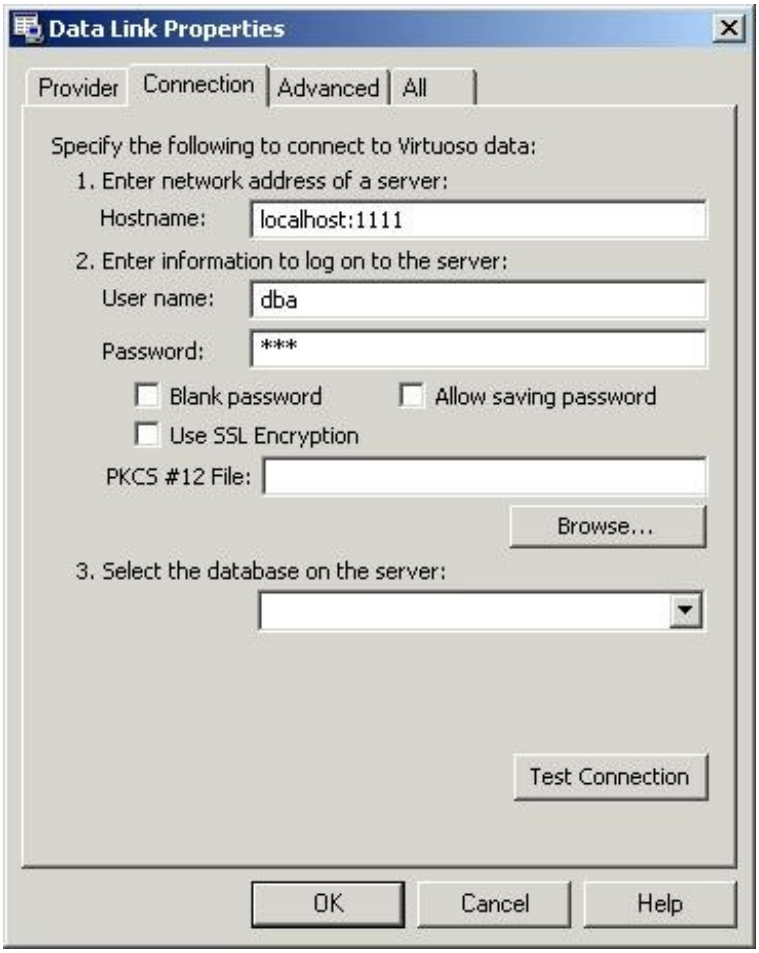

Using COM and OLE DB Interfaces Directly

Applications that utilize OLE DB Data Links component can use VIRTOLEDB without any specific measures. Applications that need to directly invoke VIRTOLEDB should follow examples provided in this section.

```
#define INITGUID
#include "virtoledb.h"

..

  IDBInitialize* pIDBInitialize = NULL;
  HRESULT hr = CoCreateInstance(CLSID_VIRTOLEDB, NULL, CLSCTX_INPROC_SERVER,
                                IID_IDBInitialize, (void**) &pIDBInitialize);
  if (FAILED(hr))
    goto EXIT;
```

ADO Applications

```
Dim strConn As String
Dim objConn As ADODB.Connection

strConn = "Provider=VIRTOLEDB;Data Source=localhost:1111;User Id=dba;Password=dba;Initial Catalog=Demo;Pr

Set objConn = New ADODB.Connection
objConn.CursorLocation = adUseServer
objConn.Open strConn
```

7.5.2. Known Limitations

- Per-column properties are not supported.
- Reference accessors are not supported.
- Optimized accessors are not supported.
- Asynchronous execution is not supported.

7.5.3. Data Types

Data Type Mappings in Rowsets and Parameters

The methods that provide information about rowset columns and command parameters (IColumnsInfo::GetColumnInfo, ICommandWithParameters::GetParameterInfo) use the mapping of Virtuoso data types into OLE DB data types shown in the following table.

Table 7.18. Data Type Mappings

Virtuoso Type	OLE DB Type
CHAR	DBTYPE_STR
VARCHAR	DBTYPE_STR
LONG VARCHAR	DBTYPE_STR
NCHAR	DBTYPE_WSTR
NVARCHAR	DBTYPE_WSTR
LONG NVARCHAR	DBTYPE_WSTR
NUMERIC	DBTYPE_NUMERIC
DECIMAL	DBTYPE_NUMERIC
SMALLINT	DBTYPE_I2
INTEGER	DBTYPE_I4
FLOAT	DBTYPE_R8
DOUBLE	DBTYPE_R8
REAL	DBTYPE_R4
VARBINARY	DBTYPE_BYTES
LONG VARBINARY	DBTYPE_BYTES
DATE	DBTYPE_DBDATE
TIME	DBTYPE_DBTIME
DATETIME	DBTYPE_DBTIMESTAMP
TIMESTAMP	BINARY

Data Type Conversions

Applications can bind column and parameter values using data types different from those described in the section called “Data Type Mappings in Rowsets and Parameters” . In such cases VIRTOLEDB uses OLE DB Data Conversion Library. See MDAC documentation for the list of supported data type conversions.

Long Data Types

Long data types include LONG VARCHAR, LONG NVARCHAR, and LONG VARBINARY. A long value can only be bound to a buffer that have one of these OLE DB types:

- DBTYPE_IUNKNOWN
- DBTYPE_STR
- DBTYPE_STR | DBTYPE_BYREF
- DBTYPE_WSTR
- DBTYPE_WSTR | DBTYPE_BYREF
- DBTYPE_BYTES
- DBTYPE_BYTES | DBTYPE_BYREF

Other type conversions are not supported.

If a long data is bound to a DBTYPE_IUNKNOWN type, this implies the use of the ISequentialStream interface. VIRTOLEDB supports the ISequentialStream::Read method both when getting and setting data. The ISequentialStream::Write method is never supported.

7.5.4. Metadata

Schema Rowsets

VIRTOLEDB supports schema rowsets listed in the following table.

Table 7.19. Supported Schema Rowsets

Schema Rowset	Supported Restrictions
DBSCHEMA_CATALOGS	All (CATALOG_NAME)
DBSCHEMA_COLUMN_PRIVILEGES	All (TABLE_CATALOG, TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, GRANTOR, GRANTEE)
DBSCHEMA_COLUMNS	All (TABLE_CATALOG, TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME)
DBSCHEMA_FOREIGN_KEYS	All (PK_TABLE_CATALOG, PK_TABLE_SCHEMA, PK_TABLE_NAME, FK_TABLE_CATALOG, FK_TABLE_SCHEMA, FK_TABLE_NAME)
DBSCHEMA_INDEXES	1, 2, 3, and 5 (TABLE_CATALOG, TABLE_SCHEMA, INDEX_NAME, TABLE_NAME)
DBSCHEMA_PRIMARY_KEYS	All (TABLE_CATALOG, TABLE_SCHEMA, TABLE_NAME)
DBSCHEMA_PROCEDURE_PARAMETERS	All (PROCEDURE_CATALOG, PROCEDURE_SCHEMA, PROCEDURE_NAME, PARAMETER_NAME)
DBSCHEMA_PROCEDURES	All (PROCEDURE_CATALOG, PROCEDURE_SCHEMA, PROCEDURE_NAME, PROCEDURE_TYPE)
DBSCHEMA_PROVIDER_TYPES	All (DATA_TYPE, BEST_MATCH)
DBSCHEMA_SCHEMATA	All (CATALOG_NAME, SCHEMA_NAME, SCHEMA_OWNER)
DBSCHEMA_TABLE_PRIVILEGES	All (TABLE_CATALOG, TABLE_SCHEMA, TABLE_NAME, GRANTOR, GRANTEE)
DBSCHEMA_TABLES	All (TABLE_CATALOG, TABLE_SCHEMA, TABLE_NAME, TABLE_TYPE)

Columns Rowset

VIRTOLEDB supports the following columns in the columns rowset.

- DBCOLUMN_IDNAME
- DBCOLUMN_GUID
- DBCOLUMN_PROPID
- DBCOLUMN_NAME
- DBCOLUMN_NUMBER
- DBCOLUMN_TYPE
- DBCOLUMN_TYPEINFO
- DBCOLUMN_COLUMNSIZE
- DBCOLUMN_PRECISION
- DBCOLUMN_SCALE
- DBCOLUMN_FLAGS
- DBCOLUMN_BASECATALOGNAME
- DBCOLUMN_BASECOLUMNNAME
- DBCOLUMN_BASESCHEMANAME
- DBCOLUMN_BASETABLENAME
- DBCOLUMN_COMPUTEMODE
- DBCOLUMN_DATETIMEPRECISION
- DBCOLUMN_ISCASESENSITIVE
- DBCOLUMN_ISSEARCHABLE
- DBCOLUMN_OCTETLENGTH
- DBCOLUMN_KEYCOLUMN

7.5.5. Supported Interfaces

VIRTOLEDB supports the interfaces listed in the following table.

Table 7.20. Supported Interfaces

Object	Interface	Notes
Data Source	IDBCreateSession	
	IDBInitialize	
	IDBProperties	
	IPersist	
	IDBInfo	
	IPersistFile	
	ISupportErrorInfo	
Session	IGetDataSource	
	IOpenRowset	
	ISessionProperties	
	IDBCreateCommand	
	IDBSchemaRowset	
	ISupportErrorInfo	
	ITransaction	
	ITransactionJoin	
	ITransactionLocal	
Command	IAccessor	
	IColumnsInfo	
	ICommand	
	ICommandProperties	
	ICommandText	
	IConvertType	
	IColumnsRowset	
	ICommandPrepare	
	ICommandWithParameters	
	ISupportErrorInfo	
Multiple Results	IMultipleResults	
	ISupportErrorInfo	
Rowset	IAccessor	
	IColumnsInfo	
	IConvertType	
	IRowset	
	IRowsetInfo	
	IColumnsRowset	
	IConnectionPointContainer	For IRowsetNotify interface.
	IRowsetChange	
	IRowsetIdentity	
	IRowsetLocate	
	IRowsetRefresh	
	IRowsetResynch	
	IRowsetScroll	
	IRowsetUpdate	
	ISupportErrorInfo	

Object	Interface	Notes
Error Lookup	IErrorLookup	

7.5.6. Data Source Objects

Initialization and Authorization Properties

VIRTOLEDB supports the following properties in the initialization property group.

Table 7.21. Supported Initialization and Authorization Properties

Property	R/W	Default	Notes
DBPROP_AUTH_PASSWORD	Read/Write		General Info: Password
DBPROP_AUTH_USERID	Read/Write		User ID
DBPROP_AUTH_PERSIST_SENSITIVE_AUTHINFO	Read/Write	VARIANT_FALSE	Persist Security Info
DBPROP_INIT_DATASOURCE	Read/Write		Data Source
DBPROP_INIT_CATALOG	Read/Write		Initial Catalog

DBPROP_INIT_HWND	Read/Write		Window Handle
DBPROP_INIT_PROMPT	Read/Write	DBPROMPT_COMPLETE	Prompt
DBPROP_INIT_TIMEOUT	Read/Write	0	Connect Timeout

In addition, VIRTOLEDB implements a provider-specific property set DBPROPSET_VIRTUOSODBINIT with the following properties

Table 7.22. Provider-Specific Initialization and Authorization Properties

Property	R/W	Default	Notes
VIRTPROP_INIT_ENCRYPT	Read/Write	VARIANT_FALSE	Type: VT_BOOL Description: Encrypt Connection If this property is set to VARIANT_TRUE the provider uses SSL encrypted connections.
VIRTPROP_AUTH_PKCS12FILE	Read/Write		Type: VT_BSTR Description: PKCS #12 File If this property is set to a non-empty string then it is used as a name of a PKCS #12 file that authenticates the client. This also implies that the VIRTPROP_INIT_ENCRYPT property is set to VARIANT_TRUE

Data Source Properties

VIRTOLEDB supports the following properties in the data source property group.

Table 7.23. Supported Data Source Properties

Property	R/W	Default	Notes
DBPROP_CURRENTCATALOG	Read/Write		Current Catalog
DBPROP_MULTIPLECONNECTIONS	Read/Write		Multiple Connections

Data Source Information Properties

VIRTOLEDB supports the following properties in the data source information property group.

Table 7.24. Supported Data Source Information Properties

Property	R/W	Default	Notes
DBPROP_ACTIVESESSIONS	Read-Only		The number of connections the Virtuoso server is licensed to.
DBPROP_ASYNCTXNABORT	Read-Only	VARIANT_FALSE	VIRTOLEDB cannot abort transactions asynchronously.
DBPROP_ASYNCTXNCOMMIT	Read-Only	VARIANT_FALSE	VIRTOLEDB cannot commit transactions asynchronously.

7.6. Virtuoso In-Process Client

The in-process client is an efficient mechanism used by hosted applications to access the database functionality of the hosting Virtuoso server.

Normally applications access Virtuoso using the remote procedure call mechanism hidden behind some sort of higher-level API such as ADO.NET, ODBC, and so on. The RPC based mechanism is the only available interface for non-hosted applications. For hosted applications, when the application and the DBMS server reside in the same OS process, Virtuoso provides a mechanism based on direct in-process procedure calls.

The in-process call mechanism by itself is not exposed to the applications. It is hidden behind the same APIs as the RPC one: ODBC, JDBC, ADO.NET. So in both cases applications deal with the same APIs and the application logic does not change. The application chooses which mechanism to use when it opens a database connection.

To make an in-process connection to a Virtuoso server from within an application hosted by the same server it is necessary to use a special inprocess address syntax distinguishing it from the regular network "HOST:PORT" address syntax. The In-process address has the following form:

```
:in-process:PORT
```

Note that it begins with a colon, then specifies the "`in-process` " keyword, followed by another colon, and finally the port number on which the server listens for TCP connections.

This port is only used for establishing the in-process connection, after which the connection proceeds exclusively through the in-process procedure call mechanism.

The in-process connections are presently only supported by the Virtuoso ODBC driver and the ODBC-based .NET Data Provider (OpenLink.Data.VirtuosoClient). The managed .NET Data Provider (OpenLink.Data.Virtuoso) does not yet support in-process connections.

In-process ODBC connection are defined in either a DSN or a connect string directly. This is an example section of the odbc.ini file for unix/linux:

```
[InProcess]
Driver  = /opt/virtuoso/lib/virtodbc32_r.so
Address = :in-process:1111
```

To open an ADO.NET connection the in-process address should be specified in the connection string.

Here is an example of using the OpenLink.Data.VirtuosoClient adapter specifying the details on the connect string:

```
VirtuosoConnection = new VirtuosoConnection ("HOST=:in-process:1111");
```

Every in-process connection originates from the existing connection. For instance, it might be initiated by a stored procedure called from an ISQL connection, or it can be called from an ASPX session.

In-process connections always inherit the user ID from its parent connection. There is no way to set or change the connecting user ID. Therefore the user ID and password are not specified when the in-process connection is opened.

In-process connections also limit database transactions. The autocommit mode is never in effect for in-process connections. The setting of autocommit mode is silently ignored without reporting any errors.

7.7. Unix Domain Socket Connections

Client connections to Virtuoso servers running on the same Unix or Linux server host can benefit from faster connections utilizing Unix Domain Sockets. This does not apply to Windows platforms.

By default Virtuoso will open a Unix Domain listen socket in addition to the TCP listen socket. The name of the UD socket will be:

```
/tmp/virt-<tcp-listen-port>
```

When a client attempts to connect to the Virtuoso server using the specific address `localhost` it will first try connecting to the UD socket, failing that it will silently revert to the TCP socket.

Unix Domain Socket connections only work if `localhost` is explicitly specified or the host is unspecified which defaults to a localhost connection. UD socket connections will *not* work to any other address such as:

```
virt.mydomain.com:1111
127.0.0.1:1111
```

regardless of whether that is the localhost or not.

Unix Domain sockets can be disabled using the `DisableUnixSocket` parameter in the Parameters section of the Virtuoso INI file.

The `sys_connected_server_address()` function can be used to check the connection type. It will return

```
/tmp/virt-<tcp-listen-port>
```

for connections using UD sockets.

7.8. Virtuoso Data Access Clients Connection Fail over and Load Balancing Support

The Virtuoso Data Access Clients ODBC, JDBC, ADO.Net, OLE DB, Sesame, Jena and Redland as of Release 6.1 and above support round robin connections to Virtuoso server instances enabling server fail over, load balancing and fault tolerant connections to be performed across multiple server instances configured in a cluster or as separate server instances.

Fail over connections are enabled by specifying a comma delimited list of servers to failover to, in the "Host" or 'Server" connect string attribute, with the list being worked through in the order presented to determine which Virtuoso Server instance is used. A Round robin (load balanced) connection can be configured by adding the connect string attribute "RoundRobin" = [True | Yes | False | No], in which case the server for the connection is chosen at random from the comma delimited provided as for a Failover connection above.

Example connect strings for Virtuoso ODBC, JDBC, ADO.Net and OLE DB driver/providers are provided below. The Virtuoso Sesame and Jena providers which make use of the JDBC driver and Redland Provider which makes use of the ODBC driver, would simply make use of a suitably configured JDBC or ODBC connect string to enable Failover or Round Robin connections to be made with them.

7.8.1. ODBC

Failover Connect String format

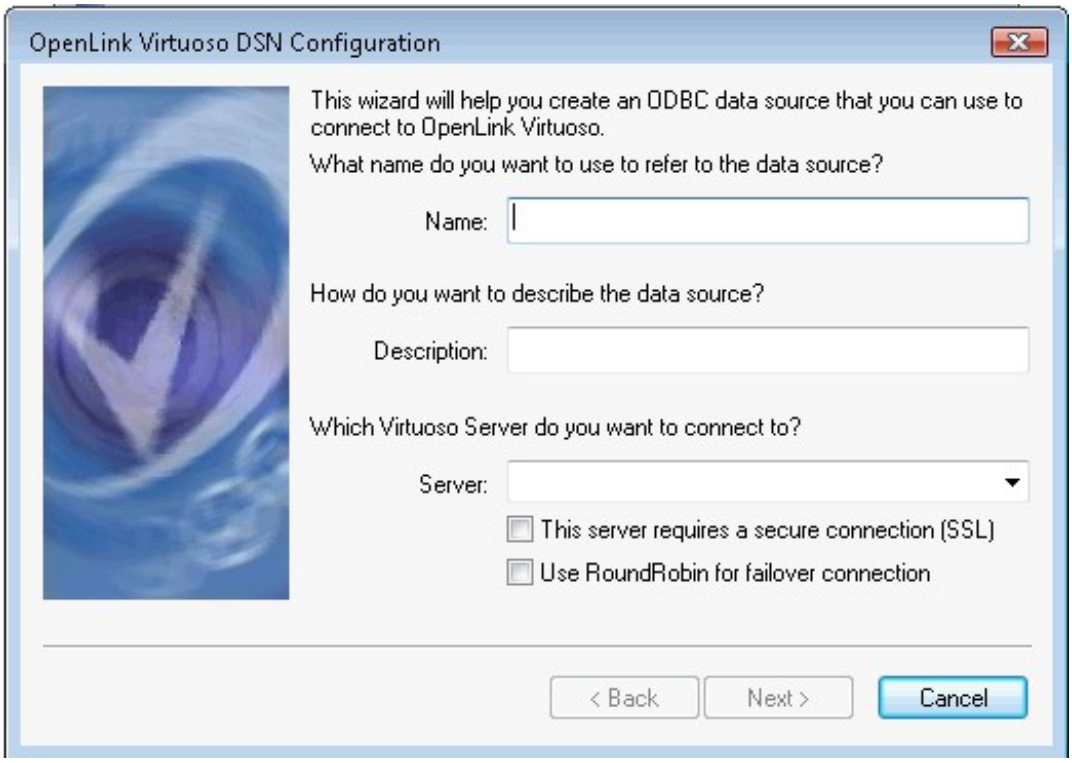
```
Driver={OpenLink Virtuoso};Host=server1:port1,server2:port2,server3:port3;UID=dba;PWD=dba;
```

Round Robin Connect String format

```
Driver={OpenLink Virtuoso};Host=server1:port1,server2:port2,server3:port3;UID=dba;PWD=dba;RoundRobin=Yes"
```

Or alternatively ensure the "use Round Robin for failover connection" check box in the setup dialog.

Figure 7.35. ODBC Round Robin Connect String format



7.8.2. ADO.Net

Failover Connect String format

```
Server=server1:port1,server2:port2,server3;UserId=dba;Password=dba;
```

Round Robin Connect String format

```
Server=server1:port1,server2:port2,server3;UserId=dba;Password=dba;Round Robin=true;Pooling=false;
```

7.8.3. JDBC

Failover Connect String format

```
jdbc:virtuoso://server1:port1,server2:port2,server3/UID=dba/PWD=dba/;
```

Round Robin Connect String format

```
jdbc:virtuoso://server1:port1,server2:port2,server3:1111/UID=dba/PWD=dba/ROUNDROBIN=yes;
```

7.8.4. OLE DB

Failover Connect String format

```
Provider=VIRTOLEDB;Data Source=server1:port1,server2:port2,server3;User Id=dba;Password=dba;Initial Catal
```

Round Robin Connect String format

```
  Provider=VIRTOLEDB;Data Source=server1:port1,server2:port2,server3;User Id=dba;
Password=dba;Initial Catalog=Demo;Prompt=NoPrompt;Round Robin=true
```

7.8.5. Sesame

Failover Connect String format

```
VirtuosoRepository("server1:port1,server2:port2,server3", "uid", "pwd");
```

Round Robin Connect String format

```
VirtuosoRepository("server1:port1,server2:port2,server3", "uid", "pwd");
((VirtuosoRepository)repository).setRoundrobin(true);
```

Chapter 8. Virtual Database Engine

Abstract

This chapter covers Remote Table Attachment, Usage of Remote Tables from ODBC, JDBC, ADO.NET, SQLX, XPath/XQuery, Linked Data Views.

8.1. Virtual Database (VDB) Engine

8.1.1. The Need for VDB Engines

Situation Analysis

As computer hardware, network protocols, database engines, applications, application servers, and desktop productivity tools, proliferate the enterprise, integration of disparate applications from disparate vendors is becoming an all too common problem.

Add the emergence of standards based Distributed Computing galvanized by the Internet infrastructure and associated Internet protocols to this picture, and the need for Integration is even higher.

Increasing the industry at large is looking to a new technology deliverable known as Universal Data Access Middleware to address these systems integration pains.

"With Universal Data Access (UDA), customers receive all of the benefits of a high-level and consistent Application Programming Interface (API) that abstracts all the database complexities while providing a capability that can be specified, controlled, and managed on its own to optimize the near universal need of programs for data access".

Source IDC, 1998 Middleware Markets & Trends

At OpenLink Software, it is our opinion that a new genre of UDA middleware called the "Virtual Database", is set to emerge as the dominant UDA middleware solution for addressing the integration challenges as they exist today, and tomorrow. This new UDA middleware format plays the role of a Universal Data Access manager, fusing traditional database functionality and traditional data access middleware functionality into a single independent packaged software solution.

Virtual Database Engines Defined

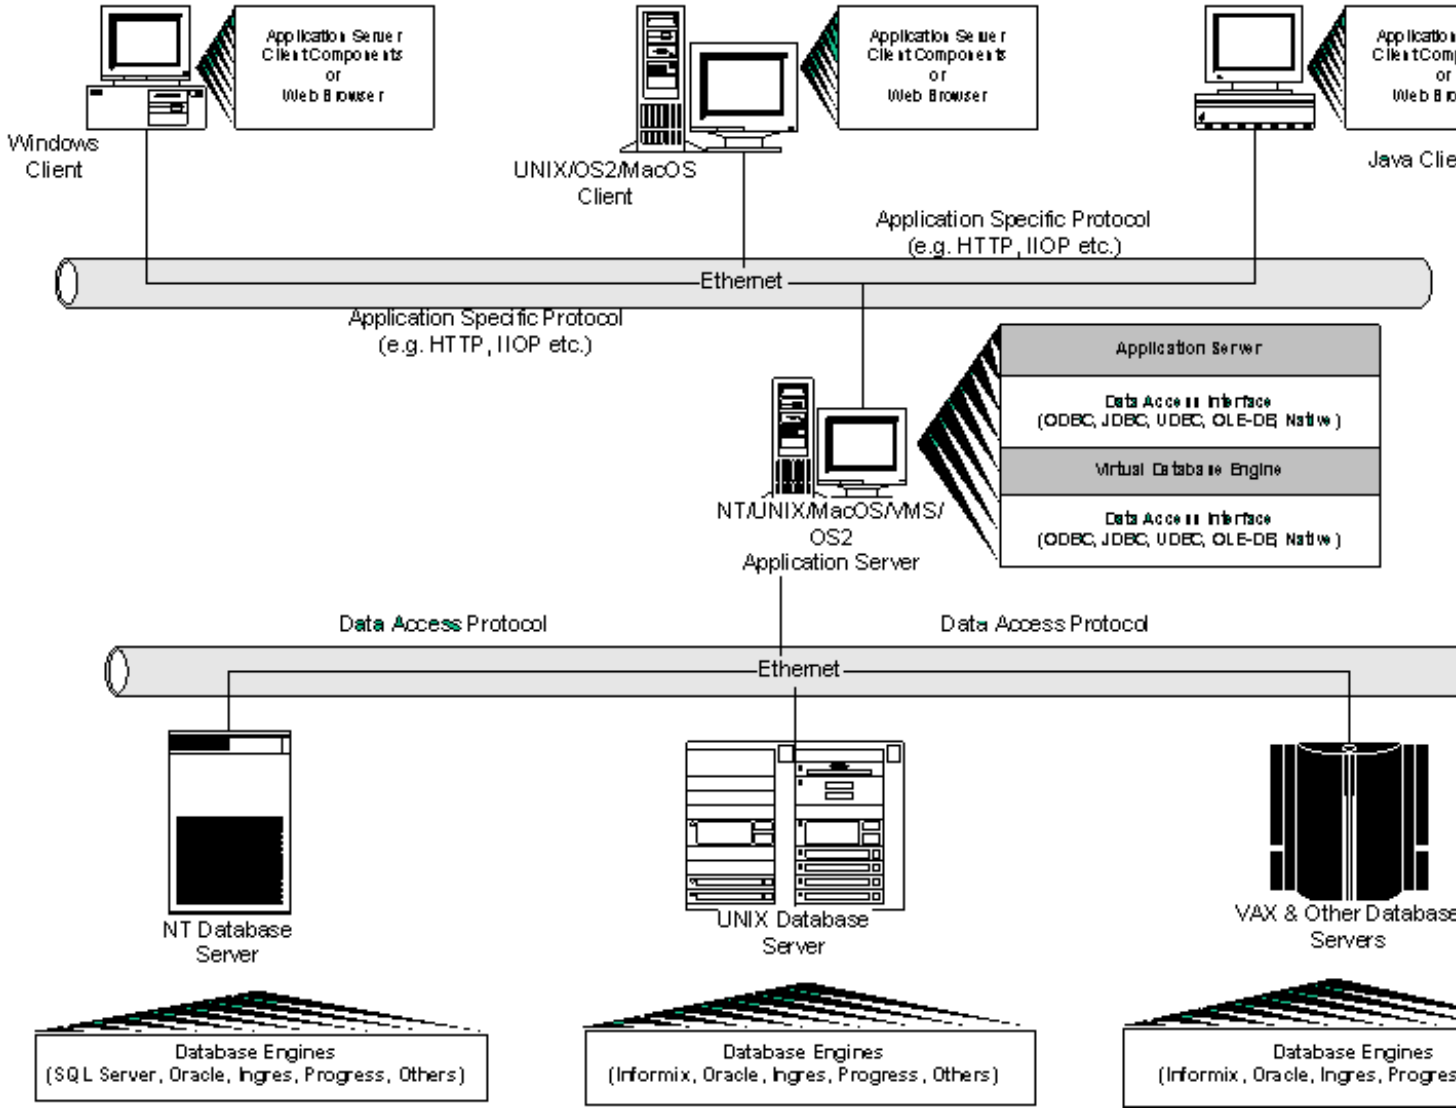
A Virtual Database (VDB) Engine is a UDA middleware format that transparently brings local and or remote heterogeneous databases together using logical database references called Data Source Names (DSN's). A VDB Engine exposes Metadata and Data held within these heterogeneous DSN's to clients applications and services homogeneously.

VDB Engines presume the existence of a number of Database Engines and Data Access Drivers provided by a variety of database vendors within an organization. VDB Engines provide transparent access to these heterogeneous databases via DSN's associated with the relevant data access drivers without exposing end-users or developers to the intricacies of heterogeneous data access.

Data Source Names (DSN's)

A Data Source Name is a logical reference that exposes database to standards compliant or native data access drivers. DSN's provide a flexible naming and binding service for database driven applications developers and end-users alike. Applications no longer need to be inextricably linked to specific database names or specific database engines.

Figure 8.1. Distributed Computing Infrastructure Incorporating A Virtual Database Engine



8.1.2. First Generation Virtual Database Products

Although the strict VDB definition may be new, there are a number of products that have been around for a while that attempt to address VDB issues. The list of such products includes The Microsoft JET Engine, Borland Database Engine (BDE), and IBM DataJoiner.

Microsoft JET

The Microsoft JET Engine lies at the heart of Microsoft Access, it is the piece of technology that allows you to link external and typically remote database tables into your local Access space via ODBC Data Sources. Once this link process has been completed, Access allows you to build Queries, Reports, Forms etc. using these external database tables as though they were Local Access tables. JET can also link to external tables hosted within desktop database engines via native interfaces.

The Microsoft JET Engine services are exposed via Microsoft provided data access interfaces such as: DAO, ADO, and OLE-DB. These interfaces are integral parts of most Microsoft applications, thereby exposing the benefits of the JET VDB transparently.

Borland Database Engine

The Borland Database Engine (BDE) from Inprise like the Microsoft JET Engine also facilitates external table linkage via ODBC Data Sources. The BDE also lets you link to external database tables via native database interfaces and there is no restriction to desktop database engines when you adopt this approach.

Although the BDE has a published set of APIs, it is predominantly used by Inprise applications in very much the same way JET is used by Microsoft applications.

IBM DataJoiner

DataJoiner from IBM provides the ability access heterogeneous data sources via IBM DB/2 Client Application Enablers. It does support ODBC and JDBC as client interfaces and makes use of Native or ODBC based data access for external Data I/O.

8.1.3. VDB Implementation Issues

The essential components that affect the implementation of VDB Engines are, High-Level Data Access Interfaces, Low-Level Data Access Interfaces and Traditional Database Functionality.

High-Level Data Access Interfaces

A VDB Engine's capabilities are exposed via High Level Data Access interfaces. For the purpose of this document, a high level data access interface is an interface utilized predominantly by applications, as opposed to middleware developers for achieving application database independence. A high level data access interface sits atop Low-Level data access interfaces, providing an abstraction layer that serves to simplifying the process of database independent application development.

A number of High Level Data Access standards exist today, the more prevalent being:

Data Access Objects (DAO)
Remote Data Objects (RDO)
ActiveX Data Objects (ADO)
OLE-DB
JavaBlend
InfoBus

It is important to note that low-level Data access interfaces such as ODBC, UDBC, JDBC and OLE-DB transparently serve the high-level interfaces mentioned in the section above. Thus, in most cases VDB vendors will treat ODBC, UDBC, JDBC, and OLE-DB as high-level interfaces by providing VDB data access drivers conforming to these standards as part of the VDB deliverable.

Low-Level Data Access Interfaces

A VDB Engine's data I/O occurs via low-level data access interfaces to underlying database engines or data sources. In recent times the Open Database Connectivity (ODBC) API and the X/Open SQL Call Level Interface (CLI) have emerged as the dominant industry wide Low-Level Data Access Standards. OLE-DB from Microsoft is also emerging as a new low-level data access standard for relational and non-relational data in the Microsoft Component Object Model (COM) world. While JDBC is emerging like wise as the low-level data access standard for the burgeoning Java world.

A VDB may also be a Native Database Interface Client, making use of database engine vendor provided data access interfaces. Native interfaces are based upon Embedded SQL, an older format Low-Level data access interface that preceded the X/Open SQL CLI. It is important to note that ODBC from Microsoft, JDBC from JavaSoft, and UDBC from OpenLink Software are all derived from the X/Open SQL CLI.

Traditional Database Functionality

The degree to which a VDB implements a traditional database engine's functionality has a direct bearing on the intrinsic value of a VDB engine. Traditional database functionality is extensive, but for the purposes of this document, a core set of functionality

common to all commercial database engines has been assembled. The functionality list includes:

Query Language Support. standard syntax for interrogating, manipulating, describing, and securing data contained within a database. Examples include the Structured Query Language (SQL) for relational databases and the Object Query Language (OQL) for Object and Object-Relational Databases.

Query Processor. the mechanism used by a database engine to convert Query Language Statements into actual data retrieval instructions. In addition, this database component is responsible for ensuring Query Language syntax conformance, Query Execution Plan Assembly and Query Fulfillment.

Standard Data Types Support. data contained within a database must be describable using standard data types e.g. Character, Number, Date, etc.

VIEW Support. pre constructed query statements stored within a database, for the purpose of query simplification, or content and structural security.

Stored Procedure Support. Stored Procedures facilitate the embedding of application programming logic within a database. Their pre-compiled nature enhances data access performance by reducing message hops between database servers and database clients.

Scrollable Cursor Support. the process by which the result of a database query (known as a result-set) is traversed. Traversal occurs in either direction, backwards or forwards, using result-set chunks (known as row-sets). Resultset scrolling occurs when database engines exchange data with database clients.

Concurrency Control. the process through which a database engine supports multiple sessions running concurrently, across multiple database users and database client applications without compromising underlying data integrity or introducing quantum increases in application response times.

Transaction Support. ensures that database instructions can be grouped into logical units of execution that are Atomic, Consistent, Isolated from the effect of other units of execution affecting the same underlying data, and Durable.

Transaction Isolation. describes the ability of a database engine to provide transaction process partitioning options called Isolation Levels, that offer different ways of managing the effects of multiple and concurrent transactions affecting the same underlying data.

Distributed Transaction Support. describes the ability to preserve transaction atomicity, consistency, integrity, and durability across database servers hosted on the same or different database server machines within a networked environment. This involves supporting transaction Commits and Rollbacks using a 2-phase commit protocol.

User Definable Type Support. this is how a database engine allows end-users extend its base functionality. This is achieved by providing interfaces that allow end-users create new ways in which a database engine's data is described and manipulated.

Federated Database Support. data access and manipulation across database servers resident on the same machine.

Distributed Database Support. data access, and manipulation across database servers resident on the different machines within a networked environment.

Security. the process by which data, and data transmission is protected using a combination of database and operating system privileges, roles and roles hierarchies. It also includes the ability of a database engine to protect data transmitted to its clients using data encryption.

8.1.4. VDB Engine Components

The prior section outlined the critical implementation issues that affect the development and implementation of VDB Engines. These issues form the basis around which a component based framework for depicting VDB architectures has been derived.

The components that comprise a VDB Engine framework are as follows:

Data Access Drivers

The VDB component that forms the entry point to the VDB Engine's services, these drivers may or may not conform to industry standards. Applications and Services that sit atop a VDB Engine must have their data access layers written to the same Application Programming Interfaces (APIs) implemented by the Data Access Drivers provided by a VDB engine.

Security Manager

The VDB component that is responsible for protecting data and data transmission (using encryption) within the VDB Engine's domain. It is also responsible for managing Application, User, Group, Role and Domain privileges as they relate to the creation, manipulation and destruction of VDB data and metadata.

Query Manager

The VDB component that handles queries presented to it by the VDB Engine's data access drivers. It provides query syntax checking, query execution plan compilation, and query fulfillment services. A query processor is built in conformance to one or more query language specifications, the most notable being the Structured Query Language (SQL) for relational database engines, and the Object Query Language (OQL) for Object-Relational and Object Database engines.

Meta Data Manager

The VDB component that provides the Query Processor with information about the data entities from which the Query Processor's execution plan is derived. Metadata managers are also the components responsible for linking external data sources into the VDB domain and directing the Query Processor to the appropriate Data I/O manager.

Transaction Manager

The Transaction Manager component ensures that transactions are Atomic (clearly distinguishable units), Consistent (thereby preserving integrity of data), Isolated from the effect of other transactions, and Durable (such that the effects of committed transactions survive failure). The Transaction Manager ensures VDB Engines are capable of supporting Online Transaction Processing (OLTP) and Distributed Transaction oriented applications and services. Transaction Managers may be standards based implementing X/Open's XA Resource Manager Specifications. Distributed transaction support is implemented by using a two-phase commit protocol.

Concurrency Manager

The VDB component that ensures client applications and services are capable of opening multiple concurrent sessions that execute data INSERTS, UPDATES and DELETIONS, without implicitly reducing application response times or compromising data integrity. Concurrency control is delivered in one of two formats, Optimistic or Pessimistic depending on the response times desired by VDB client applications or services.

Local Data I/O Manager

VDB Engine's that provide local data storage uses this component for reading and writing data to disk. This is how a VDB provides traditional database engine data storage services.

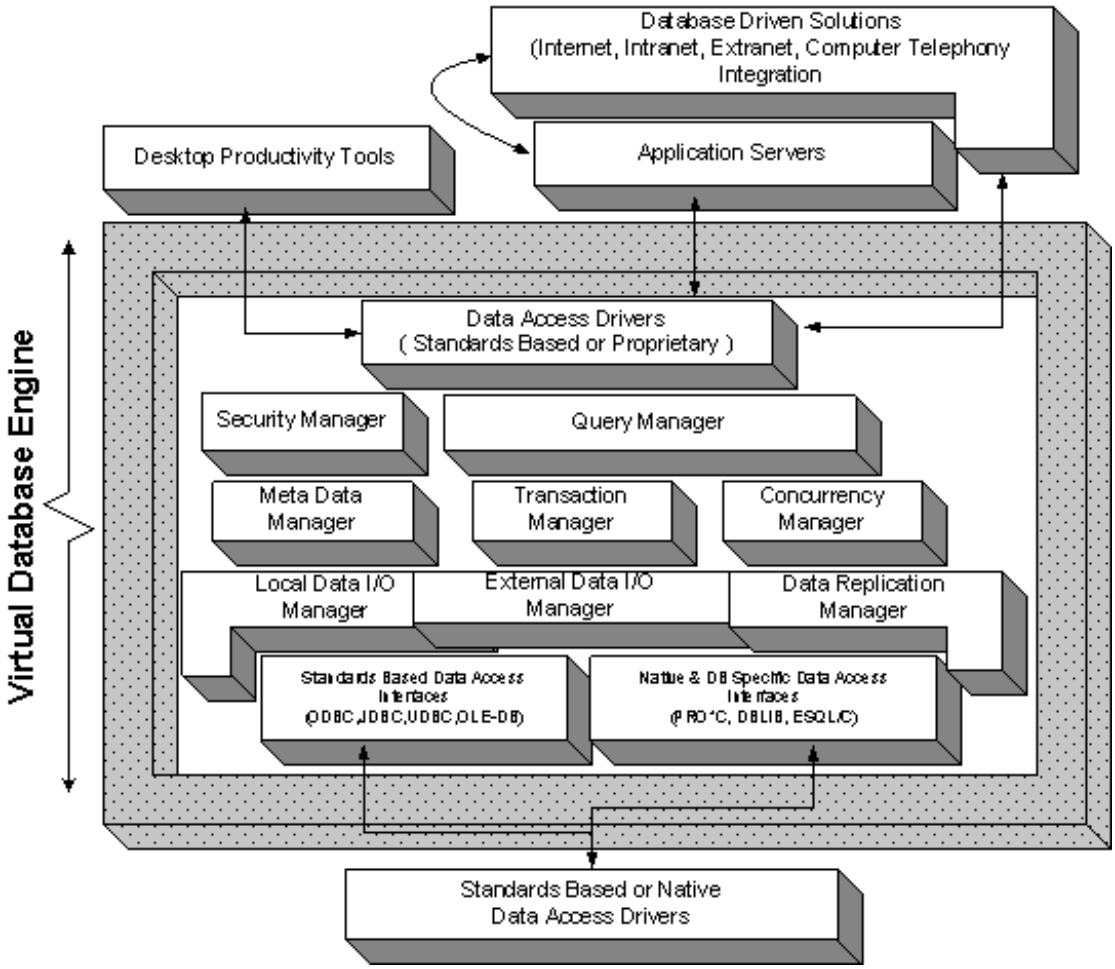
External Data I/O Manager

VDB component that handles data reads and writes to external data sources. The External Data I/O Manager be implemented using standard data access interfaces such as ODBC, JDBC, UDBC, OLE-DB or Native data source interfaces.

Replication Manager

Component that manages data migration and synchronization across two or more VDB servers within a distributed computing environment. This component acts as a data coordinator between the activities of Local Data I/O and External Data I/O Managers across VDB servers. The Replication Manager enables a VDB Engine offer automated bi-directional data, and metadata transformation services across heterogeneous data sources without end-user or developer intervention.

Figure 8.2. Virtual Database Engine Architecture & Components



VDB Implementation Approaches

There are no golden VDB implementation specifications, but the implementation of a VDB has a direct impact the degree to which you realize desired value from the VDB concept as a whole.

The VDB value proposition is simply stated as follows:

"To provide transparent access to heterogeneous data sources, independent of host operating system and underlying database engines ".

VDB implementations can be categorized as follows:

Table 8.1. VDB Implementation Categories

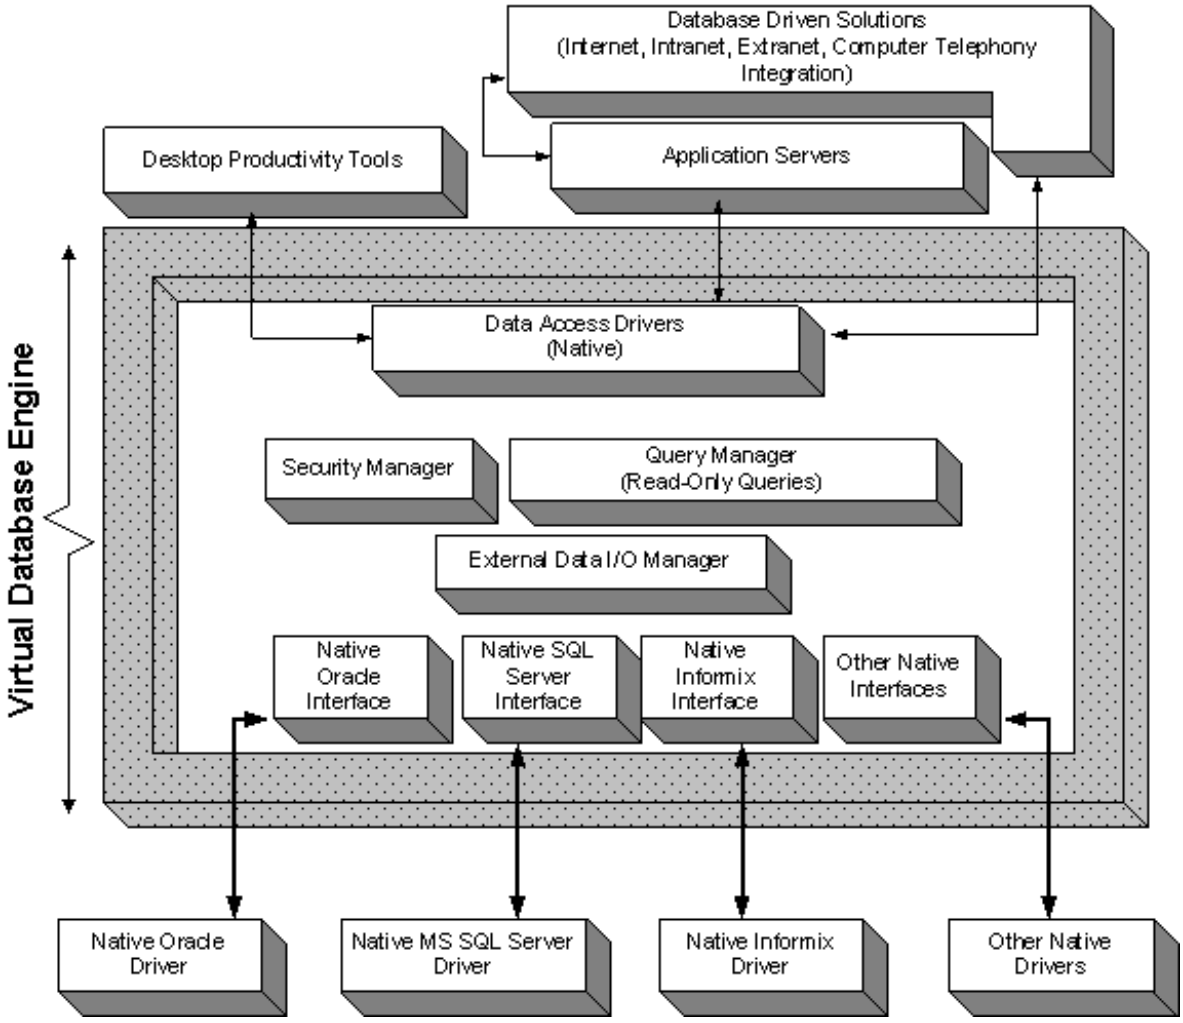
	VDB Data Access Interface	VDB External Data I/O	Traditional Database Functionality
Type 1	Native	Native	Partial
Type 2	Native	Native	Full
Type 3	Native	Standards Based	Partial
Type 4	Native	Standards Based	Full
Type 5	Standards Based	Native	Partial
Type 6	Standards Based	Native	Full
Type 7	Standards Based	Standards Based	Partial
Type 8	Standards Based	Standards Based	Full
Type 9	Standards Based	Standards Based or Native	Partial
Type 10	Standards Based	Standards Based or Native	Full

The sections that follow provide illustrations of the different VDB formats, depicting the components that provide the basis for the categorization used in the table above.

Type 1 VDB Engine

This category of VDB exposes its services to clients via Native and Proprietary high-level data access interfaces. Data I/O is achieved via native, proprietary, and data source specific low-level data access interfaces. This category of VDB does not possess a complete set of traditional database engine components.

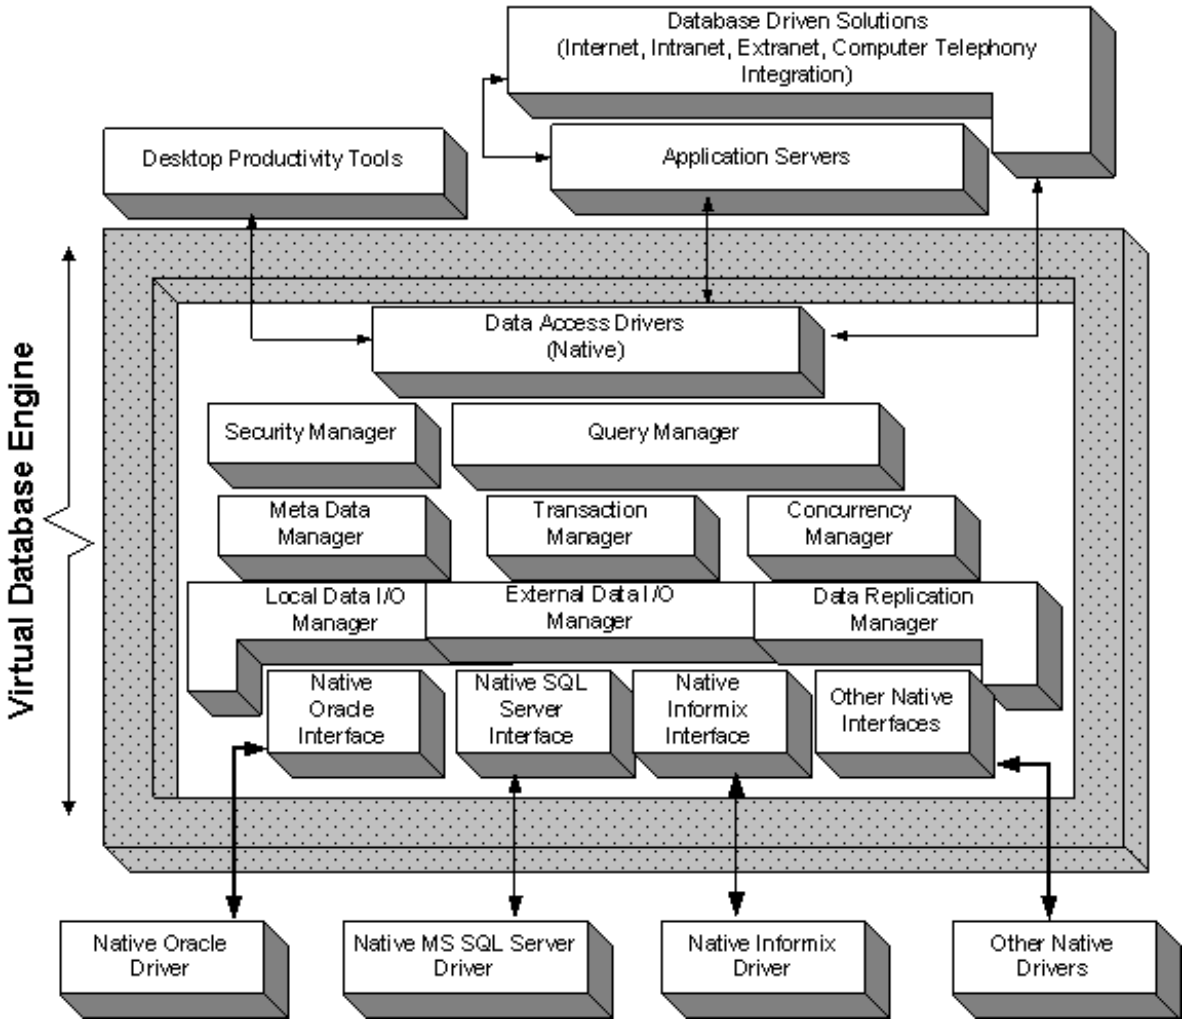
Figure 8.3. Type 1 VDB Engine Architecture



Type 2 VDB Engine

This category of VDB exposes its services to clients via Native and Proprietary high-level data access interfaces. External data I/O is achieved via native, proprietary, and data source specific low-level data access interfaces. This category of VDB possesses a complete set of traditional database engine components.

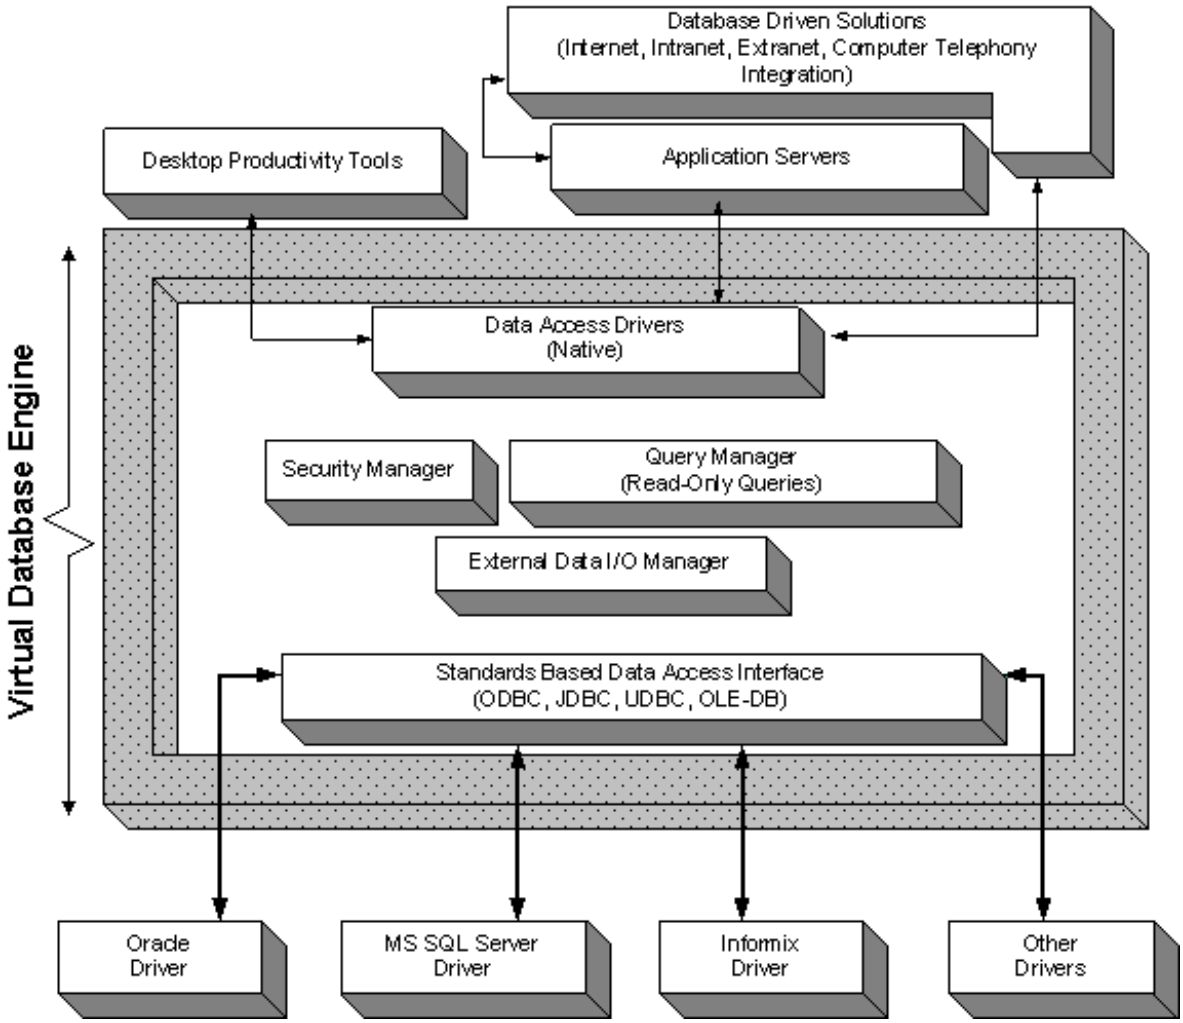
Figure 8.4. Type 2 VDB Engine Architecture



Type 3 VDB Engine

This category of VDB exposes its services to clients via Native and Proprietary high-level data access interfaces. Data I/O is achieved via Open, Standards based, and Database Independent low-level data access interfaces. This category of VDB does not possess a complete set of traditional database engine components.

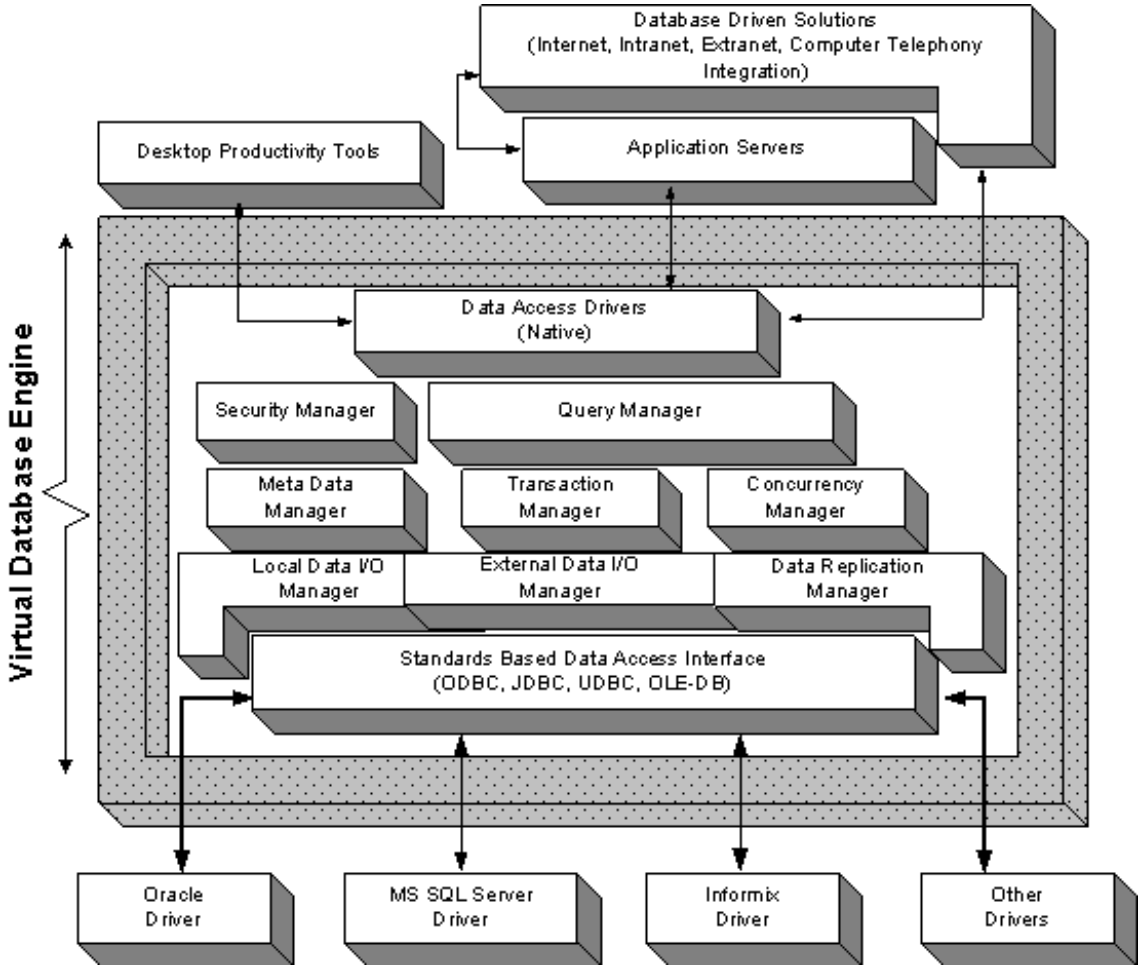
Figure 8.5. Type 3 VDB Engine Architecture



Type 4 VDB Engine

This category of VDB exposes its services to clients via Native and Proprietary high-level data access interfaces. External data I/O is achieved via Open, Standards based, and Database Independent low-level data access interfaces. This category of VDB possesses a complete set of traditional database engine components.

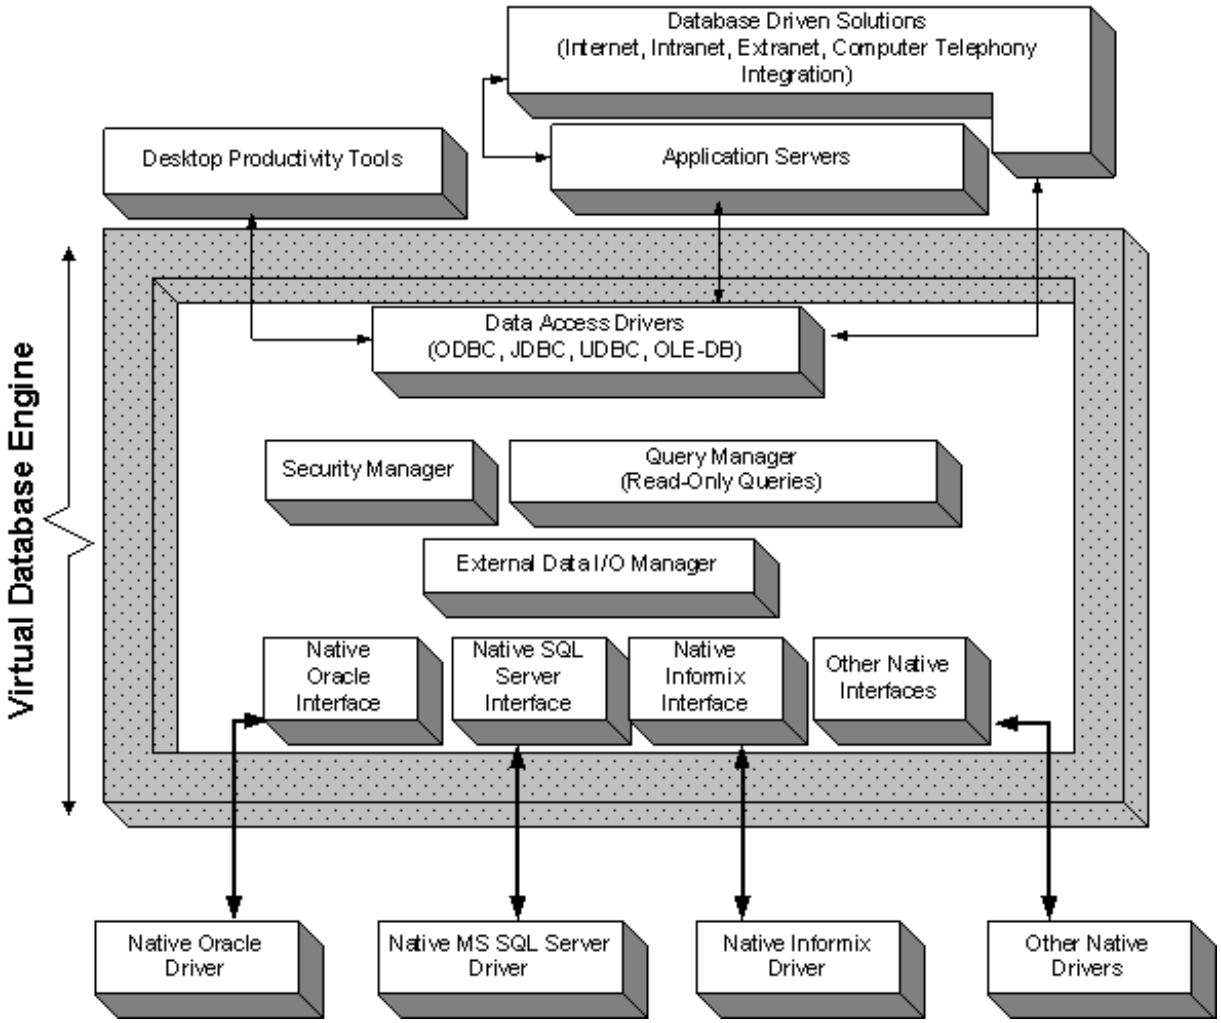
Figure 8.6. Type 4 VDB Architecture



Type 5 VDB Engine

This category of VDB exposes its services to clients via open and standards based high-level data access Interfaces. Data I/O is achieved via native, proprietary, and data source specific low-level interfaces. This category of VDB does not possess a complete set of traditional database engine components.

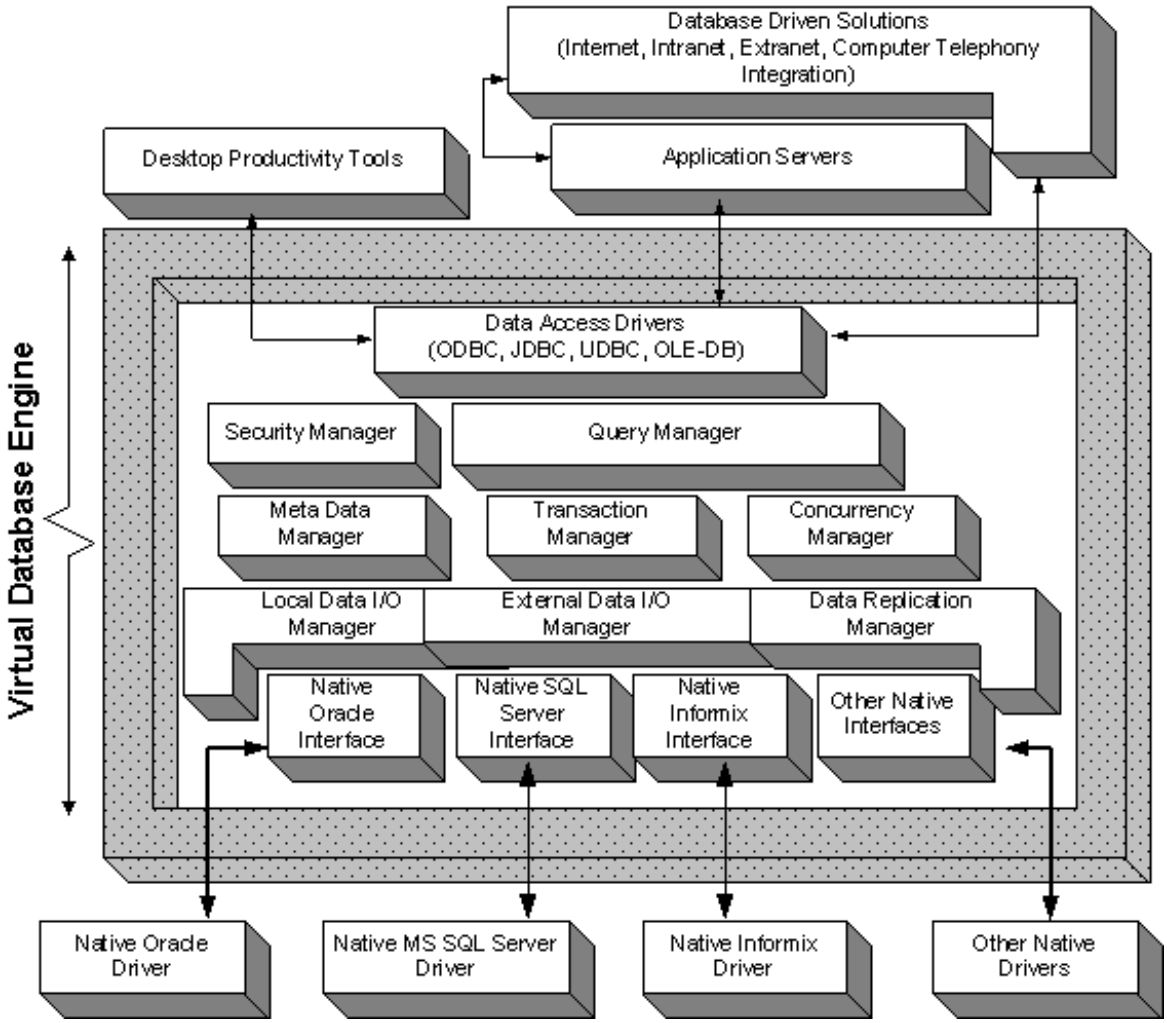
Figure 8.7. Type 5 VDB Engine Architecture



Type 6 VDB Engine

This category of VDB exposes its services to clients via open, standards based, high and low-level Interfaces. External data I/O is achieved via native, proprietary, and data source specific low-level interfaces. This category of VDB possesses a complete set of traditional database engine components.

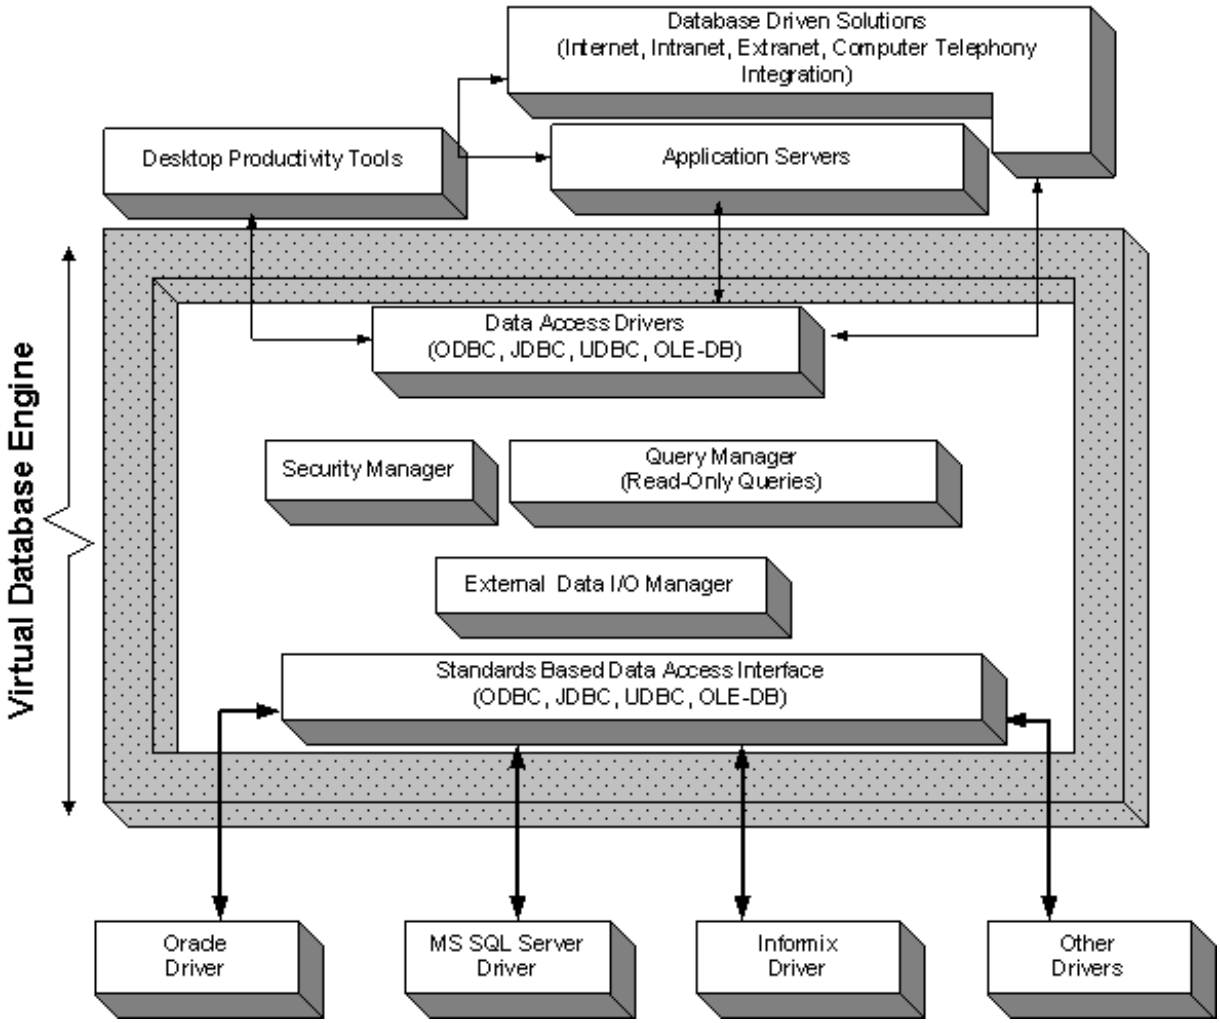
Figure 8.8. Type 6 - VDB Engine Architecture



Type 7 VDB Engine

This category of VDB exposes its services via open, standards based high-level data access interfaces. Data I/O is achieved via Open, Standards based, and Database Independent low-level data access interfaces. This category of VDB does not possess a complete set of traditional database engine components.

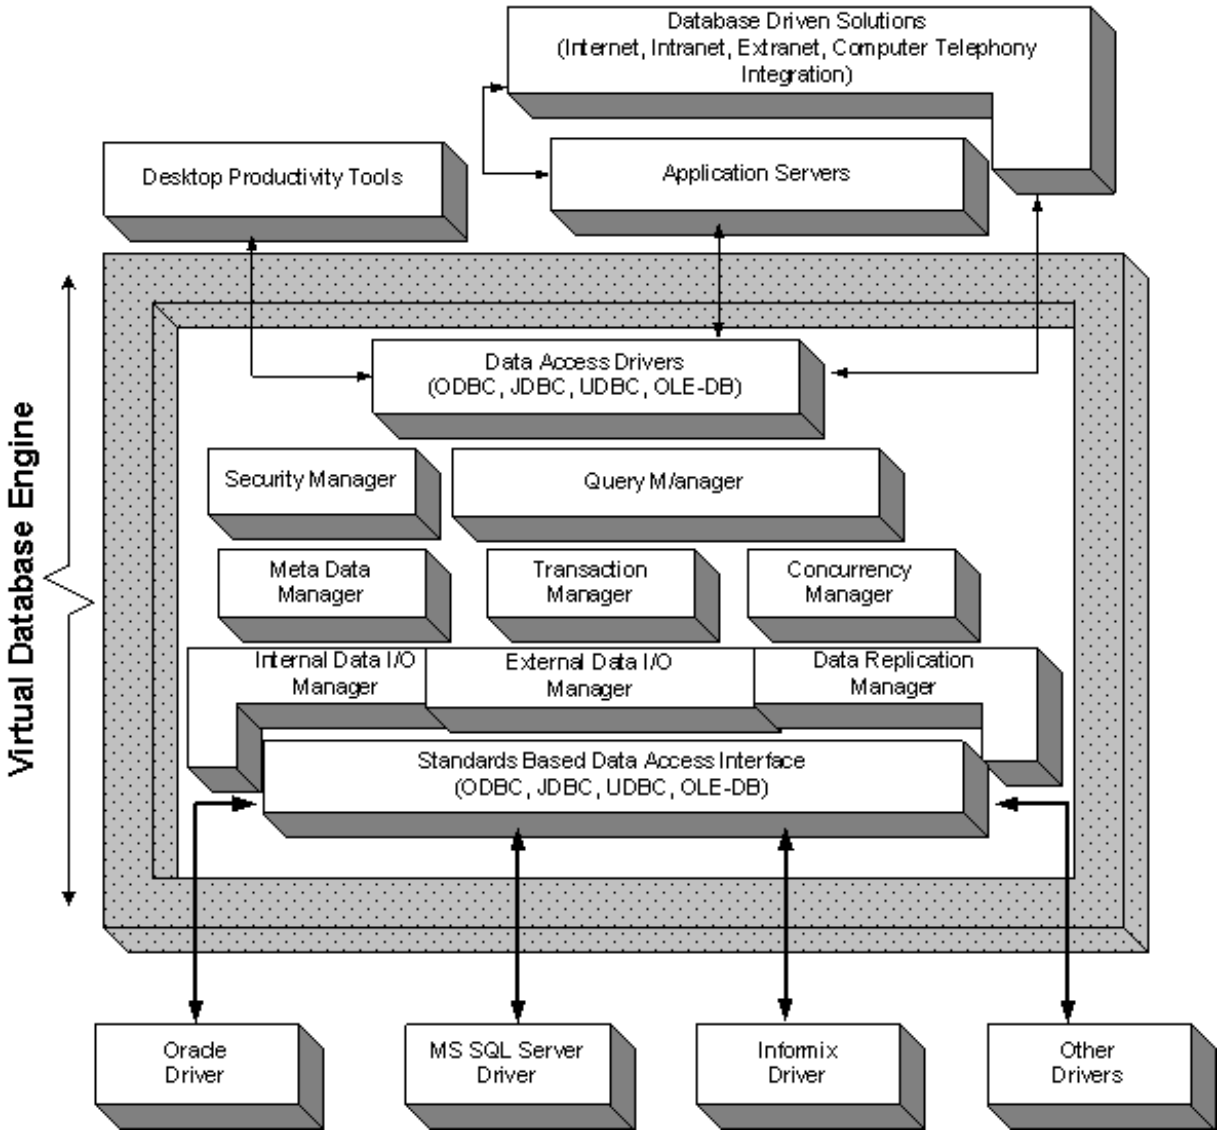
Figure 8.9. Type 7 VDB Engine Architecture



Type 8 VDB Engine

This category of VDB exposes its services via open, standards based, high and low-level interfaces. External data I/O is achieved via Open, Standards based, and Database Independent low-level data access interfaces. This category of VDB does possess a complete set of traditional database engine components.

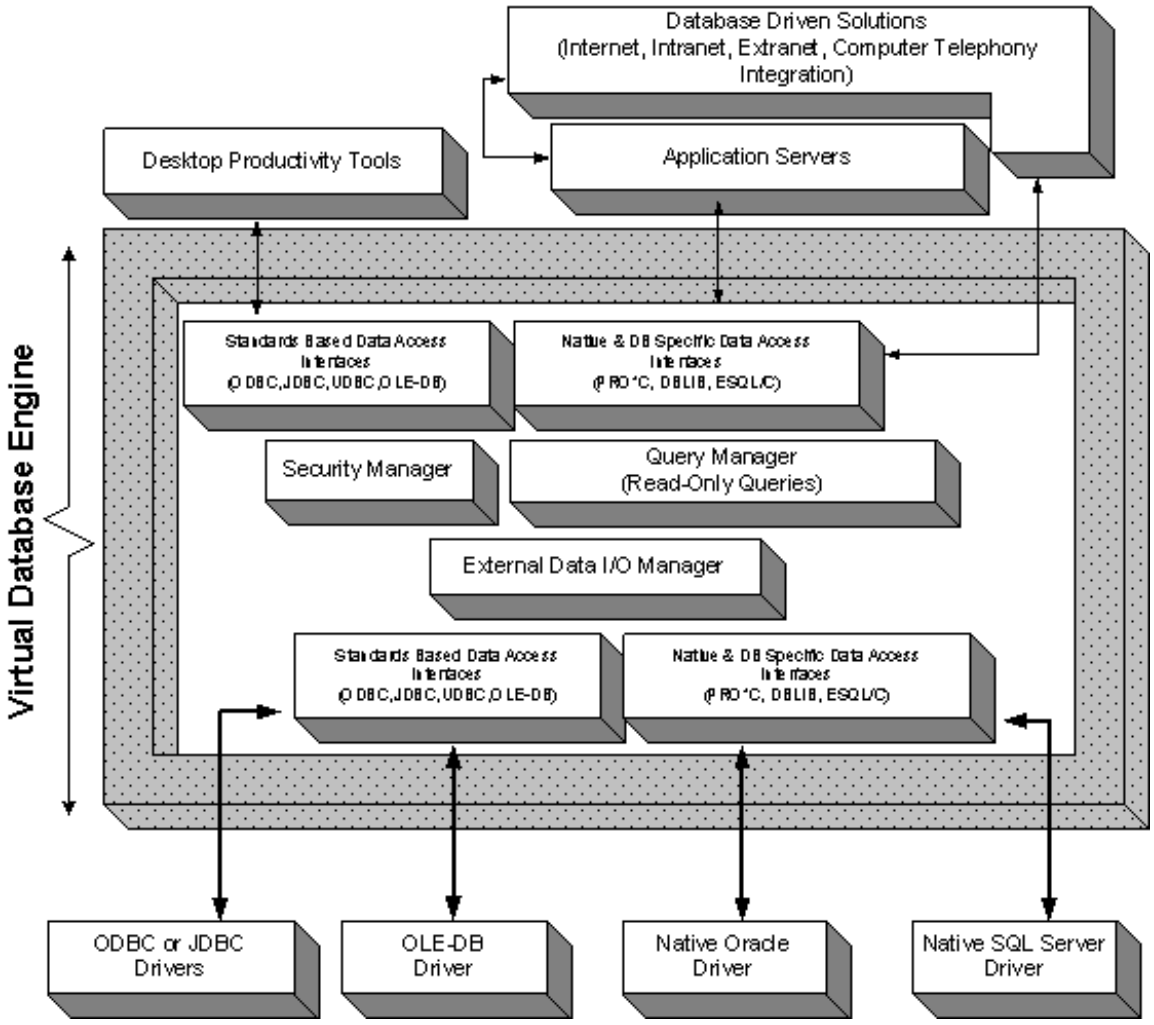
Figure 8.10. Type 8 VDB Engine Architecture



Type 9 VDB Engine

This category of VDB exposes its services via Open, Standards based, high-level data access interfaces. Data I/O is achieved by using either Open, Standards based, and Database Independent low-level data access interfaces or Native, Proprietary, and Database Specific low-level data access interfaces. This category of VDB does not possess a complete set of traditional database engine components.

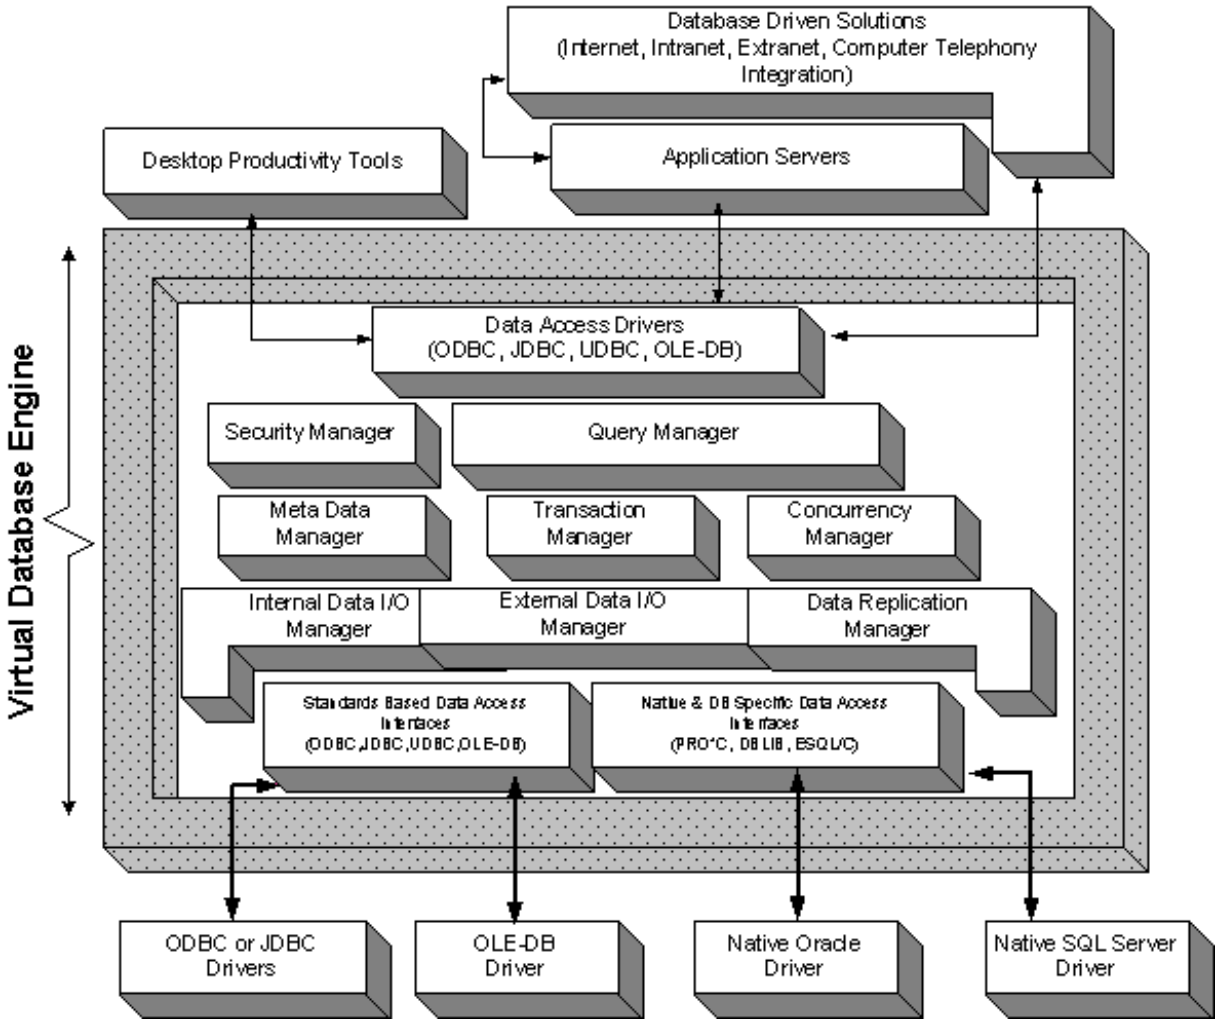
Figure 8.11. Type 9 VDB Architecture



Type 10 VDB Engine

This category of VDB exposes its services via Open, Standards based, high-level data access interfaces. External data I/O is achieved by using either Open, Standards based, and Database Independent low-level data access interfaces or Native, Proprietary, and Database Specific low-level data access interfaces. This category of VDB possesses a complete set of traditional database engine components.

Figure 8.12. Type 10 VDB Architecture



8.2. Using Microsoft Entity Frameworks to Access Oracle Schema Objects with Virtuoso

Abstract

This section details the steps required to provide Microsoft Entity Framework access to Oracle Schema Objects using the OpenLink Virtuoso Universal Server. This is achieved by linking the required Oracle Schema objects into Virtuoso using its built in Virtual Database engine, and then using the Virtuoso ADO.NET Entity Framework provider to query the remote Oracle Schema objects linked into the Virtuoso Server.

Prerequisites. The following prerequisites must be in place for this solution to be possible.

Oracle DBMS. An Oracle DBMS hosting the required Schema Objects needs to be available. In this section the *Oracle Human Resources* sample database will be used to demonstrate the process.

An Oracle DBMS hosting the required Schema Objects needs to be available. In this section the *Oracle Human Resources* sample database will be used to demonstrate the process.

ODBC Driver for Oracle. An Oracle ODBC Driver is required for Linking the Oracle Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for Oracle* will be used in this section, for which a functional ODBC Data source name of "ora10ma" will be assumed to exist on the machine hosting the Virtuoso Server.

An Oracle ODBC Driver is required for Linking the Oracle Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for Oracle* will be used in this section, for which a functional ODBC Data source name of "ora10ma" will be assumed to exist on the machine hosting the Virtuoso Server.

Virtuoso Universal Server. An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework

Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

Microsoft Visual Studio 2008 SP1. Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Tasks

Ensure Oracle Primary Keys (PKs) are not nullable. The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the Oracle database schema before attempting to generate an EDM. In the case of the Oracle Human Resources database all tables are not nullable, thus this should not be an issue in this case.

The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the Oracle database schema before attempting to generate an EDM. In the case of the Oracle Human Resources database all tables are not nullable, thus this should not be an issue in this case.

8.2.1. Install and configure OpenLink ODBC Driver for Oracle

The Virtuoso Virtual Database engine uses ODBC as the connectivity mechanism for linking remote database objects into its local schema. Thus an Oracle ODBC Driver must be available with a suitably configured DSN for connecting to the target database. The OpenLink ODBC Drivers for Oracle have been used in this section, although in theory any Oracle ODBC Driver can be used.

Installation instructions for the OpenLink ODBC Driver for Oracle are available from:

- Product Installation & Basic Configuration (ODBC)

8.2.2. Install and configure OpenLink Virtuoso Universal Server

- Install and configure OpenLink Virtuoso Universal Server

8.2.3. Linking Oracle tables into OpenLink Virtuoso

1. Start the Virtuoso Web User Interface

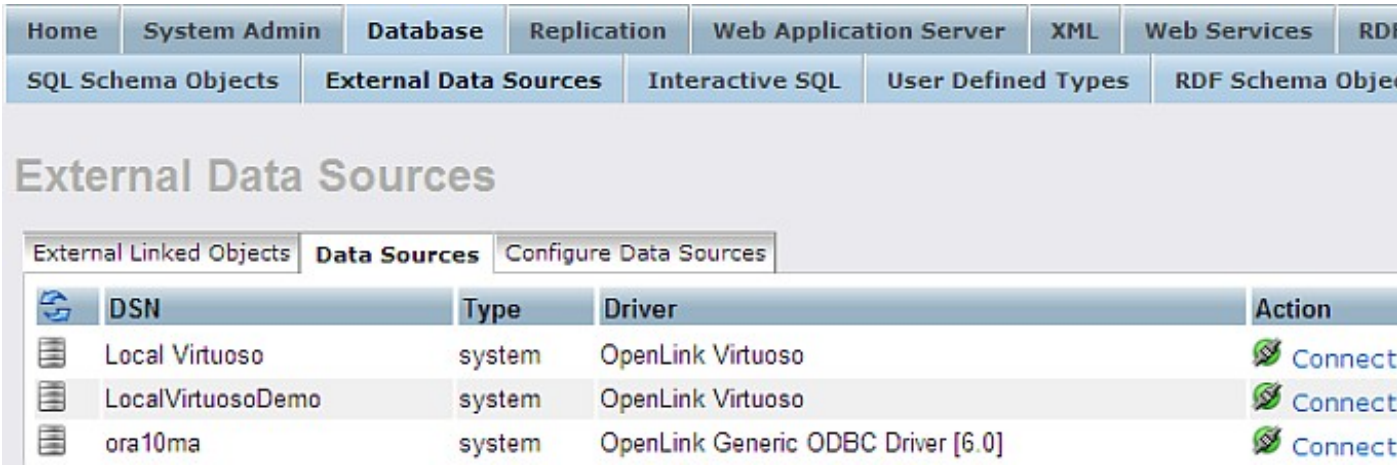
   Figure 8.13. Start

2. Select the "Conductor" link in the Left Frame and Login as the "dba" user.

Figure 8.14. Conductor

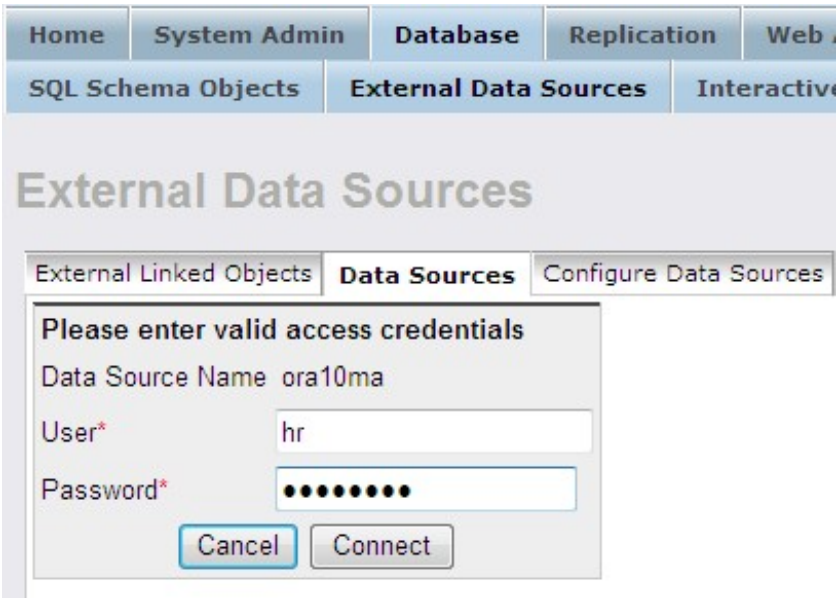
3. Select the "Databases" -> "External Data Source" -> "Data Sources" tab menu items

Figure 8.15. Databases



4. Select the "Connect" button for the "ora10ma" Oracle DSN.

Figure 8.16. Connect

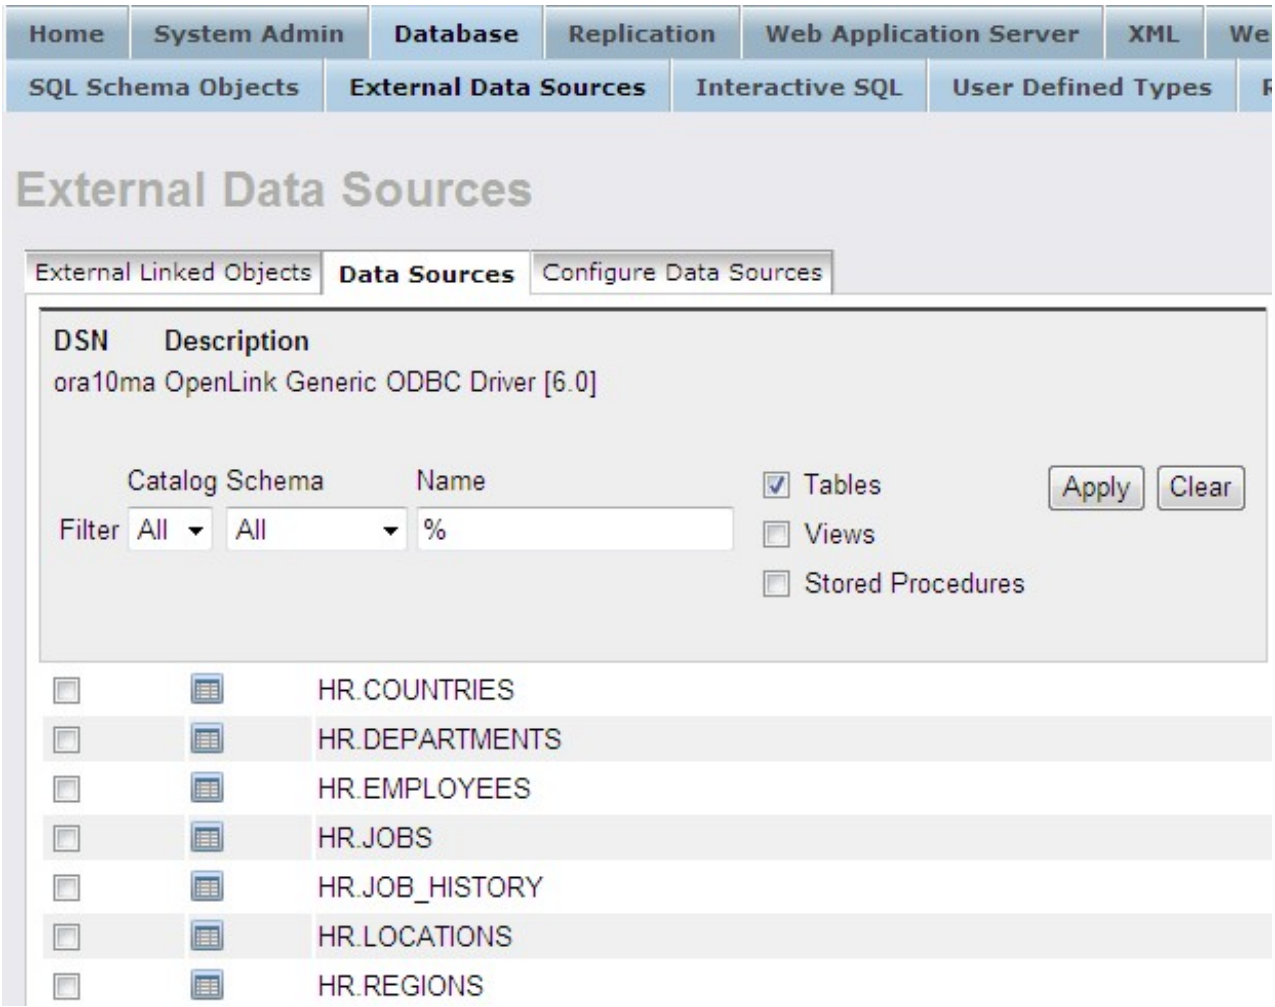


5. On successful connection Select the "Link Objects" button to obtain a list of available tables

Figure 8.17. Link Objects

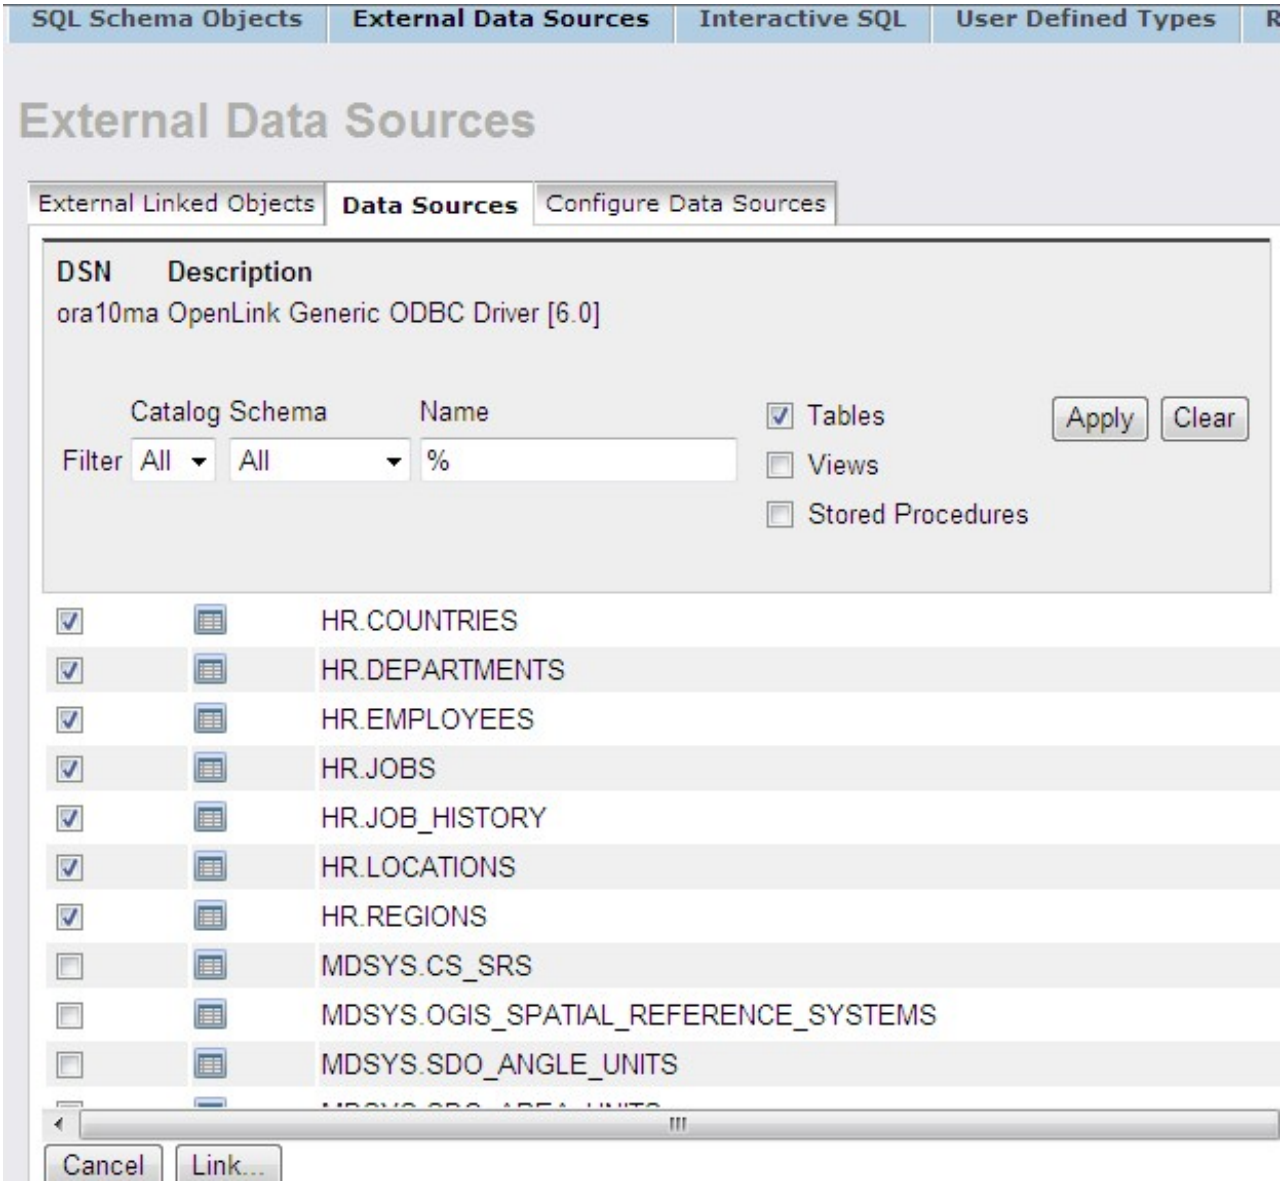
6. Select all the tables that are part of the "HR" catalog.

Figure 8.18. Select all tables



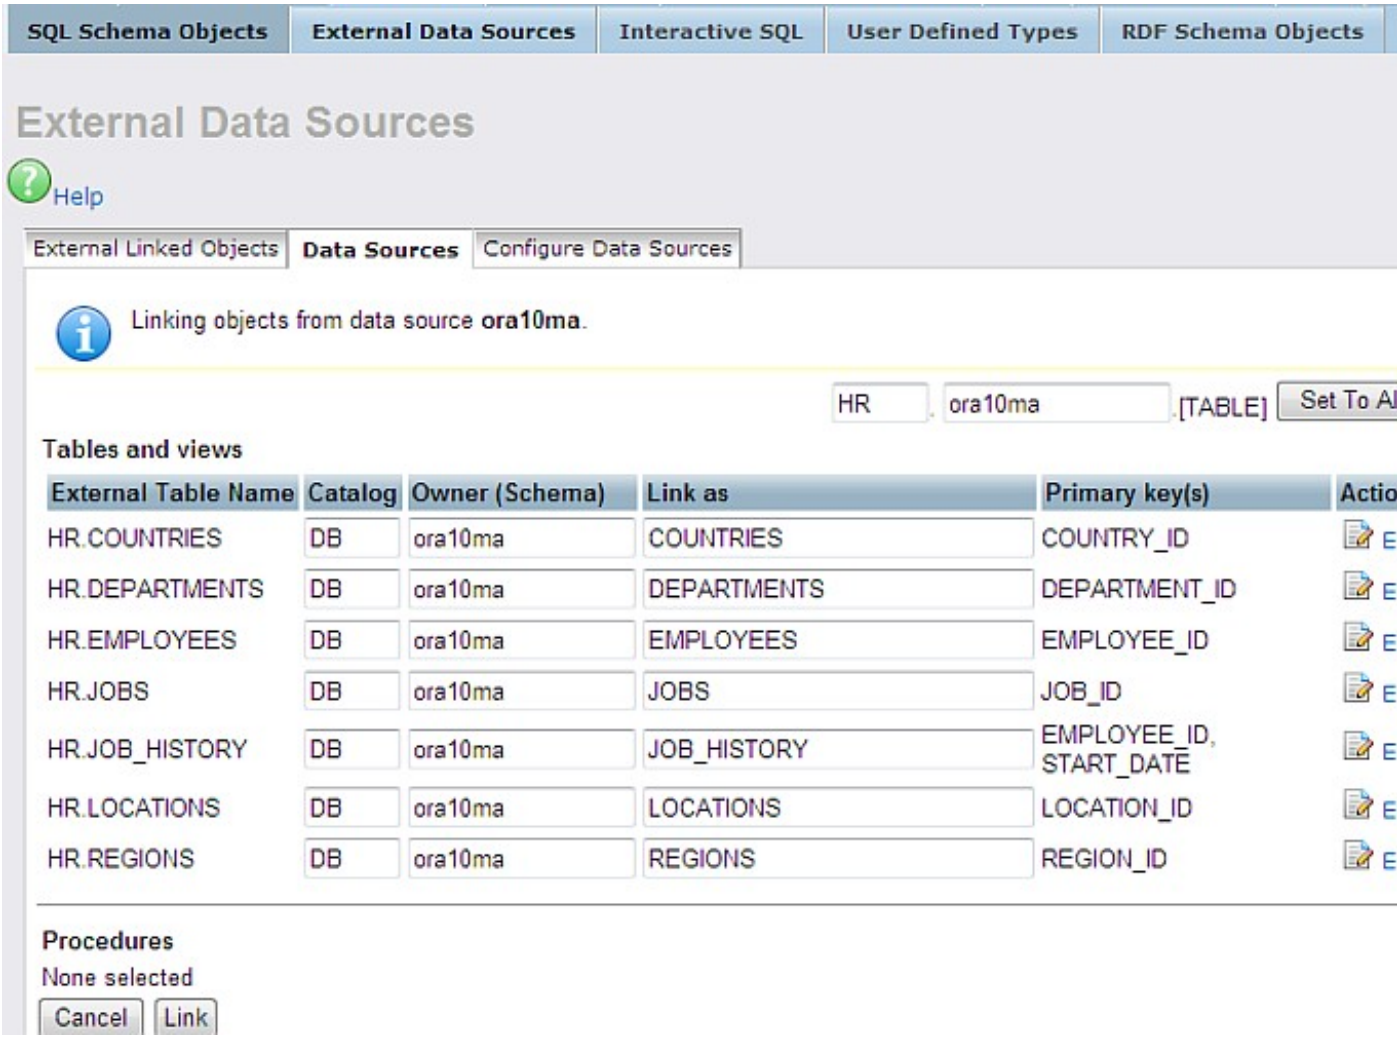
7. Change the Catalog for each table to be "HR" using the "Set All" button.

Figure 8.19. Catalog



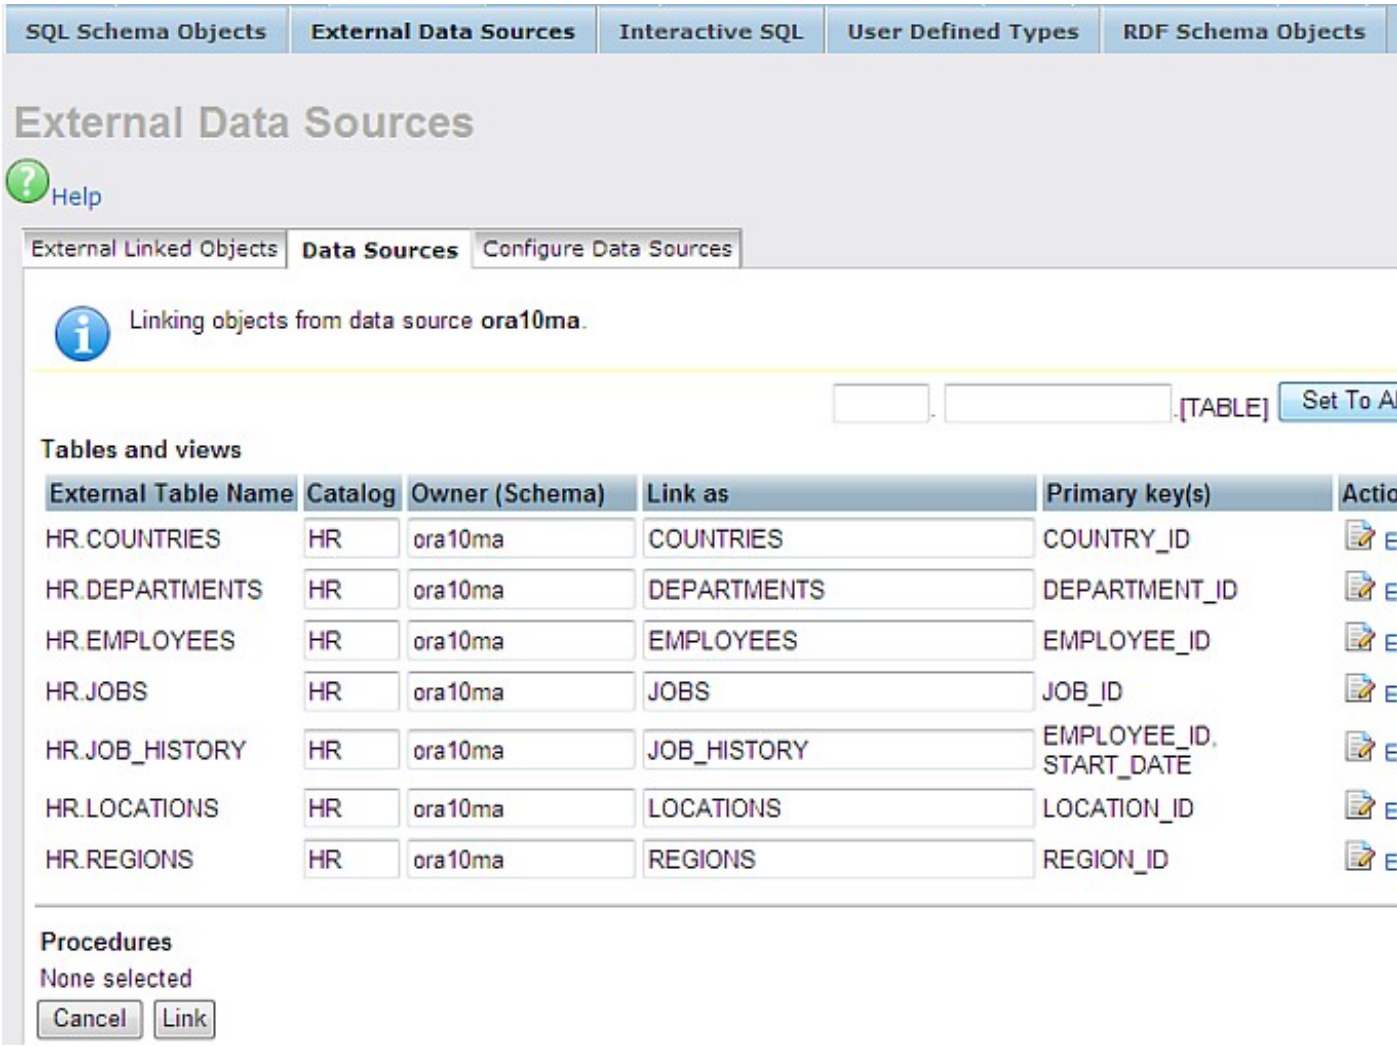
8. Ensure a primary key is assigned to all table that are to be used in the EDM generation phase.

Figure 8.20. Primary Key



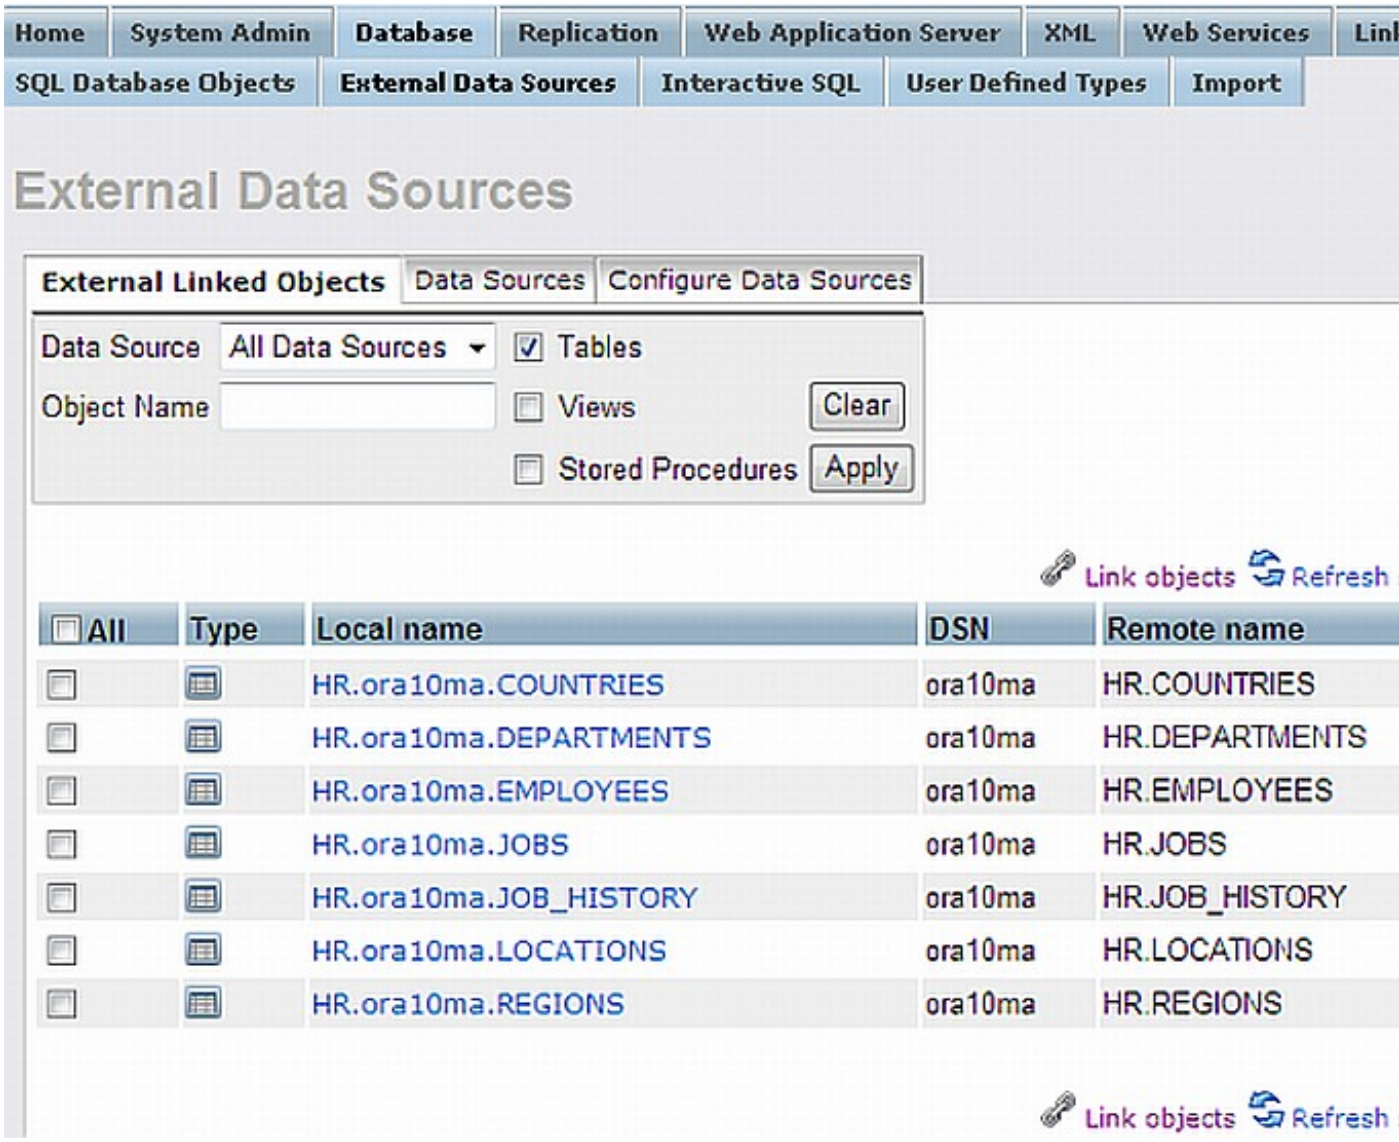
9. Select the "Link" button to link the selected tables into Virtuoso

Figure 8.21. "Link" button



10. On completion of the Link process the tables will be displayed in the "External Linked Objects" tab.

Figure 8.22. Completion

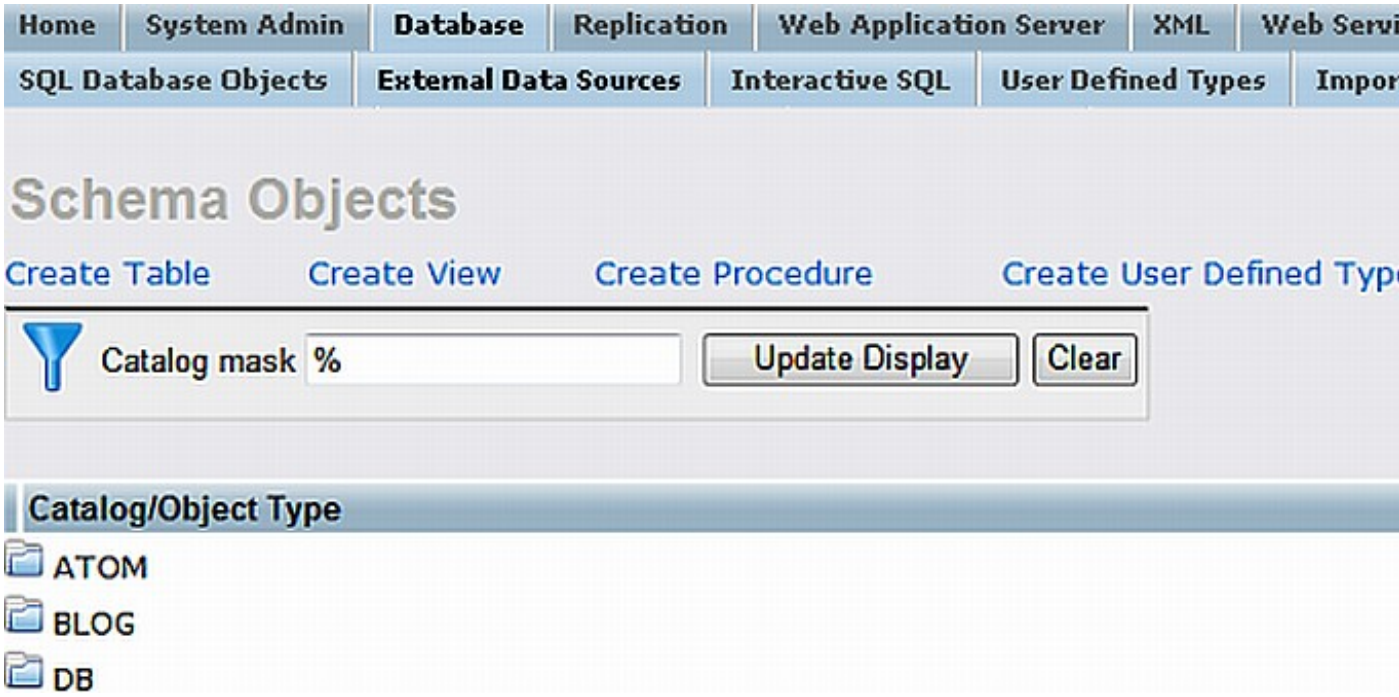


11. The linked tables can be queried by clicking on the hyperlink in the "Local Name" column of the "External Linked Objects" tab above, which loads the Virtuoso "Interactive SQL" interface with the required SQL "Select" for retrieving the remote table data . We shall use the "HR.ora10ma.COUNTRIES" table to demonstrate this.

Figure 8.23. Querying

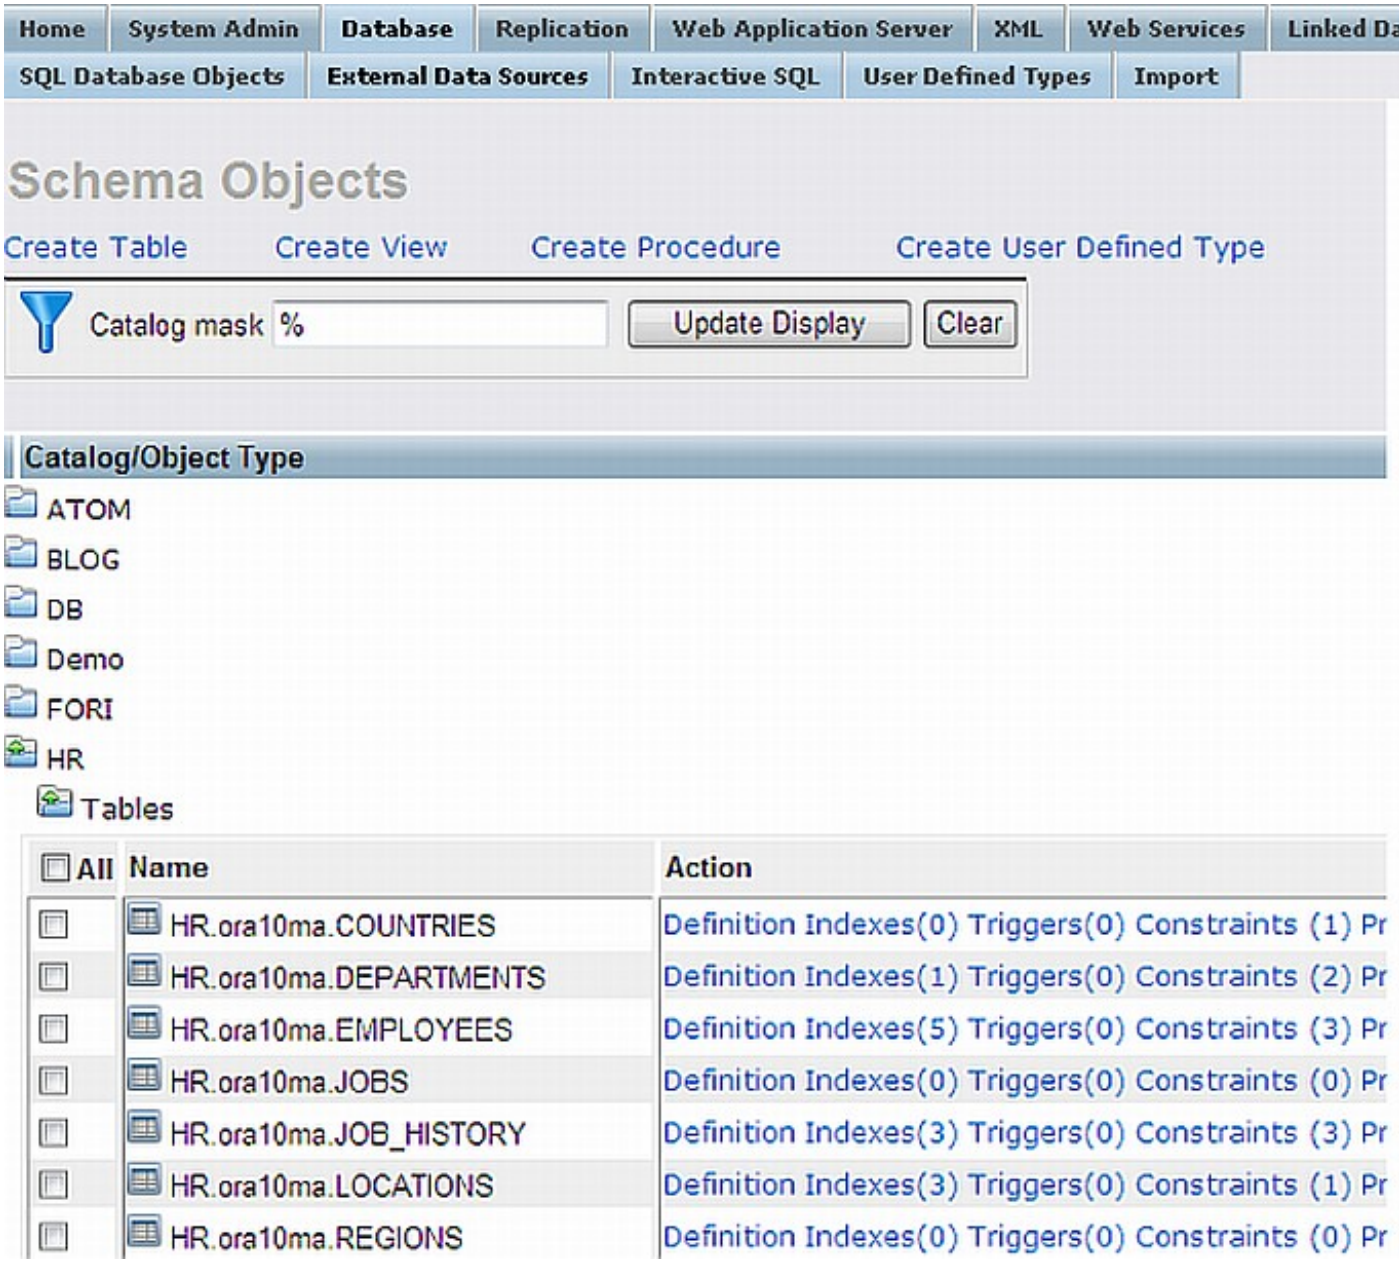
12. Then click the "Execute" button to run the query and retrieve the results from the remote table.

Figure 8.24. Execute



13. The tables can also be viewed as part of the Virtuoso "SQL Schema Objects" under the "HR" catalog name.

Figure 8.25. SQL Schema Objects



The Link process is now complete enabling the tables to be queried as if part of the Virtuoso Schema.

8.2.4. Creating EDM in Visual Studio 2008

The following steps can be used to create an Entity Data Model (EDM) for the Oracle Human Resources database:

1. Launch the Visual Studio 2008 SP1 IDE.

Figure 8.26. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

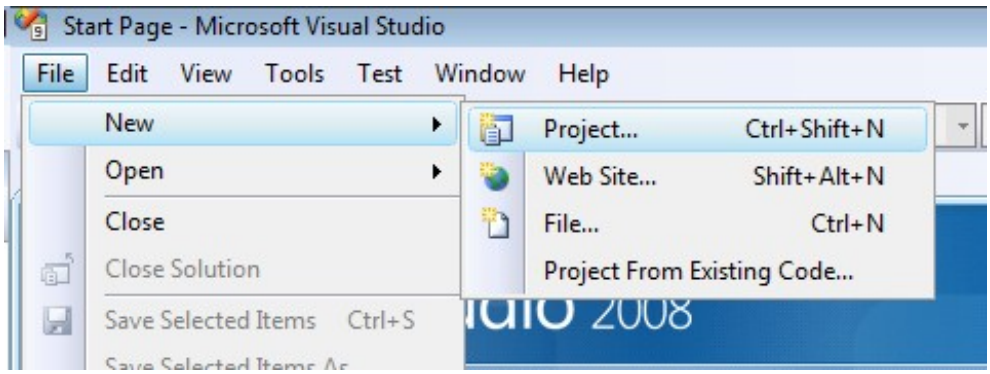
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.27. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Web

   and select

   ASP.NET Web Application

from the right-hand panel.

5. Choose a name for the project, for example

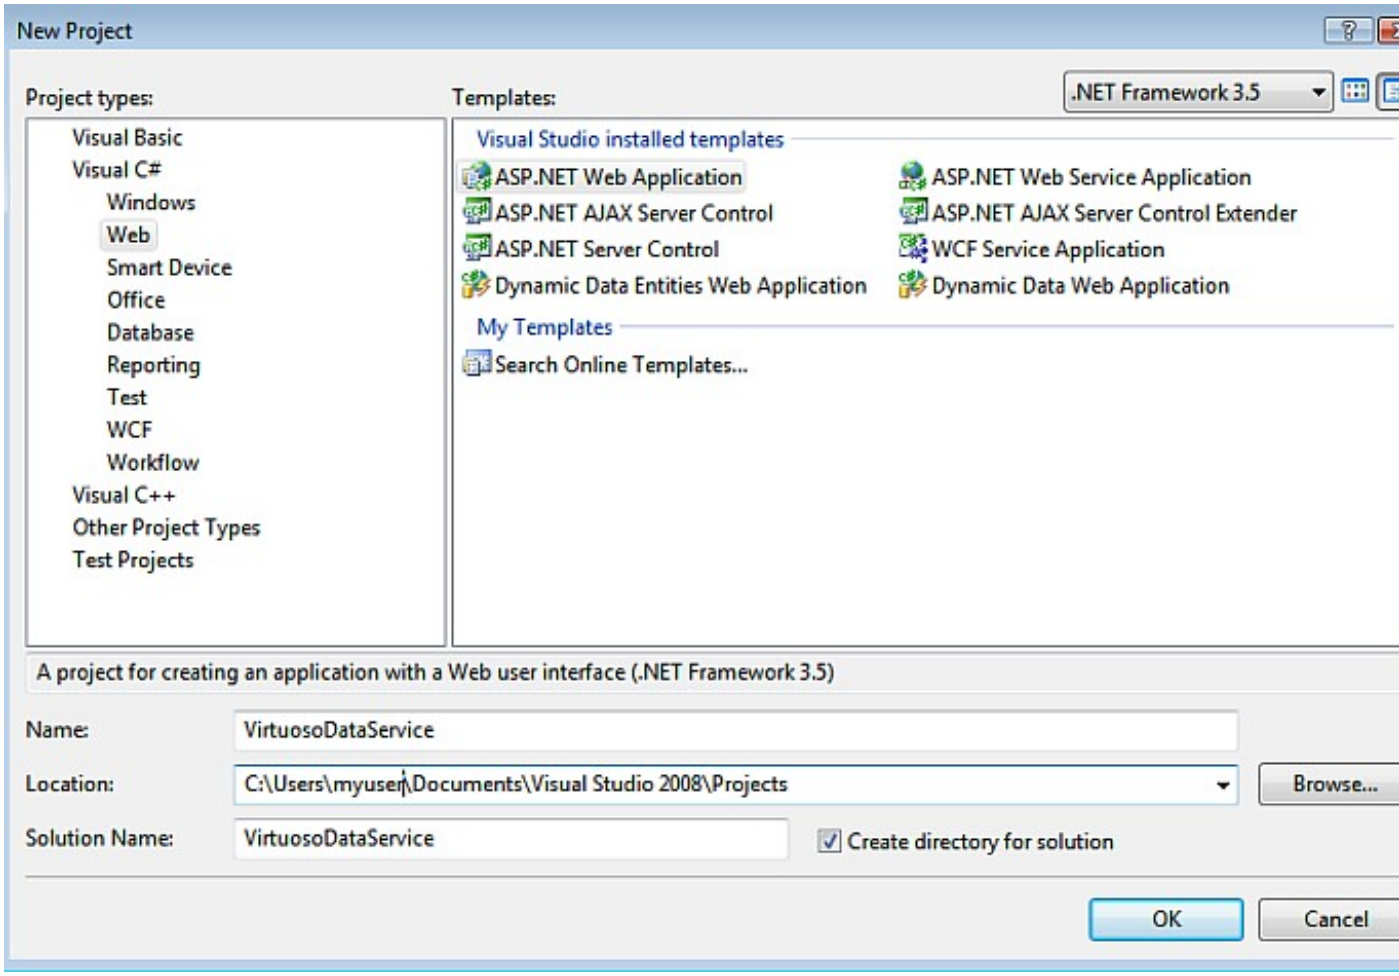
   VirtuosoDataService

   , and click

   OK

   .

Figure 8.28. name for the project

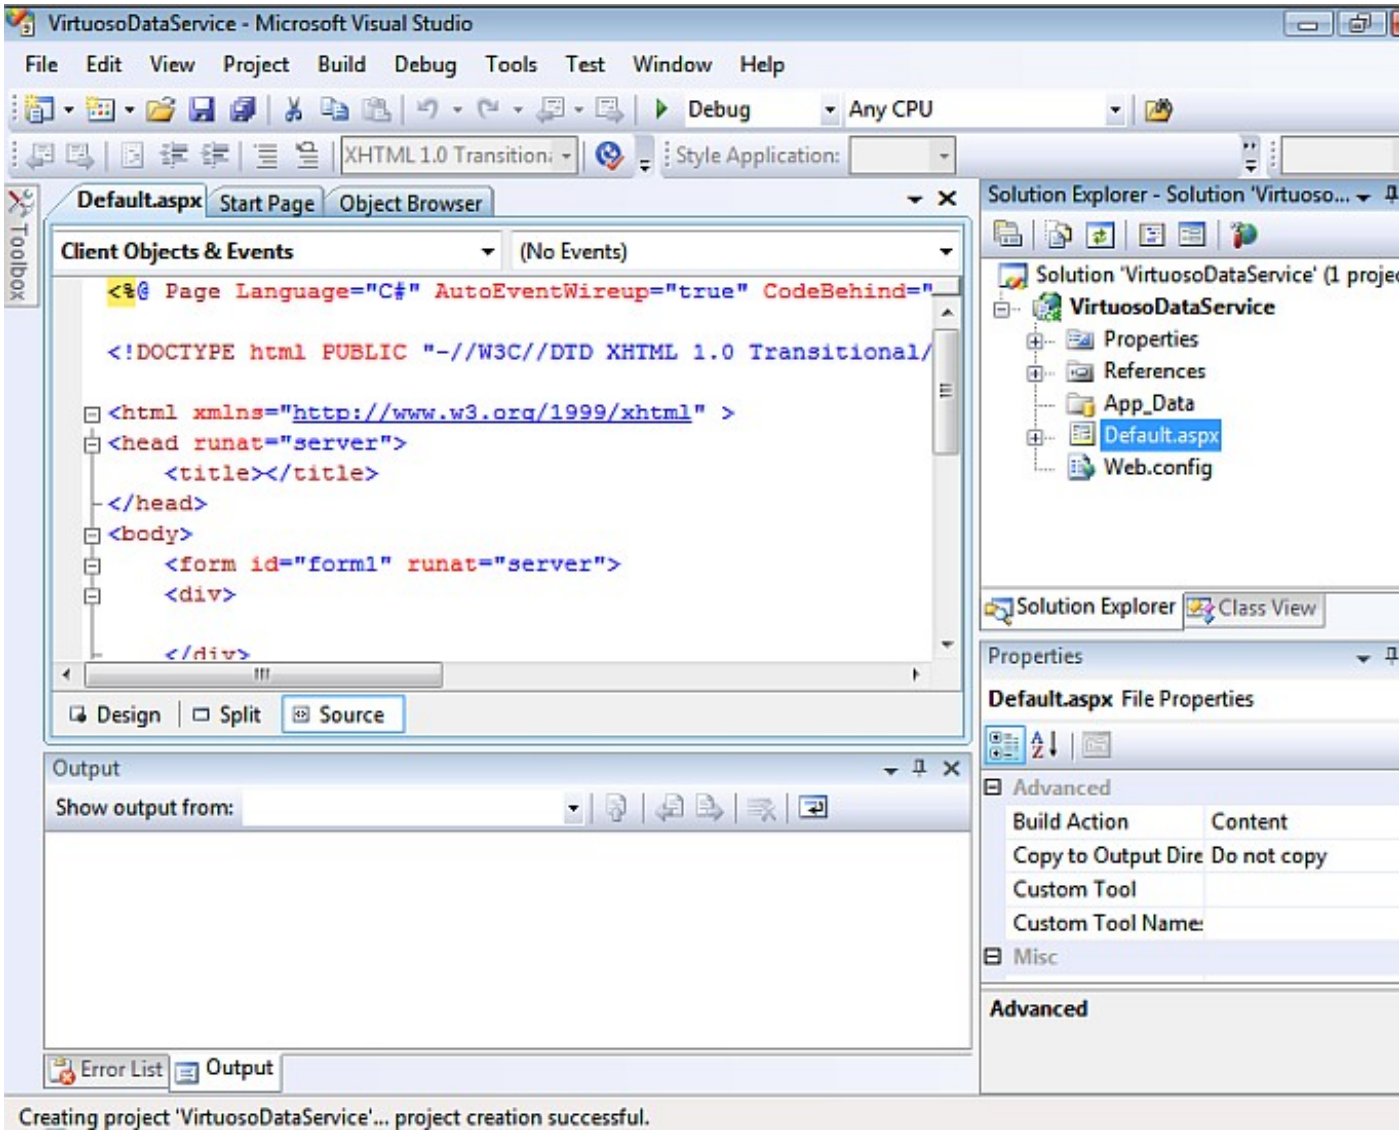


6. This will create a new project called

   VirtuosoDataService

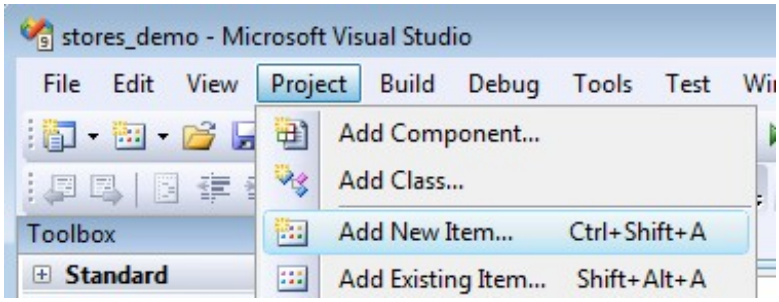
   .

Figure 8.29. create a new project



7. Select the Project -> Add New Item menu option.

Figure 8.30. VirtuosoDataService



8. The

Add New Item

dialog will appear. Choose the

ADO.NET Entity Data Model

template. Give it the name

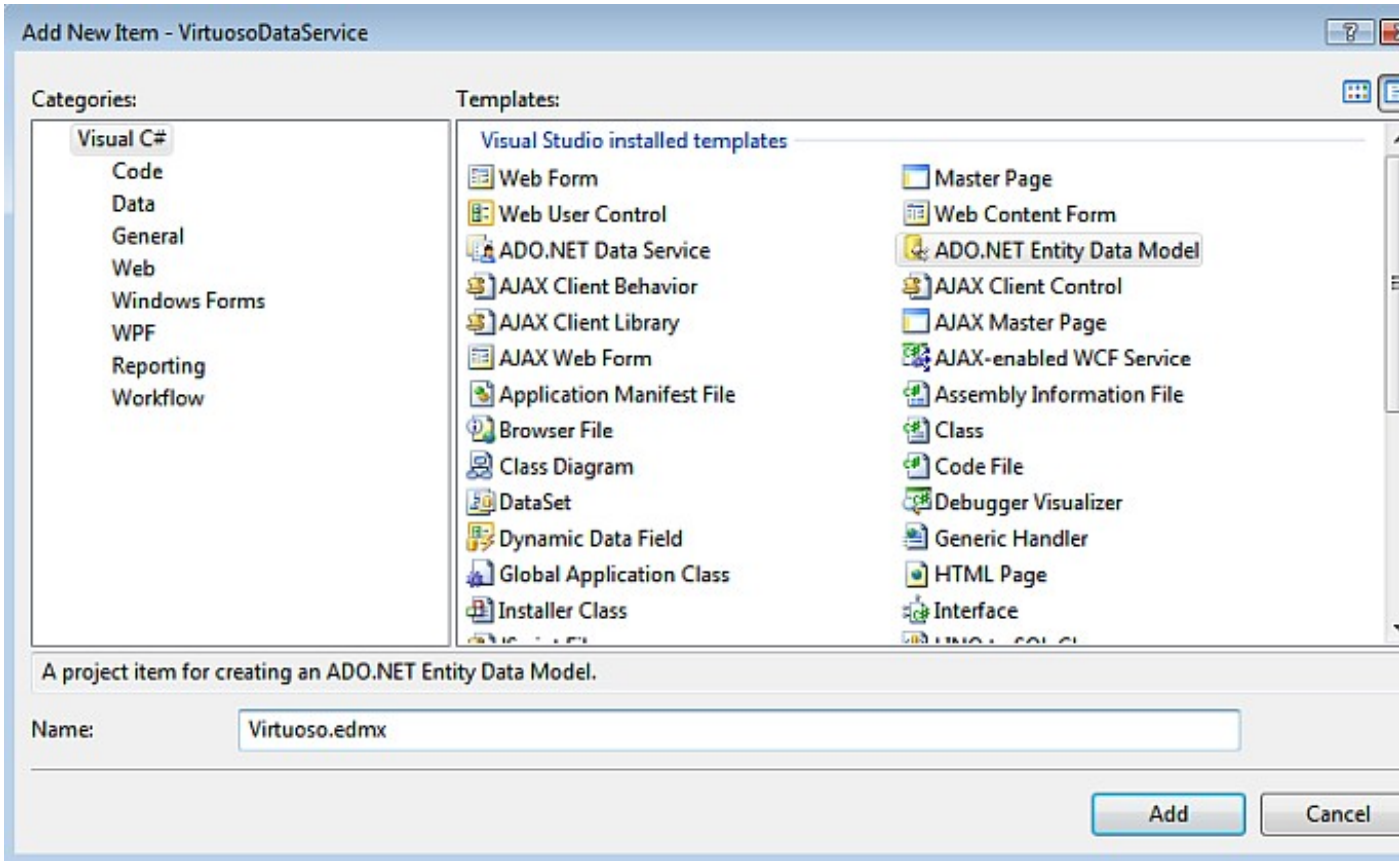
Virtuoso.edmx

and click

Add

to start the creation of the ADO.Net Entity Data Model.

Figure 8.31. Add New Item



9. In the

Entity Data Model Wizard

dialog

Choose Model Contents

page select the

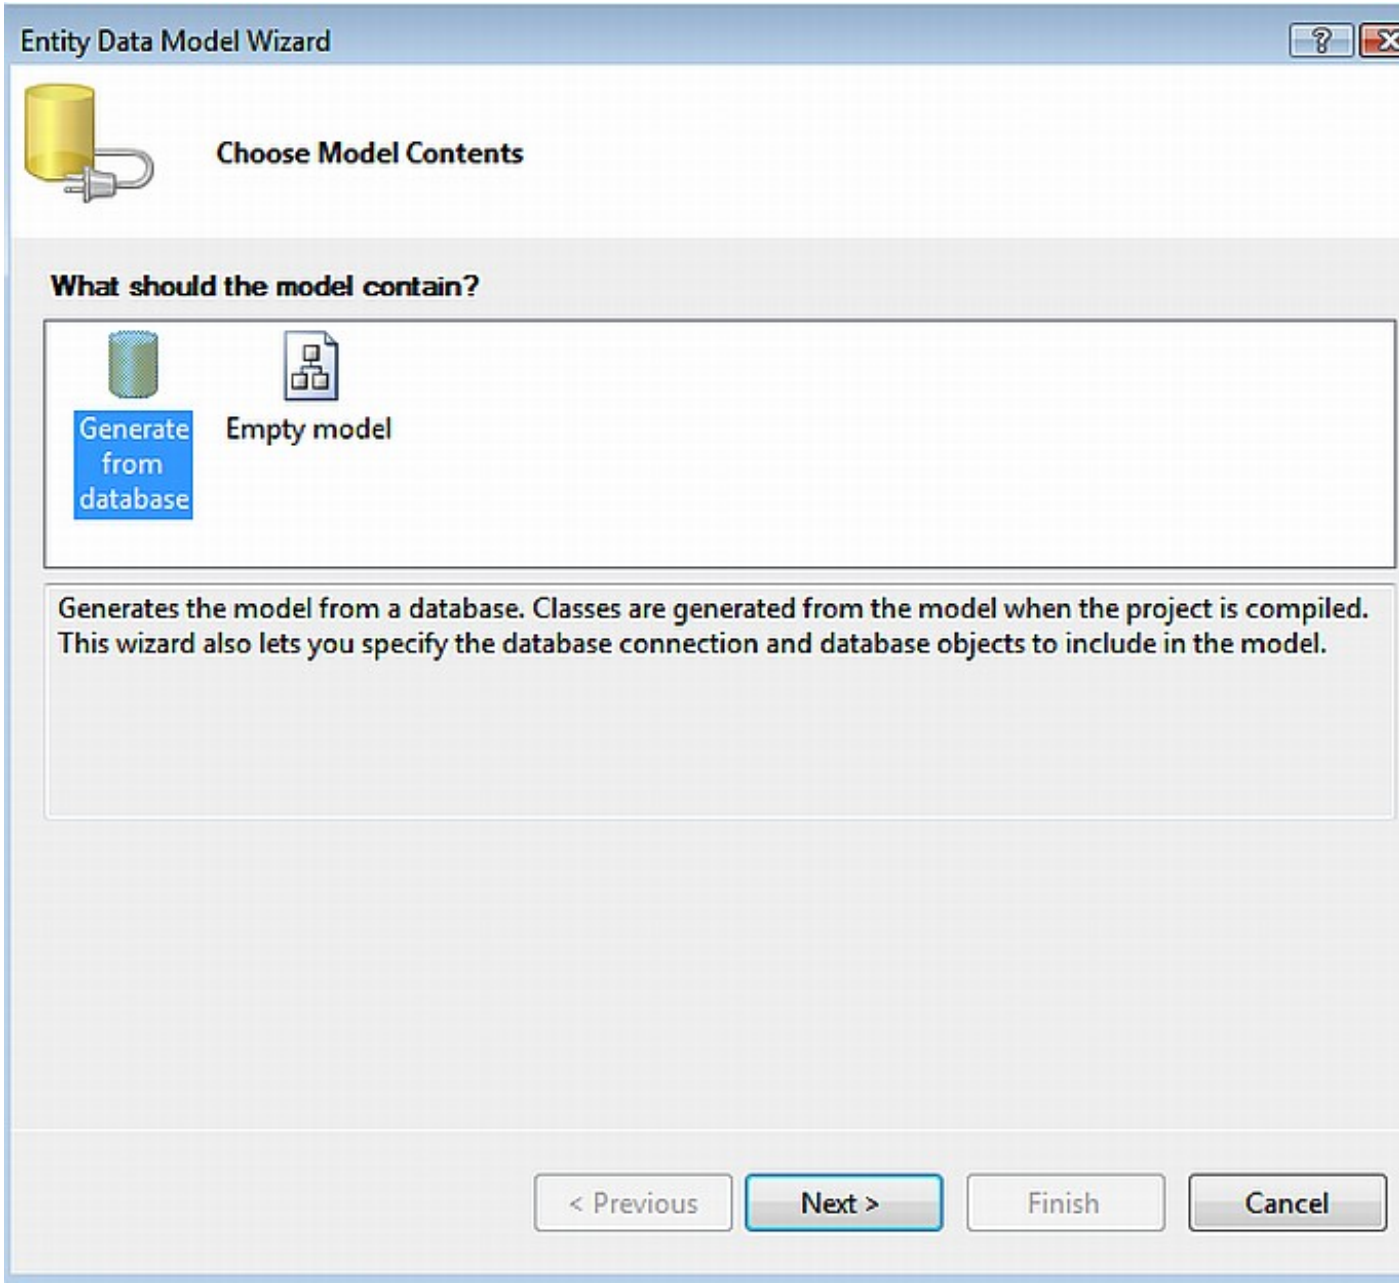
Generate from Database

model type and click

Next

.

Figure 8.32. Choose Model Contents



10. In the

    Entity Data Model Wizard

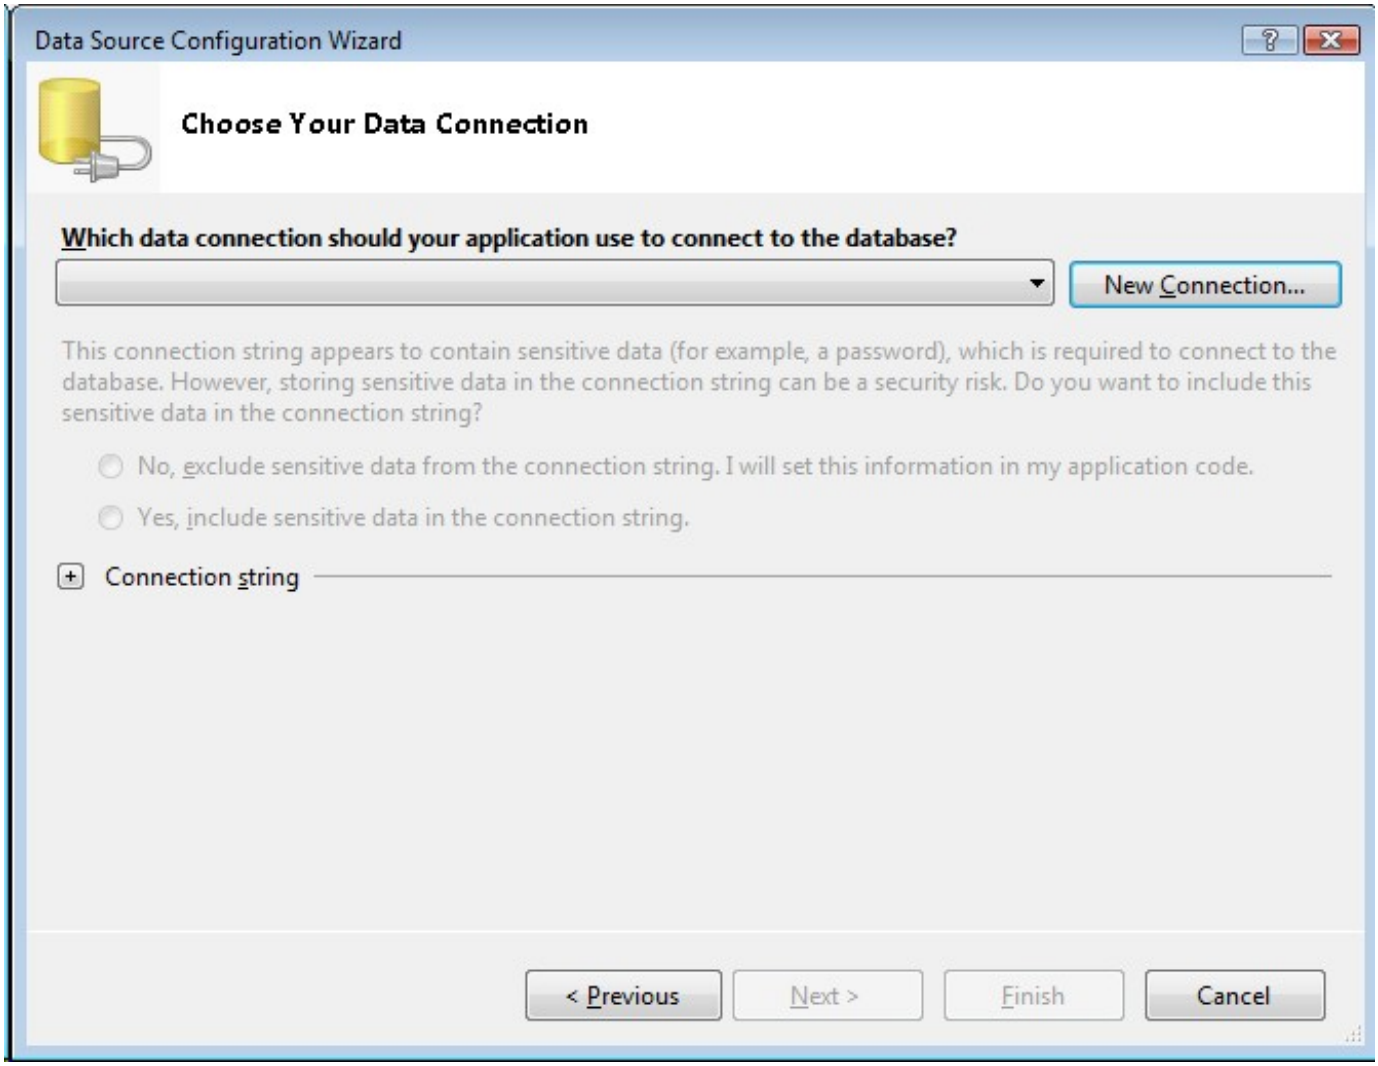
    dialog

    Choose your Data Connection

    page, select the

    New Connection button

Figure 8.33. Entity Data Model Wizard



11. In the

    Choose Data Source

    dialog, select the OpenLink

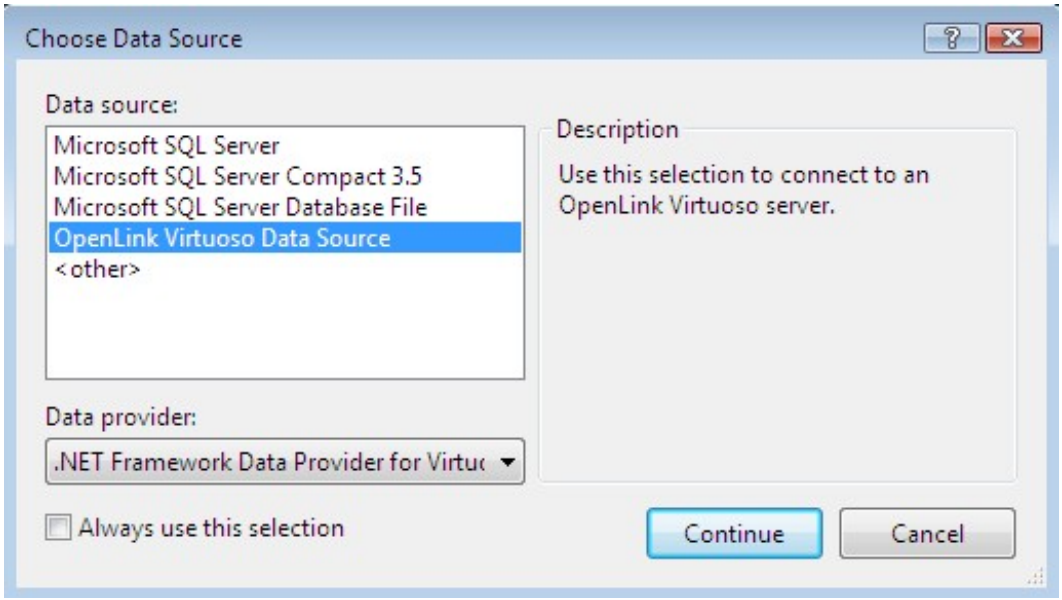
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.34. Choose Data Source



12. In the

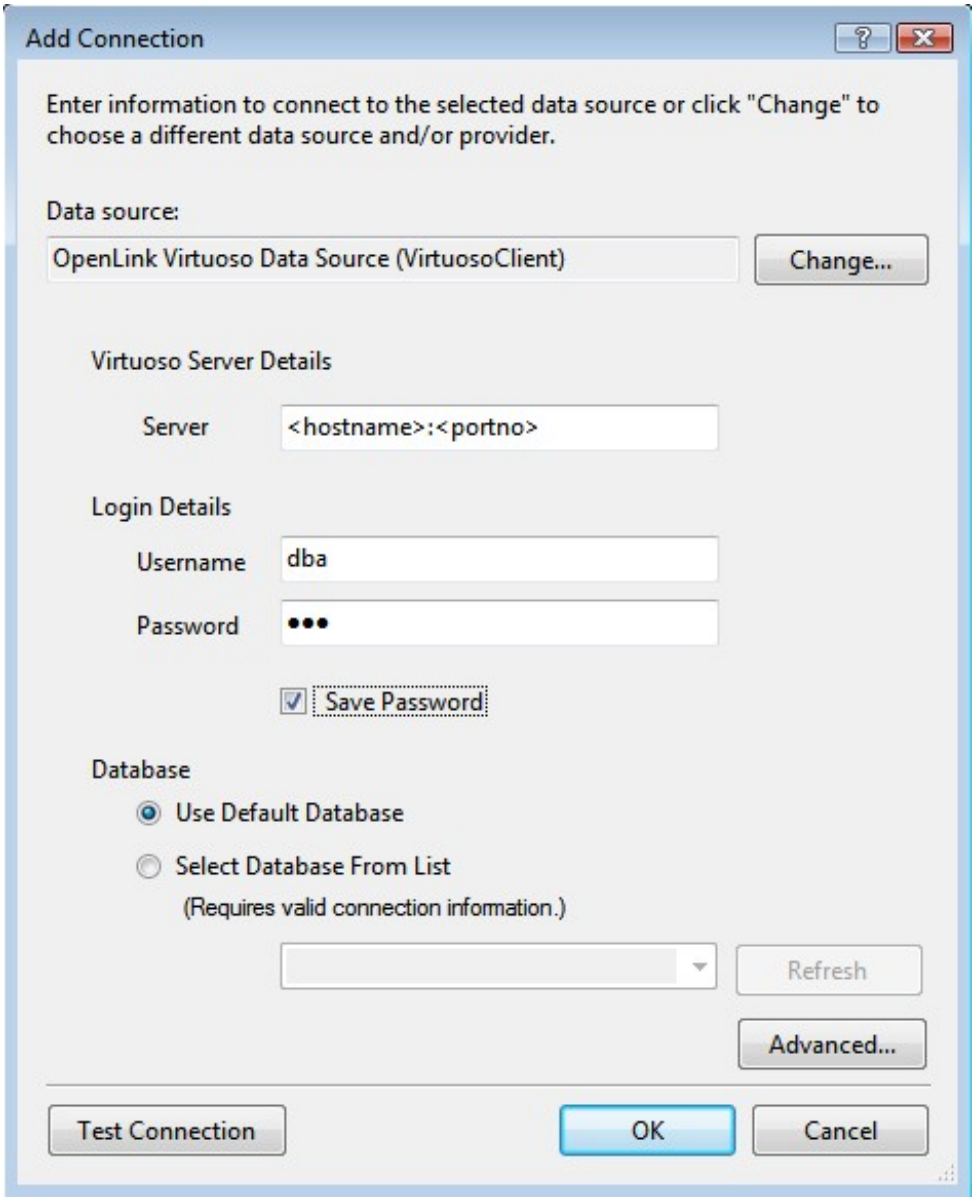
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.35. Connection Properties



13. Select the

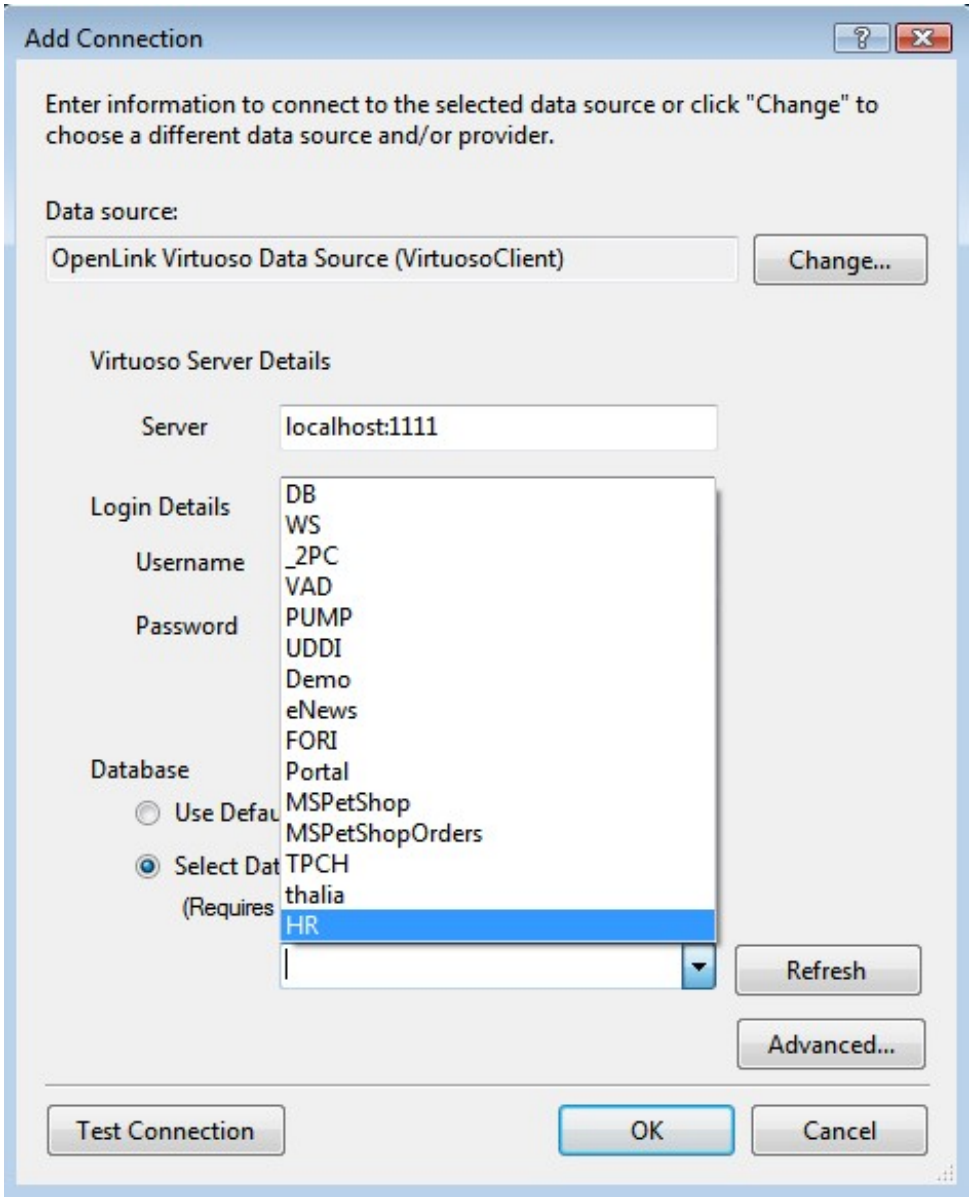
    Select Database From List

    radio button and choose the

    HR

    database from the drop down list.

Figure 8.36. Add connection

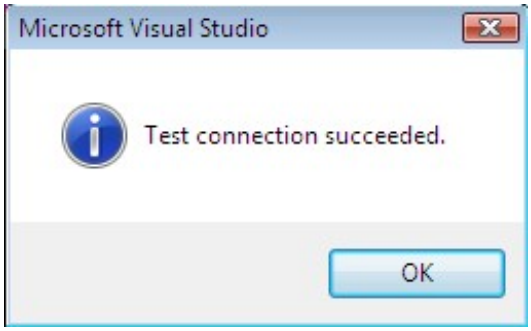


14. Press the

    Test Connection

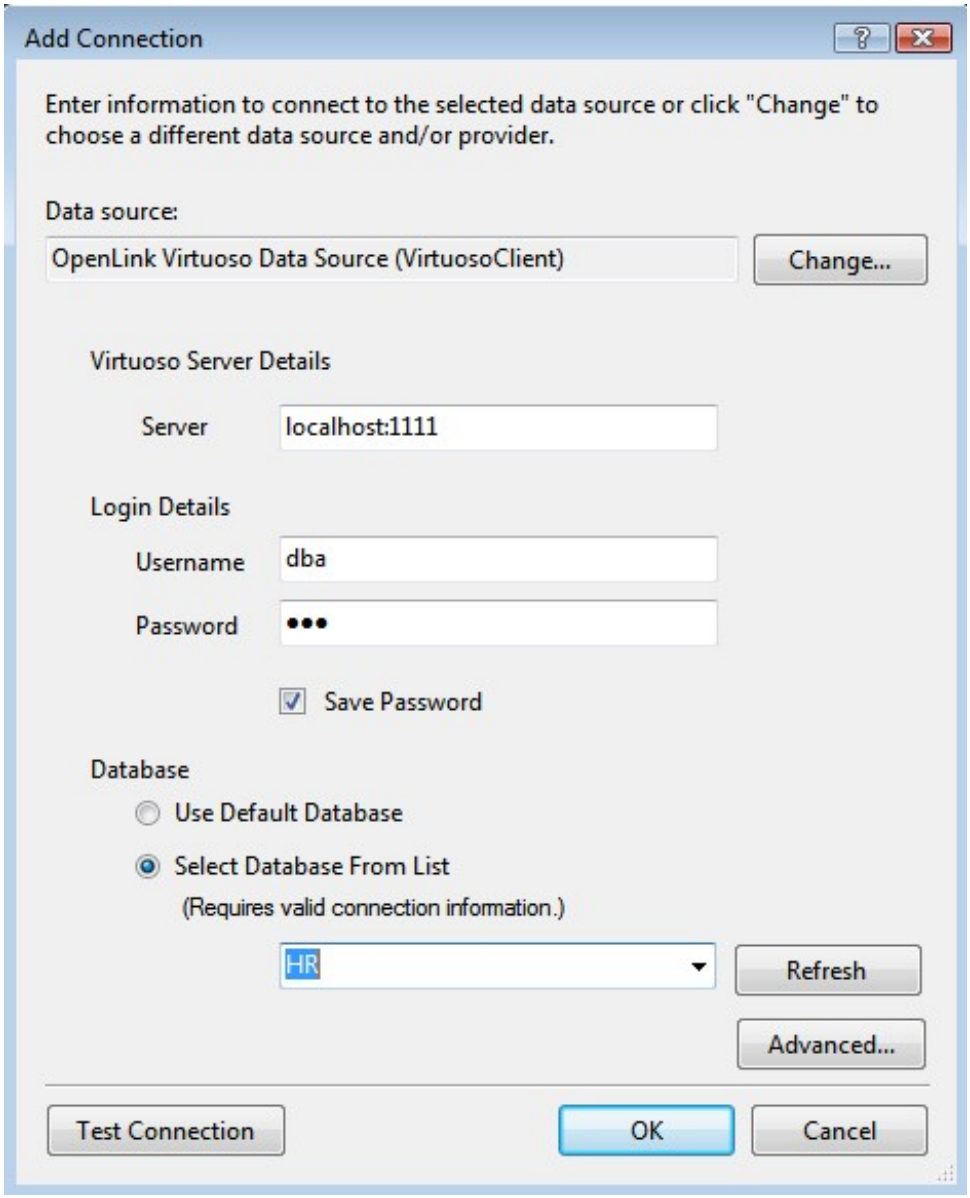
    dialog to verify that the database is accessible.

    Figure 8.37. Test Connection



15. Click OK to add the connection.

    Figure 8.38. Test Connection



16. Set the

    entity connect string

    name to

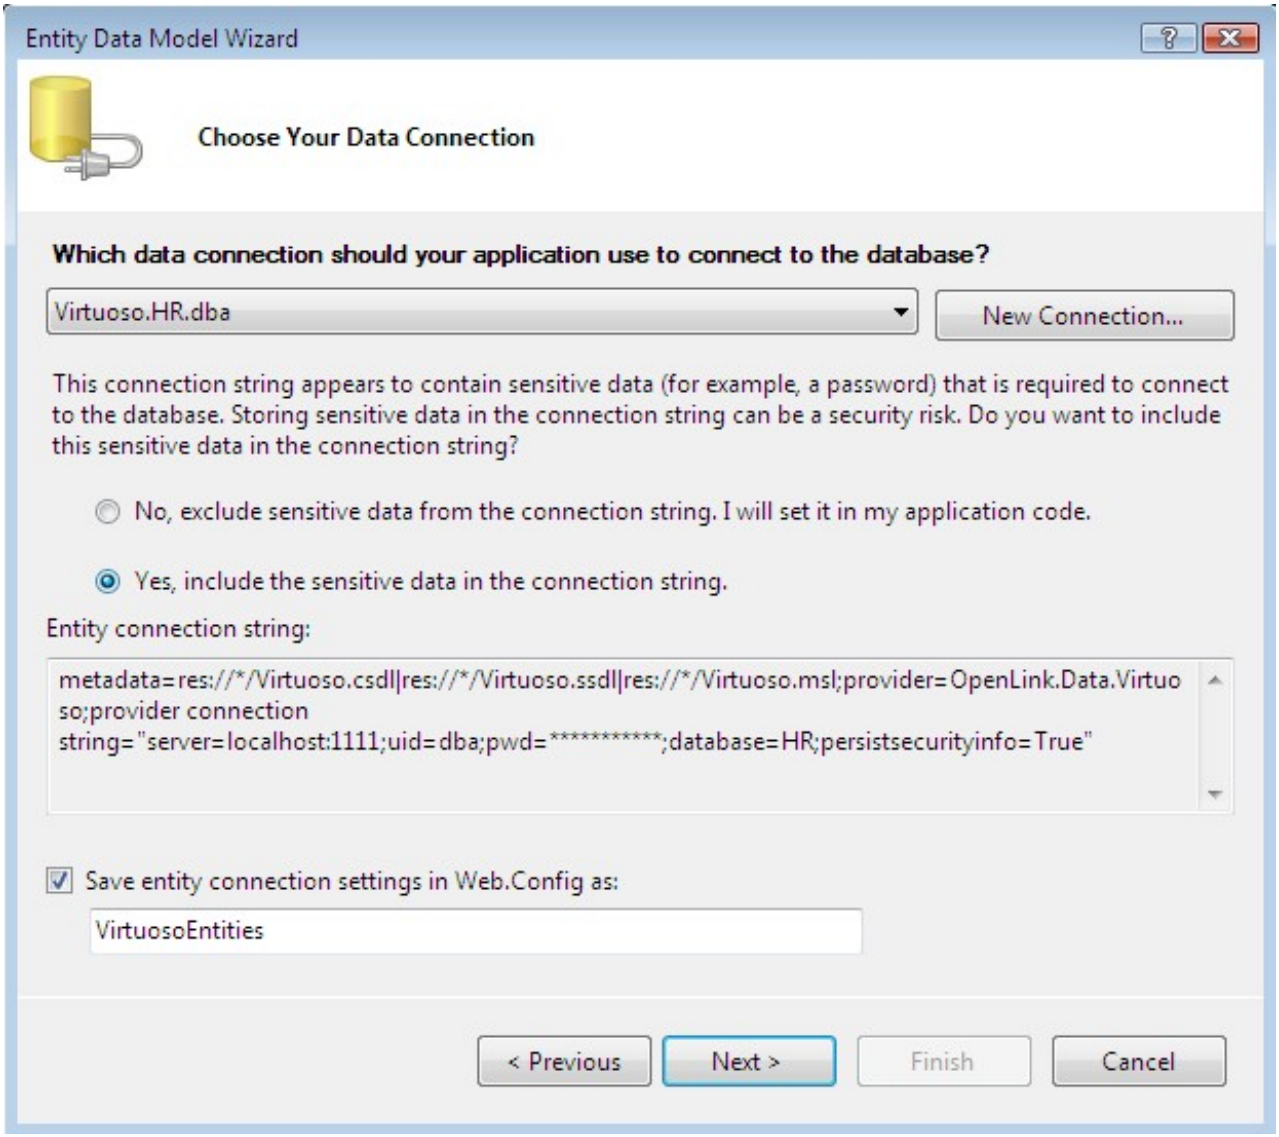
    VirtuosoEntities

    (note this name as it is required in the section on creating and ADO.Net Data Service) and click

    Next

    .

    Figure 8.39. entity connect string



17. In the

    Choose your Database Objects

    page select the

    Tables

    check box to select all tables in the HR catalog for addition to the Entity Data Model. Set the

    Model Namespace

    to

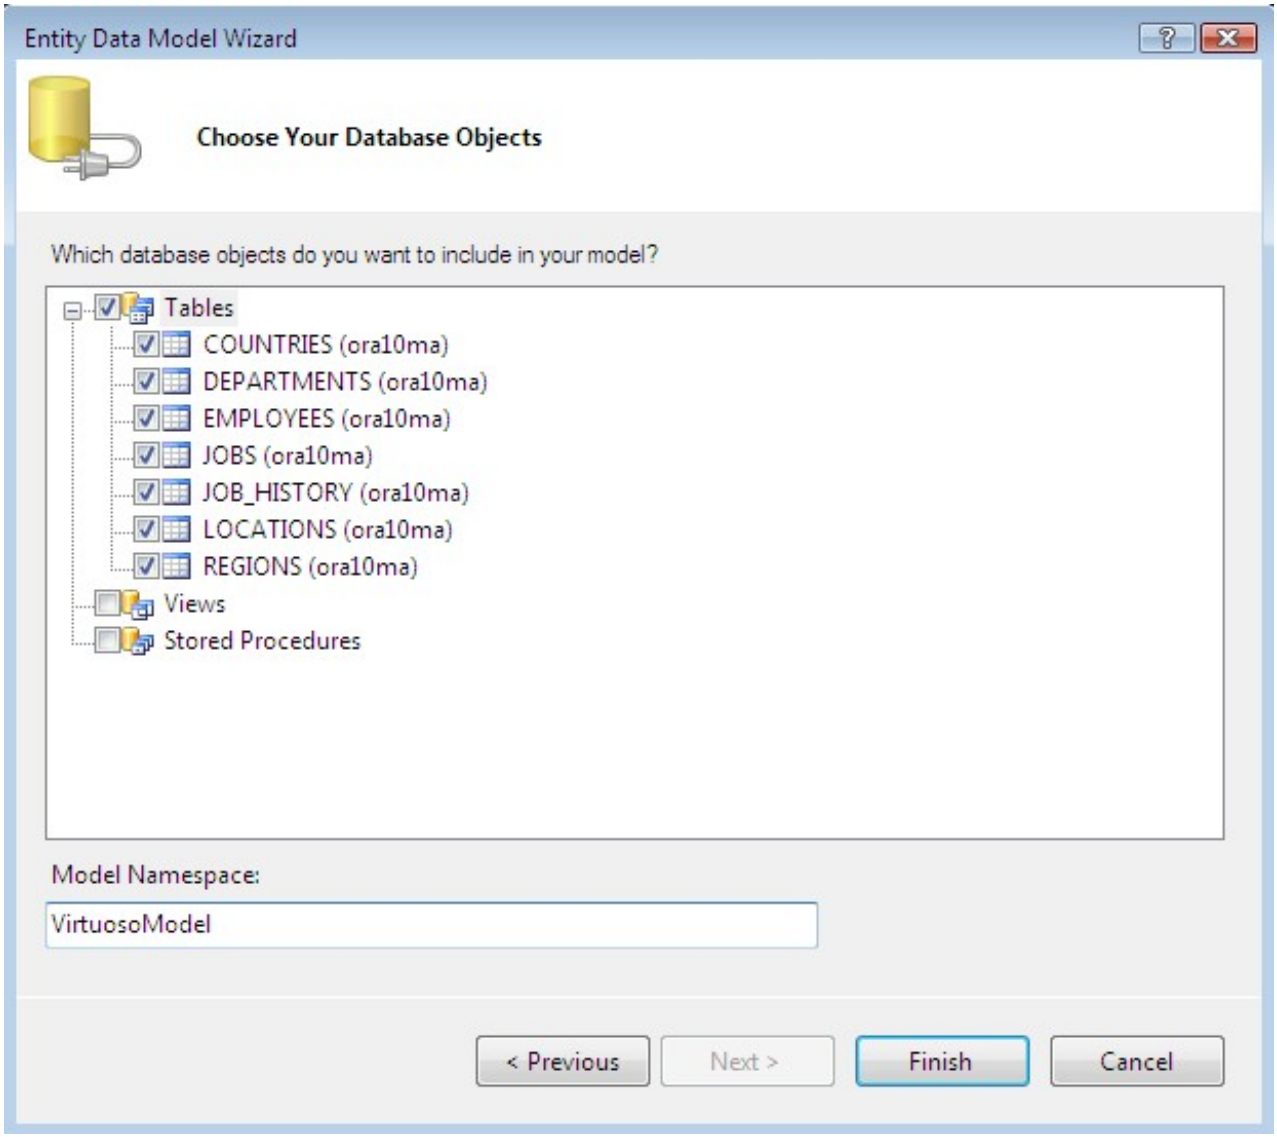
    VirtuosoModel

    and click

    Finish

    .

Figure 8.40. Database Objects

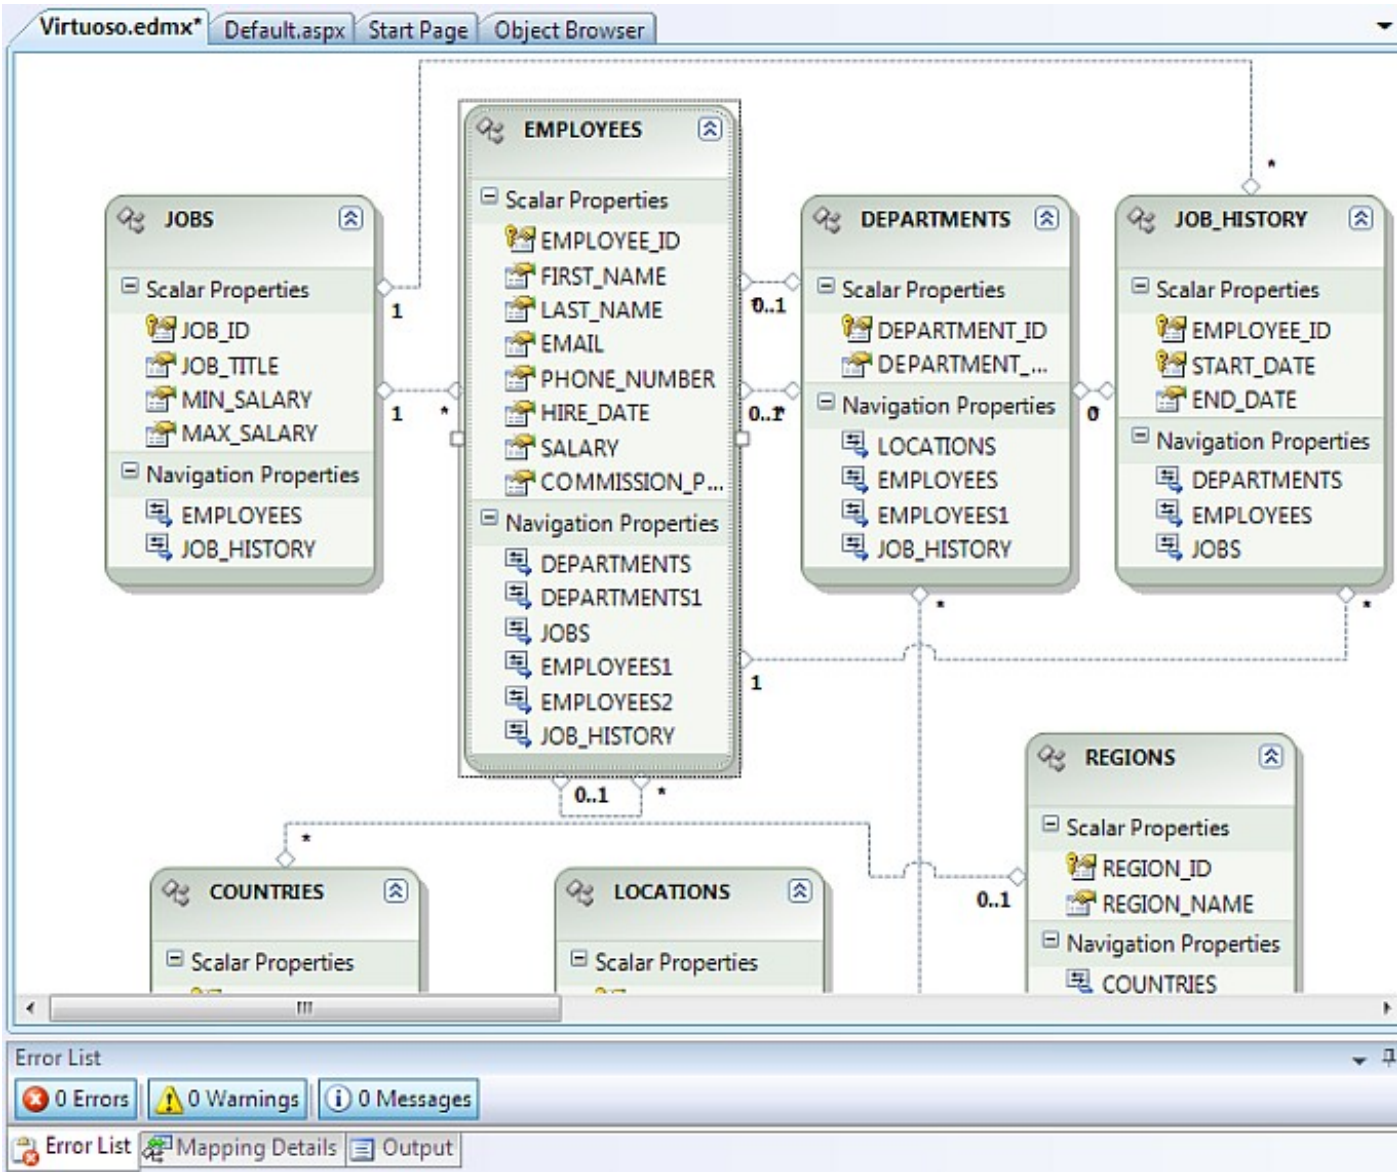


18. The

    Virtuoso.edmx

    EDM will be created with the tables and relationships displayed in the Visual Studio IDE

    Figure 8.41. Virtuoso.edmx



Creation for the Entity Data Model for the Oracle Human Resources database is now complete.

8.2.5. Using EDM to create Entity Framework based applications

Now that a Microsoft Entity Data Model has been created for the Oracle Human Resources database, Entity Framework applications can be created to make use of it.

Entity Frameworks based ADO.NET Data Service

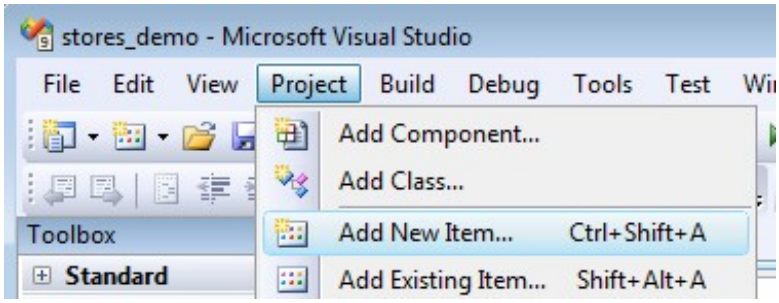
An ADO.Net Data Service for the Oracle tables can be created using the Entity Data Model created in the Creating EDM in Visual Studio 2008 section .

1. Open the

   VirtuosoDataService

   project created in the Creating EDM in Visual Studio 2008 section .
2. Select the Project -> Add New Item menu option.

Figure 8.42. VirtuosoDataService



3. The

   Add New Item

   dialog will appear. Choose the

   ADO.NET Data Service template

   . Give it the name

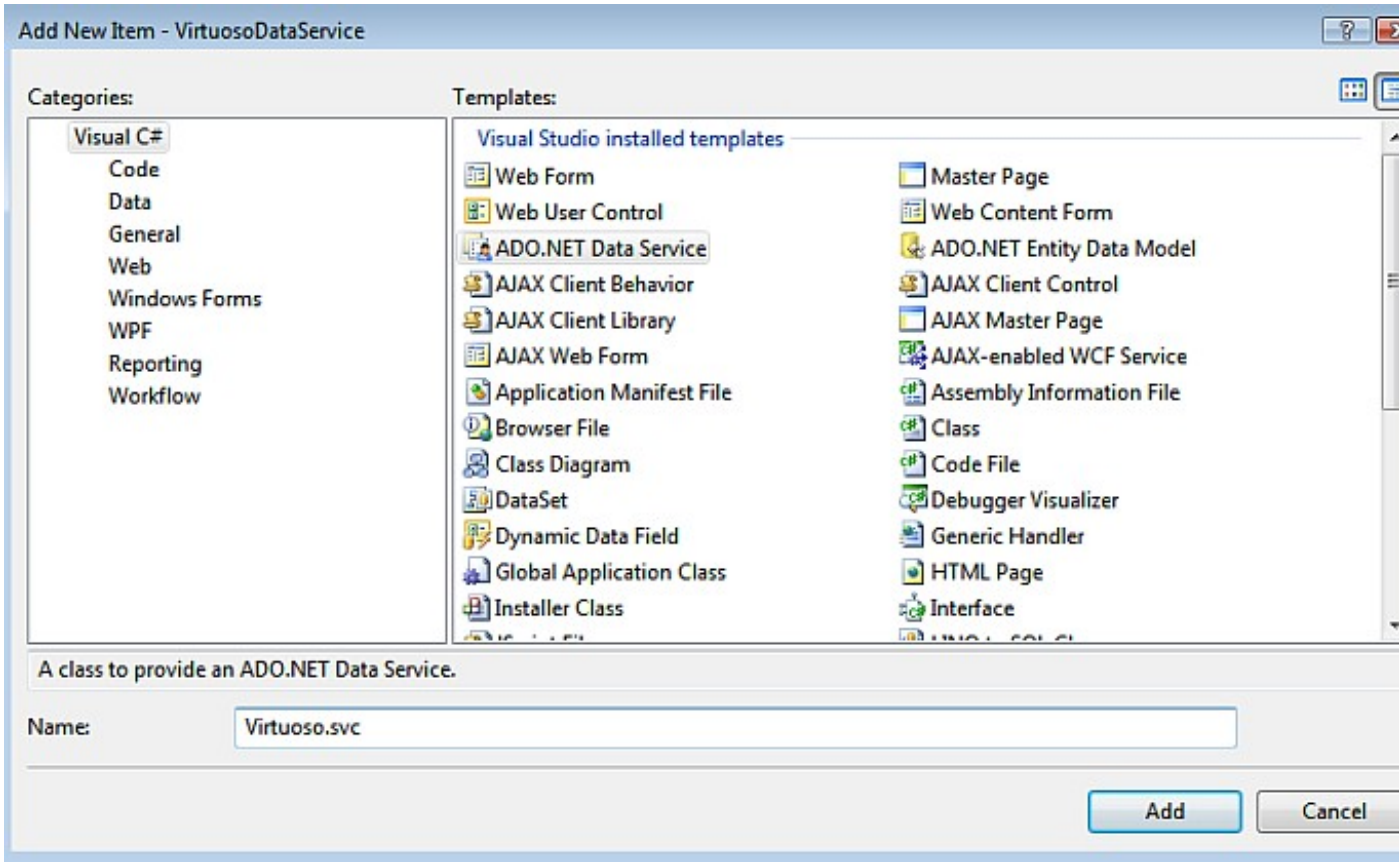
   Virtuoso.svc

   , and click

   Add

   to create the ADO.Net Data Service.

Figure 8.43. Add New Item



4. In the newly created

   Virtuoso.svc.cs

Data Service file, add the data source class name of

VirtuosoEntities

(note this is the name set in the Creating EDM in Visual Studio 2008 section) as the

DataService

name. Enable the access to the Data Service by adding the entry

config.SetEntitySetAccessRule("", EntitySetRights.All);*

in the

InitializeService

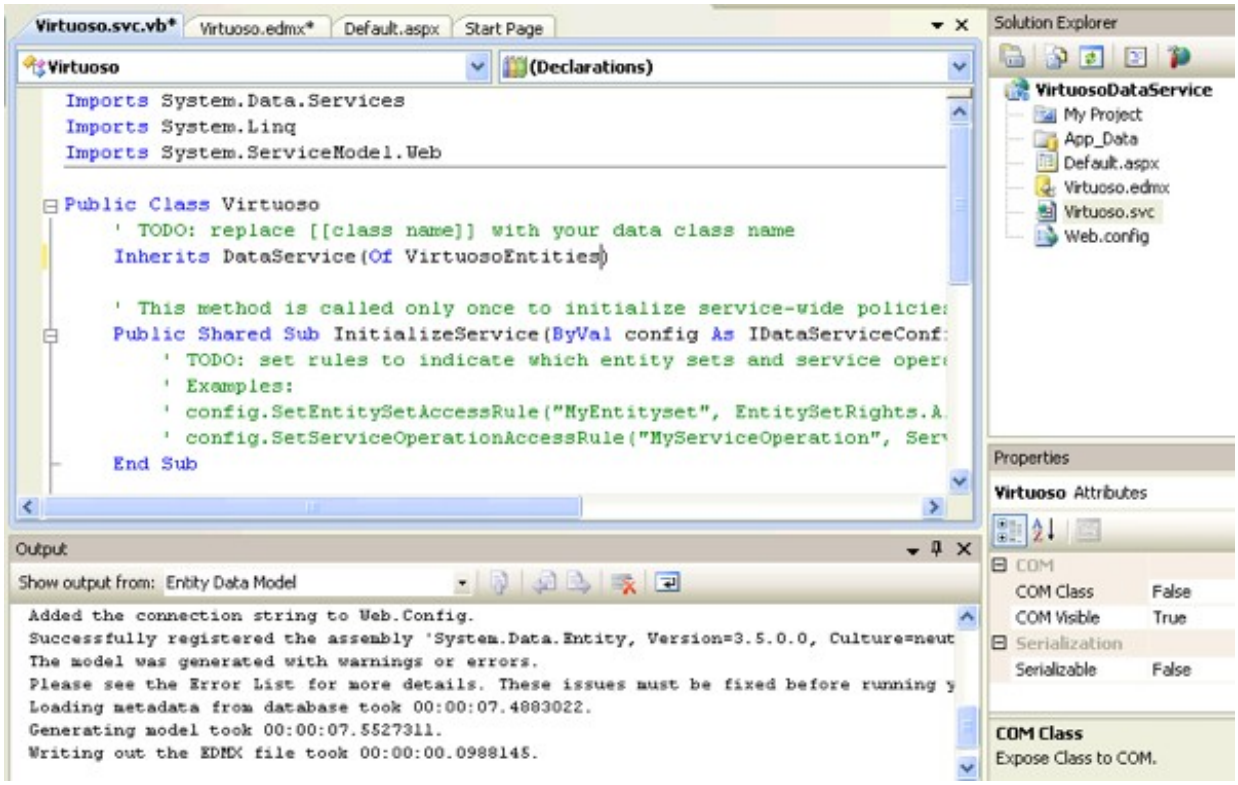
method.

```
// C#

using System;
using System.Web;
using System.Collections.Generic;
using System.ServiceModel.Web;
using System.Linq;
using System.Data.Services;

namespace SimpleDataService
{
    public class Northwind : DataService<VirtuosoDemoEntities>
    {
        public static void InitializeService(IDataServiceConfiguration  config)
        {
            config.SetEntitySetAccessRule("*", EntitySetRights.All);
        }
    }
}
```

Figure 8.44. Virtuoso.svc.cs

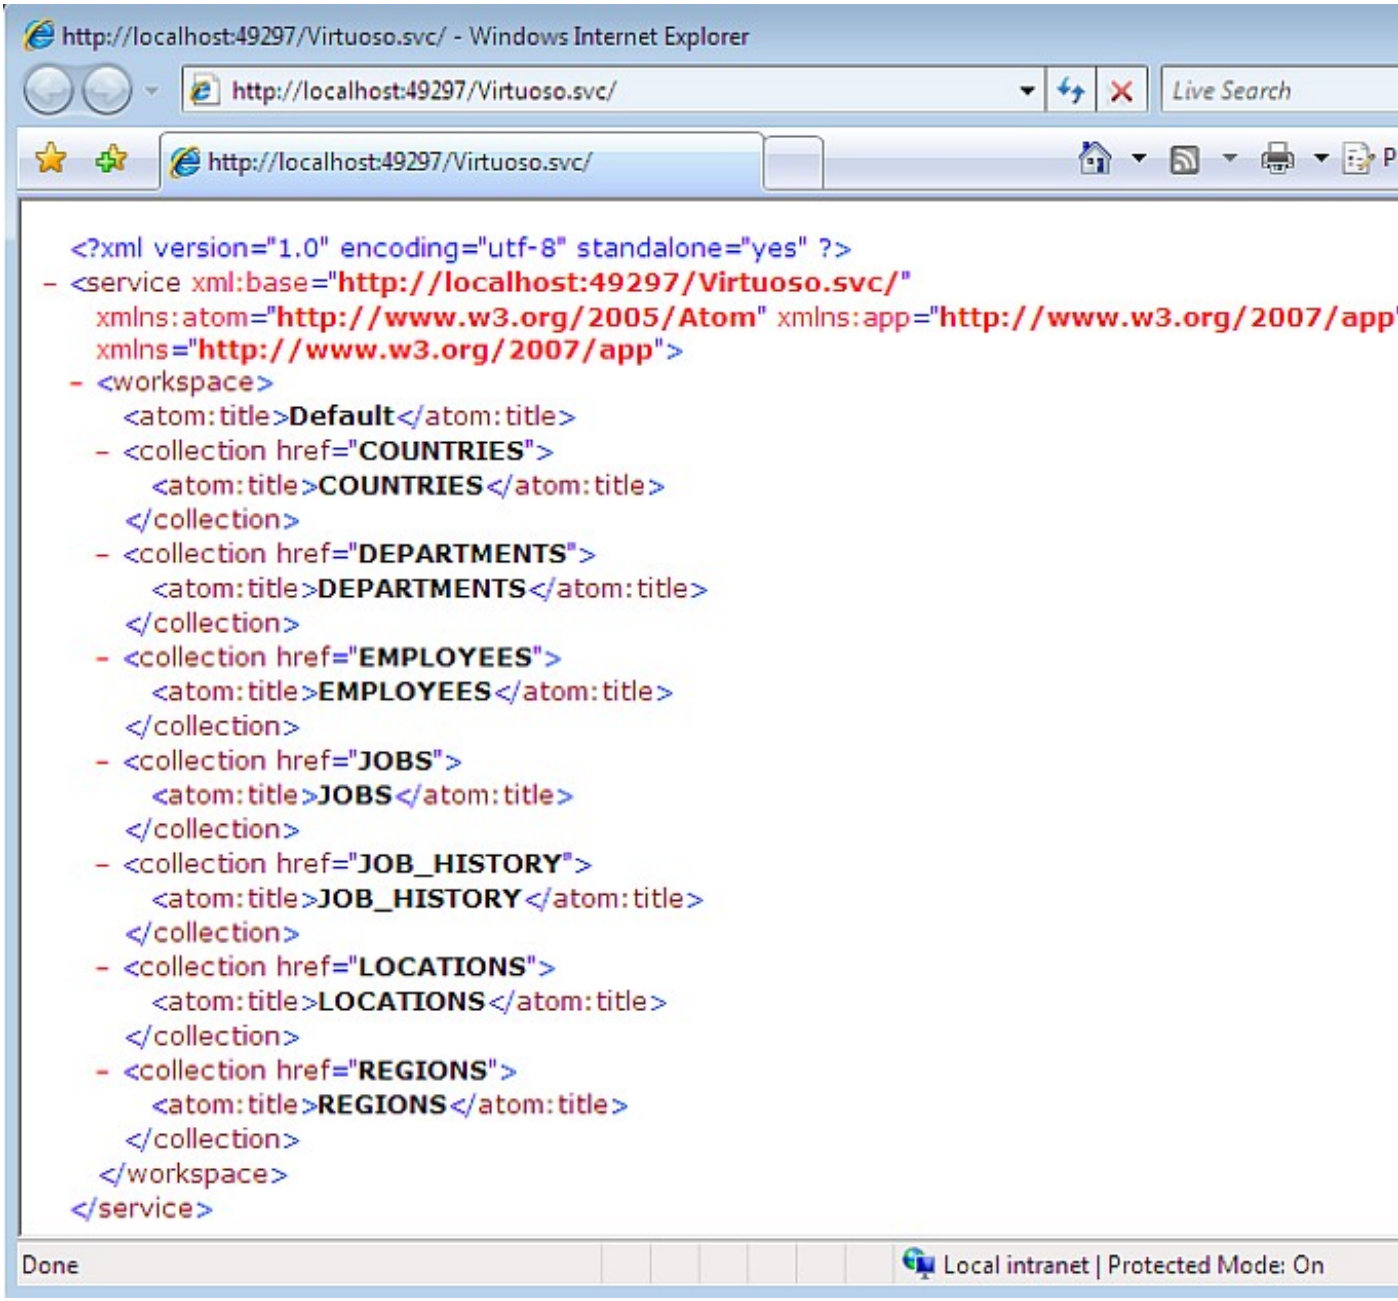


5. To test the Data Service, simply hit

   Ctrl+F5

   within Visual Studio. This will start the development web server, run the Data Services server inside and load a Web browser page displaying the list of available tables/entities for the HR database catalog.

Figure 8.45. Data Service test



6. To access a specific entity instance like the

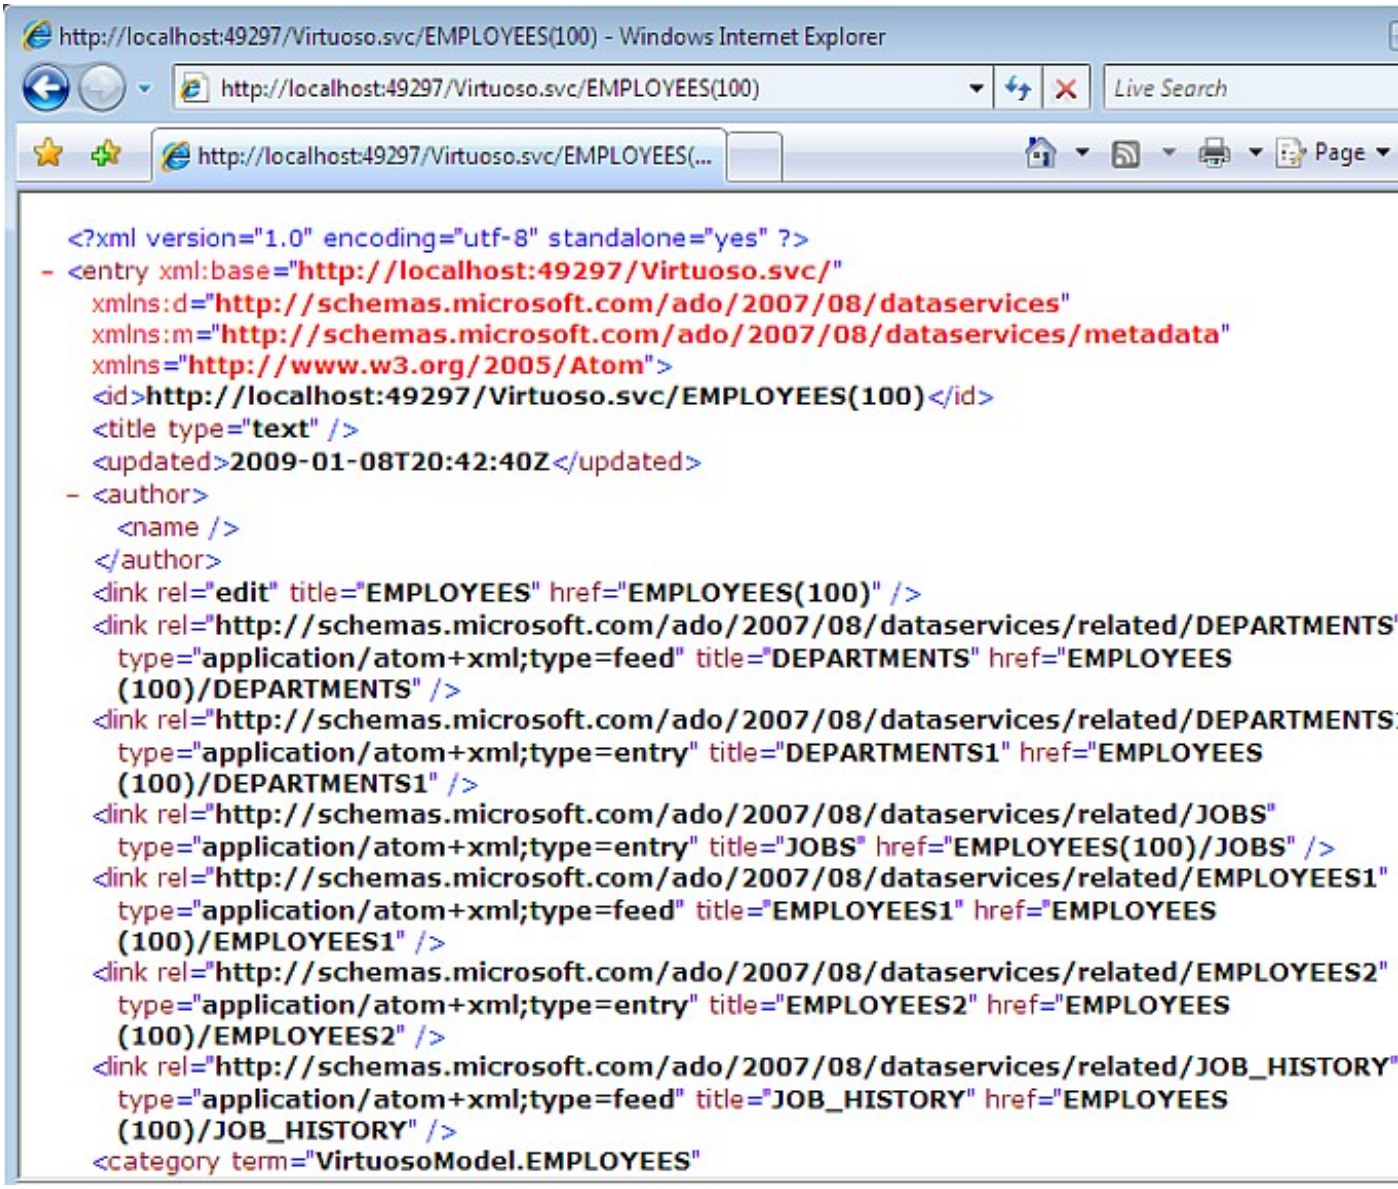
   EMPLOYEES

   table employee number

   100

   record, use this convention http://host/vdir/Virtuoso.svc/EMPLOYEES(100) .

   Figure 8.46. EMPLOYEES



Notes:

1. *Important*

   - To view

   Atom

   (the default format returned by an ADO.NET Data Service) in Internet Explorer, you must first ensure that

   Feed Reading View

   is turned

   off

   . This can be done on the

   Content tab

   of

Tools in Internet Options

.

2. If a Data Services entity instance URI page fails to load you can turn

   Verbose

   errors on by adding

   config.UseVerboseErrors = true;

   in the

   virtuoso.svc.cs InitializeService

   method to obtain more detailed information from the server as to why the page failed to load:

```
public static void InitializeService(IDataServiceConfiguration config)
{
config.UseVerboseErrors = true;
config.SetEntitySetAccessRule("*", EntitySetRights.All);
}
```

Visual Studio Windows DataGrid Form Application

This section details the steps required to create a simple Visual Studio 2008 Windows Form application, with associated DataGridView control for displaying data in selected tables from the target database.

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.47. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

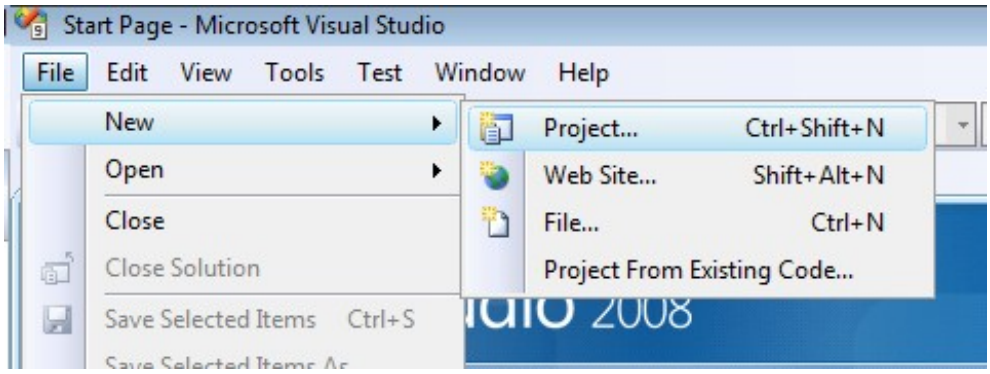
   File

   menu in Visual Studio and choosing

New Project

.

Figure 8.48. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Windows

   and select

   Windows Form Application

   from the right-hand panel.
5. Choose a name for the project, for example

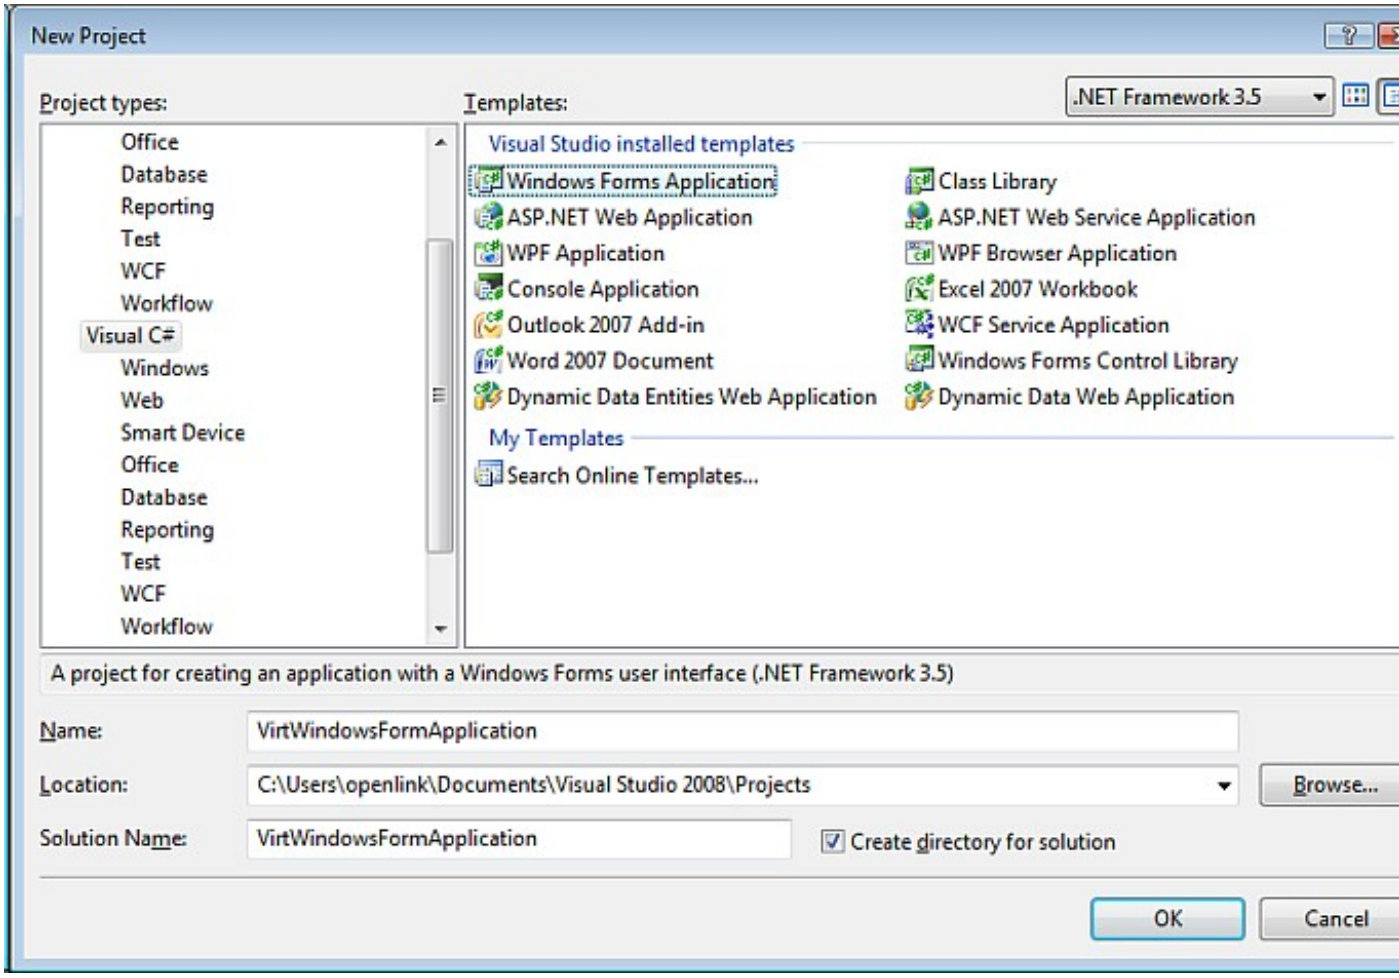
   VirtWindowsFormApplication

   , and click

   OK

   .

Figure 8.49. Web Application



6. In the

   Toolbox

   , expand

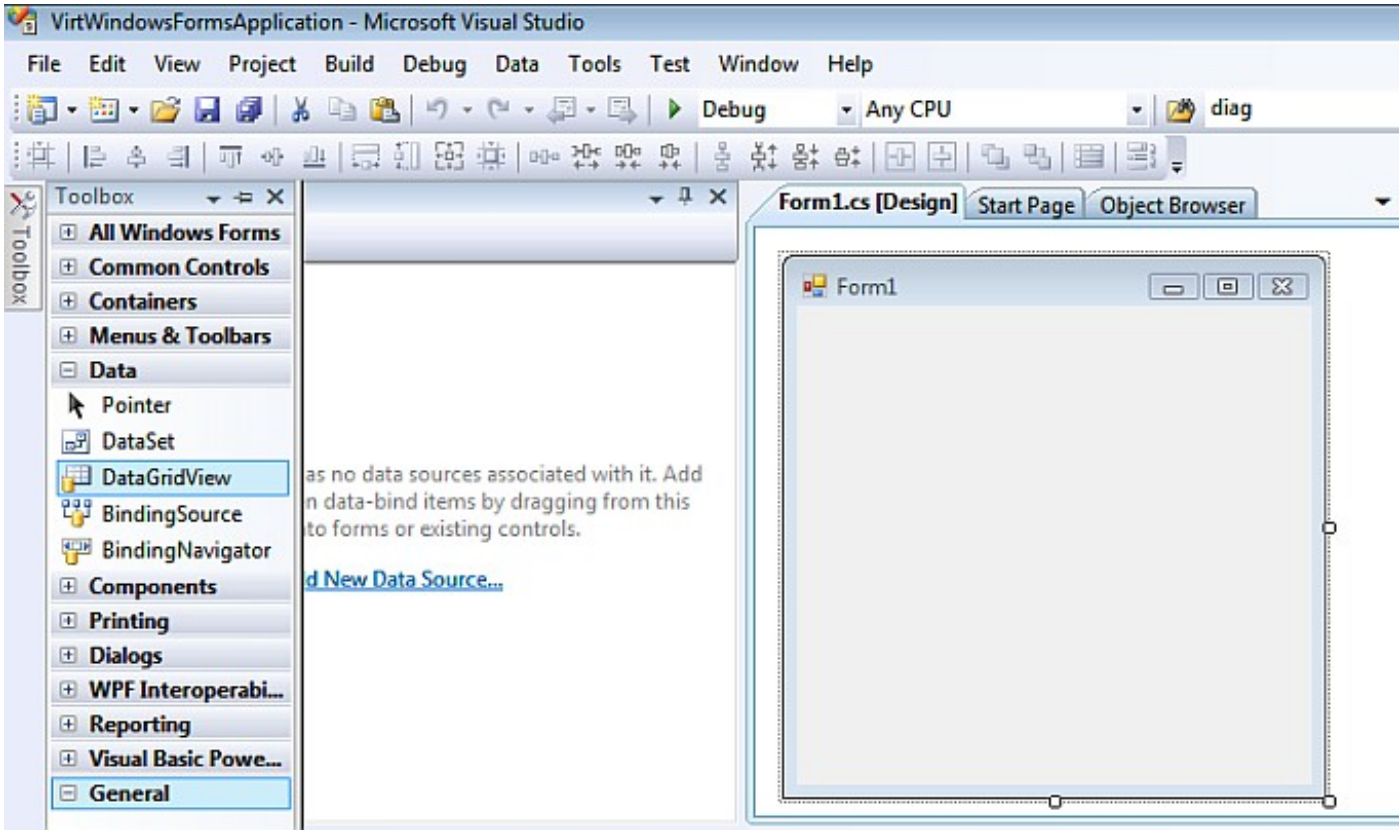
   Data Controls

   , and drag the

   DataGridView

   control onto the form.

   Figure 8.50. Toolbox



7. Click on the little

   arrow

   in the top right of the

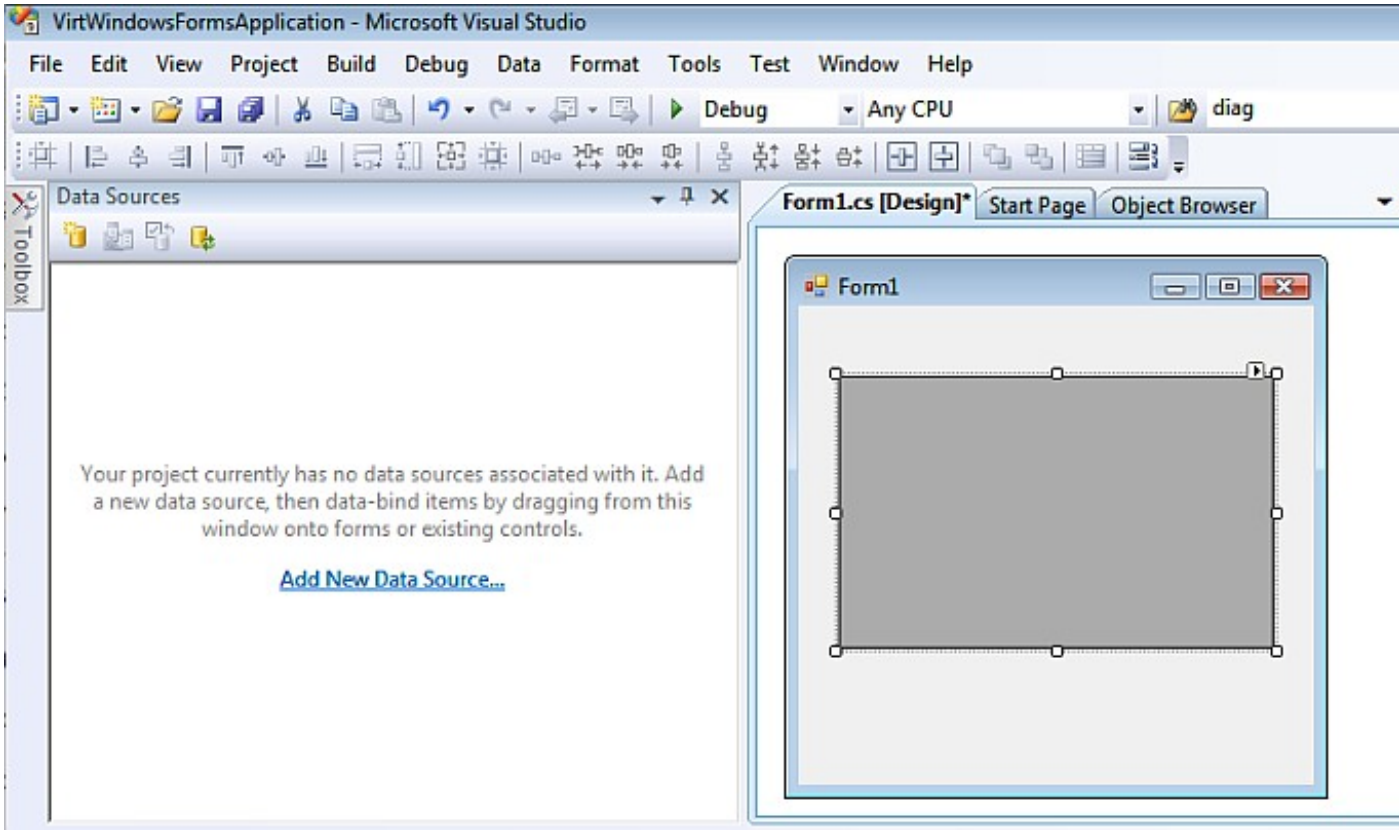
   DataGridView

   control. This loads the

   DataGridView Task

   menu.

Figure 8.51. DataGridView Task

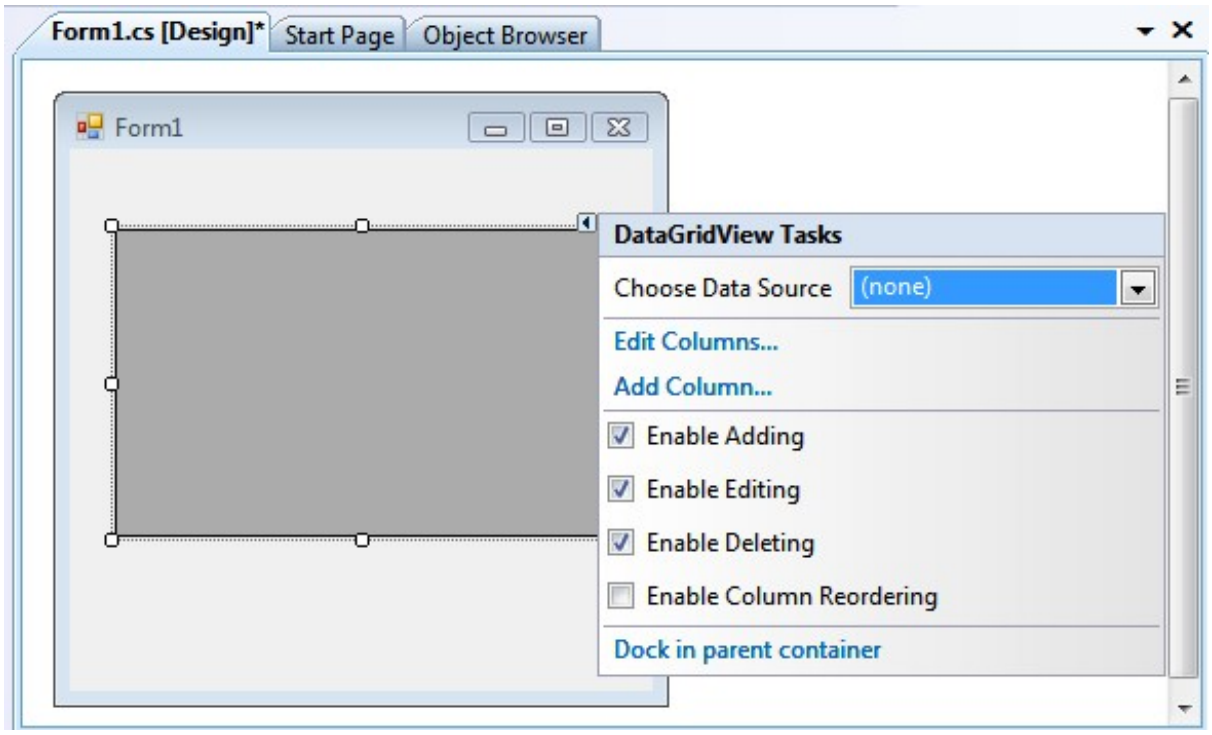


8. Click on the

   Choose Data Source

   list box.

Figure 8.52. Choose Data Source

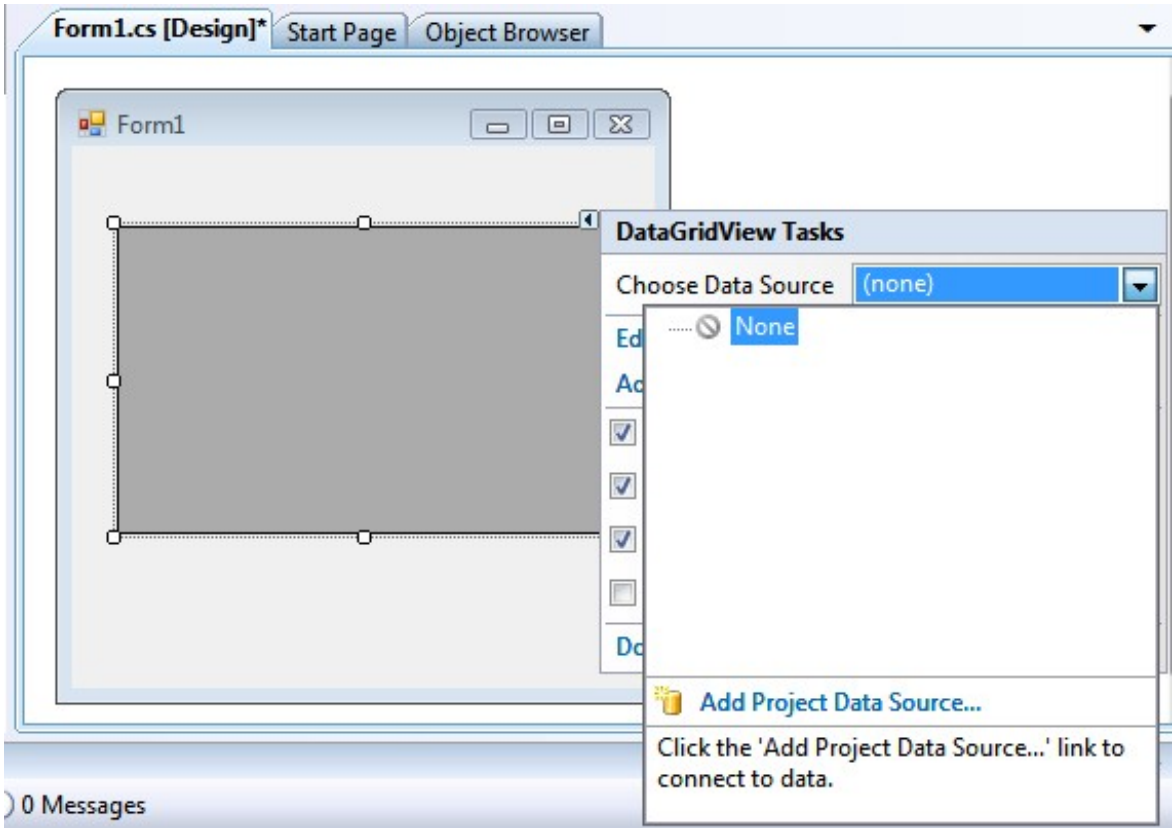


9. Click on the

   Add Project Data Source

link to connect to a data source.

Figure 8.53. Add Project Data Source



10. In the

    Data Source Configuration Wizard

    dialog

    Choose Data Source Type

    page select the

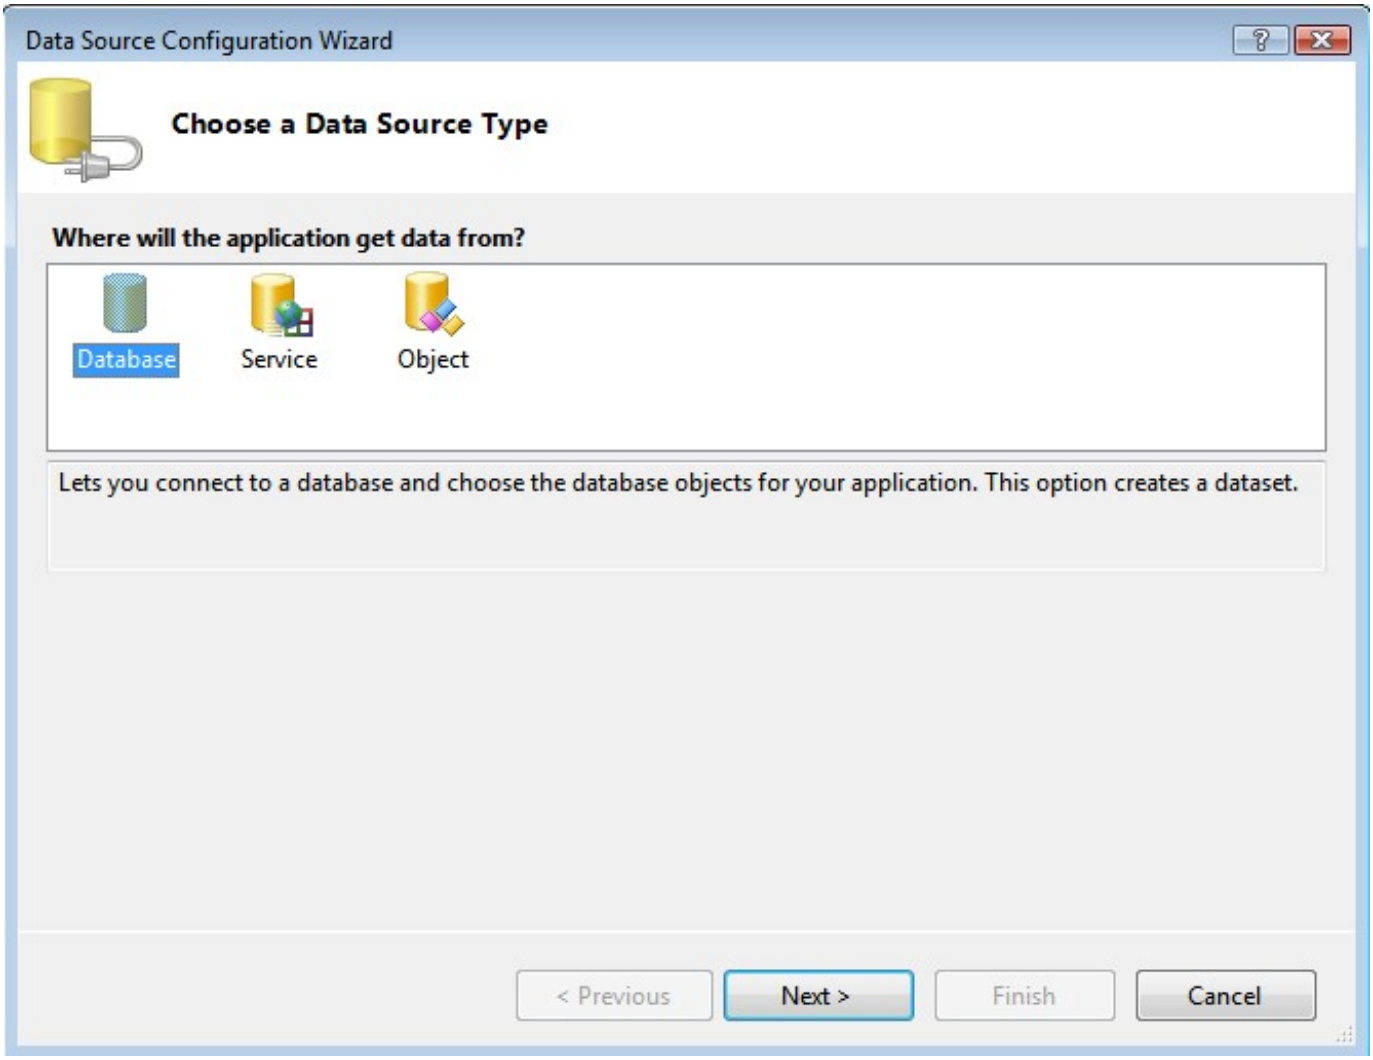
    Database

    data source type and click

    Next

    .

Figure 8.54. Data Source Type



11. In the

    Data Source Configuration Wizard

    dialog

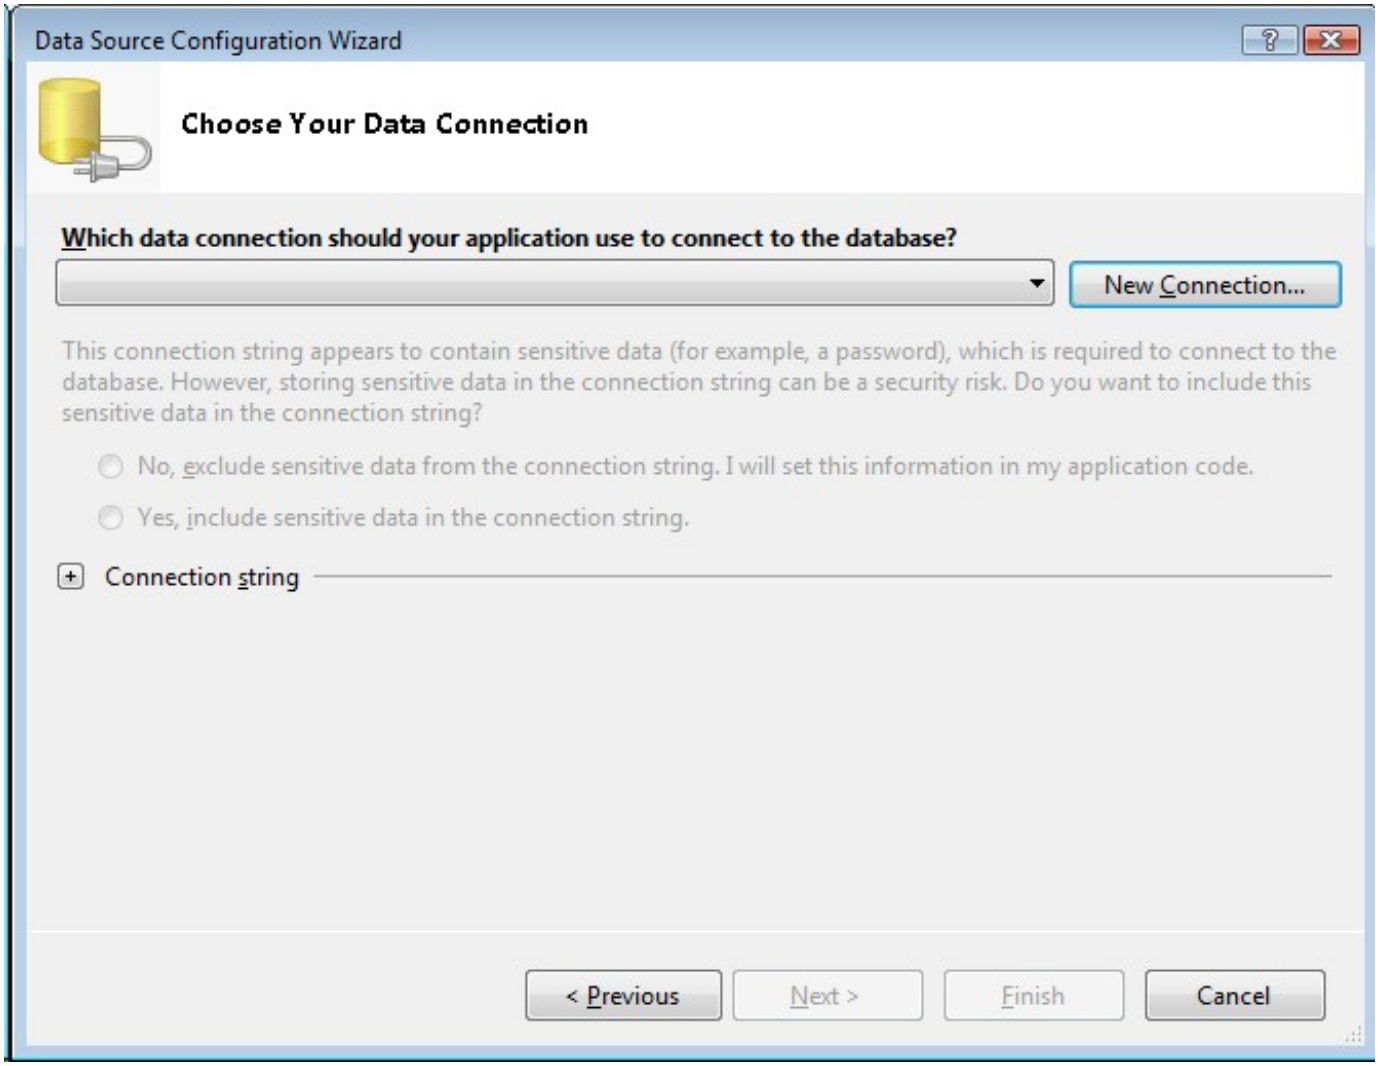
    Choose your Data Connection

    page, select the

    New Connection

    button

Figure 8.55. Data Source Configuration Wizard



12. In the

    Choose Data Source

    dialog, select the OpenLink

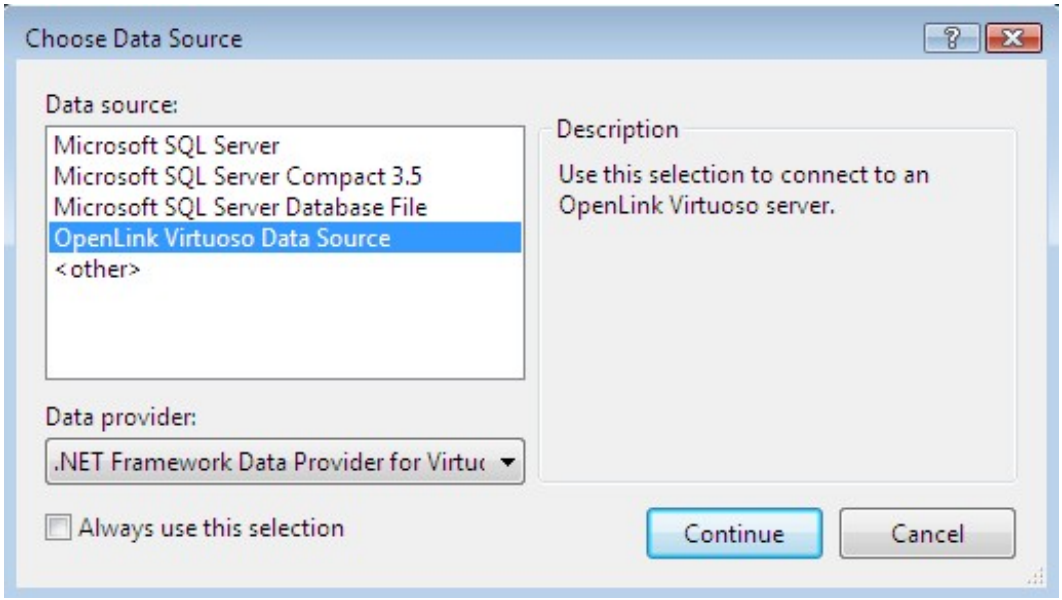
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.56. Data Source



13. In the

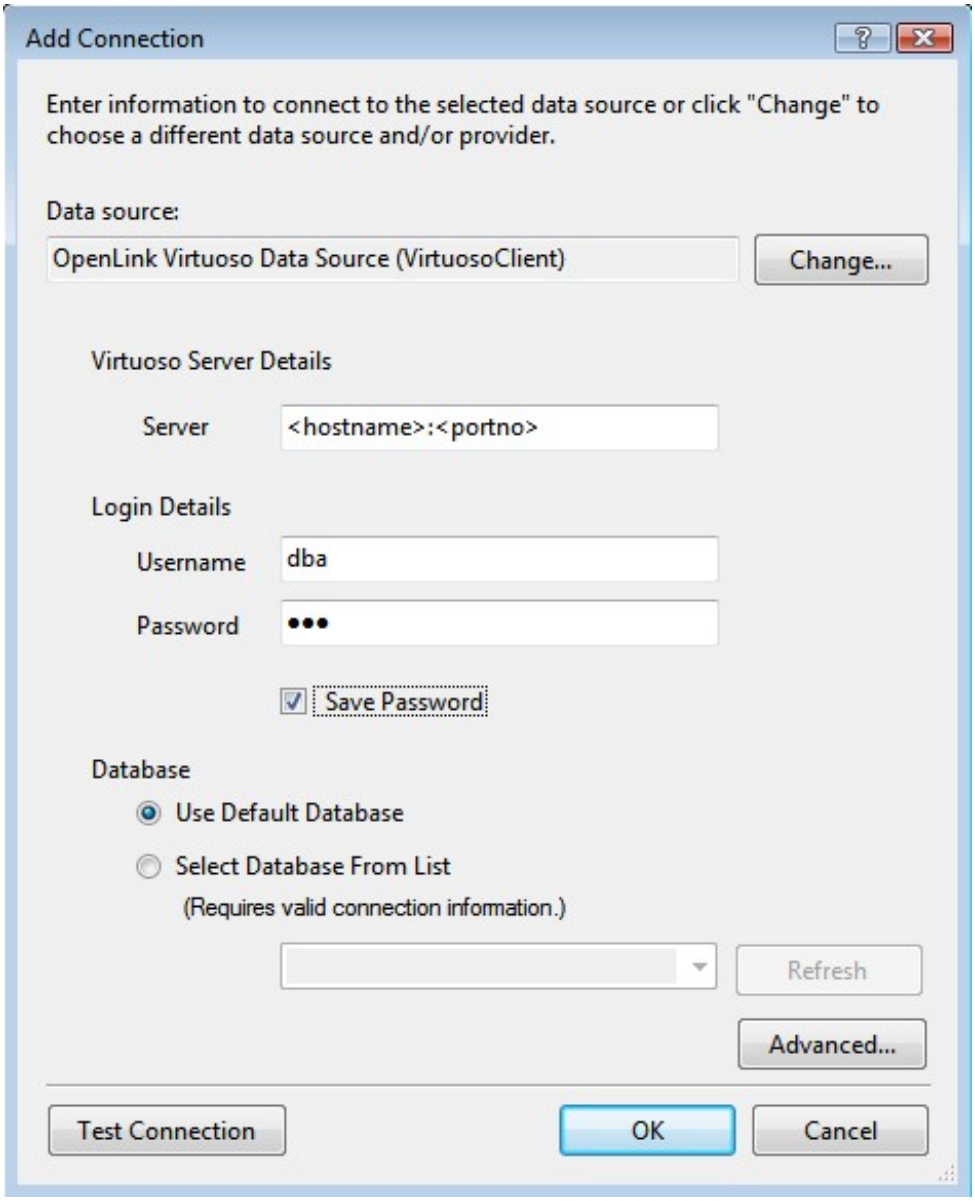
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.57. Connection Properties



14. Select the

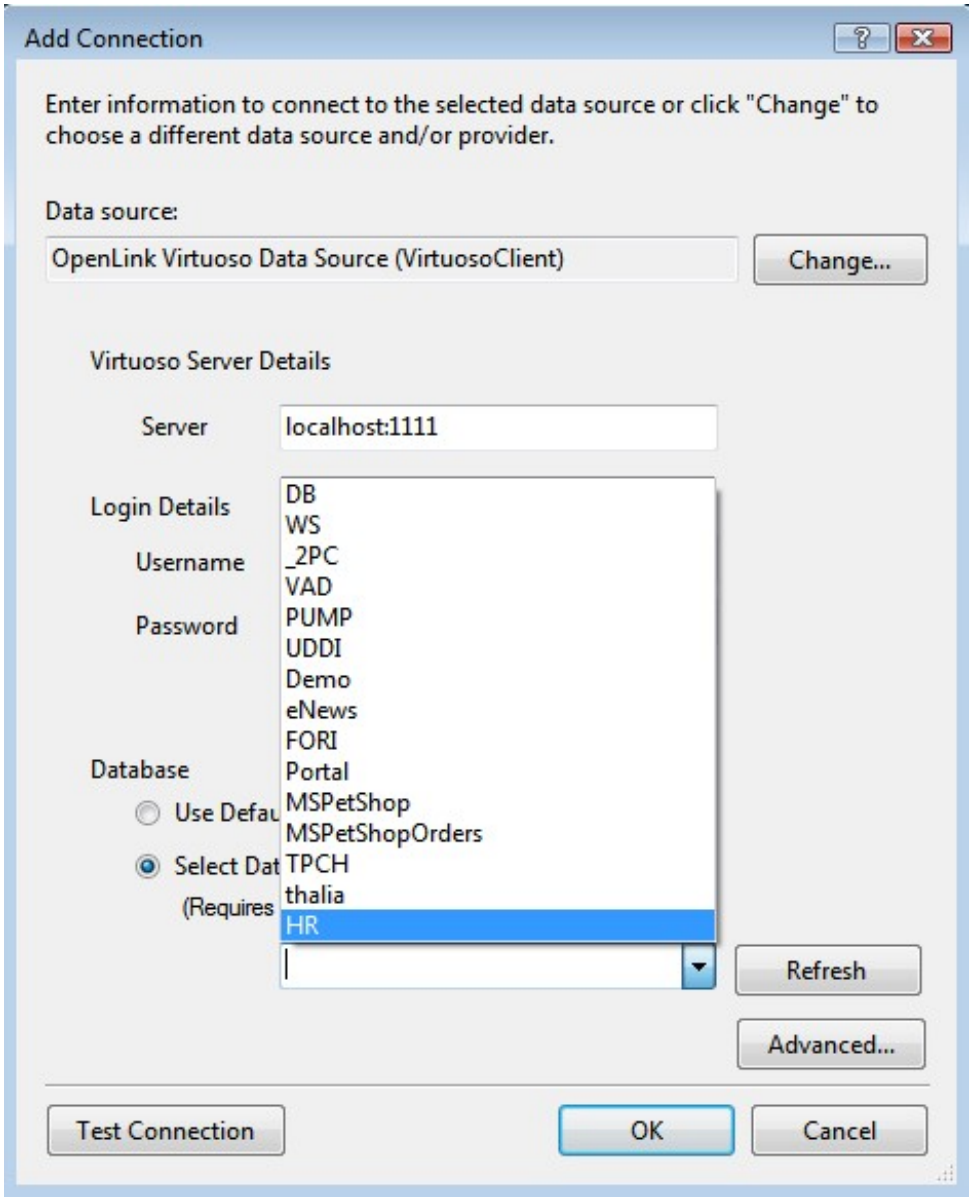
    Select Database From List

    radio button and choose the

    HR

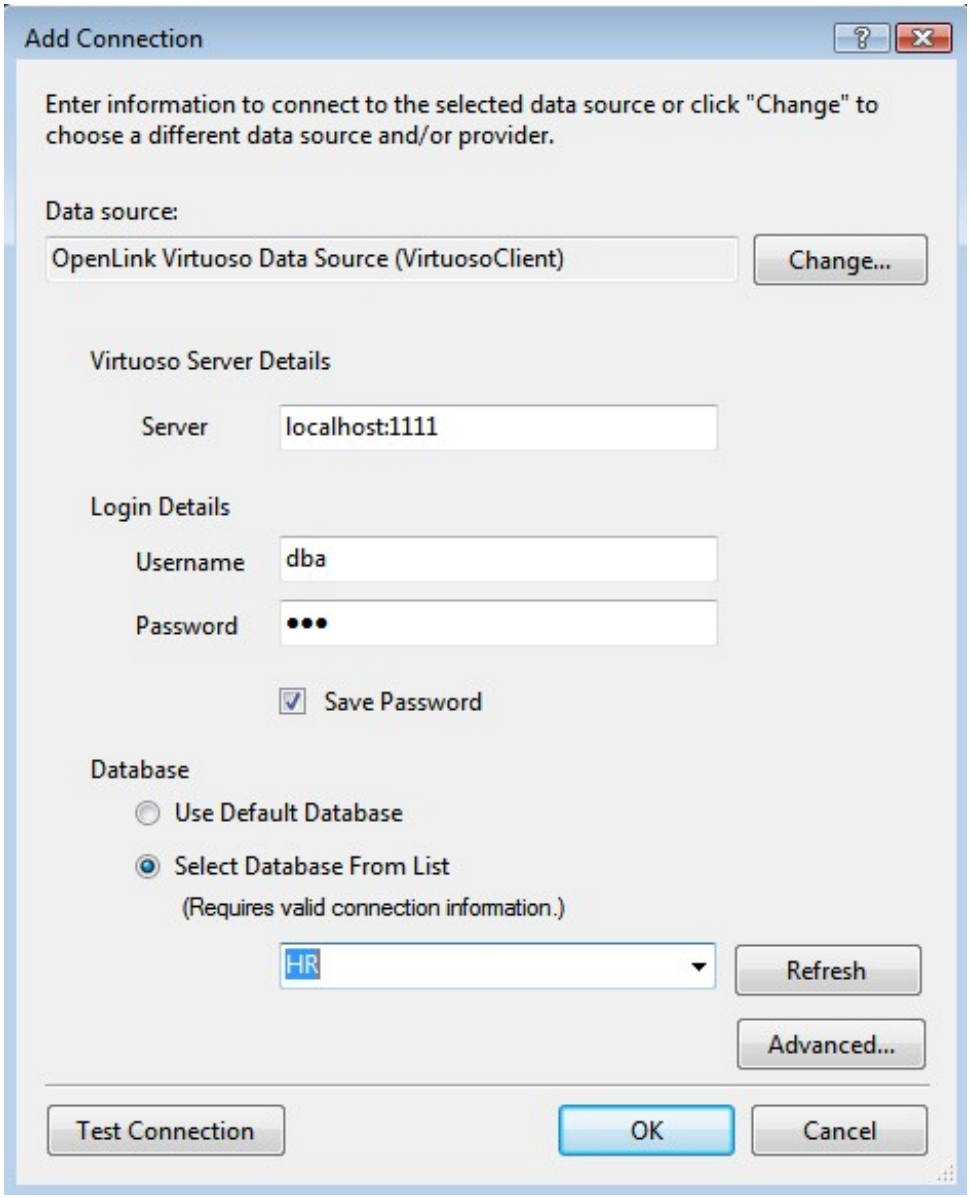
    database from the drop down list.

Figure 8.58. Add connection



15. Click OK to add the connection.

Figure 8.59. Add connection

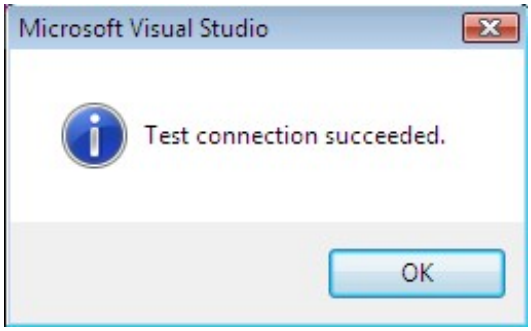


16. Press the

    Test Connection

    dialog to verify that the database is accessible.

    Figure 8.60. Test Connection



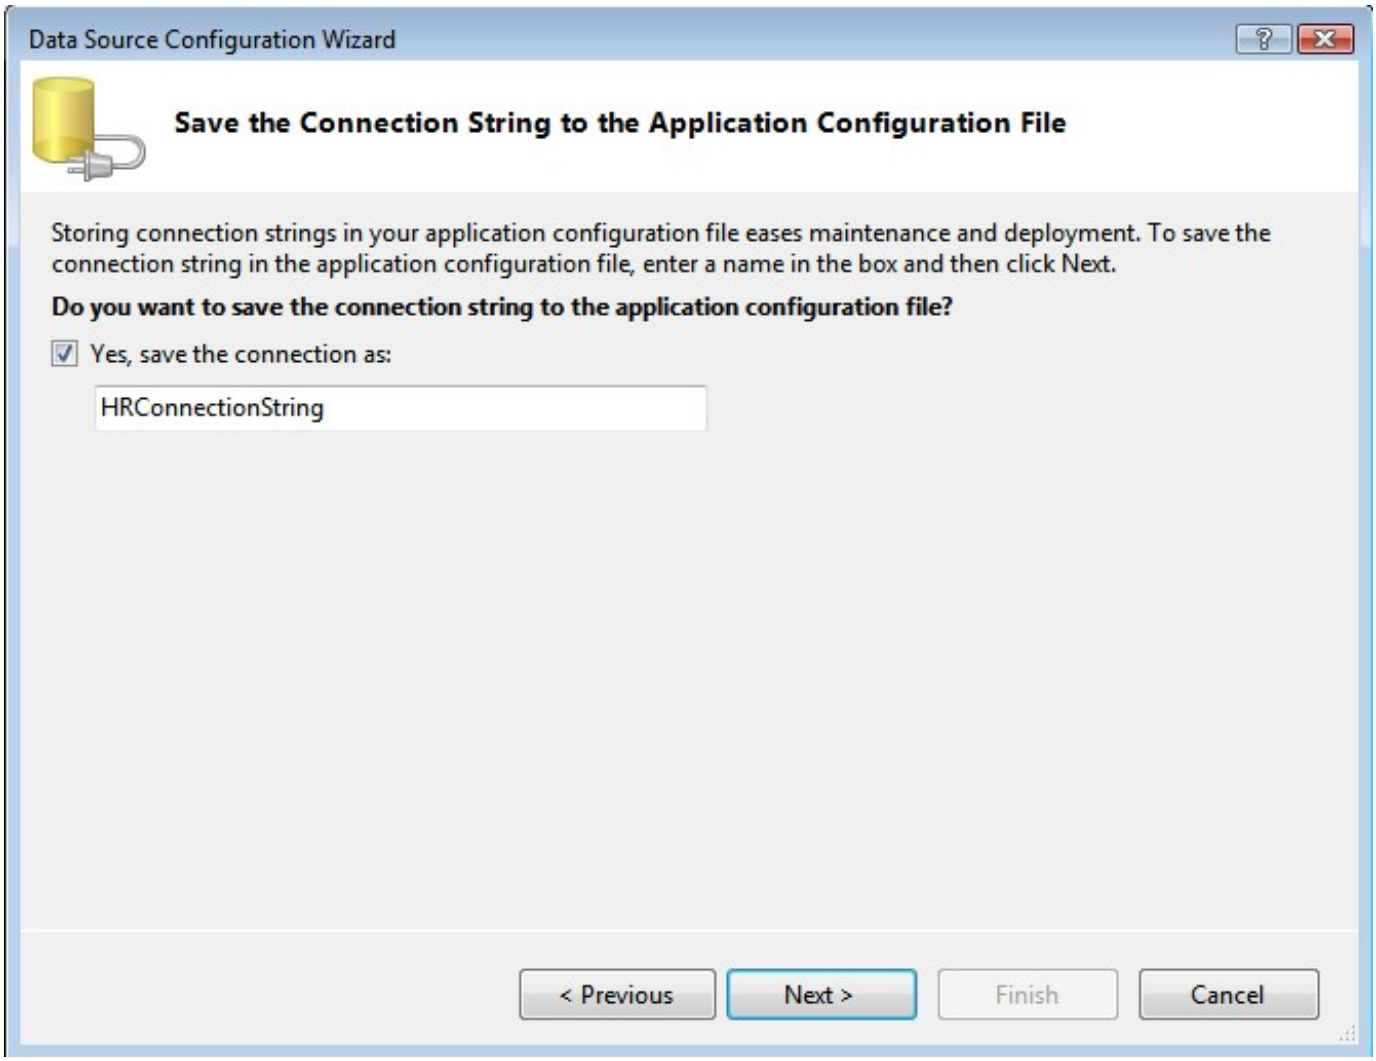
17. Leave the default connect string

    HRConnectionString

and click

Next

Figure 8.61. HRConnectionString



18. From the list of available tables returned for the HR database, select the

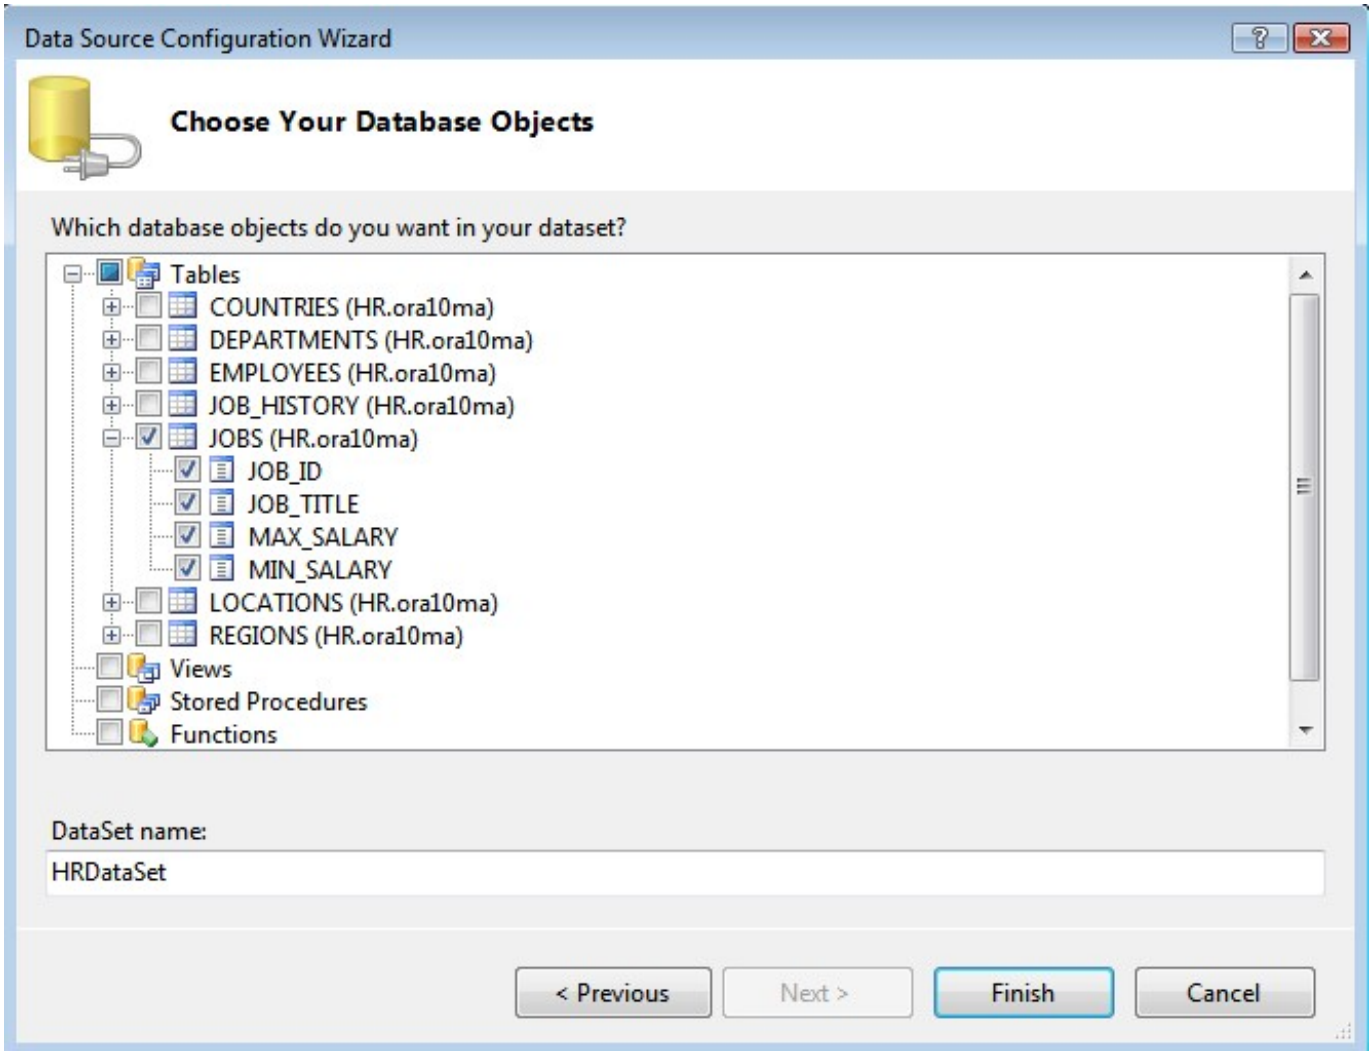
    JOBS

    table to be associated with the

    DataGridView

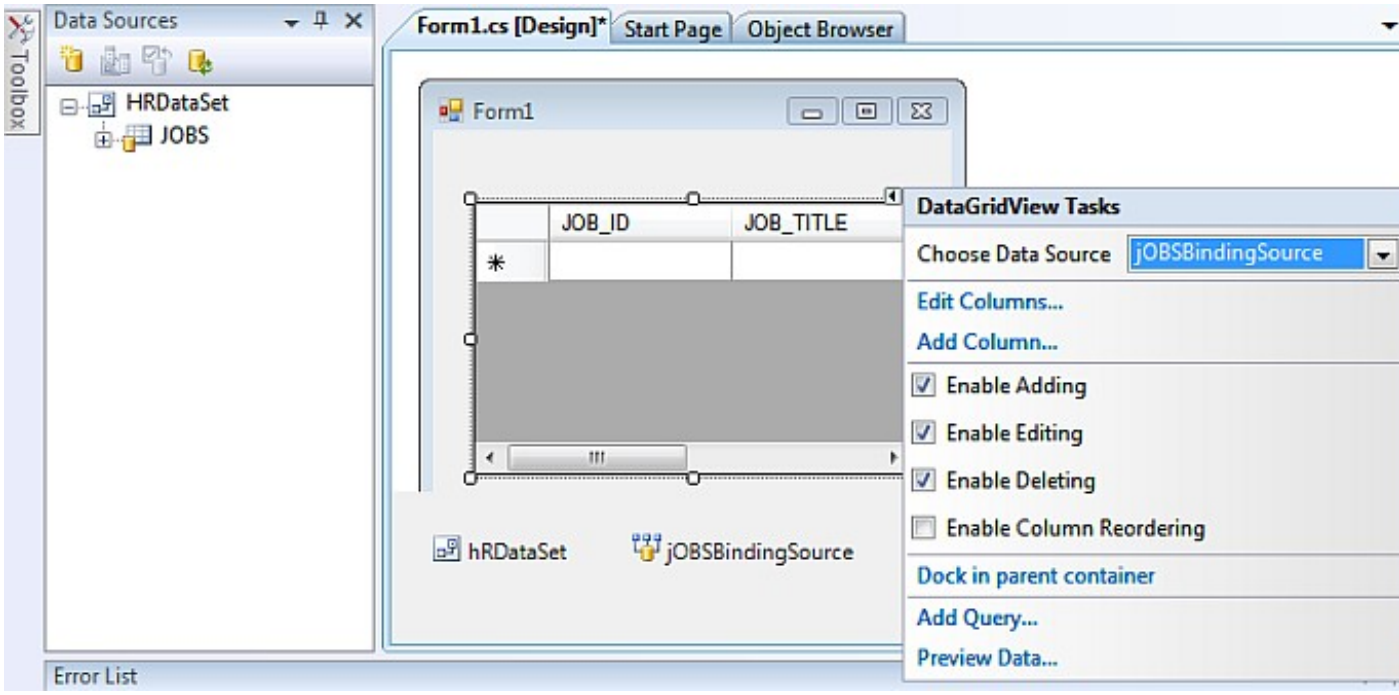
    control.

Figure 8.62. HR database



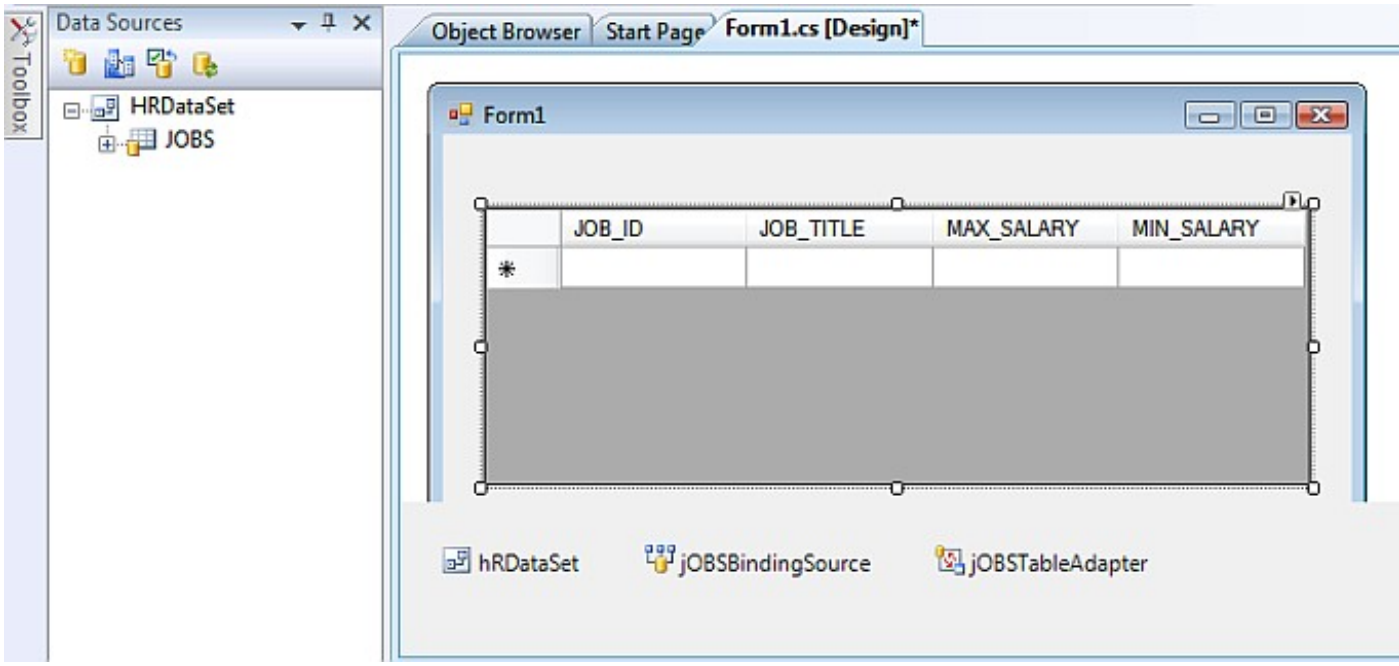
19. The columns names of the select table will be displayed in the DataGridView.

Figure 8.63. DataGridView



20. Resize the Form and DataGridView to allow all columns to be visible, if possible.

Figure 8.64. Resize the Form and DataGridView



21. To test the application, simply hit

    Ctrl+F5

    within Visual Studio or select

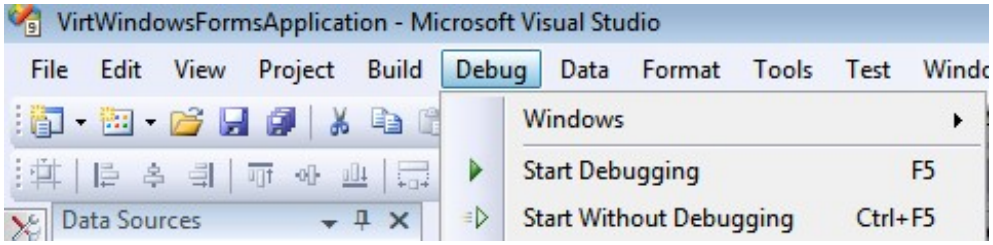
    Start Debugging

    from the

    Debug

    menu.

Figure 8.65. Start Debugging



22. The data from the

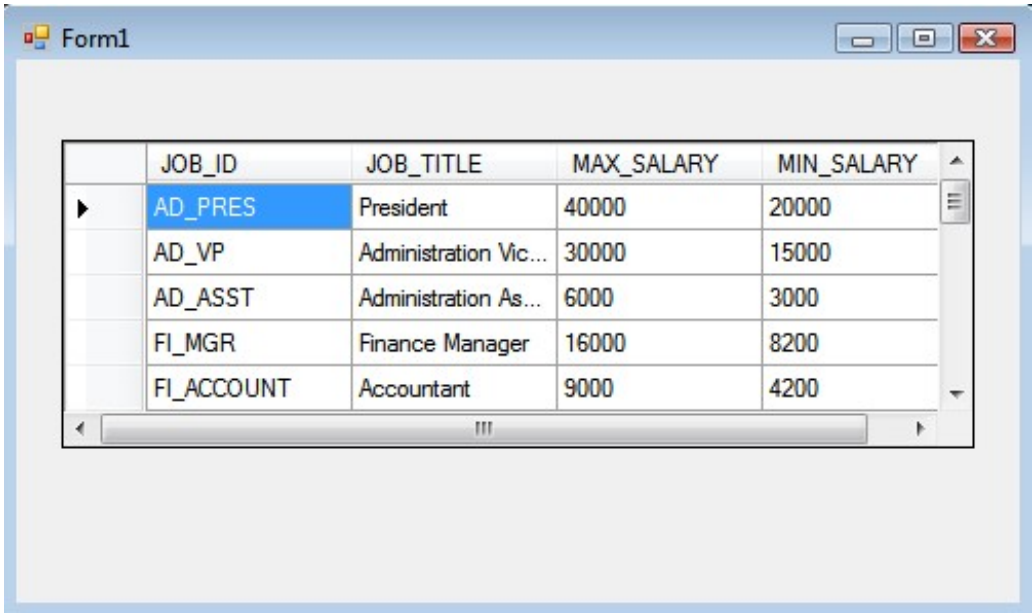
    JOBS

    table will be displayed in the

    DataGrid

    .

Figure 8.66. DataGrid



The task is now complete.

8.3. Using Microsoft Entity Frameworks to Access Progress Schema Objects with Virtuoso

Abstract

This section details the steps required to provide Microsoft Entity Framework access to Progress Schema Objects using the OpenLink Virtuoso Universal Server. This is achieved by Linking the required Progress Schema objects into Virtuoso using its built in Virtual Database engine, and then using the Virtuoso ADO.Net Entity Framework provider to query the remote Progress Schema objects linked into the Virtuoso Server.

Prerequisites

Progress OpenEdge 10. A Progress DBMS hosting the required Schema Objects needs to be available. In this section, the *isports* sample database will be used to demonstrate the process.

A Progress DBMS hosting the required Schema Objects needs to be available. In this section, the *isports* sample database will be used to demonstrate the process.

OpenLink ODBC Driver for Progress (SQL-92). A Progress ODBC Driver is required to link the Progress Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for Progress (SQL-92)* will be used in this section, for which a functional ODBC Data source name of "*prs101c* " will be assumed to exist on the machine hosting the Virtuoso Server.

A Progress ODBC Driver is required to link the Progress Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for Progress (SQL-92)* will be used in this section, for which a functional ODBC Data source name of "*prs101c* " will be assumed to exist on the machine hosting the Virtuoso Server.

OpenLink Virtuoso 5.10.x. An OpenLink Virtuoso Universal Server installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks.

An OpenLink Virtuoso Universal Server installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks.

Microsoft Visual Studio 2008 + SP1. Microsoft Visual Studio 2008 with Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Microsoft Visual Studio 2008 with Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Tasks

Ensure Progress Primary Keys (PKs) are not nullable. The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are NOT Nullable, and will fail to generate an EDM if any are nullable. Thus ensure any tables to be used are defined as not nullable in the Progress database schema before attempting to generate an EDM.

The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are NOT Nullable, and will fail to generate an EDM if any are nullable. Thus ensure any tables to be used are defined as not nullable in the Progress database schema before attempting to generate an EDM.

It seems that, by default, several Primary Keys (PKs) in the isports database allows <NULL> values. It seems somewhat nonsensical - that a unique key used, specifically, to identify a row in a table can be allowed to be <NULL>.

This issue is best addressed directly in the database schema, by redefining those PKs that allow <NULL> so as not to allow <NULL>. Progress does not seem to talk in terms of <NULL>, instead using the term "Mandatory"

The following section will provide more specific details about how to ensure Progress PKs are not nullable:

- Ensuring Progress PKs are not nullable

8.3.1. Install and configure OpenLink ODBC Driver for Progress (SQL-92)

The Virtuoso Virtual Database engine uses ODBC as the connectivity mechanism for linking remote database objects into its local schema. Thus a Progress ODBC Driver must be available with a suitably configured DSN for connecting to the target database. The OpenLink ODBC Drivers for Progress have been used in this section, although in theory any Progress ODBC Driver can be used.

Installation instructions for the OpenLink ODBC Driver for Oracle are available from:

- Product Installation & Basic Configuration (ODBC)

8.3.2. Install and configure OpenLink Virtuoso Universal Server

- Install and configure OpenLink Virtuoso Universal Server

8.3.3. Linking Progress tables into Virtuoso

1. Start the Virtuoso Web User Interface

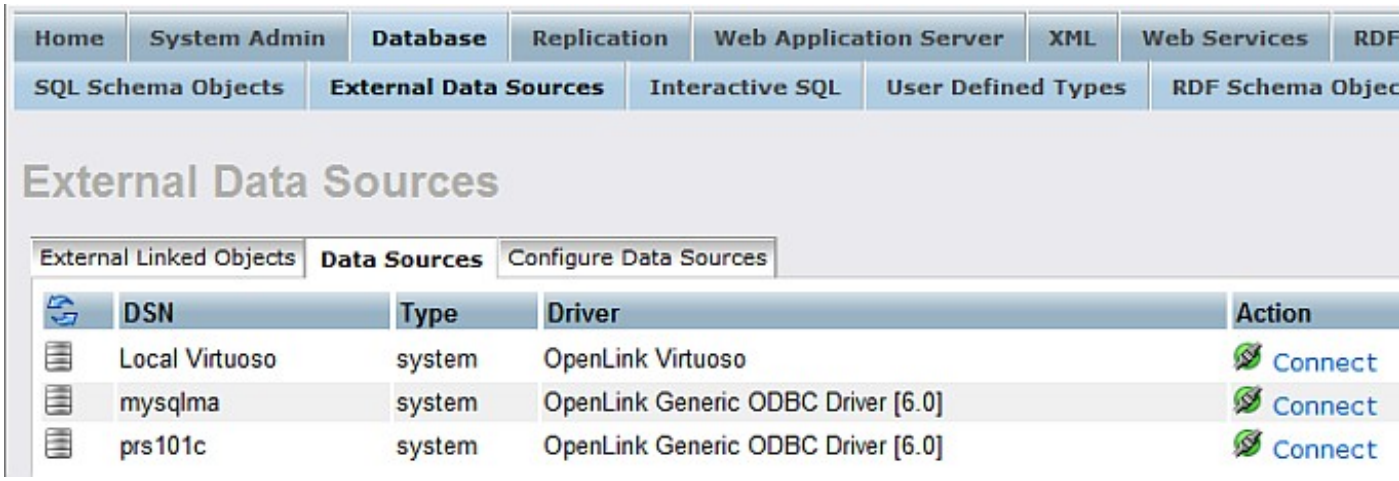
   Figure 8.67. Start

2. Select the "Conductor" link in the Left Frame and Login as the "dba" user.

Figure 8.68. Conductor

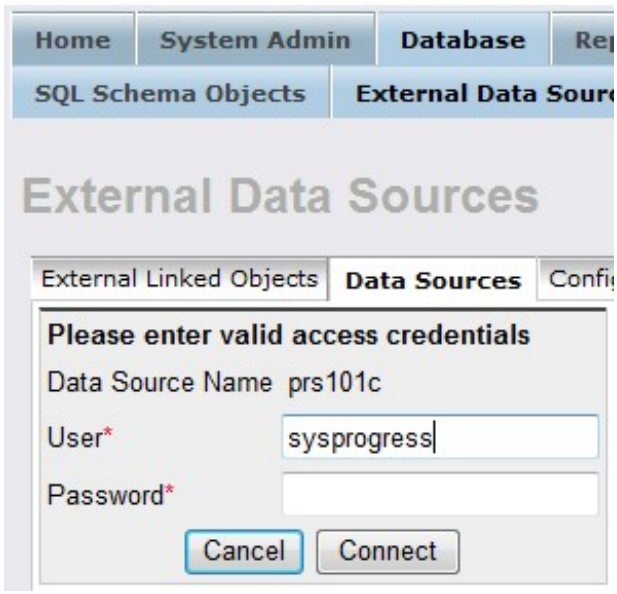
3. Select the "Databases" -> "External Data Source" -> "Data Sources" tab menu items

Figure 8.69. Databases



4. Select the "Connect" button for the "prs10ma" Oracle DSN.

Figure 8.70. Connect

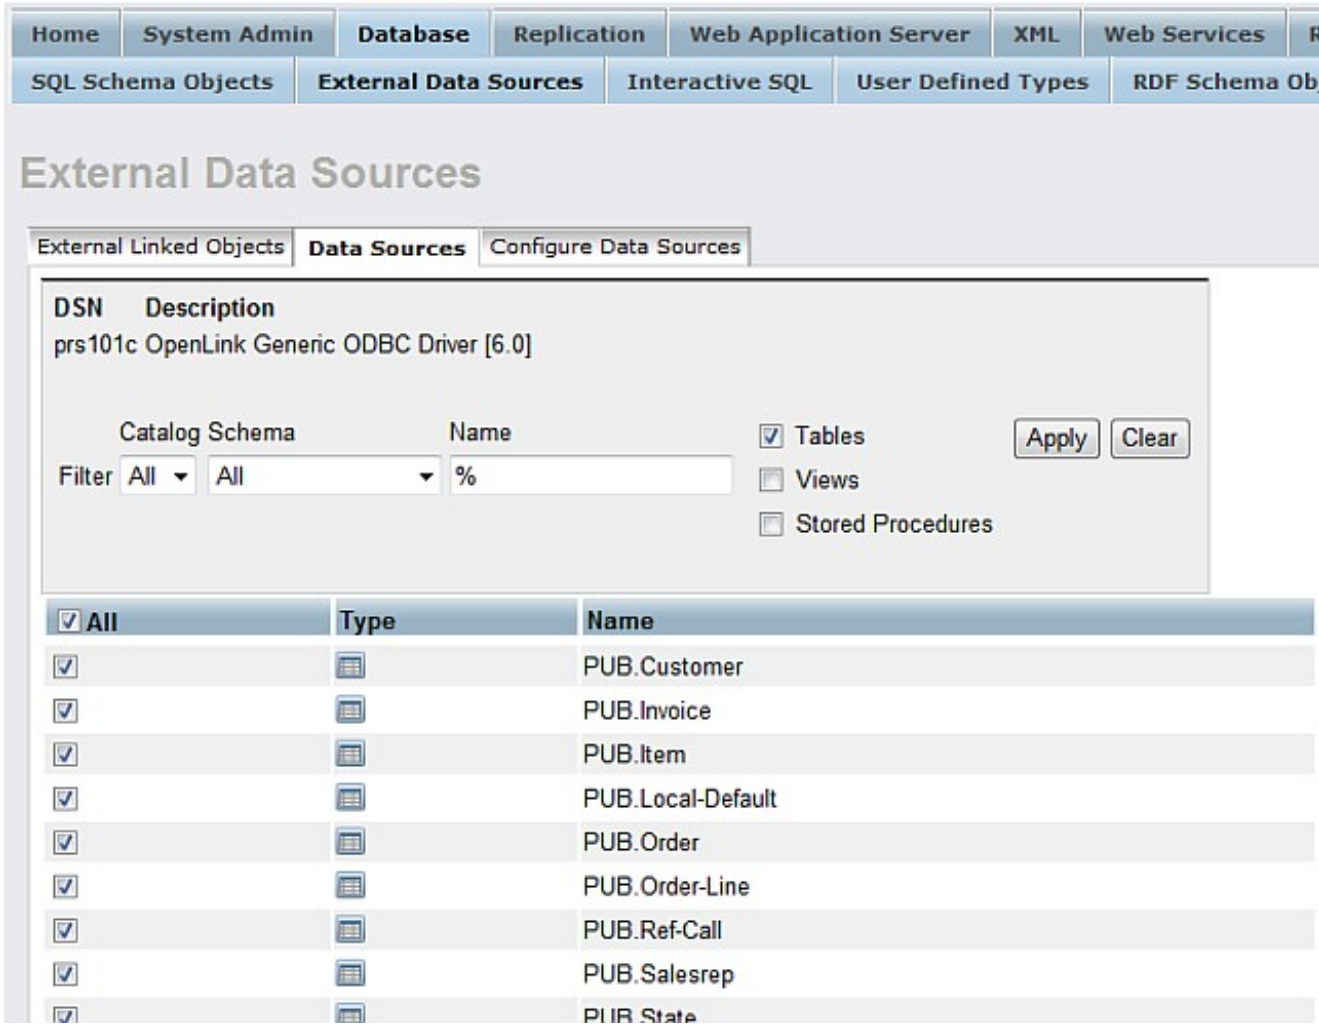


5. On successful connection Select the "Link Objects" button to obtain a list of available tables

Figure 8.71. Link Objects

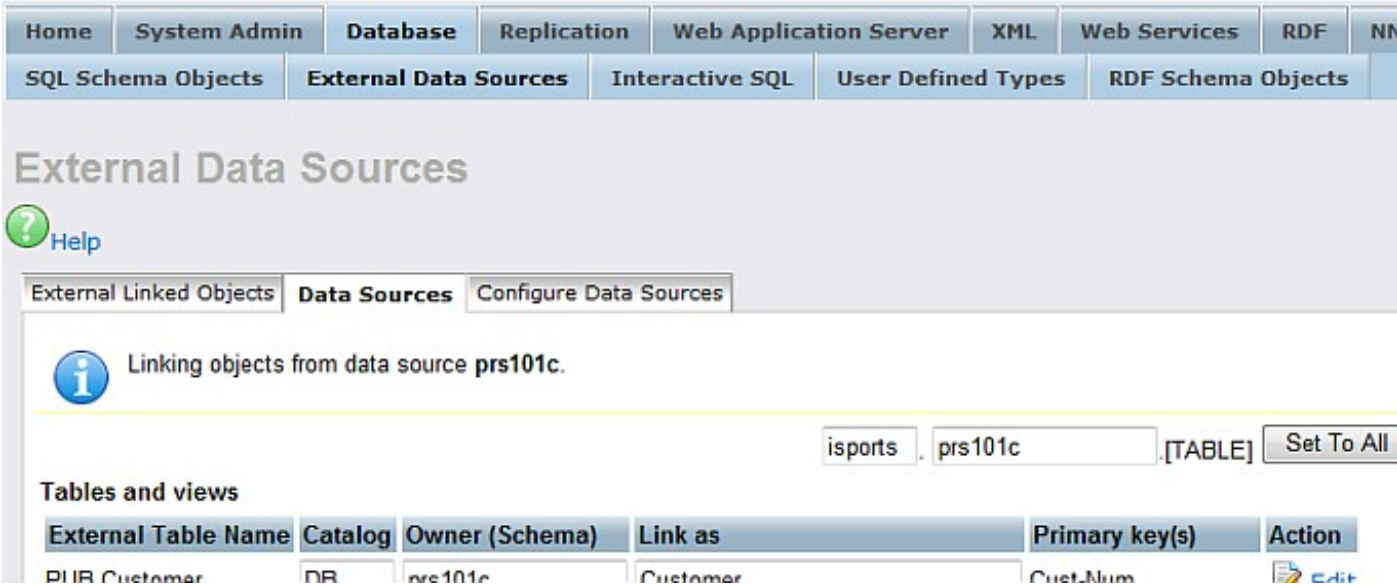
6. Select all the tables that are part of the "isports" catalog.

Figure 8.72. Select all tables



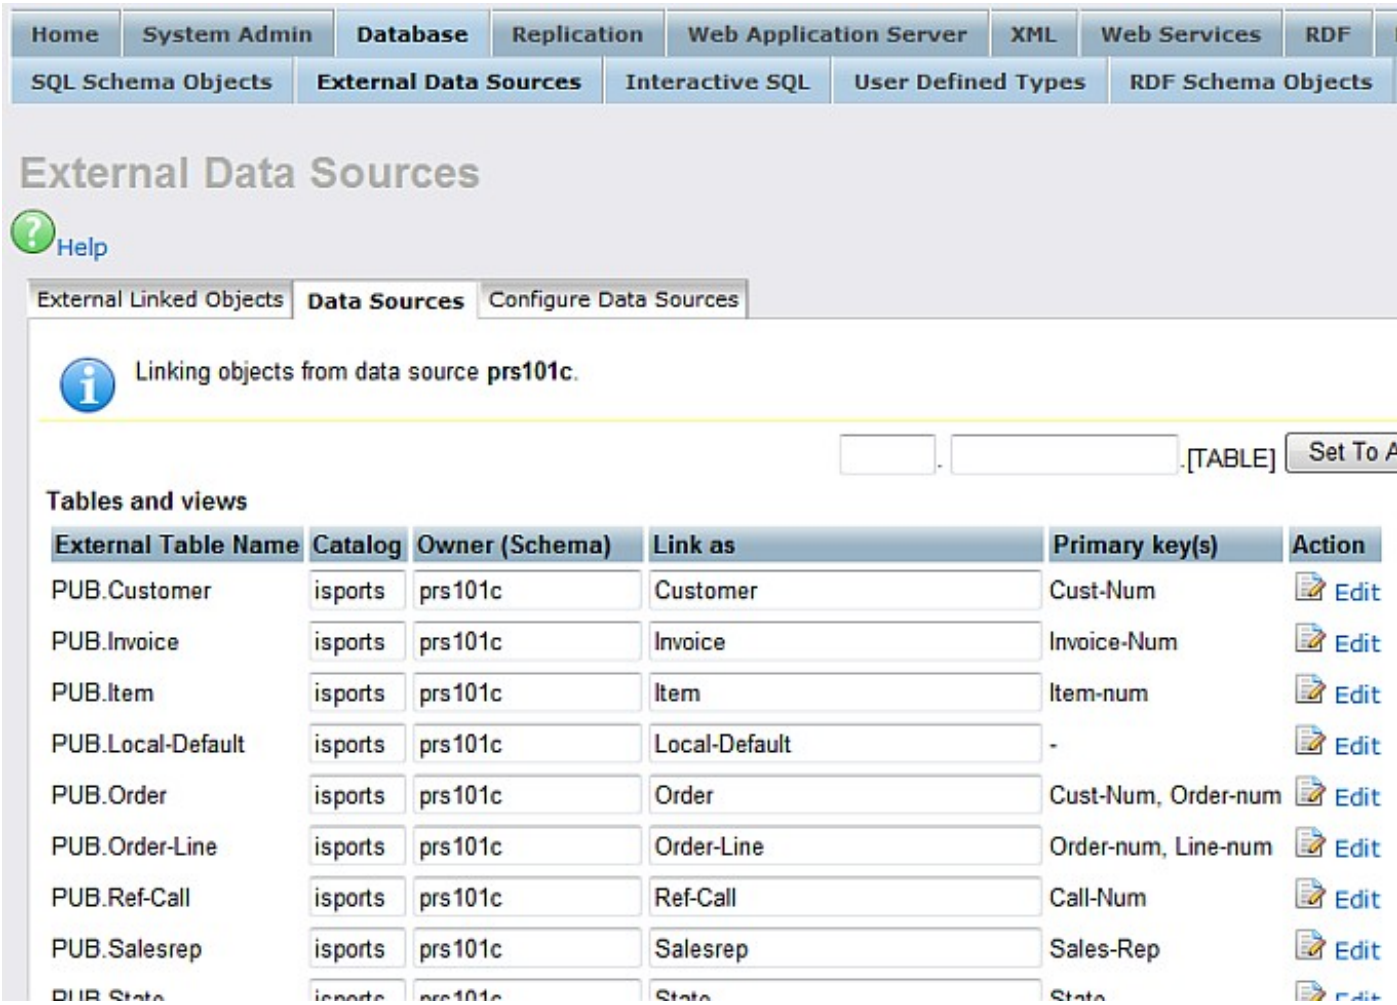
7. Change the Catalog for each table to be "isports" using the "Set All" button.

Figure 8.73. Catalog



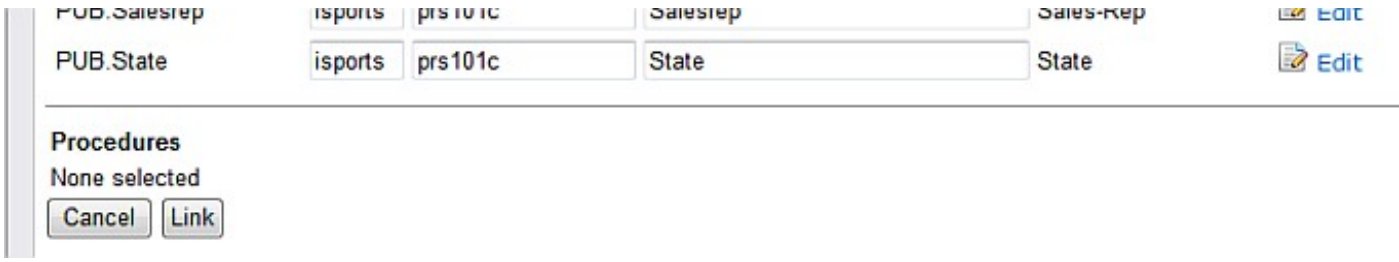
8. All the catalog names are changed to be "isports".

Figure 8.74. Catalog names



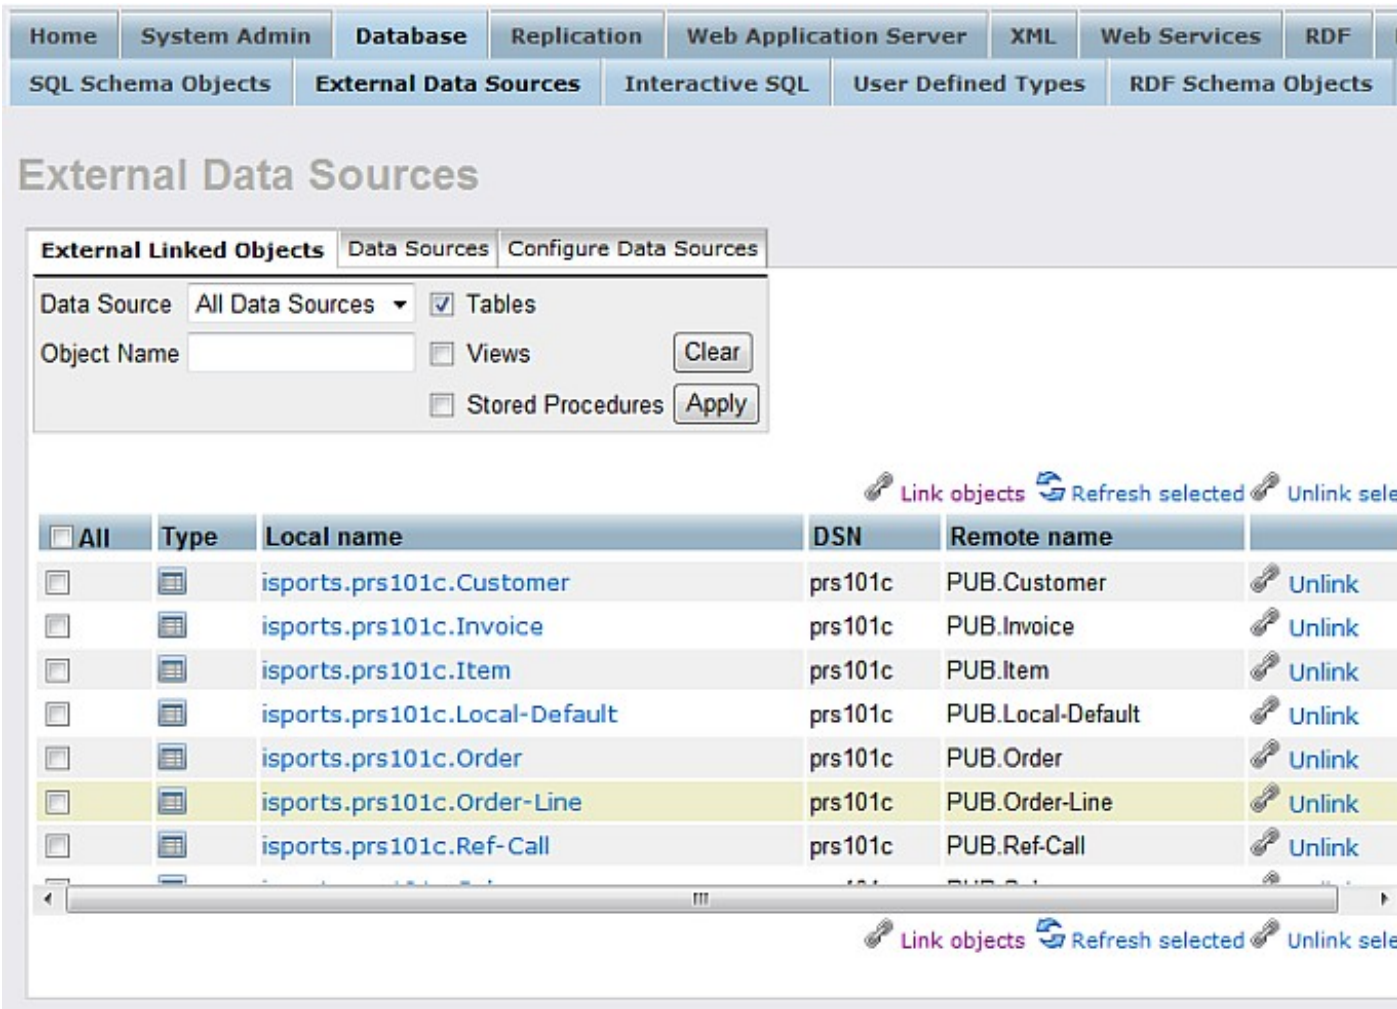
9. Select the "Link" button to link the selected tables into Virtuoso

Figure 8.75. "Link" button



10. On completion of the Link process the tables will be displayed in the "External Linked Objects" tab.

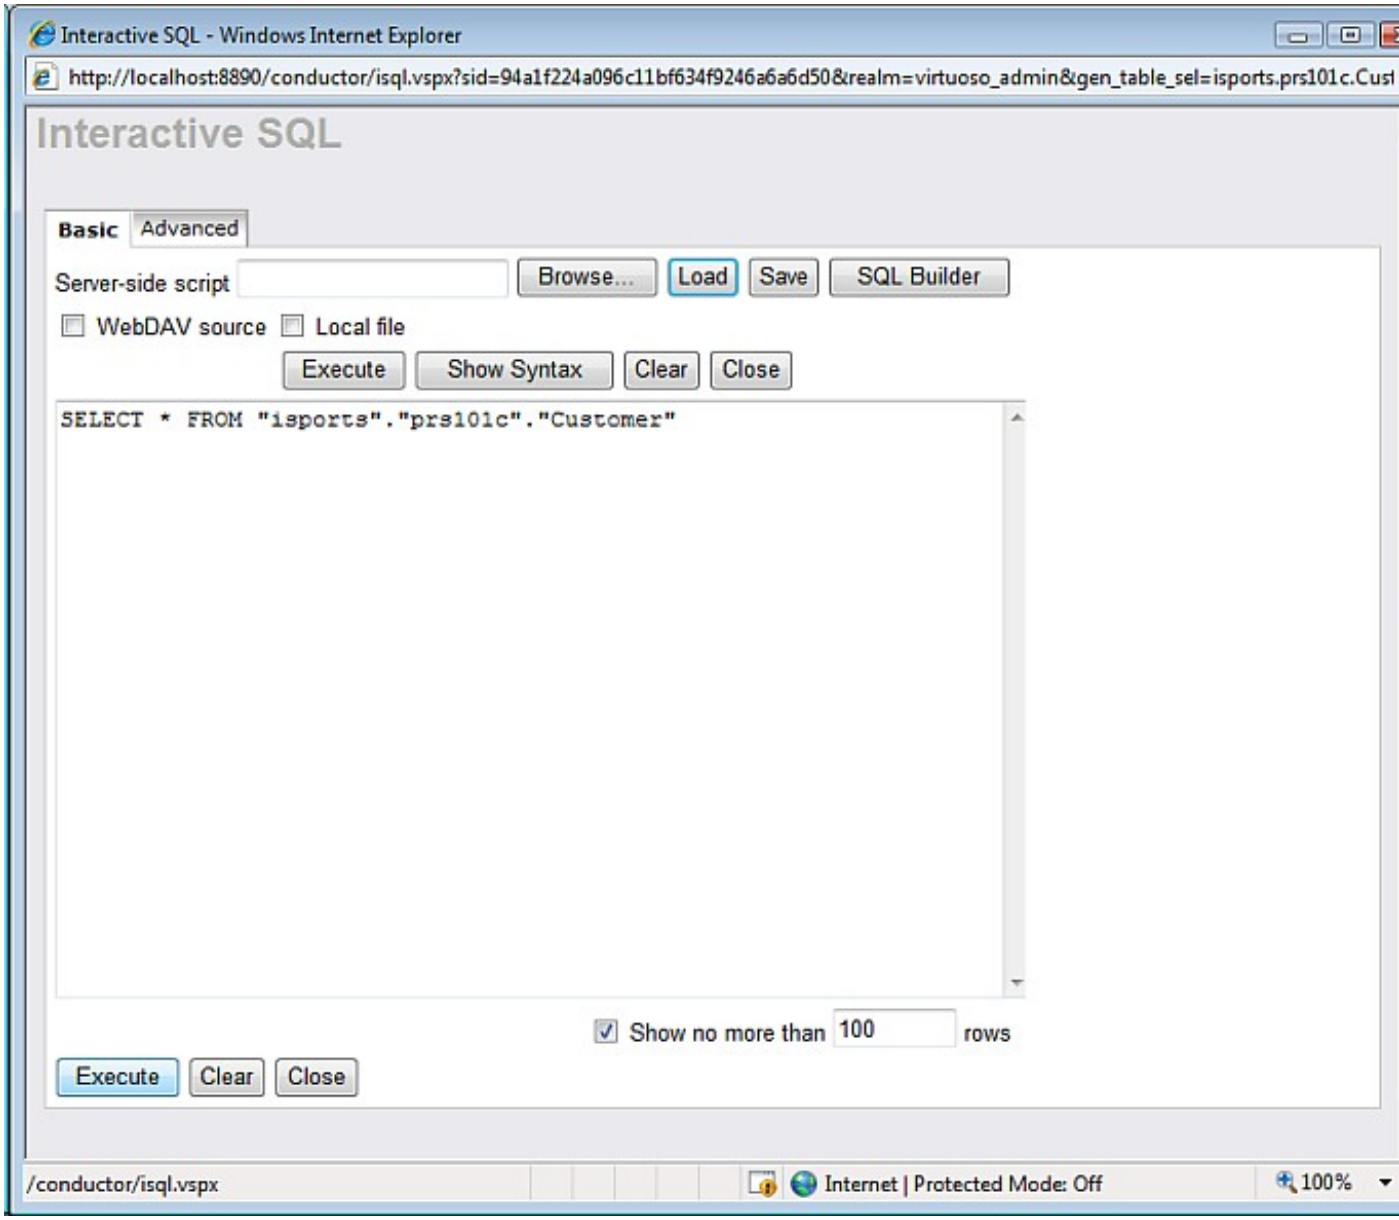
Figure 8.76. Completion



11. At this point you can test the remotely linked tables by clicking on the link that accompanies each table. e.g. isports.prs101c.Customer.

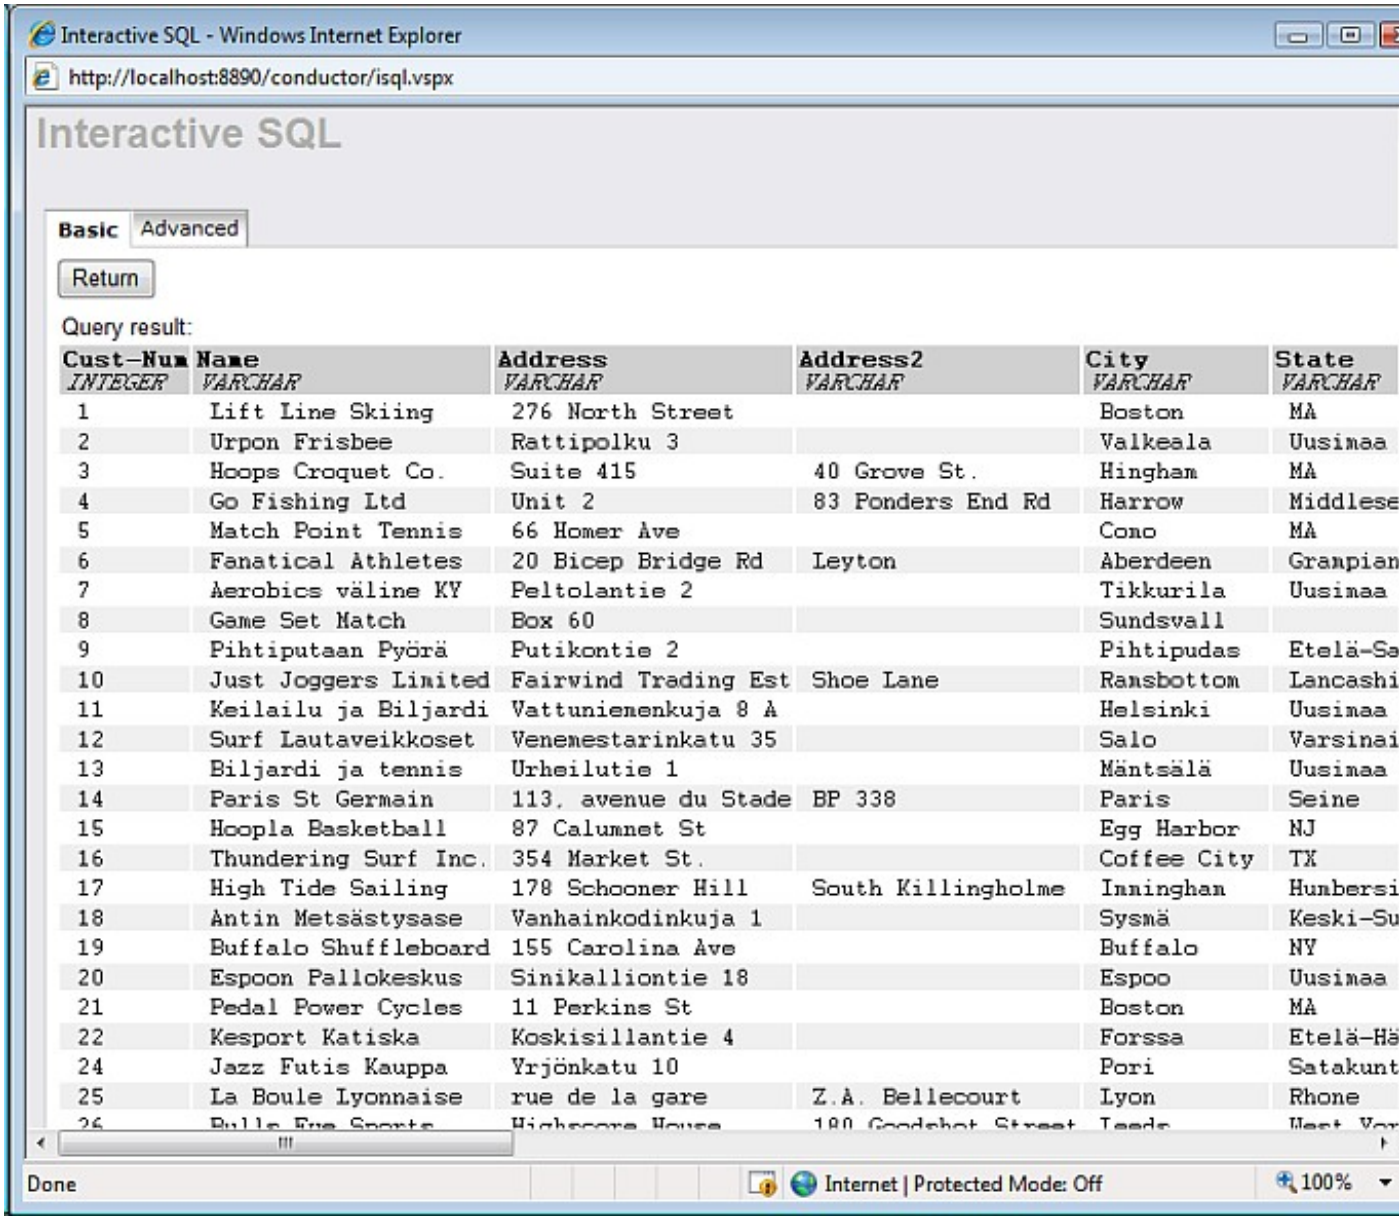
    This will display the Interactive ISQL interface which will have been already populated with a suitable SQL statement.

Figure 8.77. Querying



12. Select Execute to see data from the remotely linked table.

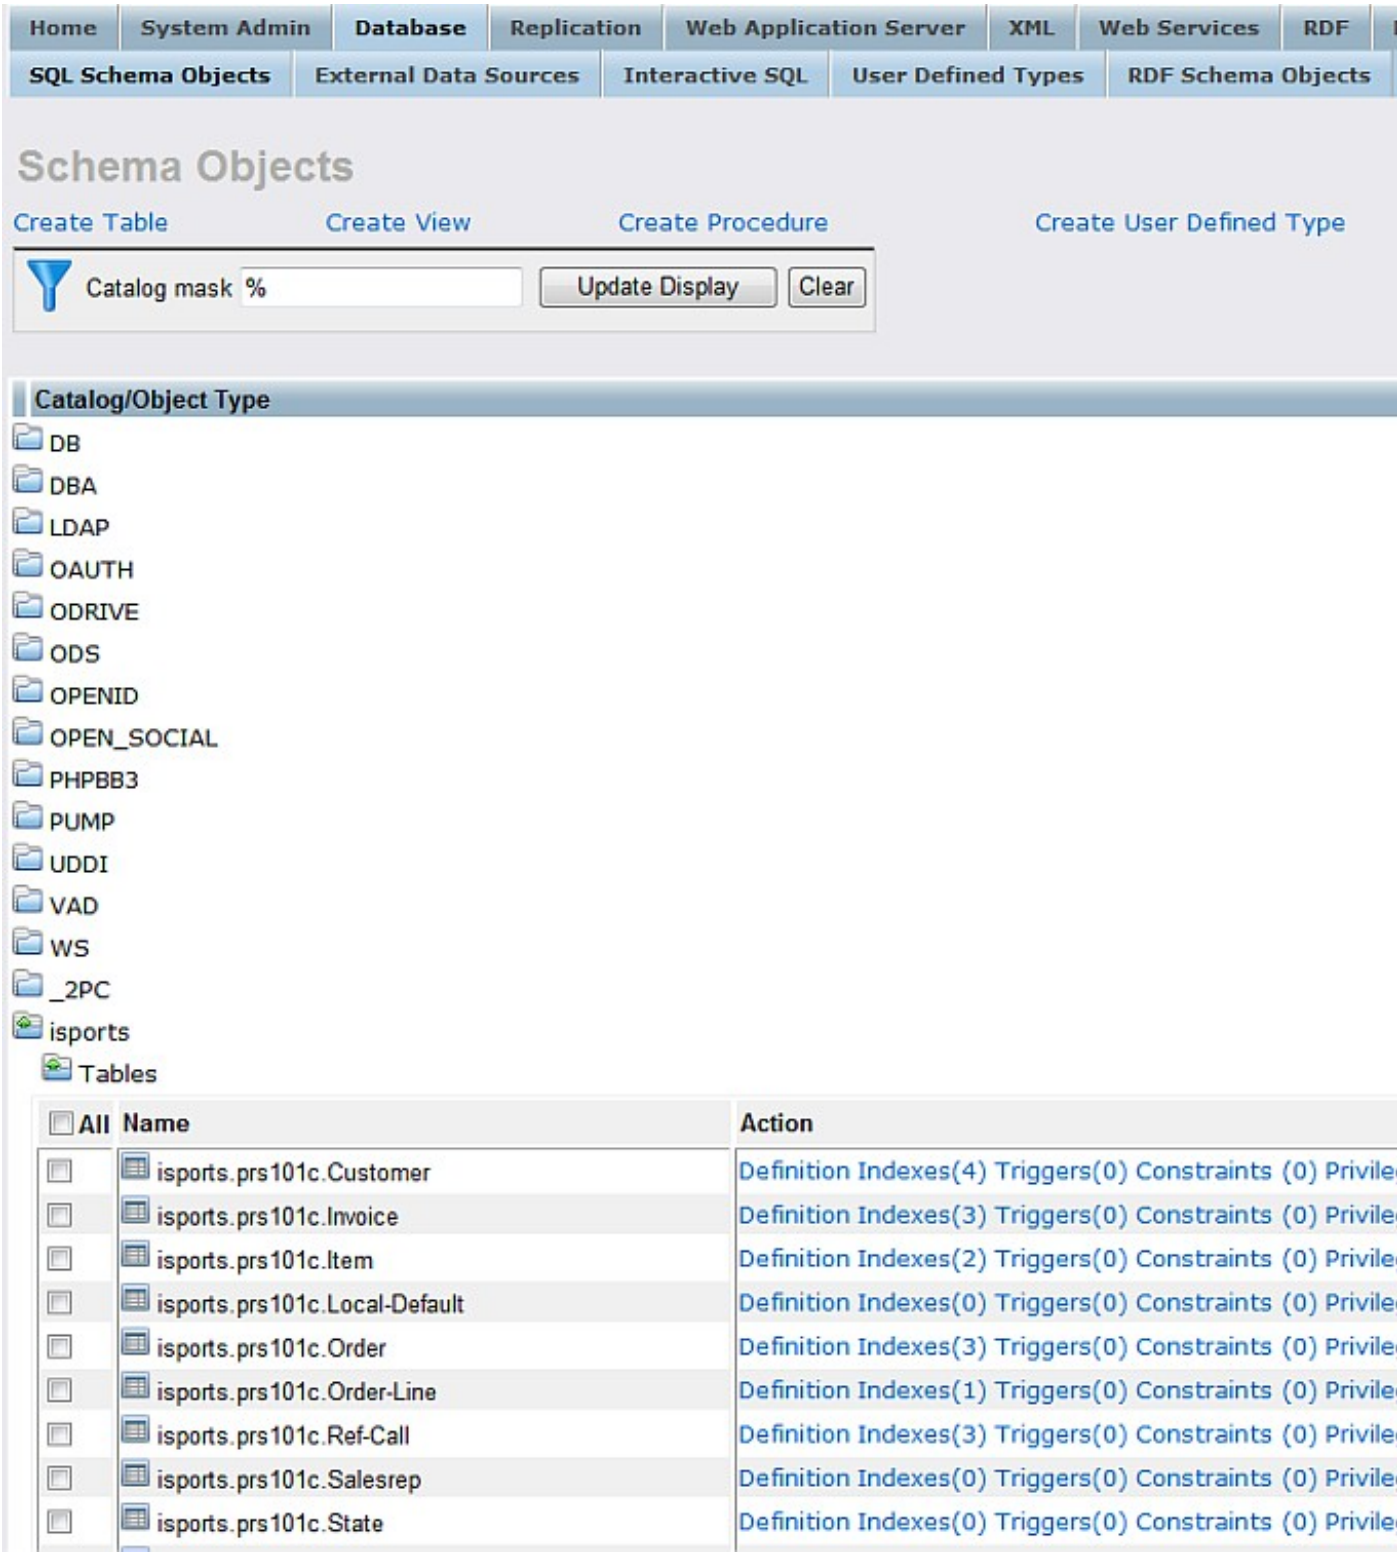
Figure 8.78. Execute



Cust-Num INTEGER	Name VARCHAR	Address VARCHAR	Address2 VARCHAR	City VARCHAR	State VARCHAR
1	Lift Line Skiing	276 North Street		Boston	MA
2	Urpon Frisbee	Rattipolku 3		Valkeala	Uusimaa
3	Hoops Croquet Co.	Suite 415	40 Grove St.	Hingham	MA
4	Go Fishing Ltd	Unit 2	83 Ponders End Rd	Harrow	Middlese
5	Match Point Tennis	66 Homer Ave		Cono	MA
6	Fanatical Athletes	20 Bicep Bridge Rd	Leyton	Aberdeen	Grampian
7	Aerobics väline KY	Peltolantie 2		Tikkurila	Uusimaa
8	Game Set Match	Box 60		Sundsvall	
9	Pihtiputaan Pyörä	Putikontie 2		Pihtipudas	Etelä-Sa
10	Just Joggers Limited	Fairvind Trading Est	Shoe Lane	Ramsbottom	Lancashi
11	Keilailu ja Biljardi	Vattuniemenkuja 8 A		Helsinki	Uusimaa
12	Surf Lautaveikkoset	Venemestarinkatu 35		Salo	Varsinai
13	Biljardi ja tennis	Urheilutie 1		Mäntsälä	Uusimaa
14	Paris St Germain	113, avenue du Stade	BP 338	Paris	Seine
15	Hoopla Basketball	87 Calumnet St		Egg Harbor	NJ
16	Thundering Surf Inc.	354 Market St.		Coffee City	TX
17	High Tide Sailing	178 Schooner Hill	South Killingholme	Inninghan	Humbersi
18	Antin Metsästysase	Vanhainkodinkuja 1		Sysmä	Keski-Su
19	Buffalo Shuffleboard	155 Carolina Ave		Buffalo	NY
20	Espoon Pallokeskus	Sinikalliontie 18		Espoo	Uusimaa
21	Pedal Power Cycles	11 Perkins St		Boston	MA
22	Kesport Katiska	Koskisillantie 4		Forssa	Etelä-Hä
24	Jazz Futis Kauppa	Yrjönkatu 10		Pori	Satakunt
25	La Boule Lyonnaise	rue de la gare	Z.A. Bellecourt	Lyon	Rhone

13. The tables can also be viewed as part of the Virtuoso "SQL Schema Objects" under the "isports" catalog name.

Figure 8.79. SQL Schema Objects



The Link process is now complete enabling the tables to be queried as if part of the Virtuoso Schema.

8.3.4. Creating EDM in Visual Studio 2008

The following steps can be used to create an Entity Data Model (EDM) for the Progress isports database:

1. Launch the Visual Studio 2008 SP1 IDE.

Figure 8.80. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

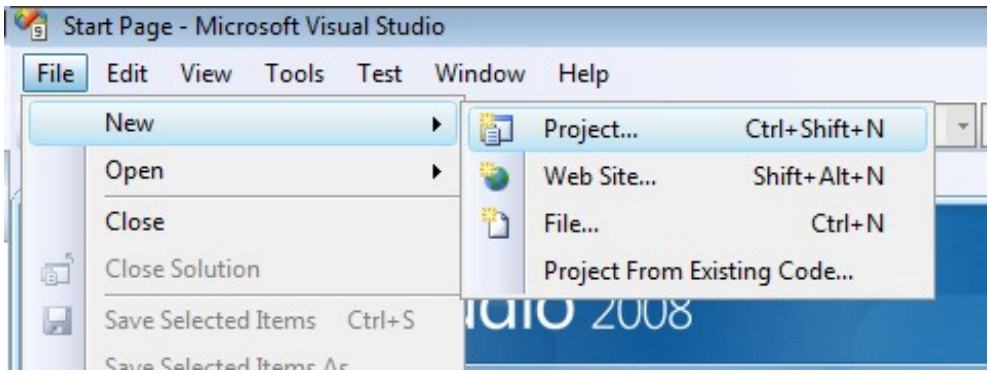
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.81. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Web

   and select

   ASP.NET Web Application

from the right-hand panel.

5. Choose a name for the project, for example

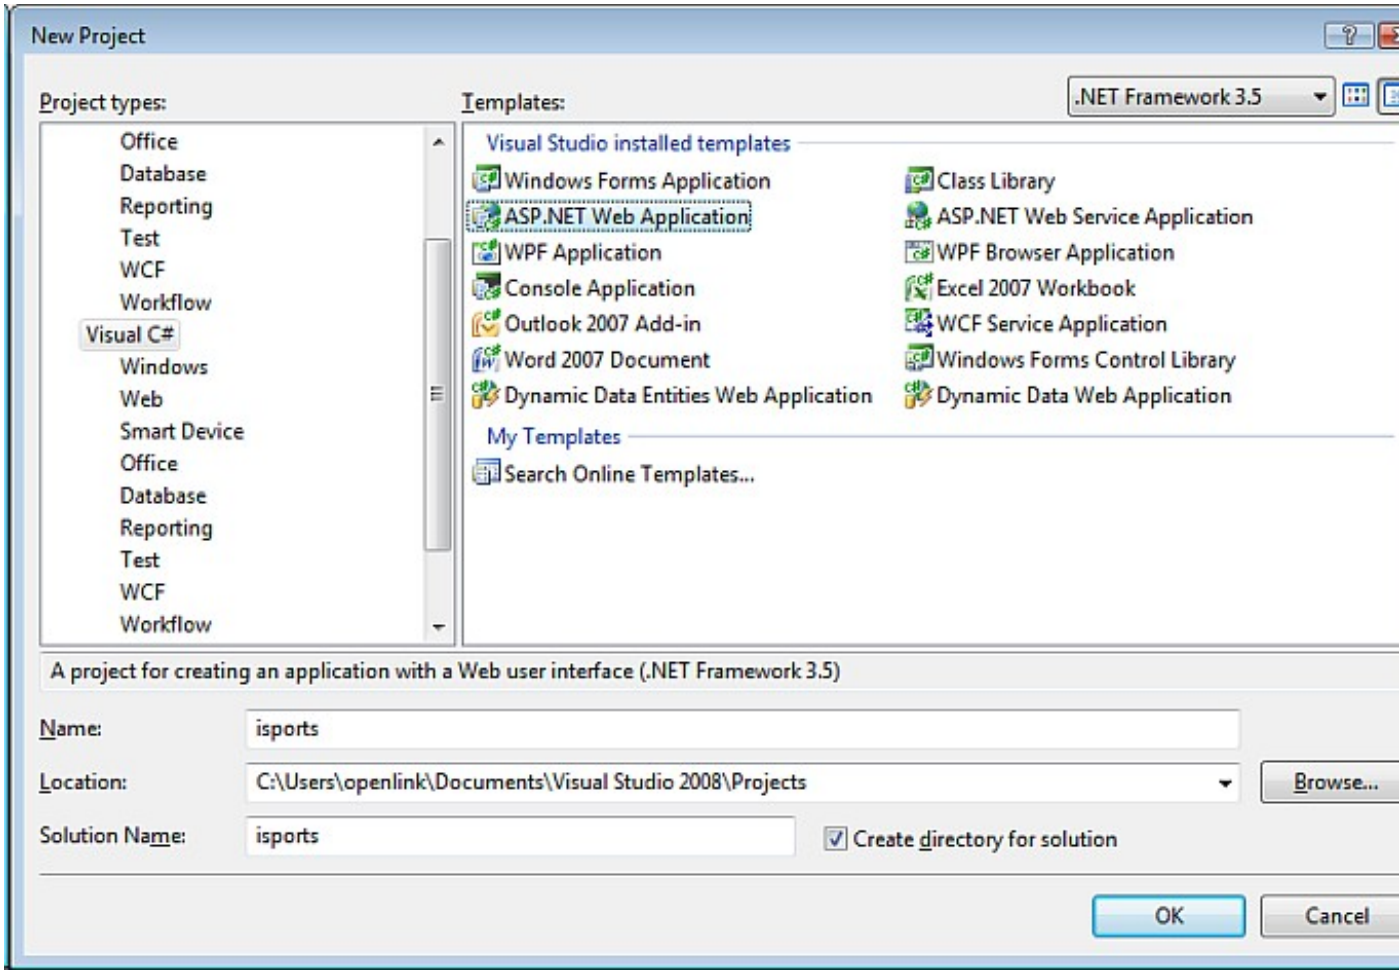
   isports

   , and click

   OK

   .

Figure 8.82. Name for the project

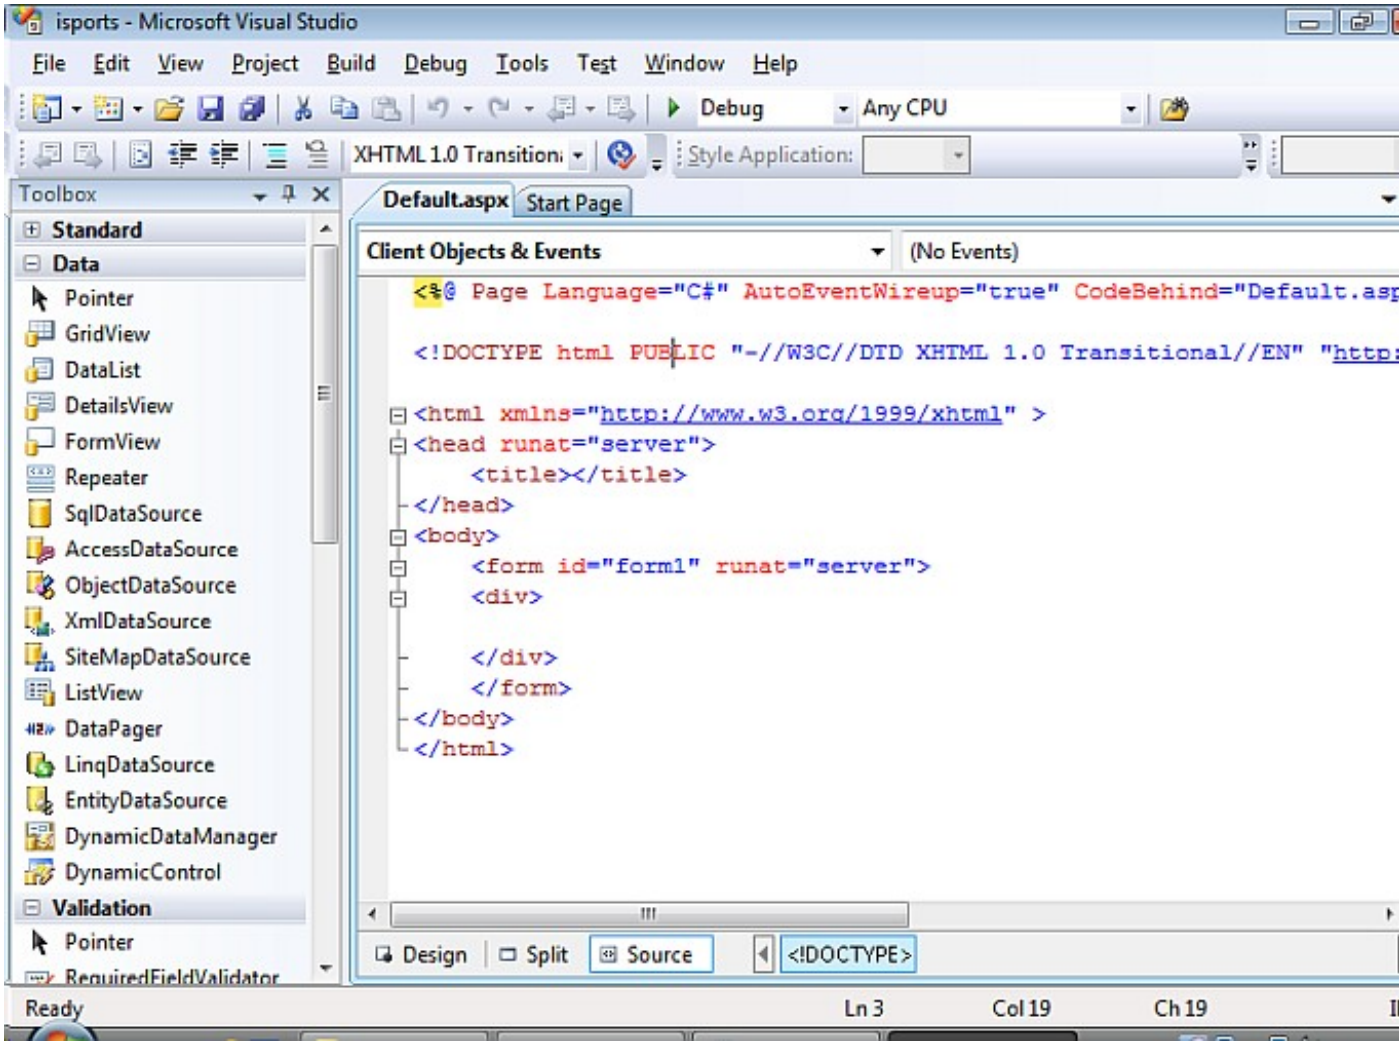


6. This will create a new project called

   isports

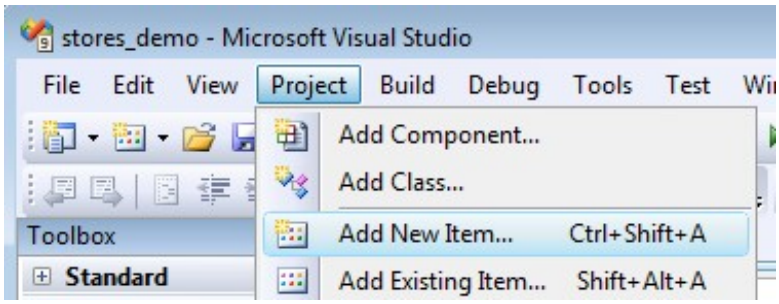
   .

Figure 8.83. create a new project



7. Select the Project -> Add New Item menu option.

Figure 8.84. New Item



8. The

Add New Item

dialog will appear. Choose the

ADO.NET Entity Data Model

template. Give it the name

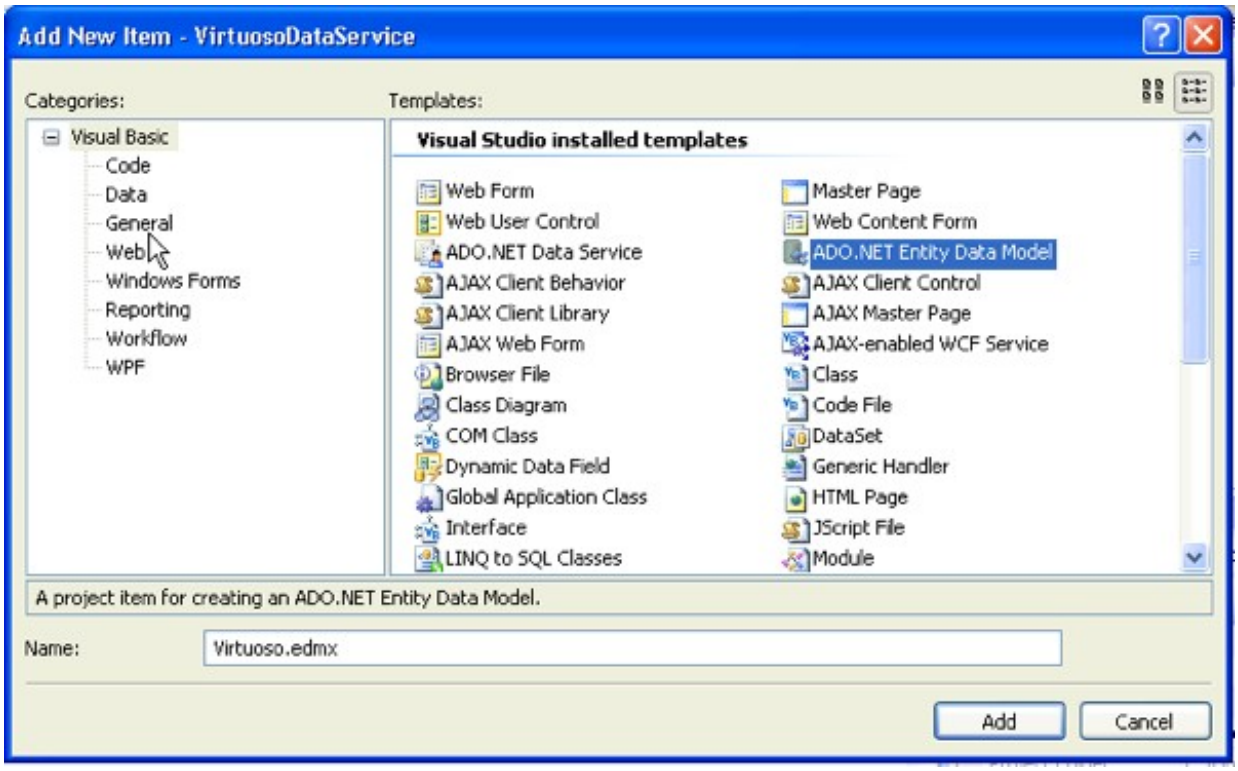
Model1.edmx

and click

Add

to start the creation of the ADO.Net Entity Data Model.

Figure 8.85. Add New Item



9. In the

Entity Data Model Wizard

dialog

Choose Model Contents

page select the

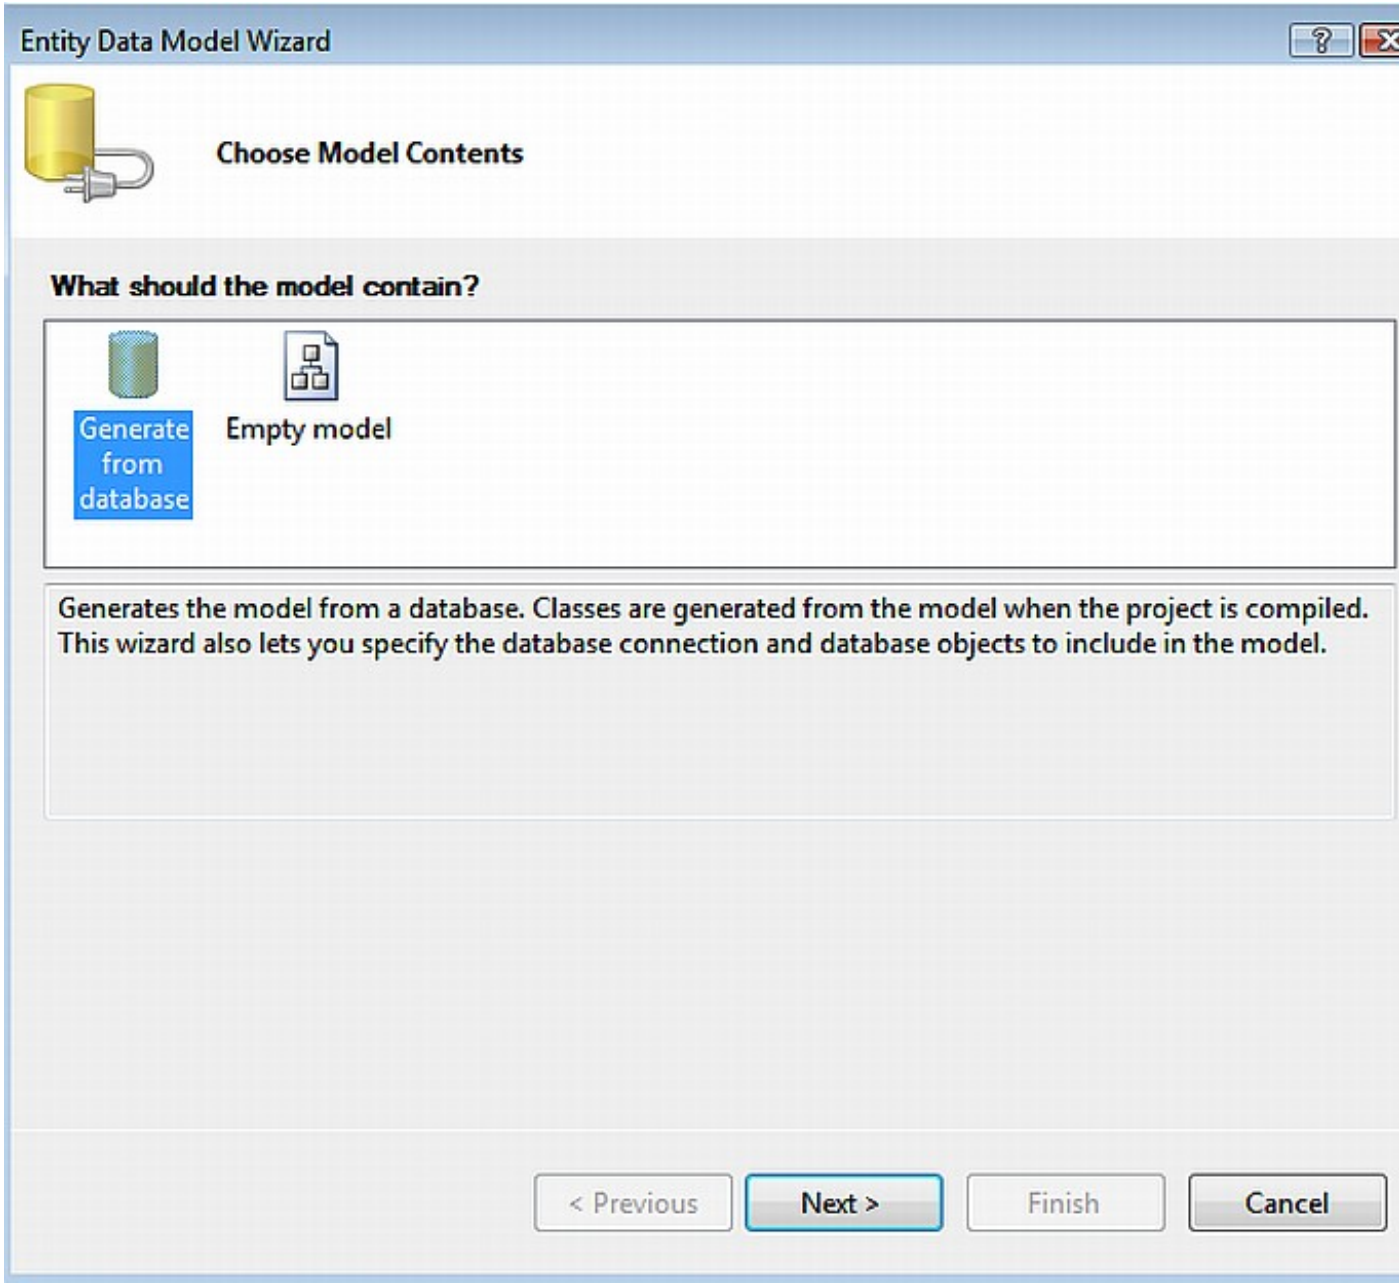
Generate from Database

model type and click

Next

.

Figure 8.86. Choose Model Contents



10. In the

    Entity Data Model Wizard

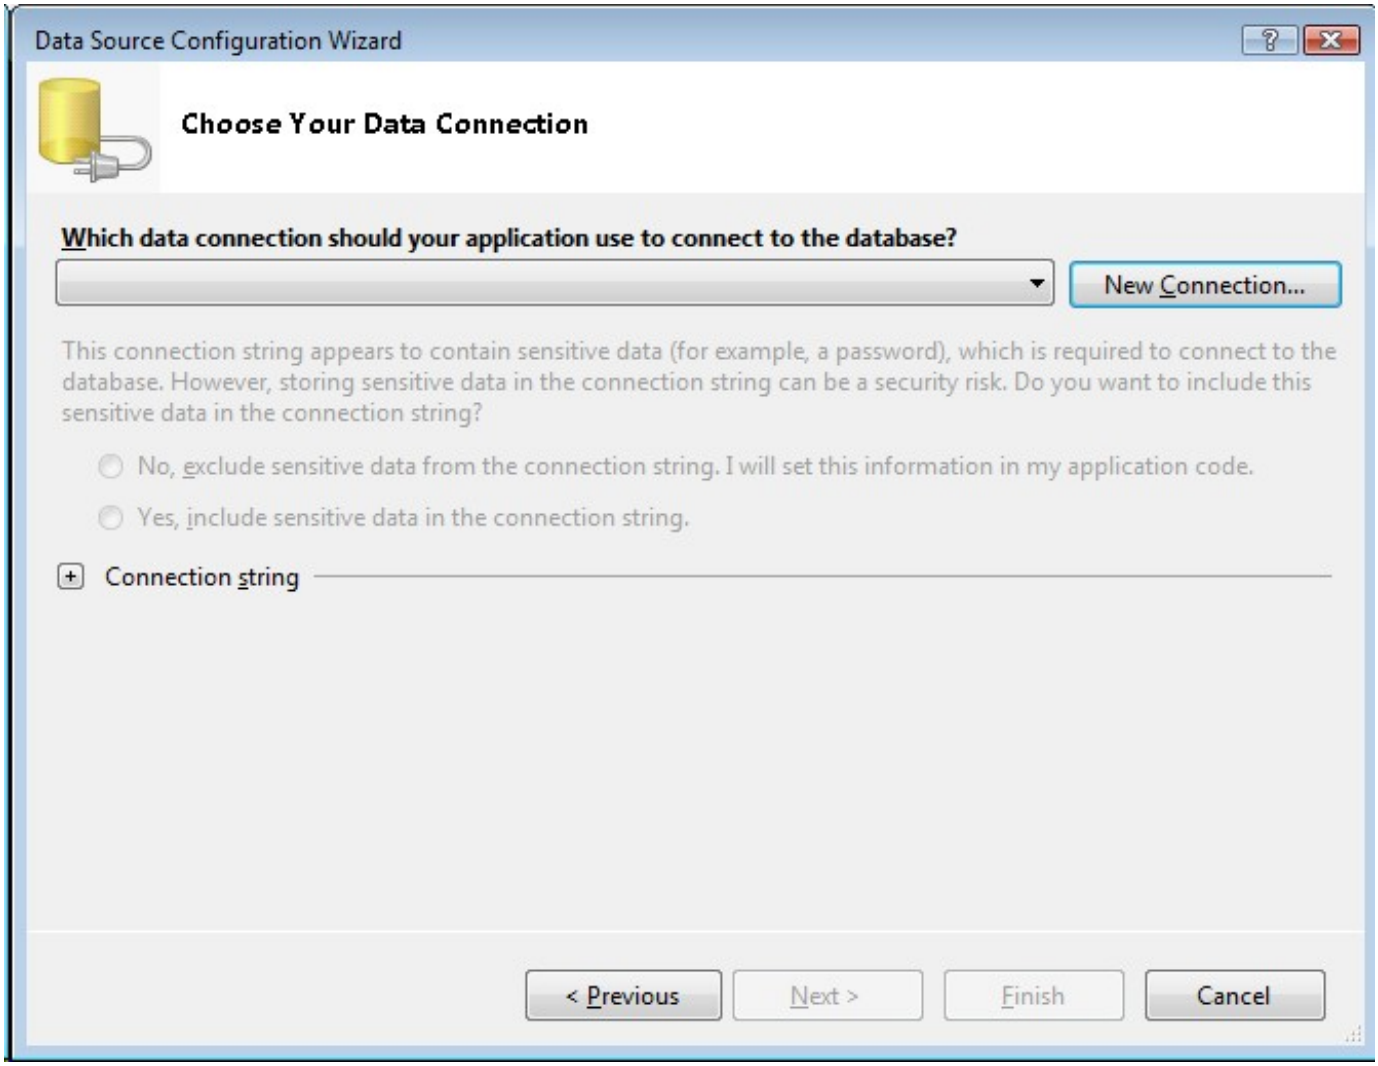
    dialog

    Choose your Data Connection

    page, select the

    New Connection button

Figure 8.87. Entity Data Model Wizard



11. In the

    Choose Data Source

    dialog, select the OpenLink

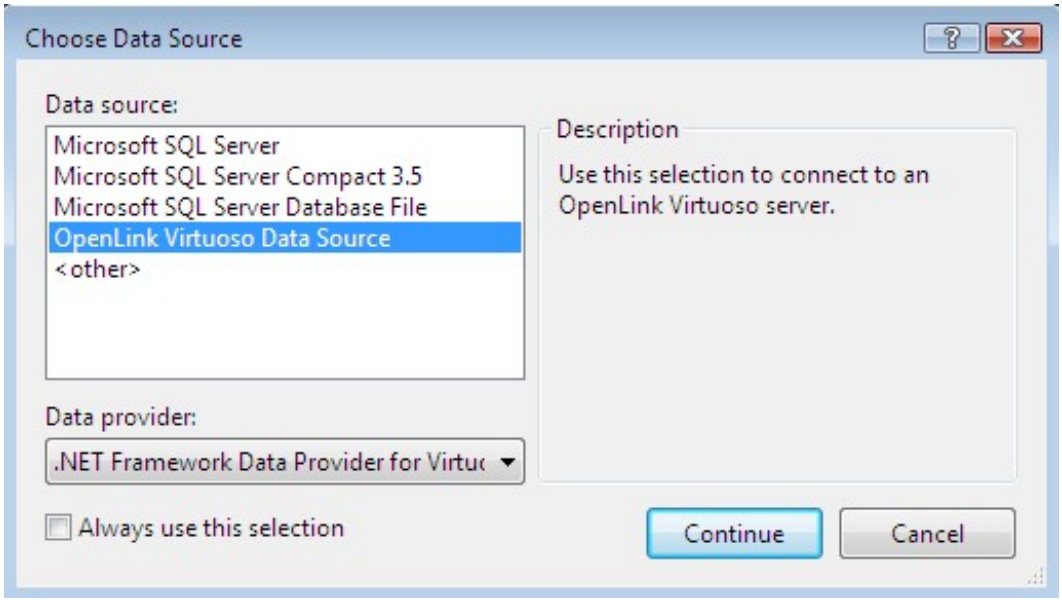
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.88. Choose Data Source



12. In the

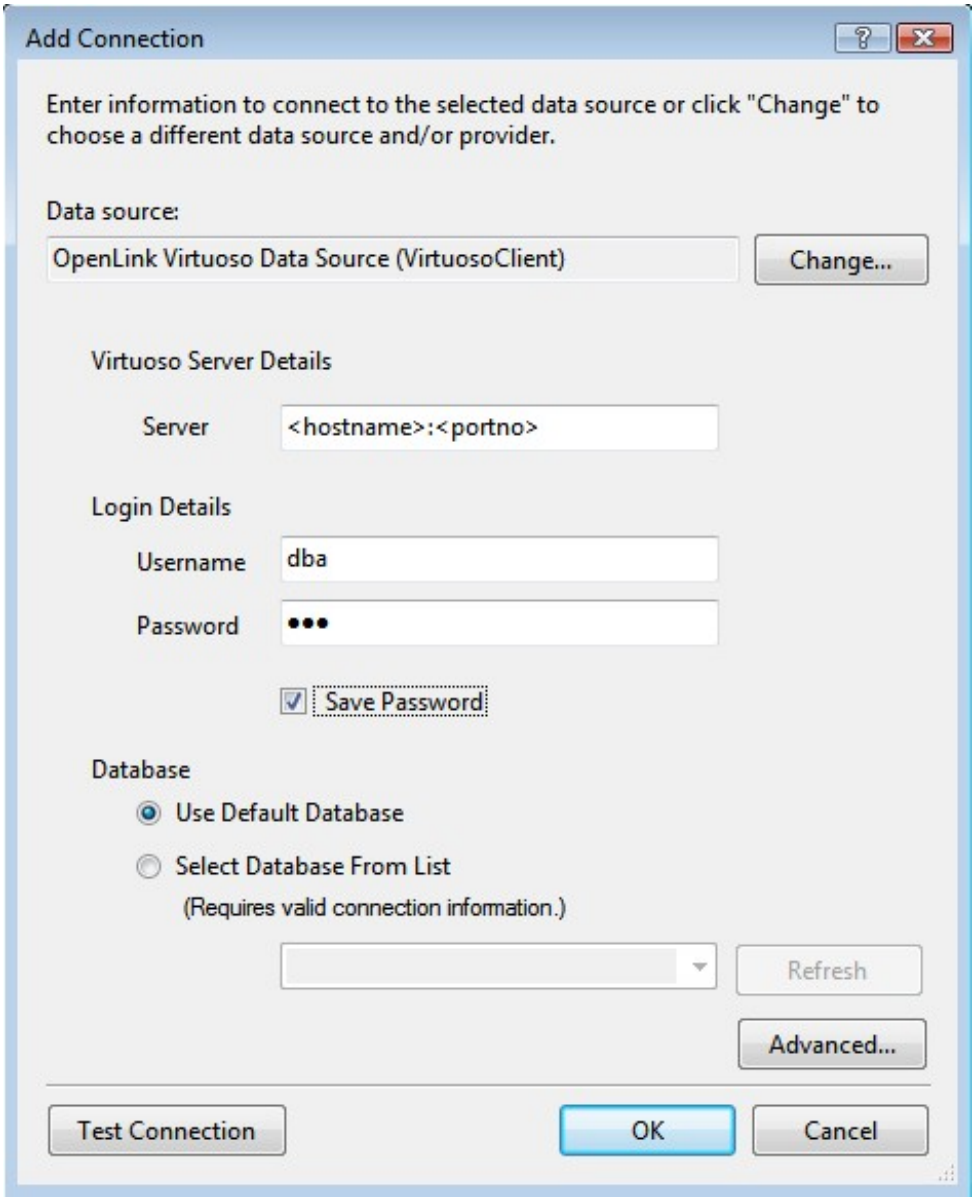
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.89. Connection Properties



13. Select the

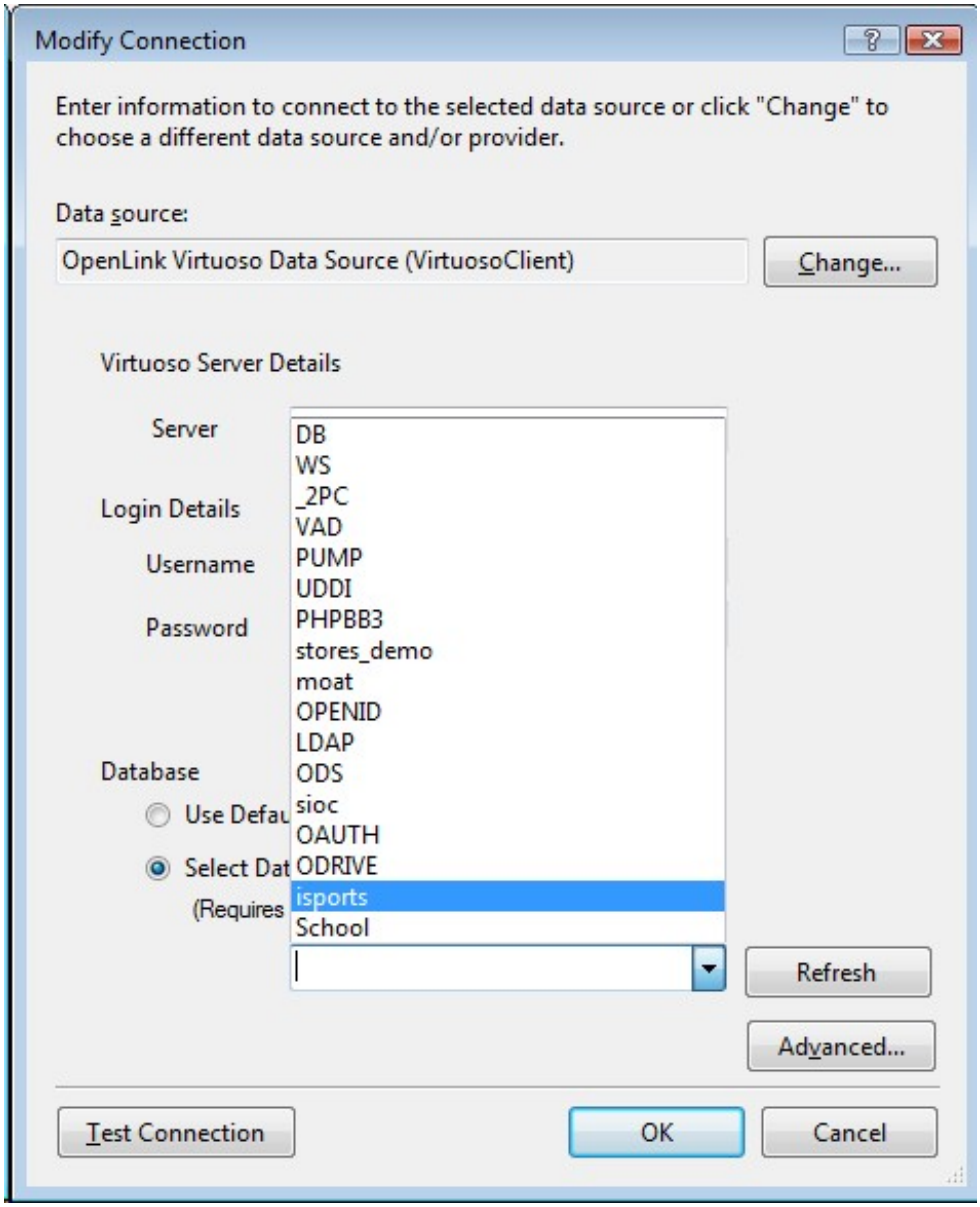
    Select Database From List

    radio button and choose the

    isports

    database from the drop down list.

Figure 8.90. Add connection

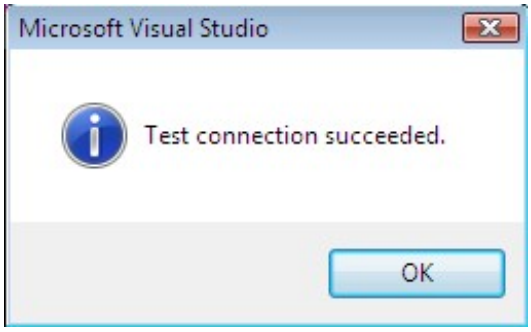


14. Press the

    Test Connection

    dialog to verify that the database is accessible.

    Figure 8.91. Test Connection



15. Set the

    entity connect string

name to

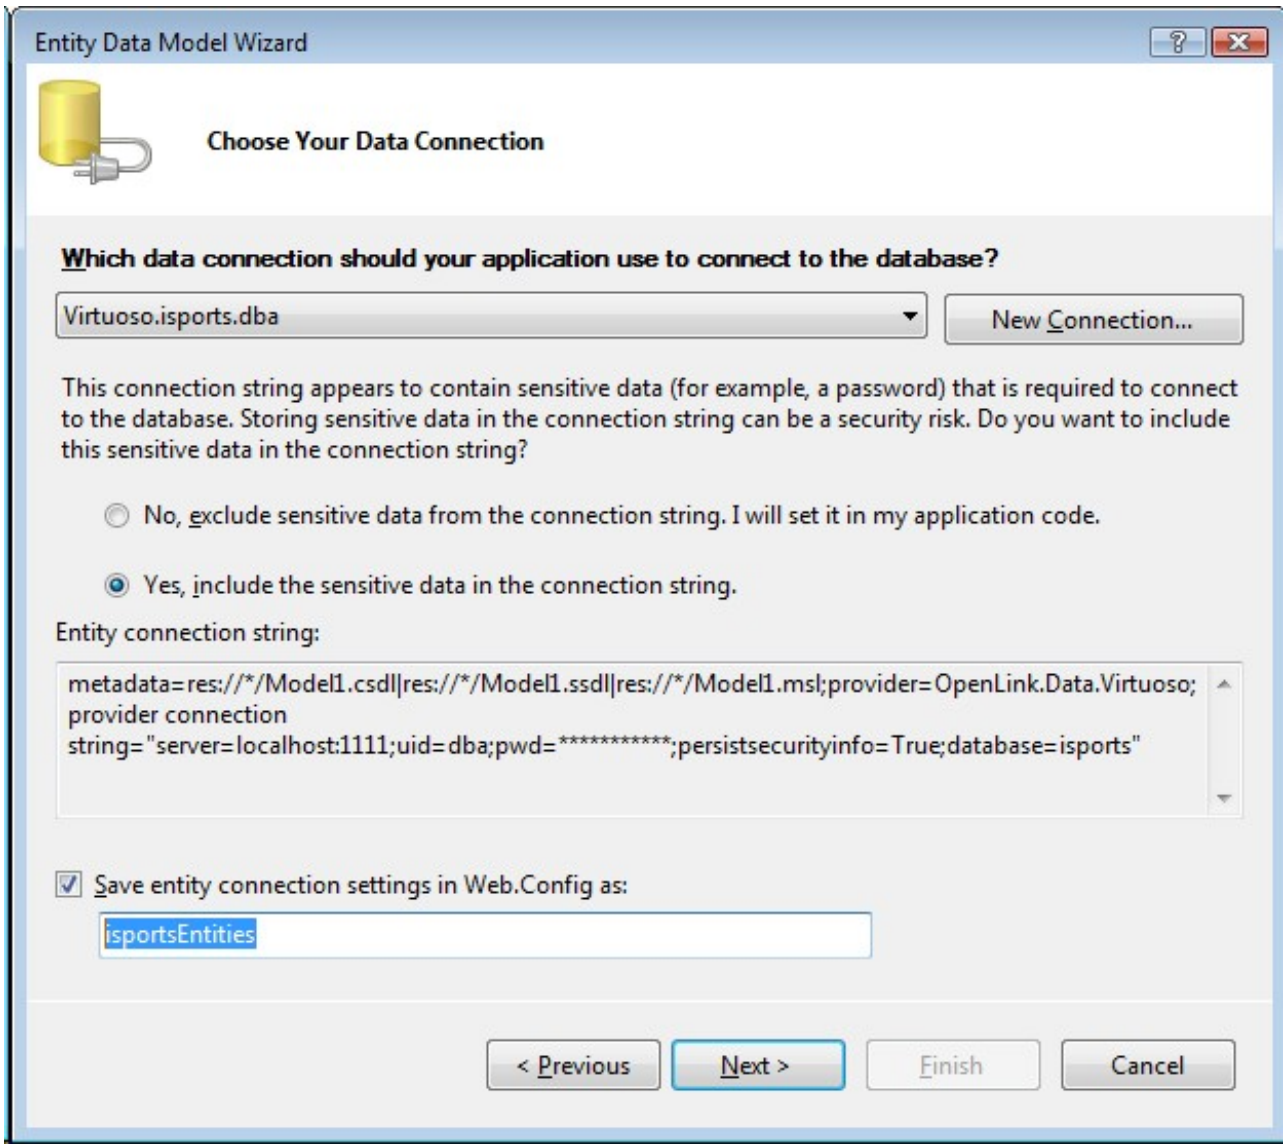
isportsEntities

(note this name as it is required in the section on creating and ADO.Net Data Service) and click

Next

.

Figure 8.92. entity connect string



16. In the

Choose your Database Objects

page select the

Tables

check box to select all tables in the isports catalog for addition to the Entity Data Model. Set the

Model Namespace

to

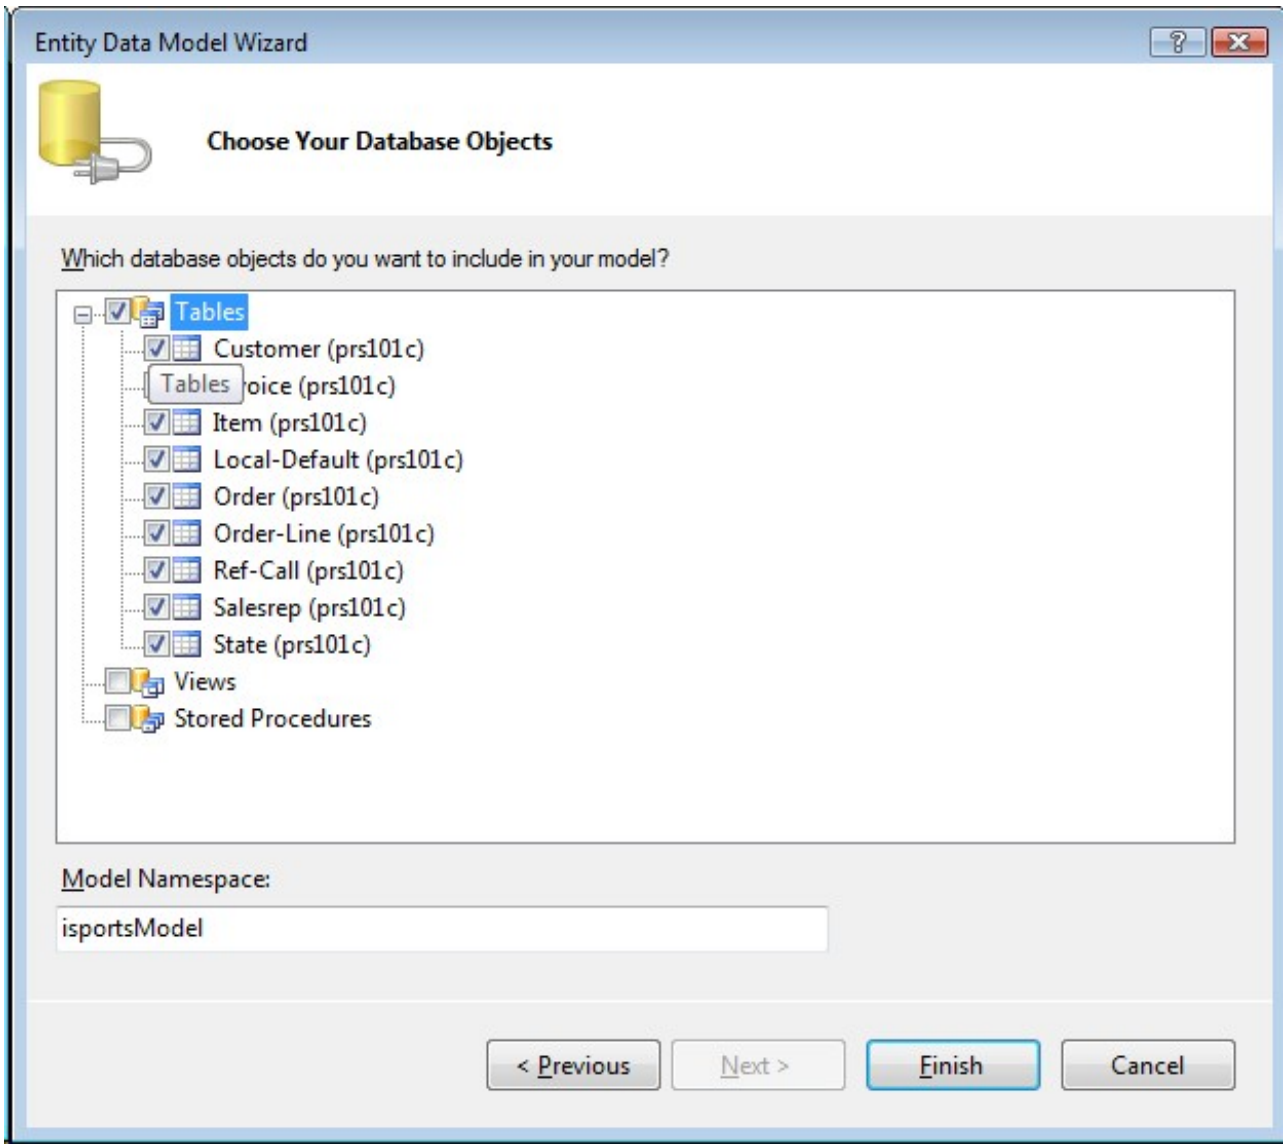
isportsModel

and click

Finish

.

Figure 8.93. Database Objects

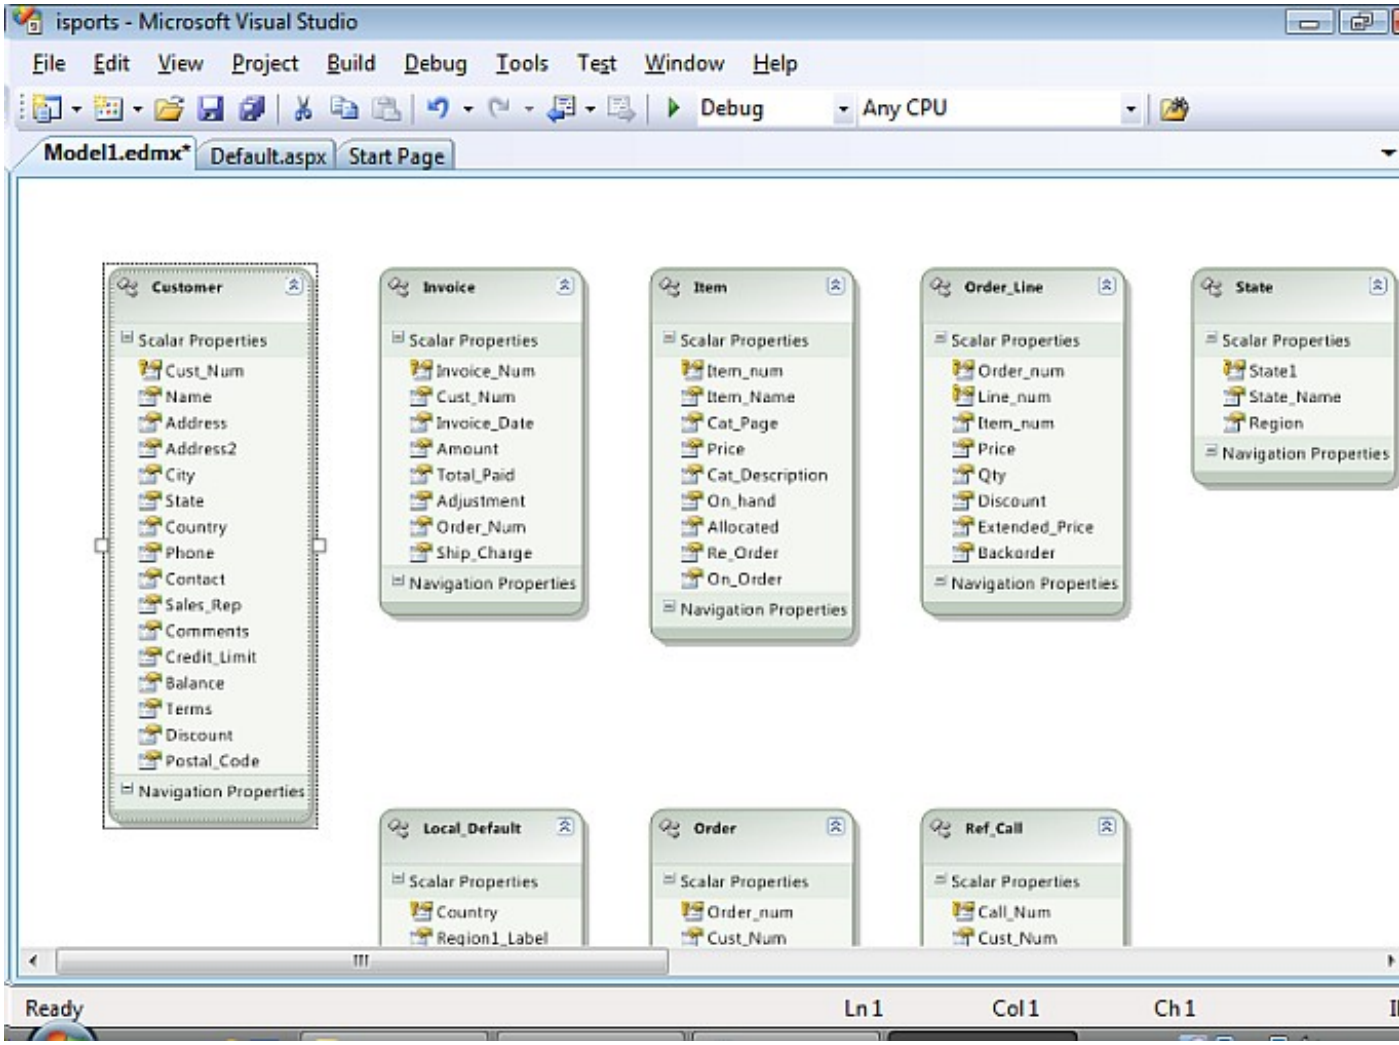


17. The

Model1.edmx

EDM will be created with the tables and relationships displayed in the Visual Studio IDE.

Figure 8.94. Virtuoso.edmx



Creation for the Entity Data Model for the Progress isports database is now complete.

8.3.5. Manually creating EDM Associations (FKs) for the Progress isports database

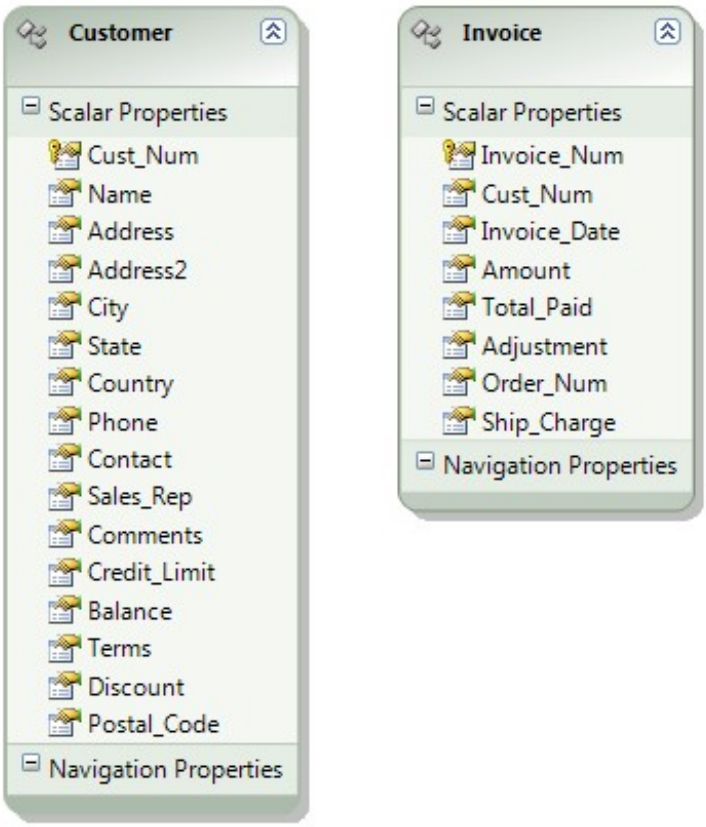
The following steps will detail what is required to manually create "Associations" in your Entity Data Model.

You will need to determine where these associations exist and their multiplicity (one-to-one, one-to-many, etc.) before commencing with the following steps.

Note: These steps will need to be repeated for each association.

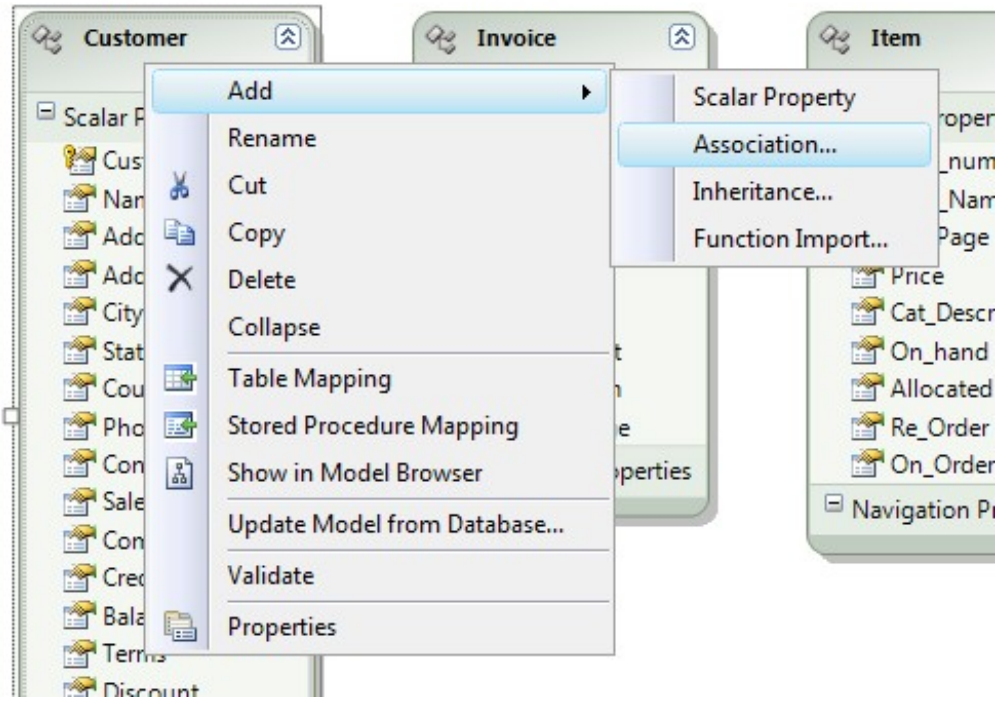
1. The first Association will deal with is the relationship between Customer and Invoice, identified by the presence of the scalar property Cust_Num in both entities. This is a one-to-many relationship, as a Customer may have any number of Invoices.

   Figure 8.95. Association



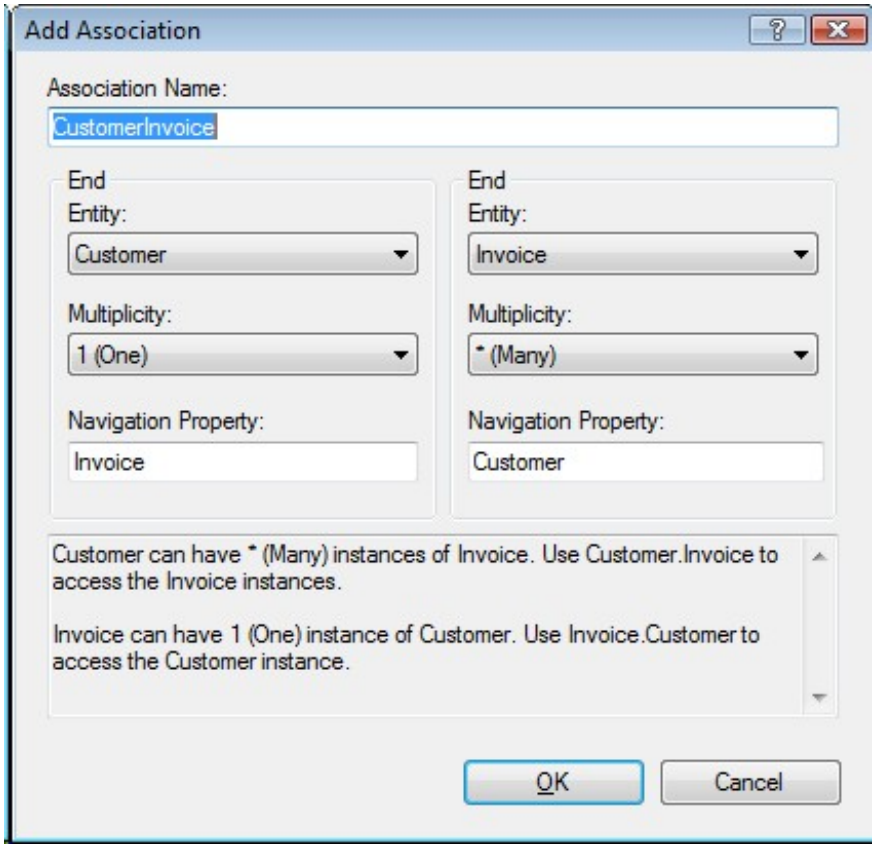
2. To add the Association, right click on the Customer entity then Add -> Association.

Figure 8.96. add the Association



3. You will now see the Add Association dialog.

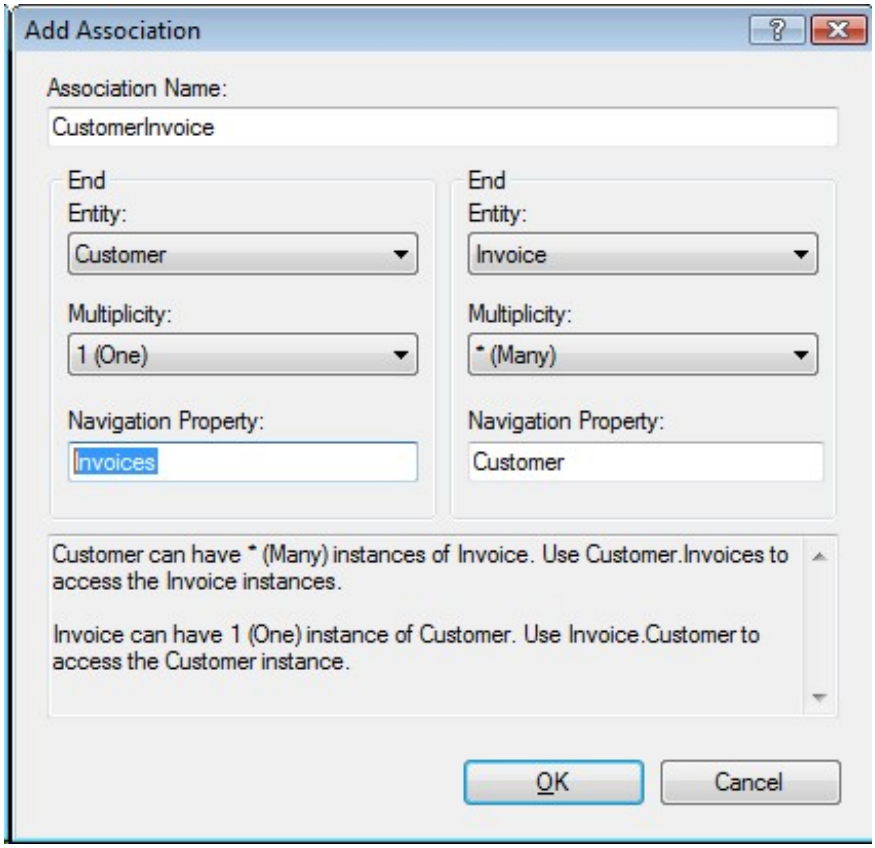
Figure 8.97. Add Association dialog



4. For this association the only thing that needs changing from the default, is the name of the Navigation Property from Invoice to invoices on the Customer end of the association.

   This better reflects the multiplicity of the association such that a Customer is associated with zero or many Invoices (plural).

Figure 8.98. Navigation Property name

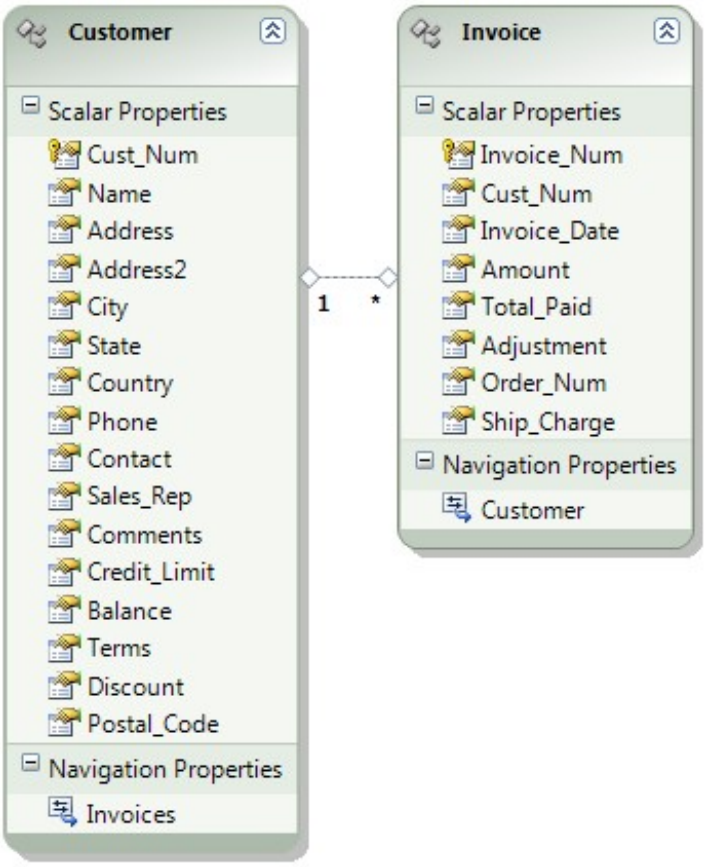


Typically, here is where you will:

- Select the entity at each end of the association
- Select the multiplicity of each end of the association, and
- Provide suitable names for the association and its navigation properties

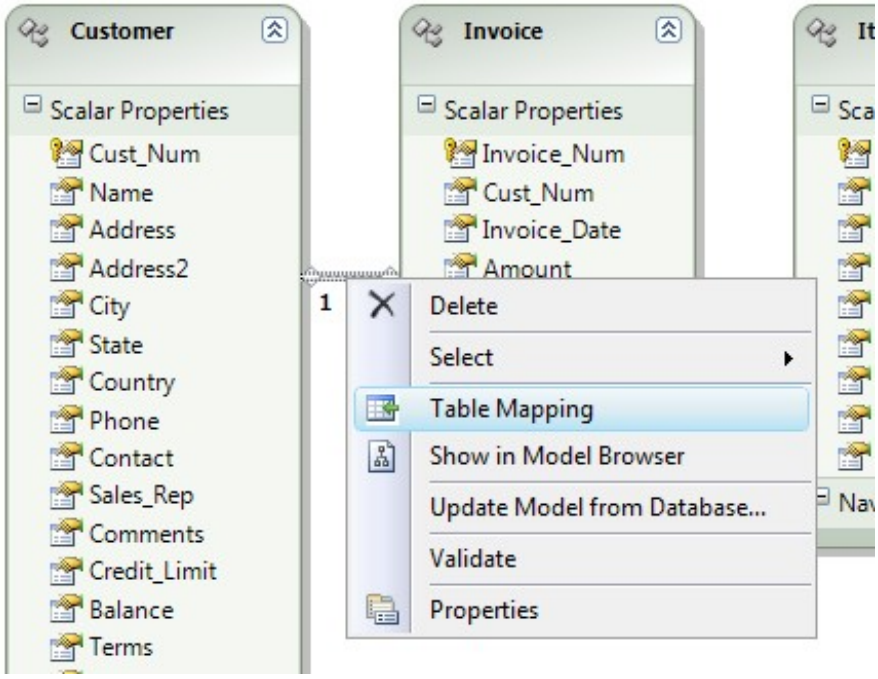
5. Once you then hit OK the diagram is refreshed to include the newly created association.

Figure 8.99. diagram



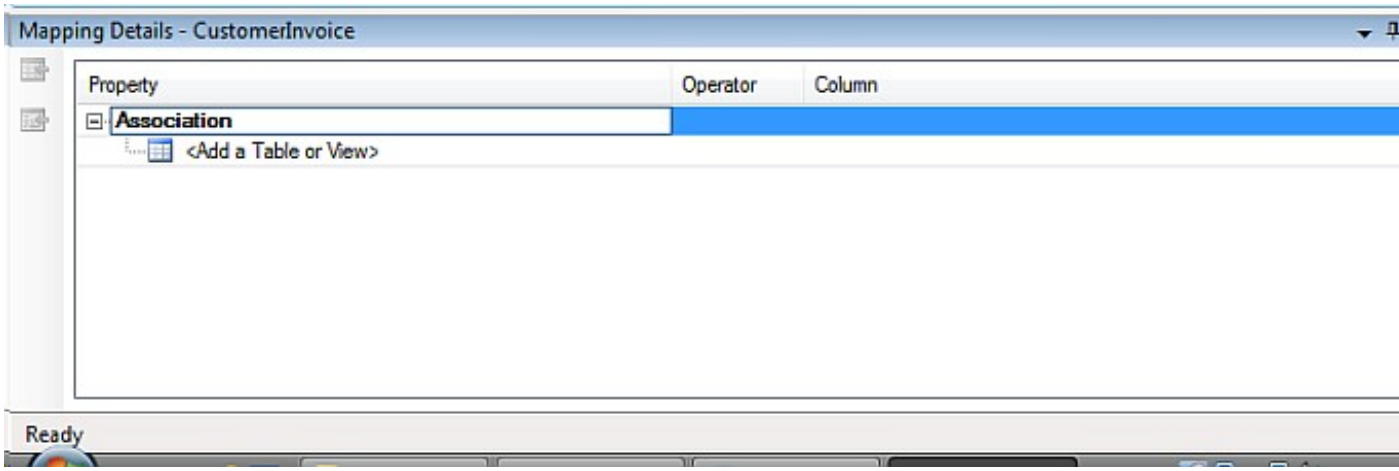
6. You now need to edit the mappings associated with the newly created association, so right-click the association on the diagram, and select Table Mapping to display the Mapping Details pane.

Figure 8.100. Table Mapping



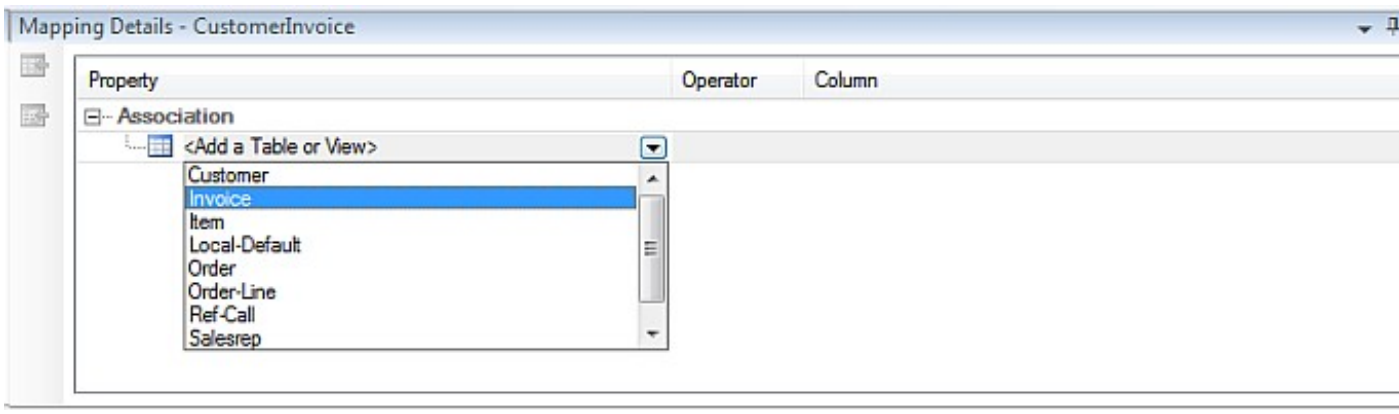
7. Click that line reading <Add a Table or View> to reveal a drop down list of all entities.

Figure 8.101. Add a Table or View



8. Here you need to select the entity on the right/far side of the association (the entity where the foreign key exists). In this example, it is the Invoice entity.

Figure 8.102. Entity



9. The Mapping Details pane now refreshes to display both ends of the association, requiring that you provide relevant target store data types in the Column column for the key fields, as depicted here.

Figure 8.103. Mapping Details

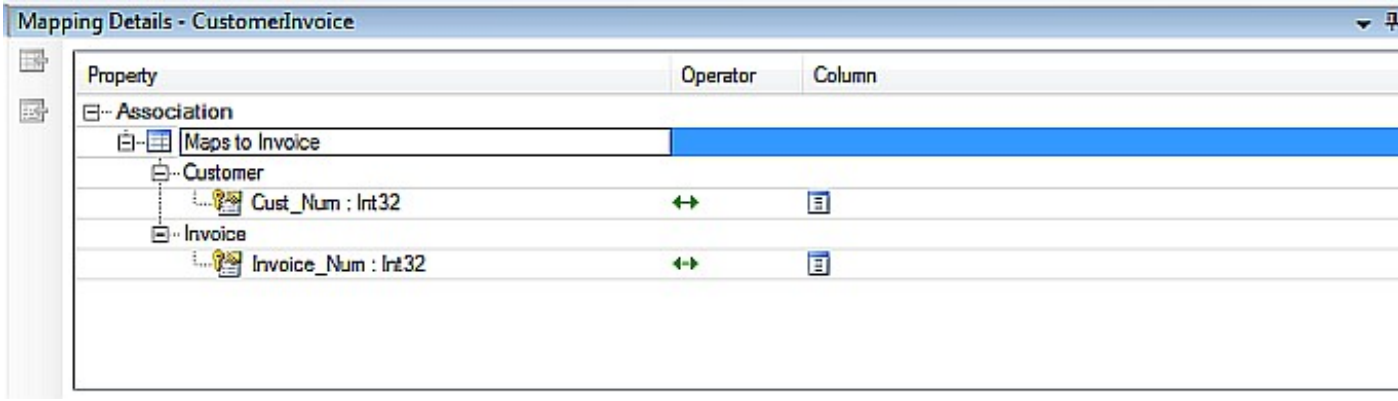


Figure 8.104. Mapping Details

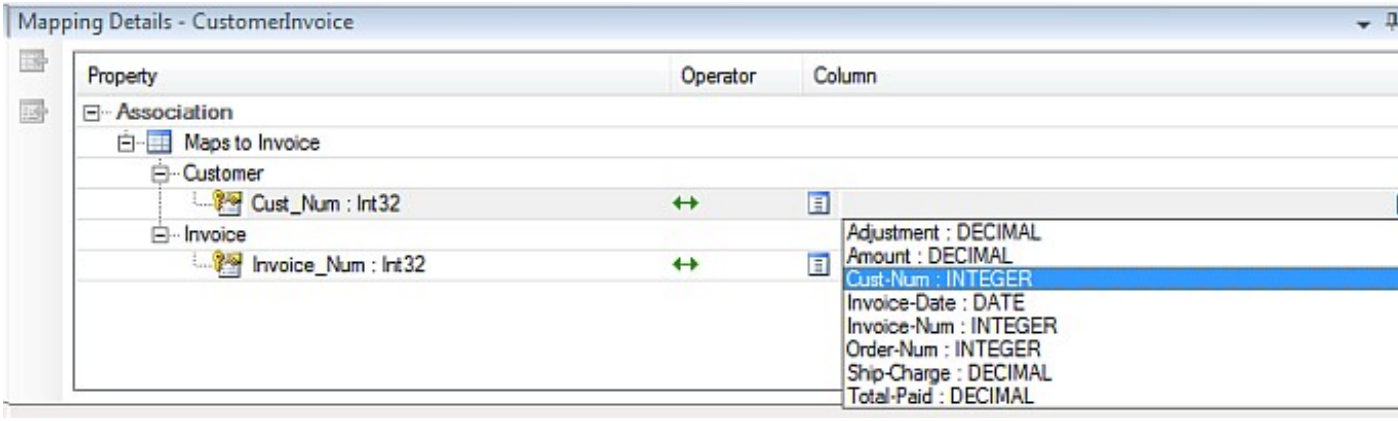

Figure 8.105. Mapping Details

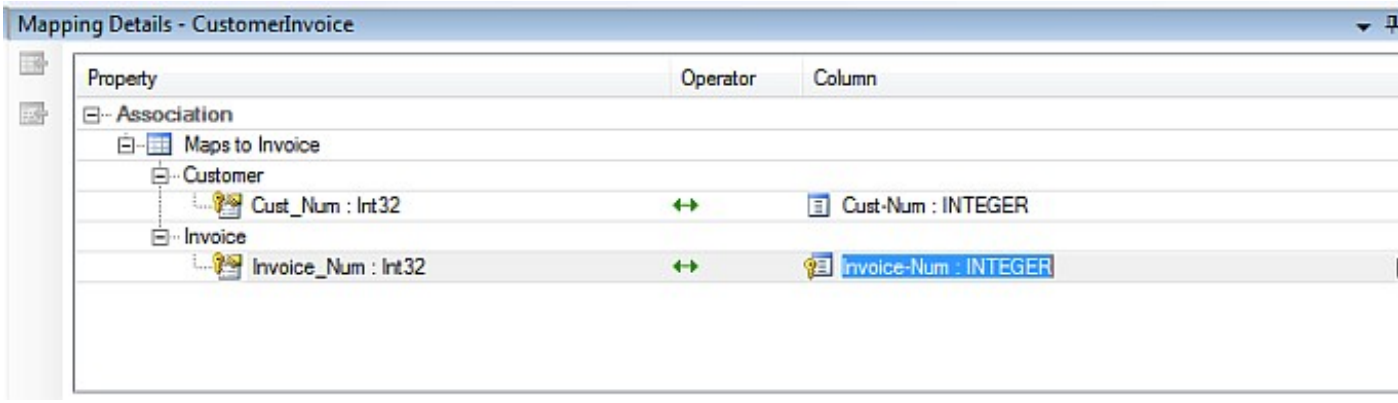
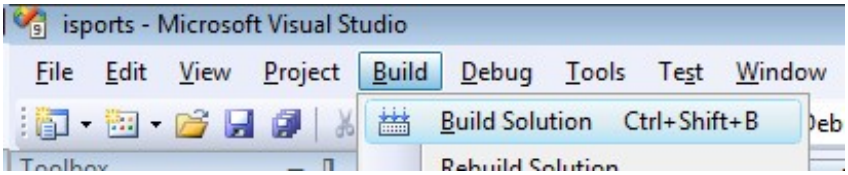


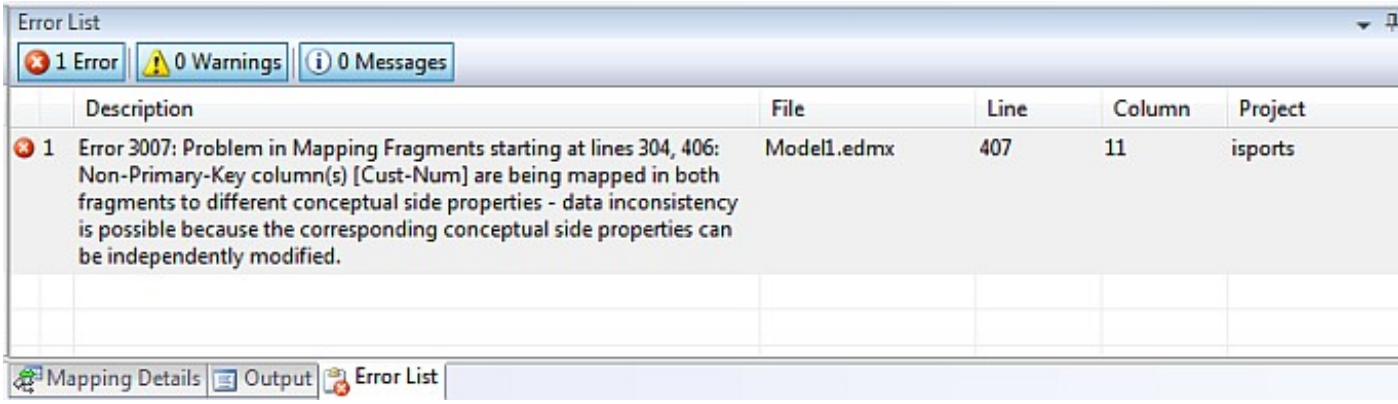
10. Once the mapping is complete, you can build the project using Build -> Build Solution. NOTE: It is worthwhile building as each association is made, since the error messages can be a little confusing.

Figure 8.106. Build the project



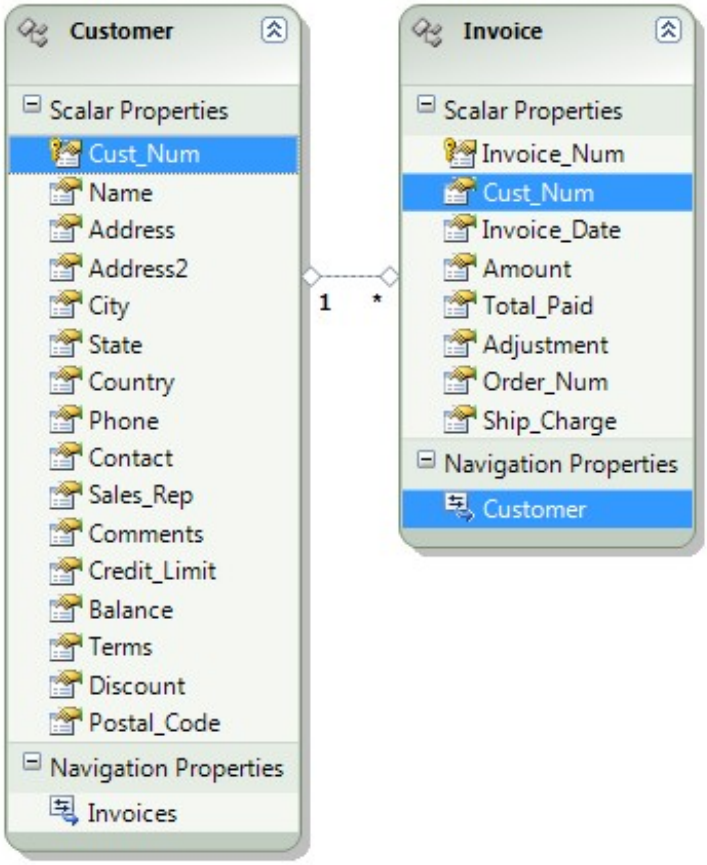
11. This should result in the following error:

Figure 8.107. Error



This error indicates that there are two source columns - in this case, the Invoice entity's Scalar Property Cust_Num and Navigation Property Customer, which are both mapped to the same target column - the Progress column Invoice.Cust_Num - and this is not supported.

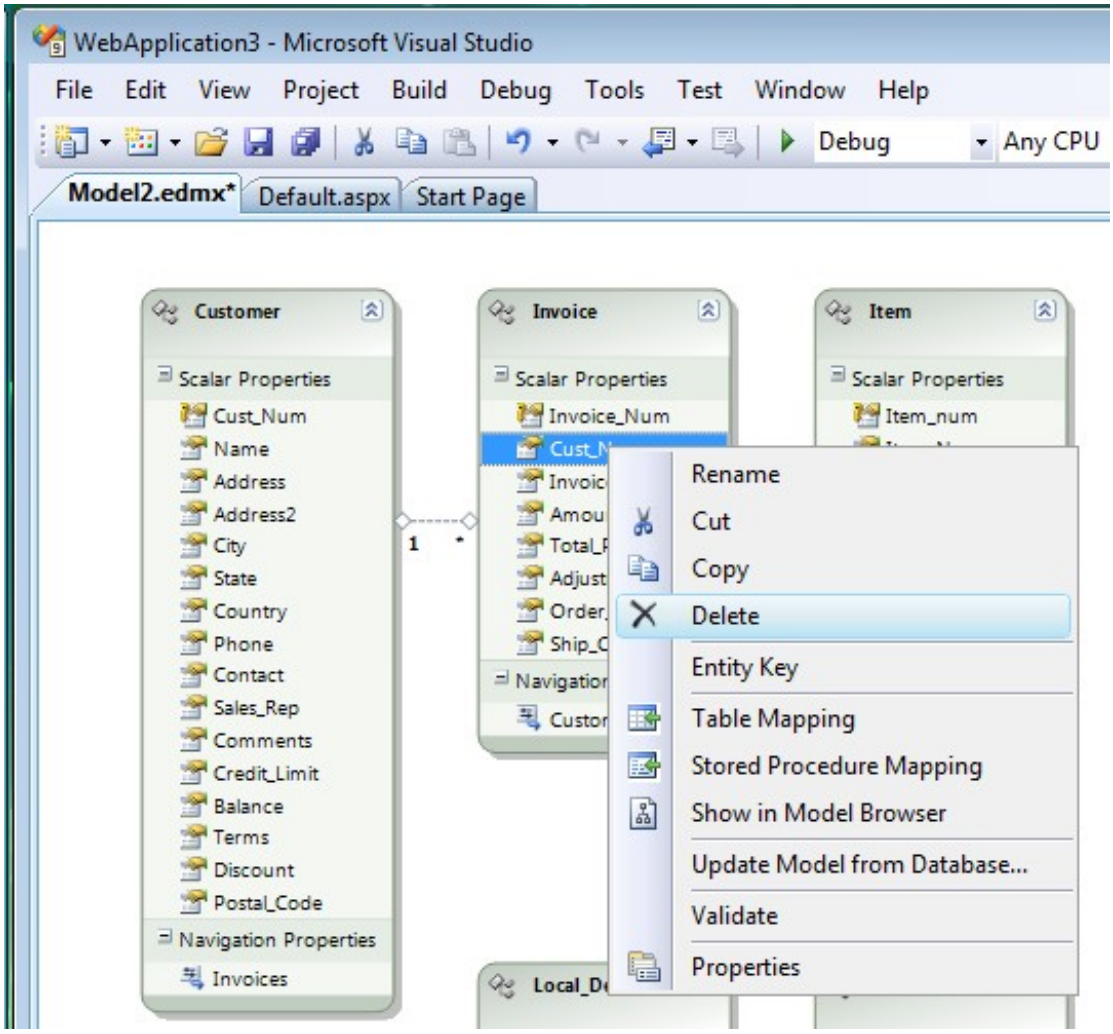
Figure 8.108. Error



12. The solution is simple! Simply delete the mapping of the Scalar Property Invoice.Cust_Num, since its only purpose is to hold data representing a relationship/association (it is a Foreign Key) which has already been represented by the newly created association and resulting Navigation Property Customer.

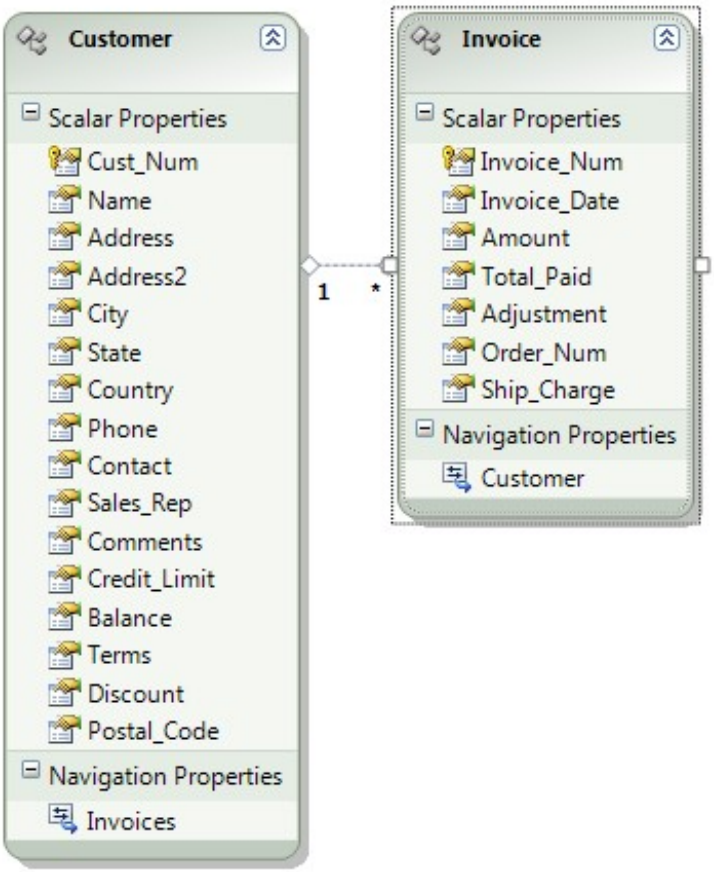
    Right click on Invoice.Cust_Num then Delete.

Figure 8.109. delete the mapping



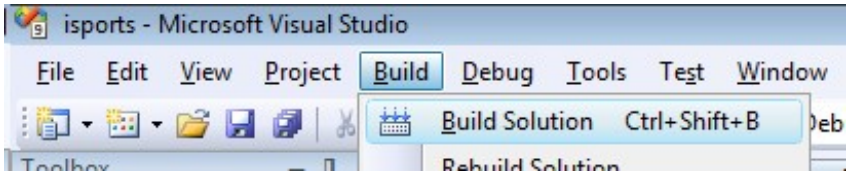
13. The model diagram will refresh to reflect this change.

Figure 8.110. Model Diagram



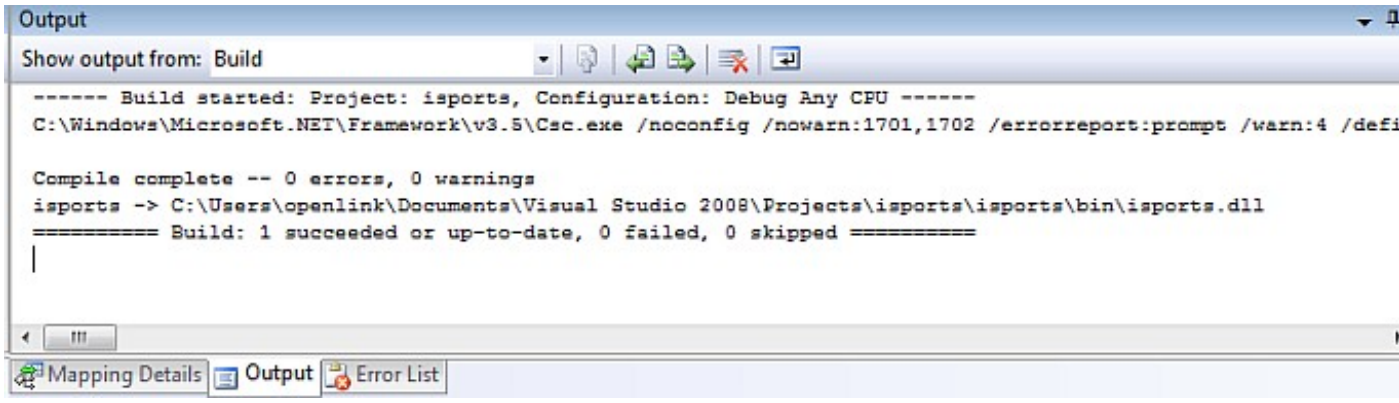
14. Build the project, again, using Build -> Build Solution.

Figure 8.111. Build project



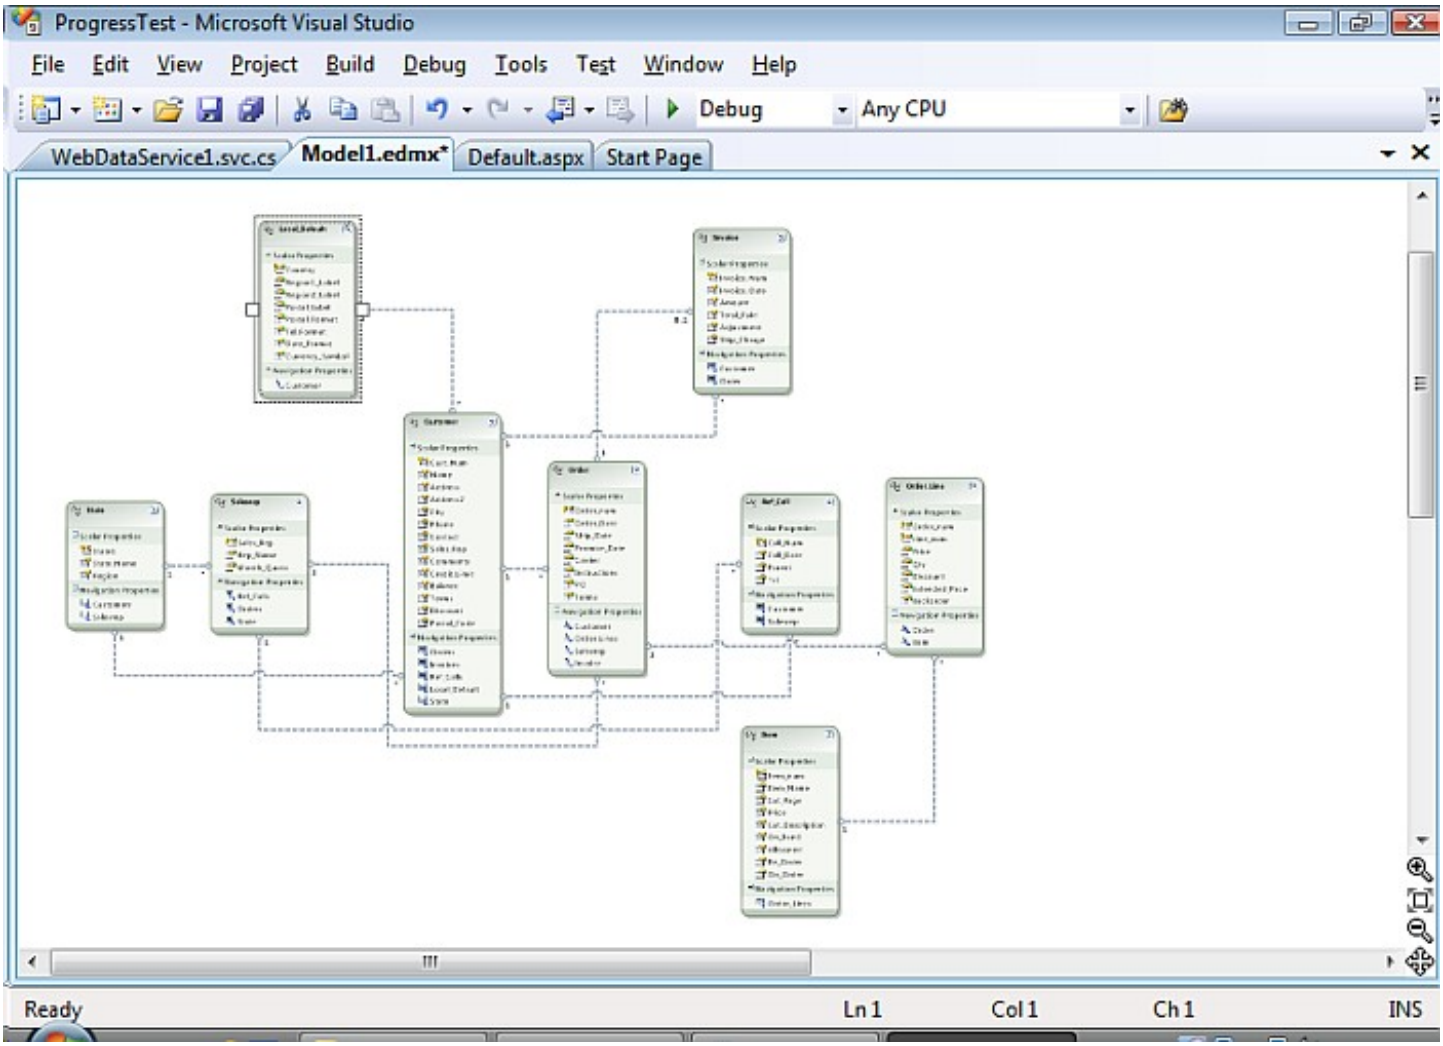
15. The project should now be fine.

Figure 8.112. Build Project



You will need to repeat these steps for each association until you have a completed Entity Data Model.

Figure 8.113. Entity Data Model



8.3.6. Using EDM to create Entity Framework based applications

Now that a Microsoft Entity Data Model has been created for the Progress isports database, Entity Framework applications can be created to make use of it.

Entity Framework Data Service

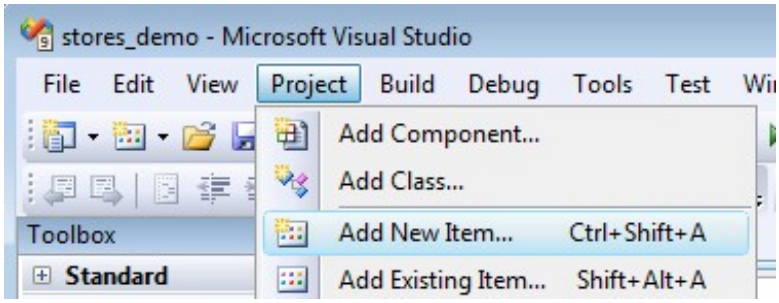
An ADO.Net Data Service for the Progress tables can be created using the Entity Data Model created in the Creating EDM in Visual Studio 2008 section .

1. Open the

   VirtuosoDataService

   project created in the Creating EDM in Visual Studio 2008 section .
2. Select the Project -> Add New Item menu option.

   Figure 8.114. VirtuosoDataService



3. The

   Add New Item

   dialog will appear. Choose the

   ADO.NET Data Service template

   . Give it the name

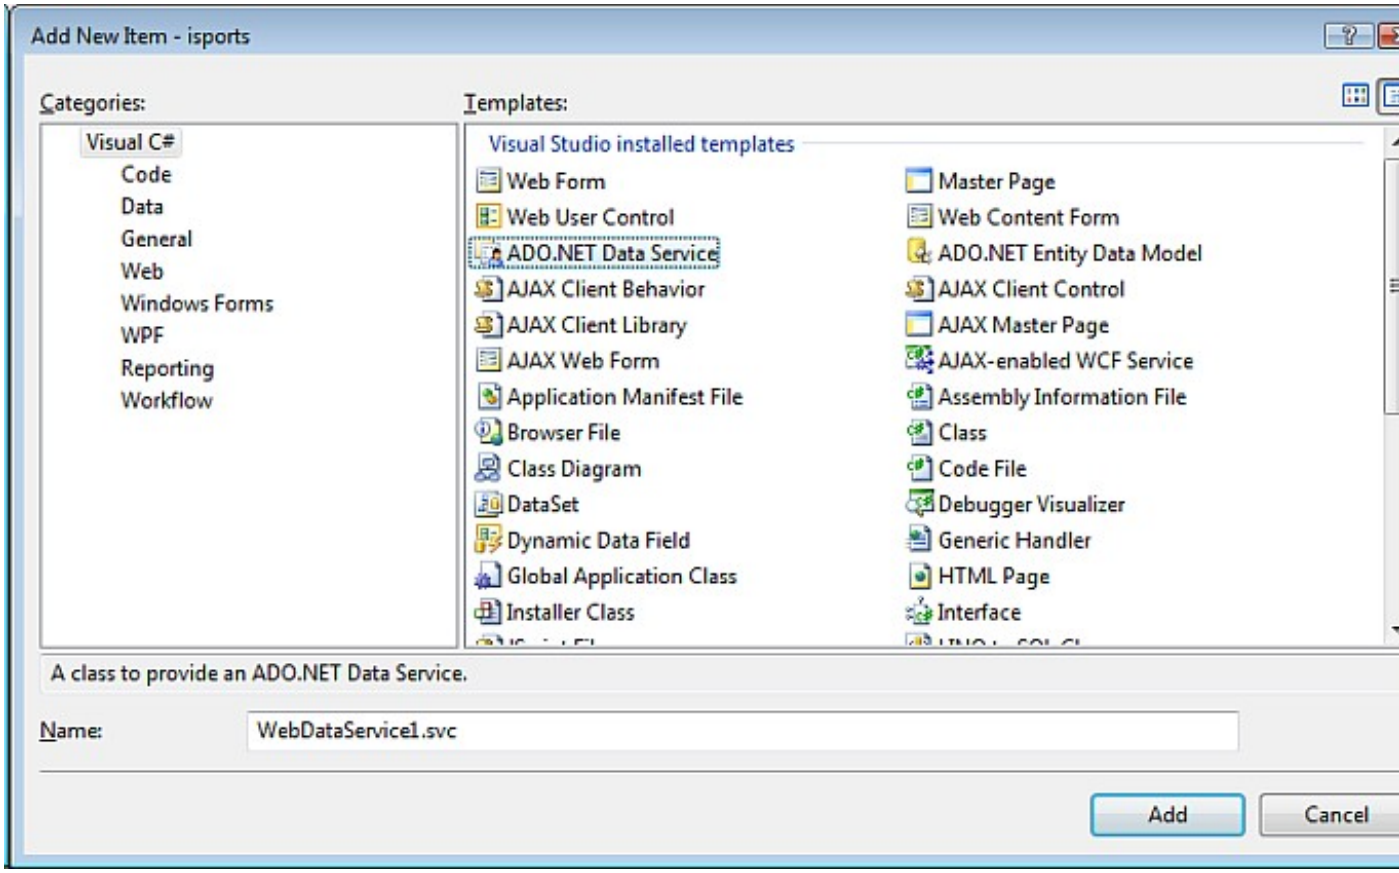
   WebDataService.svc

   , and click

   Add

   to create the ADO.Net Data Service.

   Figure 8.115. Add New Item



4. In the

   WebDataService1.svc.cs

Data Service file created add the data source class name of

isportsEntities

(note this is the name set in the Creating EDM in Visual Studio 2008 section) as the

DataService

name and enable the access to the Data Service by adding the entry

config.SetEntitySetAccessRule("", EntitySetRights.All);*

in the

InitializeService

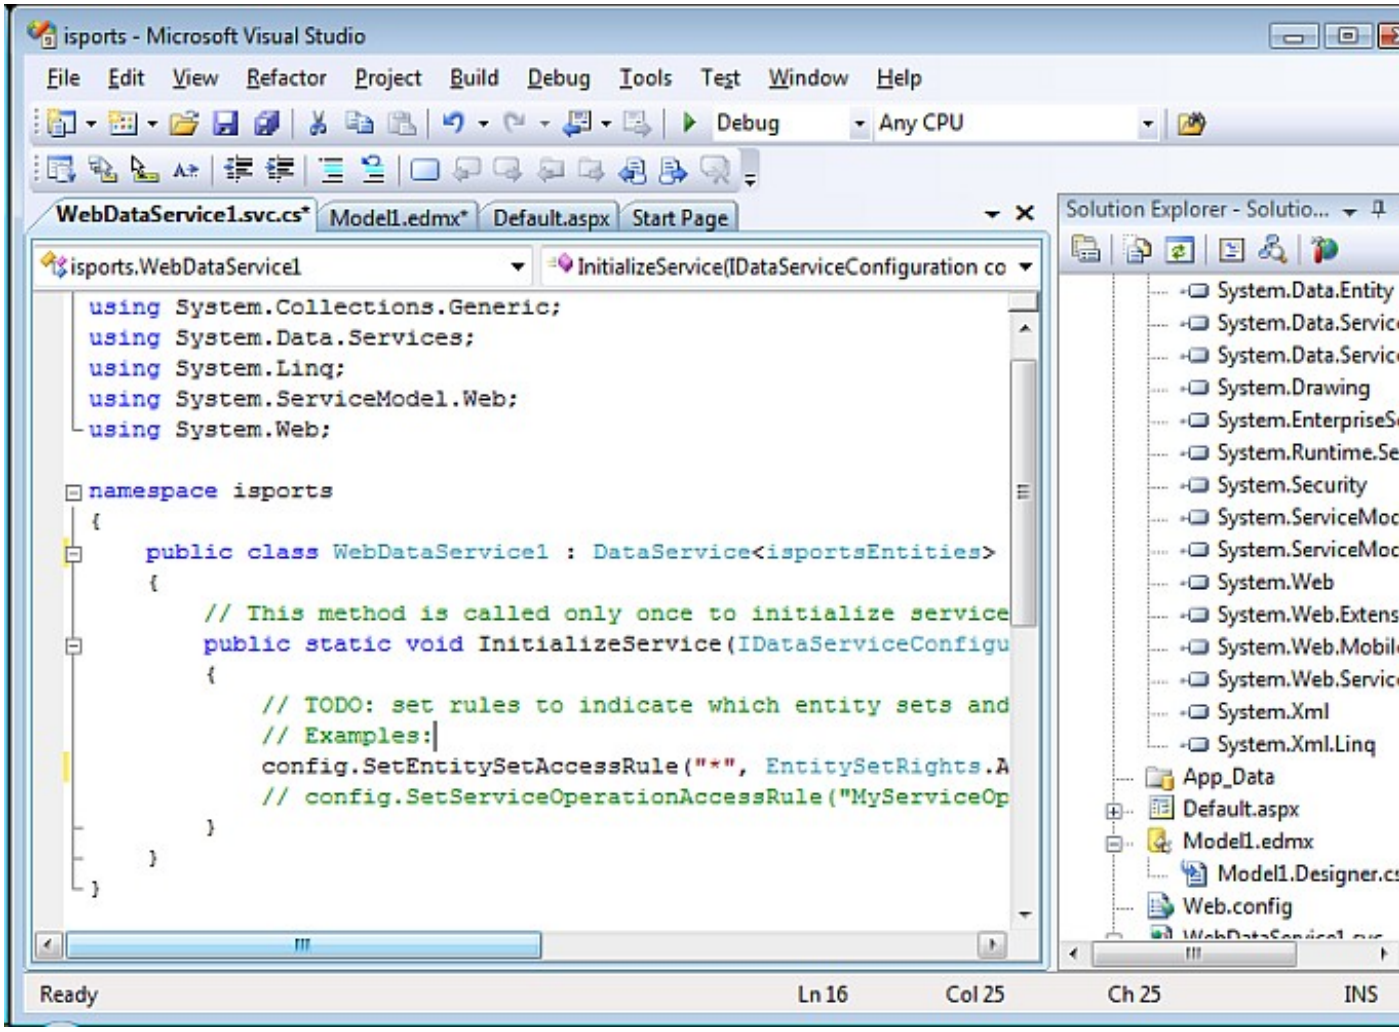
method.

```
// C#

using System;
using System.Web;
using System.Collections.Generic;
using System.ServiceModel.Web;
using System.Linq;
using System.Data.Services;

namespace SimpleDataService
{
    public class Northwind : DataService<VirtuosoDemoEntities>
    {
        public static void InitializeService(IDataServiceConfiguration  config)
        {
            config.SetEntitySetAccessRule("*", EntitySetRights.All);
        }
    }
}
```

Figure 8.116. WebDataService1.svc.cs

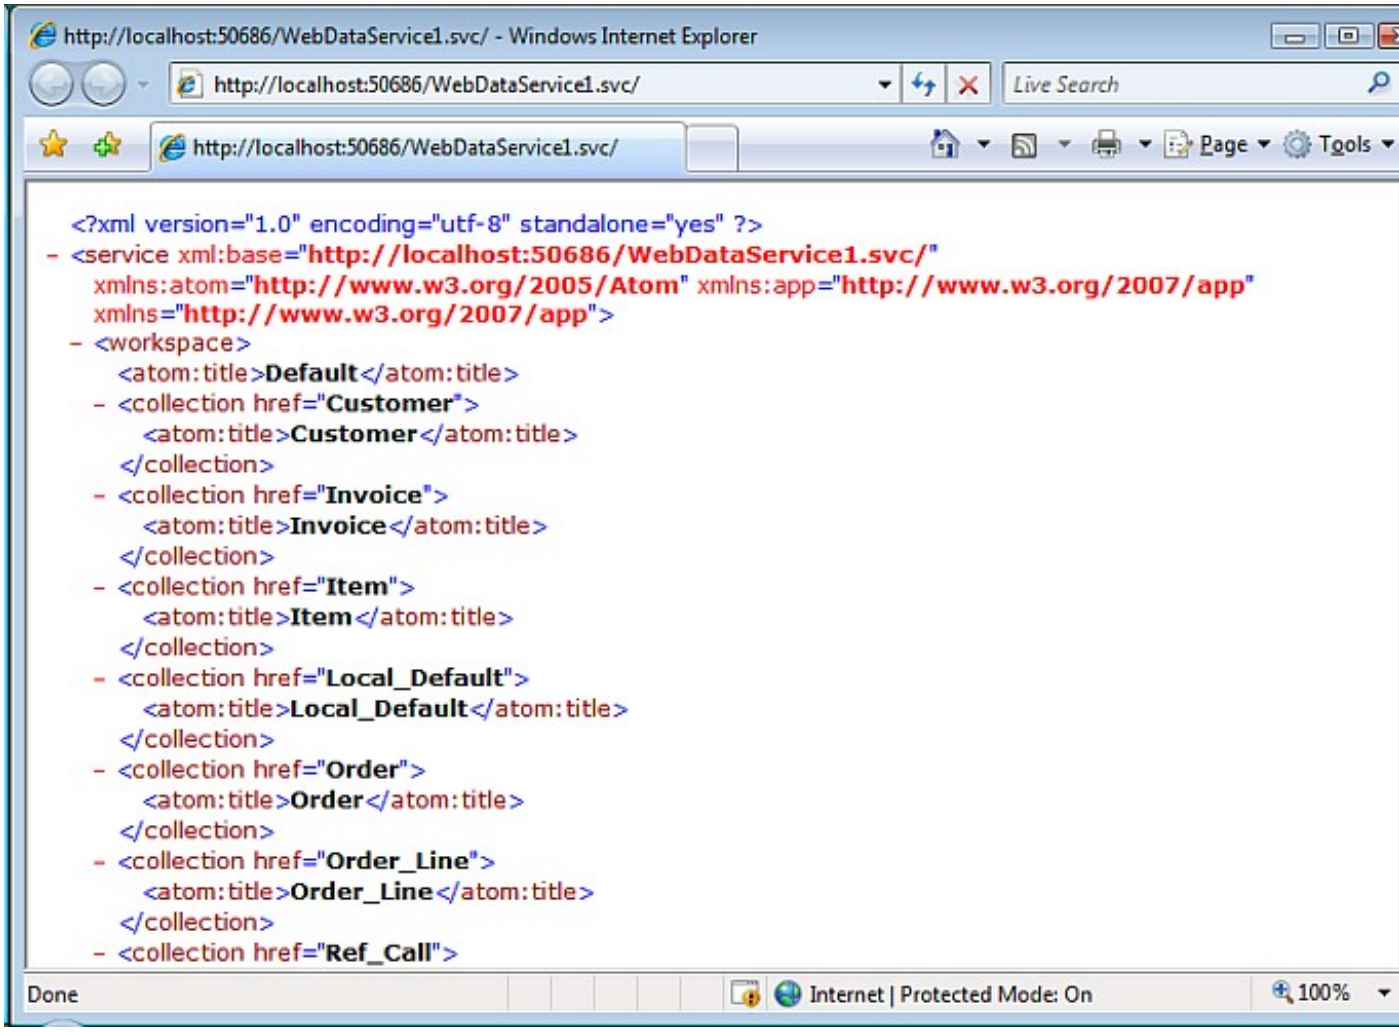


5. To test the Data Service, simply hit

   Ctrl+F5

   within Visual Studio. This will start the development web server, run the Data Services server inside and load a Web browser page displaying the list of available tables/entities for the isports database catalog.

Figure 8.117. Data Service test



6. To access a specific entity instance like the

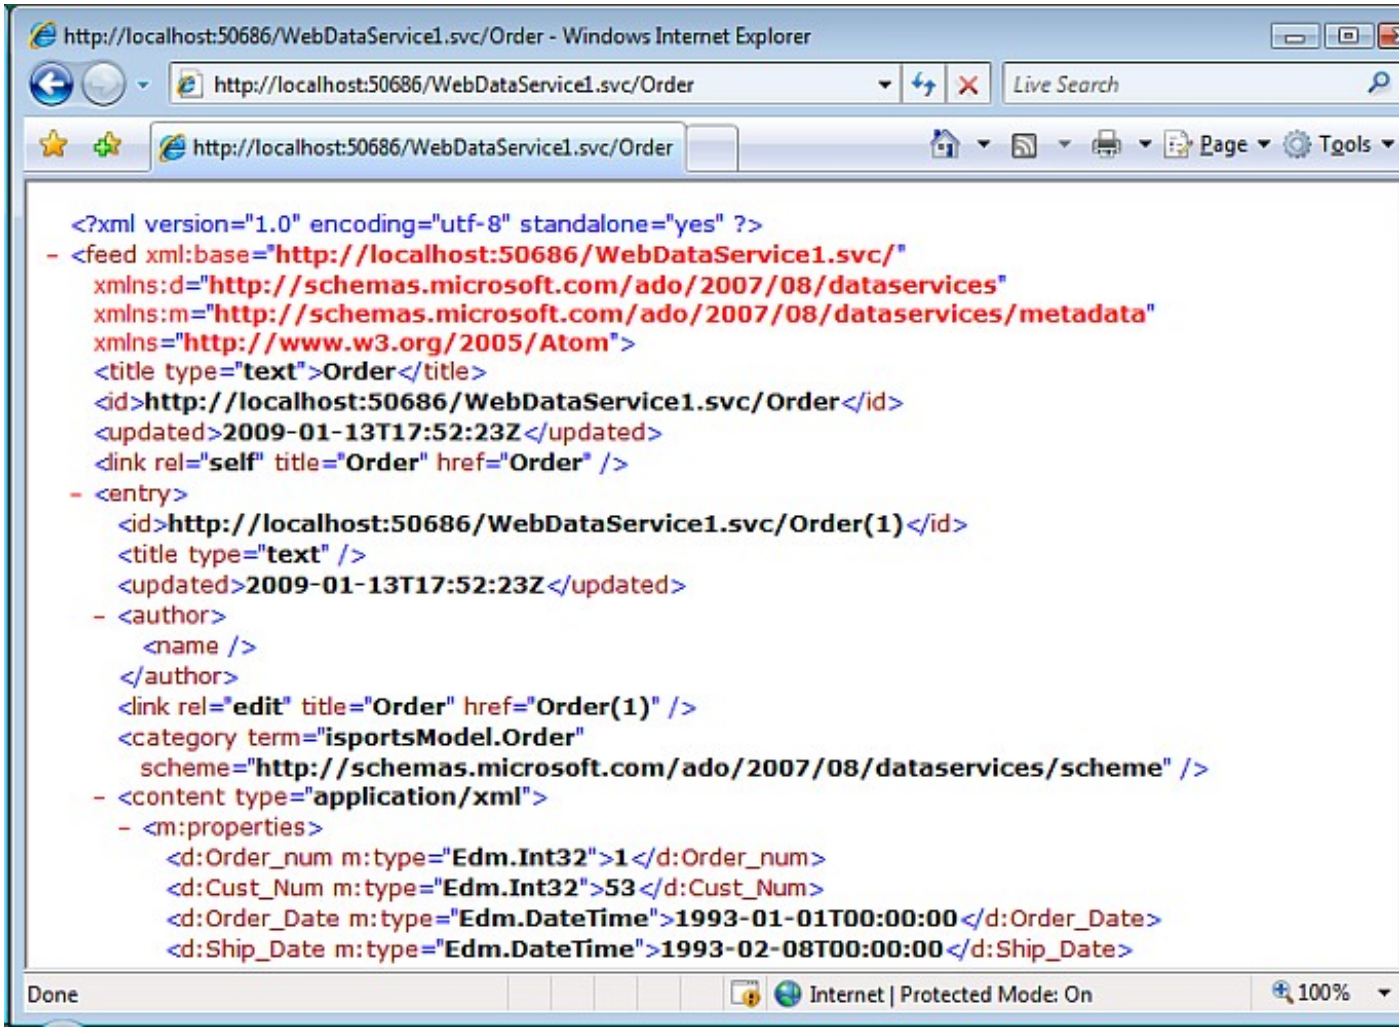
   EMPLOYEES

   table employee number

   100

   record, use this convention http://host/vdir/Virtuoso.svc/EMPLOYEES(100) .

   Figure 8.118. EMPLOYEES



Notes:

1. *Important*

   - To view

   Atom

   (the default format returned by an ADO.NET Data Service) in Internet Explorer, you must first ensure that

   Feed Reading View

   is turned

   off

   . This can be done on the

   Content tab

   of

   Tools in Internet Options

   .
2. If a Data Services entity instance URI page fails to load you can turn

Verbose

errors on by adding

config.UseVerboseErrors = true;

in the

virtuoso.svc.cs InitializeService

method to obtain more detailed information from the server as to why the page failed to load:

```
public static void InitializeService(IDataServiceConfiguration config)
{
config.UseVerboseErrors = true;
config.SetEntitySetAccessRule("*", EntitySetRights.All);
}
```

Visual Studio Windows DataGrid Form Application

This section details the steps required to create a simple Visual Studio 2008 Windows Form application, with associated DataGridView control for displaying data in selected tables from the target database.

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.119. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

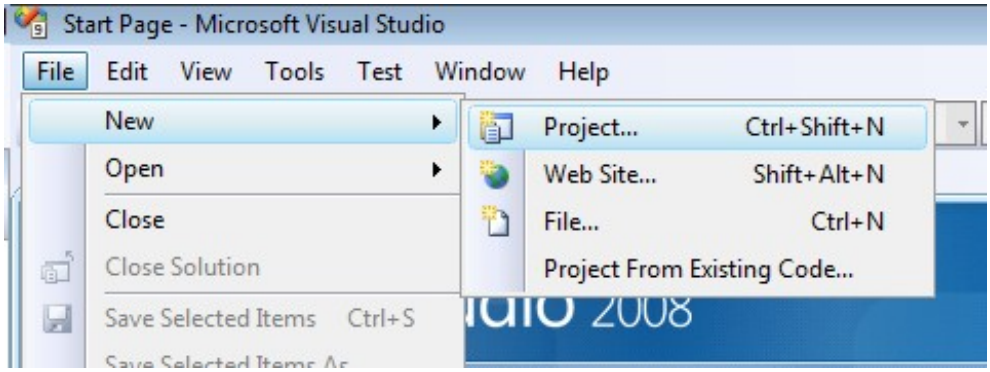
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.120. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Windows

   and select

   Windows Form Application

   from the right-hand panel.
5. Choose a name for the project, for example

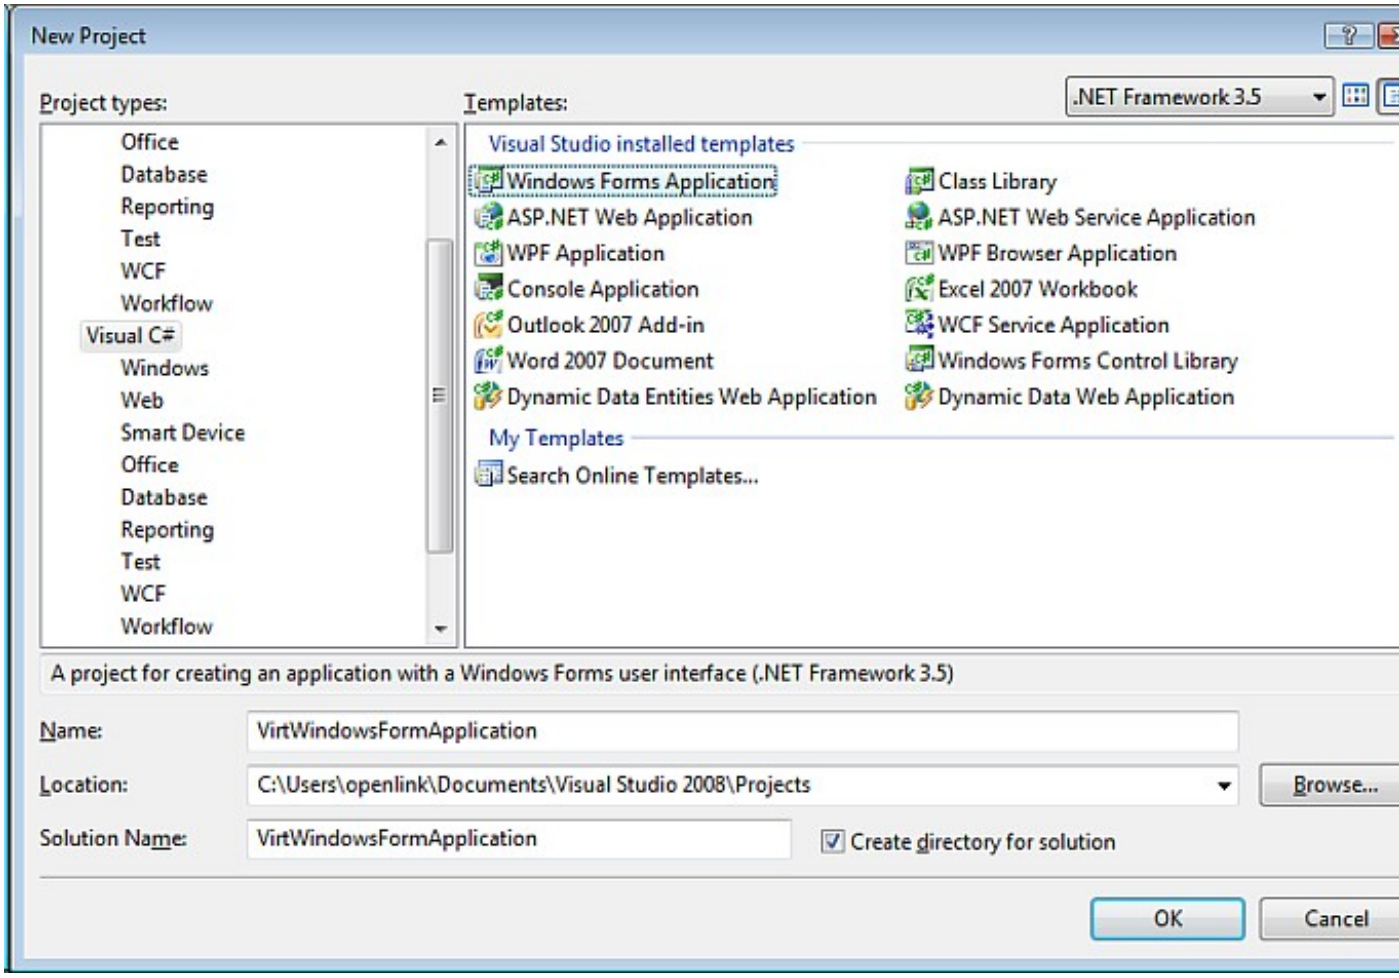
   VirtWindowsFormApplication

   , and click

   OK

   .

   Figure 8.121. Web Application



6. In the

   Toolbox

   , expand

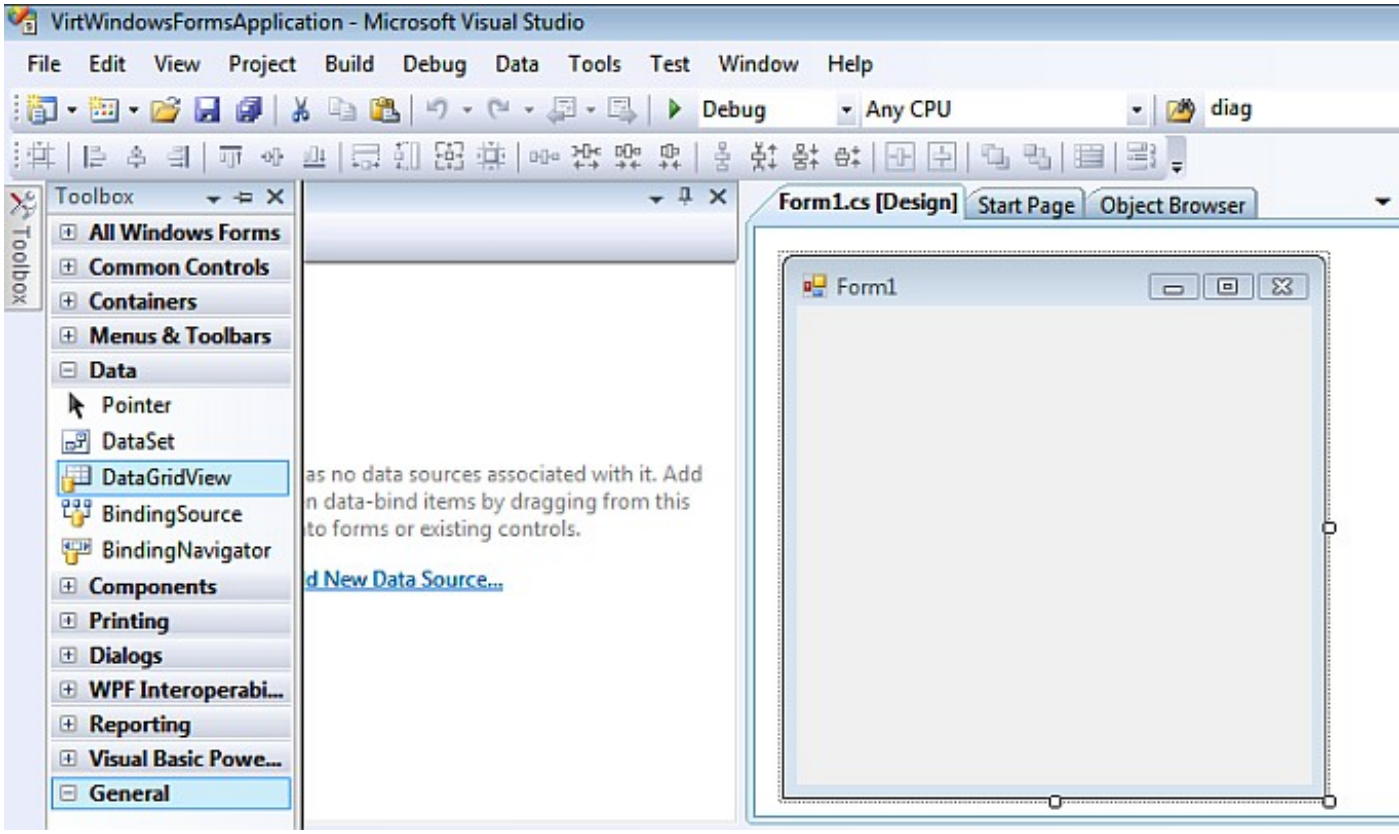
   Data Controls

   , and drag the

   DataGridView

   control onto the form.

   Figure 8.122. Toolbox



7. Click on the little

   arrow

   in the top right of the

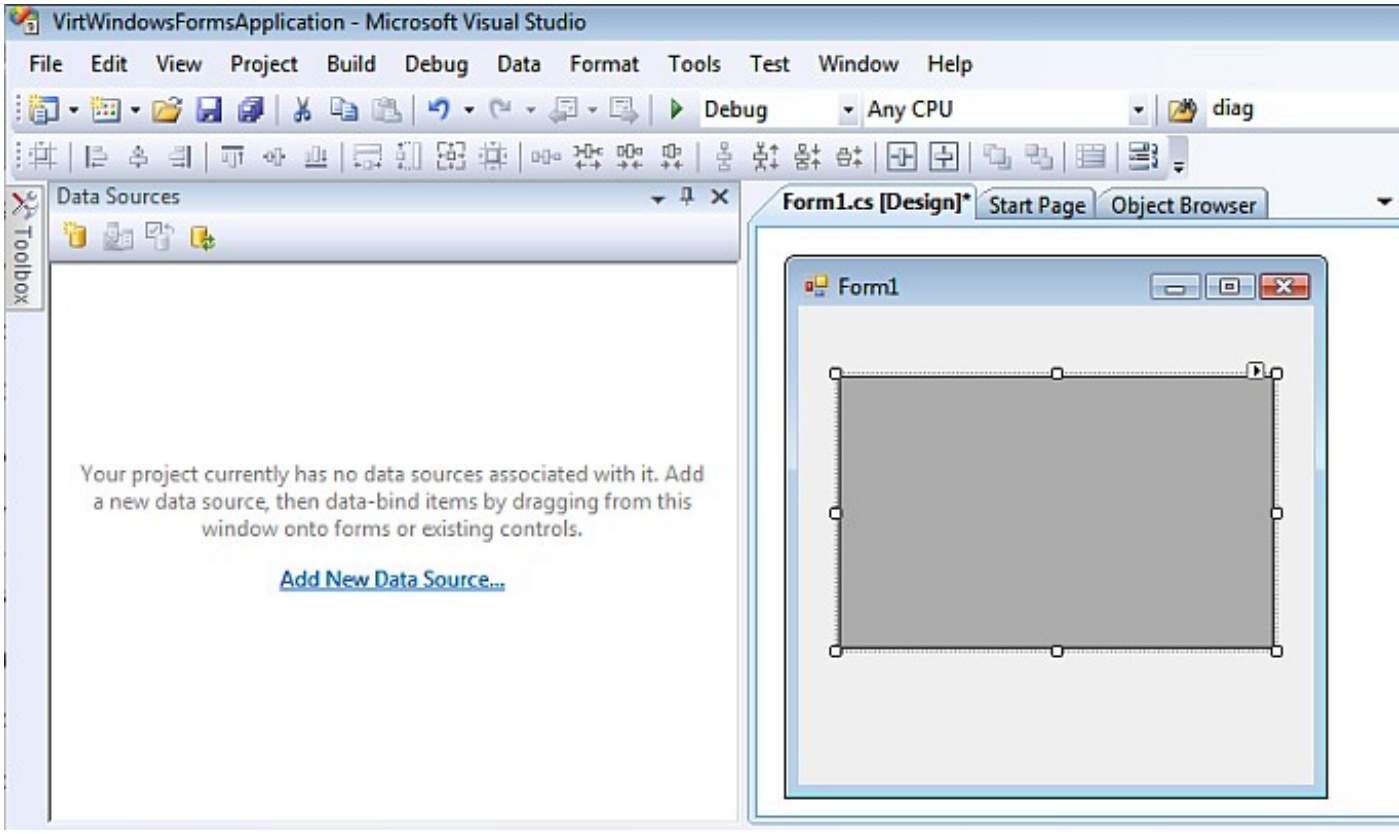
   DataGridView

   control. This loads the

   DataGridView Task

   menu.

Figure 8.123. DataGridView Task

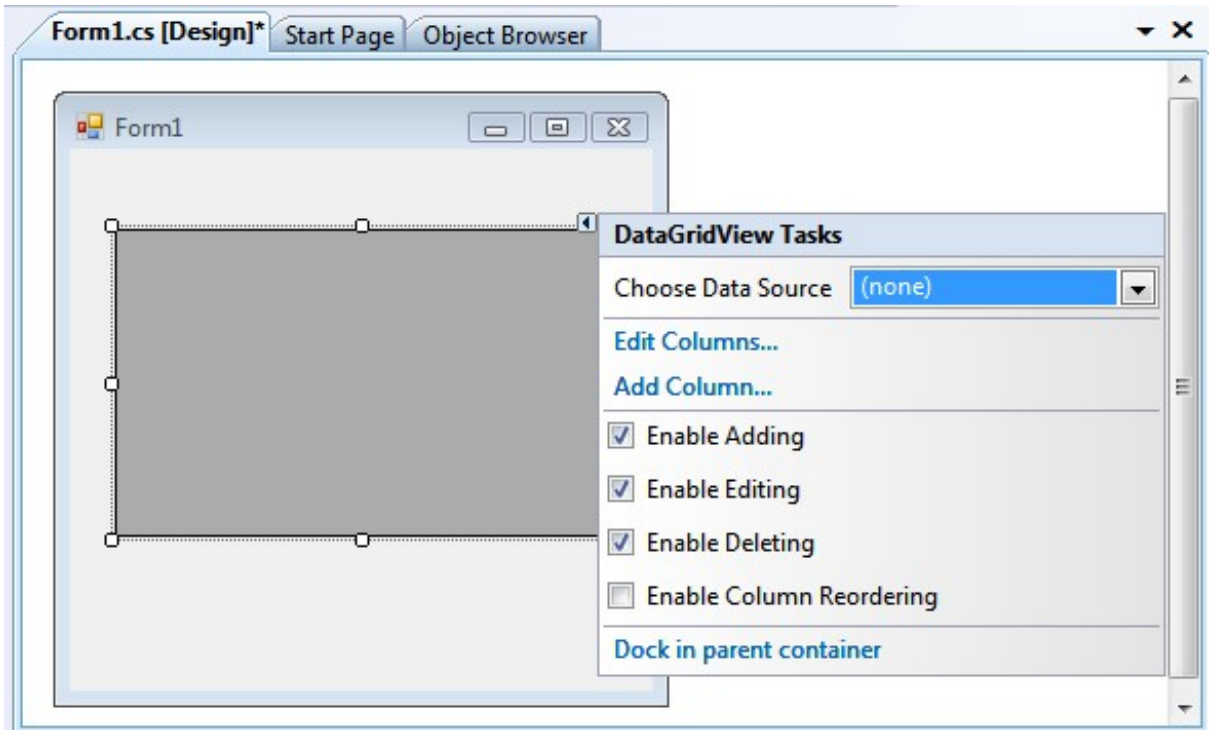


8. Click on the

   Choose Data Source

   list box.

Figure 8.124. Choose Data Source

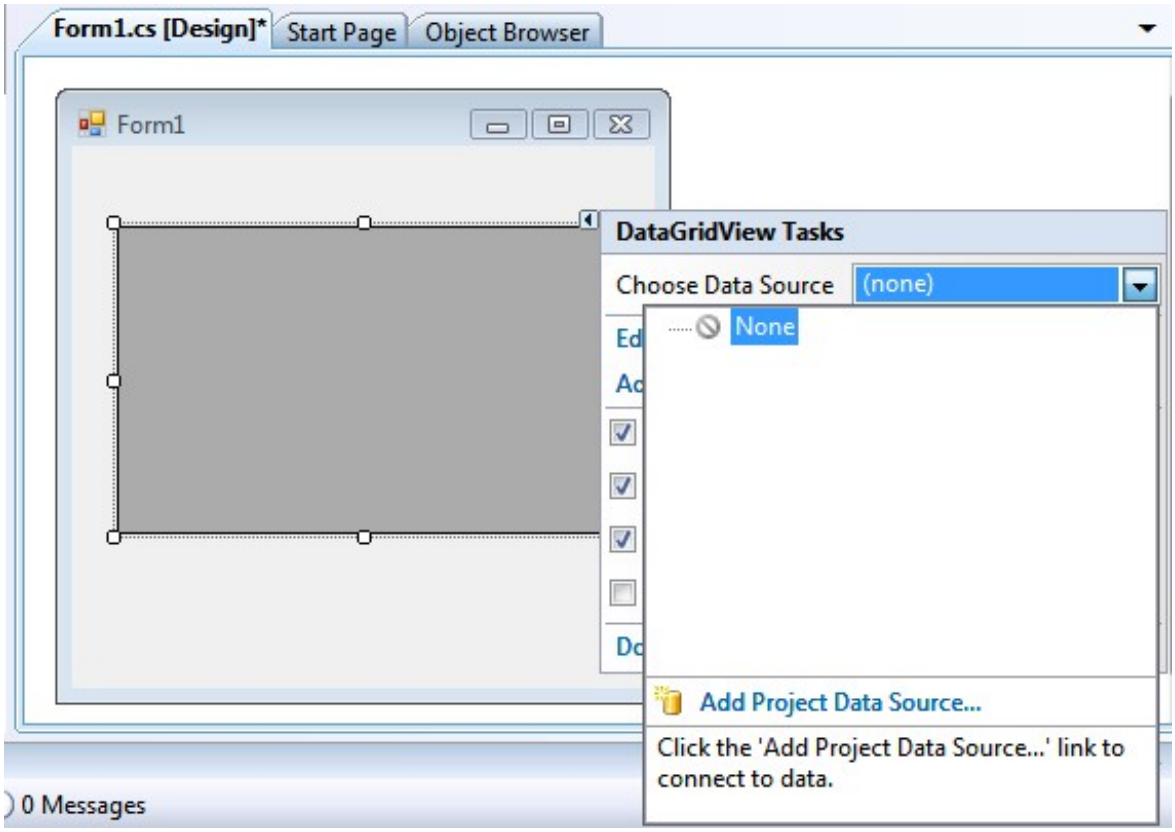


9. Click on the

   Add Project Data Source

link to connect to a data source.

Figure 8.125. Add Project Data Source



10. In the

    Data Source Configuration Wizard

    dialog

    Choose Data Source Type

    page select the

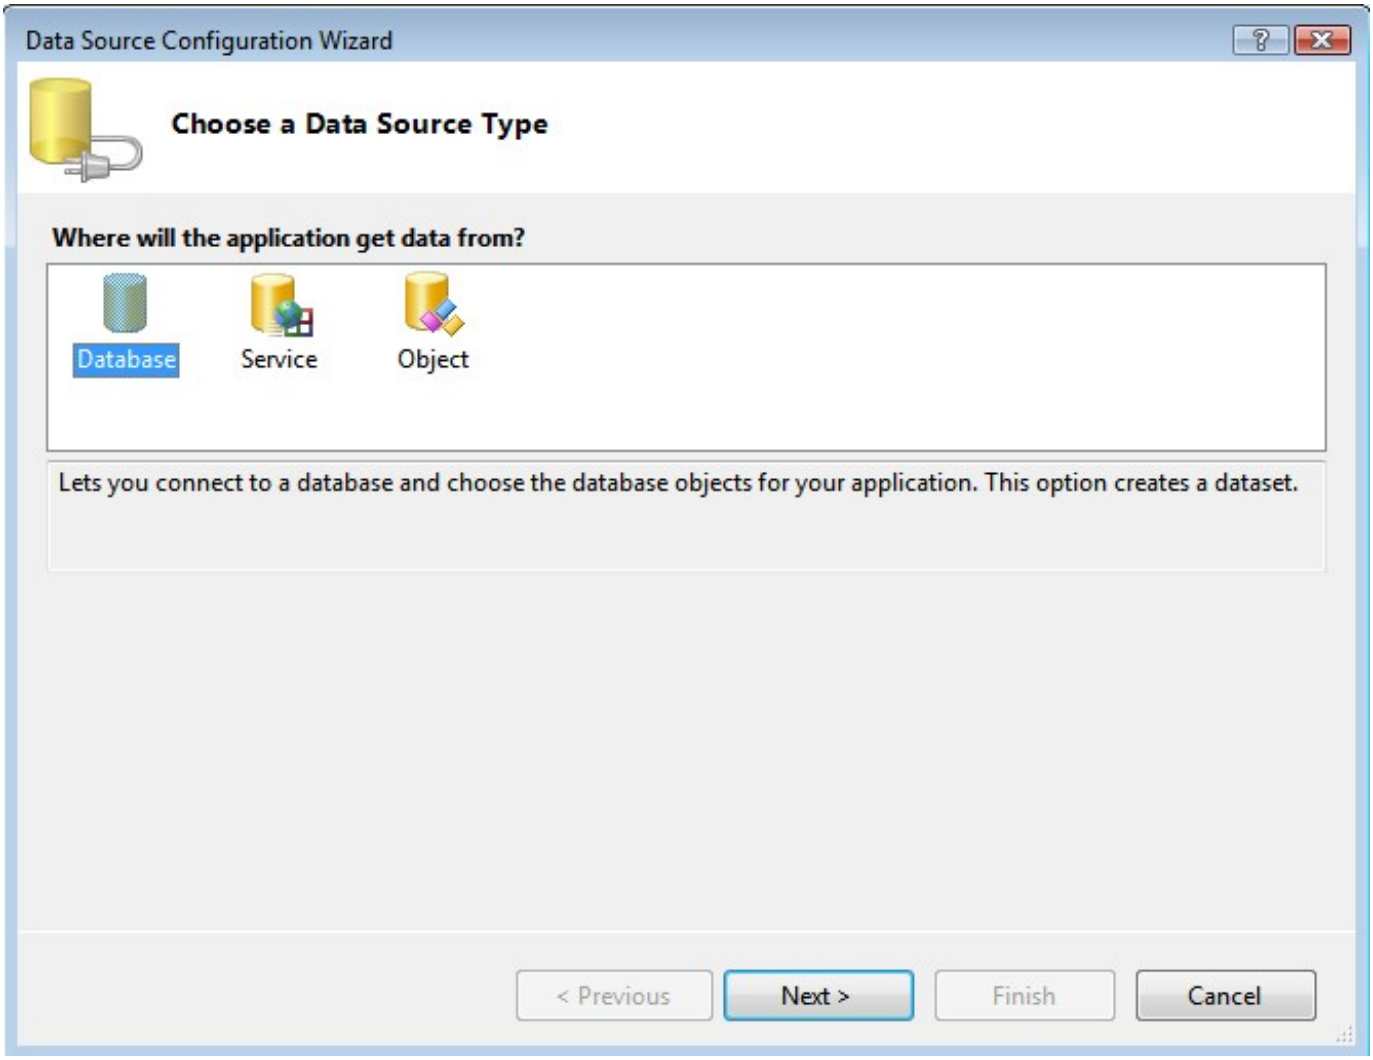
    Database

    data source type and click

    Next

    .

Figure 8.126. Data Source Type



11. In the

    Data Source Configuration Wizard

    dialog

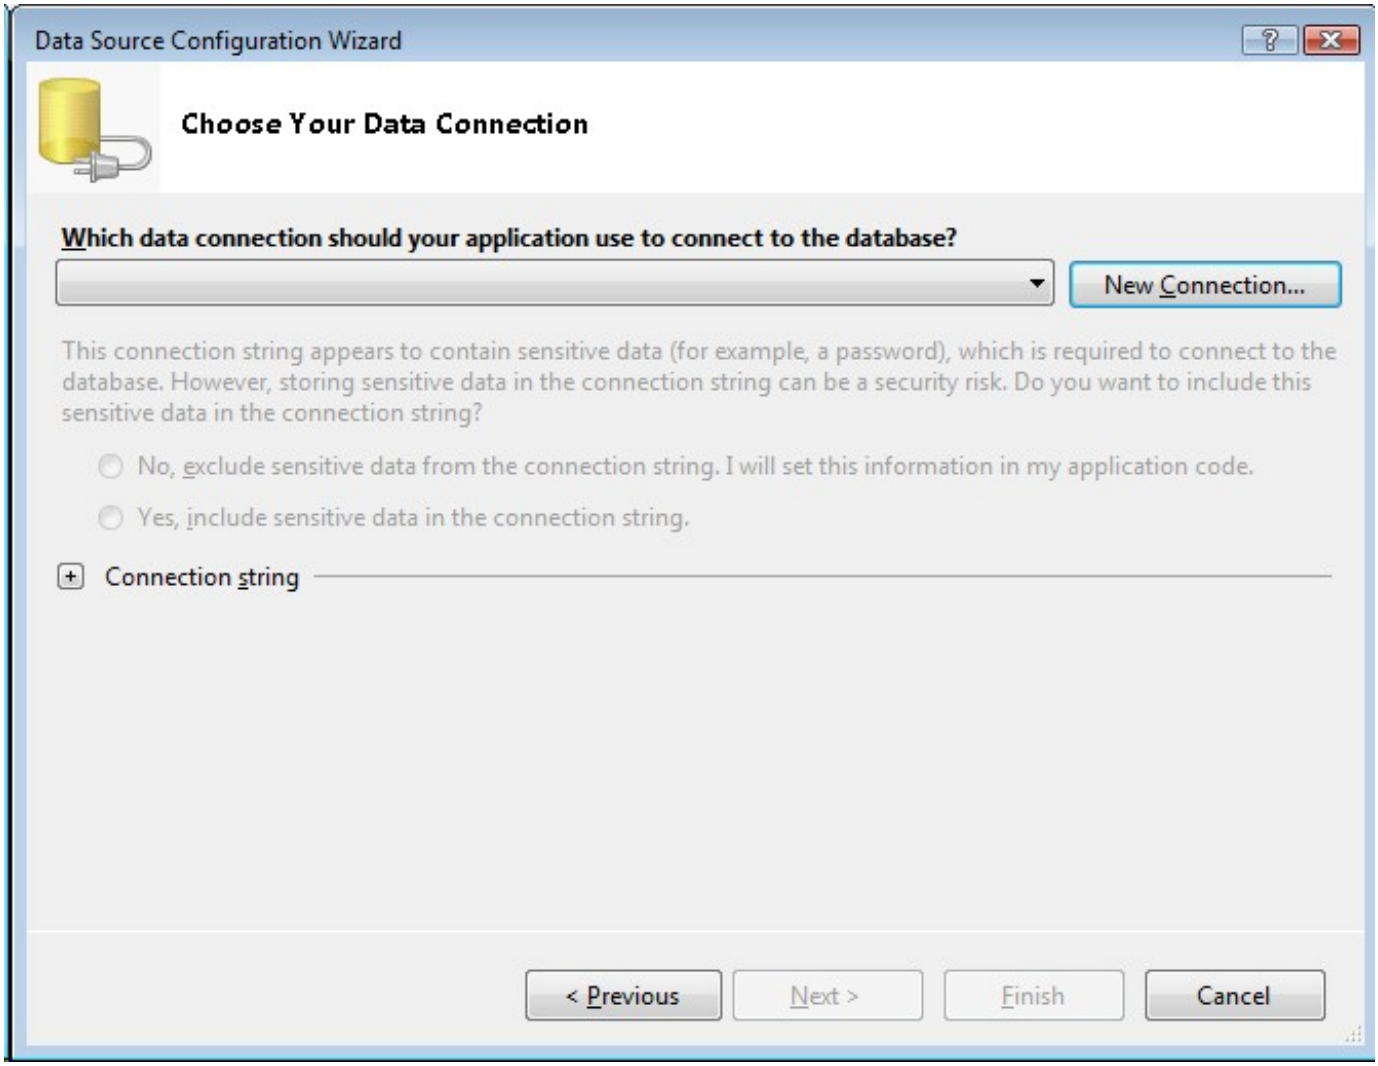
    Choose your Data Connection

    page, select the

    New Connection

    button

Figure 8.127. Data Source Configuration Wizard



12. In the

    Choose Data Source

    dialog, select the OpenLink

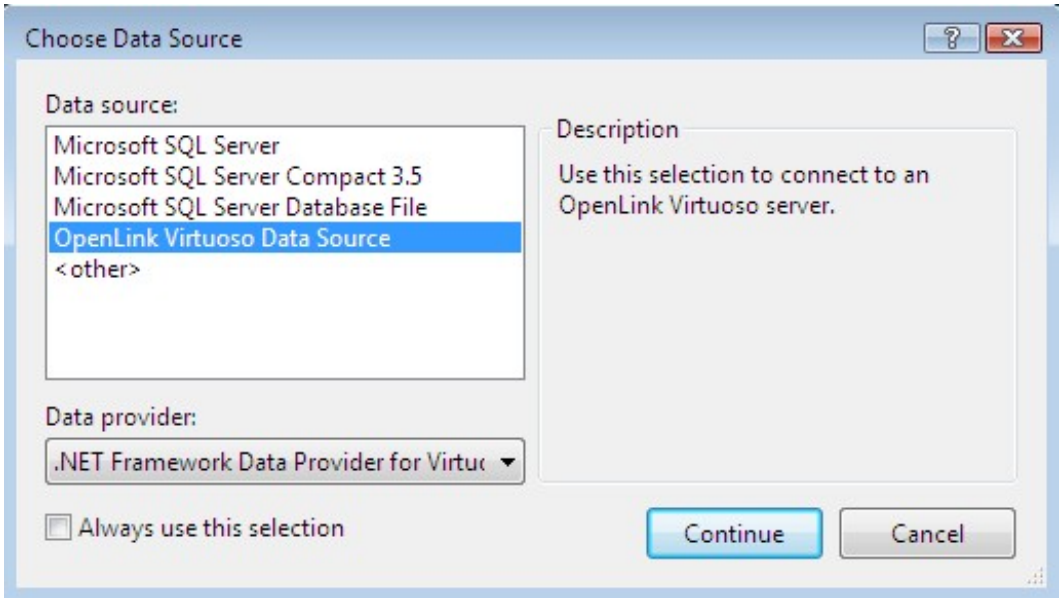
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.128. Data Source



13. In the

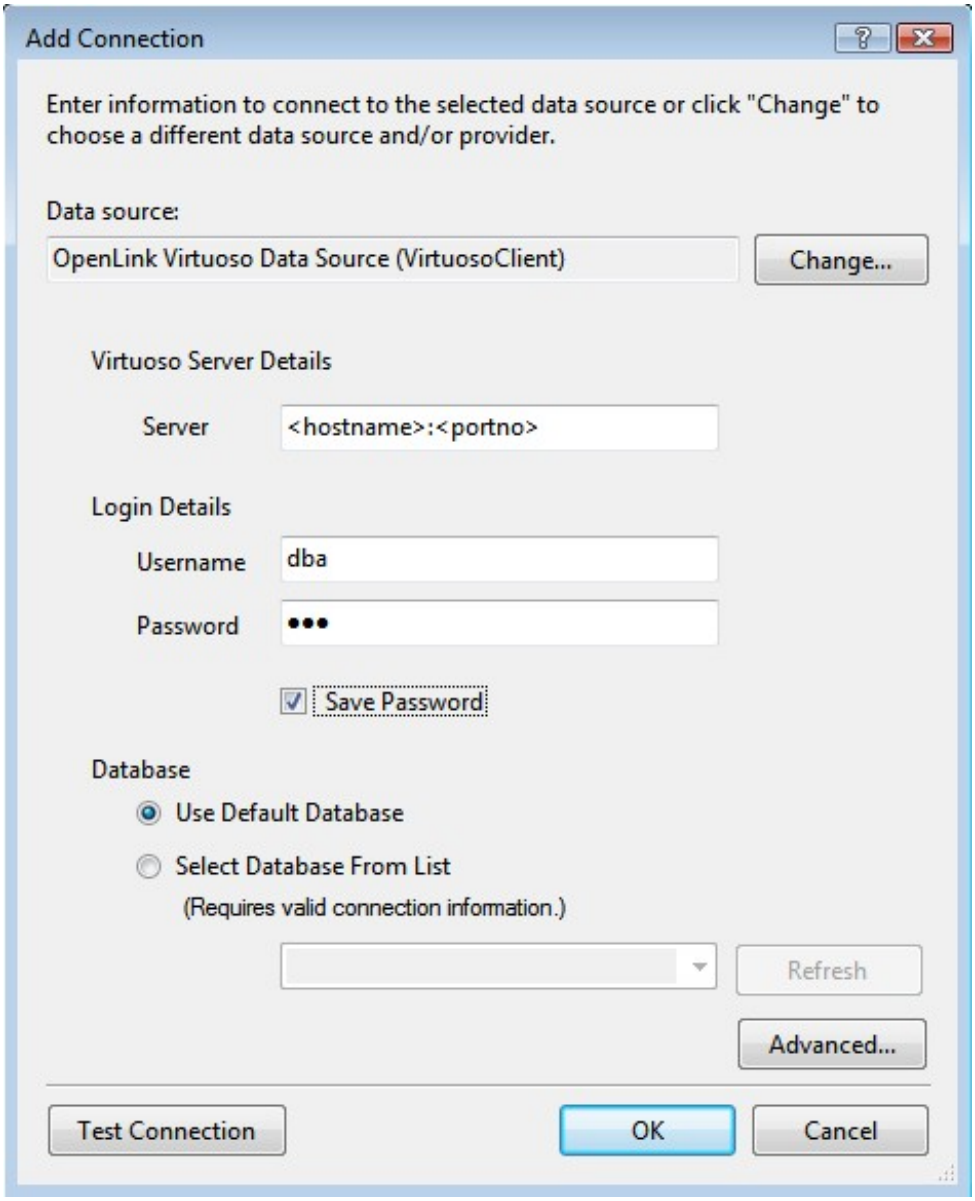
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.129. Connection Properties



14. Select the

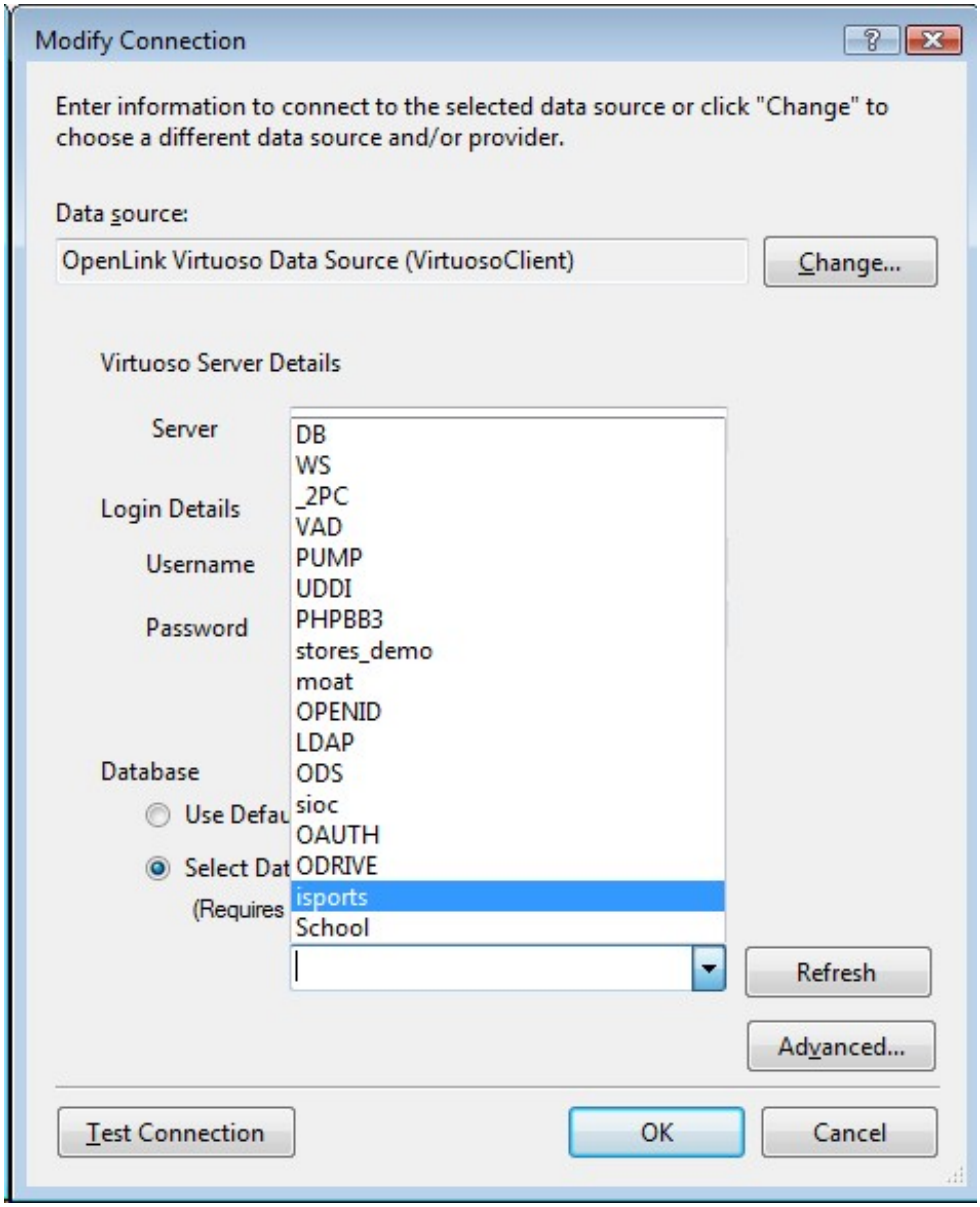
    Select Database From List

    radio button and choose

    isports

    from the drop down list.

    Figure 8.130. Add conneciton

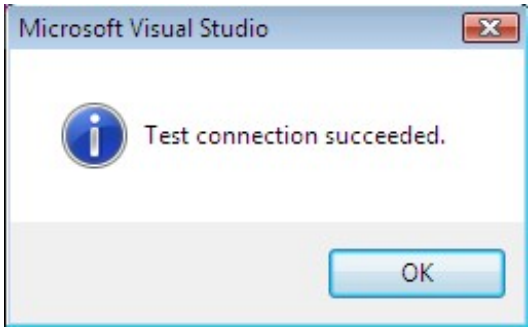


15. Press the

    Test Connection

    dialog to verify that the database is accessible.

    Figure 8.131. Test Connection



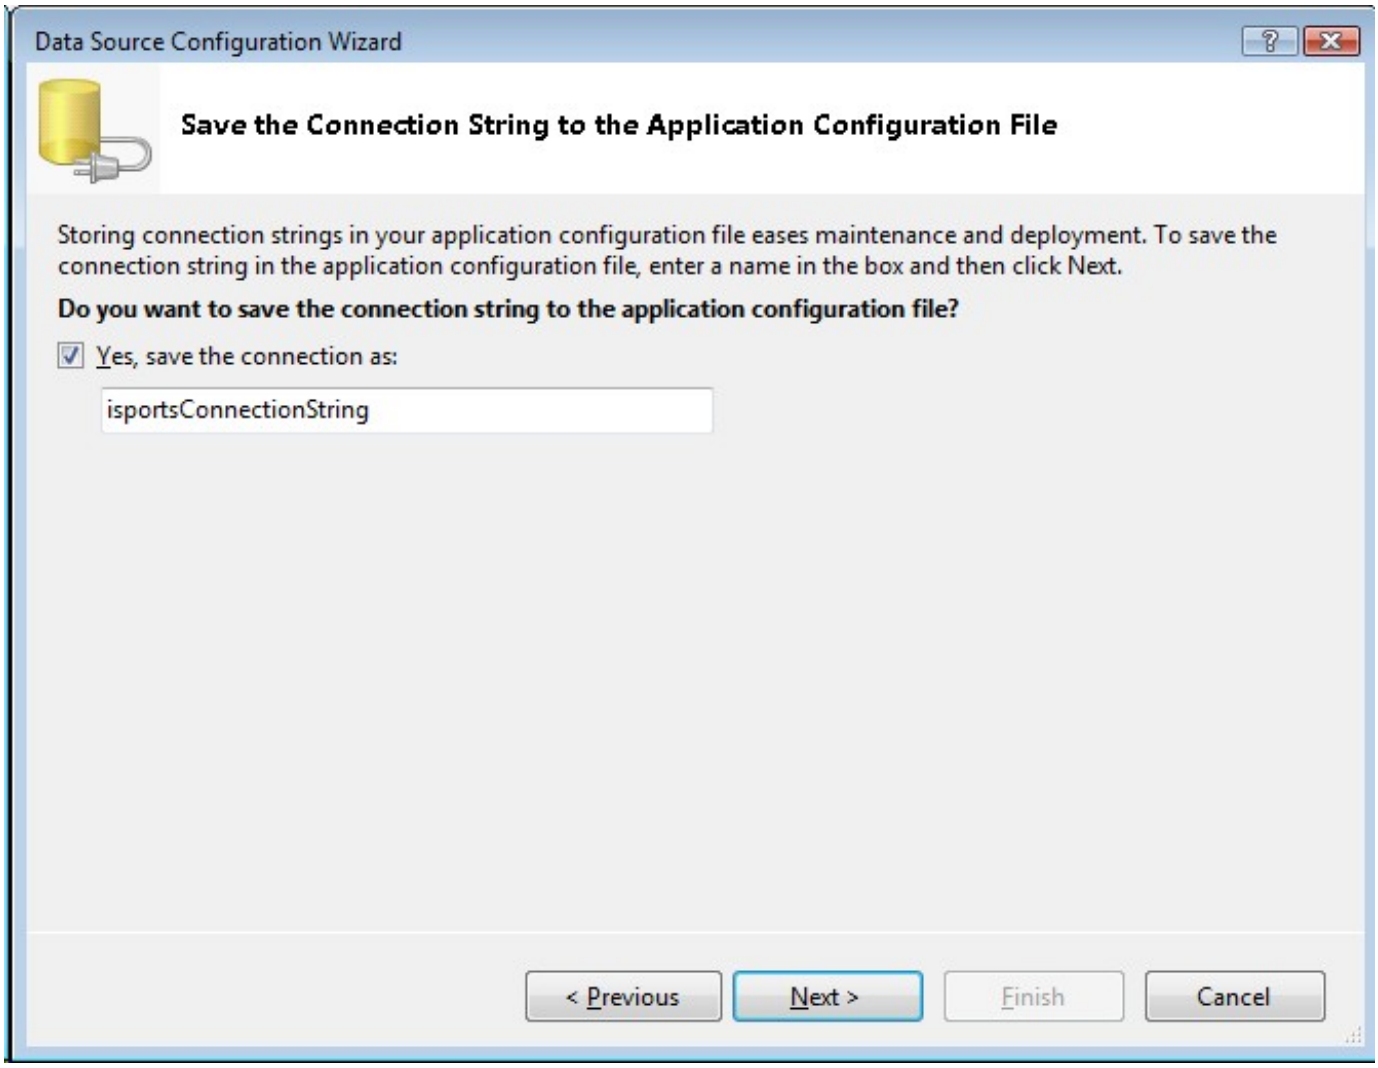
16. Leave the default connect string

    isportsConnectionString

and click

Next

Figure 8.132. isportsConnectionString



17. From the list of available tables returned for the isports database, select the

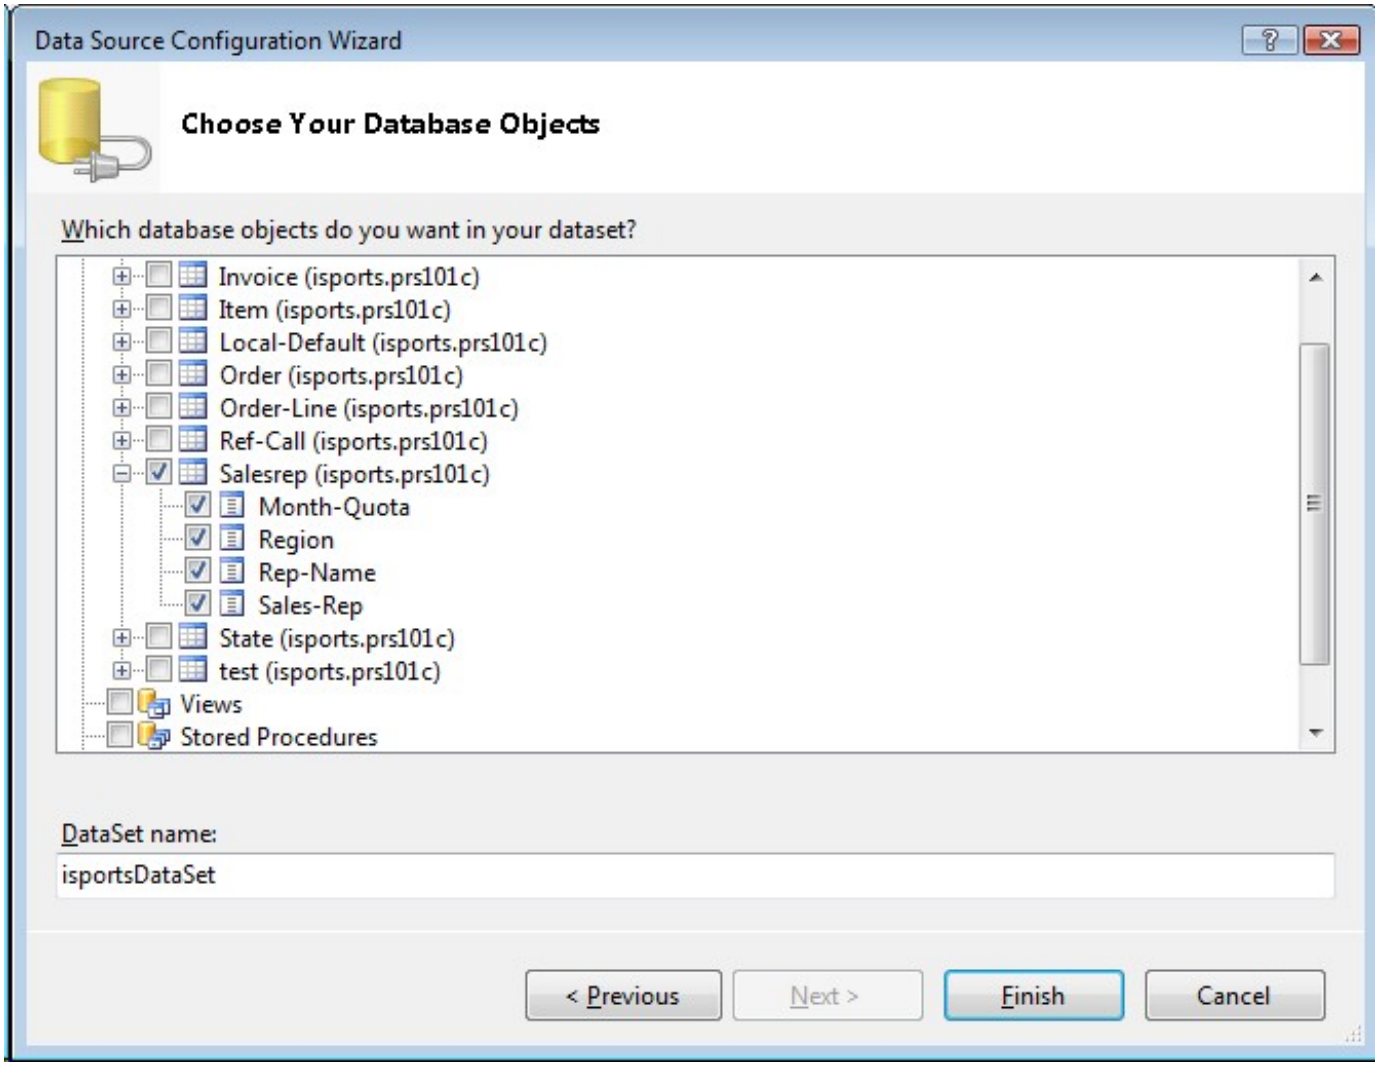
    JOBS

    table to be associated with the

    DataGridView

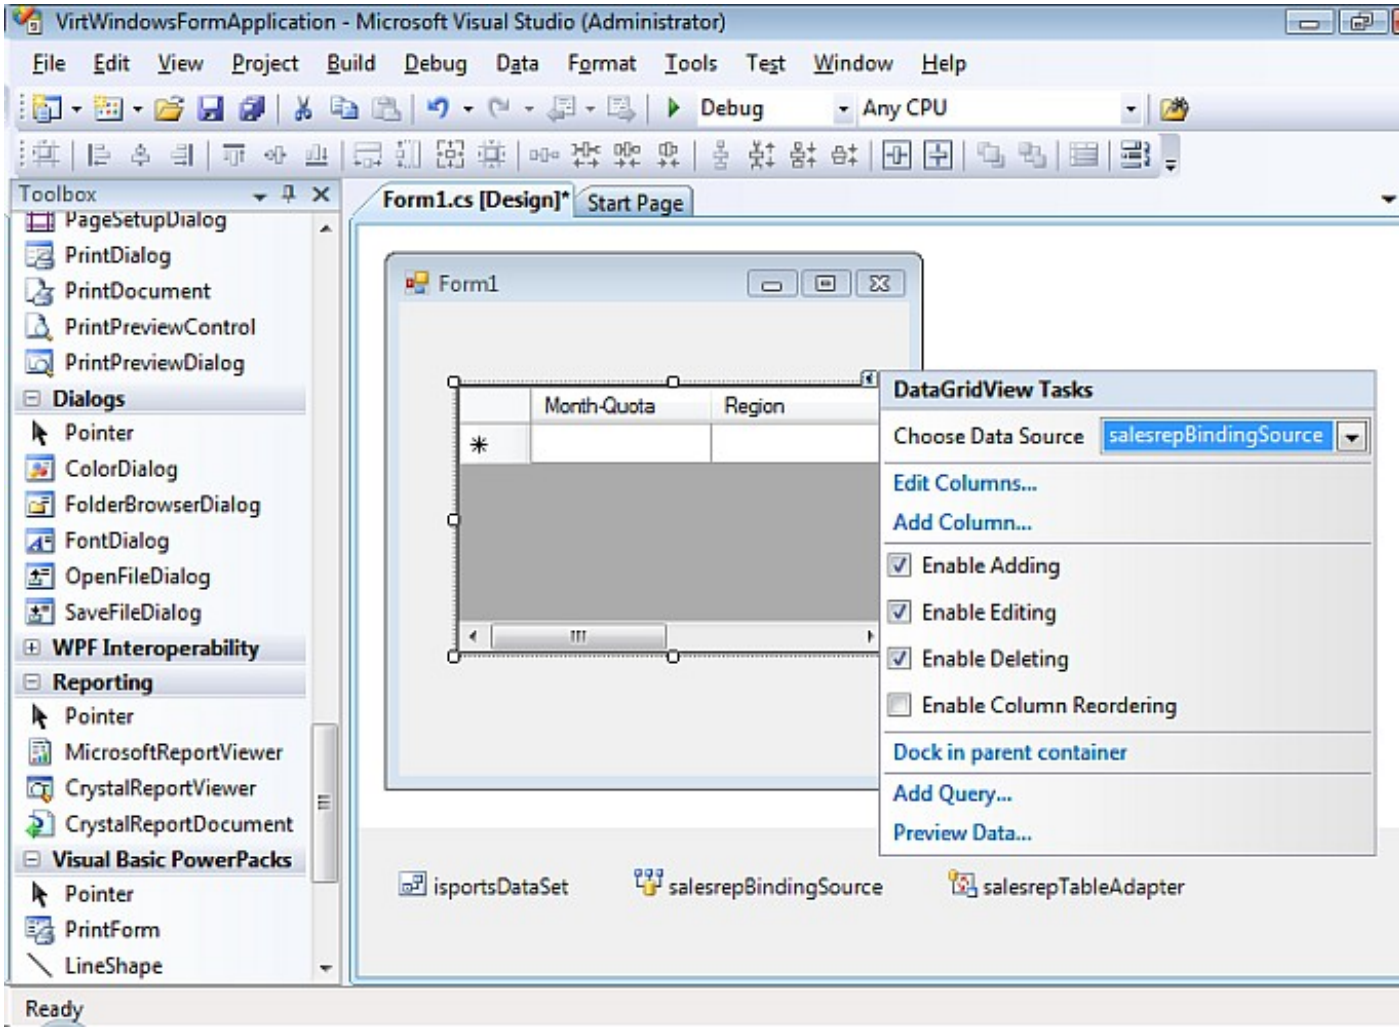
    control.

    Figure 8.133. isports database



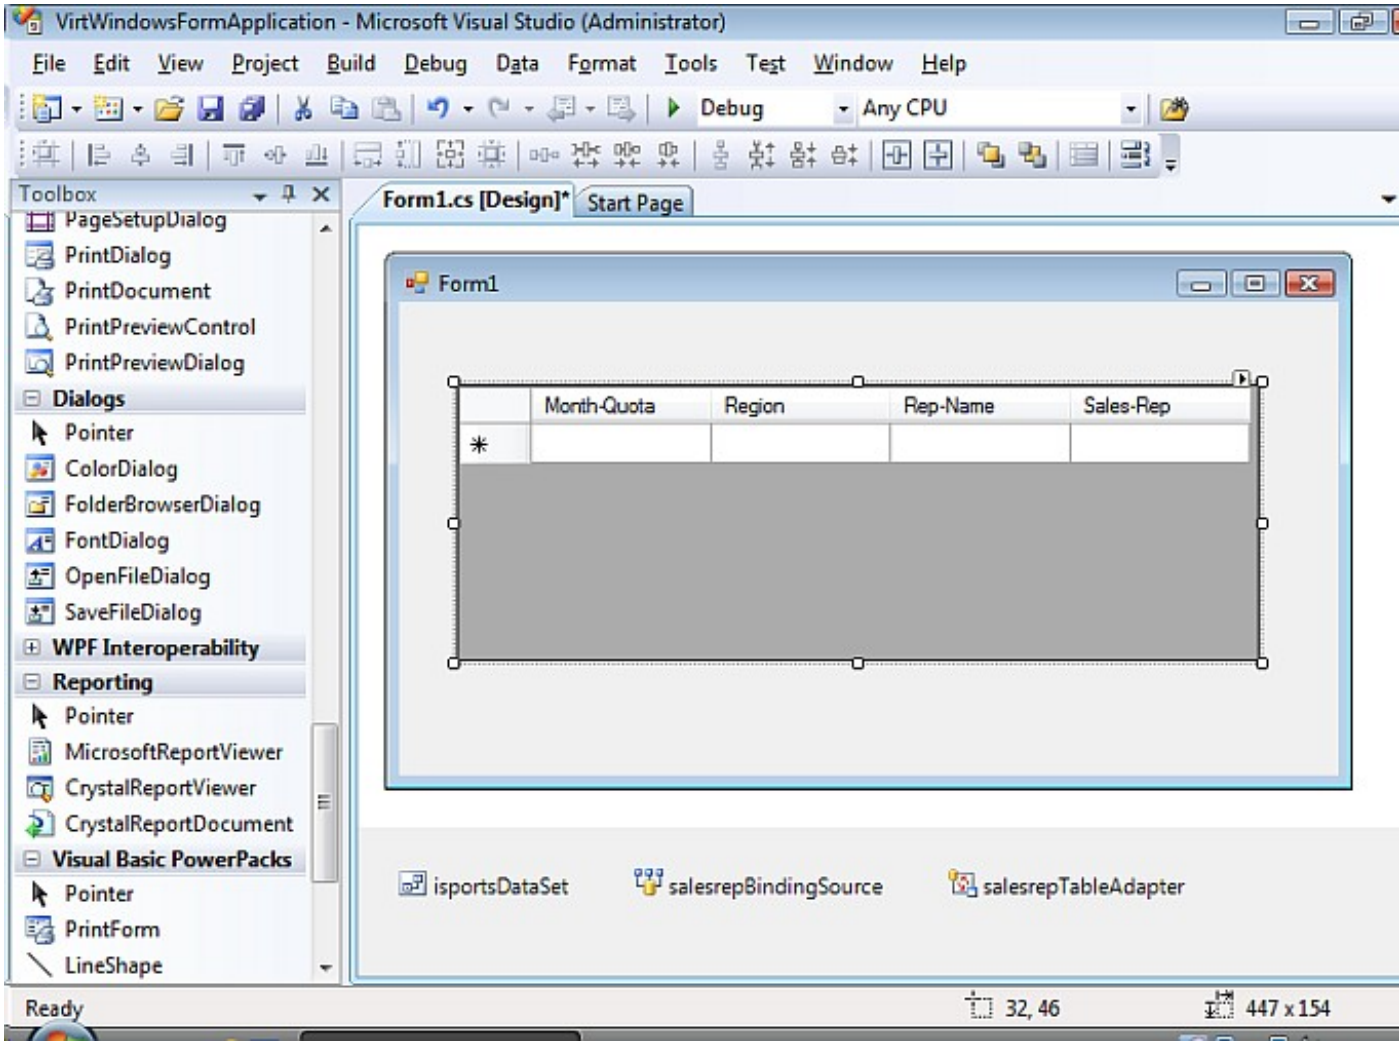
18. The columns names of the select table will be displayed in the DataGridView.

Figure 8.134. DataGridView



19. Resize the Form and DataGridView to allow all columns to be visible, if possible.

Figure 8.135. Resize the Form and DataGridView



20. To test the application, simply hit

    Ctrl+F5

    within Visual Studio or select

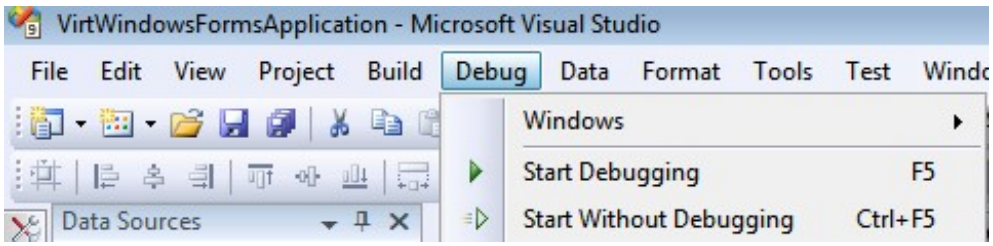
    Start Debugging

    from the

    Debug

    menu.

Figure 8.136. Start Debugging



21. The data from the

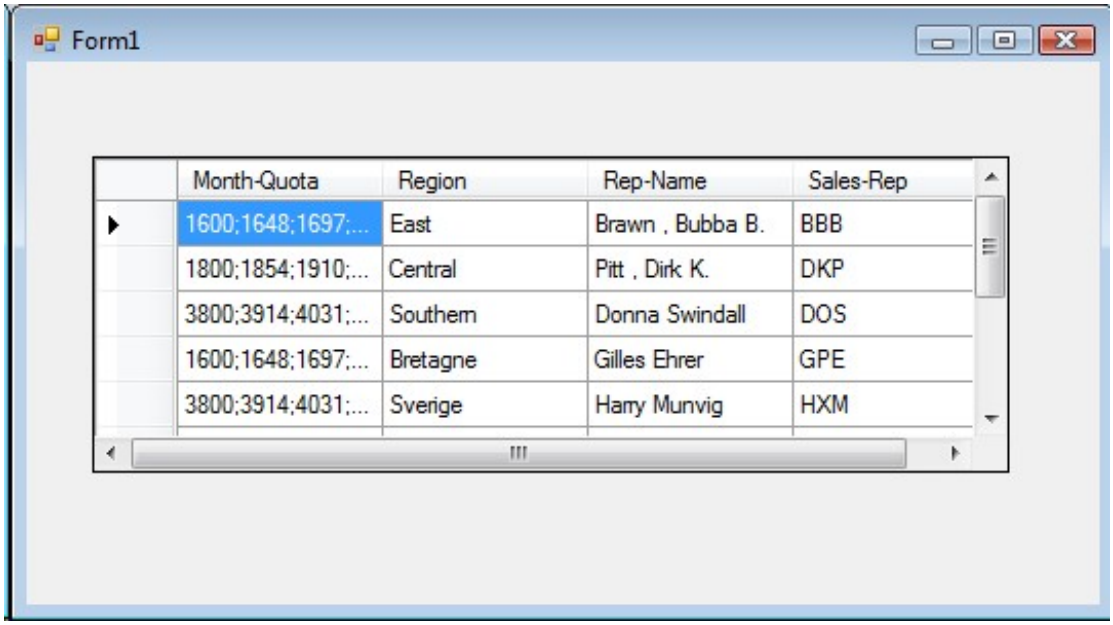
    JOBS

table will be displayed in the

DataGrid

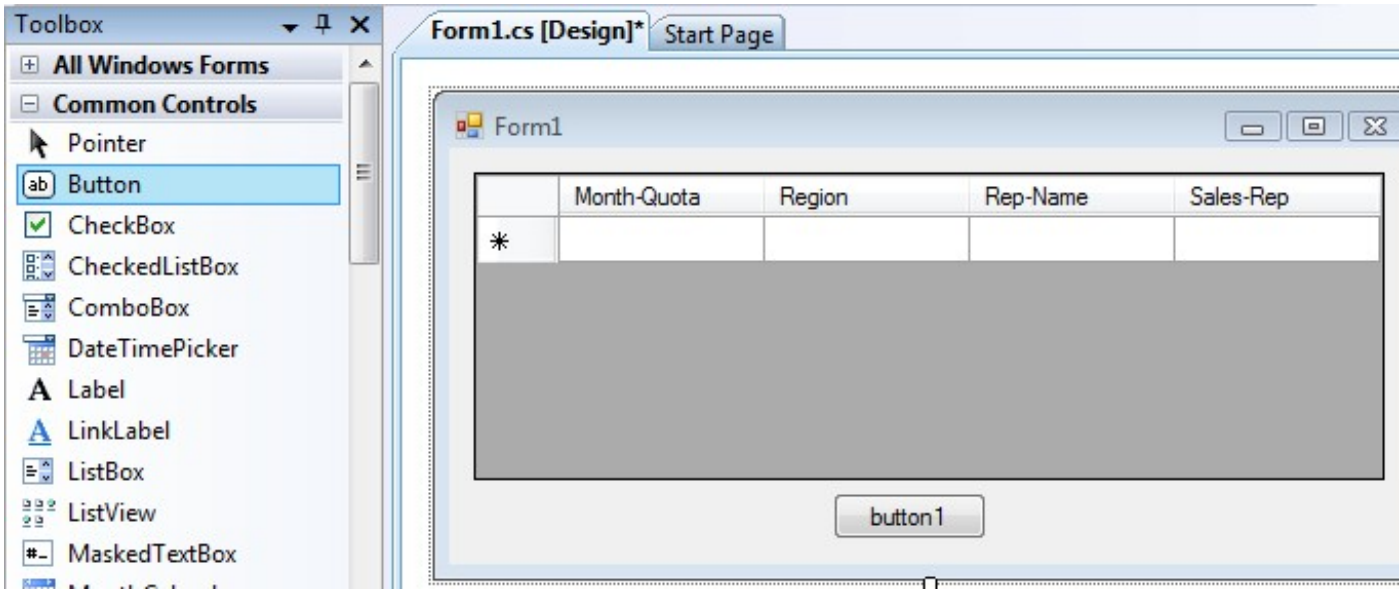
.

Figure 8.137. DataGrid



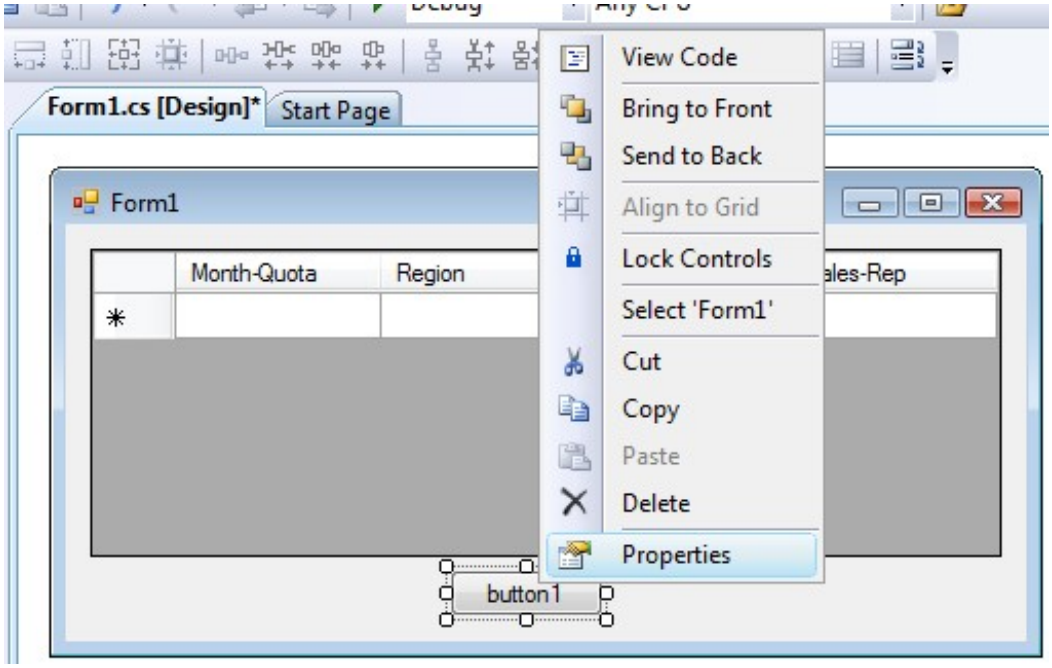
22. To make the DataGridView updateable, you will need to manually add some code to the project along with a suitable control to invoke the code. Drag a Button control onto the form.

Figure 8.138. DataGrid



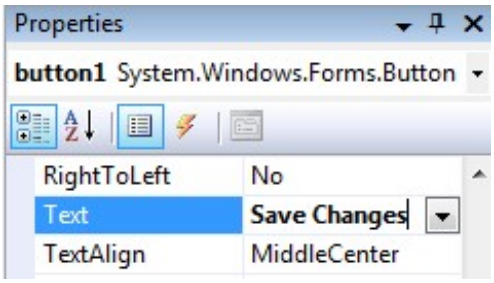
23. Right click on the Button and select Properties.

Figure 8.139. DataGrid



24. In the Properties view, edit the buttons Text property to read Save Changes and its (Name) property to read saveChanges.

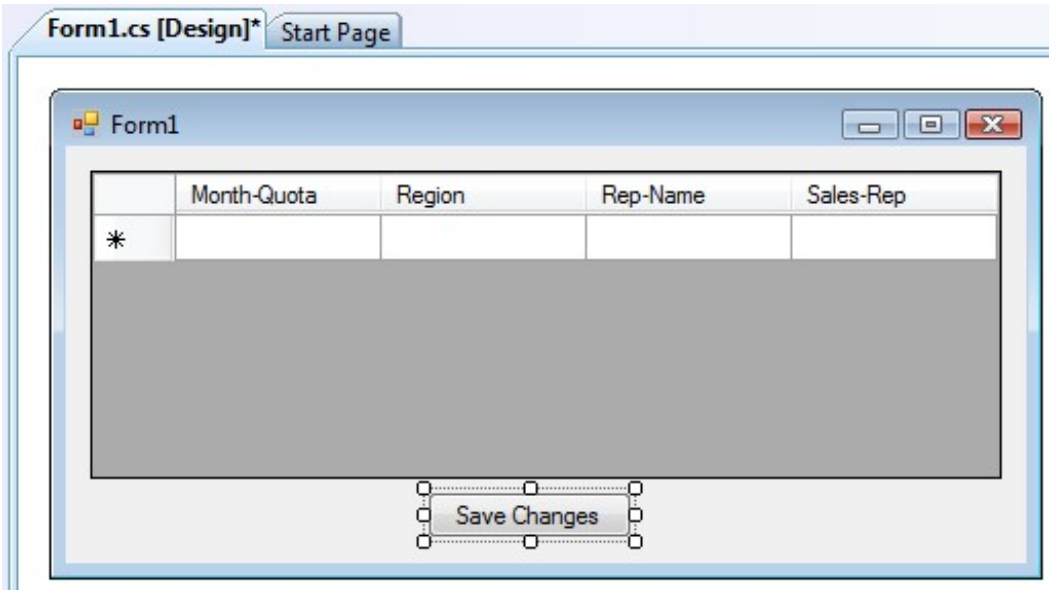
Figure 8.140. DataGrid



25. The button will now update to reflect these changes.

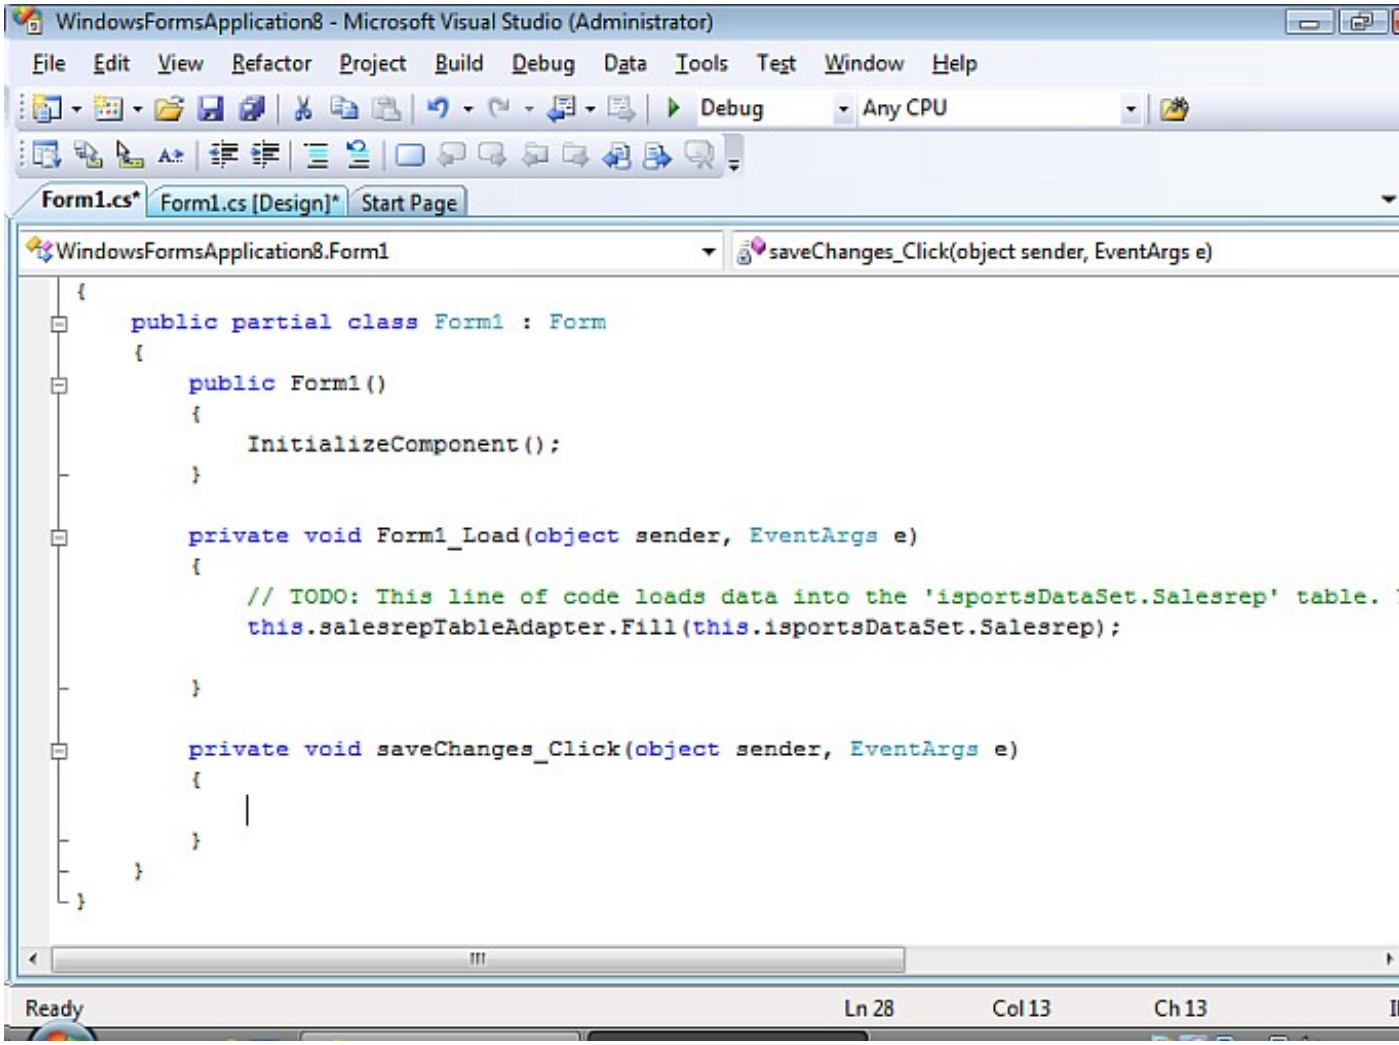
NOTE: You will need to resize the button to make the new text visible.

Figure 8.141. DataGrid



26. Double click the new button to generate the required event handler. It should take you directly to the area of code that will execute when the button is clicked.

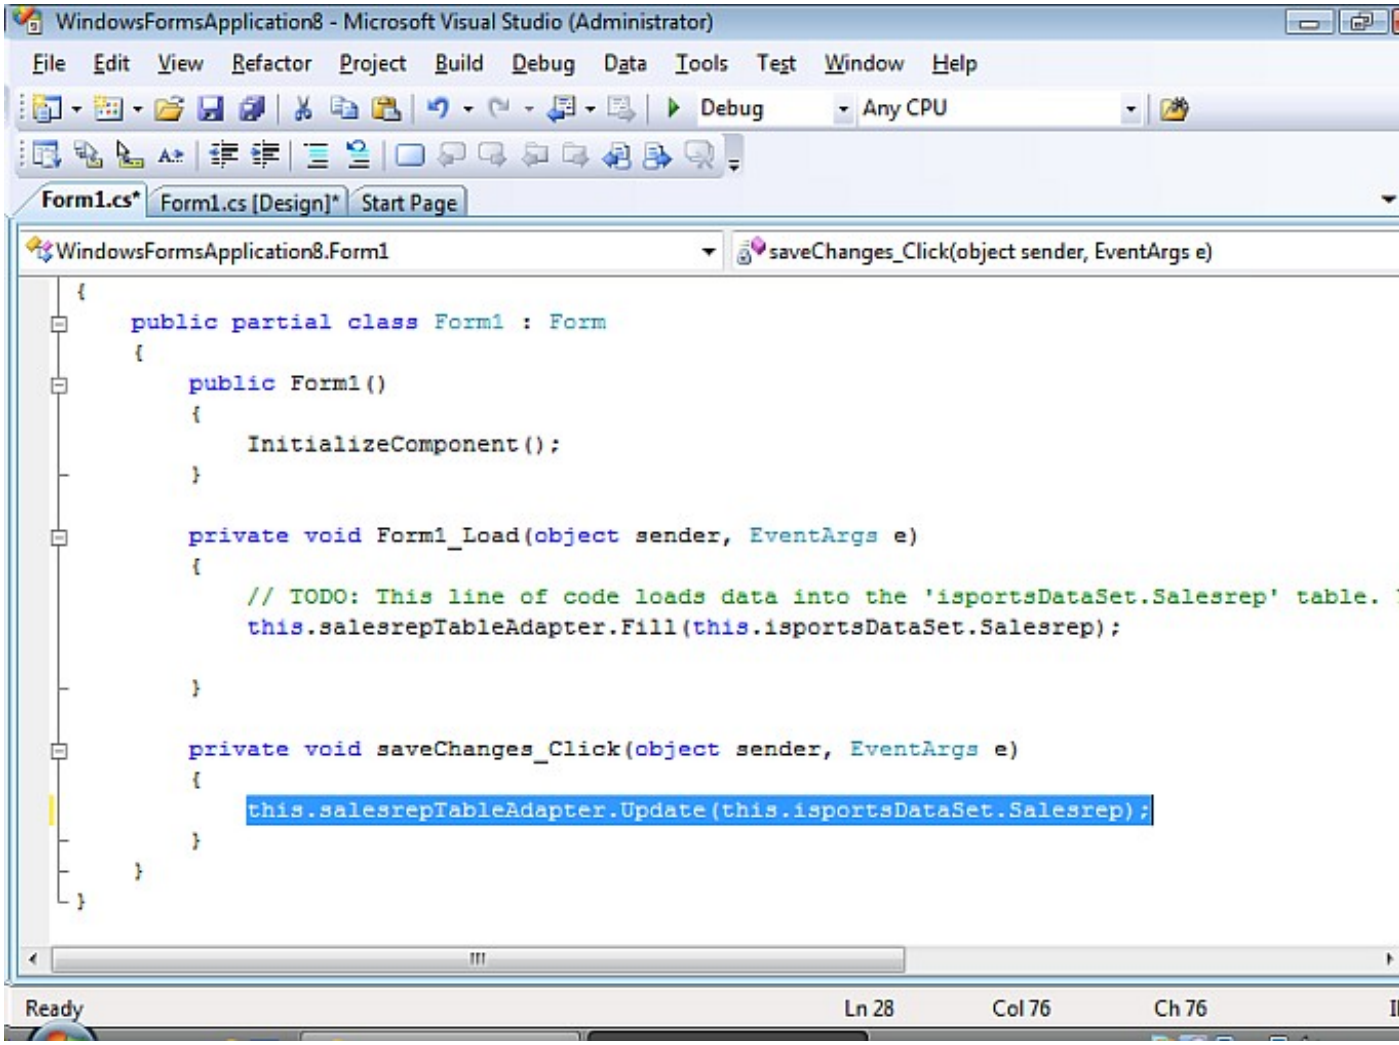
Figure 8.142. DataGrid



27. Edit the saveChanges_Click event handler code to include the following line.

```
private void saveChanges_Click(object sender, EventArgs e)
{
  this.msgsTableAdapter.Update(this.isportsDataSet.msgs);
}
```

Figure 8.143. DataGrid

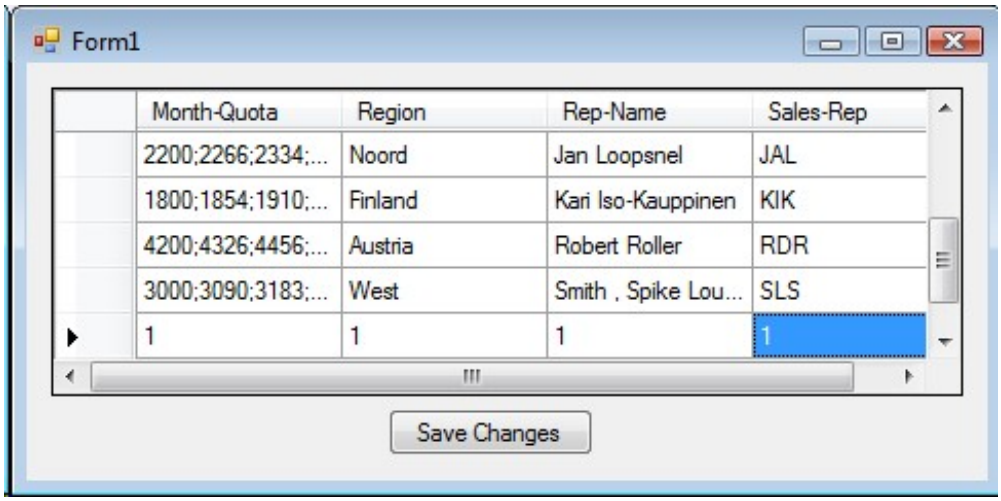


28. Now test the application again by hitting Ctrl+F5.

    Scroll to the empty row, at the bottom, and enter data for a new row then select Save Changes which will write the new row back to the database.

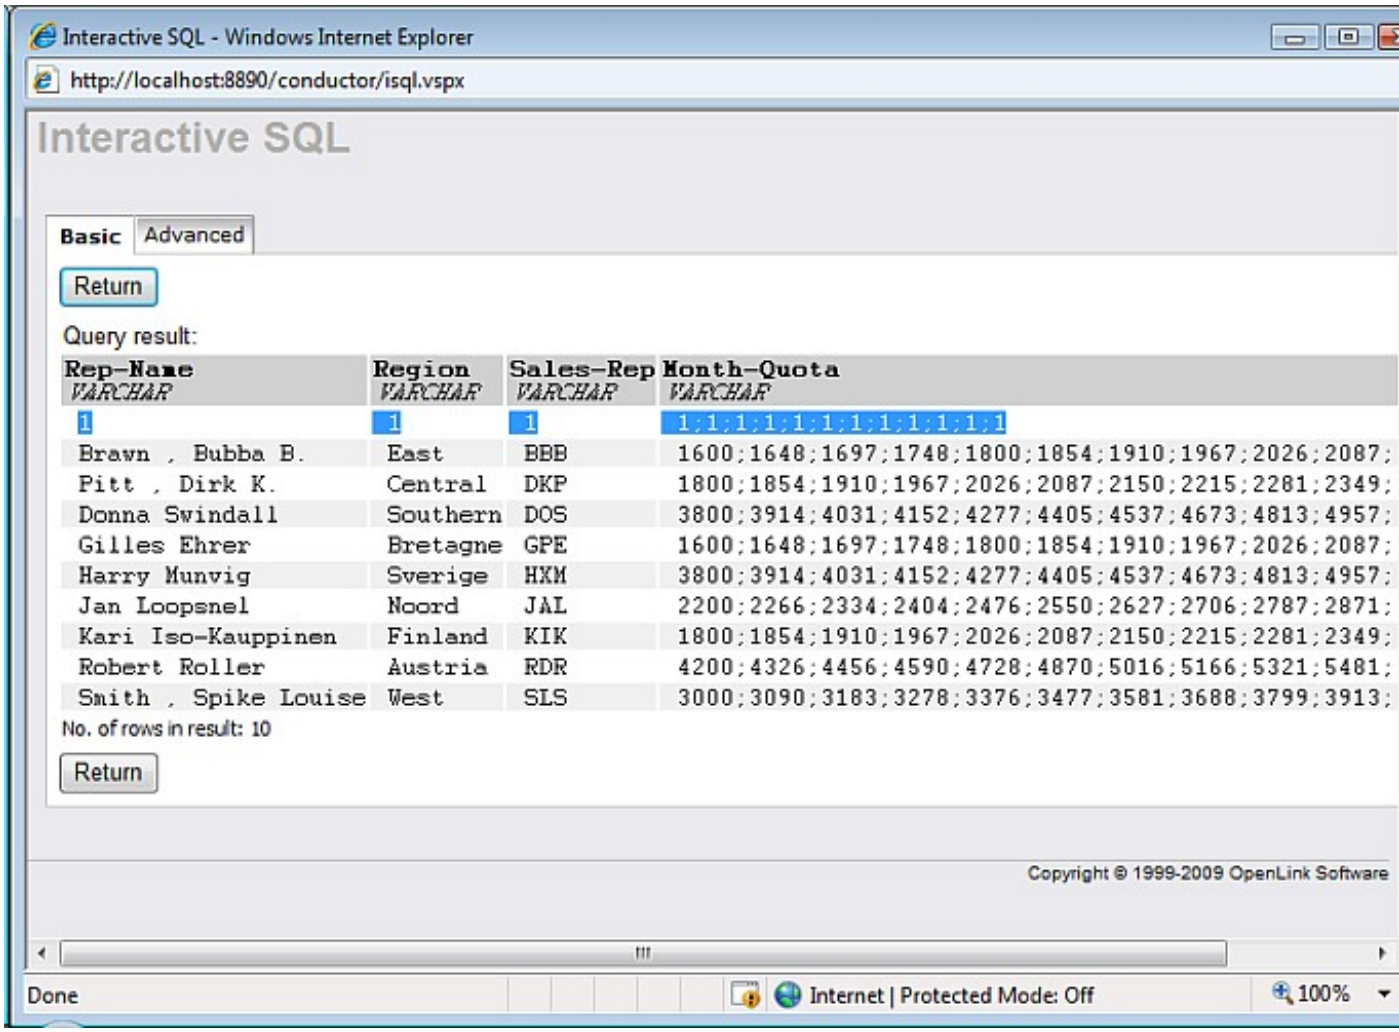
    Updates and deletes can be performed similarly.

Figure 8.144. DataGrid



29. You can use Interactive ISQL to test that the changes that have been written. Interactive ISQL Interface is detailed in the Linking Progress tables section.

Figure 8.145. DataGrid



The task is now complete.

8.4. Using Microsoft Entity Frameworks to Access Ingres Schema Objects with Virtuoso

Abstract

This section details the steps required to provide Microsoft Entity Framework access to Ingres Schema Objects using the OpenLink Virtuoso Universal Server. This is achieved by linking the required Ingres Schema objects into Virtuoso using its built in Virtual Database engine, and then using the Virtuoso ADO.NET Entity Framework provider to query the remote Ingres Schema objects linked into the Virtuoso Server.

Prerequisites. The following prerequisites must be in place for this solution to be possible.

Ingres DBMS. An Ingres DBMS hosting the required Schema Objects needs to be available. In this section the Ingres Tutorial sample database will be used to demonstrate the process.

An Ingres DBMS hosting the required Schema Objects needs to be available. In this section the Ingres Tutorial sample database will be used to demonstrate the process.

ODBC Driver for Ingres. An Ingres ODBC Driver is required for Linking the Ingres Schema Objects into the Virtuoso Server. The *OpenLink ODBC Driver for Ingres* will be used in this section, for which a functional ODBC Data source name of *ingiima* will be assumed to exist on the machine hosting the Virtuoso Server.

An Ingres ODBC Driver is required for Linking the Ingres Schema Objects into the Virtuoso Server. The *OpenLink ODBC Driver for Ingres* will be used in this section, for which a functional ODBC Data source name of *ingiima* will be assumed to exist on the machine hosting the Virtuoso Server.

Virtuoso Universal Server. An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

Microsoft Visual Studio 2008 SP1. Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Tasks

Ensure Ingres Primary Keys (PKs) are not nullable. The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the Ingres database schema before attempting to generate an EDM. In the case of the Ingres database all tables are not nullable, thus this should not be an issue in this case.

The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the Ingres database schema before attempting to generate an EDM. In the case of the Ingres database all tables are not nullable, thus this should not be an issue in this case.

8.4.1. Install and configure OpenLink ODBC Driver for Ingres

The Virtuoso Virtual Database engine uses ODBC as the connectivity mechanism for linking remote database objects into its local schema. Thus an Ingres ODBC Driver must be available with a suitably configured DSN for connecting to the target database. The OpenLink ODBC Drivers for Ingres have been used in this section, although in theory any Ingres ODBC Driver can be used.

Installation instructions for the OpenLink ODBC Driver for Ingres are available from:

- Product Installation & Basic Configuration (ODBC)

8.4.2. Install and configure OpenLink Virtuoso Universal Server

- Install and configure OpenLink Virtuoso Universal Server

8.4.3. Linking Ingres tables into OpenLink Virtuoso

1. Start the Virtuoso Web User Interface

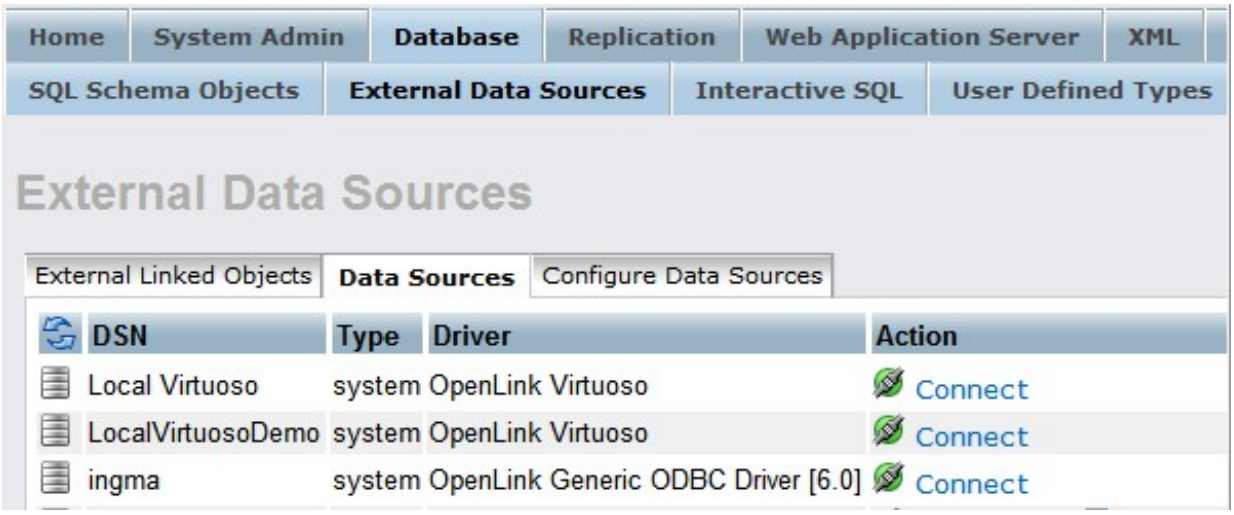
   Figure 8.146. Start

2. Select the "Conductor" link in the Left Frame and Login as the "dba" user.

Figure 8.147. Conductor

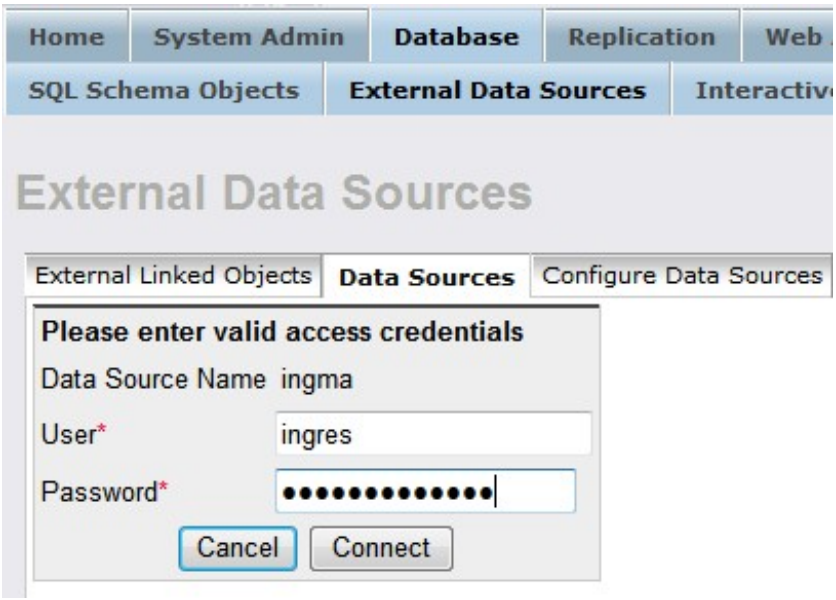
3. Select the "Databases" -> "External Data Source" -> "Data Sources" tab menu items

Figure 8.148. Databases



4. Select the "Connect" button for the "Ing10ma" Ingres DSN.

Figure 8.149. Connect

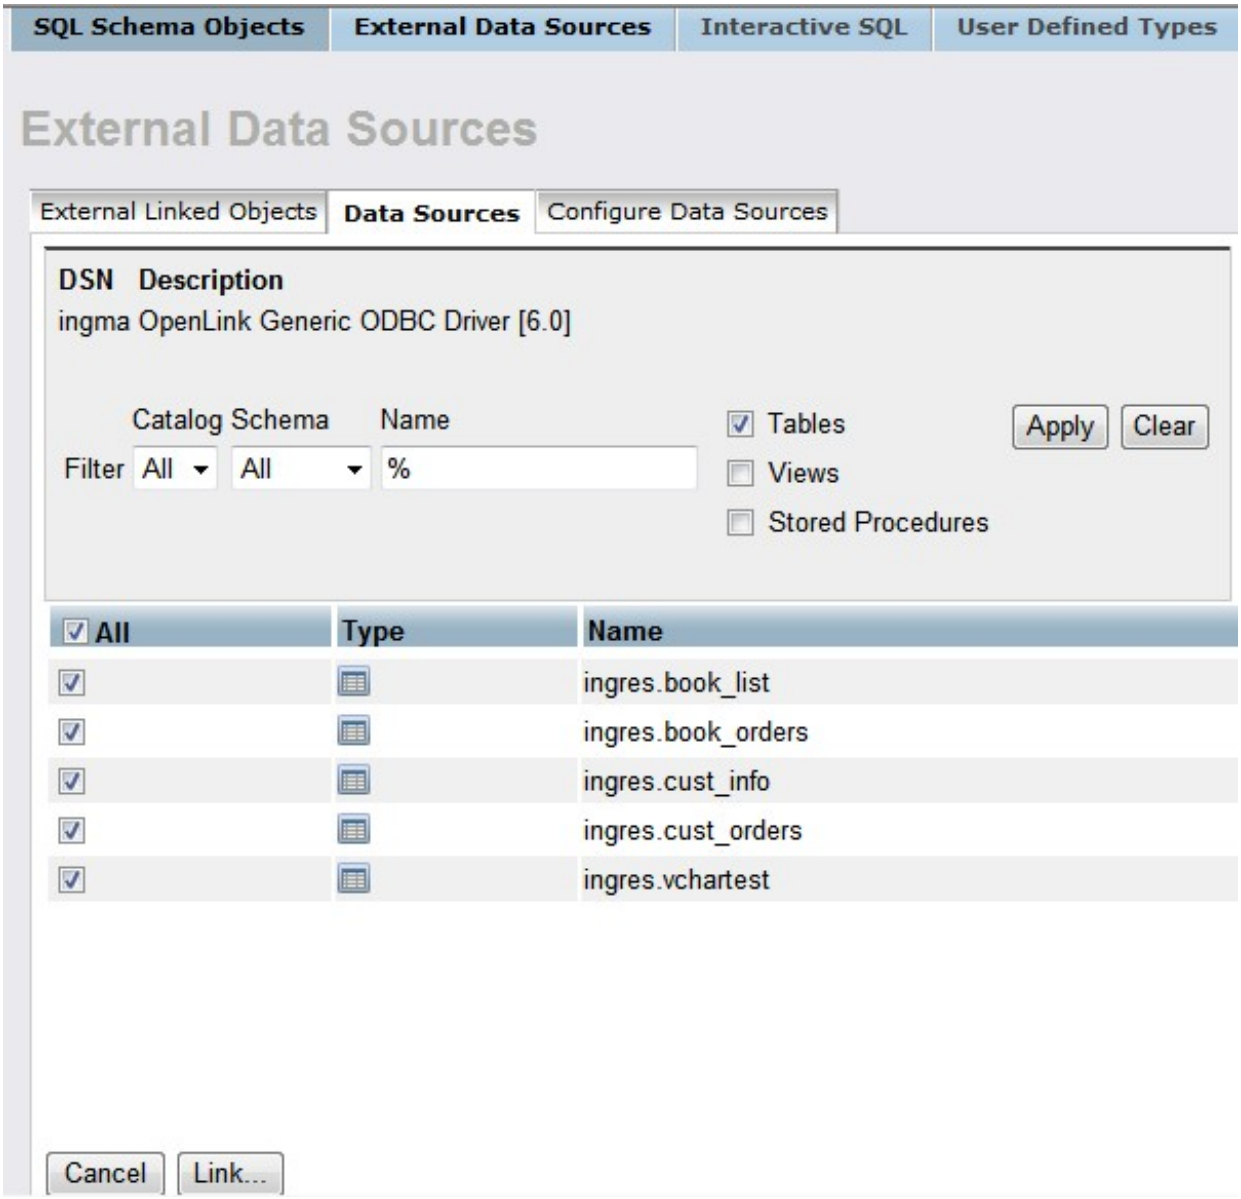


5. On successful connection Select the "Link Objects" button to obtain a list of available tables

Figure 8.150. Link Objects

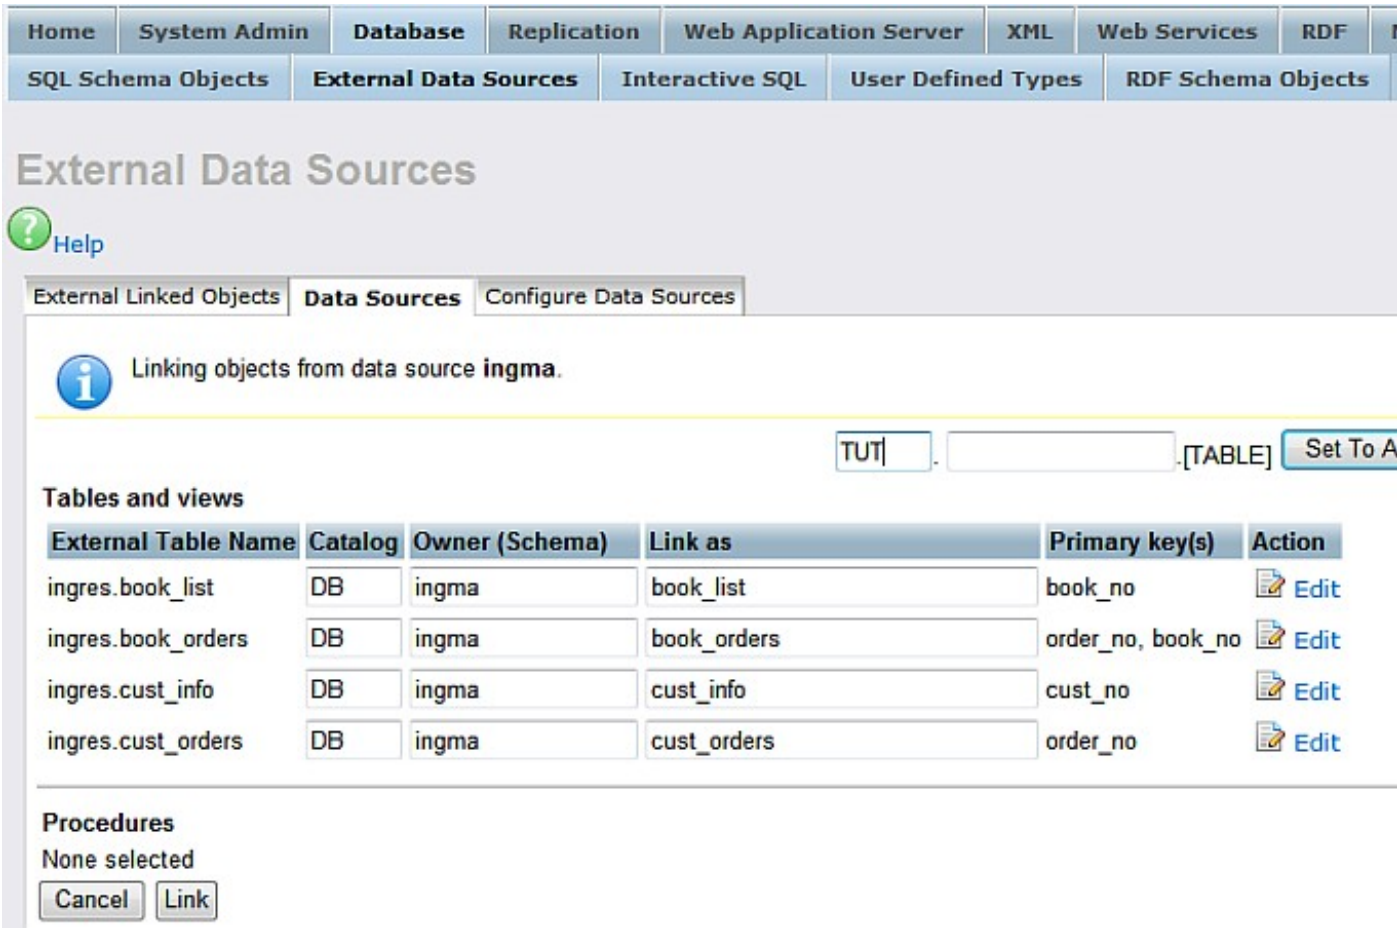
6. Select all the tables that are part of the "TUT" catalog and press the "Link" button to commence the linking process

Figure 8.151. Select all tables



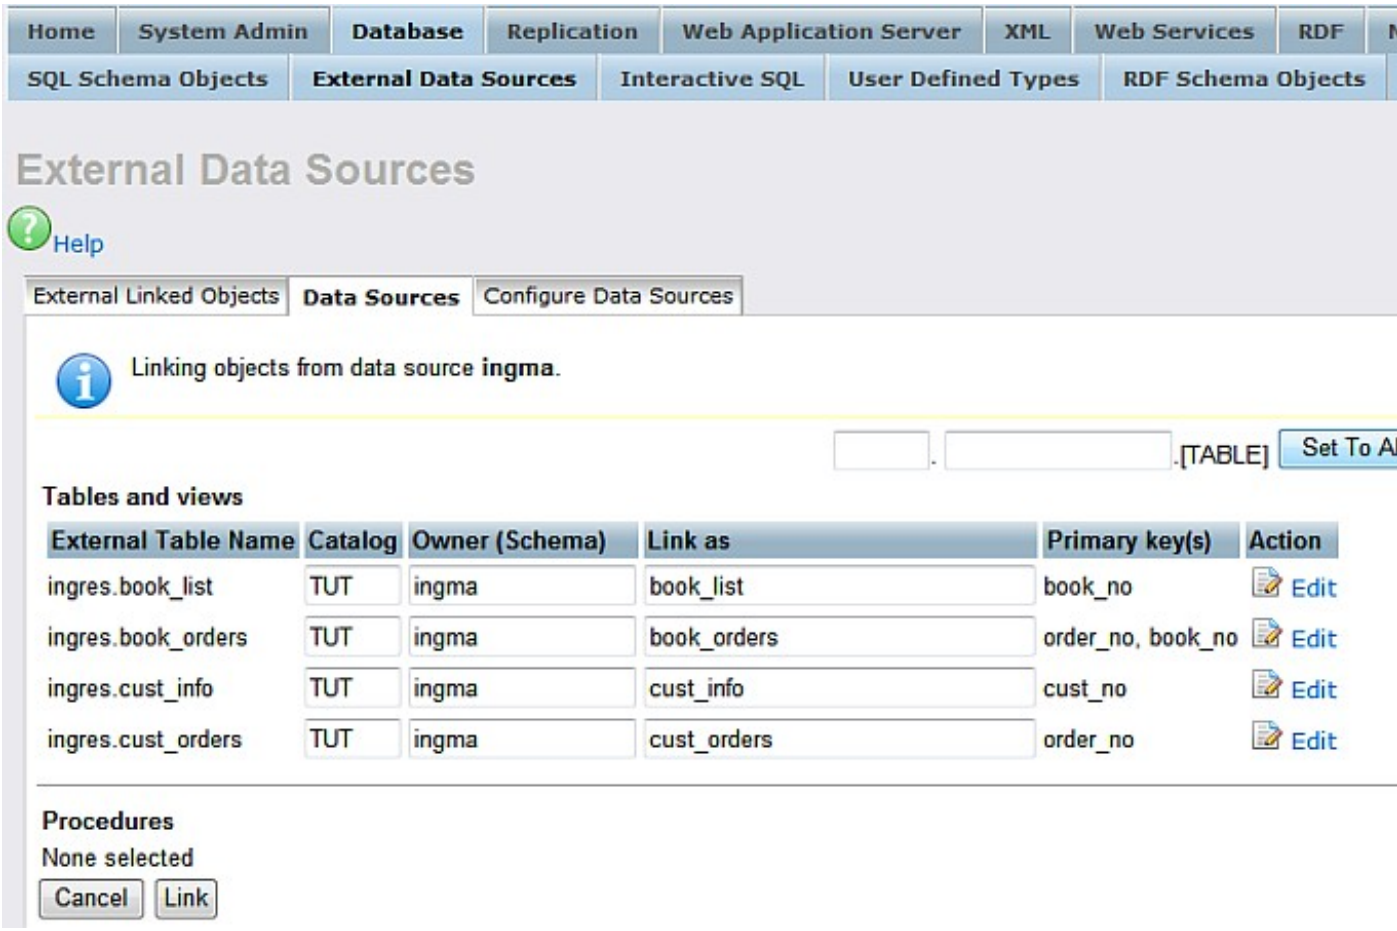
7. Change the Catalog for each table to be "TUT" using the "Set All" button.

Figure 8.152. Catalog



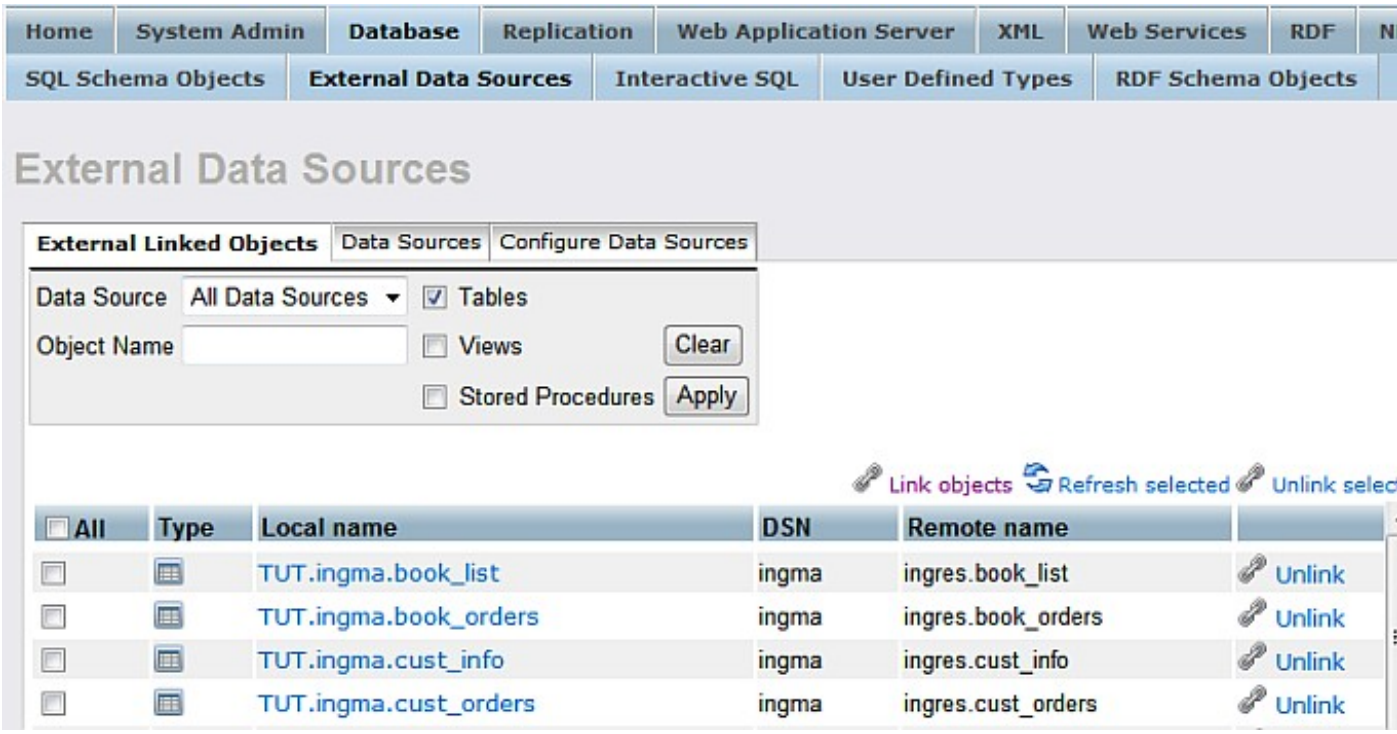
8. All the catalog names are changed to be "TUT".
9. Select the "Link" button to link the selected tables into Virtuoso

Figure 8.153. "Link" button



10. On completion of the Link process the tables will be displayed in the "External Linked Objects" tab.

Figure 8.154. Completion

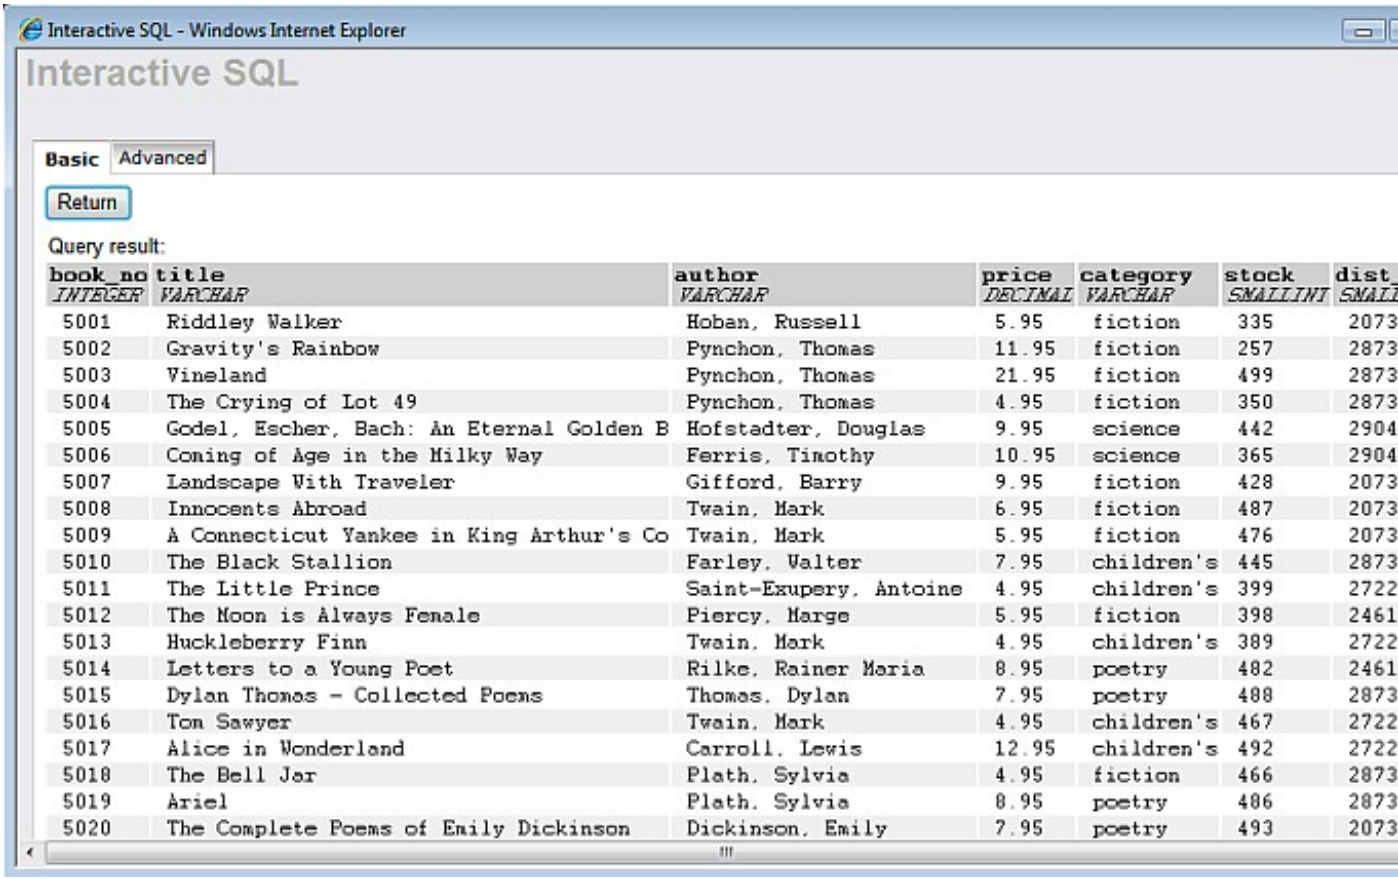


11. The linked tables can be queried by clicking on the hyperlink in the "Local Name" column of the "External Linked Objects" tab above, which loads the Virtuoso "Interactive SQL" interface with the required SQL "Select" for retrieving the remote table data. We shall use the "TUT.ingma.book_list" table to demonstrate this.

Figure 8.155. Querying

12. Then click the "Execute" button to run the query and retrieve the results from the remote table.

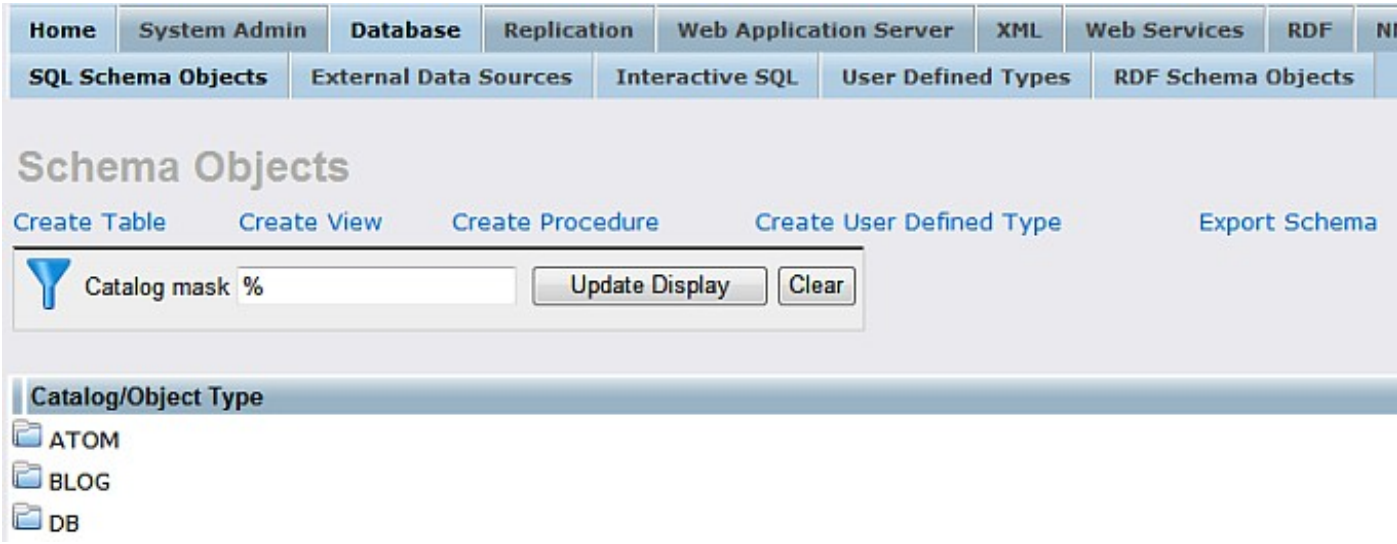
Figure 8.156. Execute



book_no INTEGER	title VARCHAR	author VARCHAR	price DECIMAL	category VARCHAR	stock SMALLINT	dist SMALL
5001	Riddley Walker	Hoban, Russell	5.95	fiction	335	2073
5002	Gravity's Rainbow	Pynchon, Thomas	11.95	fiction	257	2873
5003	Vineland	Pynchon, Thomas	21.95	fiction	499	2873
5004	The Crying of Lot 49	Pynchon, Thomas	4.95	fiction	350	2873
5005	Godel, Escher, Bach: An Eternal Golden B	Hofstadter, Douglas	9.95	science	442	2904
5006	Coming of Age in the Milky Way	Ferris, Timothy	10.95	science	365	2904
5007	Landscape With Traveler	Gifford, Barry	9.95	fiction	428	2073
5008	Innocents Abroad	Twain, Mark	6.95	fiction	487	2073
5009	A Connecticut Yankee in King Arthur's Co	Twain, Mark	5.95	fiction	476	2073
5010	The Black Stallion	Farley, Walter	7.95	children's	445	2873
5011	The Little Prince	Saint-Exupery, Antoine	4.95	children's	399	2722
5012	The Moon is Always Female	Piercy, Marge	5.95	fiction	398	2461
5013	Huckleberry Finn	Twain, Mark	4.95	children's	389	2722
5014	Letters to a Young Poet	Rilke, Rainer Maria	8.95	poetry	482	2461
5015	Dylan Thomas - Collected Poems	Thomas, Dylan	7.95	poetry	488	2873
5016	Tom Sawyer	Twain, Mark	4.95	children's	467	2722
5017	Alice in Wonderland	Carroll, Lewis	12.95	children's	492	2722
5018	The Bell Jar	Plath, Sylvia	4.95	fiction	466	2873
5019	Ariel	Plath, Sylvia	8.95	poetry	486	2873
5020	The Complete Poems of Emily Dickinson	Dickinson, Emily	7.95	poetry	493	2073

13. The tables can also be viewed as part of the Virtuoso "SQL Schema Objects" under the "TUT" catalog name.

Figure 8.157. SQL Schema Objects



The Link process is now complete enabling the tables to be queried as if part of the Virtuoso Schema.

8.4.4. Creating EDM in Visual Studio 2008

The following steps can be used to create an Entity Data Model (EDM) for the Ingres Tutorial database:

1. Launch the Visual Studio 2008 SP1 IDE.

Figure 8.158. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

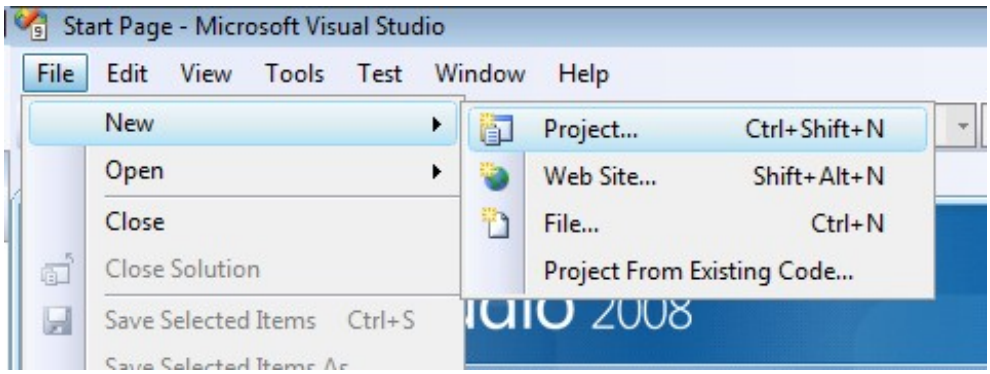
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.159. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Web

   and select

   ASP.NET Web Application

from the right-hand panel.

5. Choose a name for the project, for example

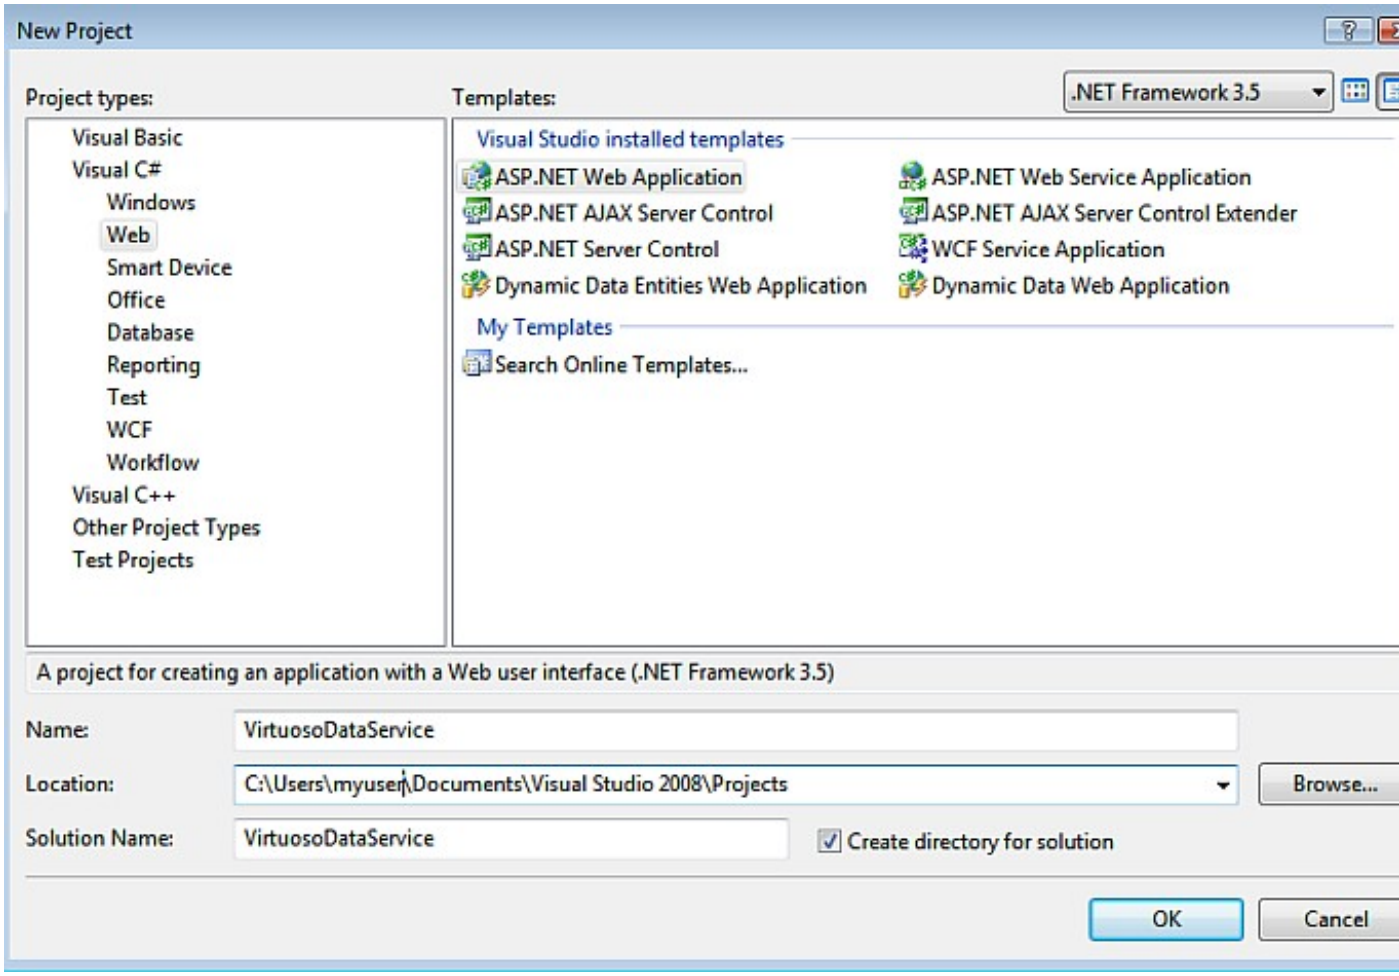
   VirtuosoDataService

   , and click

   OK

   .

   Figure 8.160. name for the project

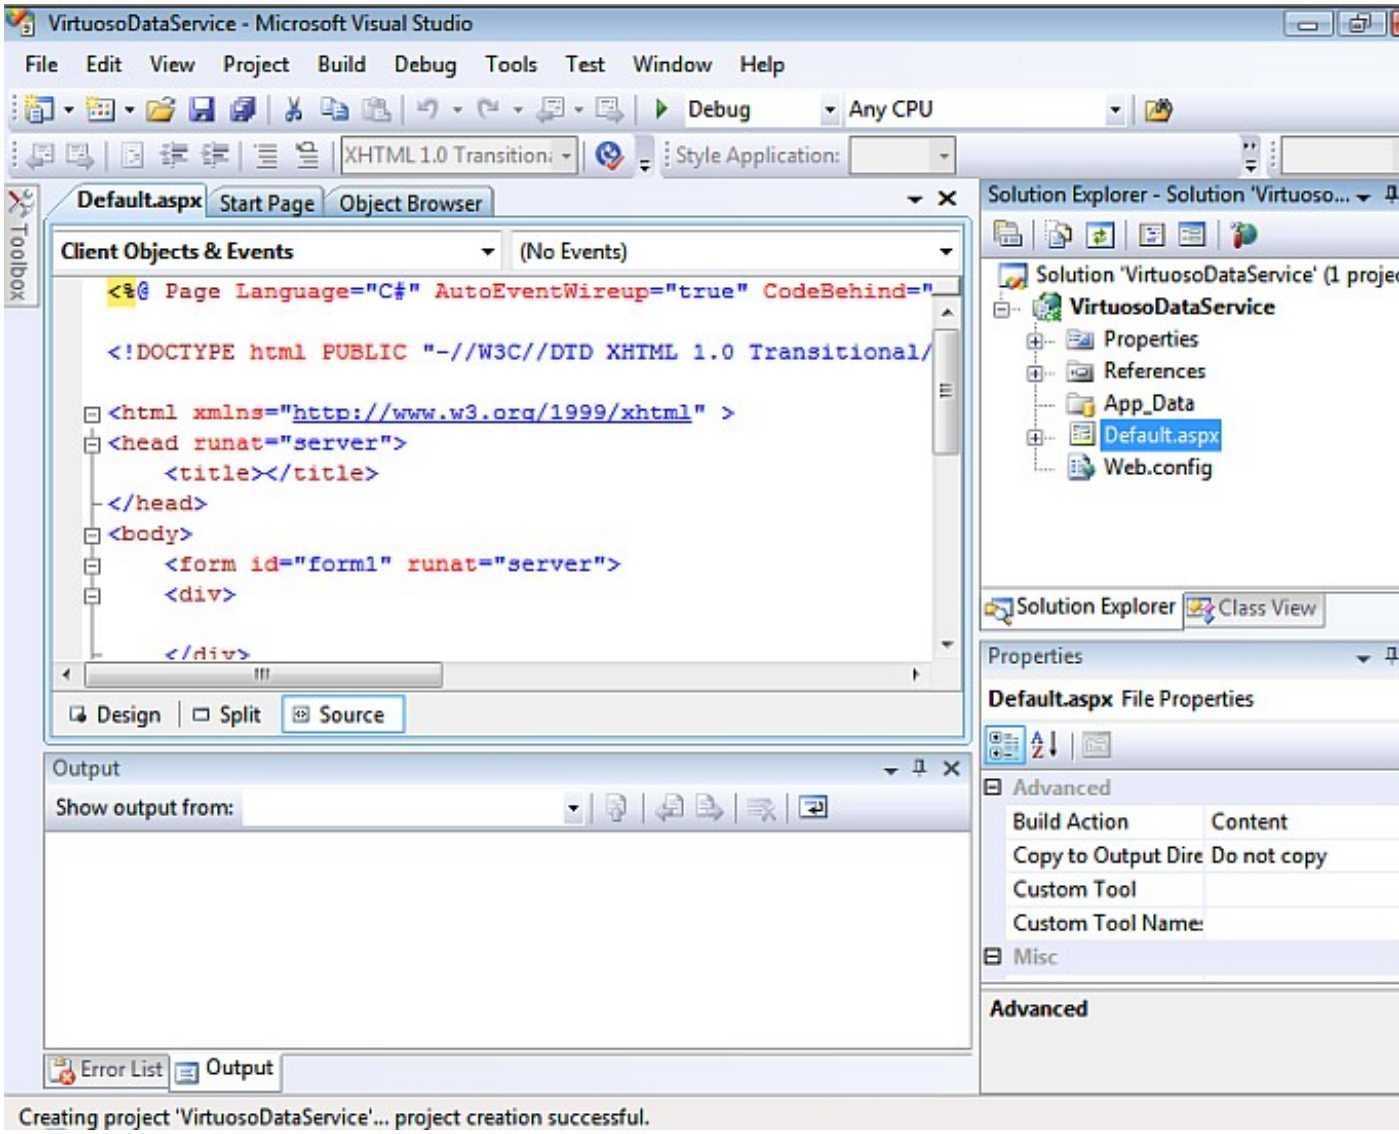


6. This will create a new project called

   VirtuosoDataService

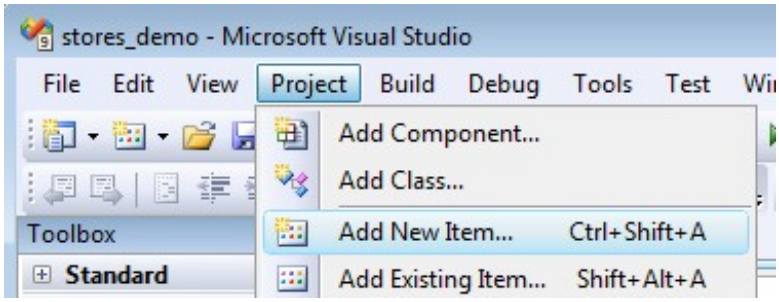
   .

   Figure 8.161. create a new project



7. Select the Project -> Add New Item menu option.

Figure 8.162. VirtuosoDataService



8. The

Add New Item

dialog will appear. Choose the

ADO.NET Entity Data Model

template. Give it the name

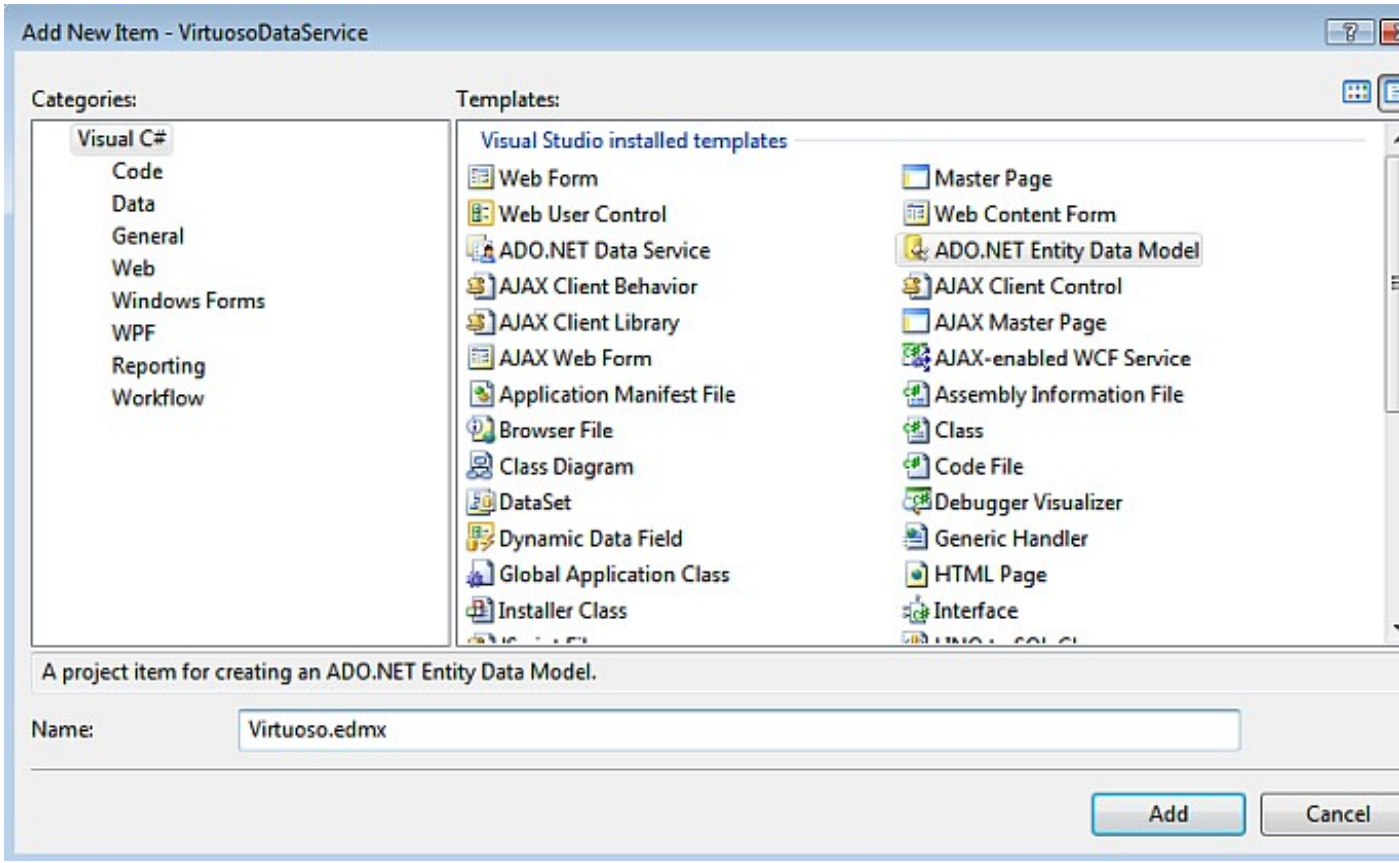
Virtuoso.edmx

and click

Add

to start the creation of the ADO.Net Entity Data Model.

Figure 8.163. Add New Item



9. In the

Entity Data Model Wizard

dialog

Choose Model Contents

page select the

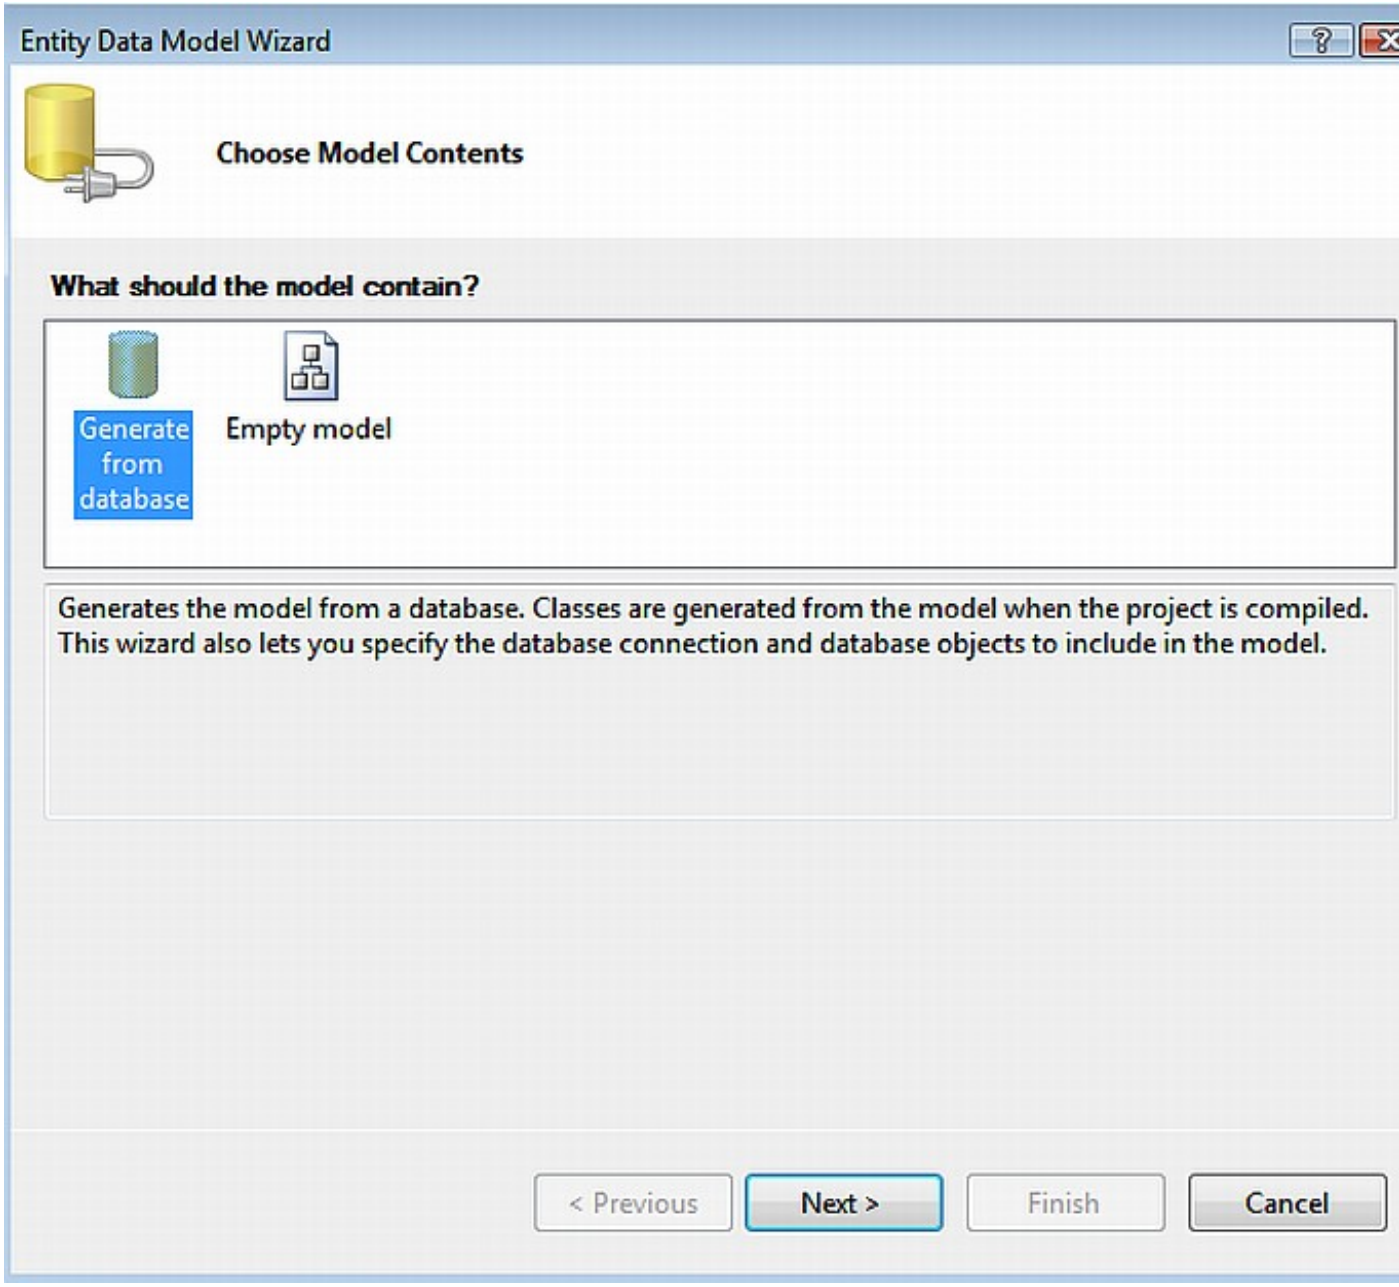
Generate from Database

model type and click

Next

.

Figure 8.164. Choose Model Contents



10. In the

    Entity Data Model Wizard

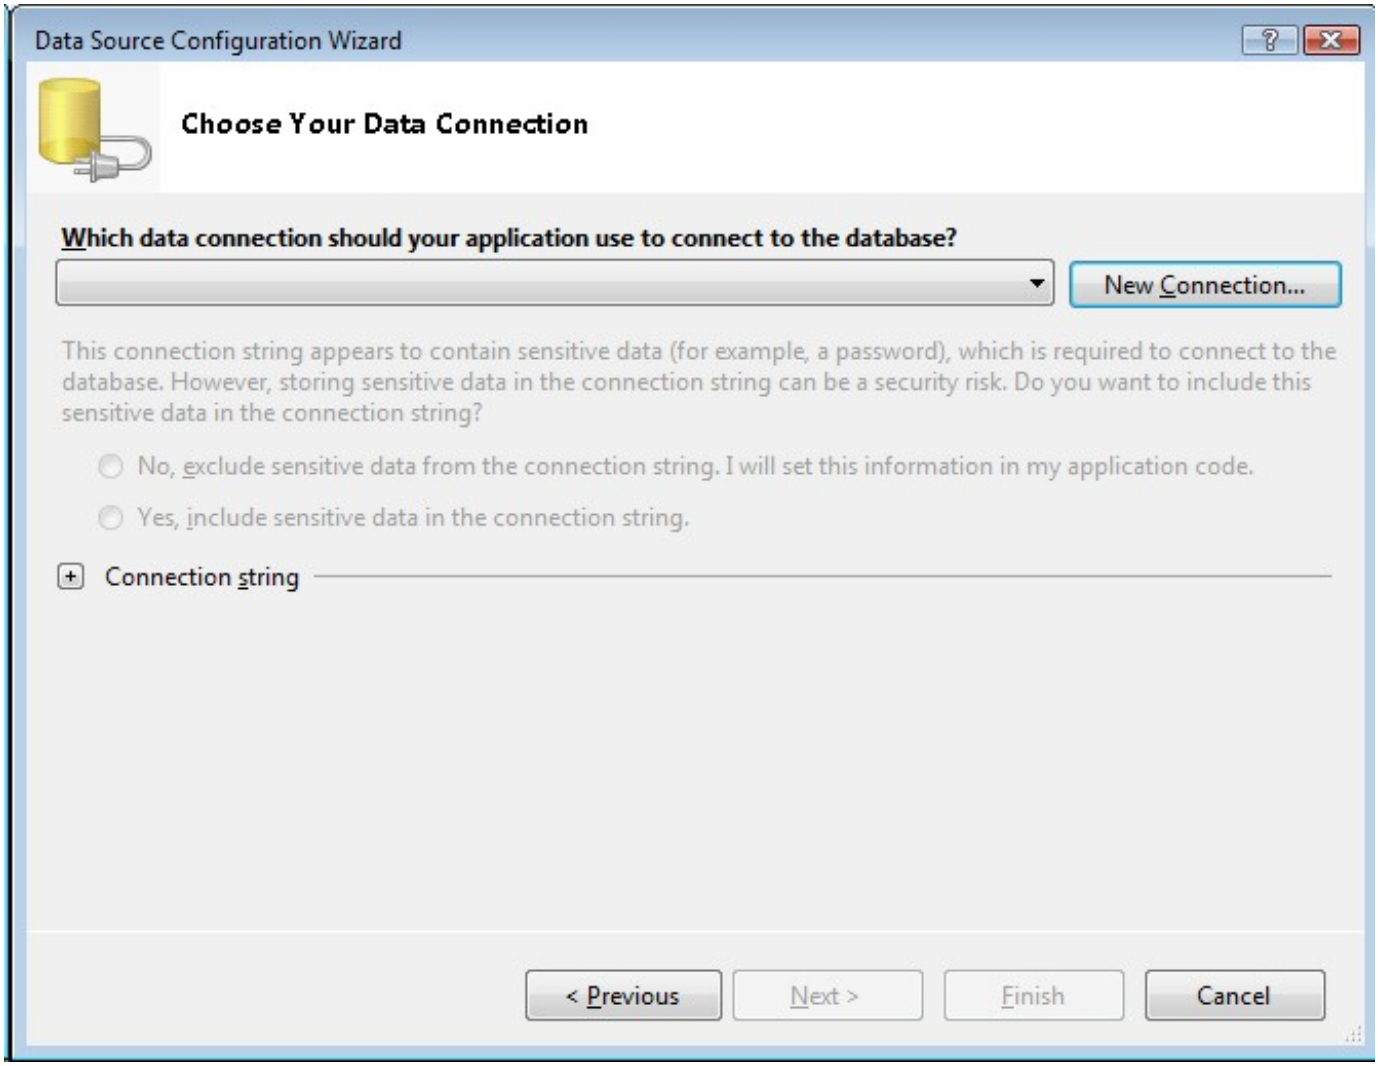
    dialog

    Choose your Data Connection

    page, select the

    New Connection button

Figure 8.165. Entity Data Model Wizard



11. In the

    Choose Data Source

    dialog, select the OpenLink

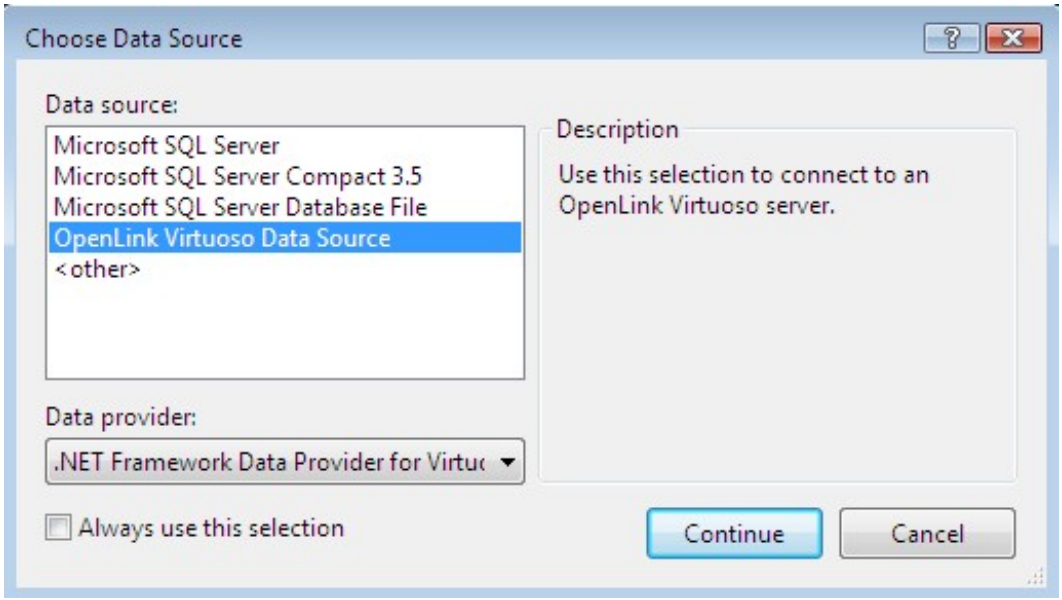
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.166. Choose Data Source



12. In the

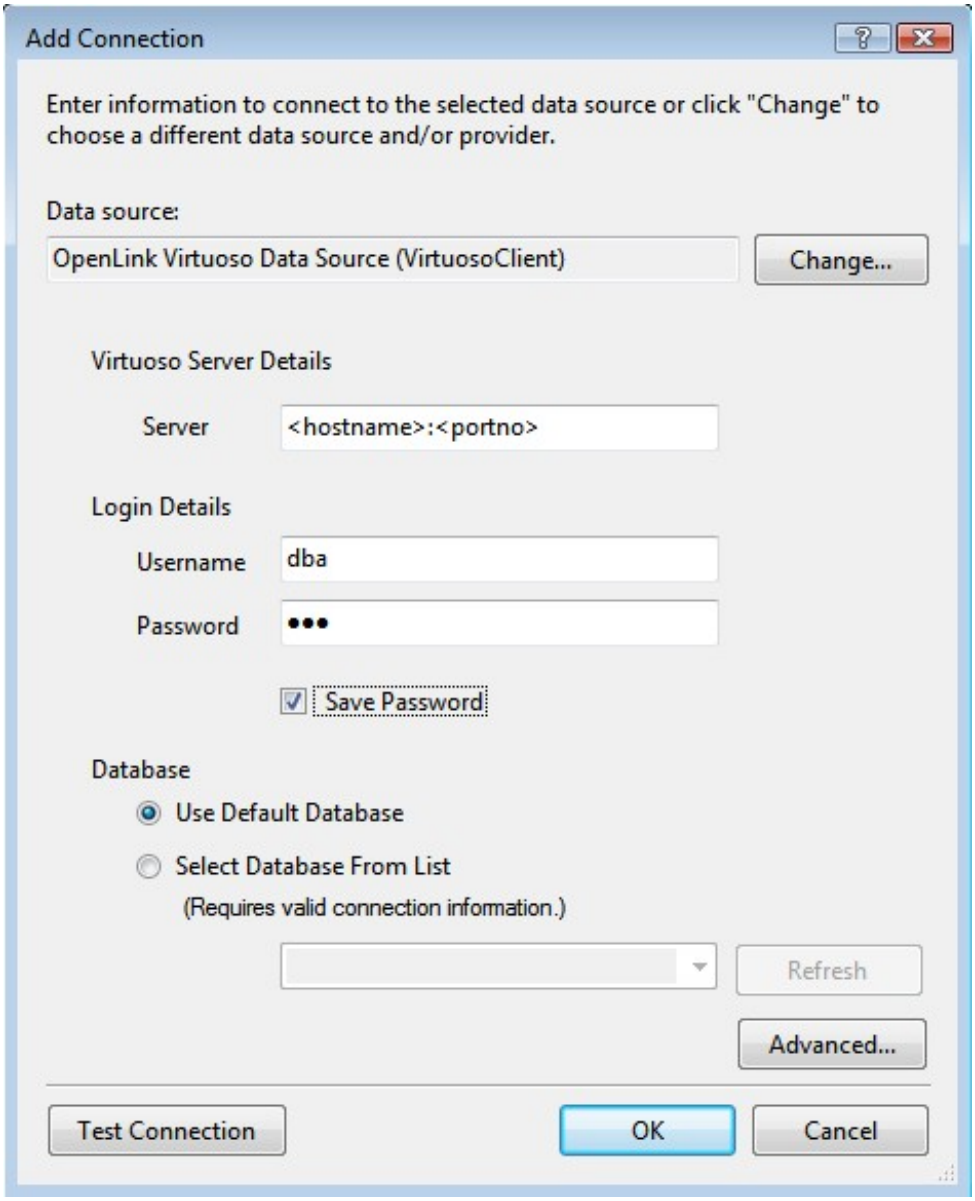
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.167. Connection Properties



13. Select the

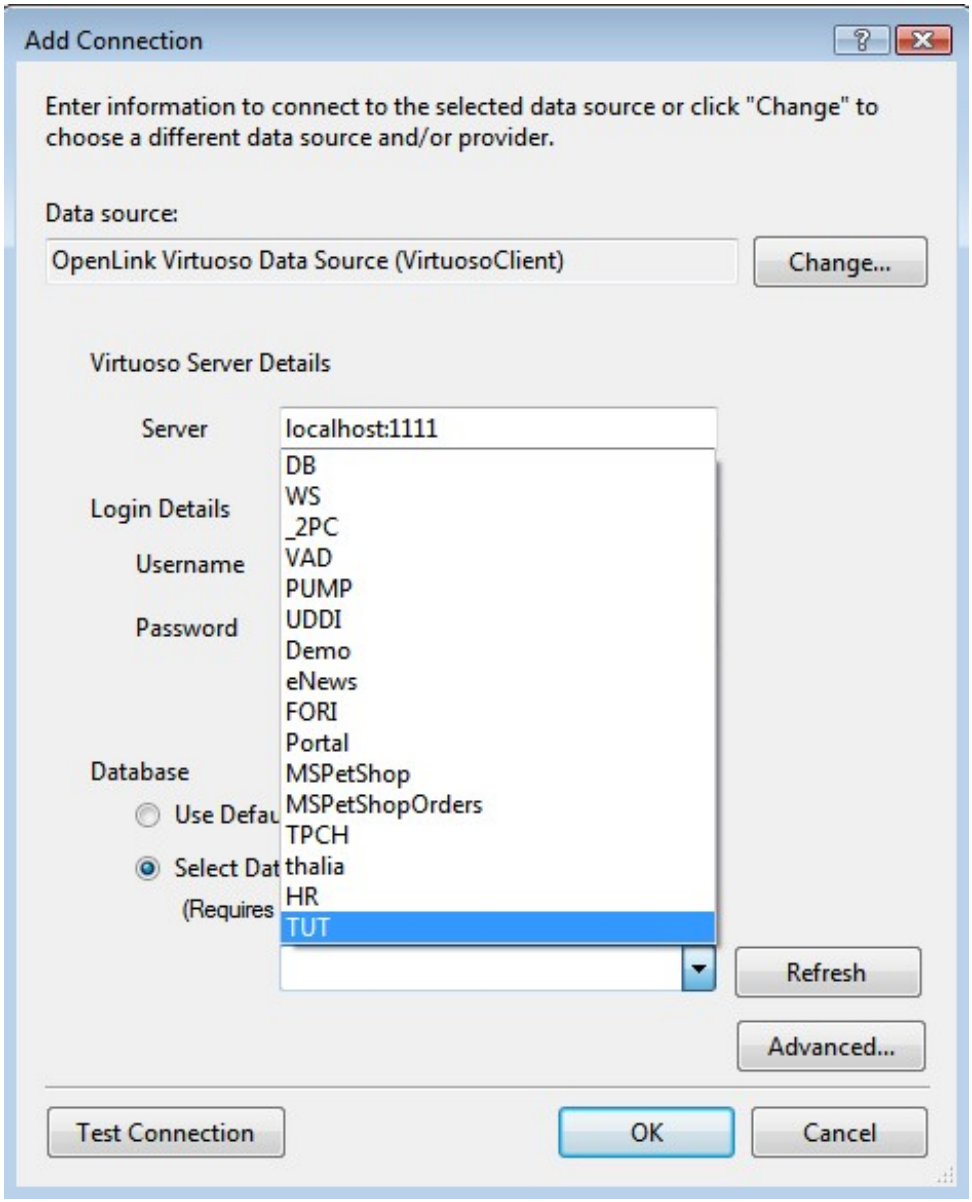
    Select Database From List

    radio button and choose the

    TUT

    database from the drop down list.

Figure 8.168. Add conneciton

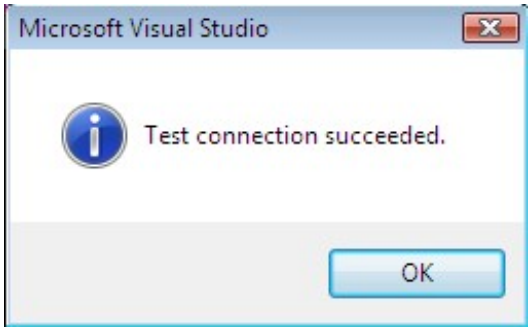


14. Press the

    Test Connection

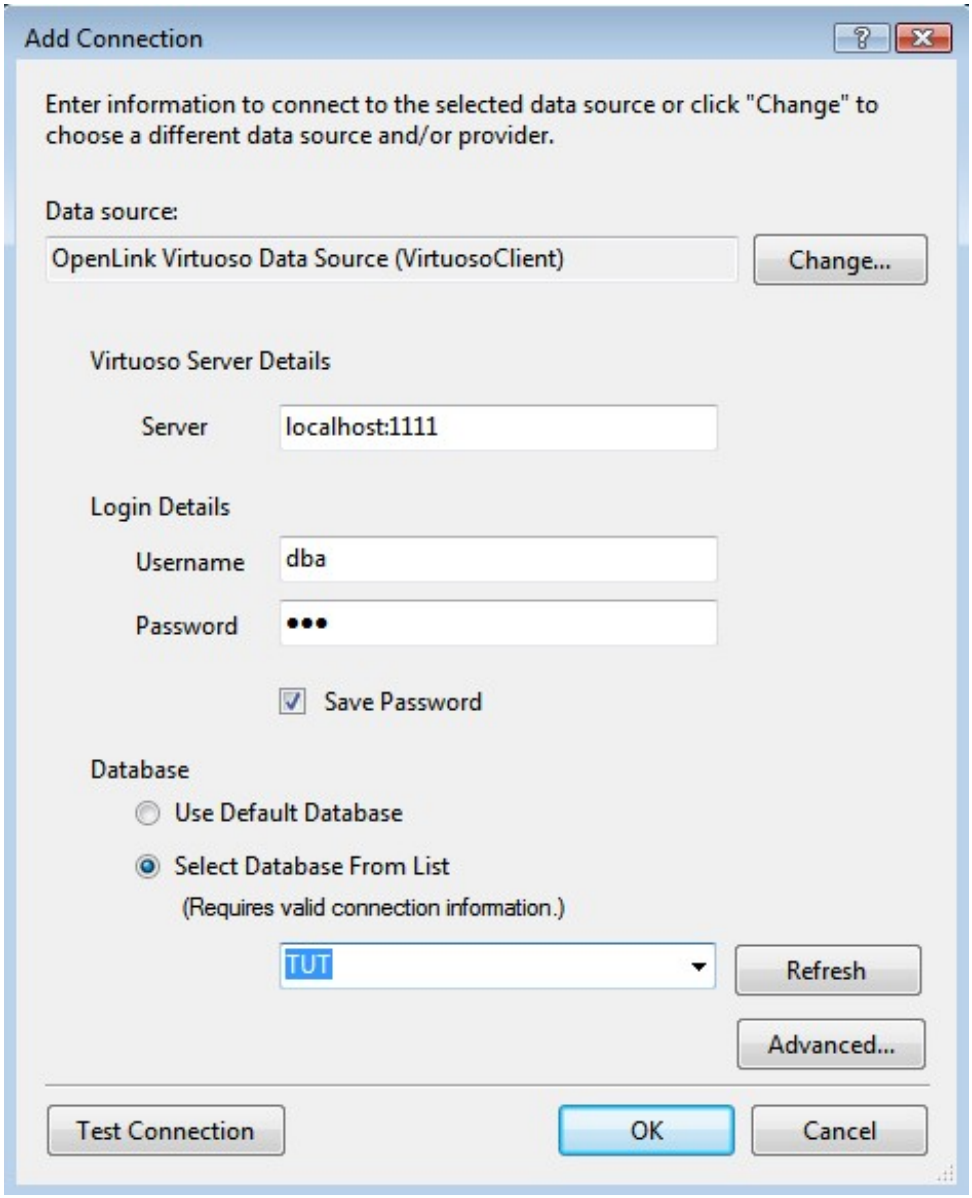
    dialog to verify that the database is accessible.

Figure 8.169. Test Connection



15. Click OK to add the connection.

Figure 8.170. Test Connection



16. Set the

    entity connect string

    name to

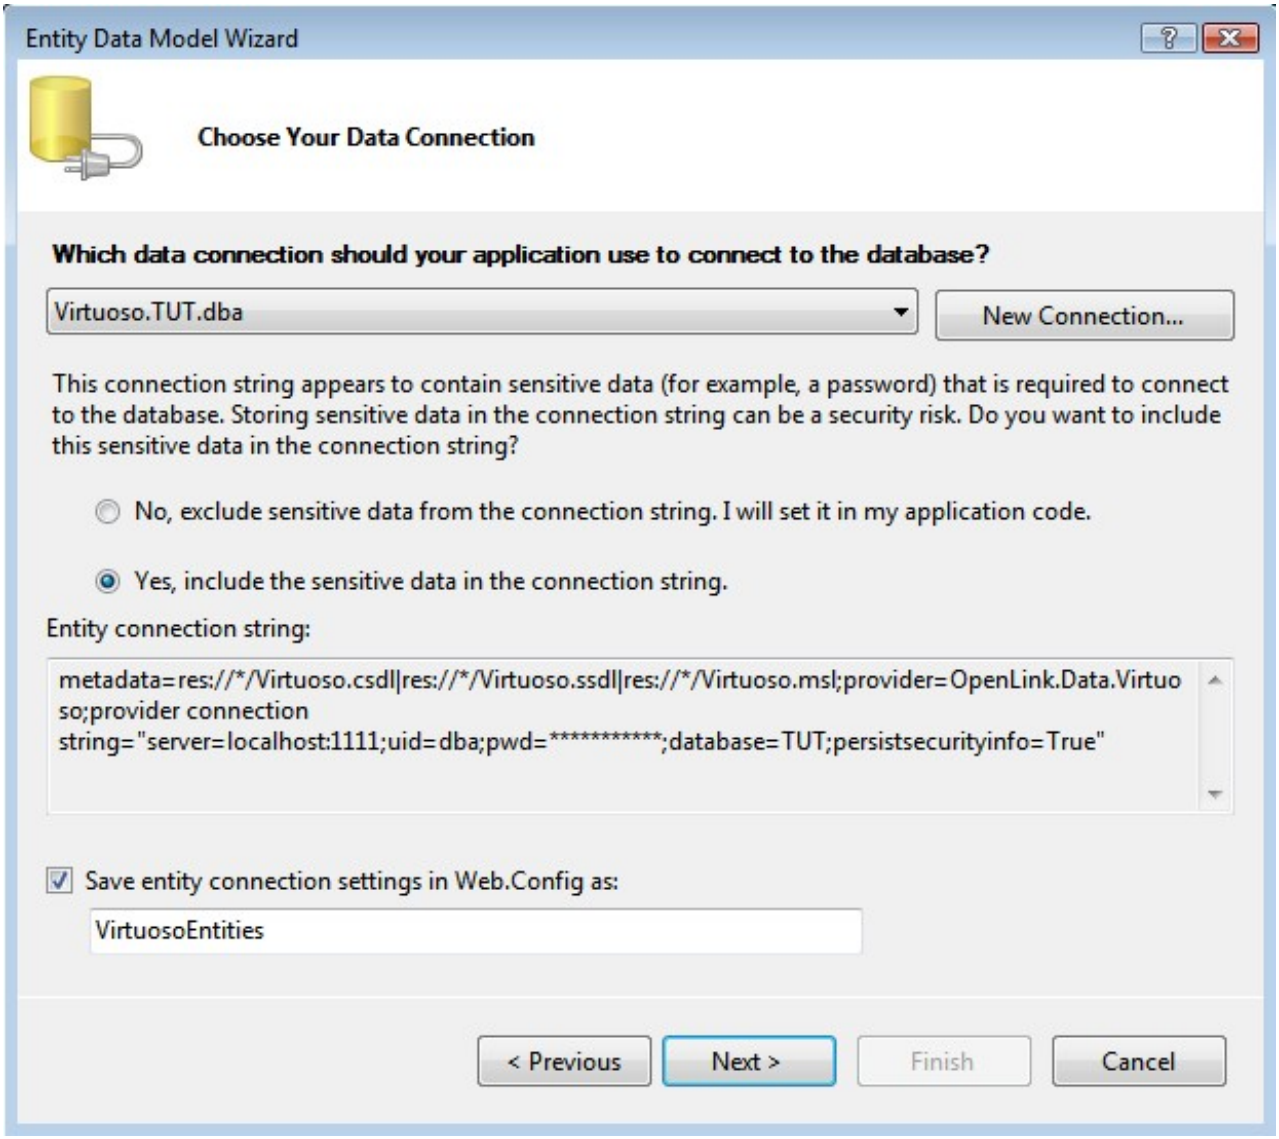
    VirtuosoEntities

    (note this name as it is required in the section on creating and ADO.Net Data Service) and click

    Next

    .

    Figure 8.171. entity connect string



17. In the

    Choose your Database Objects

    page, tick the

    Tables

    check box to select all tables in the TUT catalog for addition to the Entity Data Model. Set the

    Model Namespace

    to

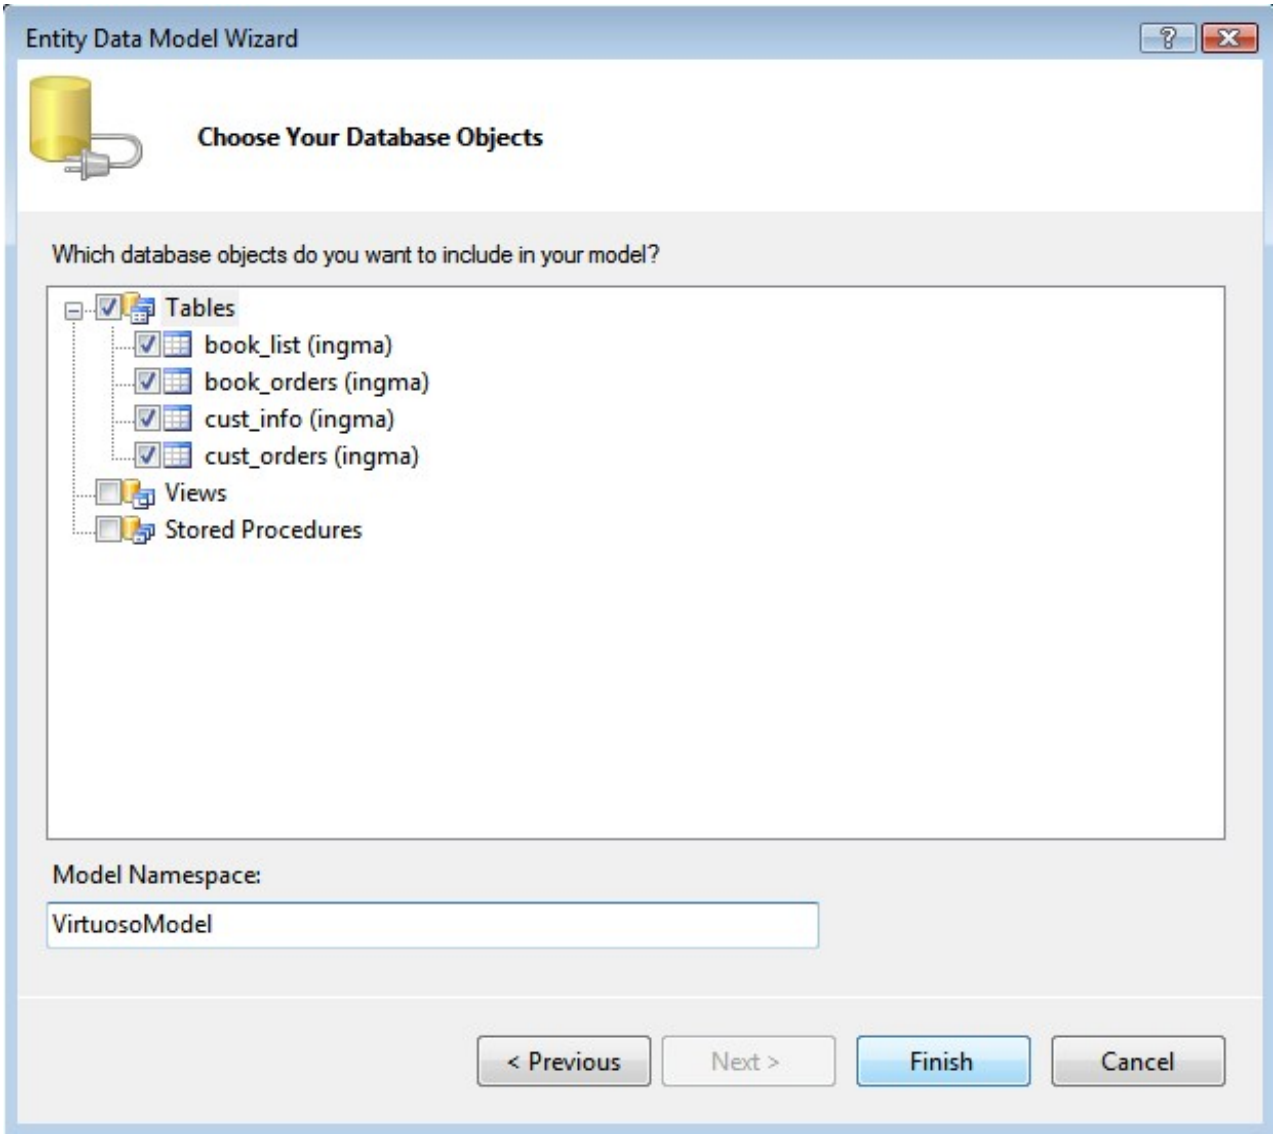
    VirtuosoModel

    and click

    Finish

    .

Figure 8.172. Database Objects

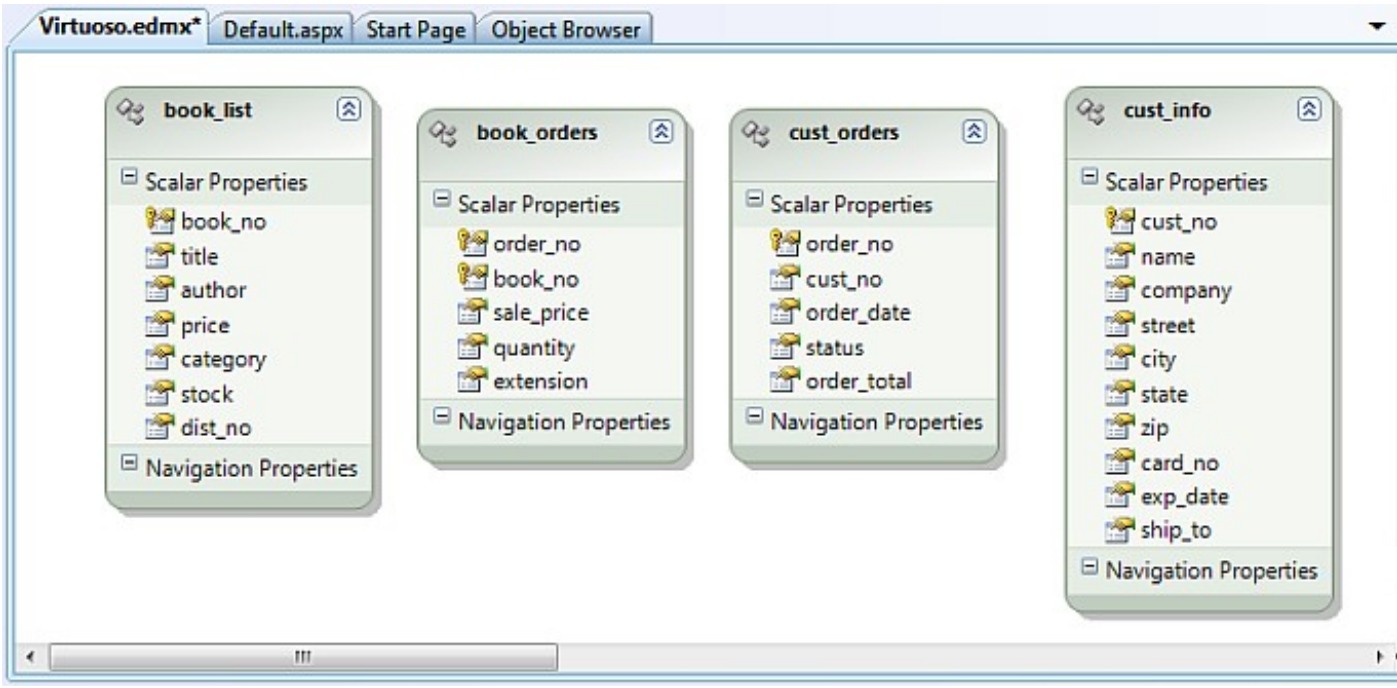


18. The

    Virtuoso.edmx

    EDM will be created with the tables and relationships displayed in the Visual Studio IDE

    Figure 8.173. Virtuoso.edmx



Creation for the Entity Data Model for the Ingres Tutorial database is now complete.

8.4.5. Manually creating EDM Associations (FKs) for the Ingres Tutorial database

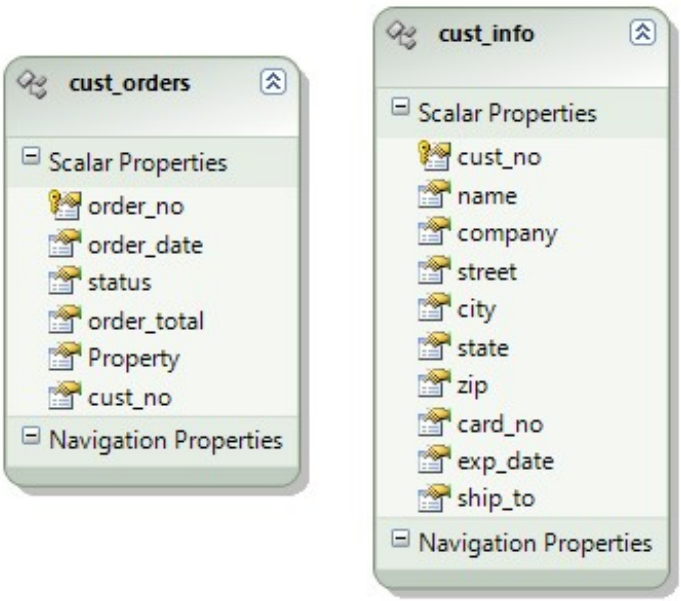
The following steps will detail what is required to manually create "Associations" in your Entity Data Model.

Before commencing the process, you will need to determine where these associations exist and their multiplicity (e.g., one-to-one, one-to-many, etc.).

Note: These steps will need to be repeated for each association.

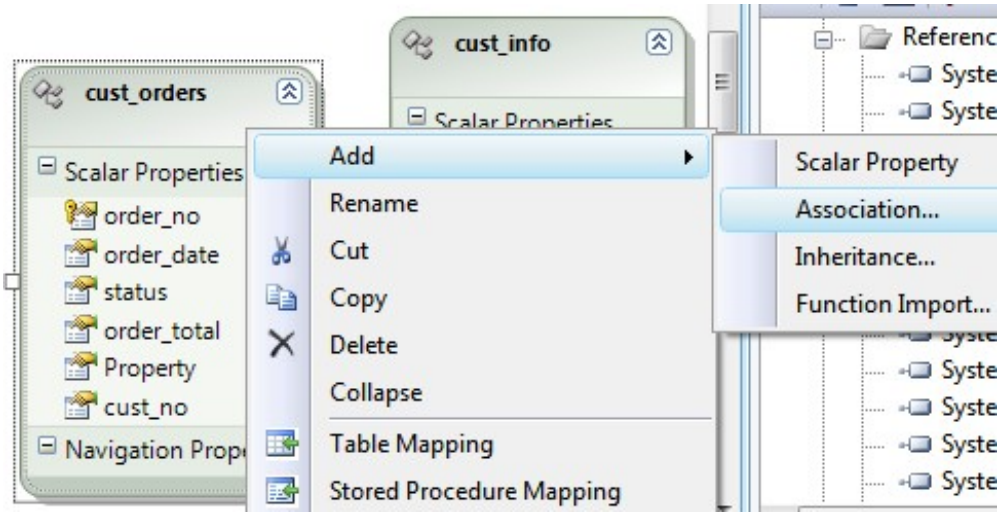
1. The first Association I will deal with is the relationship between cust_orders and cust_info, identified by the presence of the Scalar Property cust_no in both entities. This is a one-to-one mpmprelationship, as an entry in a customer order may only be associated with one customer's information.

   Figure 8.174. Association



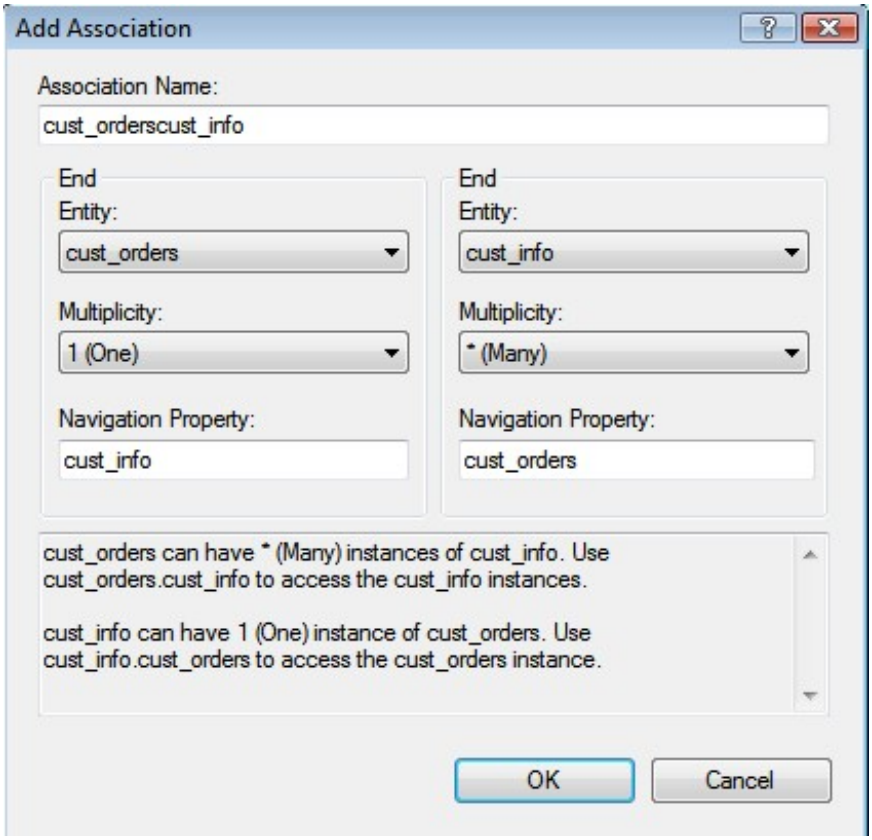
2. To add the Association, right click on the Customer entity then Add -> Association.

Figure 8.175. add the Association



3. You will now see the Add Association dialog.

Figure 8.176. Add Association dialog



4. Once you then hit OK the diagram is refreshed to include the newly created association.
5. You now need to edit the mappings associated with the newly created association, so right-click the association on the diagram and select

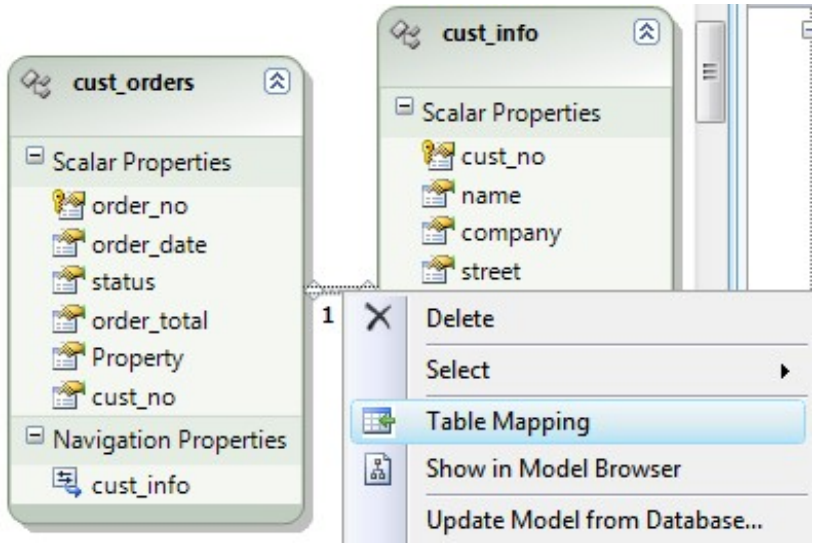
   Table Mapping

   to display the

   Mapping Details

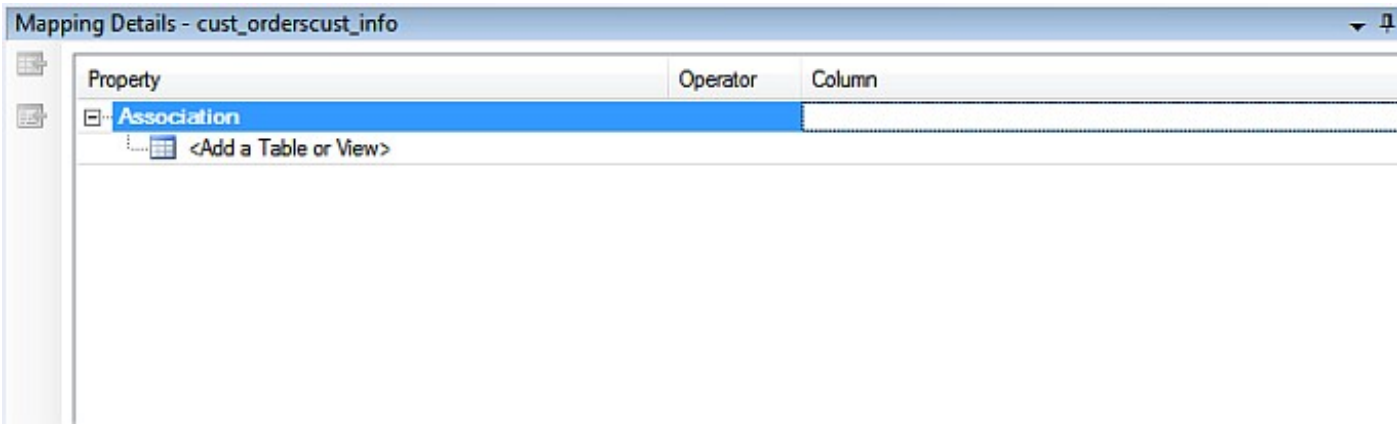
pane.

Figure 8.177. Navigation Property name



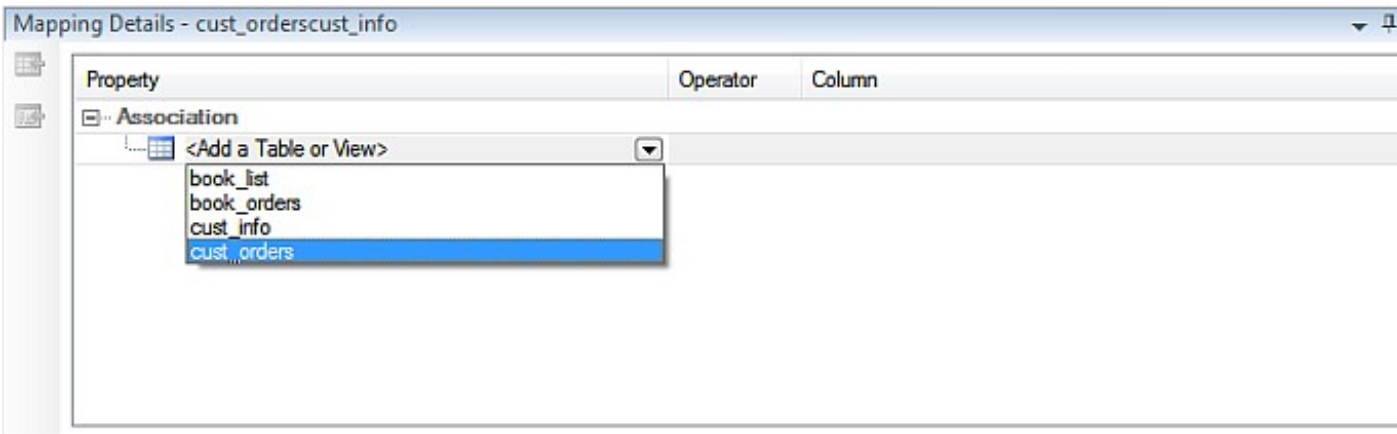
6. Click that line reading <Add a Table or View> to reveal a drop down list of all entities.

Figure 8.178. Add a Table or View



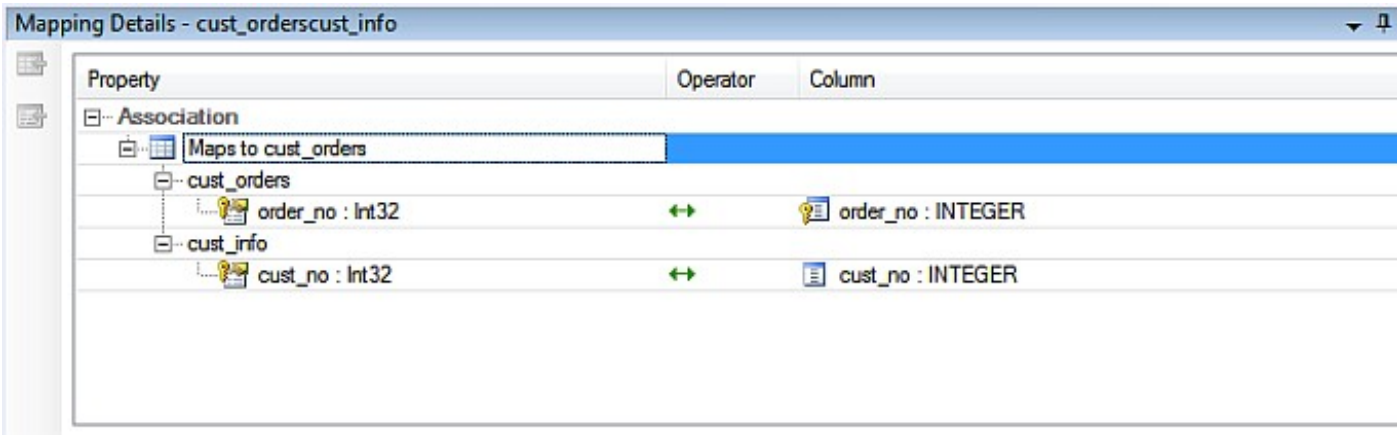
7. Here you need to select the entity on the right/far side of the association (the entity where the foreign key exists). In this example, it is the cust_orders entity.

Figure 8.179. Entity



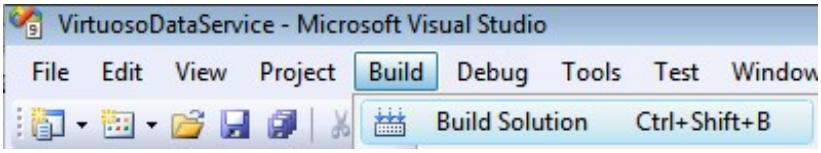
8. The Mapping Details pane now refreshes to display both ends of the association, requiring that you provide relevant target store data types in the Column column for the key fields, as depicted here.

Figure 8.180. Mapping Details



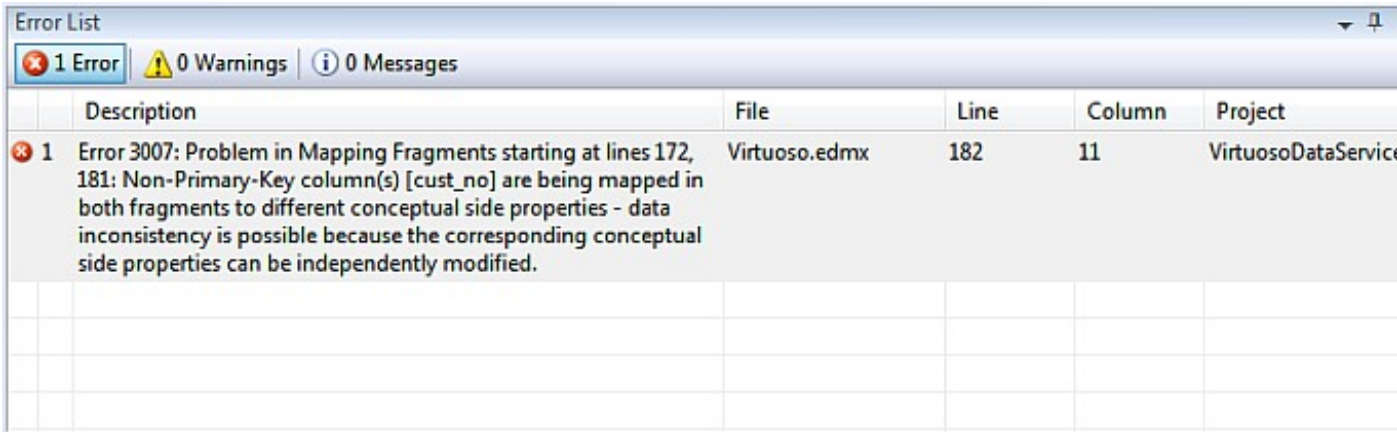
9. Once the mapping is complete, you can build the project using Build -> Build Solution. NOTE: It is worthwhile building as each association is made, since the error messages can be a little confusing.

Figure 8.181. Build the project



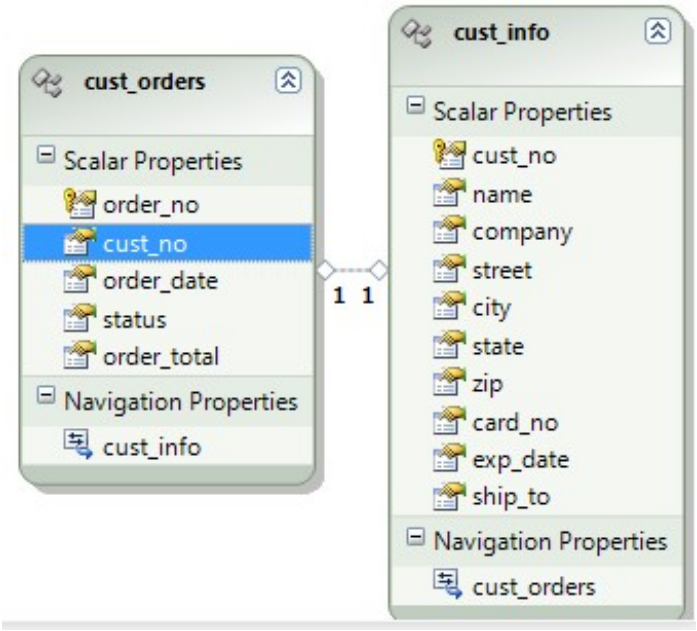
10. This should result in the following error:

Figure 8.182. Error



This error indicates that there are two sources - in this case, the cust_orders entity's Scalar Property cust_no and the Navigation Property cust_info in - which are being mapped to the same target column - the Ingres column cust_orders.cust_no - which is not supported.

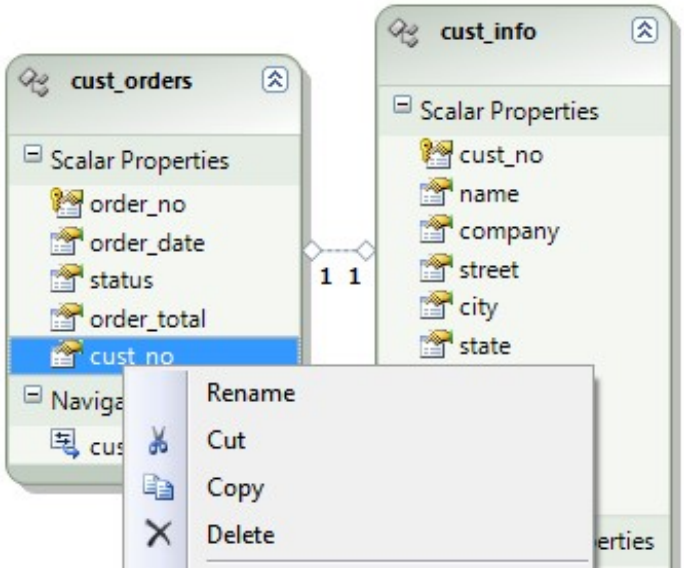
Figure 8.183. Error



11. The solution is simple! Simply delete the mapping for Scalar Property cust_orders.cust_no since its only purpose is to hold data representing a relationship/association (it is a Foreign Key), which has already been represented by the newly-created association and resulting Navigation Property cust_no.

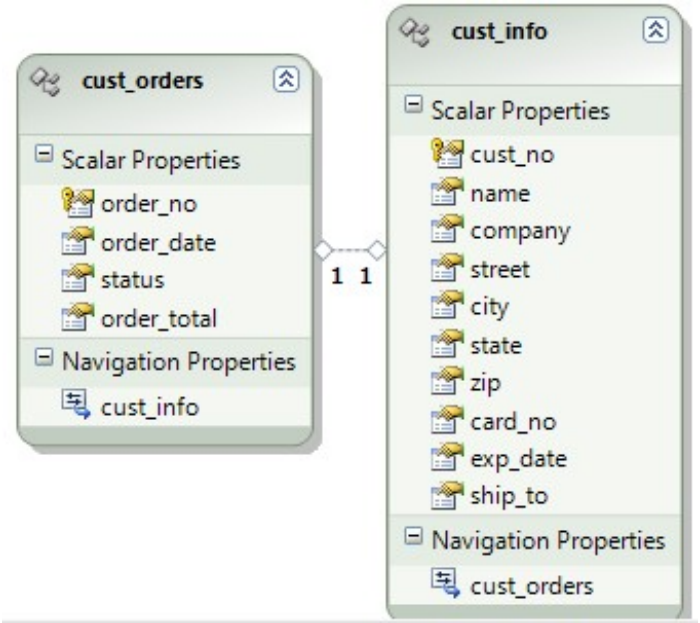
    Right-click on cust_orders.cust_no then Delete.

    Figure 8.184. delete the mapping



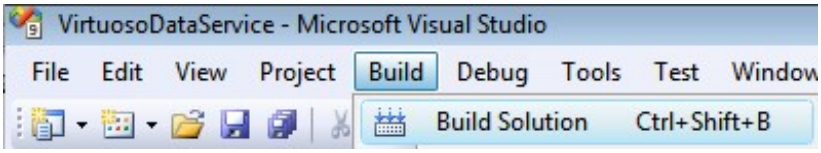
12. The model diagram will refresh to reflect this change.

    Figure 8.185. Model Diagram



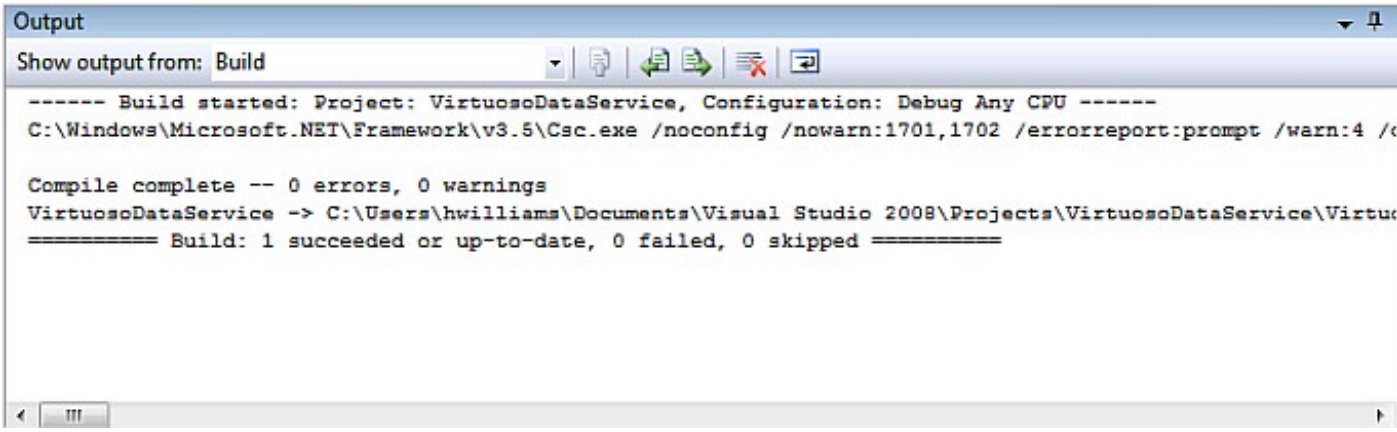
13. Build the project, again, using Build -> Build Solution.

Figure 8.186. Build project



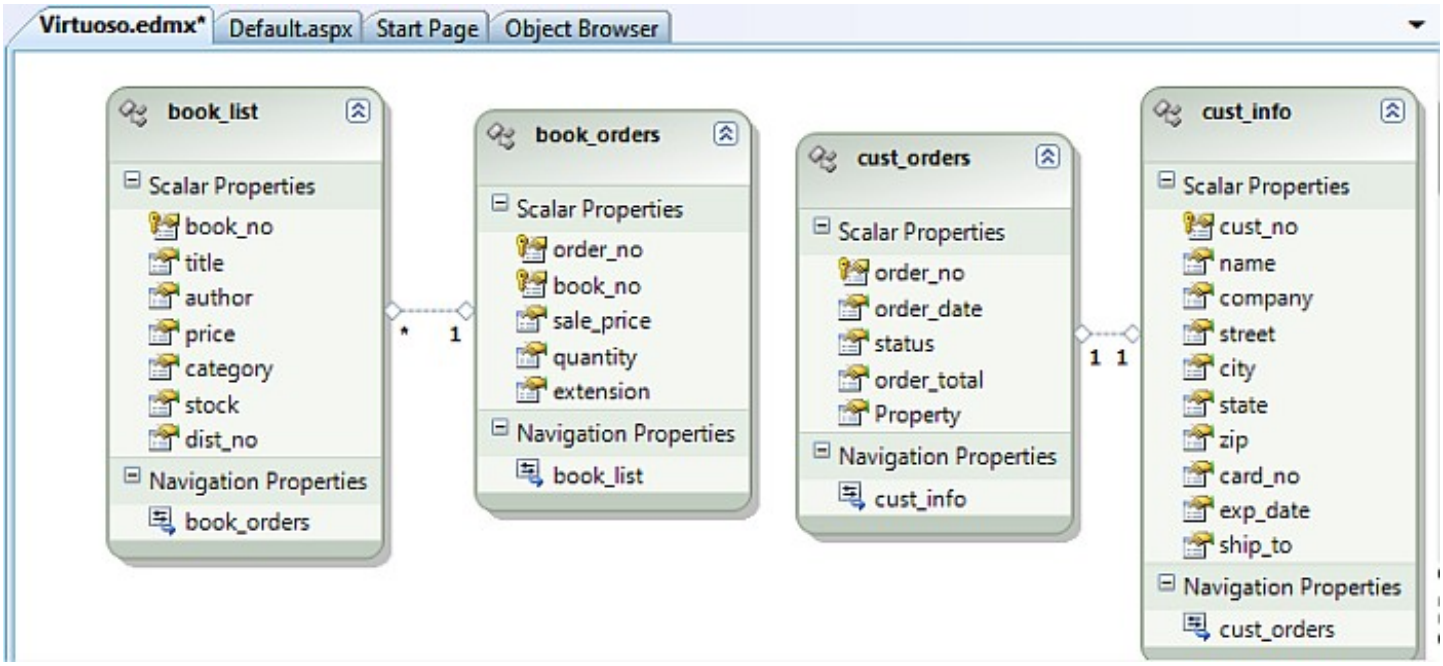
14. The project should now be fine.

Figure 8.187. Build Project



You will need to repeat these steps for each association until you have a completed Entity Data Model.

Figure 8.188. Entity Data Model



8.4.6. Using EDM to create Entity Framework based applications

Now that a Microsoft Entity Data Model has been created for the Ingres Tutorial database, Entity Framework applications can be created to make use of it.

Entity Frameworks based ADO.NET Data Service

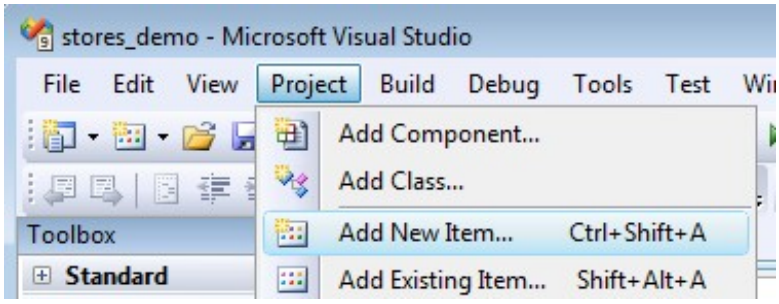
An ADO.Net Data Service for the Ingres tables can be created using the Entity Data Model created in the Creating EDM in Visual Studio 2008 section .

1. Open the

   VirtuosoDataService

   project created in the Creating EDM in Visual Studio 2008 section .
2. Select the Project -> Add New Item menu option.

   Figure 8.189. VirtuosoDataService

3. The

   Add New Item

   dialog will appear. Choose the

   ADO.NET Data Service template

   . Give it the name

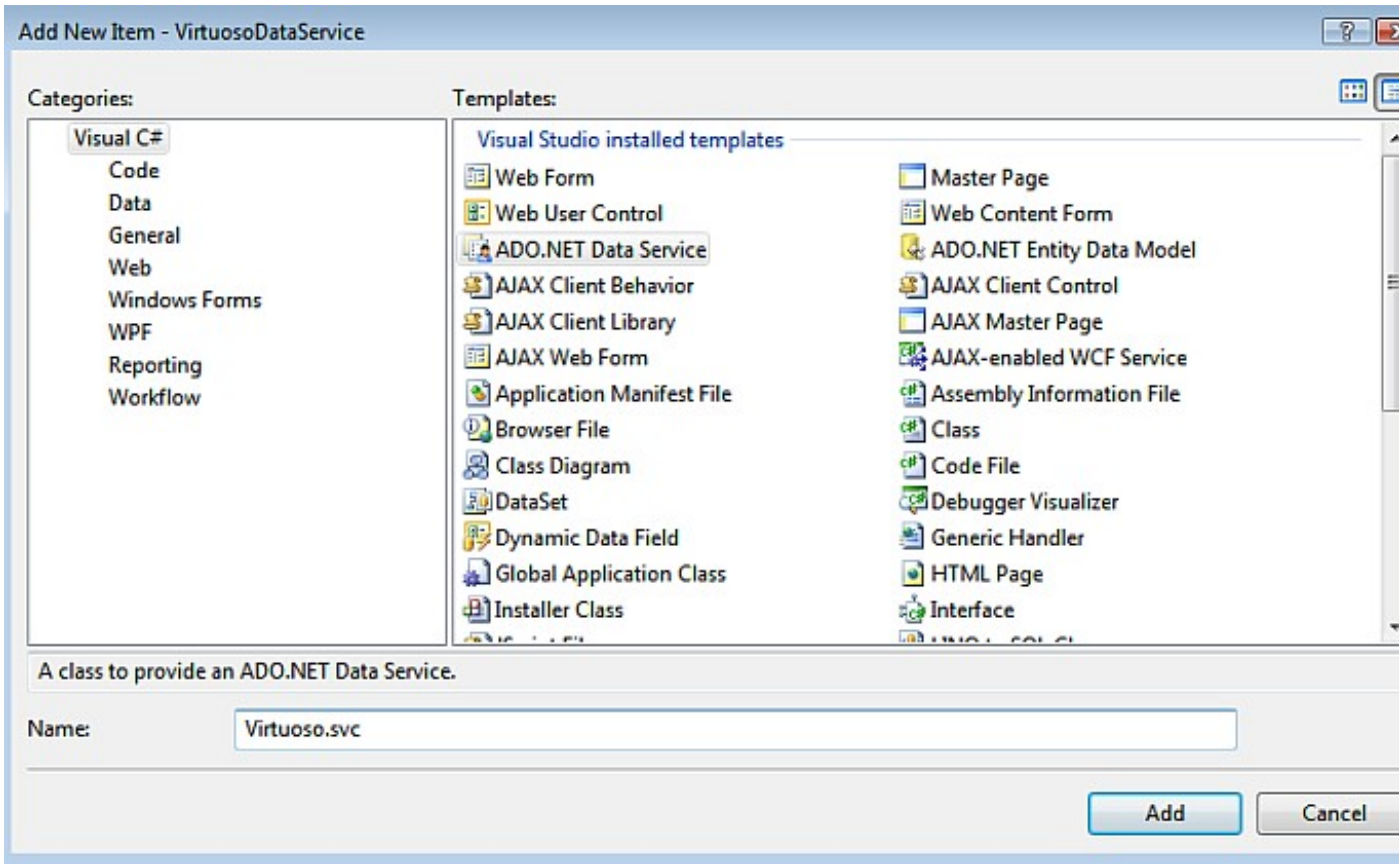
Virtuoso.svc

, and click

Add

to create the ADO.Net Data Service.

Figure 8.190. Add New Item



4. In the newly created

   Virtuoso.svc.cs

   Data Service, add the data source class name of

   VirtuosoEntities

   (note this is the name set in the Creating EDM in Visual Studio 2008 section) as the

   DataService

   name. Enable the access to the Data Service by adding the entry

   config.SetEntitySetAccessRule("", EntitySetRights.All);*

   in the

   InitializeService

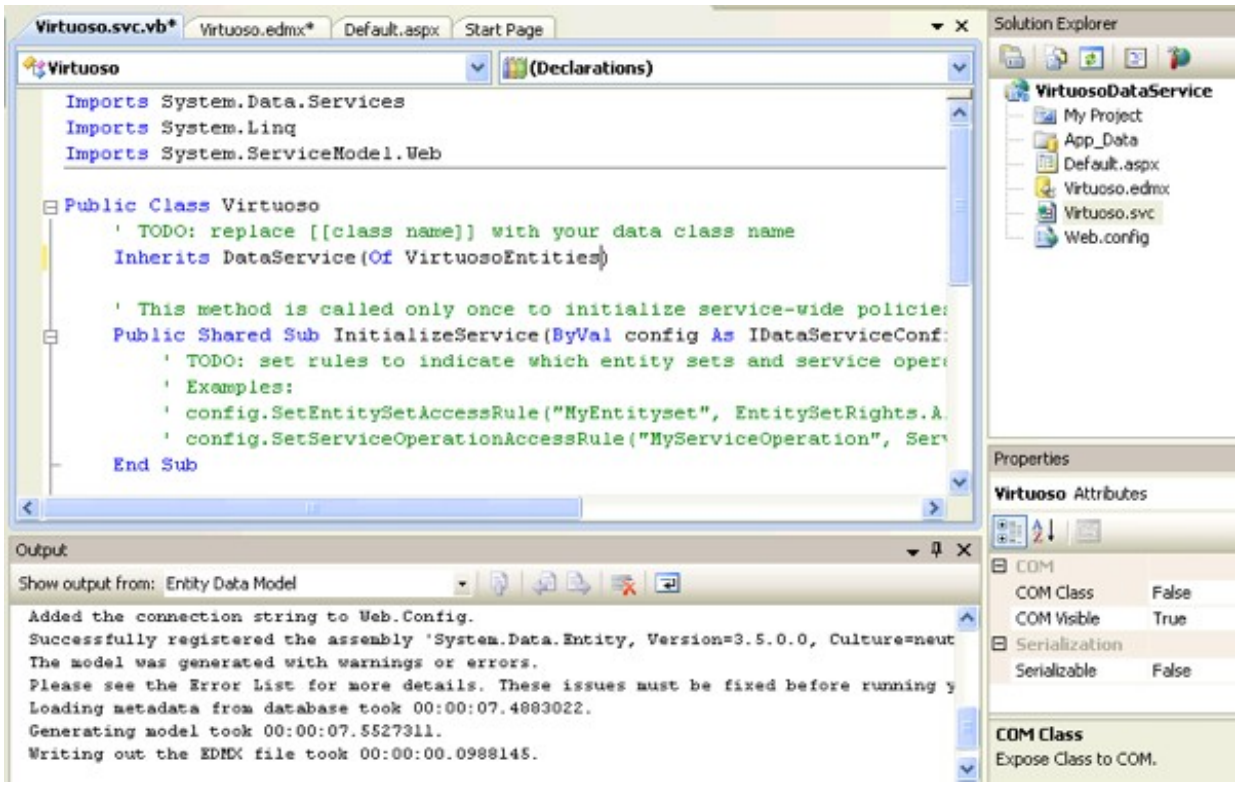
   method.

   ```
   // C#
   ```

```
using System;
using System.Web;
using System.Collections.Generic;
using System.ServiceModel.Web;
using System.Linq;
using System.Data.Services;

namespace SimpleDataService
{
    public class Northwind : DataService<VirtuosoDemoEntities>
    {
        public static void InitializeService(IDataServiceConfiguration  config)
        {
            config.SetEntitySetAccessRule("*", EntitySetRights.All);
        }
    }
}
```

Figure 8.191. Virtuoso.svc.cs

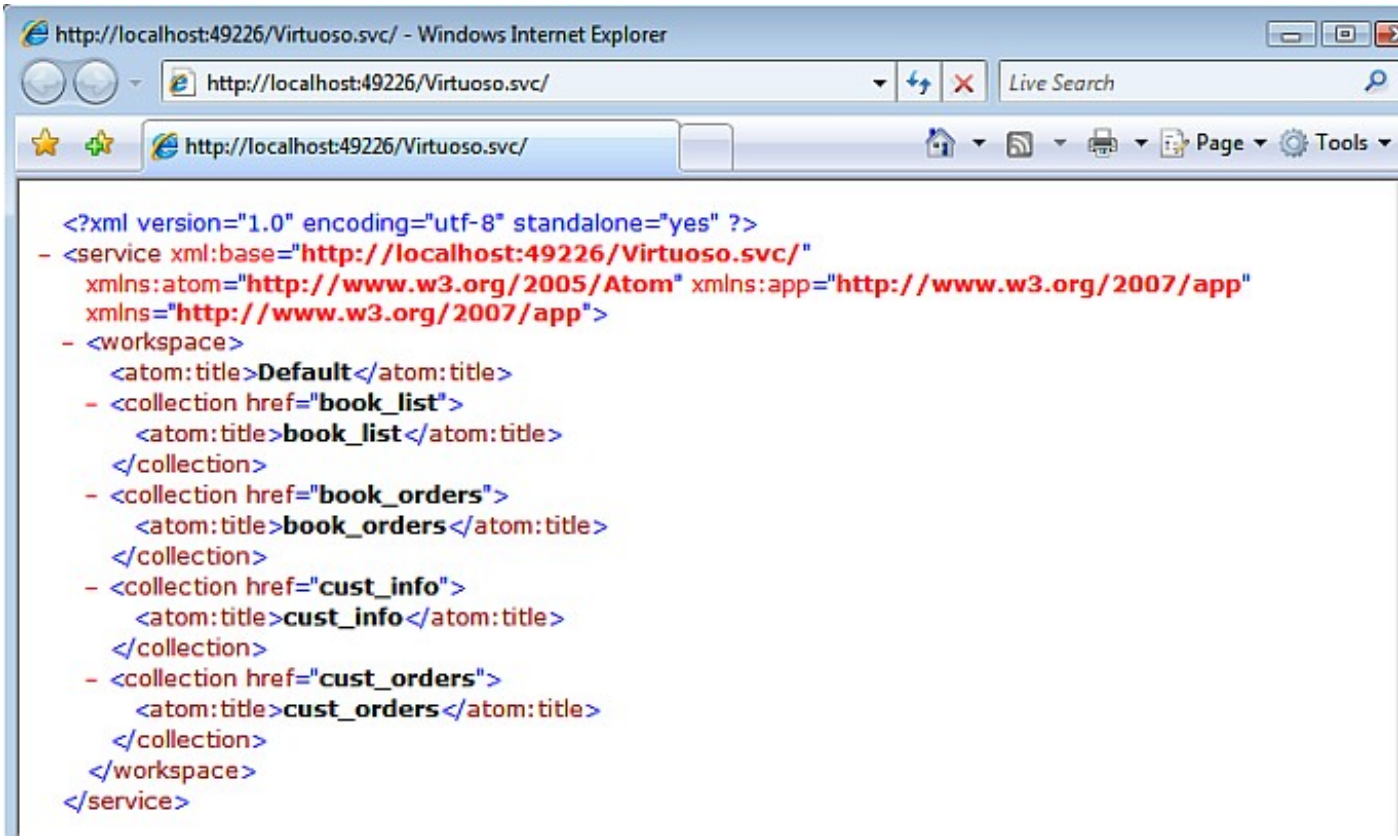


5. To test the Data Service, simply hit

   Ctrl+F5

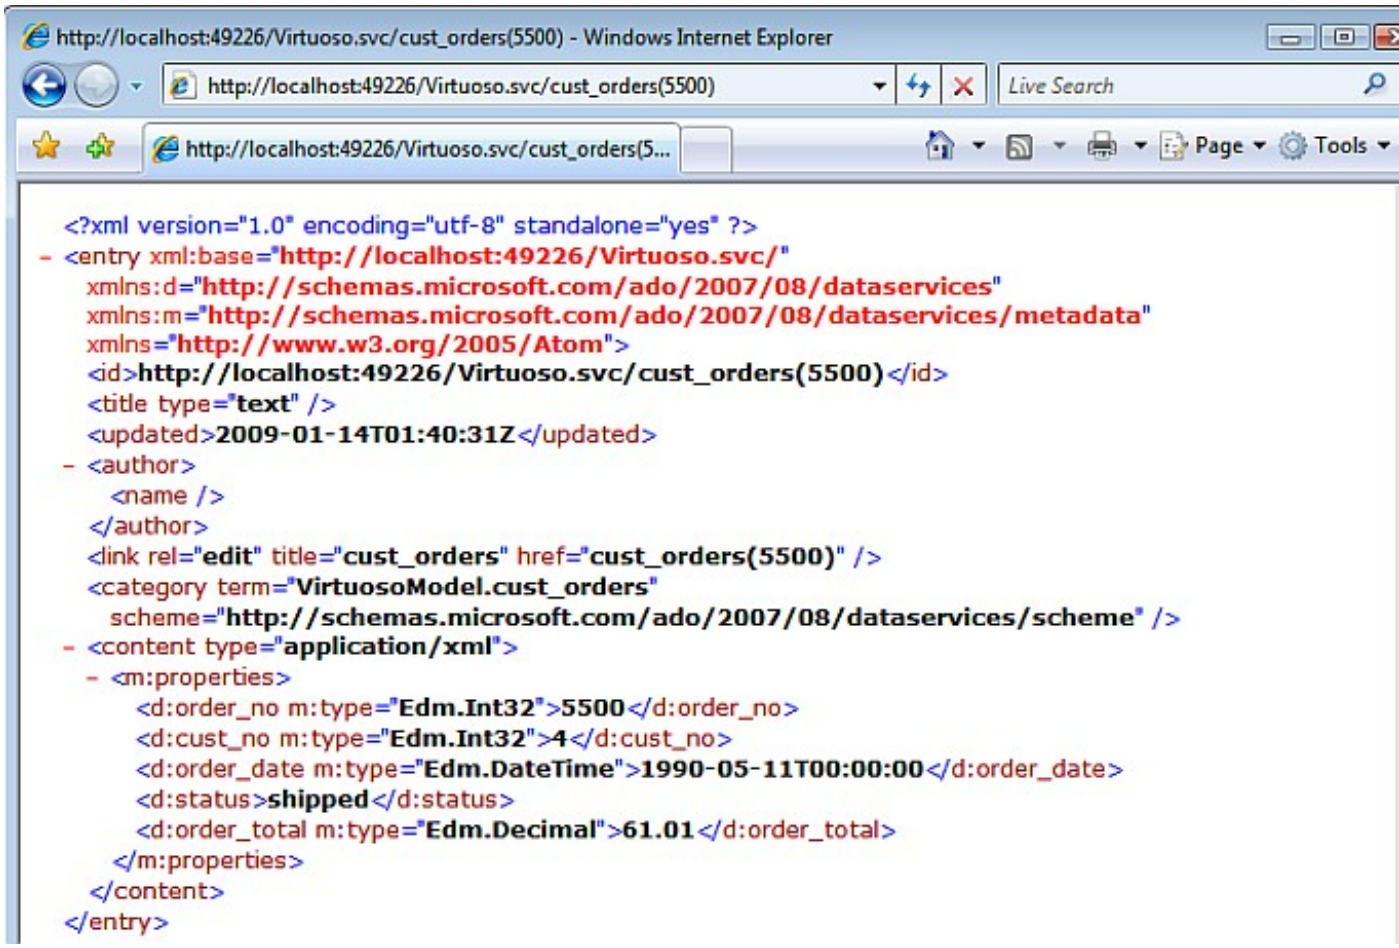
   within Visual Studio. This will start the development web server, run the Data Services server inside, and load a Web browser page displaying the list of available tables/entities for the Ingres Tutorial database catalog.

Figure 8.192. Data Service test



6. To access a specific entity instance like the cust_orders table order number 5500 record, use this convention: http://host/vdir/Virtuoso.svc/cust_orders(5500) .

Figure 8.193. Orders



Notes:

1. *Important*

   - To view

   Atom

   (the default format returned by an ADO.NET Data Service) in Internet Explorer, you must first ensure that

   Feed Reading View

   is turned

   off

   . This can be done on the

   Content tab

   of

   Tools in Internet Options

   .
2. If a Data Services entity instance URI page fails to load you can turn

   Verbose

   errors on by adding

   config.UseVerboseErrors = true;

   in the

   virtuoso.svc.cs InitializeService

   method to obtain more detailed information from the server as to why the page failed to load:

```
public static void InitializeService(IDataServiceConfiguration config)
{
config.UseVerboseErrors = true;
config.SetEntitySetAccessRule("*", EntitySetRights.All);
}
```

Visual Studio Windows DataGrid Form Application

This section details the steps required to create a simple Visual Studio 2008 Windows Form application, with associated DataGridView control for displaying data in selected tables from the target database.

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.194. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

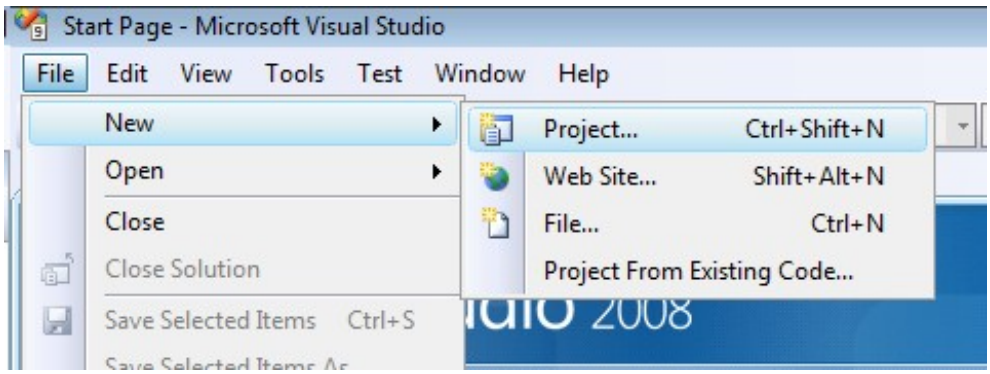
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.195. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Windows

   and select

   Windows Form Application

from the right-hand panel.

5. Choose a name for the project, for example

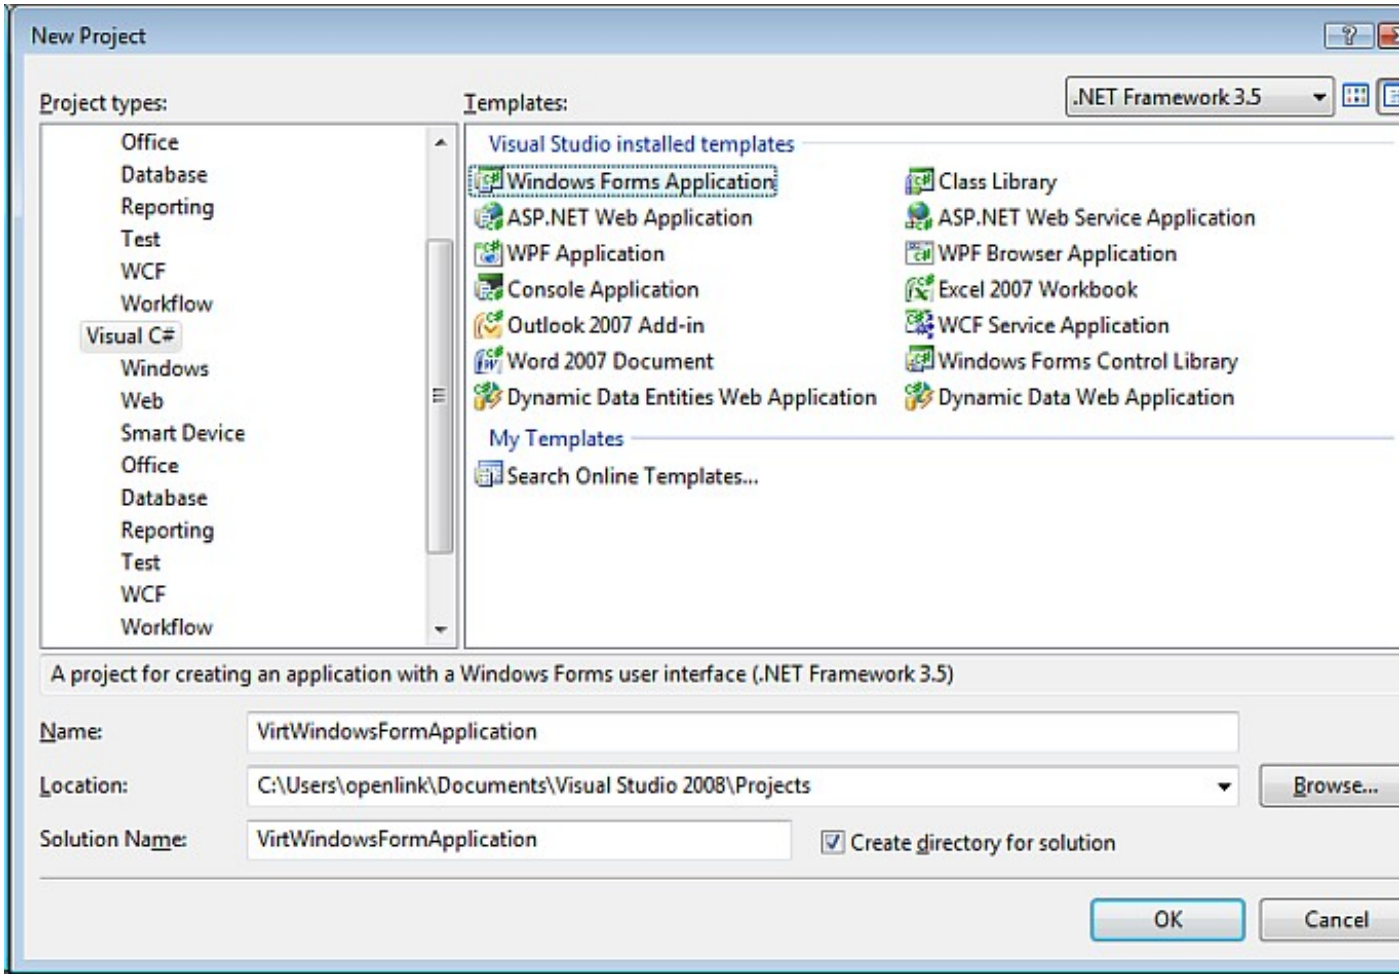
   VirtWindowsFormApplication

   , and click

   OK

   .

   Figure 8.196. Web Application



6. In the

   Toolbox

   , expand

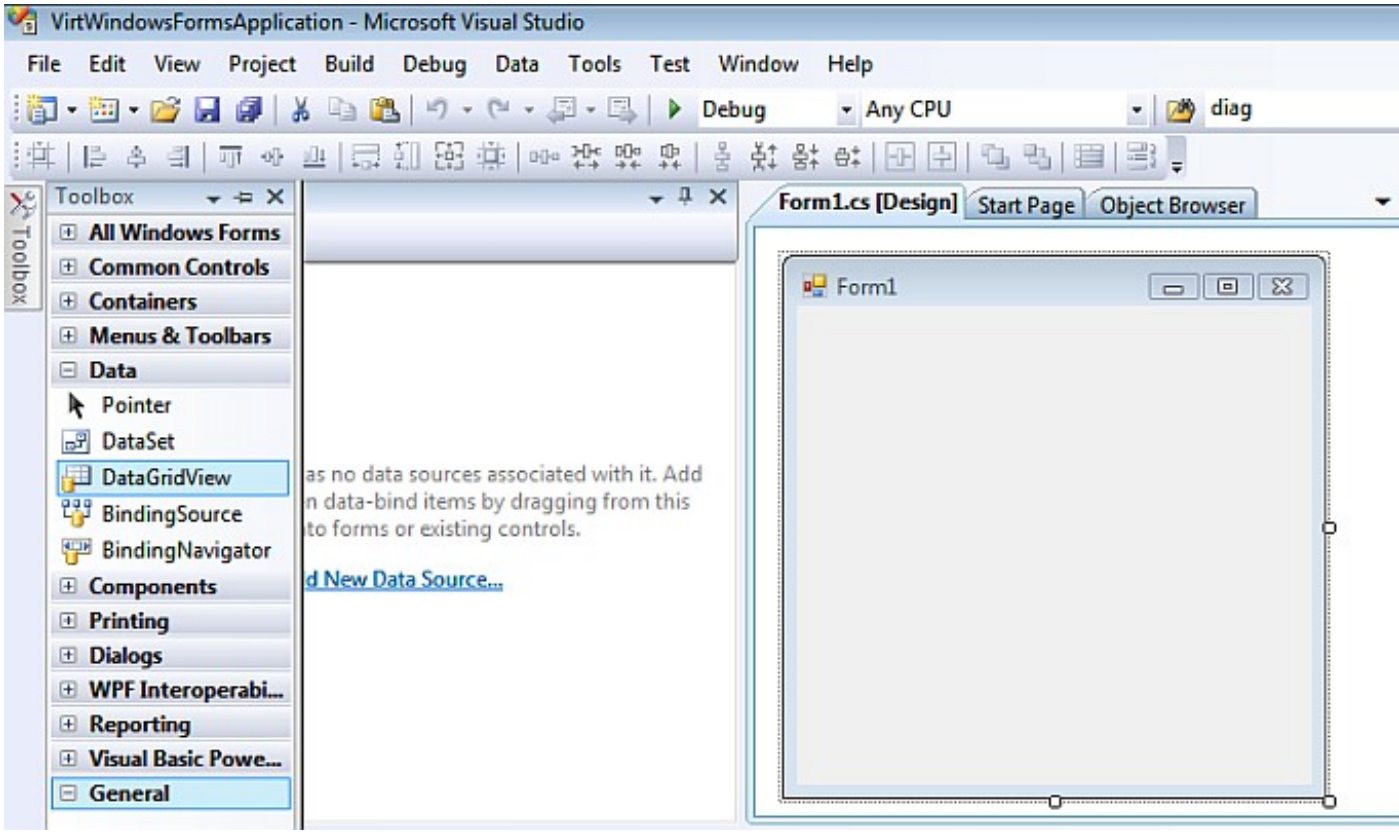
   Data Controls

   , and drag the

   DataGridView

   control onto the form.

   Figure 8.197. Toolbox



7. Click on the little

   arrow

   in the top right of the

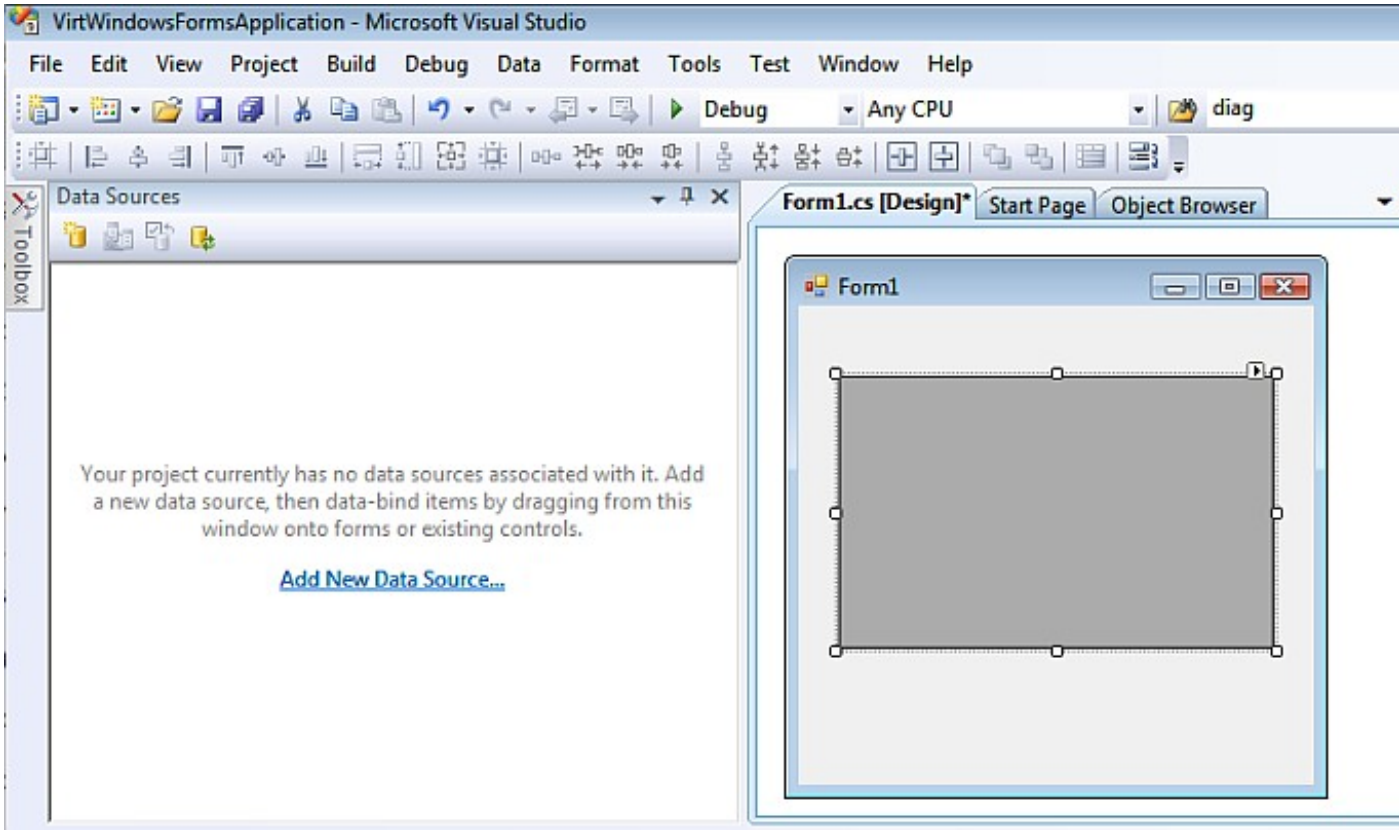
   DataGridView

   control. This loads the

   DataGridView Task

   menu.

Figure 8.198. DataGridView Task

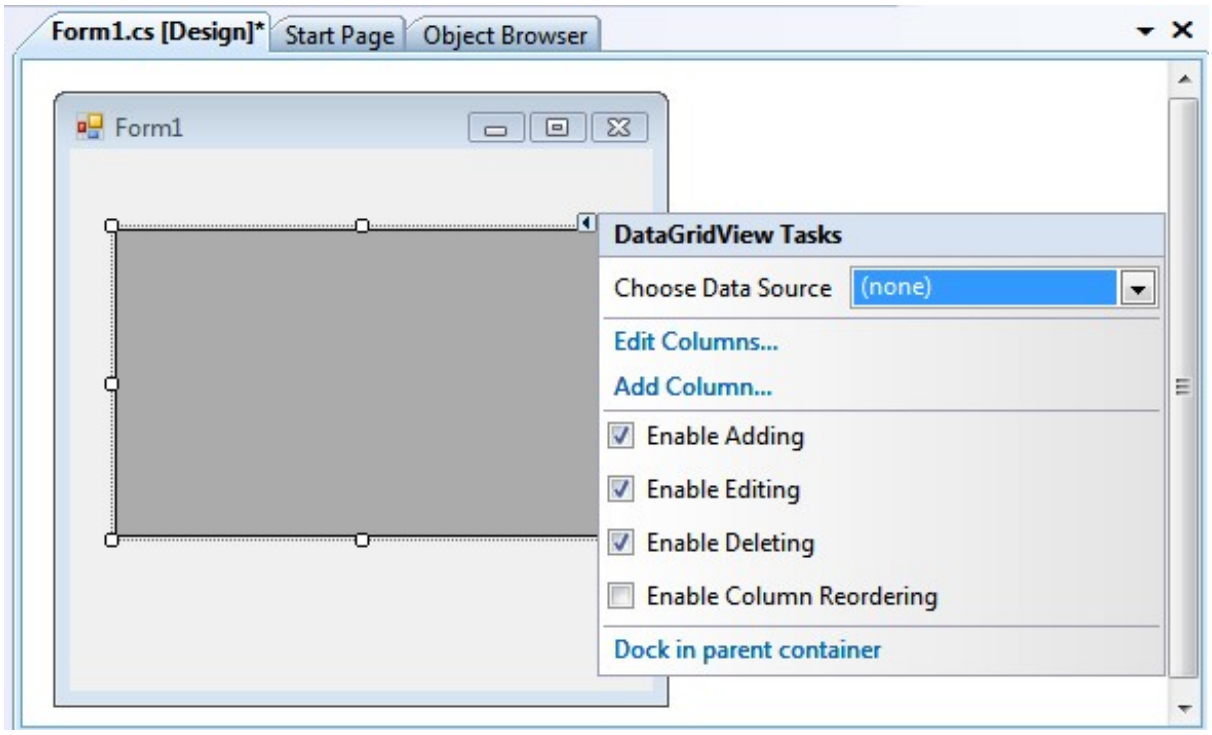


8. Click on the

   Choose Data Source

   list box.

   Figure 8.199. Choose Data Source

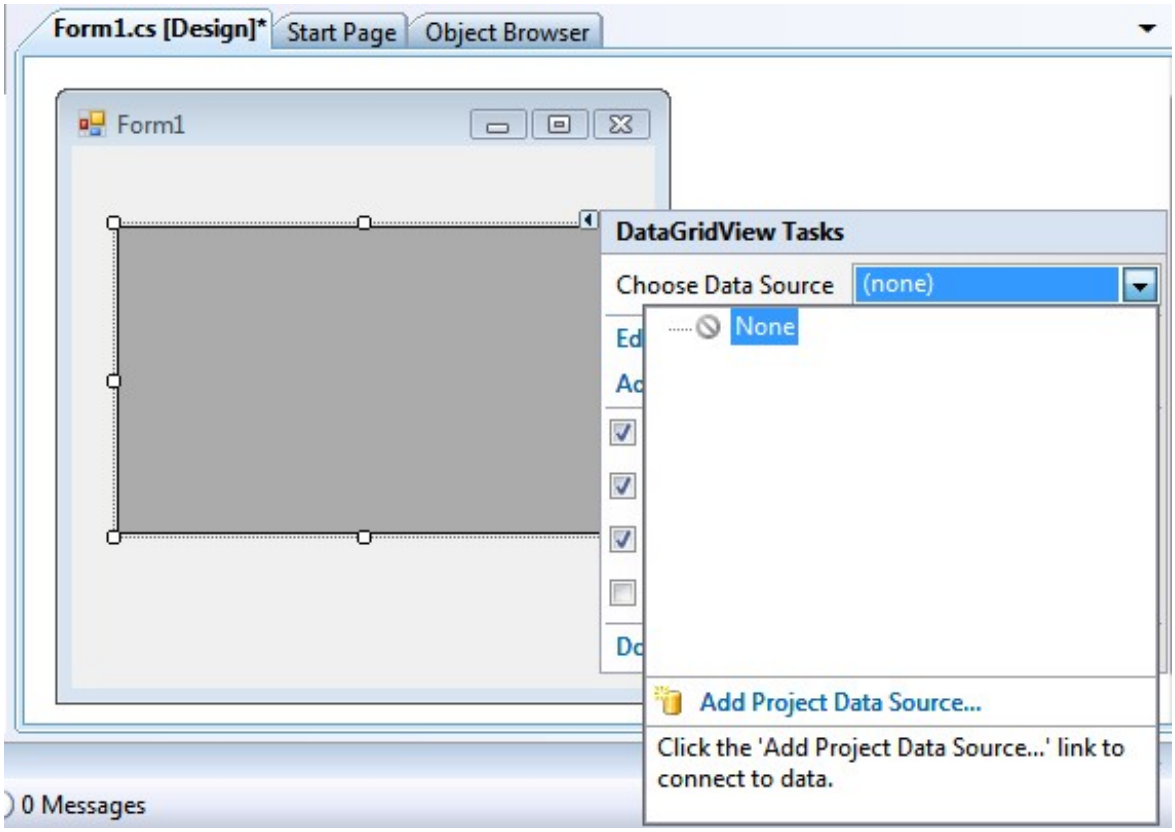


9. Click on the

   Add Project Data Source

link to connect to a data source.

Figure 8.200. Add Project Data Source



10. In the

    Data Source Configuration Wizard

    dialog

    Choose Data Source Type

    page select the

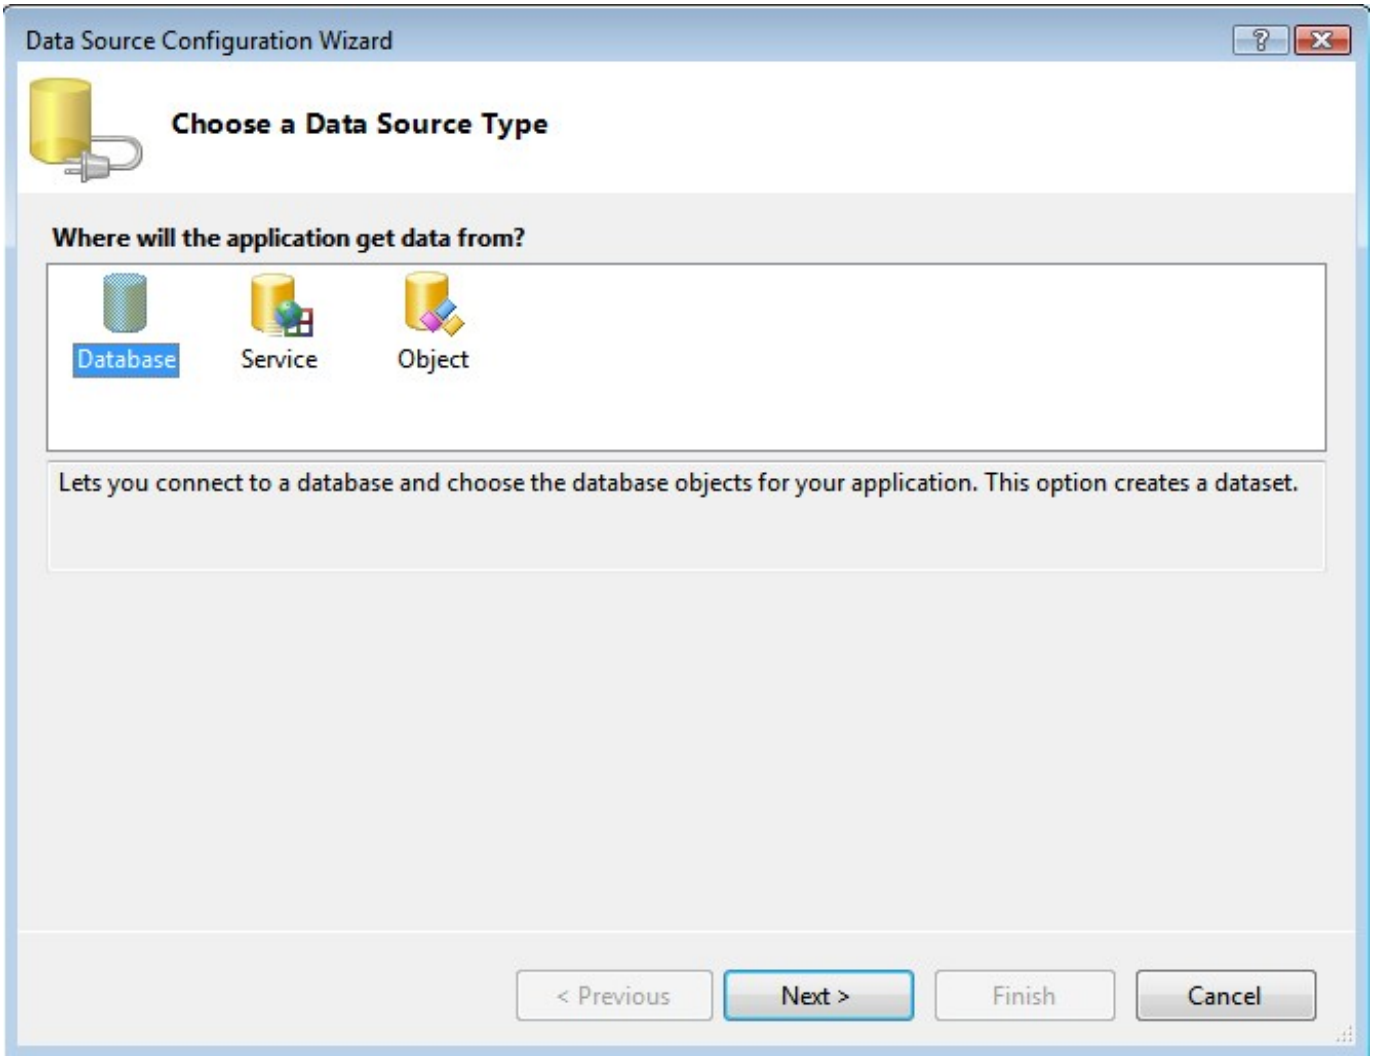
    Database

    data source type and click

    Next

    .

Figure 8.201. Data Source Type



11. In the

    Data Source Configuration Wizard

    dialog

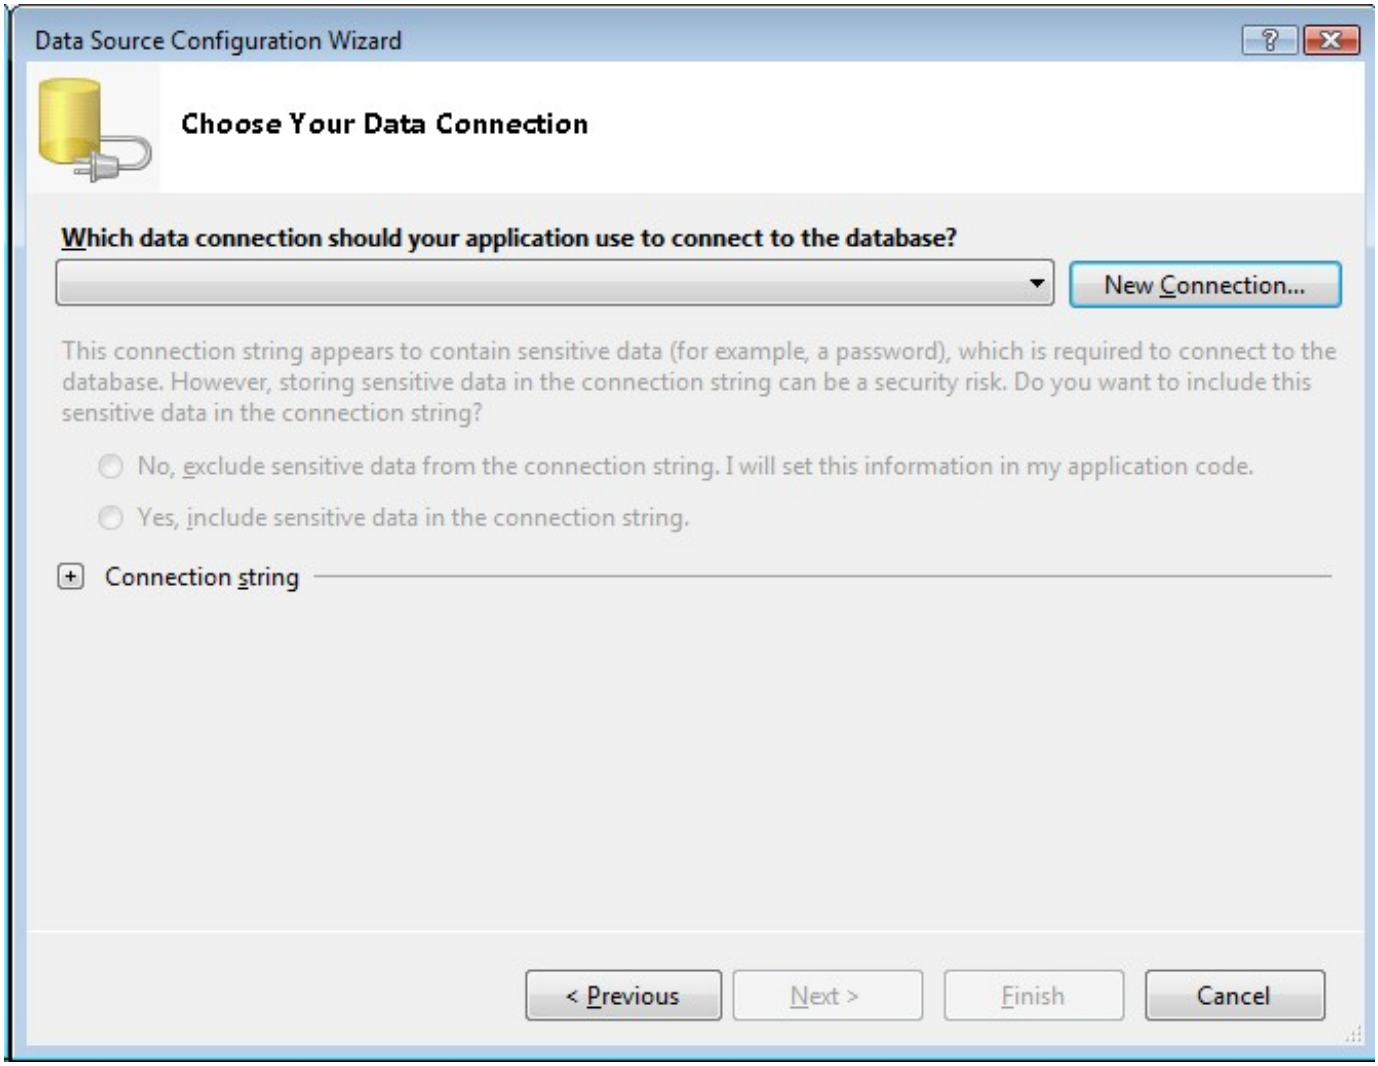
    Choose your Data Connection

    page, select the

    New Connection

    button

Figure 8.202. Data Source Configuration Wizard



12. In the

    Choose Data Source

    dialog, select the OpenLink

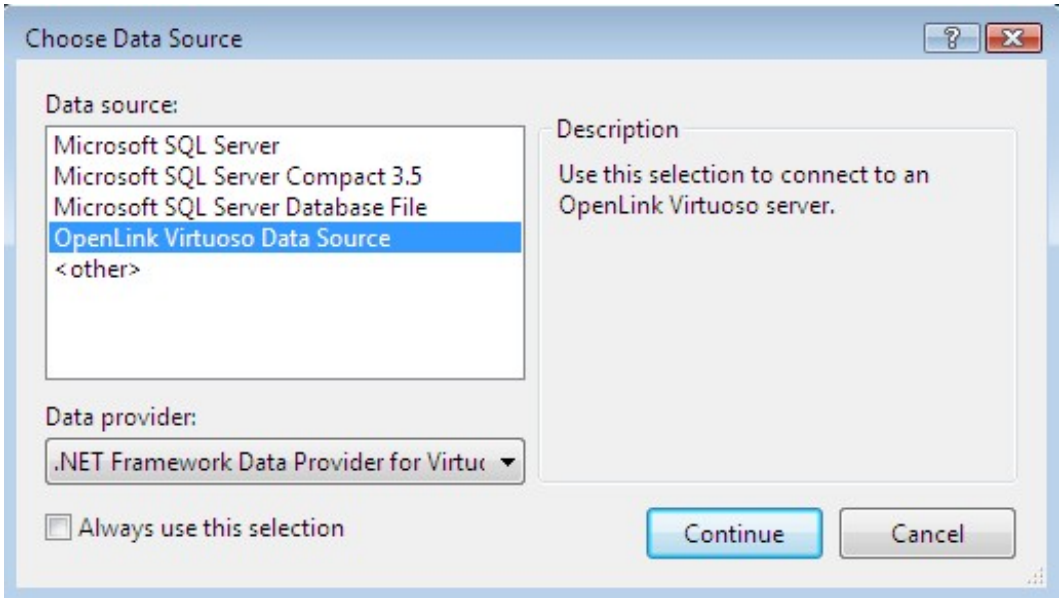
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.203. Data Source



13. In the

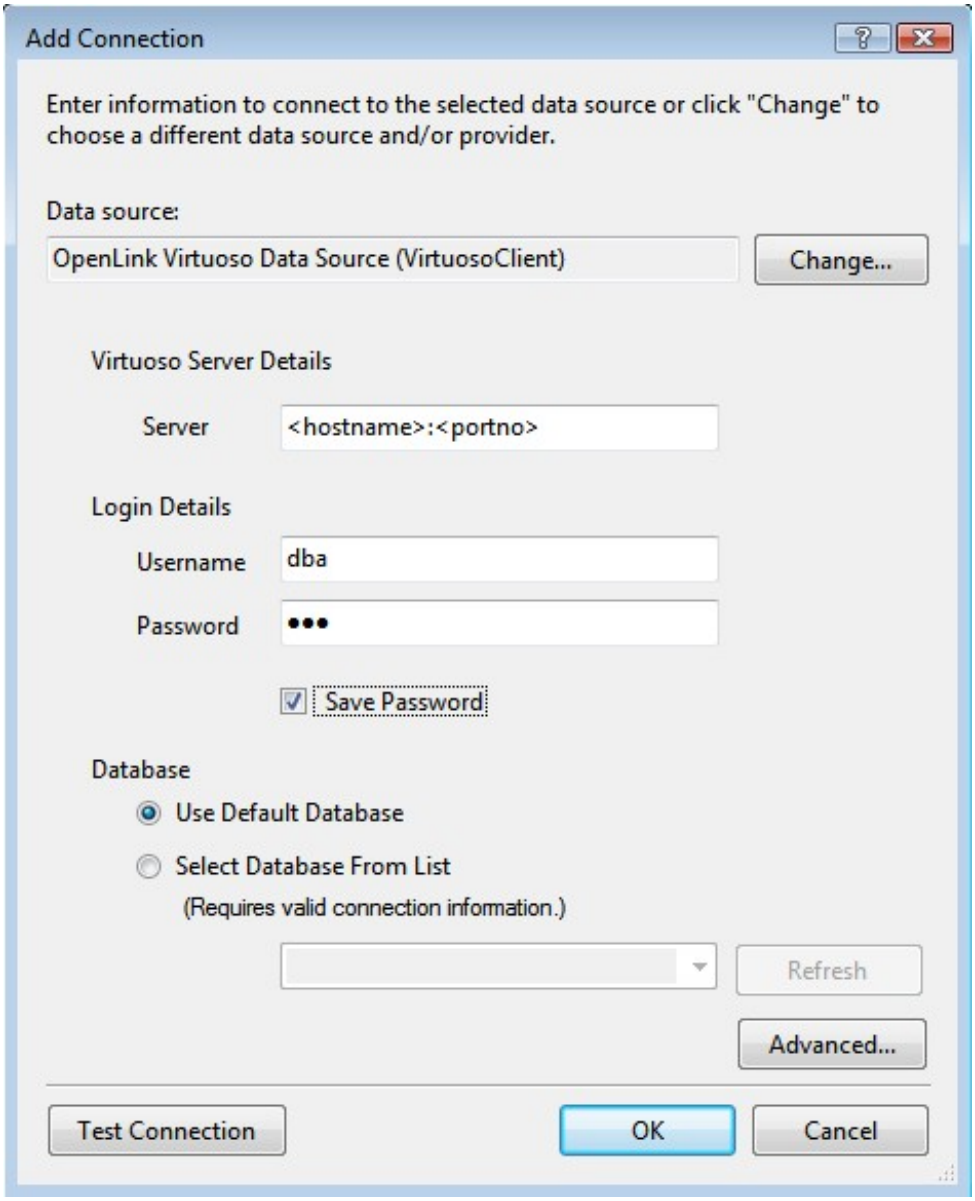
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.204. Connection Properties



14. Select the

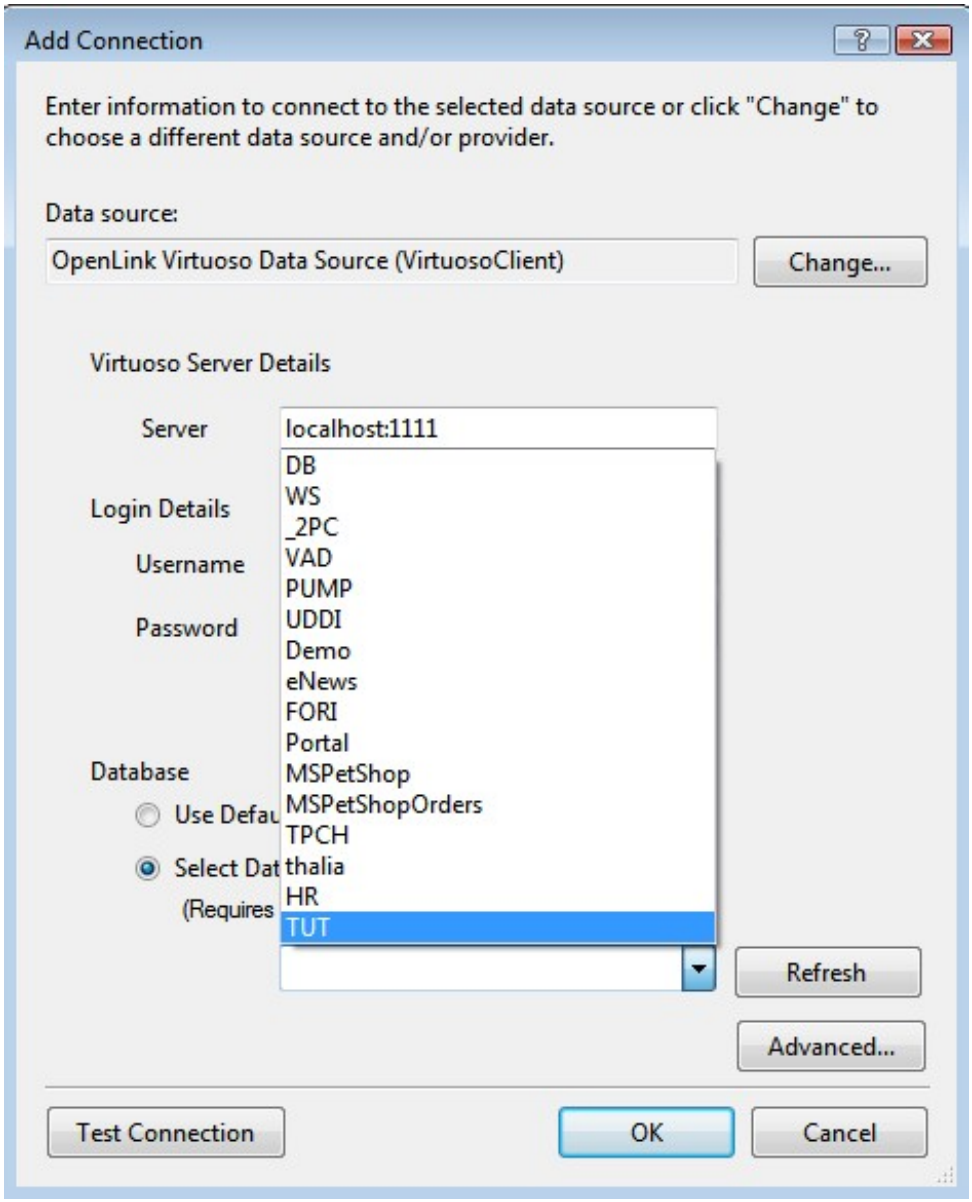
    Select Database From List

    radio button and choose the

    TUT

    database from the drop down list.

Figure 8.205. Add connection

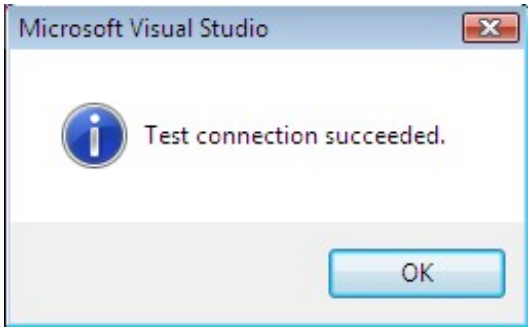


15. Press the

    Test Connection

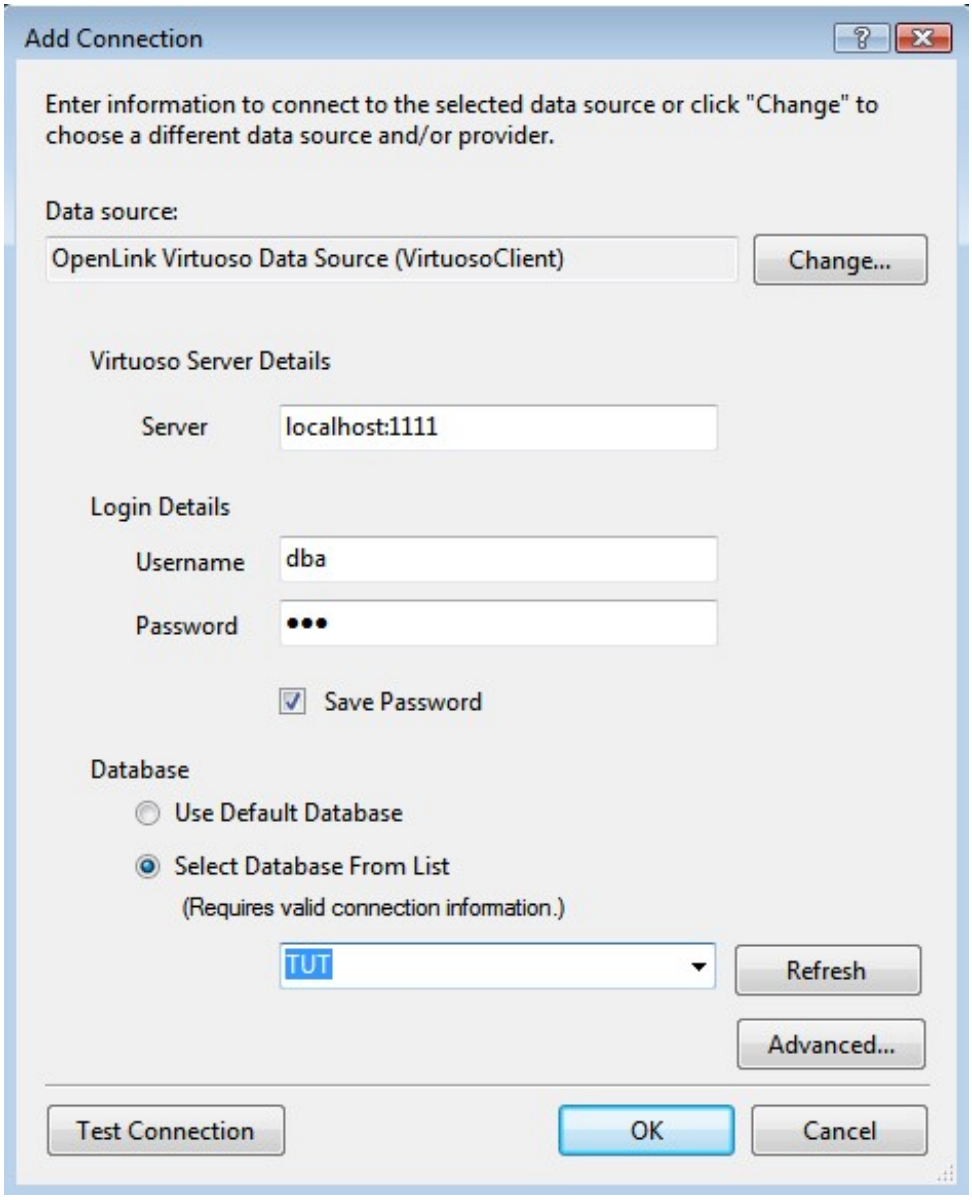
    dialog to verify that the database is accessible.

Figure 8.206. Test Connection



16. Click OK to add the connection.

Figure 8.207. Test Connection



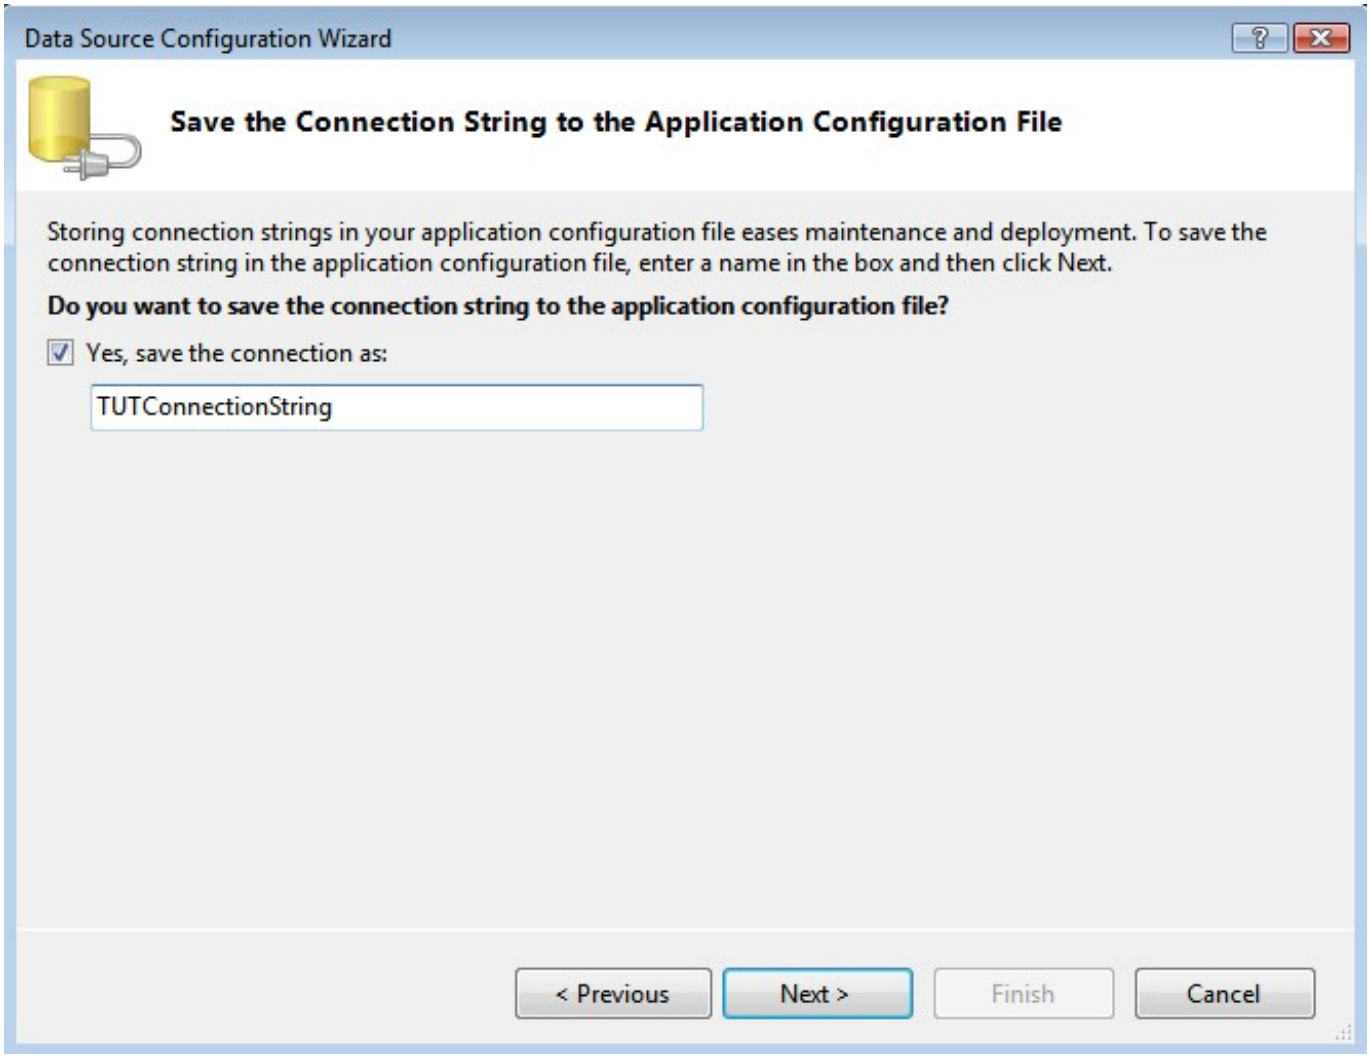
17. Leave the name of the connect string to the default of

    TUTConnectionString

    and click

    Next

    Figure 8.208. TUTConnectionString



18. From the list of available tables returned for the TUT database, select the

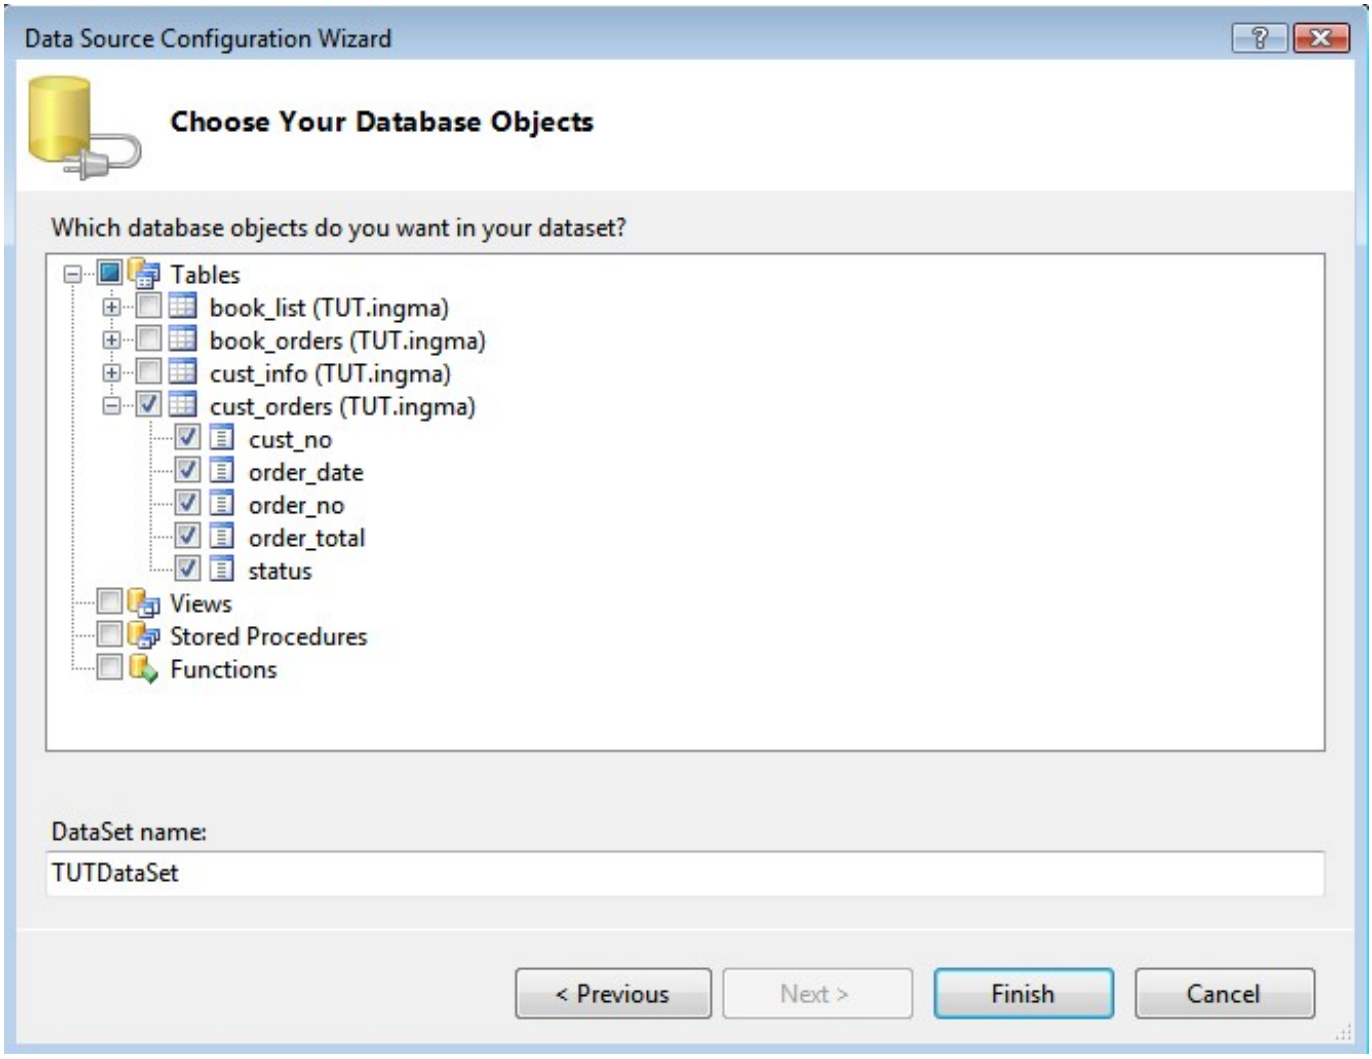
    cust_orders

    table to be associated with the

    DataGridView

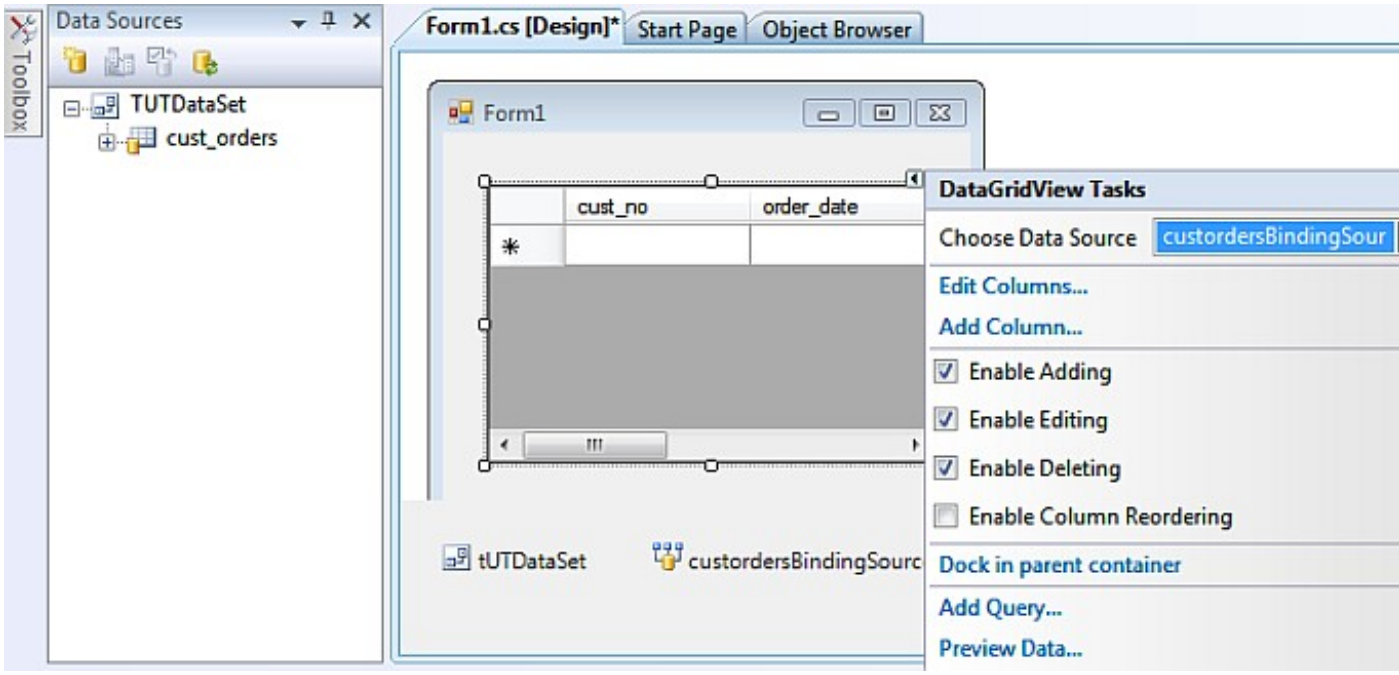
    control.

    Figure 8.209. TUT database



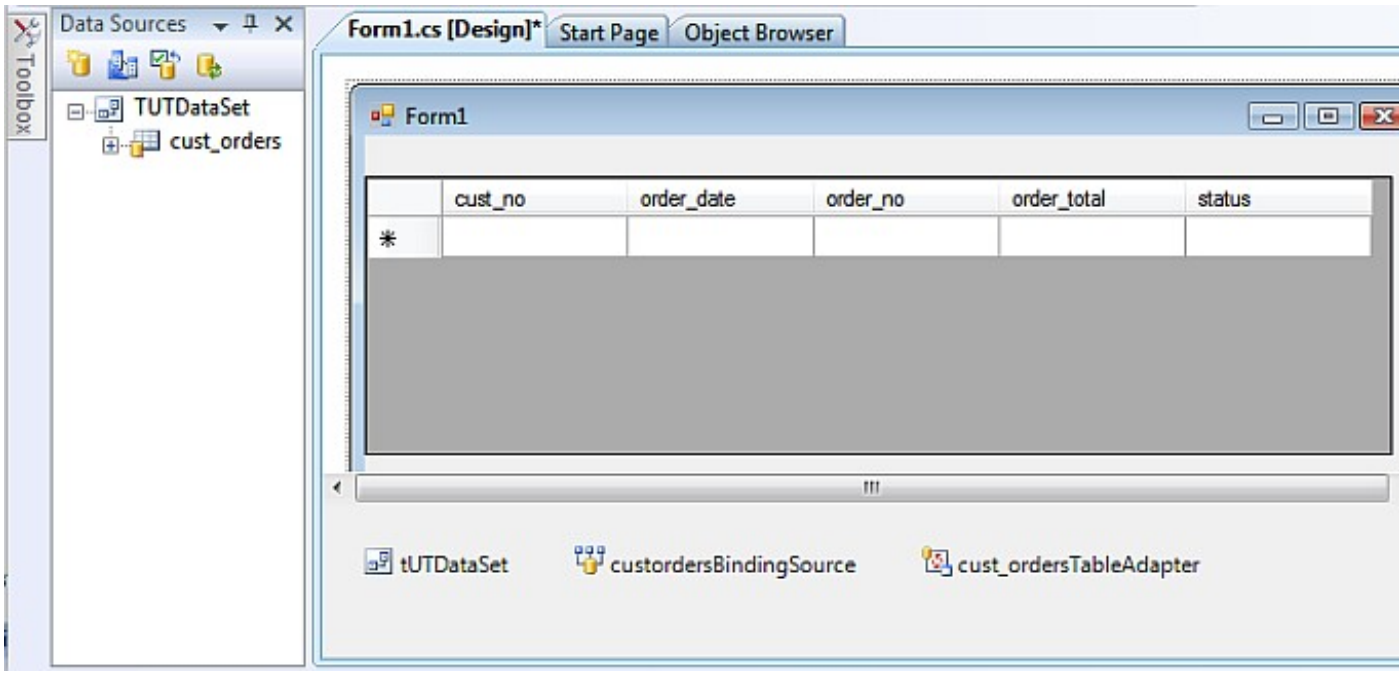
19. The columns names of the select table will be displayed in the DataGridView.

Figure 8.210. DataGridView



20. Resize the Form and DataGridView to allow all columns to be visible, if possible.

Figure 8.211. Resize the Form and DataGridView



21. To test the application, simply hit

    Ctrl+F5

    within Visual Studio or select

    Start Debugging

    from the

    Debug

    menu.

    Figure 8.212. Start Debugging

22. The data from the

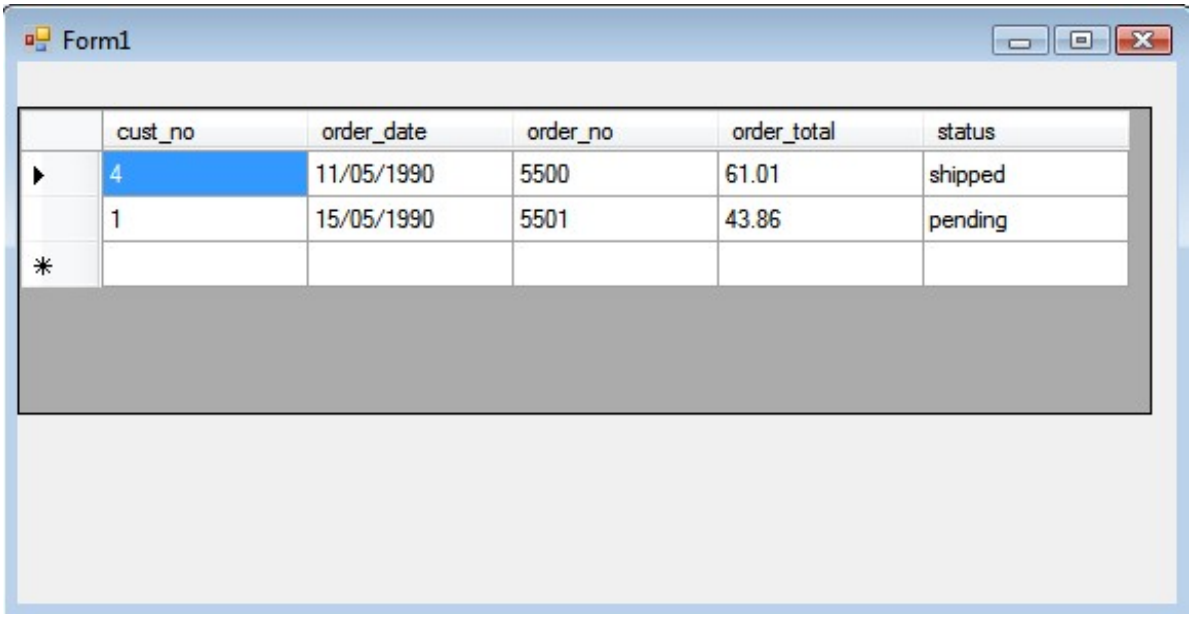
    cust_orders

    table will be displayed in the

    DataGrid

    .

    Figure 8.213. DataGrid



The task is now complete.

8.5. Using Microsoft Entity Frameworks to Access Informix Schema Objects with Virtuoso

Abstract

This section details the steps required to provide Microsoft Entity Framework access to Informix Schema Objects using the OpenLink Virtuoso Universal Server. This is achieved by linking the required Informix Schema objects into Virtuoso using its built in Virtual Database engine, and then using the Virtuoso ADO.NET Entity Framework provider to query the remote Informix Schema objects linked into the Virtuoso Server.

Prerequisites. The following prerequisites must be in place for this solution to be possible.

Informix DBMS. An Informix DBMS hosting the required Schema Objects needs to be available. In this section the *Informix stores_demo* sample database will be used to demonstrate the process.

An Informix DBMS hosting the required Schema Objects needs to be available. In this section the *Informix stores_demo* sample database will be used to demonstrate the process.

ODBC Driver for Informix. An Informix ODBC Driver is required for Linking the Informix Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for Informix* will be used in this section, for which a functional ODBC Data source name of "inf10ma" will be assumed to exist on the machine hosting the Virtuoso Server.

An Informix ODBC Driver is required for Linking the Informix Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for Informix* will be used in this section, for which a functional ODBC Data source name of "inf10ma" will be assumed to exist on the machine hosting the Virtuoso Server.

Virtuoso Universal Server. An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

Microsoft Visual Studio 2008 SP1. Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Tasks

Ensure Informix Primary Keys (PKs) are not nullable. The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the Informix database schema before attempting to generate an EDM. In the case of the Informix stores_demo database many tables have primary keys that are nullable so these will need to be redeclared.

The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the Informix database schema before attempting to generate an EDM. In the case of the Informix stores_demo database many tables have primary keys that are nullable so these will need to be redeclared.

This is possible using dbaccess however care needs to be taken, particularly with the following

- Amending a PK field to be not nullable can results in the primary key constraint being removed.
- Amending a PK field to be not nullable when the primary key is referenced by a foreign key constraint results in the foreign key constraint being removed.

In both of the cases above the primary key and foreign key constraints that are removed will have to be manually recreated.

8.5.1. Install and configure OpenLink ODBC Driver for Informix

The Virtuoso Virtual Database engine uses ODBC as the connectivity mechanism for linking remote database objects into its local schema. Thus an Informix ODBC Driver must be available with a suitably configured DSN for connecting to the target database. The OpenLink ODBC Drivers for Informix have been used in this section, although in theory any Informix ODBC Driver can be used.

Installation instructions for the OpenLink ODBC Driver for Informix are available from:

- Product Installation & Basic Configuration (ODBC)

8.5.2. Install and configure OpenLink Virtuoso Universal Server

- Install and configure OpenLink Virtuoso Universal Server

8.5.3. Linking Informix tables into OpenLink Virtuoso

1. Start the Virtuoso Web User Interface

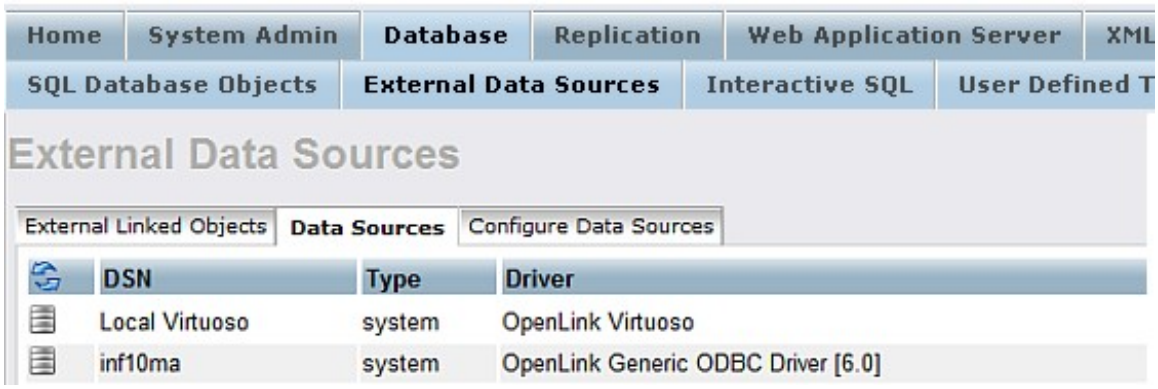
   Figure 8.214. Start

2. Select the "Conductor" link in the Left Frame and Login as the "dba" user.

Figure 8.215. Conductor

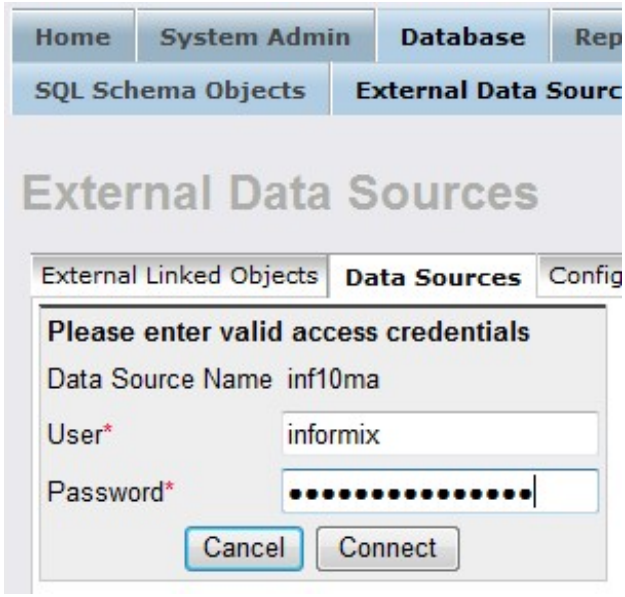
3. Select the "Databases" -> "External Data Source" -> "Data Sources" tab menu items

Figure 8.216. Databases



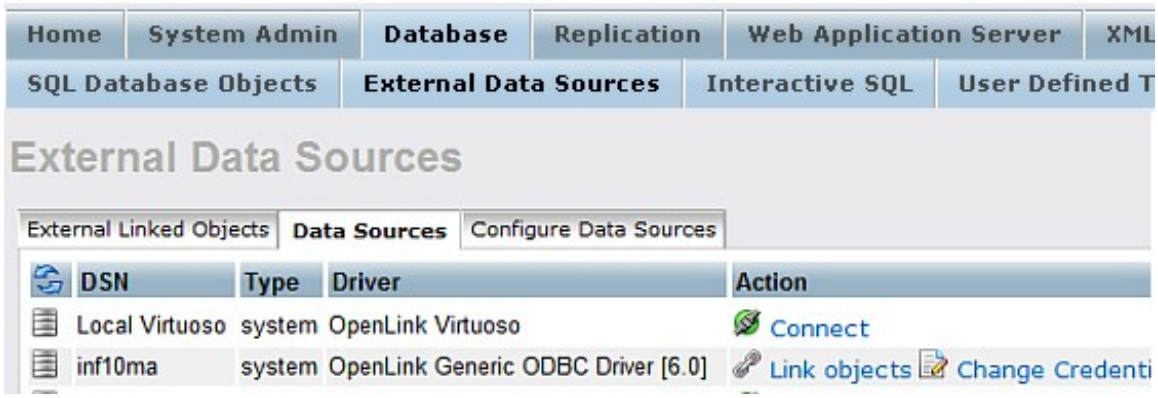
4. Select the "Connect" button for the "inf10ma" Informix DSN.

Figure 8.217. Connect



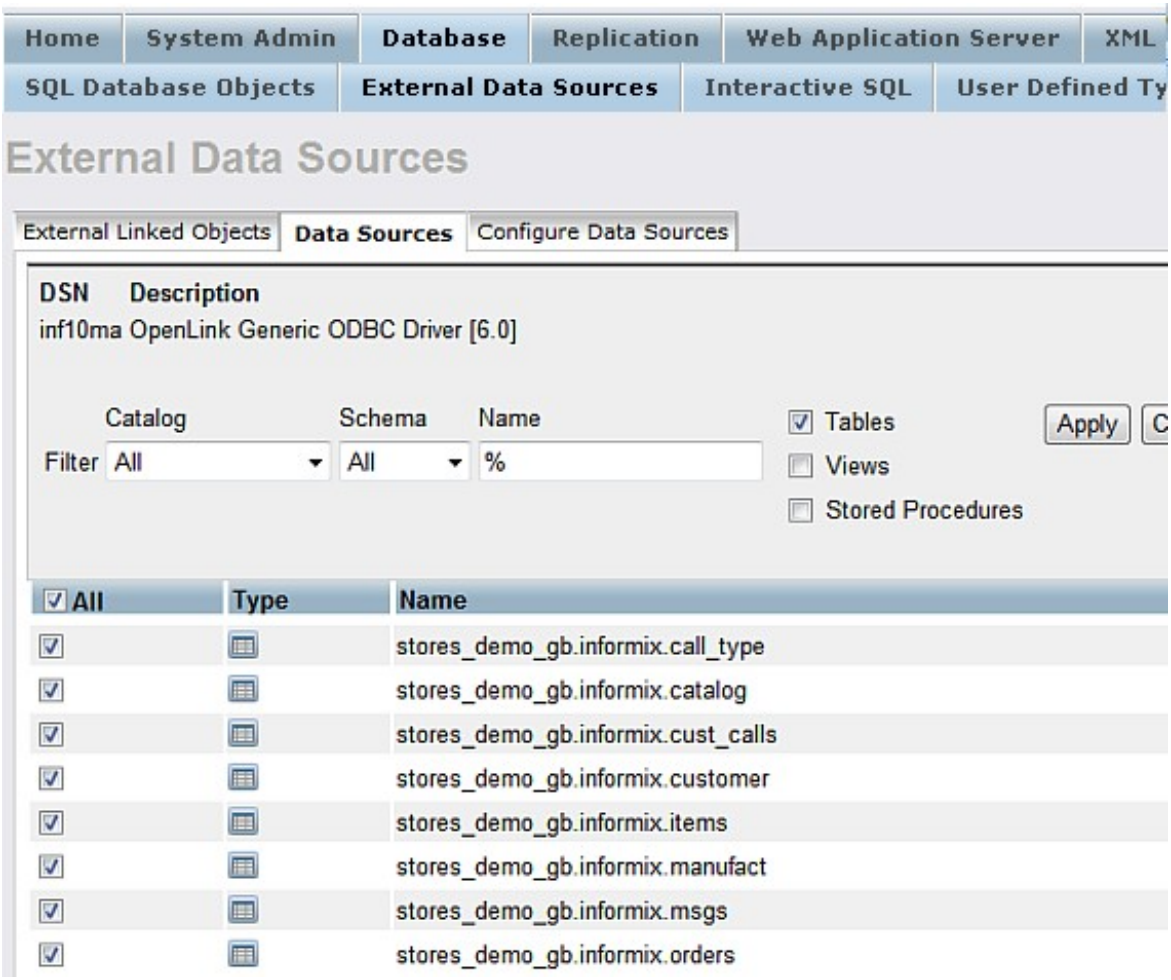
5. On successful connection Select the "Link Objects" button to obtain a list of available tables

Figure 8.218. Link Objects



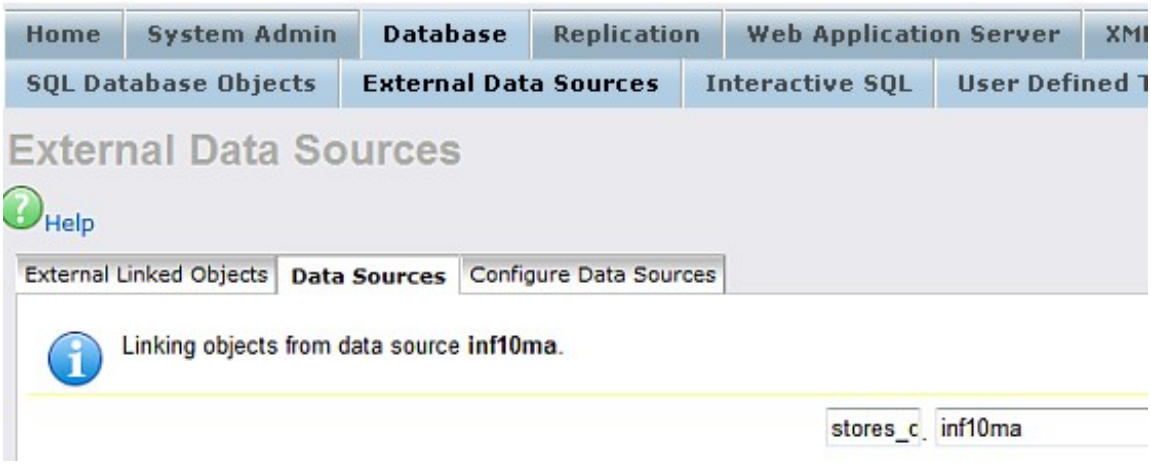
6. Select all the tables that are part of the "stores_demo" catalog.

Figure 8.219. Select all tables



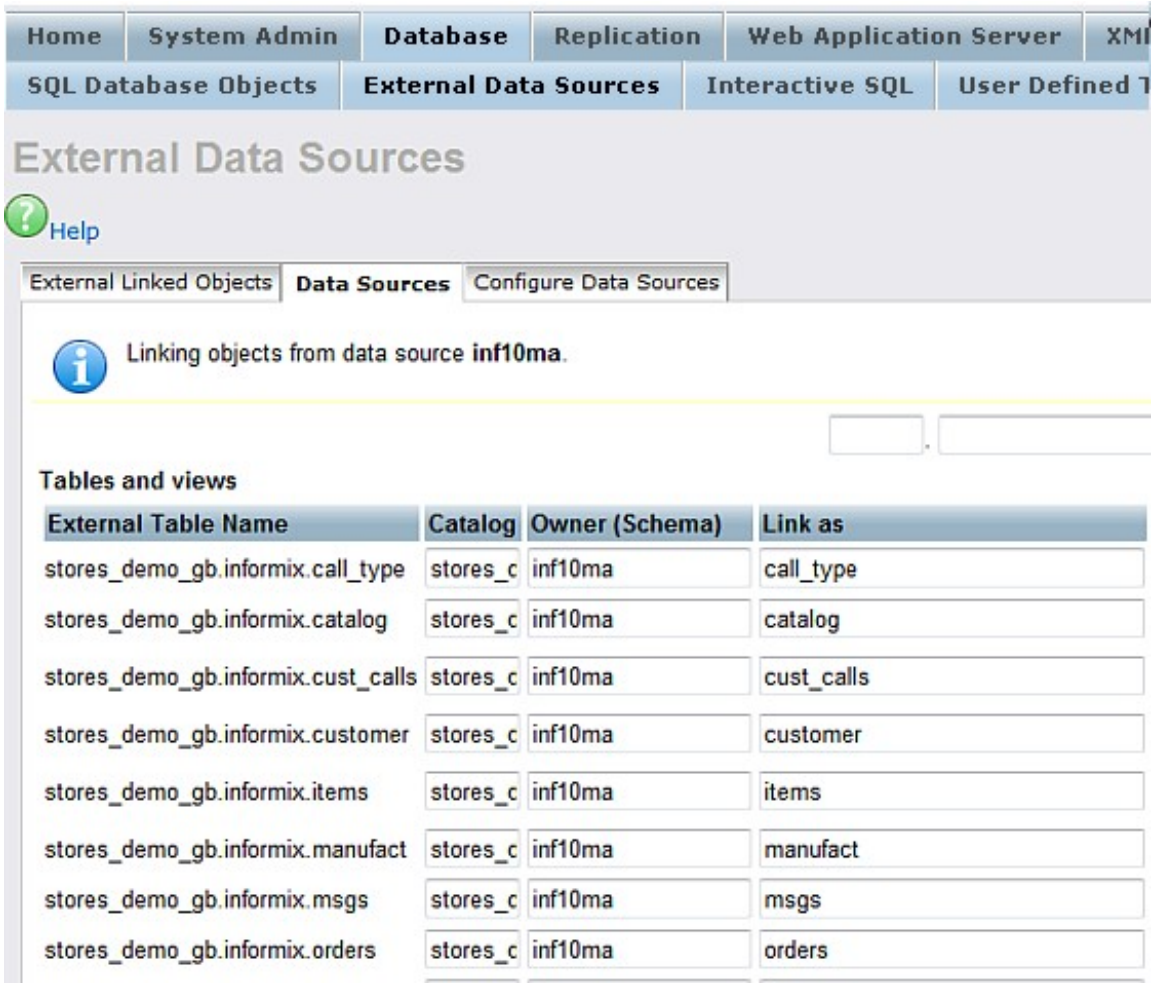
7. Change the Catalog for each table to be "stores_demo" using the "Set All" button.

Figure 8.220. Catalog



8. All the catalog names are changed to be "stores_demo".

Figure 8.221. catalog names

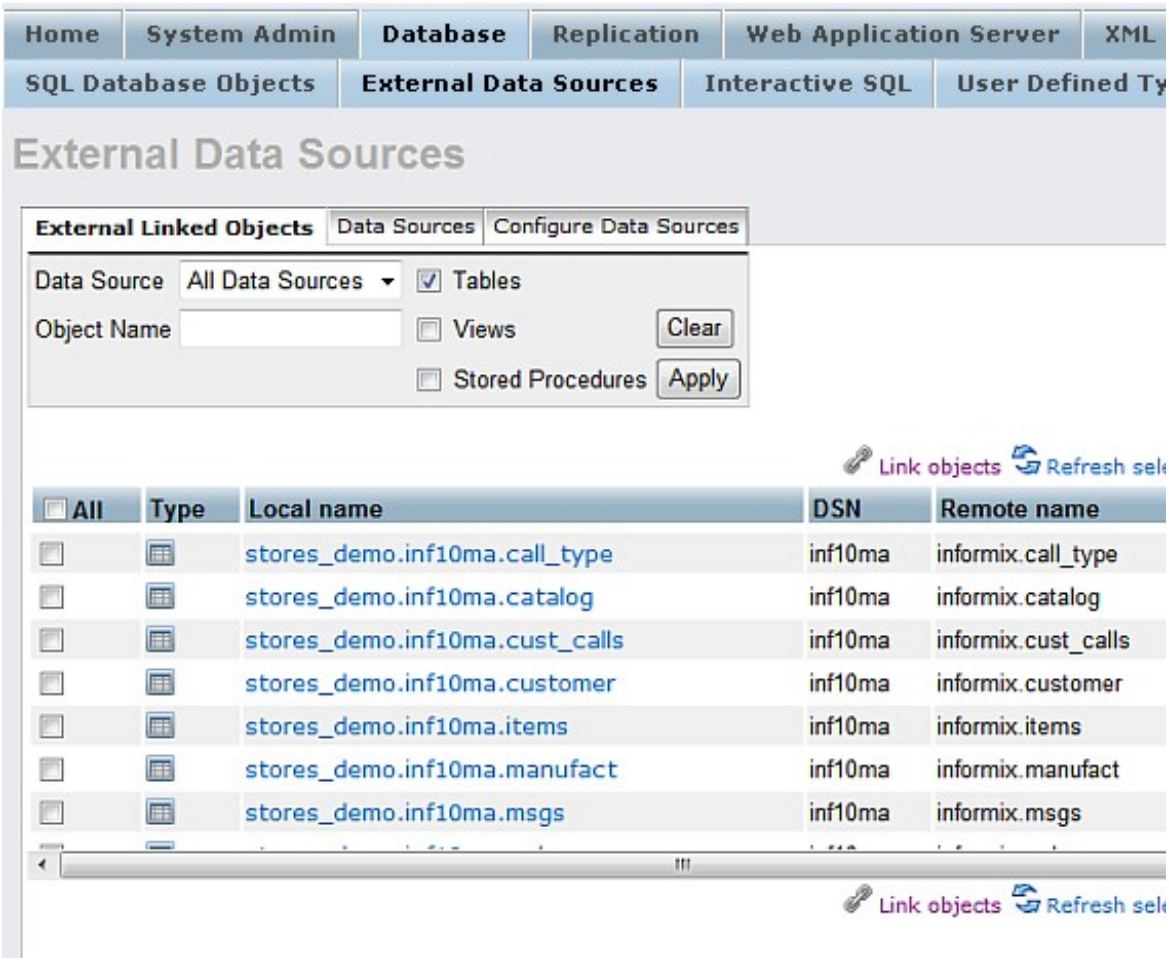


9. Select the "Link" button to link the selected tables into Virtuoso

Figure 8.222. "Link" button

10. On completion of the Link process the tables will be displayed in the "External Linked Objects" tab.

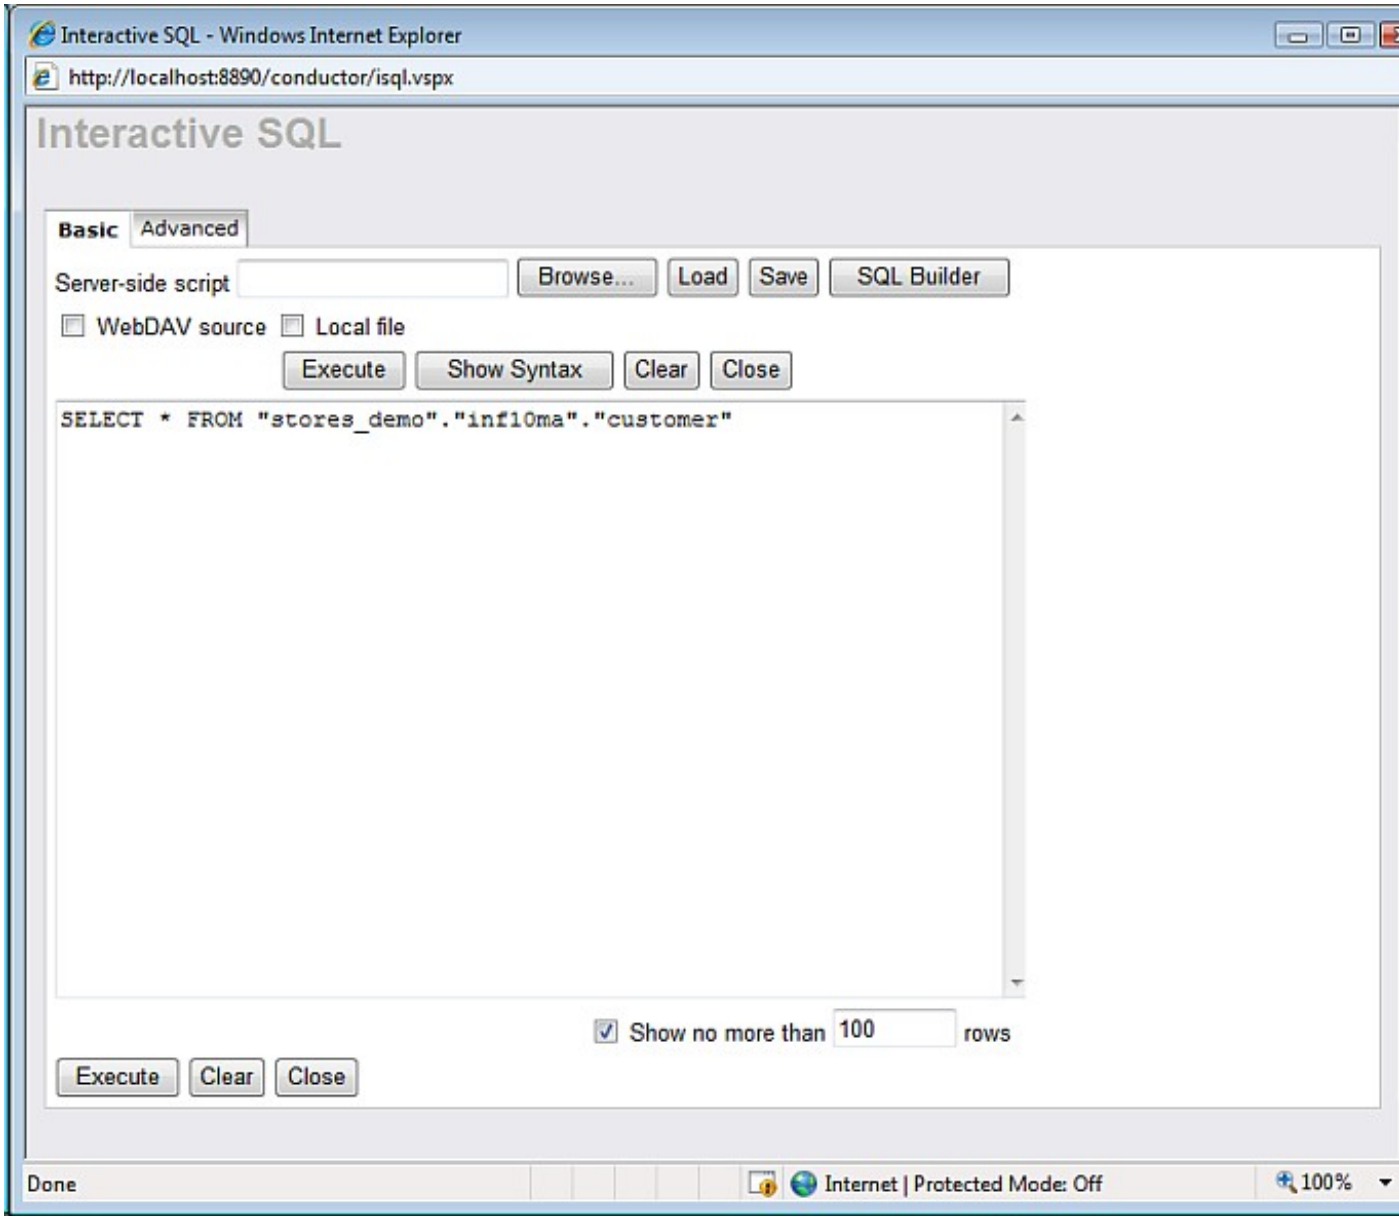
Figure 8.223. Completion



11. At this point you can test the remotely linked tables by clicking on the link that accompanies each table. e.g. stores_demo.inf10ma.customer.

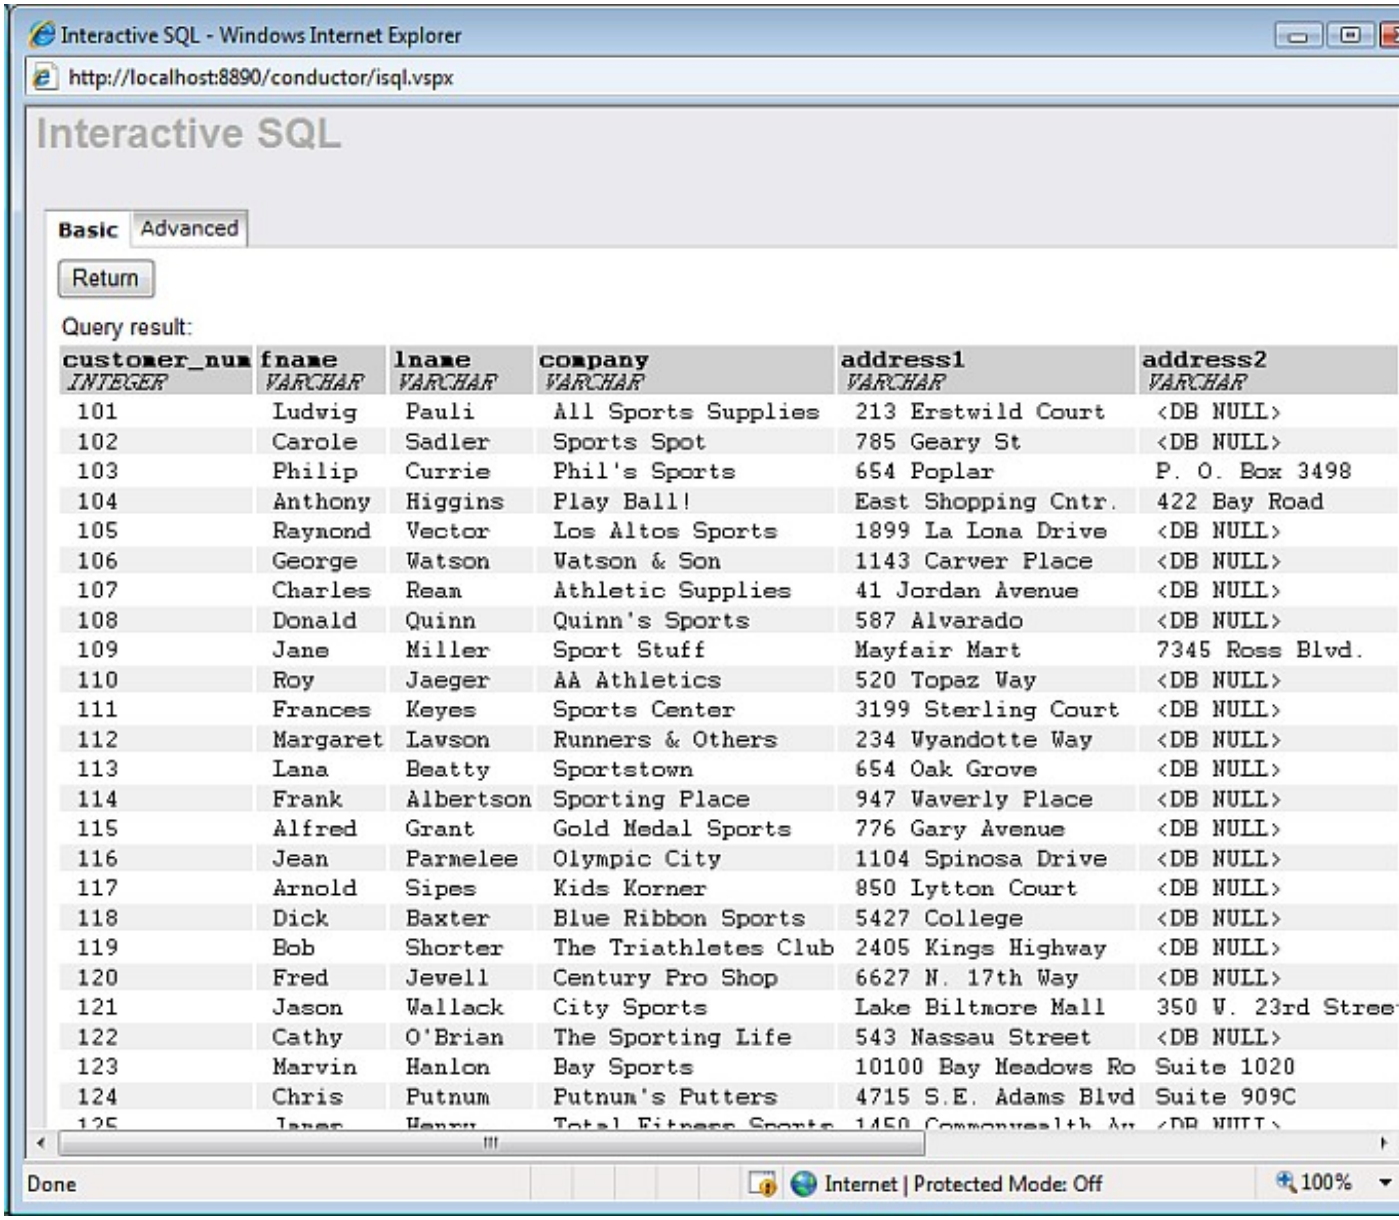
    This will display the Interactive ISQL interface which will have been already populated with a suitable SQL statement.

Figure 8.224. Querying



12. Select Execute to see data from the remotely linked table.

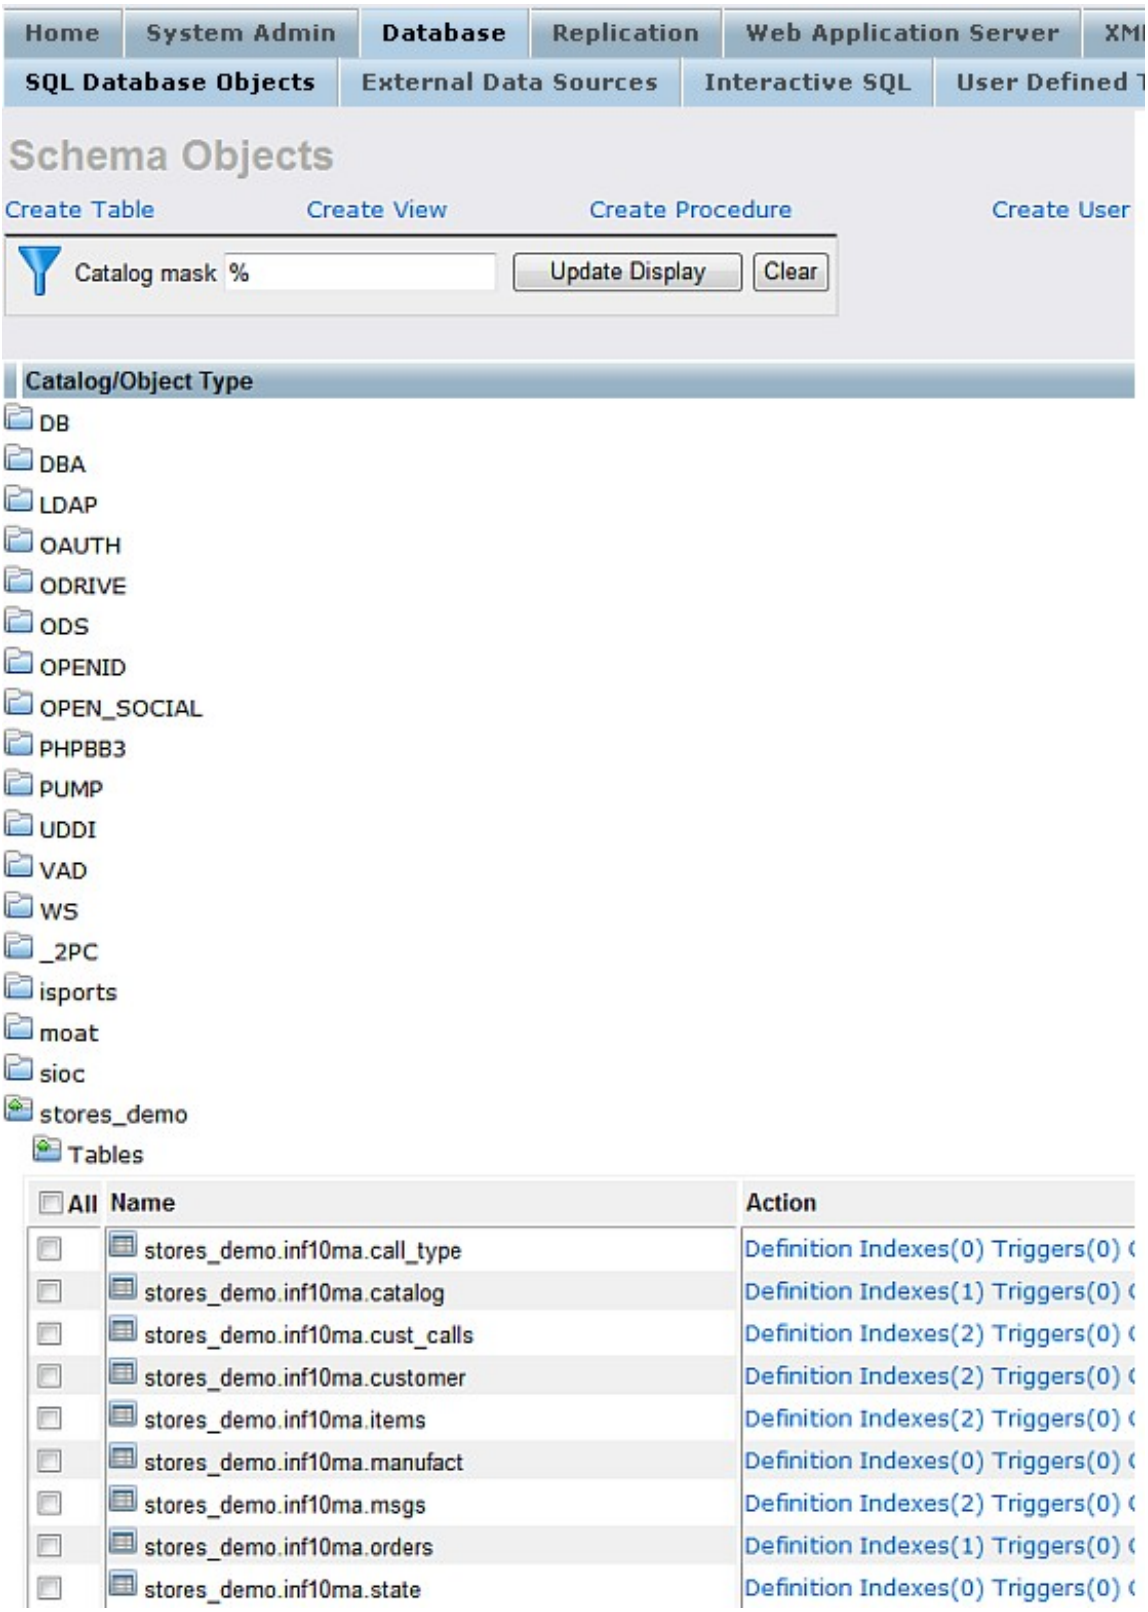
Figure 8.225. Execute



customer_num INTEGER	fname VARCHAR	lname VARCHAR	company VARCHAR	address1 VARCHAR	address2 VARCHAR
101	Ludvig	Pauli	All Sports Supplies	213 Erstwild Court	<DB NULL>
102	Carole	Sadler	Sports Spot	785 Geary St	<DB NULL>
103	Philip	Currie	Phil's Sports	654 Poplar	P. O. Box 3498
104	Anthony	Higgins	Play Ball!	East Shopping Cntr.	422 Bay Road
105	Raymond	Vector	Los Altos Sports	1899 La Loma Drive	<DB NULL>
106	George	Watson	Watson & Son	1143 Carver Place	<DB NULL>
107	Charles	Ream	Athletic Supplies	41 Jordan Avenue	<DB NULL>
108	Donald	Quinn	Quinn's Sports	587 Alvarado	<DB NULL>
109	Jane	Miller	Sport Stuff	Mayfair Mart	7345 Ross Blvd.
110	Roy	Jaeger	AA Athletics	520 Topaz Way	<DB NULL>
111	Frances	Keyes	Sports Center	3199 Sterling Court	<DB NULL>
112	Margaret	Lawson	Runners & Others	234 Wyandotte Way	<DB NULL>
113	Lana	Beatty	Sportstown	654 Oak Grove	<DB NULL>
114	Frank	Albertson	Sporting Place	947 Waverly Place	<DB NULL>
115	Alfred	Grant	Gold Medal Sports	776 Gary Avenue	<DB NULL>
116	Jean	Parmelee	Olympic City	1104 Spinosa Drive	<DB NULL>
117	Arnold	Sipes	Kids Korner	850 Lytton Court	<DB NULL>
118	Dick	Baxter	Blue Ribbon Sports	5427 College	<DB NULL>
119	Bob	Shorter	The Triathletes Club	2405 Kings Highway	<DB NULL>
120	Fred	Jewell	Century Pro Shop	6627 N. 17th Way	<DB NULL>
121	Jason	Wallack	City Sports	Lake Biltmore Mall	350 W. 23rd Stree
122	Cathy	O'Brian	The Sporting Life	543 Nassau Street	<DB NULL>
123	Marvin	Hanlon	Bay Sports	10100 Bay Meadows Ro	Suite 1020
124	Chris	Putnum	Putnum's Putters	4715 S.E. Adams Blvd	Suite 909C

13. The tables can also be viewed as part of the Virtuoso "SQL Schema Objects" under the "stores_demo" catalog name.

Figure 8.226. SQL Schema Objects



The Link process is now complete enabling the tables to be queried as if part of the Virtuoso Schema.

8.5.4. Creating EDM in Visual Studio 2008

The following steps can be used to create an Entity Data Model (EDM) for the Informix stores_demo database:

1. Launch the Visual Studio 2008 SP1 IDE.

Figure 8.227. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

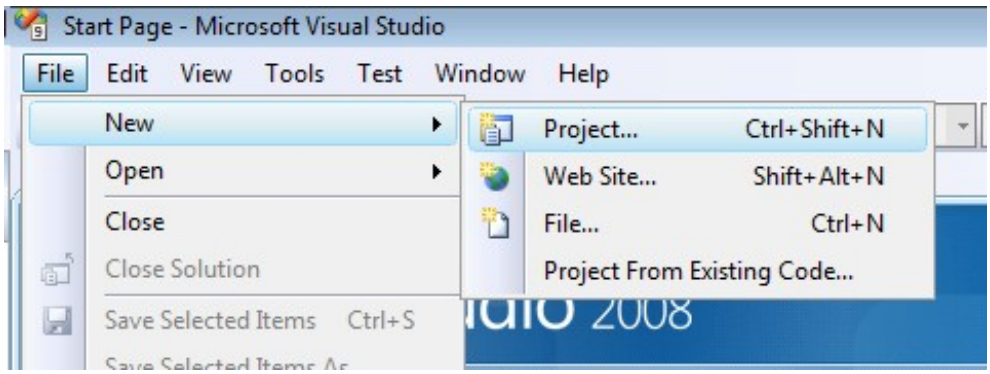
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.228. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Web

   and select

   ASP.NET Web Application

from the right-hand panel.

5. Choose a name for the project, for example

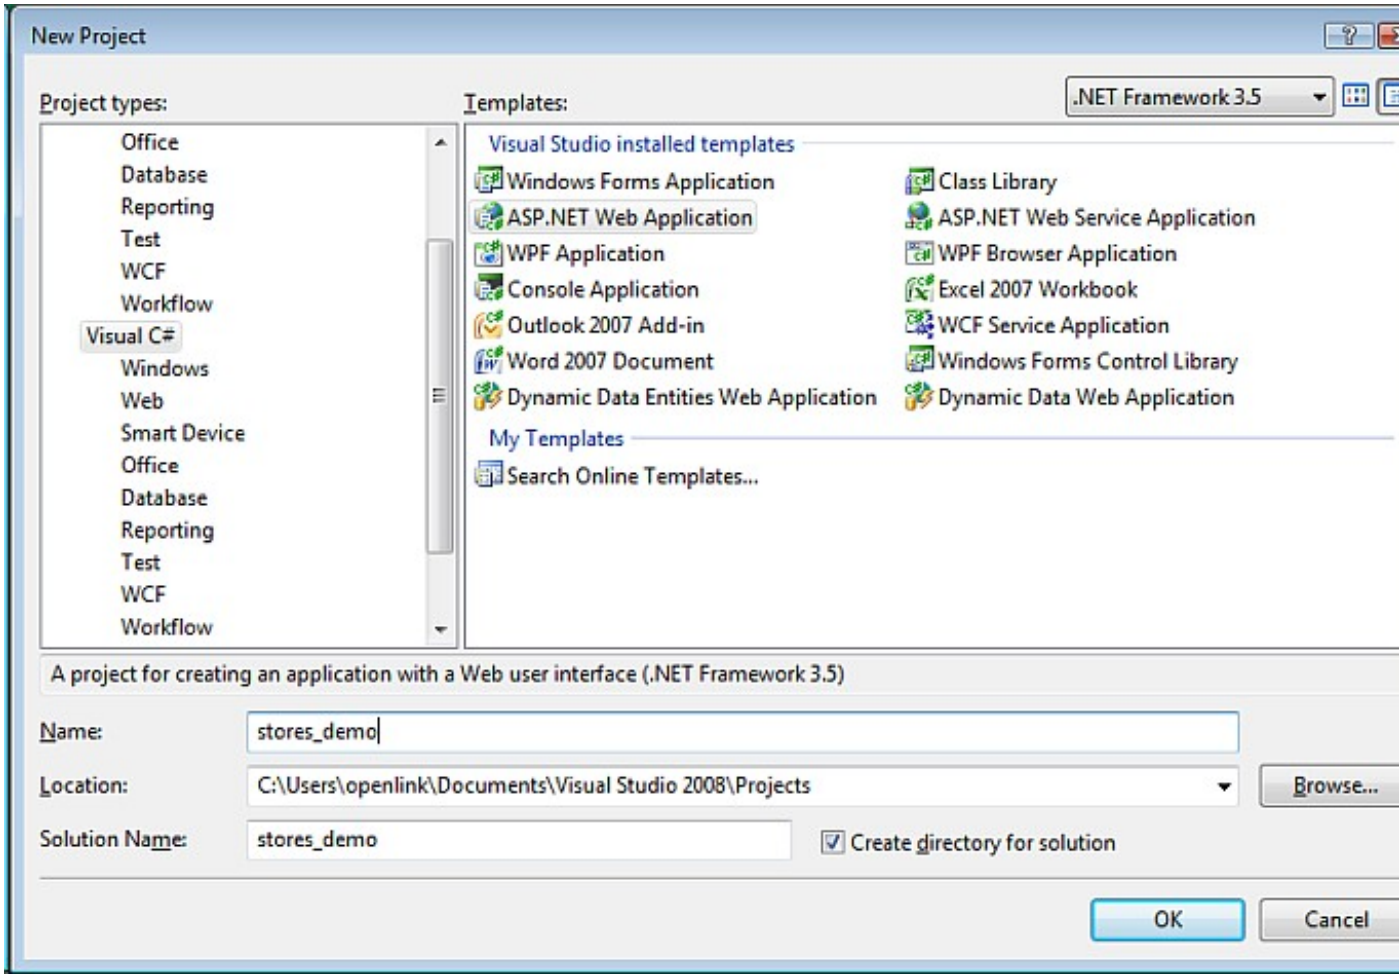
   stores_demo

   , and click

   OK

   .

   Figure 8.229. name for the project

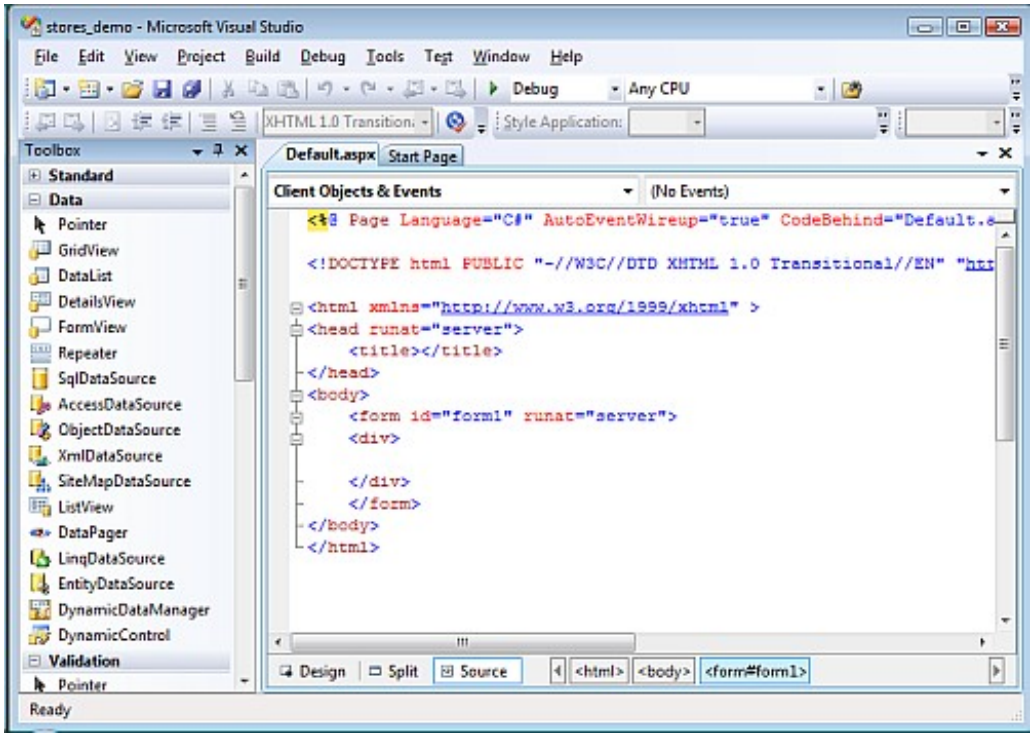


6. This will create a new project called

   stores_demo

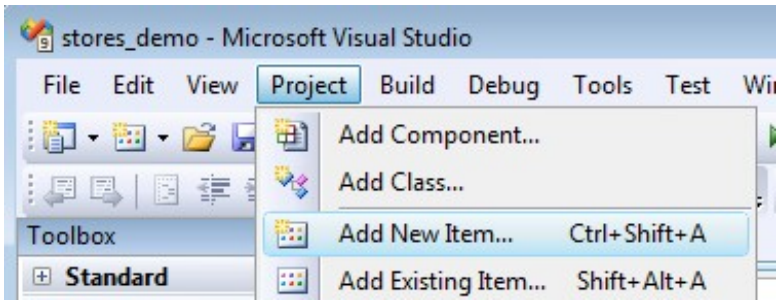
   .

   Figure 8.230. create a new project



7. Select the Project -> Add New Item menu option.

Figure 8.231. New Item



8. The

Add New Item

dialog will appear. Choose the

ADO.NET Entity Data Model

template. Give it the name

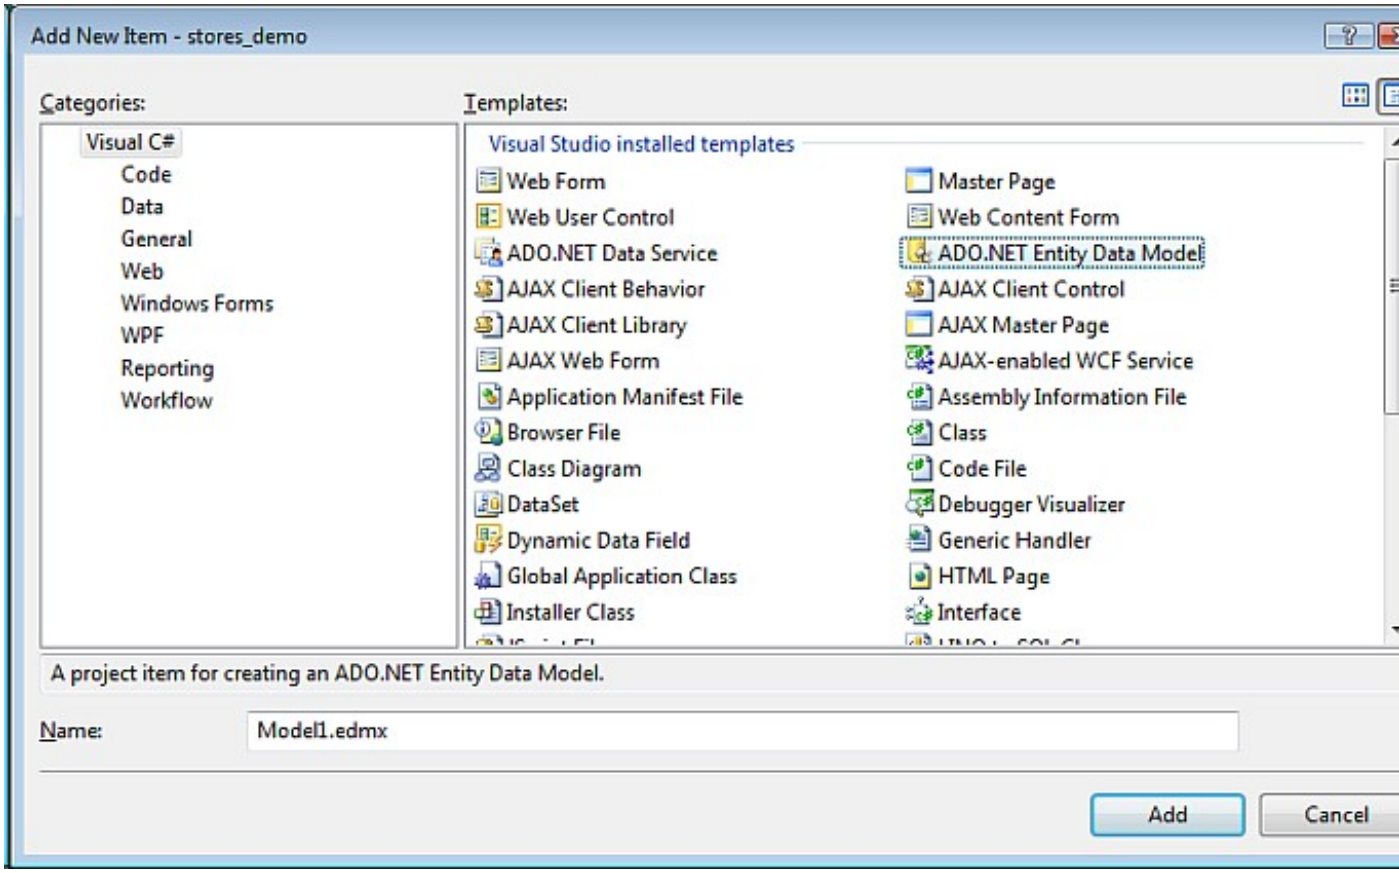
Model1.edmx

e and click

Add

to start the creation of the ADO.Net Entity Data Model.

Figure 8.232. Add New Item



9. In the

   Entity Data Model Wizard

   dialog

   Choose Model Contents

   page select the

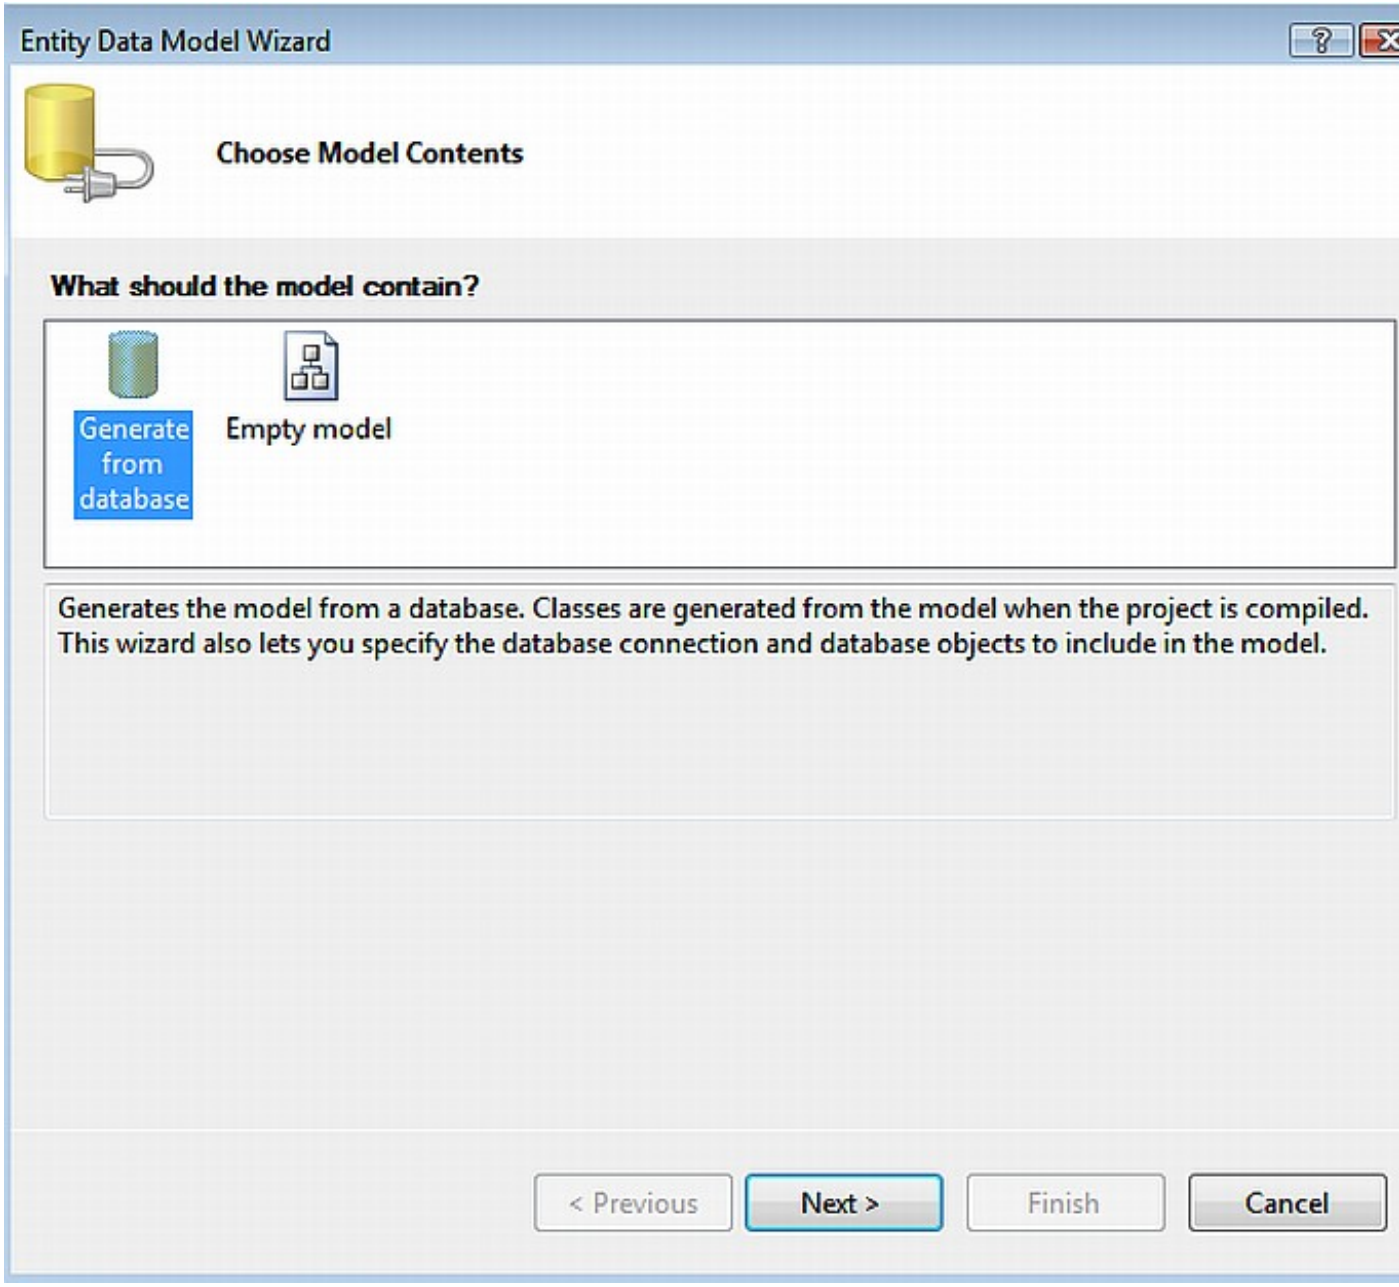
   Generate from Database

   model type and click

   Next

   .

Figure 8.233. Choose Model Contents



10. In the

    Entity Data Model Wizard

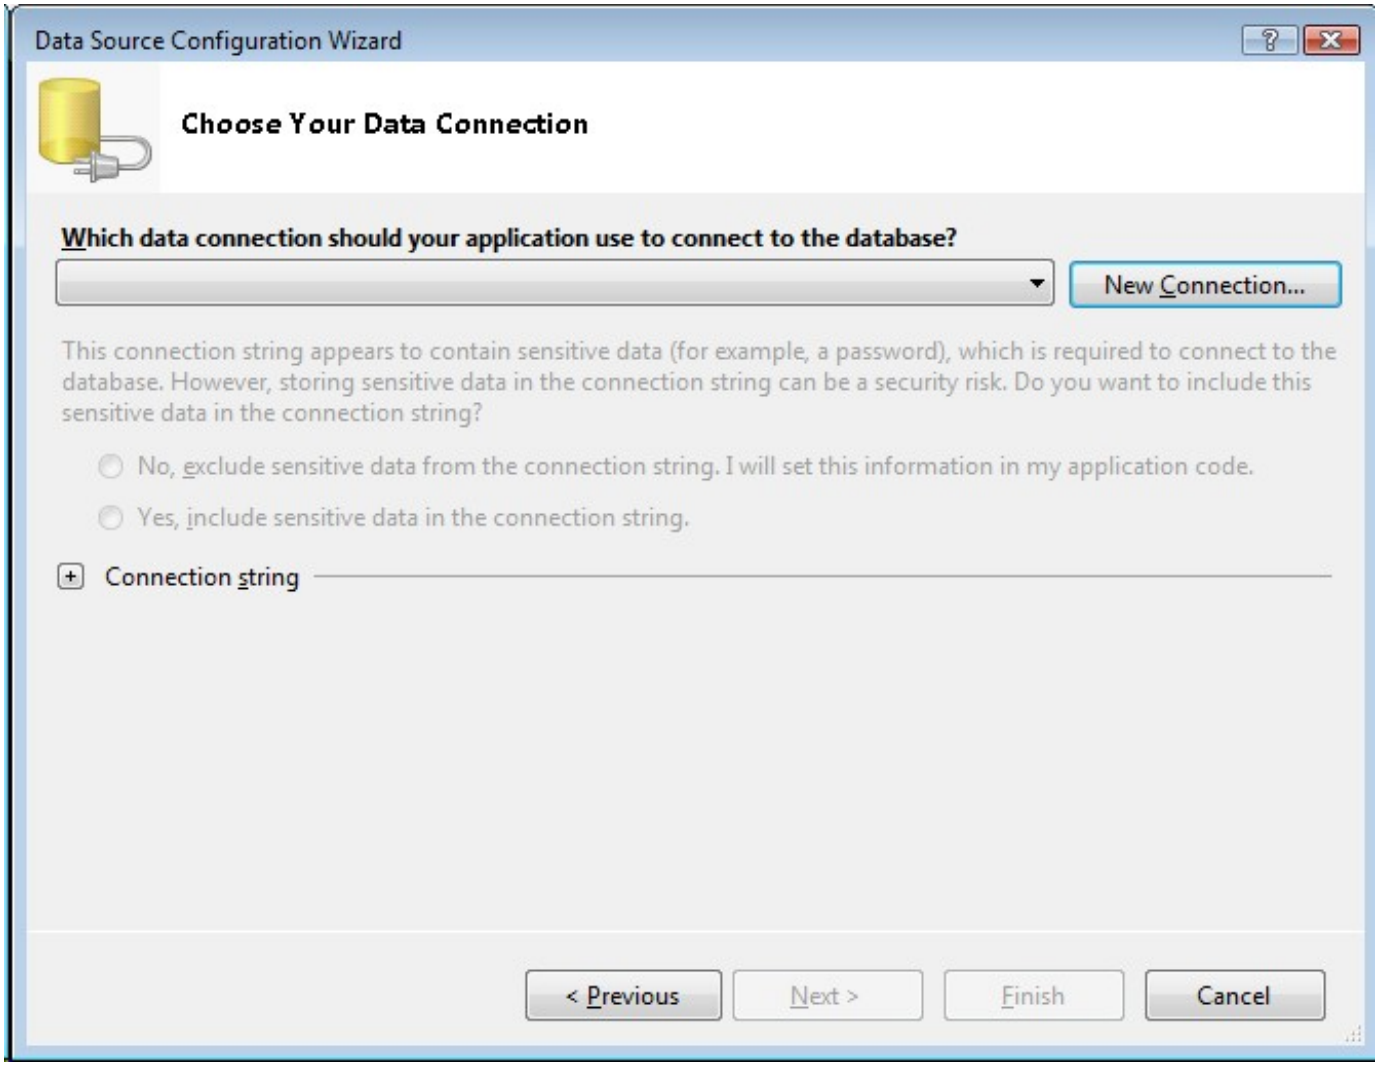
    dialog

    Choose your Data Connection

    page, select the

    New Connection button

Figure 8.234. Entity Data Model Wizard



11. In the

    Choose Data Source

    dialog, select the OpenLink

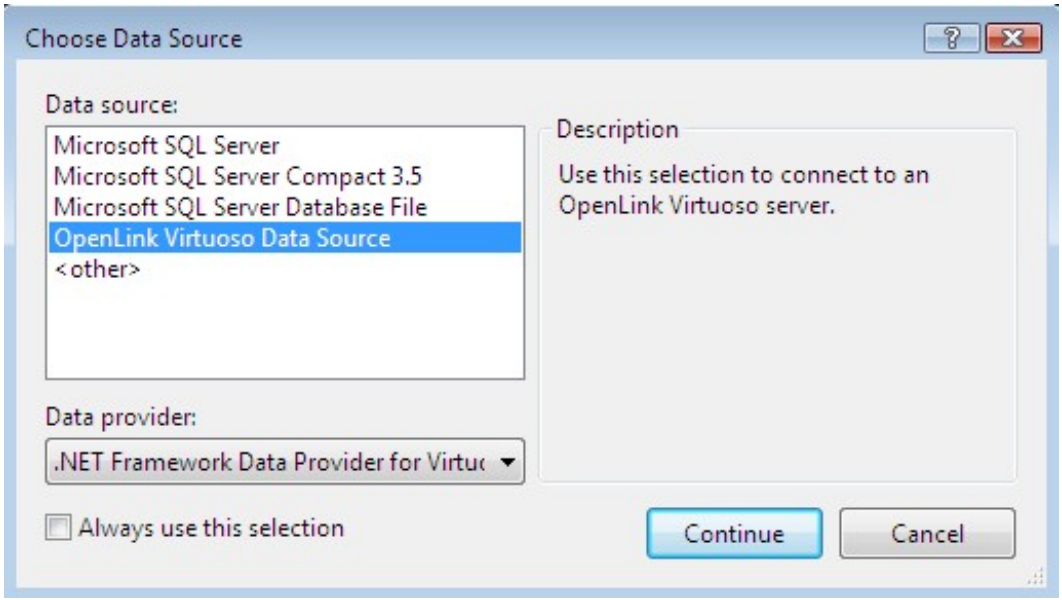
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.235. Choose Data Source



12. In the

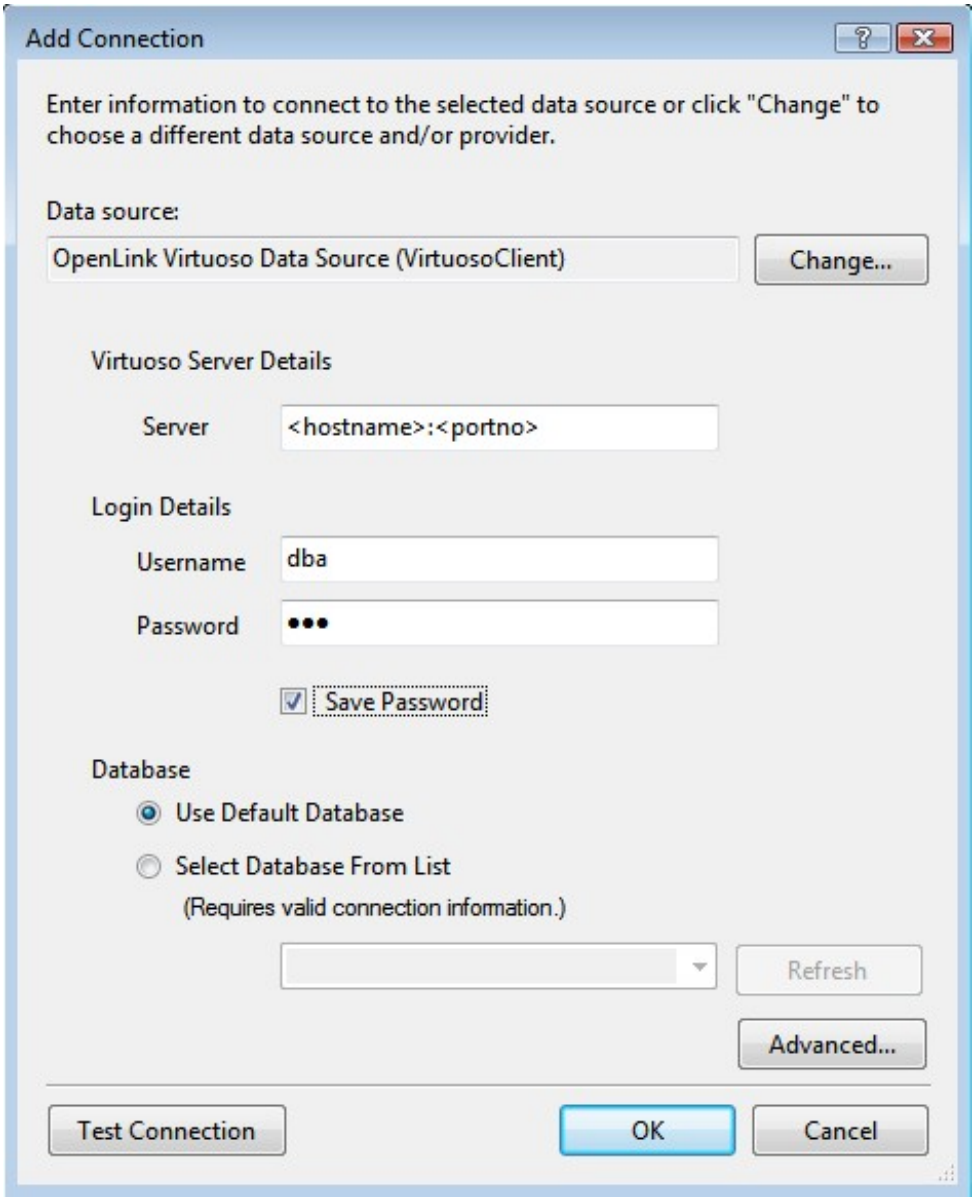
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.236. Connection Properties



13. Select the

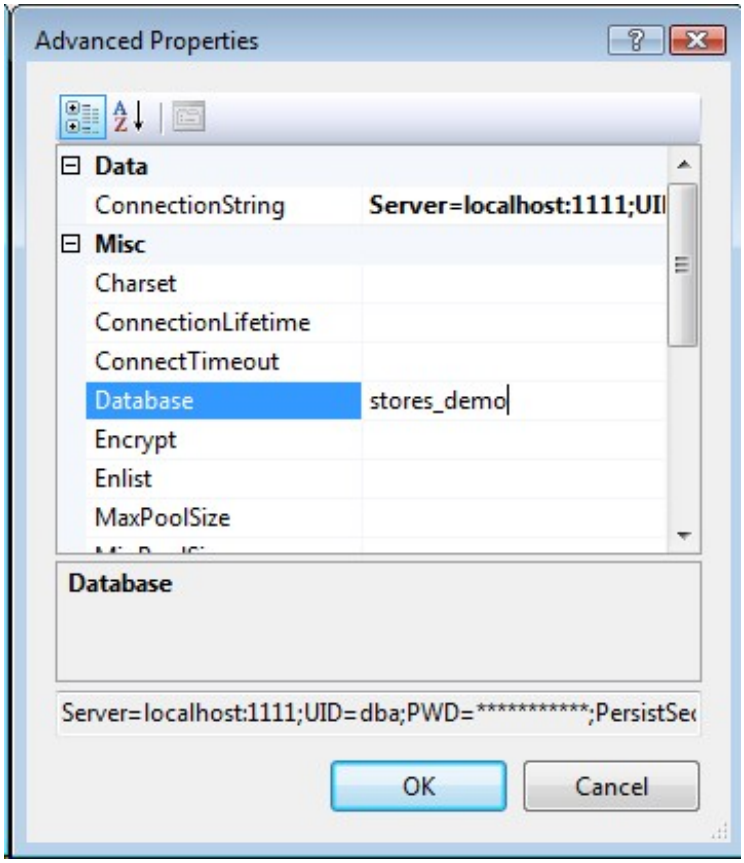
    Select Database From List

    radio button and choose the

    stores_demo

    database from the drop down list.

Figure 8.237. Add connection

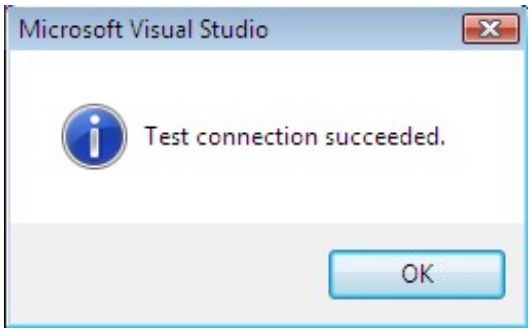


14. Press the

    Test Connection

    dialog to verify that the database is accessible.

    Figure 8.238. Test Connection



15. Set the

    entity connect string

    name to

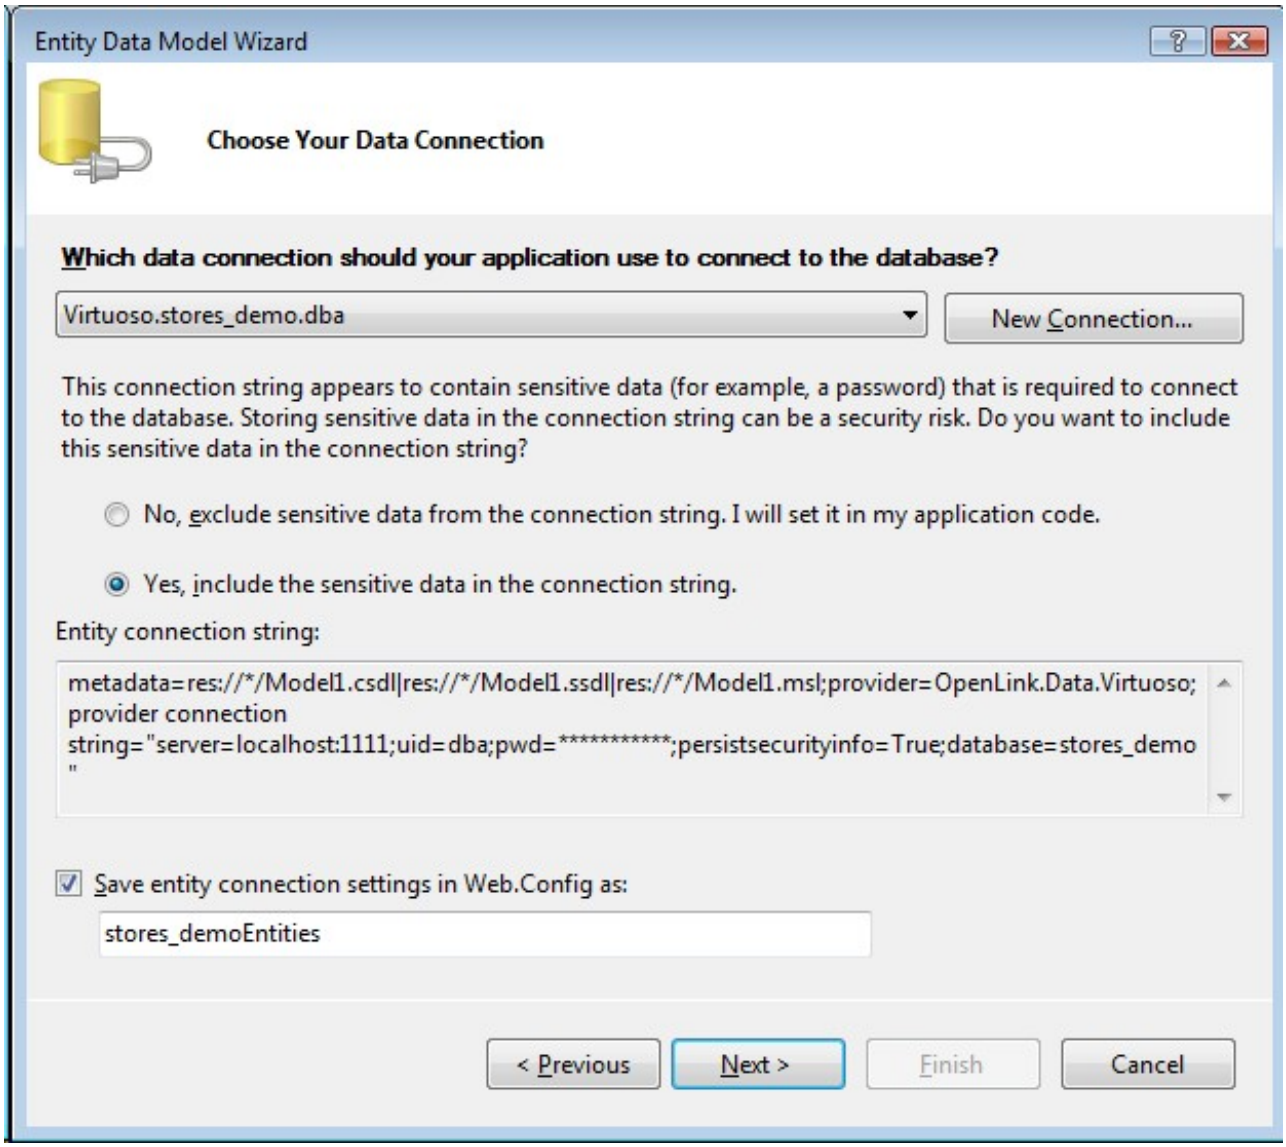
    stores_demoEntities

    (note this name as it is required in the section on creating and ADO.Net Data Service) and click

    Next

    .

Figure 8.239. entity connect string



16. In the

    Choose your Database Objects

    page tick the

    Tables

    check box to select all tables in the stores_demo catalog for addition to the Entity Data Model. Set the

    Model Namespace

    to

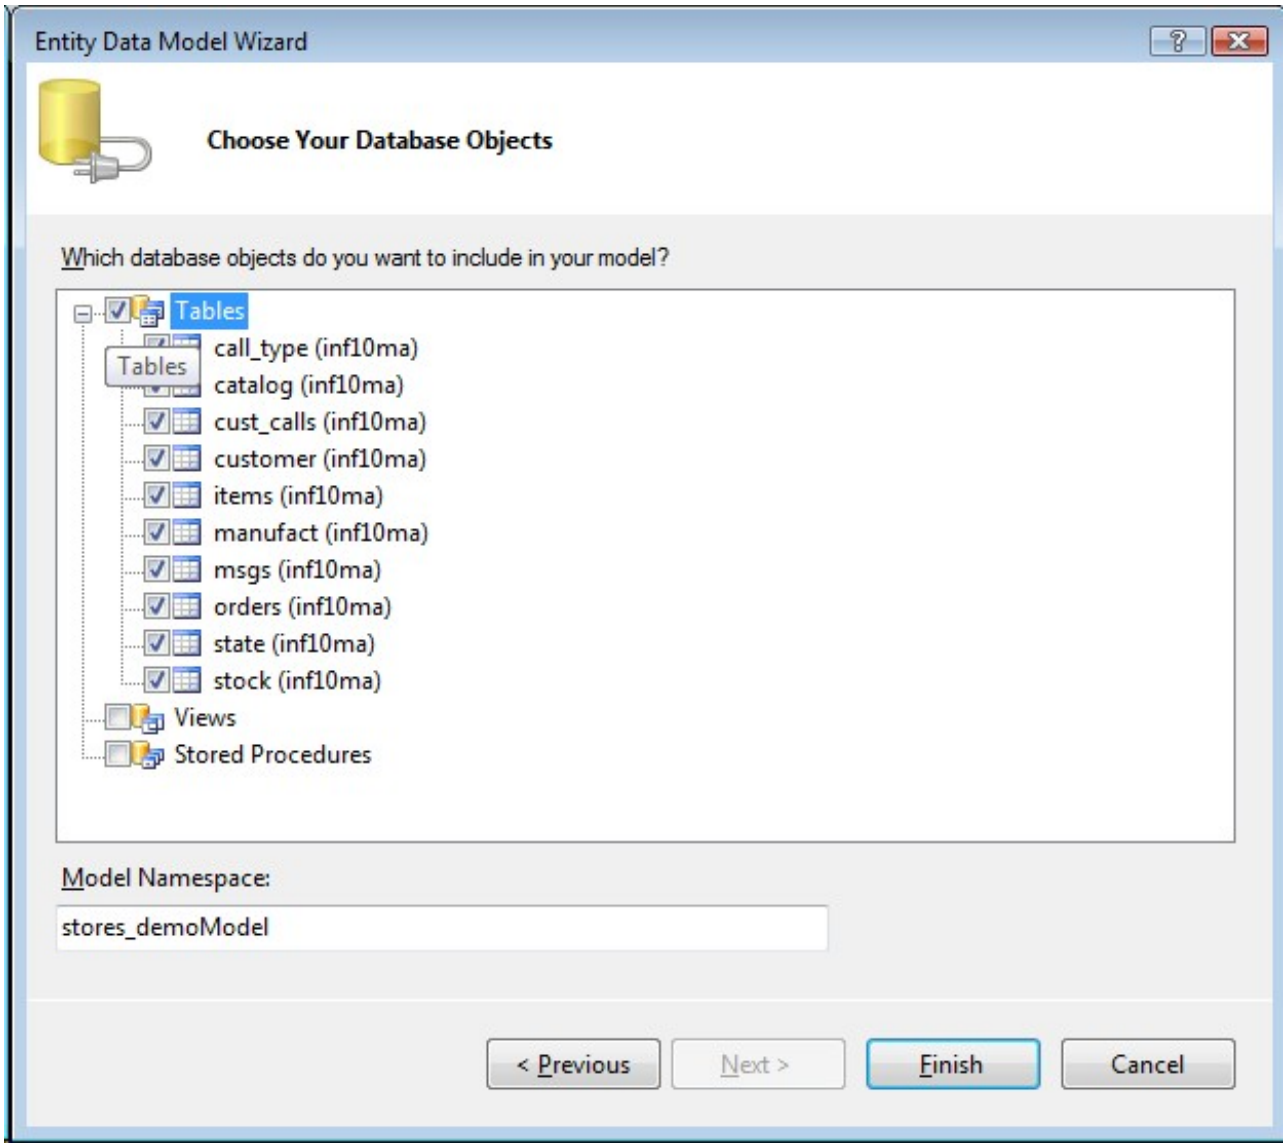
    stores_demoModel

    and click

    Finish

    .

Figure 8.240. Database Objects

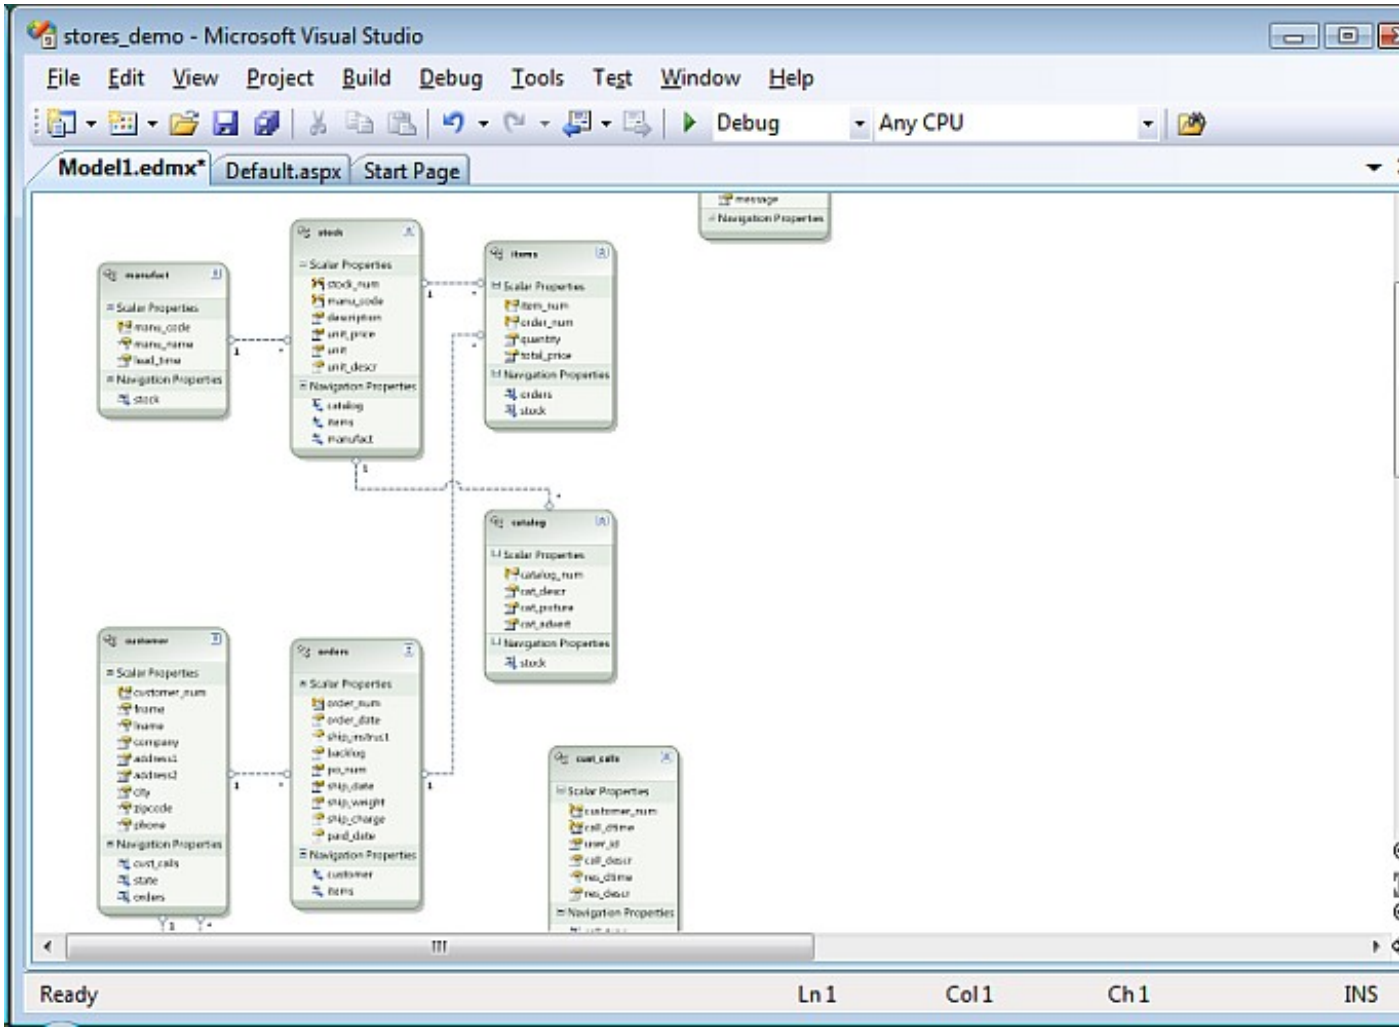


17. The

    Model1.edmx

    EDM will be created with the tables and relationships displayed in the Visual Studio IDE

Figure 8.241. Virtuoso.edmx



Creation for the Entity Data Model for the Informix stores_demo database is now complete.

8.5.5. Using EDM to create Entity Framework based applications

Now that a Microsoft Entity Data Model has been created for the Informix stores_demo database, Entity Framework applications can be created to make use of it.

Entity Frameworks based finf

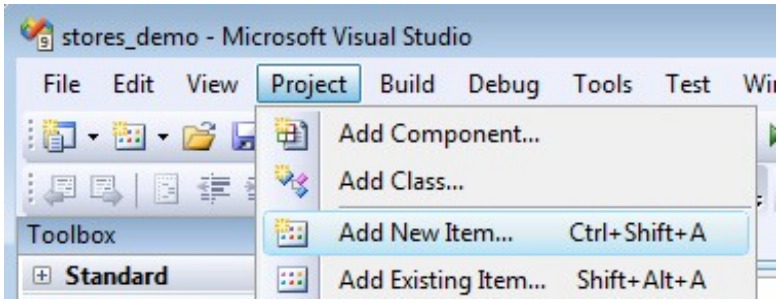
An ADO.Net Data Service for the Informix tables can be created using the Entity Data Model created in the Creating EDM in Visual Studio 2008 section .

1. Open the

   stores_demo

   project created in the Creating EDM in Visual Studio 2008 section .
2. Select the Project -> Add New Item menu option.

Figure 8.242. VirtuosoDataService



3. The

   Add New Item

   dialog will appear. Choose the

   ADO.NET Data Service template

   . Give it the name

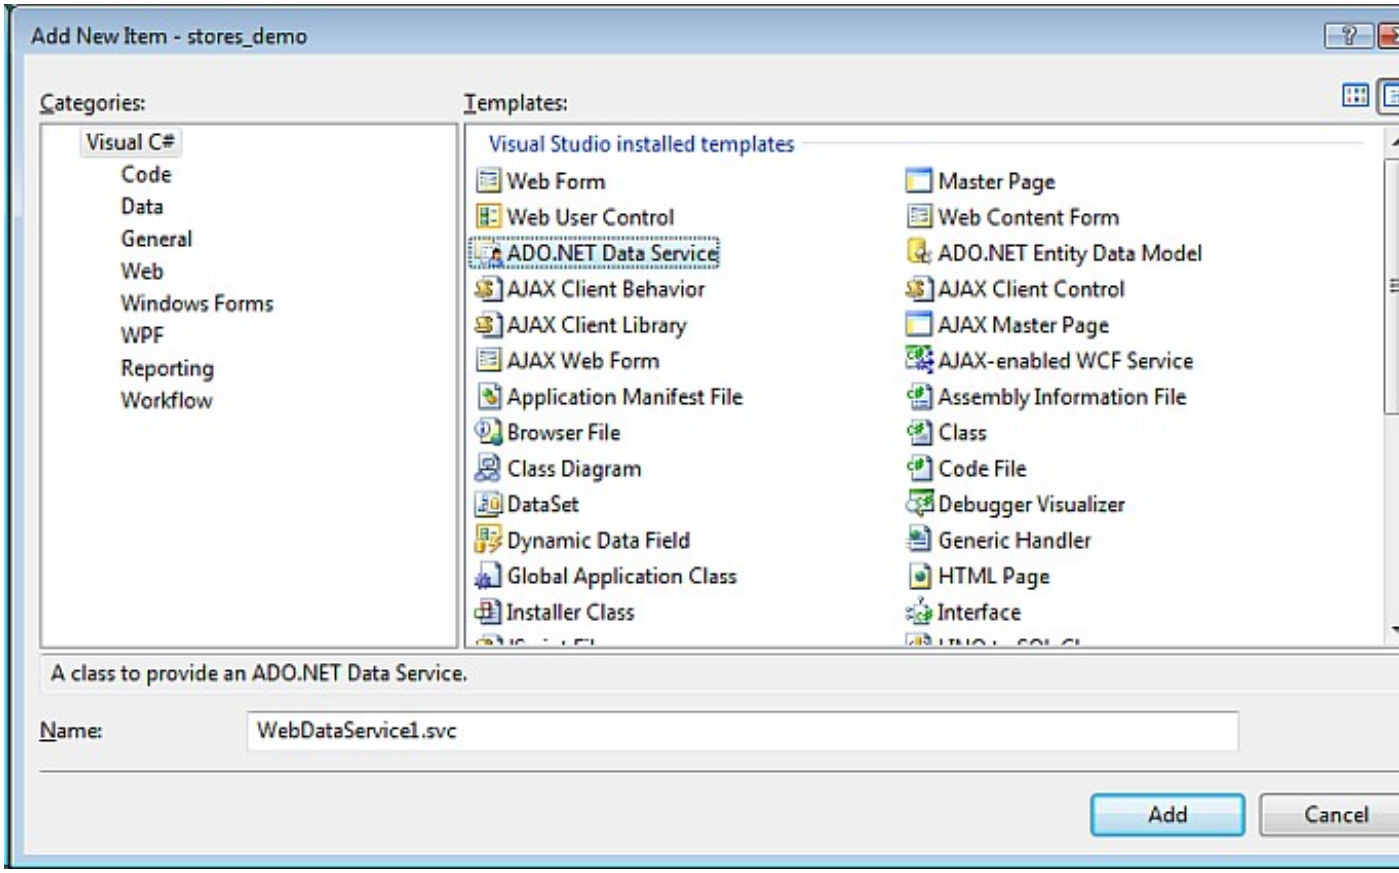
   WebDataService.svc

   and click

   Add

   to create the ADO.Net Data Service.

   Figure 8.243. Add New Item



4. In the newly created

   WebDataService1.svc.cs

Data Service file, add the data source class name of

stores_demoEntities

(note this is the name set in the Creating EDM in Visual Studio 2008 section) as the

DataService

name. Enable the access to the Data Service by adding the entry

config.SetEntitySetAccessRule("", EntitySetRights.All);*

in the

InitializeService

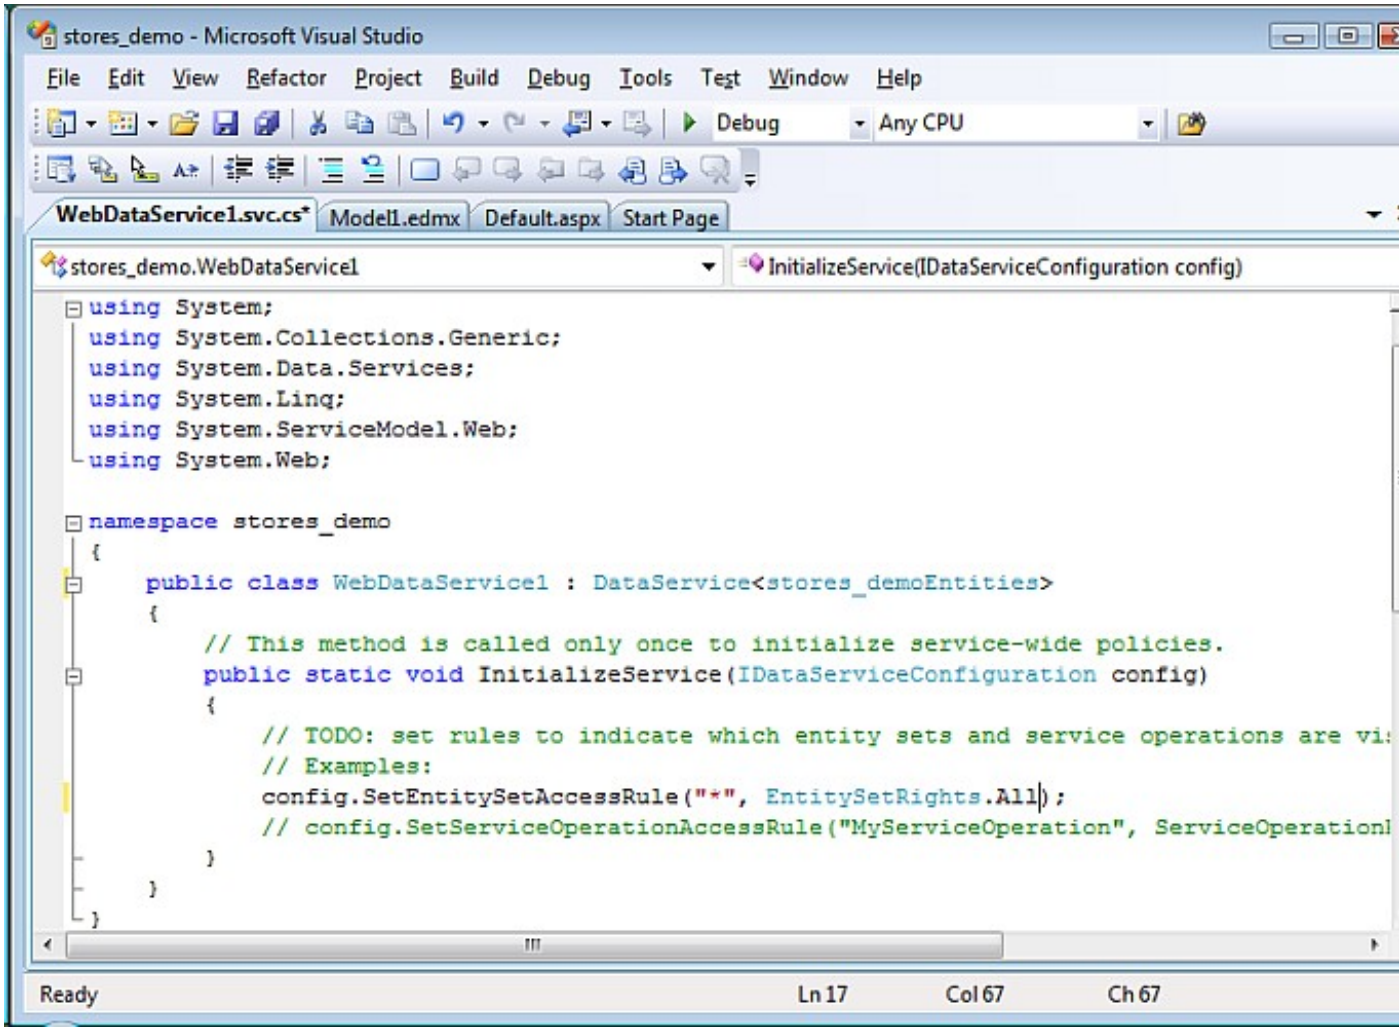
method.

```
// C#

using System;
using System.Web;
using System.Collections.Generic;
using System.ServiceModel.Web;
using System.Linq;
using System.Data.Services;

namespace SimpleDataService
{
    public class Northwind : DataService<stores_demoDemoEntities>
    {
        public static void InitializeService(IDataServiceConfiguration  config)
        {
            config.SetEntitySetAccessRule("*", EntitySetRights.All);
        }
    }
}
```

Figure 8.244. WebDataService1.svc.cs

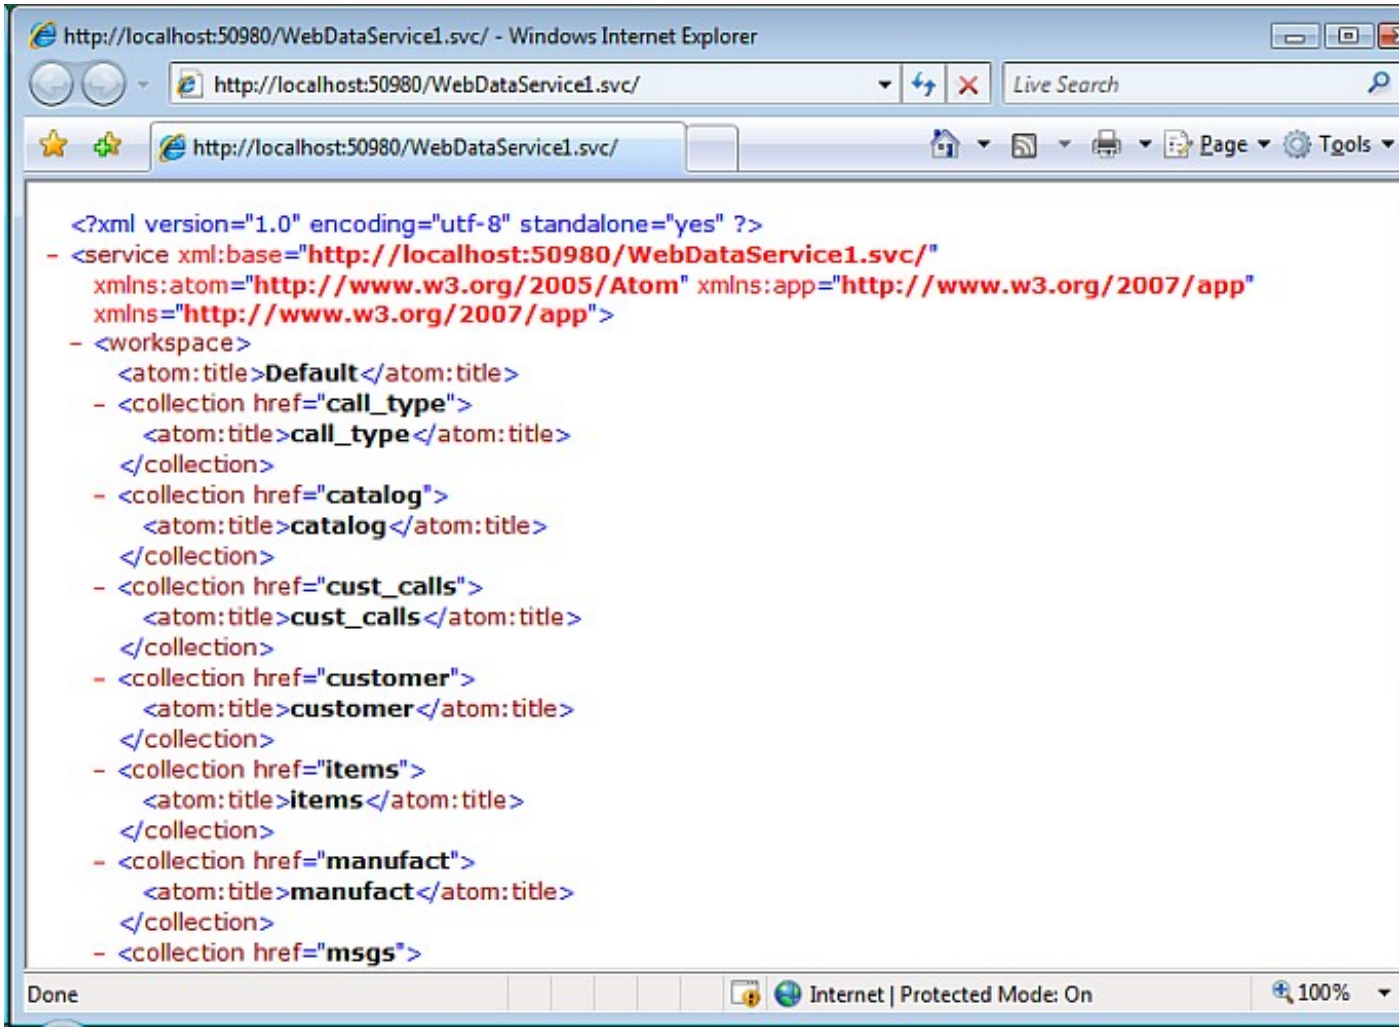


5. To test the Data Service, simply hit

   Ctrl+F5

   within Visual Studio. This will start the development web server, run the Data Services server inside, and load a Web browser page displaying the list of available tables/entities for the stores_demo database catalog.

Figure 8.245. Data Service test



6. To access a specific entity instance like the

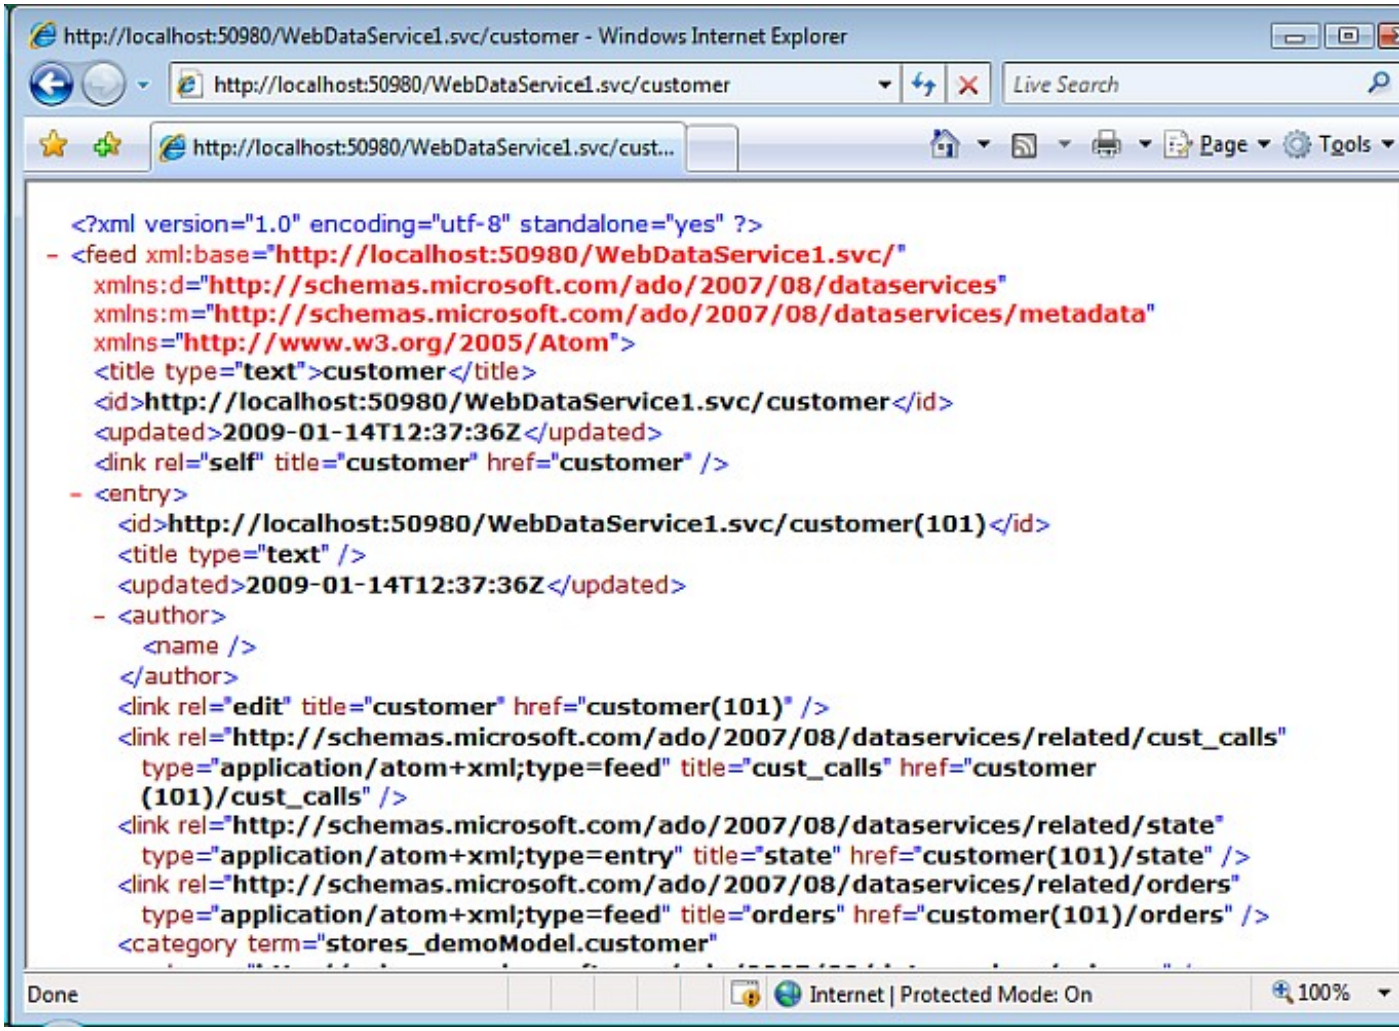
   CUSTOMERS

   table customer number

   101

   record, use this convention http://host/vdir/WebDataService1.svc/customer(101).

   Figure 8.246. custmers



Notes:

1. *Important*

   - To view

   Atom

   (the default format returned by an ADO.NET Data Service) in Internet Explorer, you must first ensure that

   Feed Reading View

   is turned

   off

   . This can be done on the

   Content tab

   of

   Tools in Internet Options

   .
2. If a Data Services entity instance URI page fails to load you can turn

Verbose

errors on by adding

config.UseVerboseErrors = true;

in the

virtuoso.svc.cs InitializeService

method to obtain more detailed information from the server as to why the page failed to load:

```
public static void InitializeService(IDataServiceConfiguration config)
{
config.UseVerboseErrors = true;
config.SetEntitySetAccessRule("*", EntitySetRights.All);
}
```

Visual Studio Windows DataGrid Form Application

This sectiond details the steps required to create a simple Visual Studio 2008 Windows Form application, with associated DataGridView control for displaying data in selected tables from the target database.

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.247. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

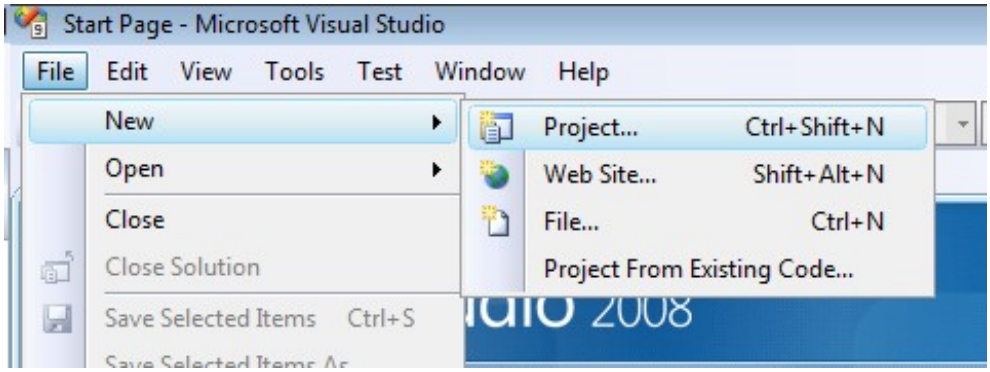
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.248. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Windows

   and select

   Windows Form Application

   from the right-hand panel.
5. Choose a name for the project, for example

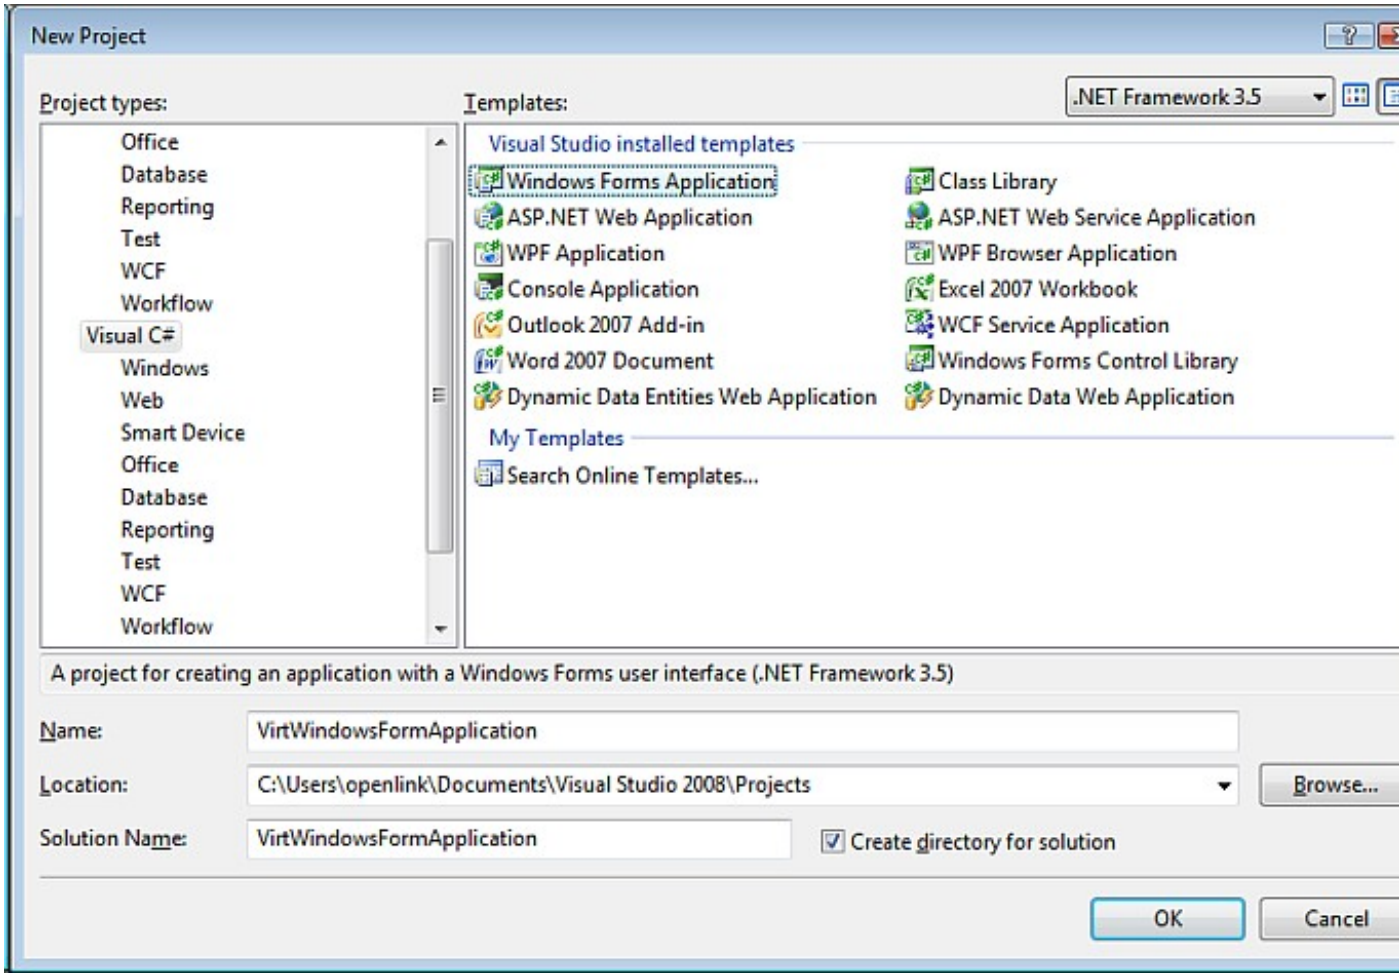
   VirtWindowsFormApplication

   , and click

   OK

   .

   Figure 8.249. Web Application



6. In the

   Toolbox

   , expand

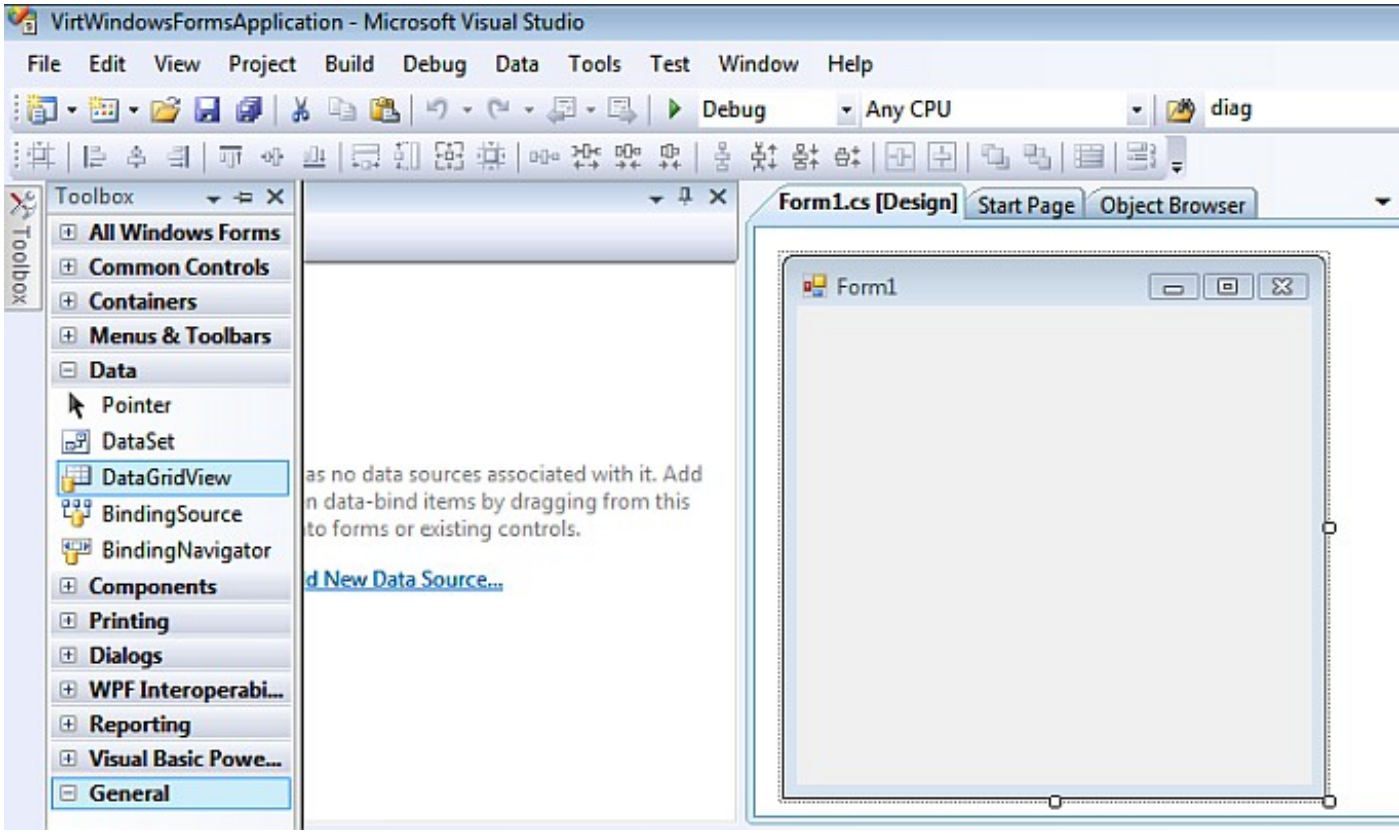
   Data Controls

   , and drag the

   DataGridView

   control onto the form.

   Figure 8.250. Toolbox



7. Click on the little

   arrow

   in the top right of the

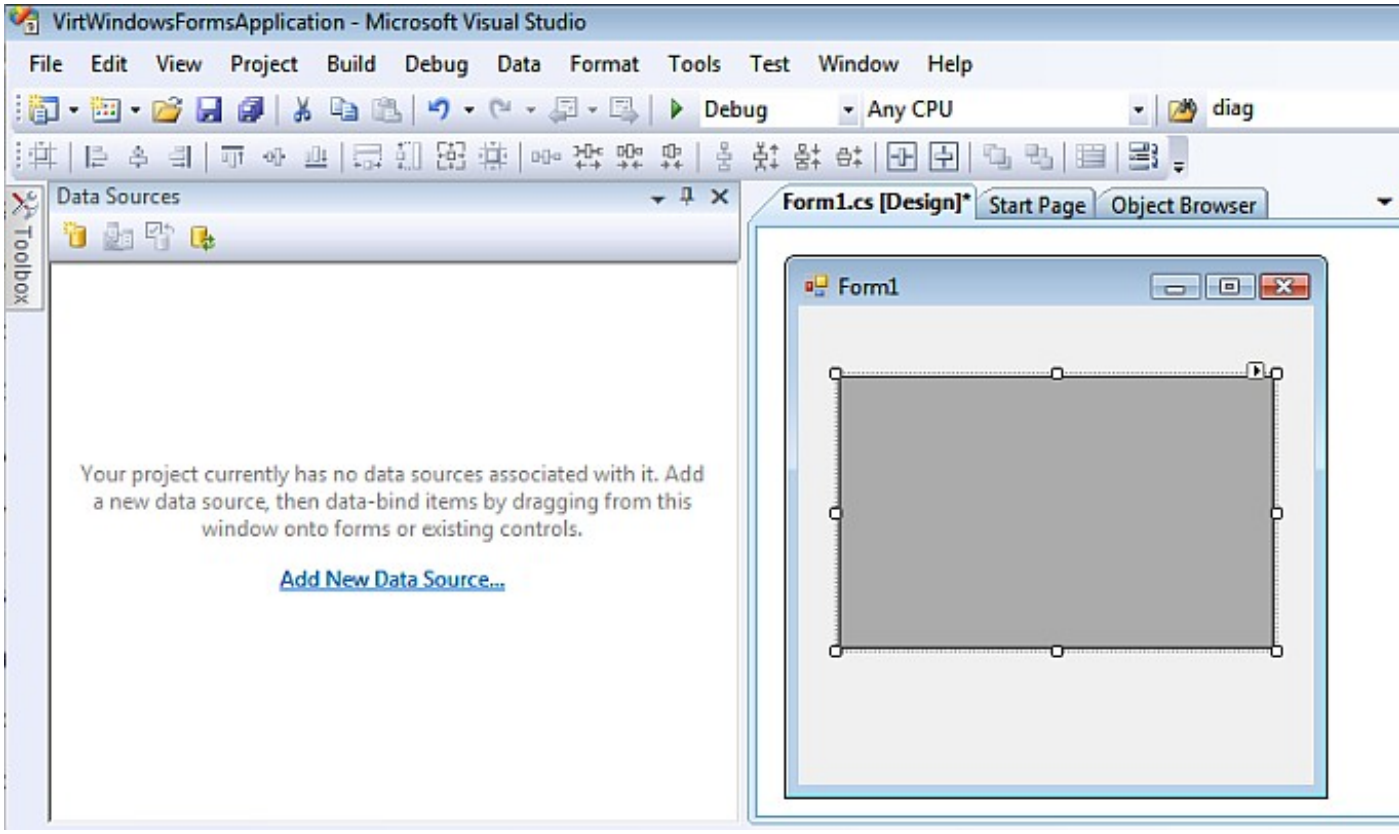
   DataGridView

   control. This loads the

   DataGridView Task

   menu.

Figure 8.251. DataGridView Task

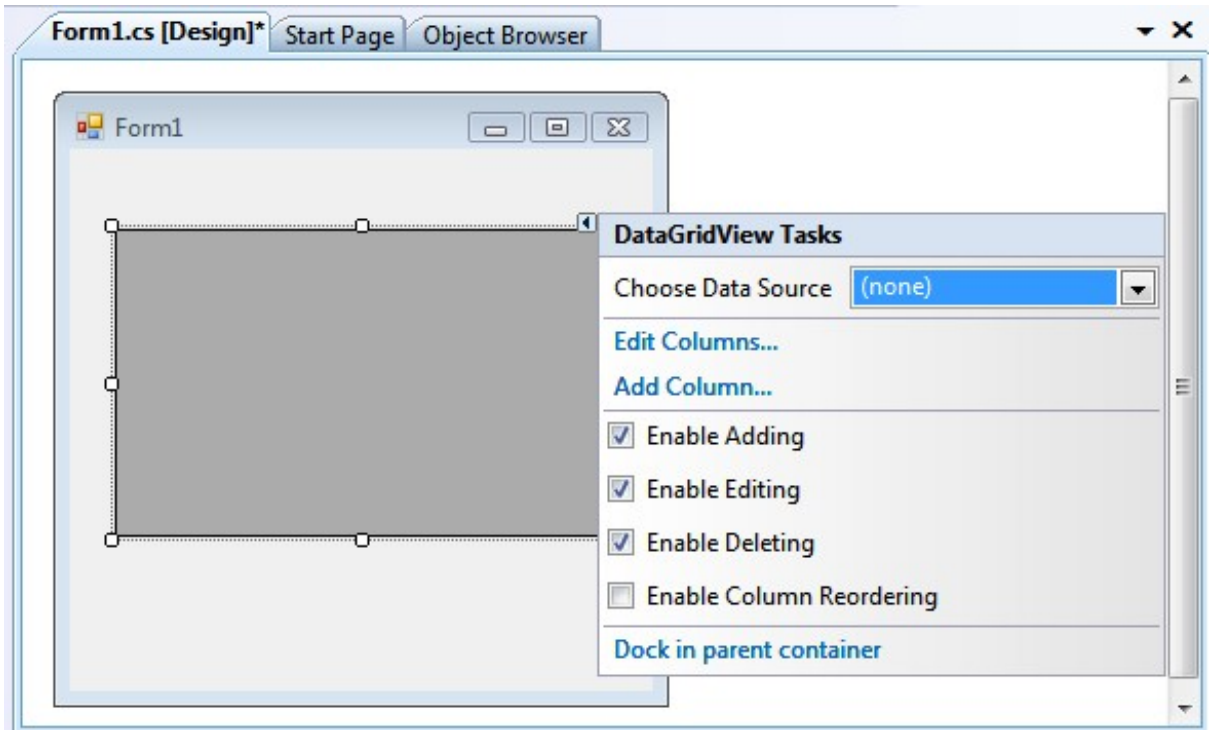


8. Click on the

   Choose Data Source

   list box.

   Figure 8.252. Choose Data Source

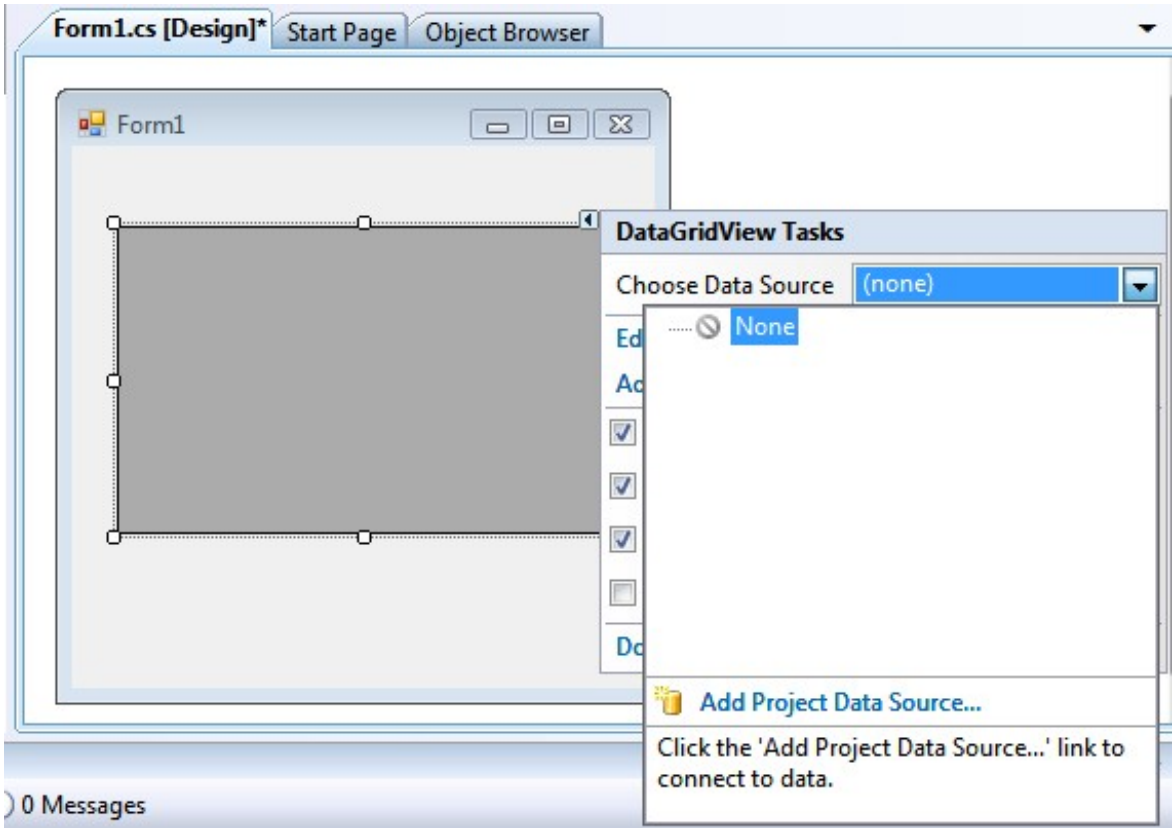


9. Click on the

   Add Project Data Source

link to connect to a data source.

Figure 8.253. Add Project Data Source



10. In the

    Data Source Configuration Wizard

    dialog

    Choose Data Source Type

    page select the

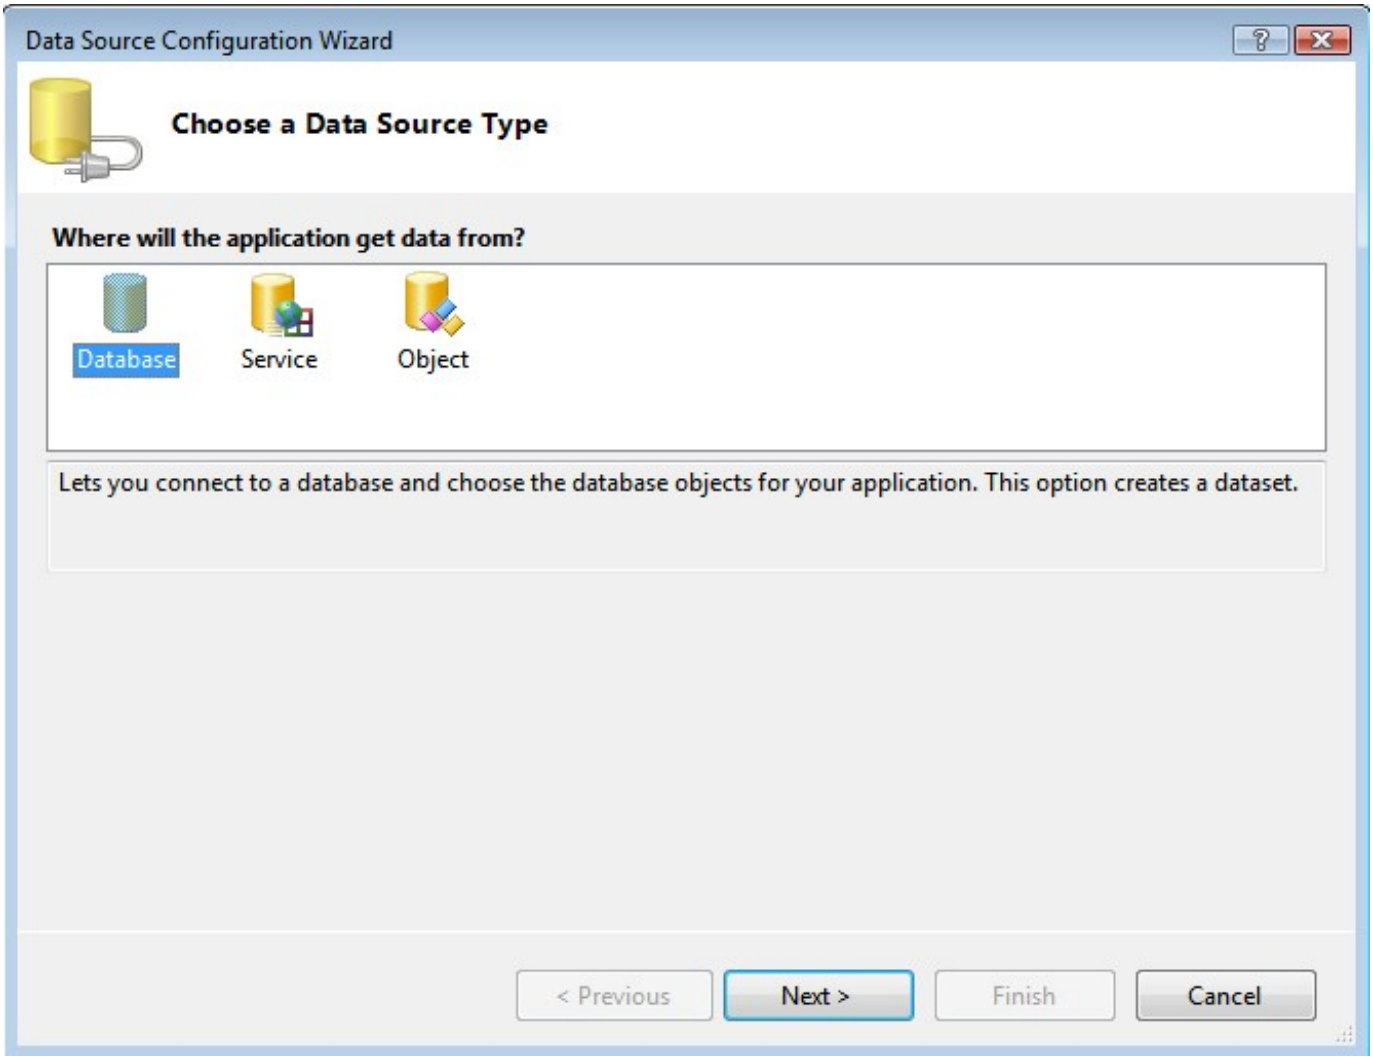
    Database

    data source type and click

    Next

    .

Figure 8.254. Data Source Type



11. In the

    Data Source Configuration Wizard

    dialog

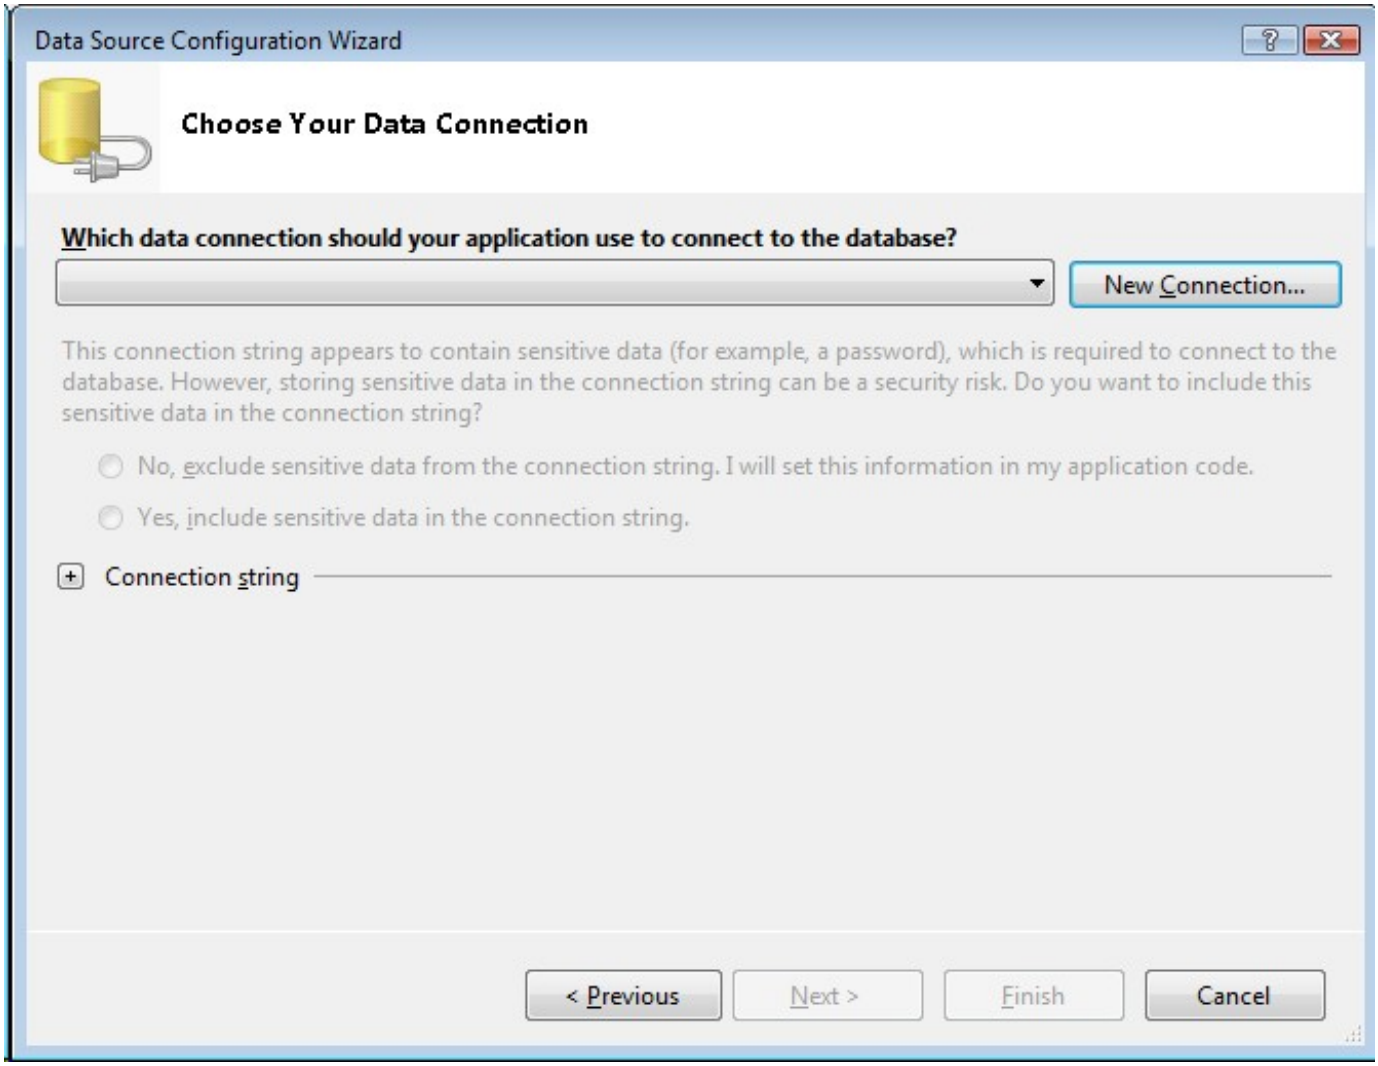
    Choose your Data Connection

    page, select the

    New Connection

    button

Figure 8.255. Data Source Configuration Wizard



12. In the

    Choose Data Source

    dialog, select the OpenLink

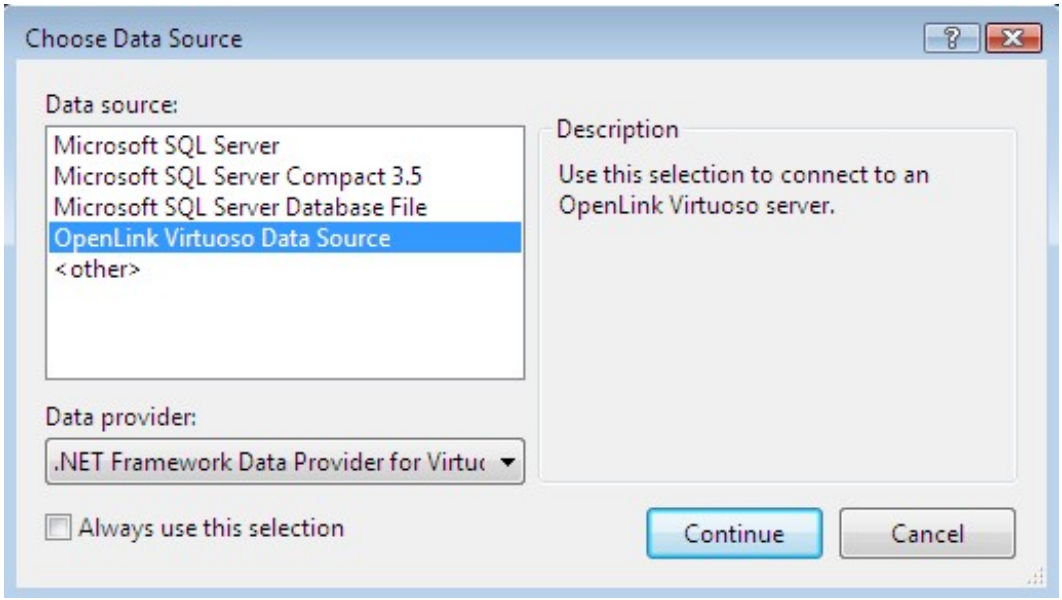
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.256. Data Source



13. In the

    Add Connection

    dialog, specify the

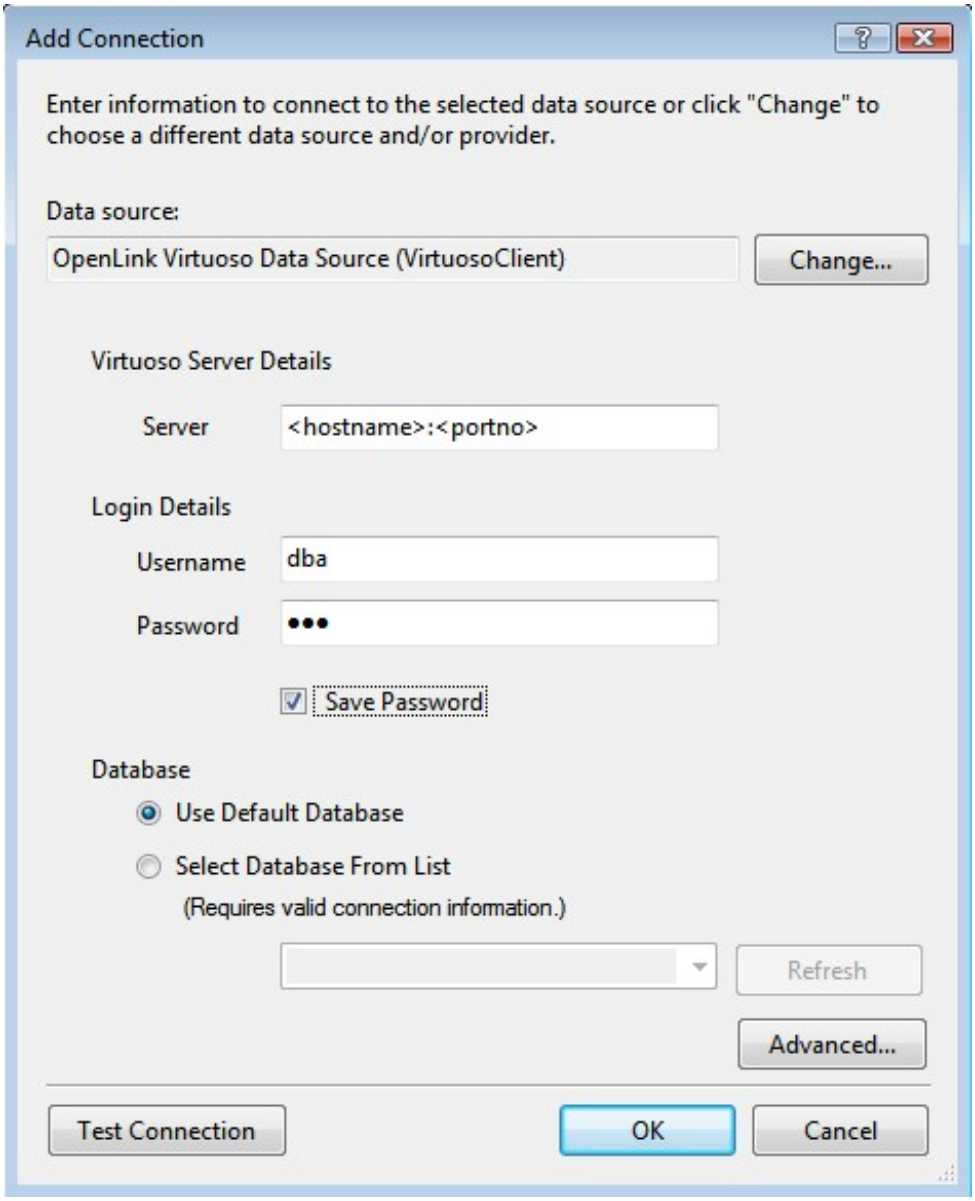
    hostname, portno, username and password

    for the target Virtuoso Server and check the

    Save Password

    check box.

    Figure 8.257. Connection Properties

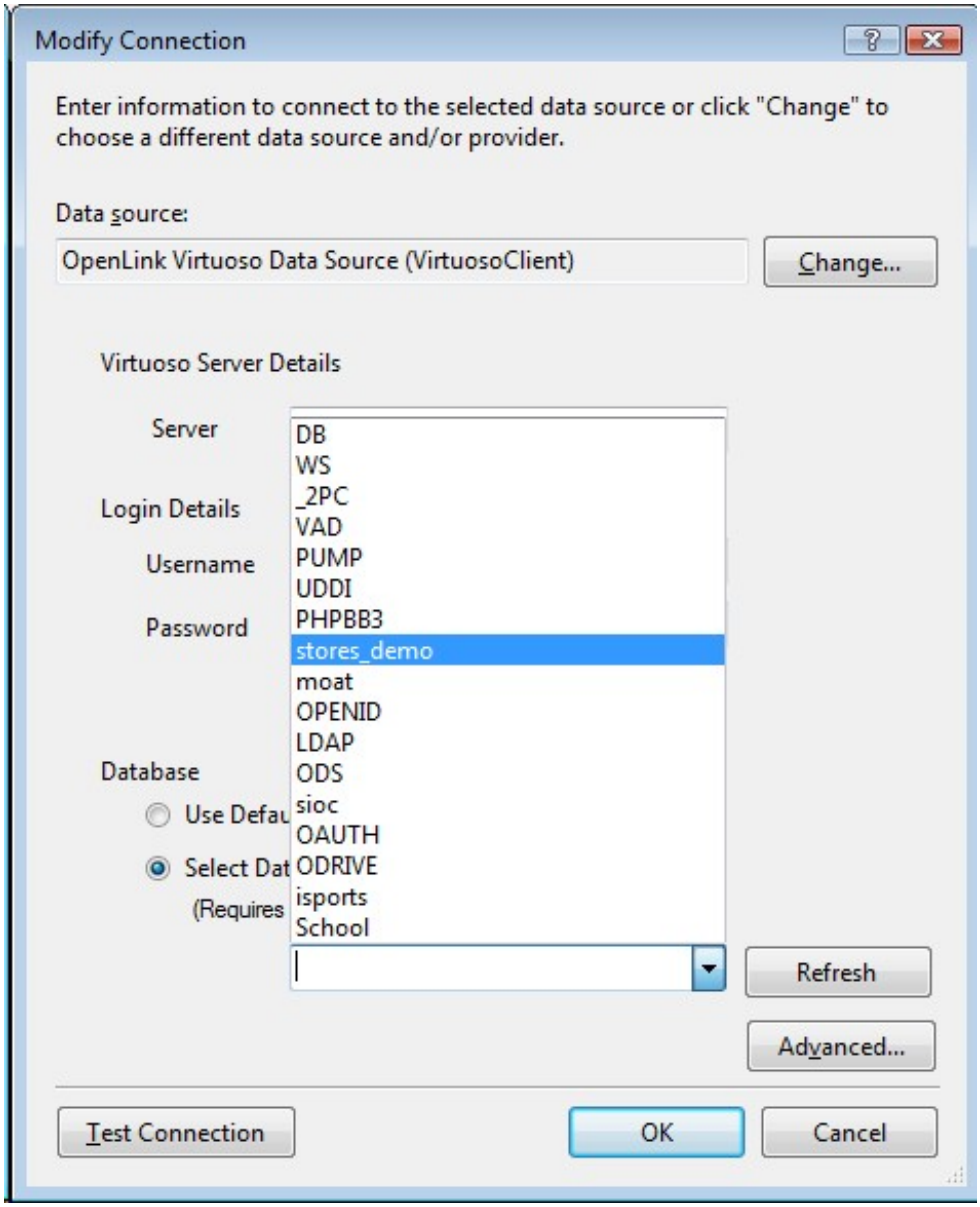


14. Select the Select Database From List radio button and choose the

    stores_demo

    from the drop down list.

Figure 8.258. Add connection

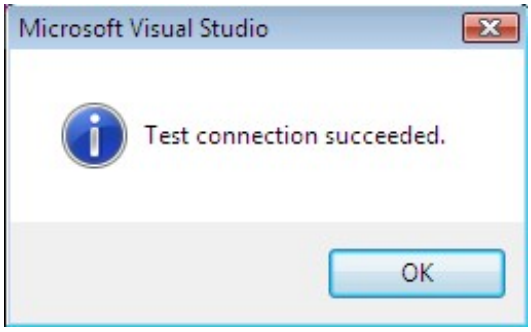


15. Press the

    Test Connection

    dialog to verify that the database is accessible.

    Figure 8.259. Test Connection



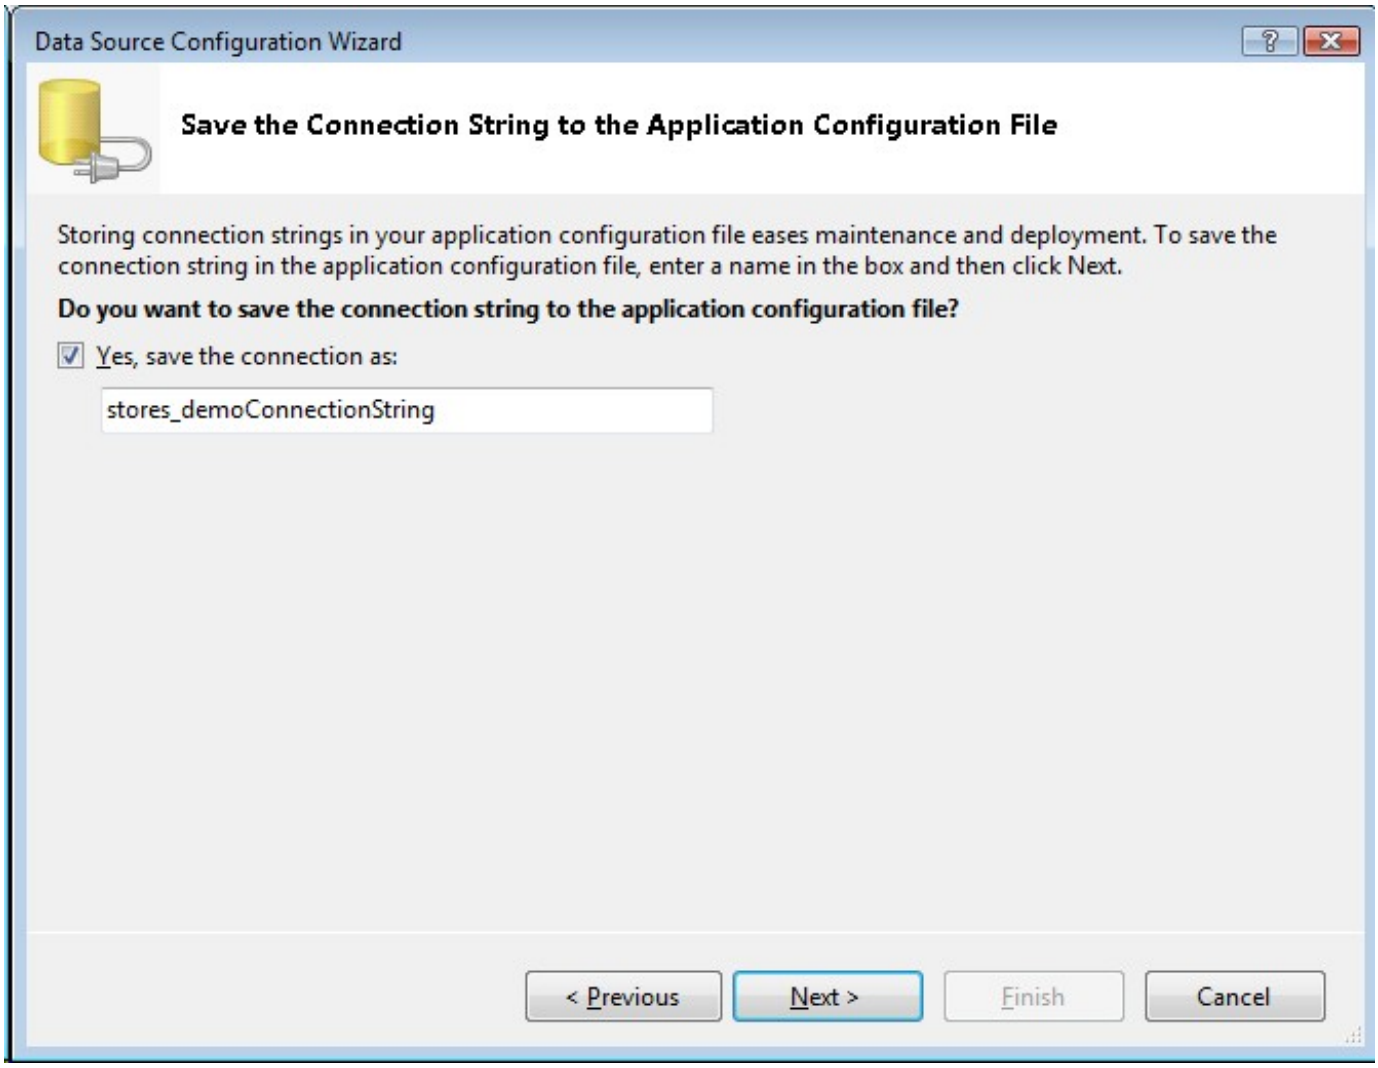
16. Leave the default connect string

    stores_demoConnectionString

and click

Next

Figure 8.260. stores_demoConnectionString



17. From the list of available tables returned for the stores_demo database, select the

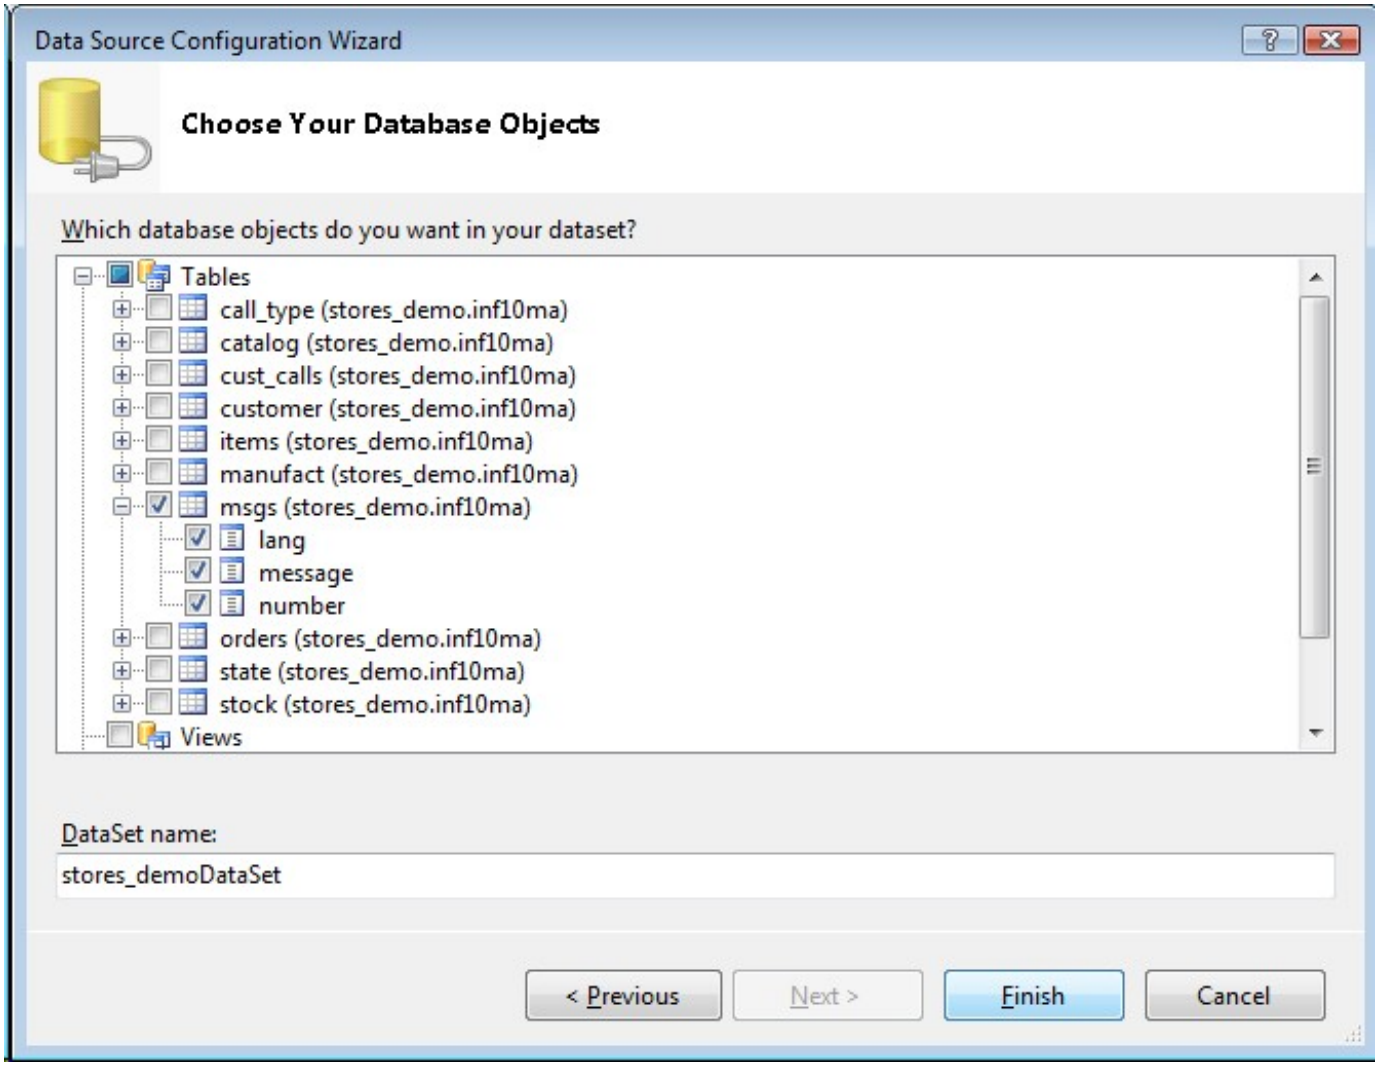
    msgs

    table to be associated with the

    DataGridView

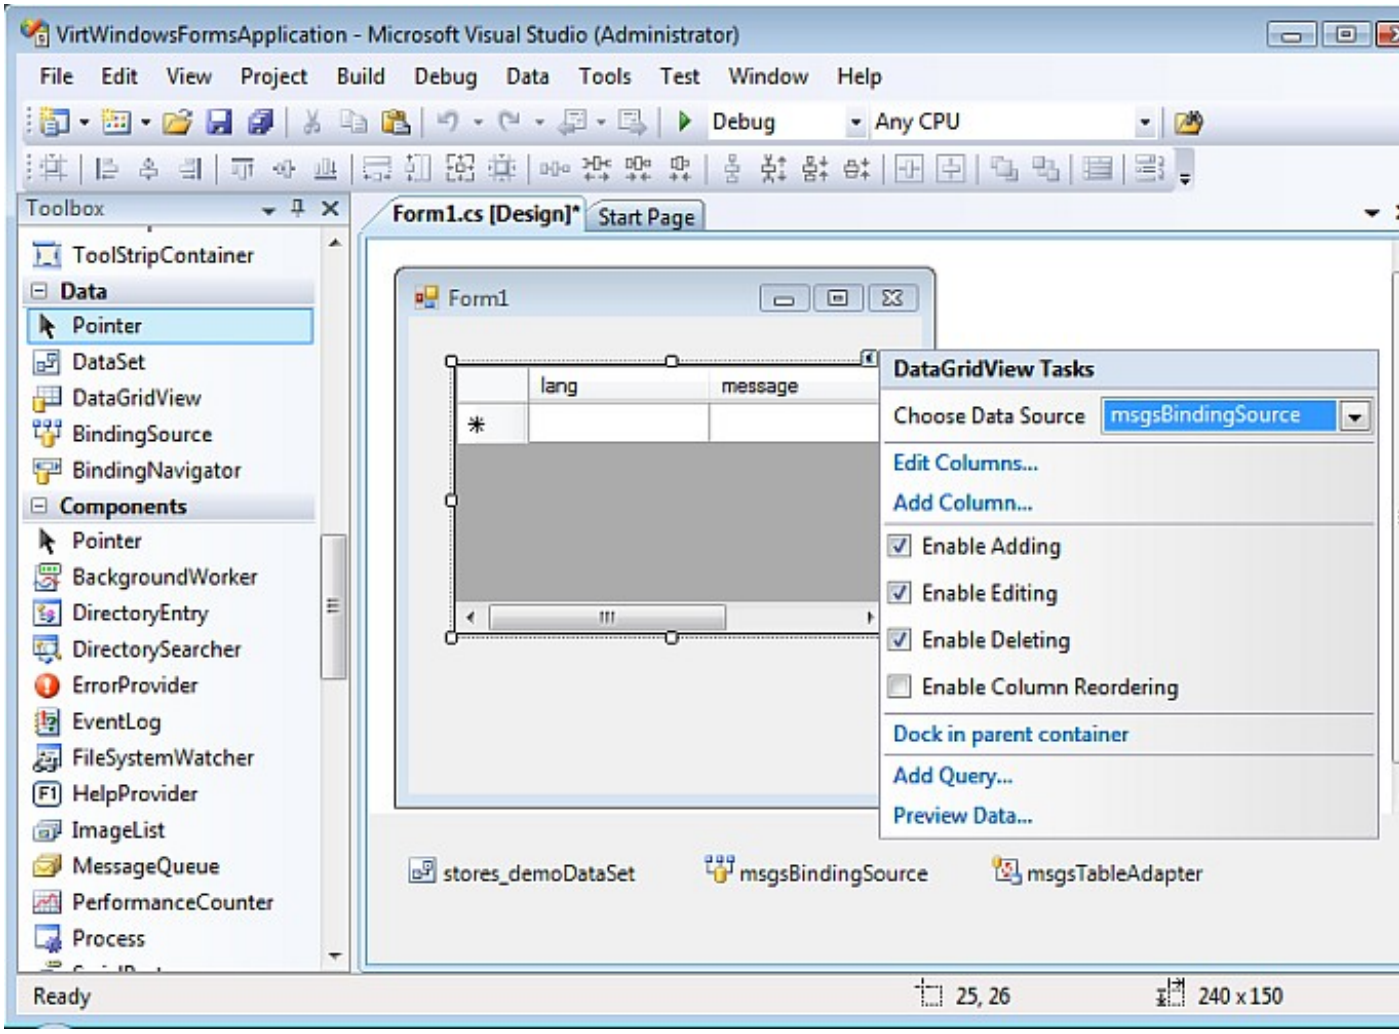
    control.

Figure 8.261. stores_demo database



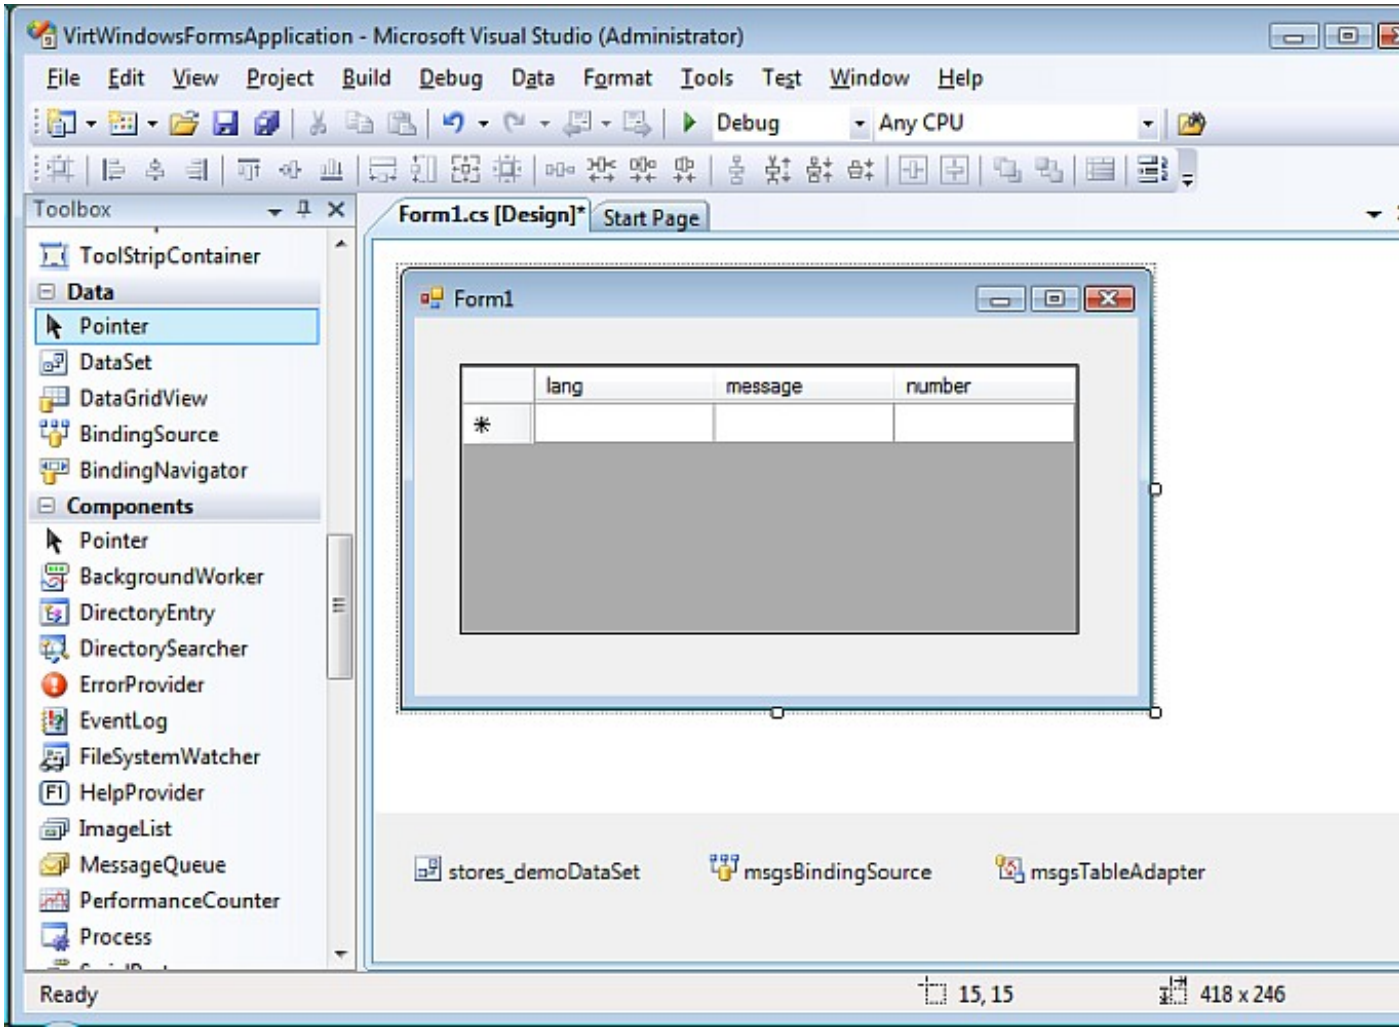
18. The columns names of the select table will be displayed in the DataGridView.

Figure 8.262. DataGridView



19. Resize the Form and DataGridView to allow all columns to be visible, if possible.

Figure 8.263. Resize the Form and DataGridView



20. To test the application, simply hit

    Ctrl+F5

    within Visual Studio or select

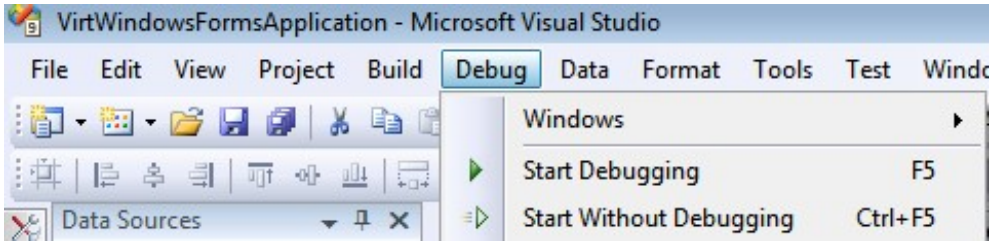
    Start Debugging

    from the

    Debug

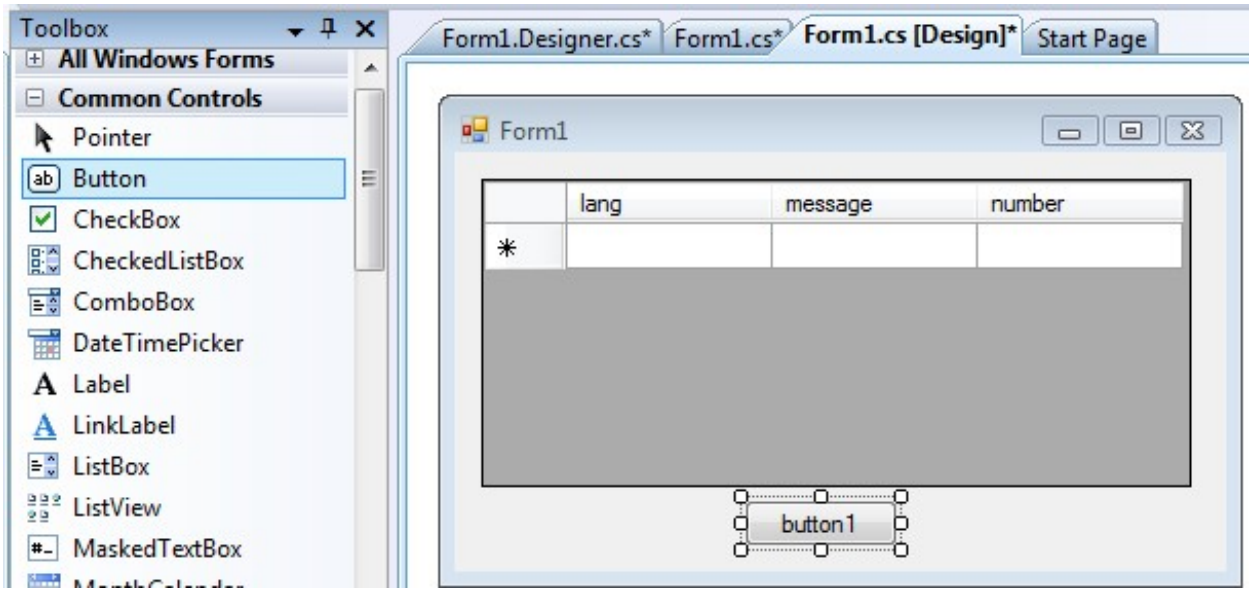
    menu.

Figure 8.264. Start Debugging



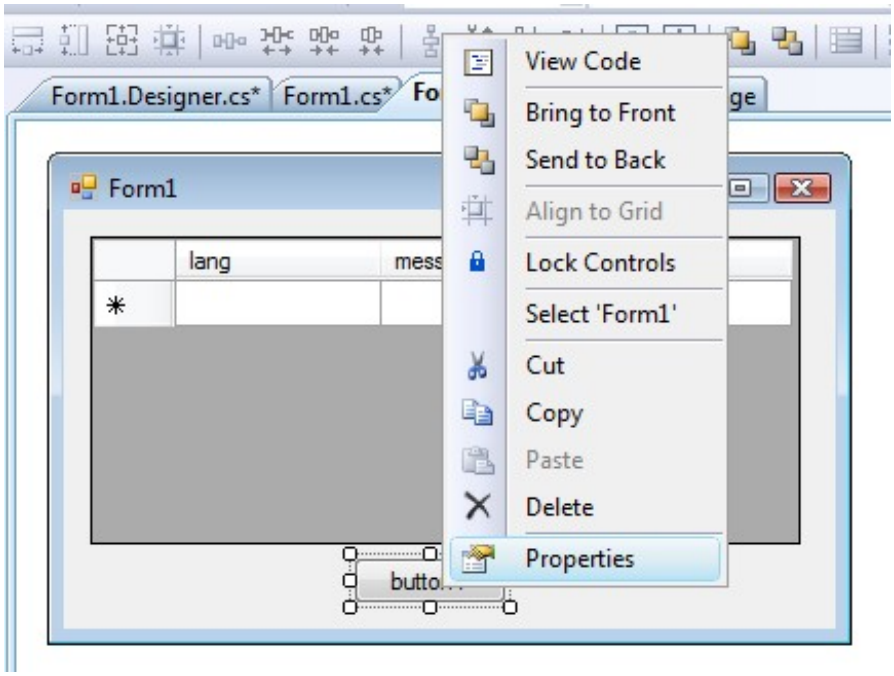
21. To make the DataGridView updateable, you will need to manually add some code to the project along with a suitable control to invoke the code. Drag a Button control onto the form.

Figure 8.265. DataGrid



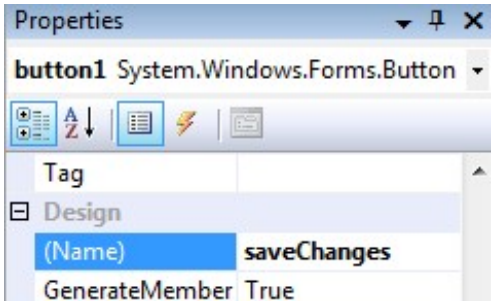
22. Right click on the Button and select Properties.

Figure 8.266. DataGrid



23. In the Properties view, edit the buttons Text property to read Save Changes and its (Name) property to read saveChanges.

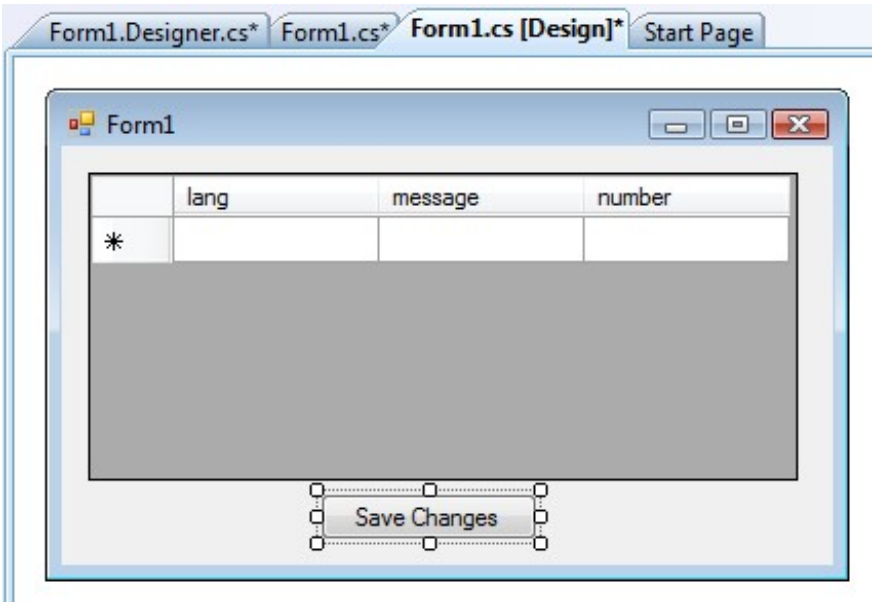
Figure 8.267. DataGrid



24. The button will now update to reflect these changes.

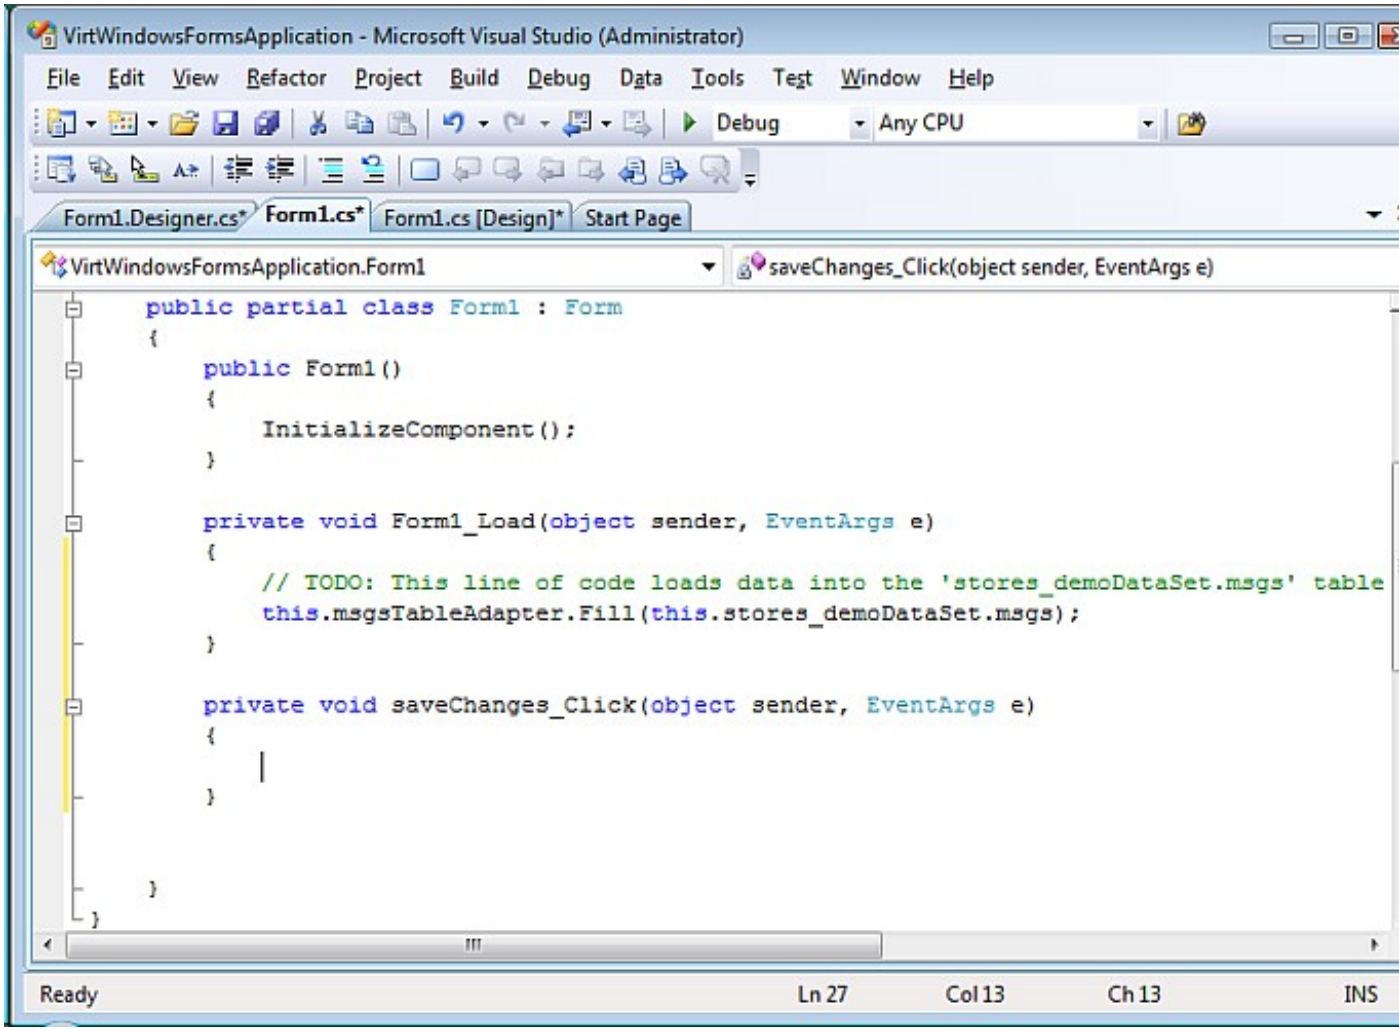
NOTE: You will need to resize the button to make the new text visible.

Figure 8.268. DataGrid



25. Double click the new button to generate the required event handler. It should take you directly to the area of code that will execute when the button is clicked.

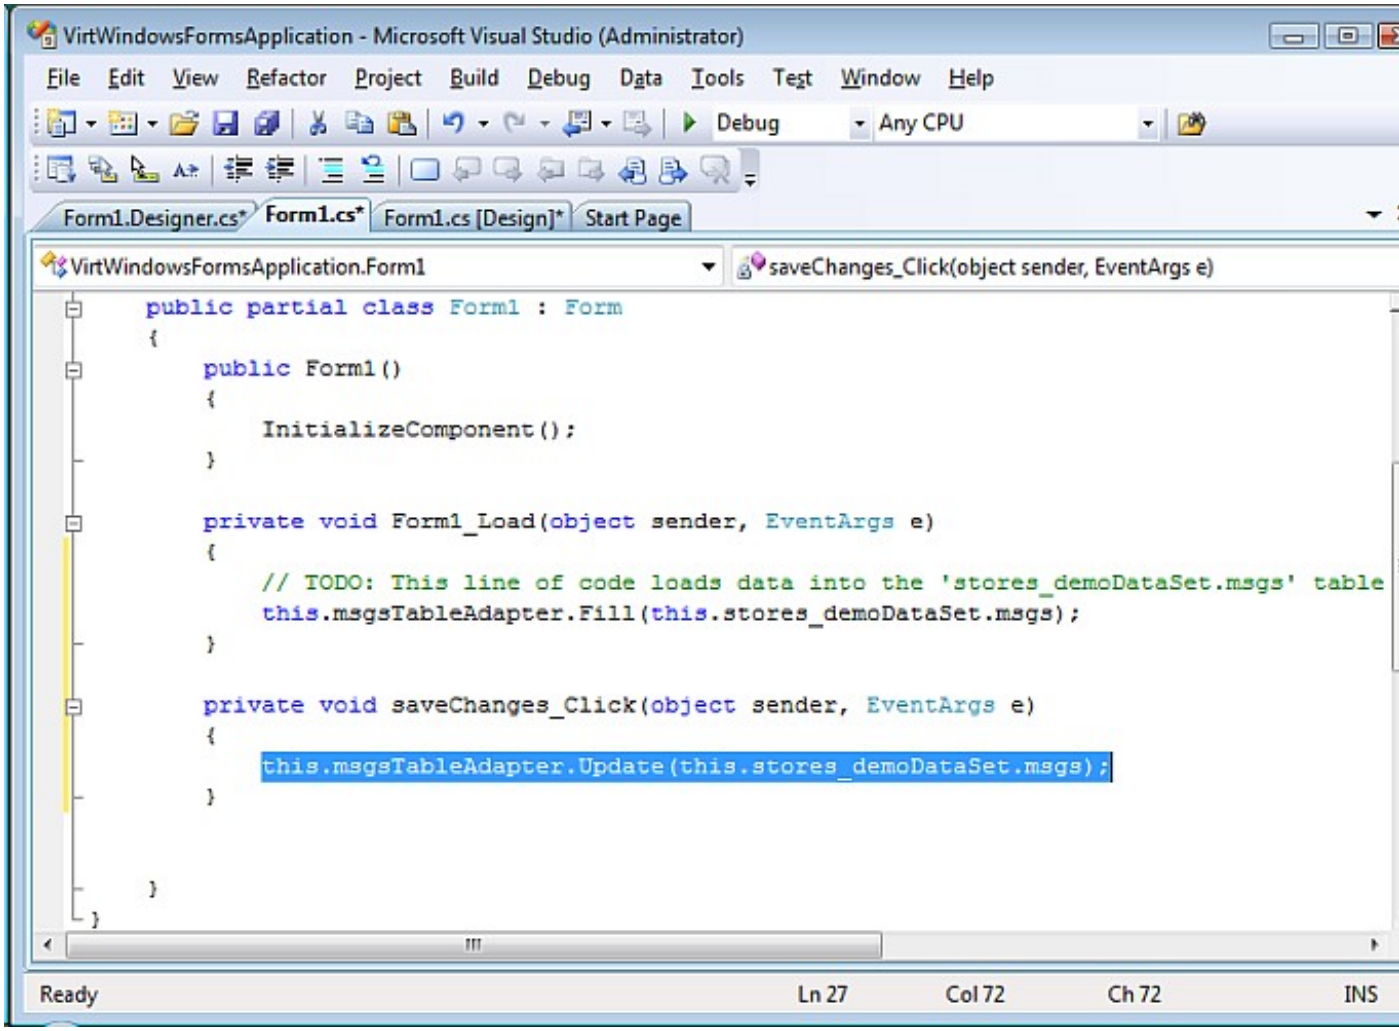
Figure 8.269. DataGrid



26. Edit the saveChanges_Click event handler code to include the following line.

```
private void saveChanges_Click(object sender, EventArgs e)
{
  this.msgsTableAdapter.Update(this.stores_demoDataSet.msgs);
}
```

Figure 8.270. DataGrid

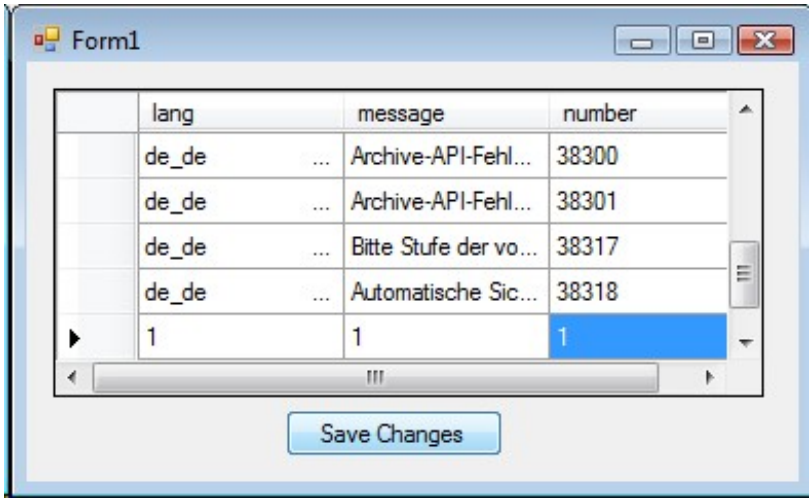


27. Now test the application again by hitting Ctrl+F5.

    Scroll to the empty row, at the bottom, and enter data for a new row. Then, select Save Changes which will write the new row back to the database.

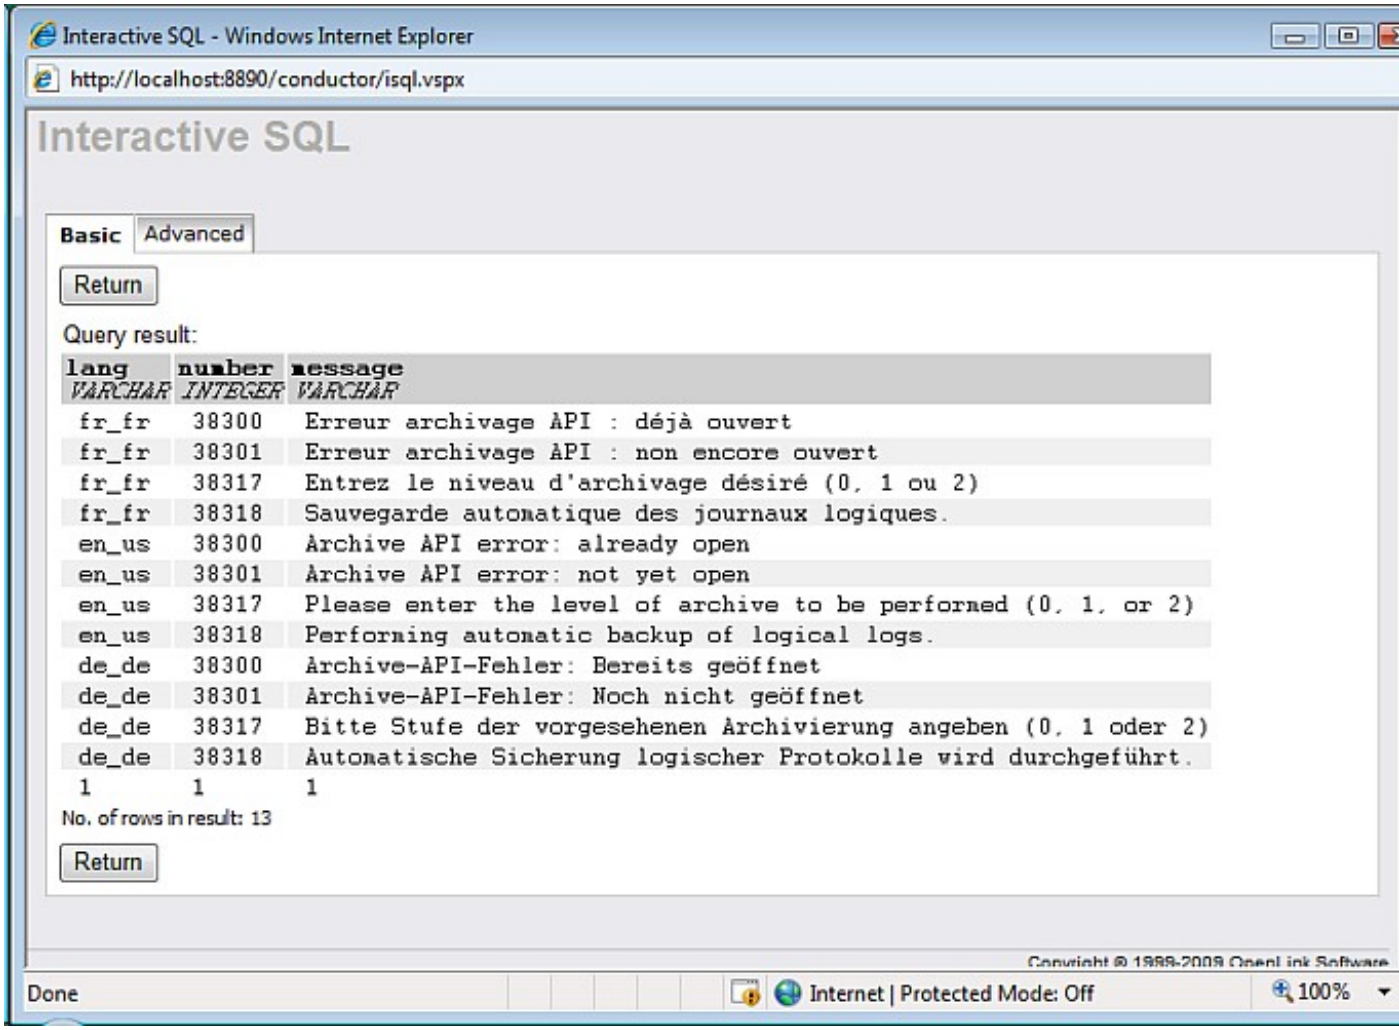
    Updates and deletes can be performed similarly.

Figure 8.271. DataGrid



28. You can use Interactive ISQL to test that the changes that have been written. Interactive ISQL Interface is detailed in the Linking Informix tables section.

Figure 8.272. DataGrid



The task is now complete.

8.6. Using Microsoft Entity Frameworks to Access DB2 Schema Objects with Virtuoso

Abstract

This section details the steps required to provide Microsoft Entity Framework access to DB2 Schema Objects using the OpenLink Virtuoso Universal Server. This is achieved by linking the required DB2 Schema objects into Virtuoso using its built in Virtual Database engine, and then using the Virtuoso ADO.NET Entity Framework provider to query the remote DB2 Schema objects linked into the Virtuoso Server.

Prerequisites. The following prerequisites must be in place for this solution to be possible.

DB2 DBMS. An DB2 DBMS hosting the required Schema Objects needs to be available. In this section the *DB2 sample* database will be used to demonstrate the process.

An DB2 DBMS hosting the required Schema Objects needs to be available. In this section the *DB2 sample* database will be used to demonstrate the process.

ODBC Driver for DB2. An DB2 ODBC Driver is required for Linking the DB2 Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for DB2* will be used in this section, for which a functional ODBC Data source name of "db2v8ma" will be assumed to exist on the machine hosting the Virtuoso Server.

An DB2 ODBC Driver is required for Linking the DB2 Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for DB2* will be used in this section, for which a functional ODBC Data source name of "db2v8ma" will be assumed to exist on the machine hosting the Virtuoso Server.

Virtuoso Universal Server. An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

Microsoft Visual Studio 2008 SP1. Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Tasks

Ensure DB2 Primary Keys (PKs) are not nullable. The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the DB2 database schema before attempting to generate an EDM. In the case of the DB2 sample database all tables are not nullable, thus this should not be an issue in this case.

The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the DB2 database schema before attempting to generate an EDM. In the case of the DB2 sample database all tables are not nullable, thus this should not be an issue in this case.

8.6.1. Install and configure OpenLink ODBC Driver for DB2

The Virtuoso Virtual Database engine uses ODBC as the connectivity mechanism for linking remote database objects into its local schema. Thus an DB2 ODBC Driver must be available with a suitably configured DSN for connecting to the target database. The OpenLink ODBC Drivers for DB2 have been used in this section, although in theory any DB2 ODBC Driver can be used.

Installation instructions for the OpenLink ODBC Driver for DB2 are available from:

- Product Installation & Basic Configuration (ODBC)

8.6.2. Install and configure OpenLink Virtuoso Universal Server

- Install and configure OpenLink Virtuoso Universal Server

8.6.3. Linking DB2 tables into OpenLink Virtuoso

1. Start the Virtuoso Web User Interface

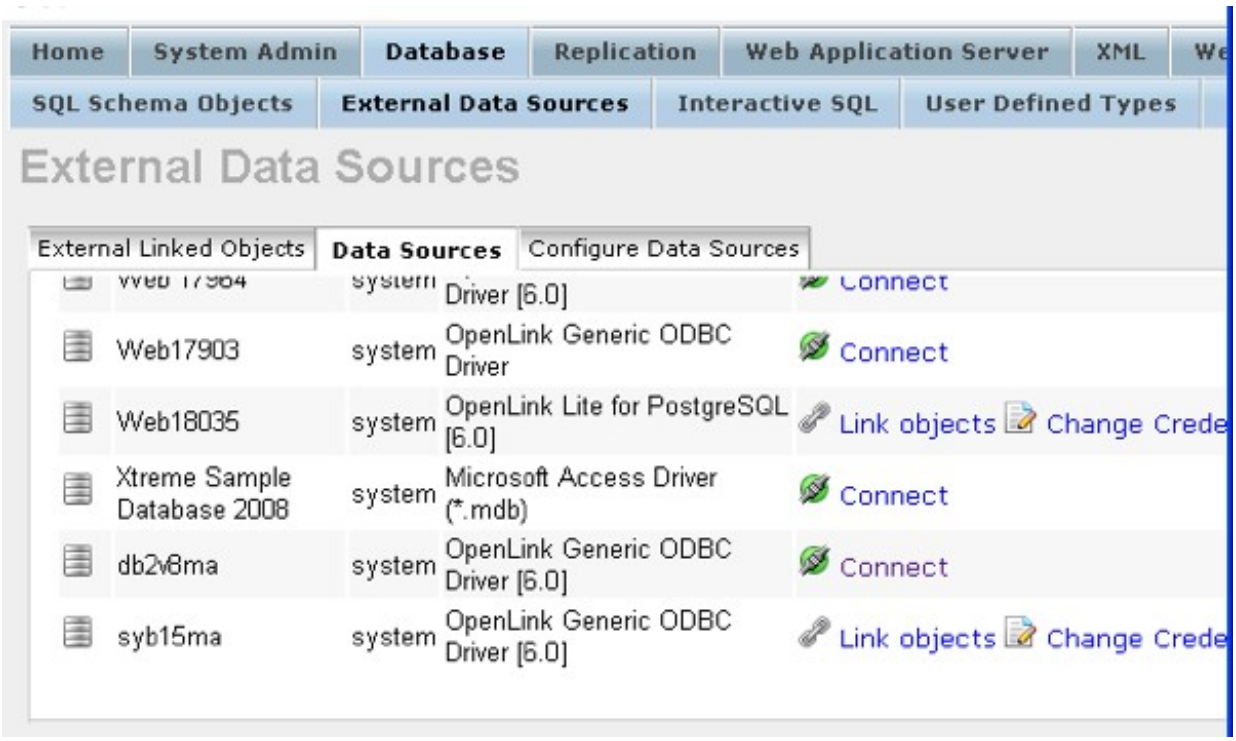
Figure 8.273. Start

2. Select the "Conductor" link in the Left Frame and Login as the "dba" user.

Figure 8.274. Conductor

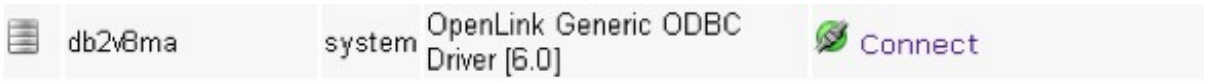
3. Select the "Databases" -> "External Data Source" -> "Data Sources" tab menu items

Figure 8.275. Databases



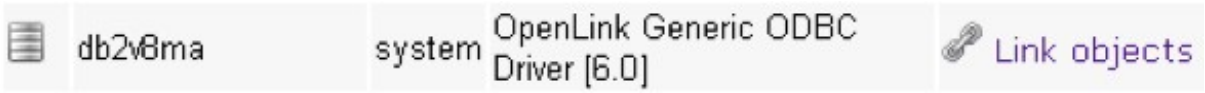
4. Select the "Connect" button for the "db2v8ma" DB2 DSN.

Figure 8.276. Connect



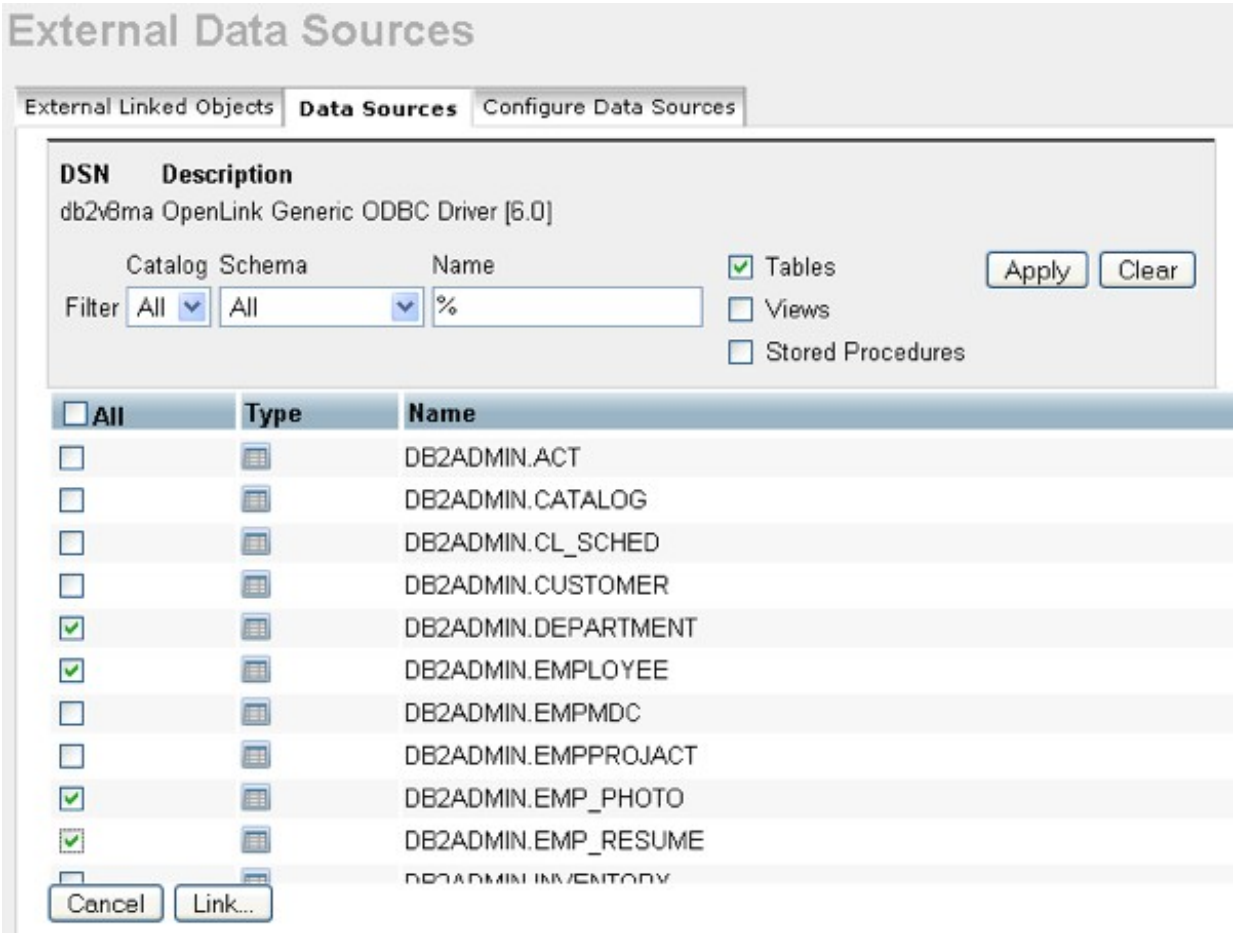
5. On successful connection Select the "Link Objects" button to obtain a list of available tables

Figure 8.277. Link Objects



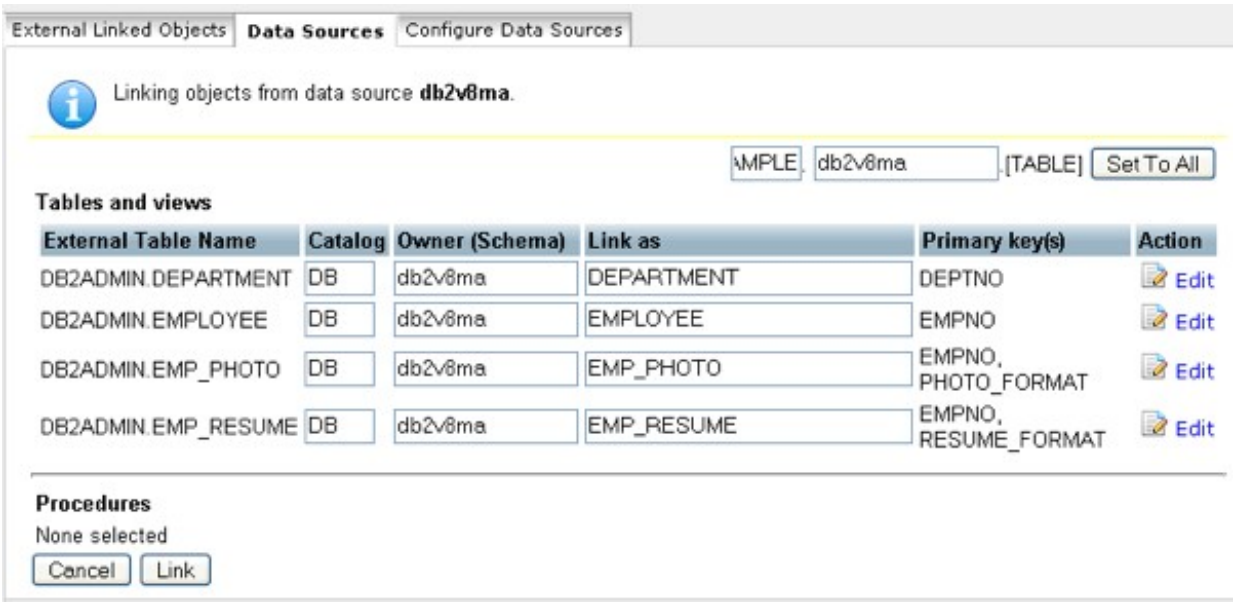
6. Select the tables that you would like to link.

Figure 8.278. Select tables



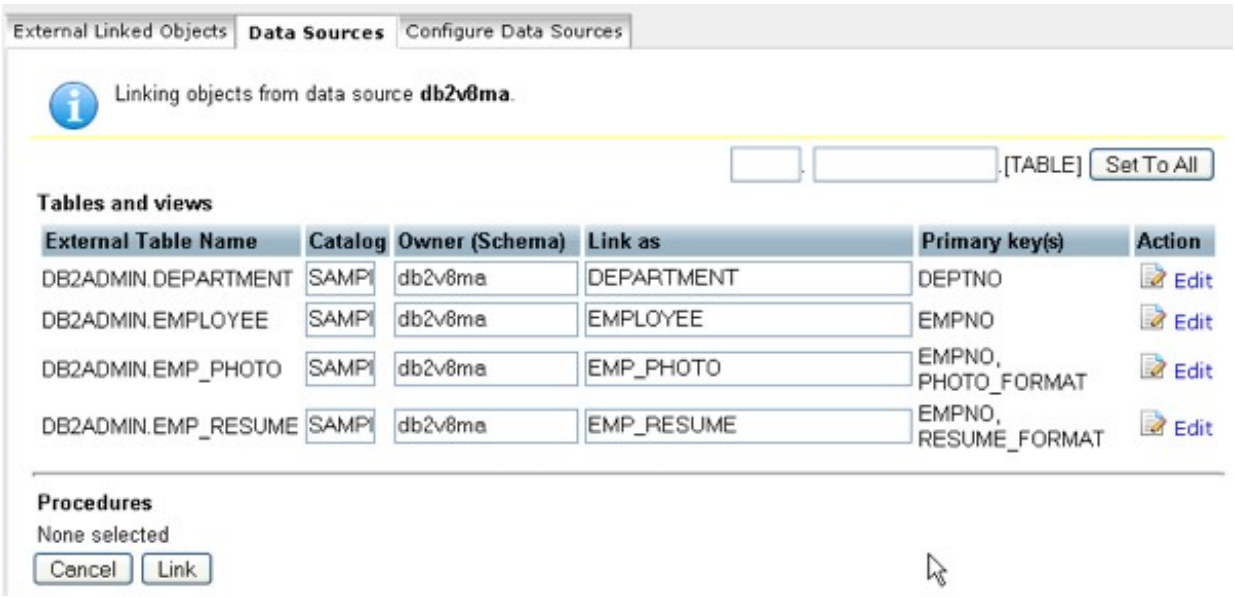
7. Change the Catalog for each table to be "SAMPLE" using the "Set All" button.

Figure 8.279. Catalog



8. All the catalog names are changed to be "SAMPLE".

Figure 8.280. catalog names

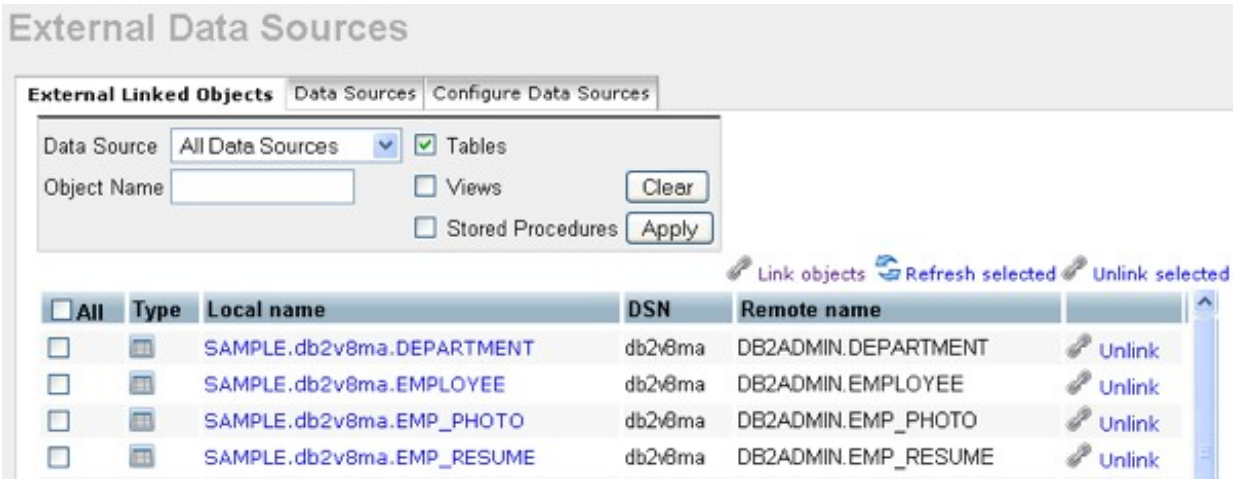


9. Select the "Link" button to link the selected tables into Virtuoso

Figure 8.281. "Link" button

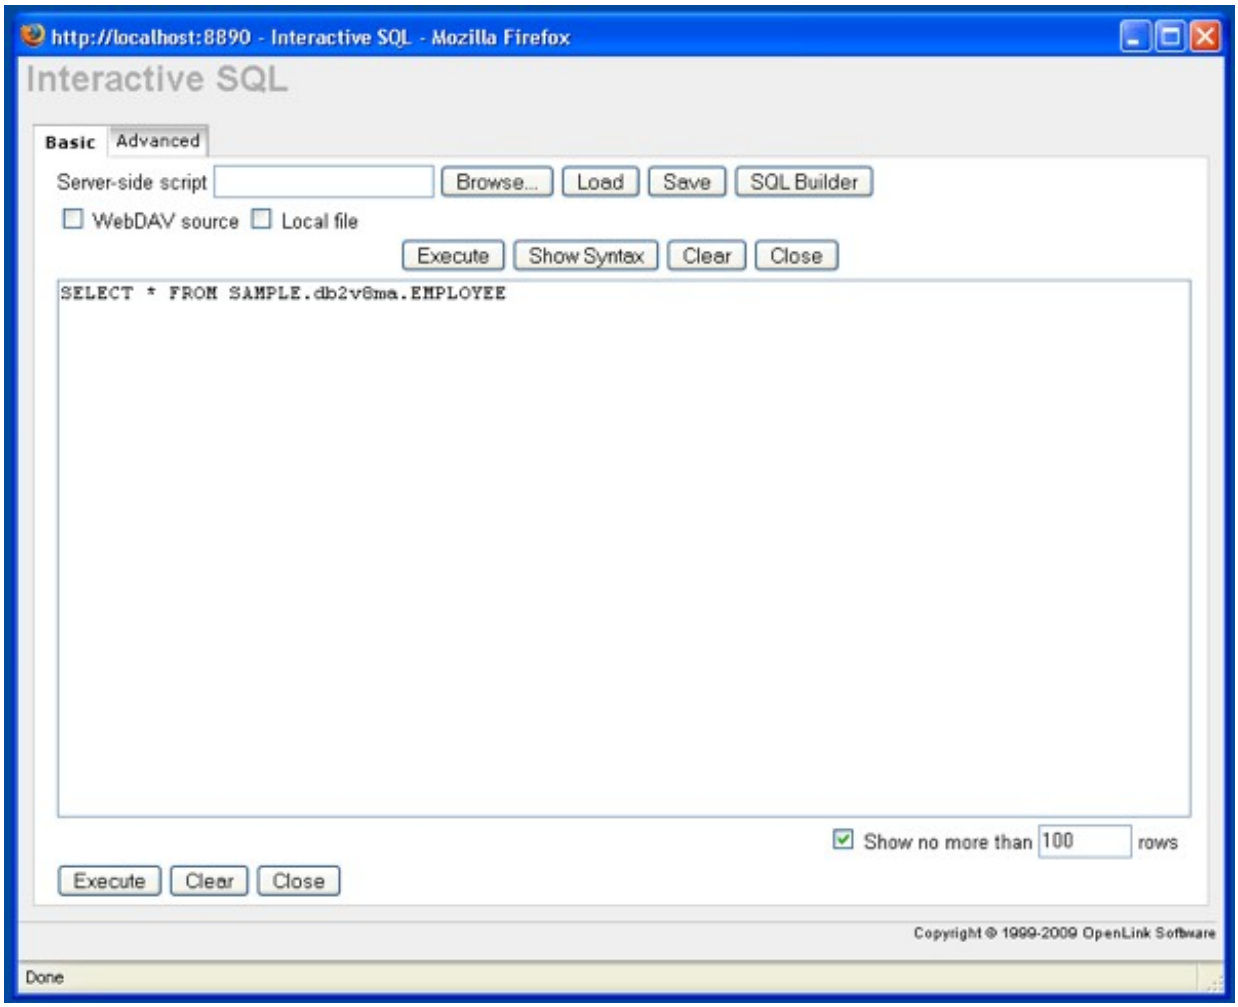
10. On completion of the Link process the tables will be displayed in the "External Linked Objects" tab.

Figure 8.282. Completion



11. The linked tables can be queried by clicking on the hyperlink in the Local Name column of the External Linked Objects tab above. This loads the Virtuoso Interactive SQL interface with the required SQL Select for retrieving the remote table data . We shall use the SAMPLE.db2v8ma.EMPLOYEE table to demonstrate this.

Figure 8.283. view tables



12. Click the Execute button to run the query and retrieve the results from the remote table.

Figure 8.284. Execute

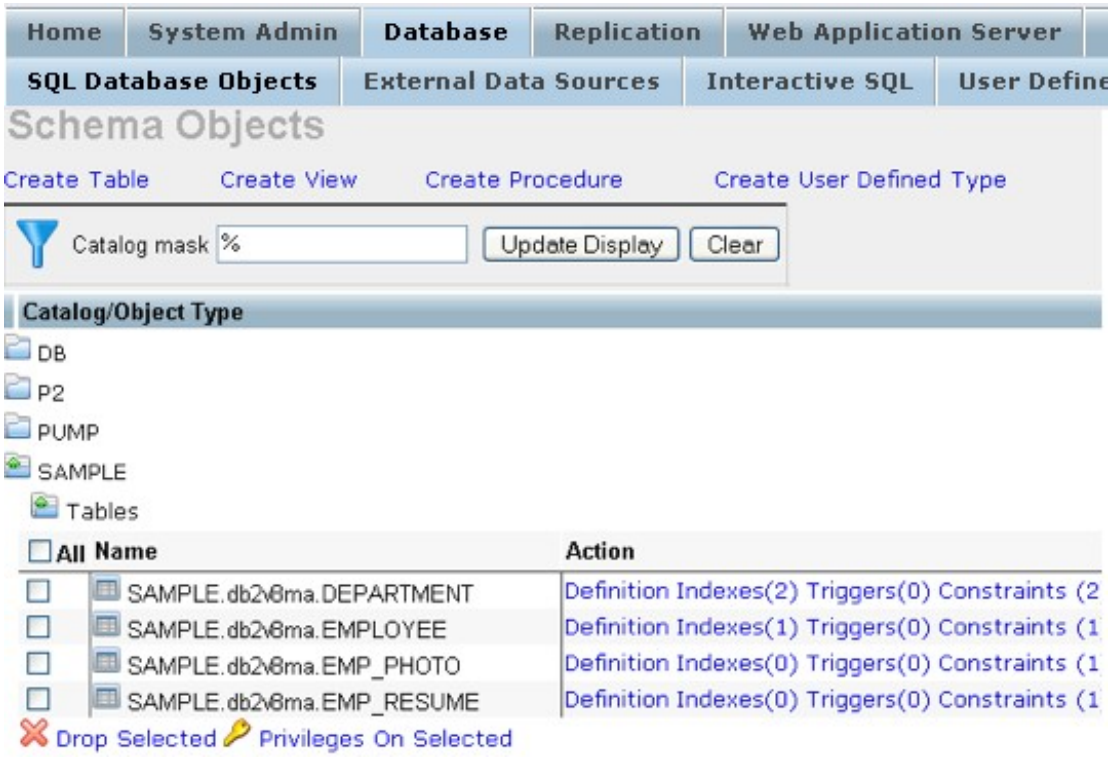
13. The tables can also be viewed as part of the Virtuoso SQL Schema Objects under the SAMPLE catalog name.

Figure 8.285. SQL Schema Objects



The Link process is now complete enabling the tables to be queried as if part of the Virtuoso Schema.

8.6.4. Creating EDM in Visual Studio 2008

The following steps can be used to create an Entity Data Model (EDM) for the DB2 Samples database:

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.286. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

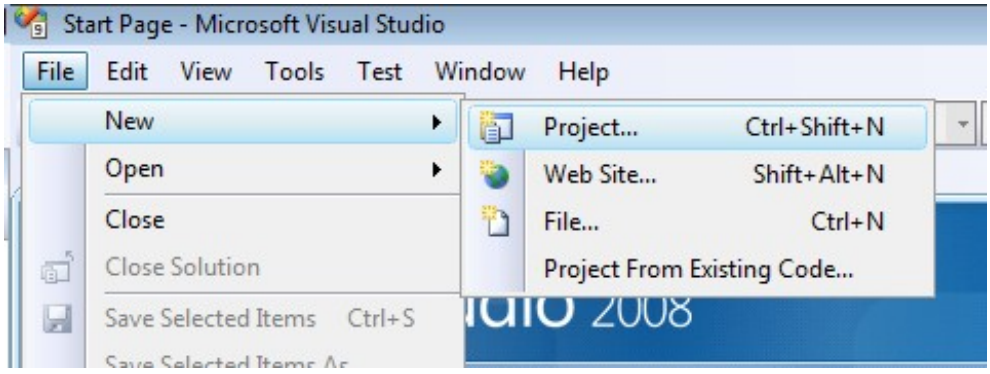
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.287. Web Application

3. When the New Project window appears, choose either

   Visual Basic

   or

Visual C#

as your programming language.

4. Within the language category, click on

   Web

   and select

   ASP.NET Web Application

   from the right-hand panel.
5. Choose a name for the project, for example

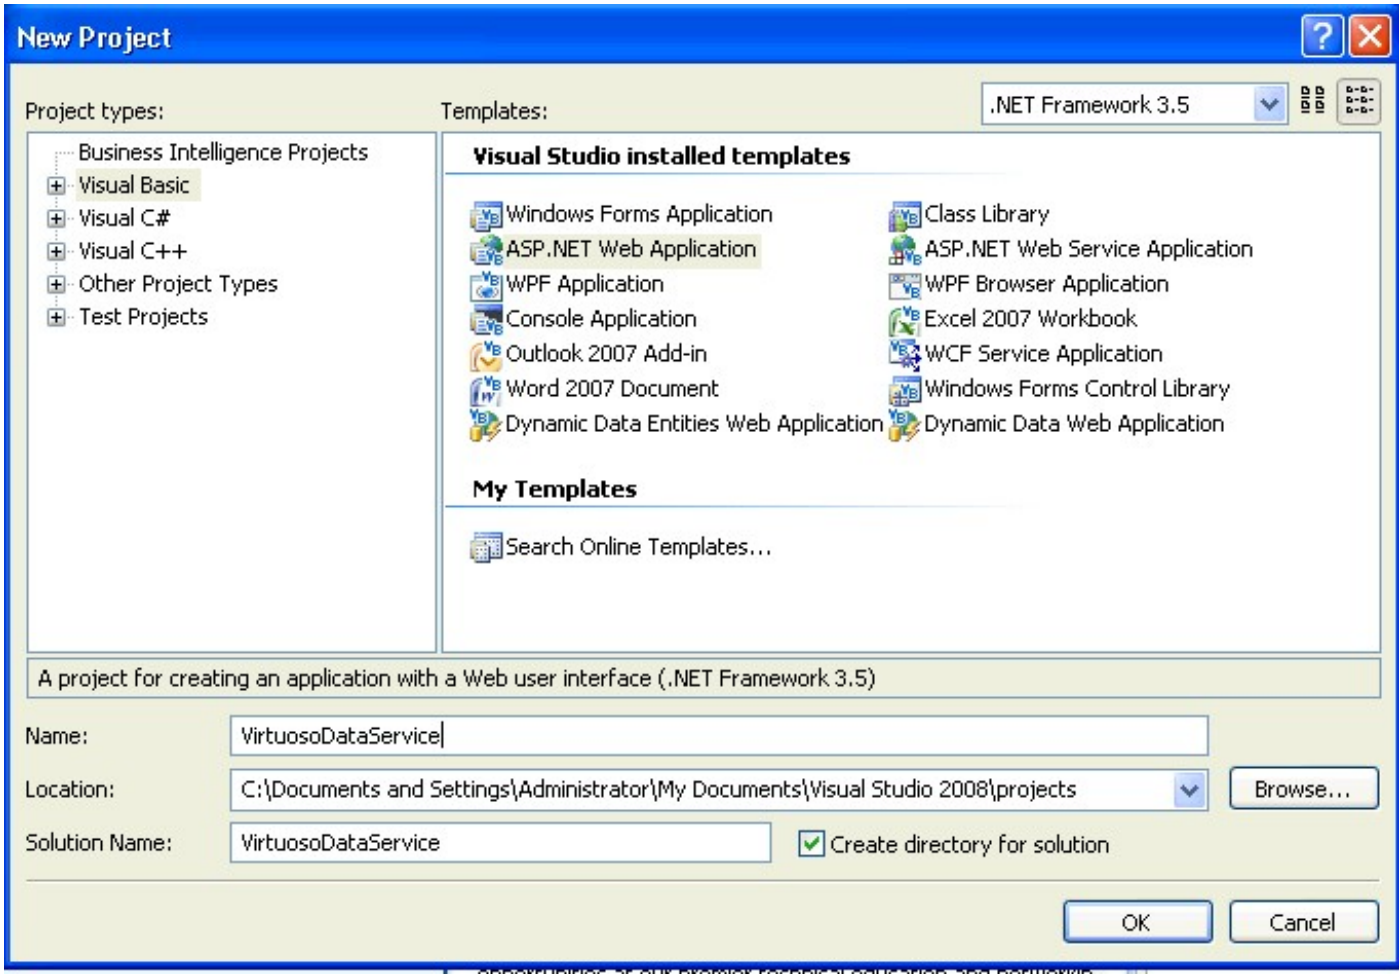
   VirtuosoDataService

   , and click

   OK

   .

   Figure 8.288. name for the project

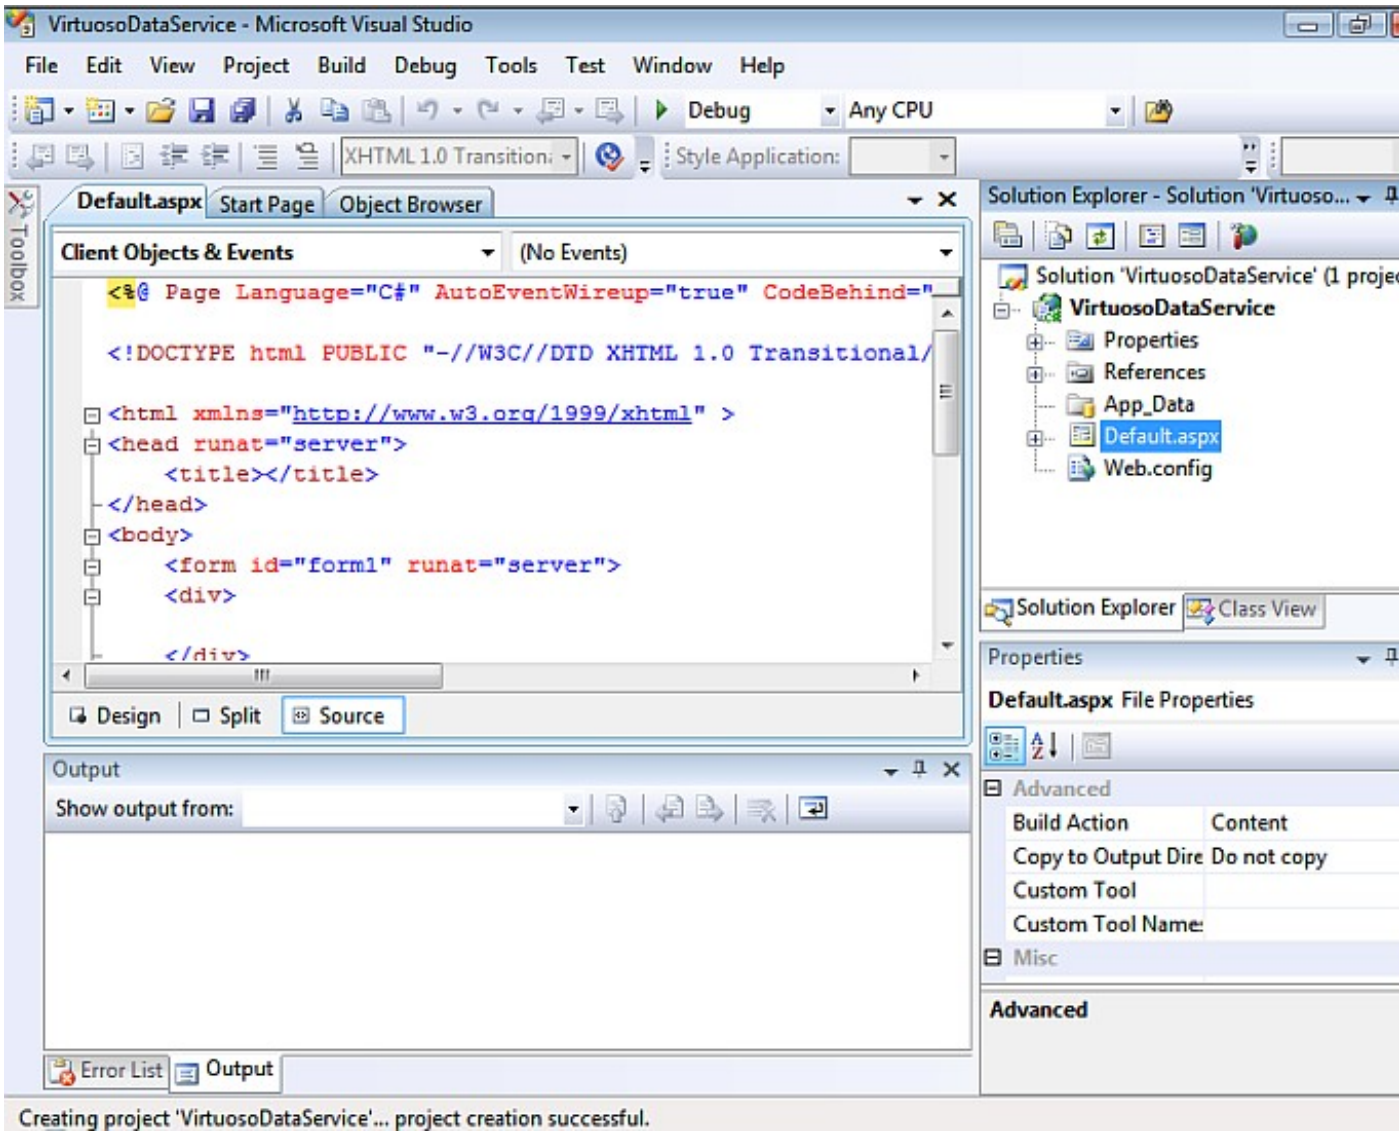


6. This will create a new project called

   VirtuosoDataService

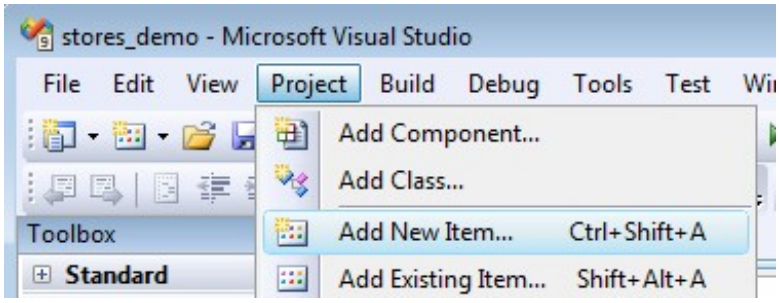
   .

Figure 8.289. create a new project



7. Select the Project -> Add New Item menu option.

Figure 8.290. VirtuosoDataService



8. The

Add New Item

dialog will appear. Choose the

ADO.NET Entity Data Model

template. Give it the name

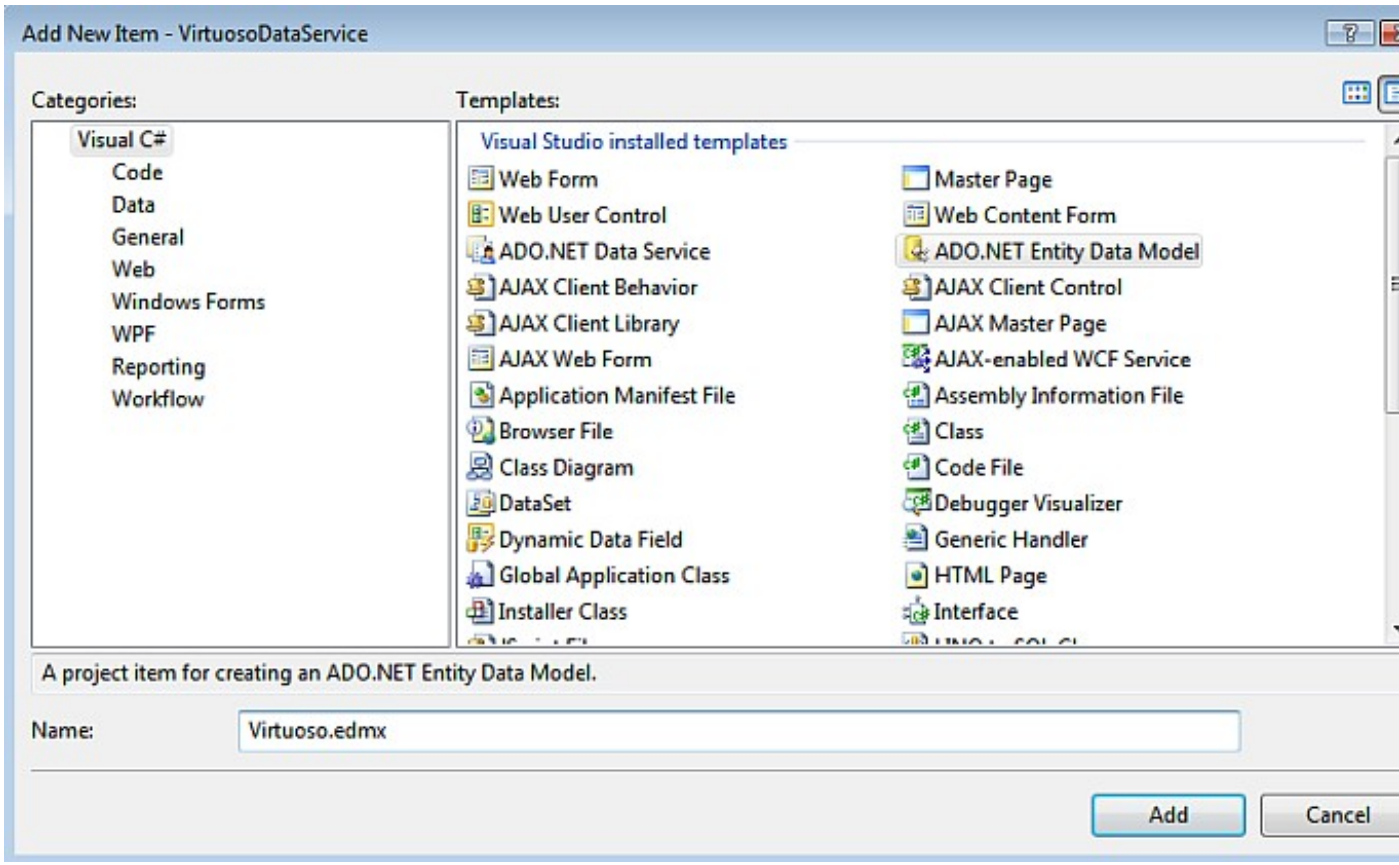
Virtuoso.edmx

and click

Add

to start the creation of the ADO.Net Entity Data Model.

Figure 8.291. Add New Item



9. In the

Entity Data Model Wizard

dialog

Choose Model Contents

page select the

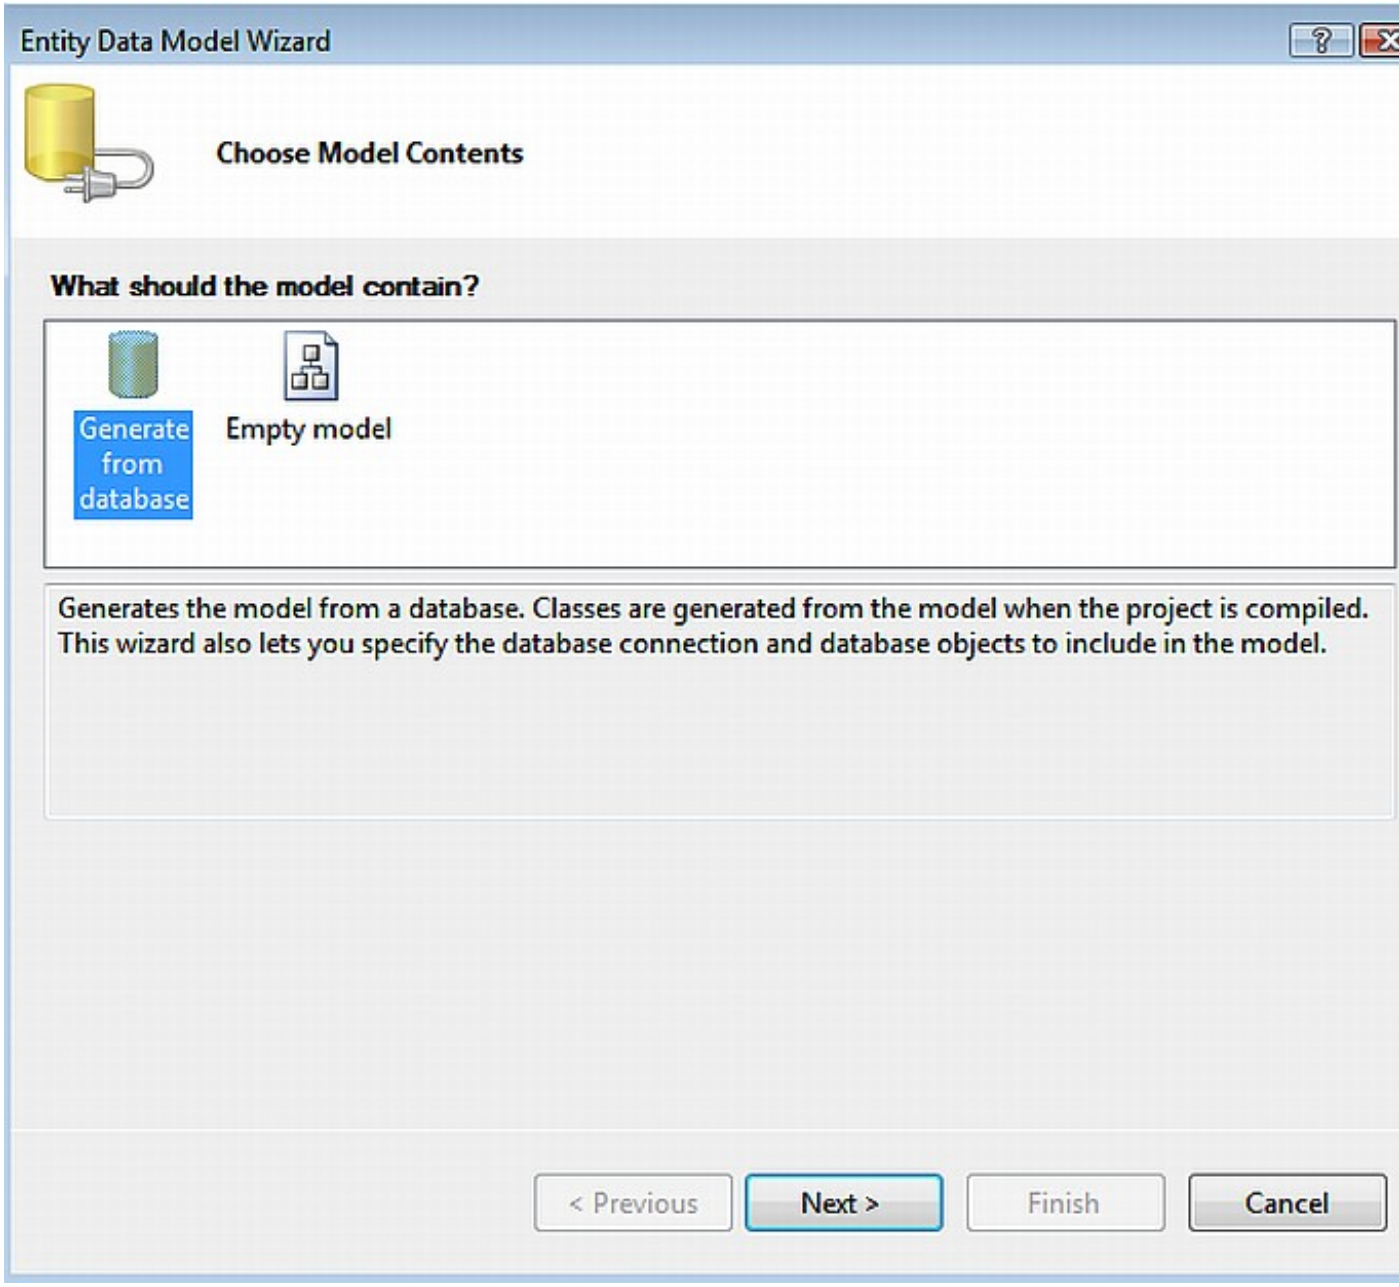
Generate from Database

model type and click

Next

.

Figure 8.292. Choose Model Contents



10. In the

    Entity Data Model Wizard

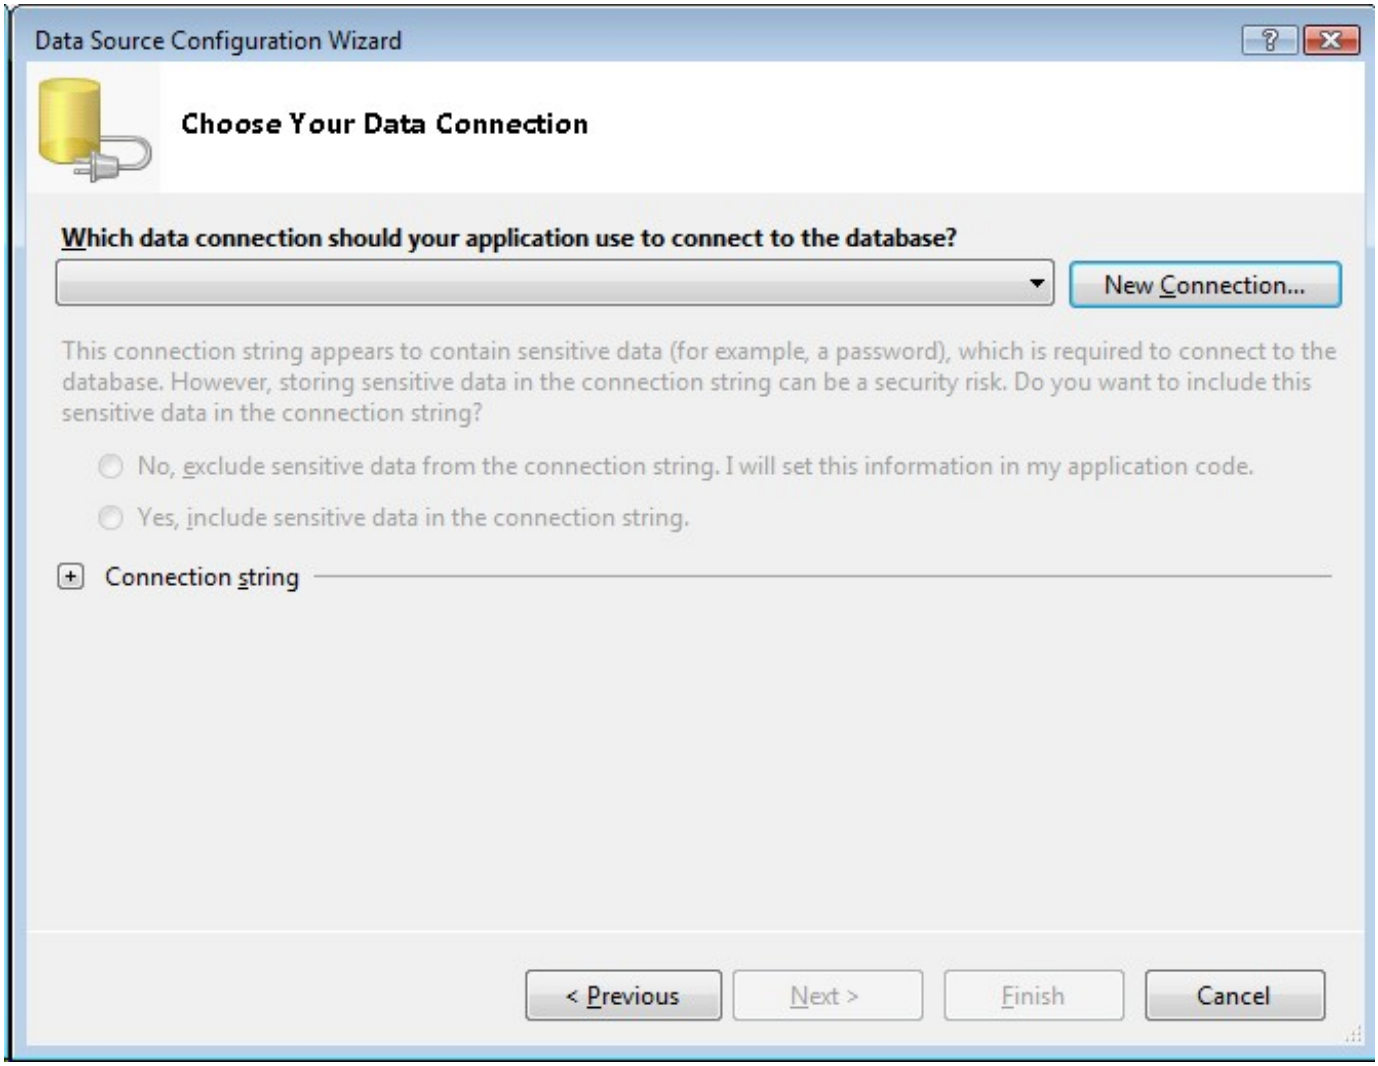
    dialog

    Choose your Data Connection

    page, select the

    New Connection button

Figure 8.293. Entity Data Model Wizard



11. In the

    Choose Data Source

    dialog, select the OpenLink

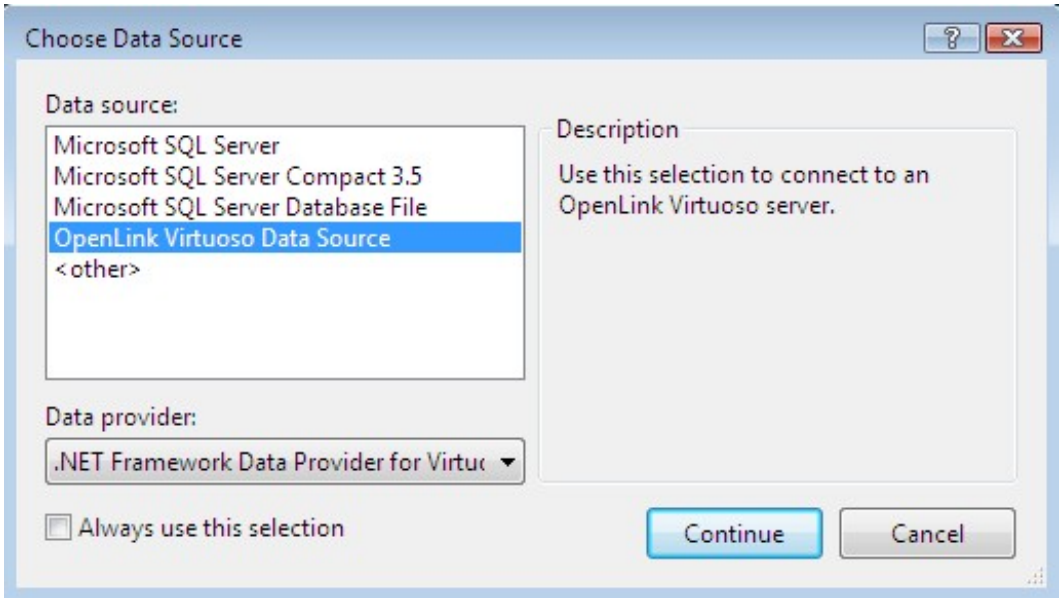
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.294. Choose Data Source



12. In the

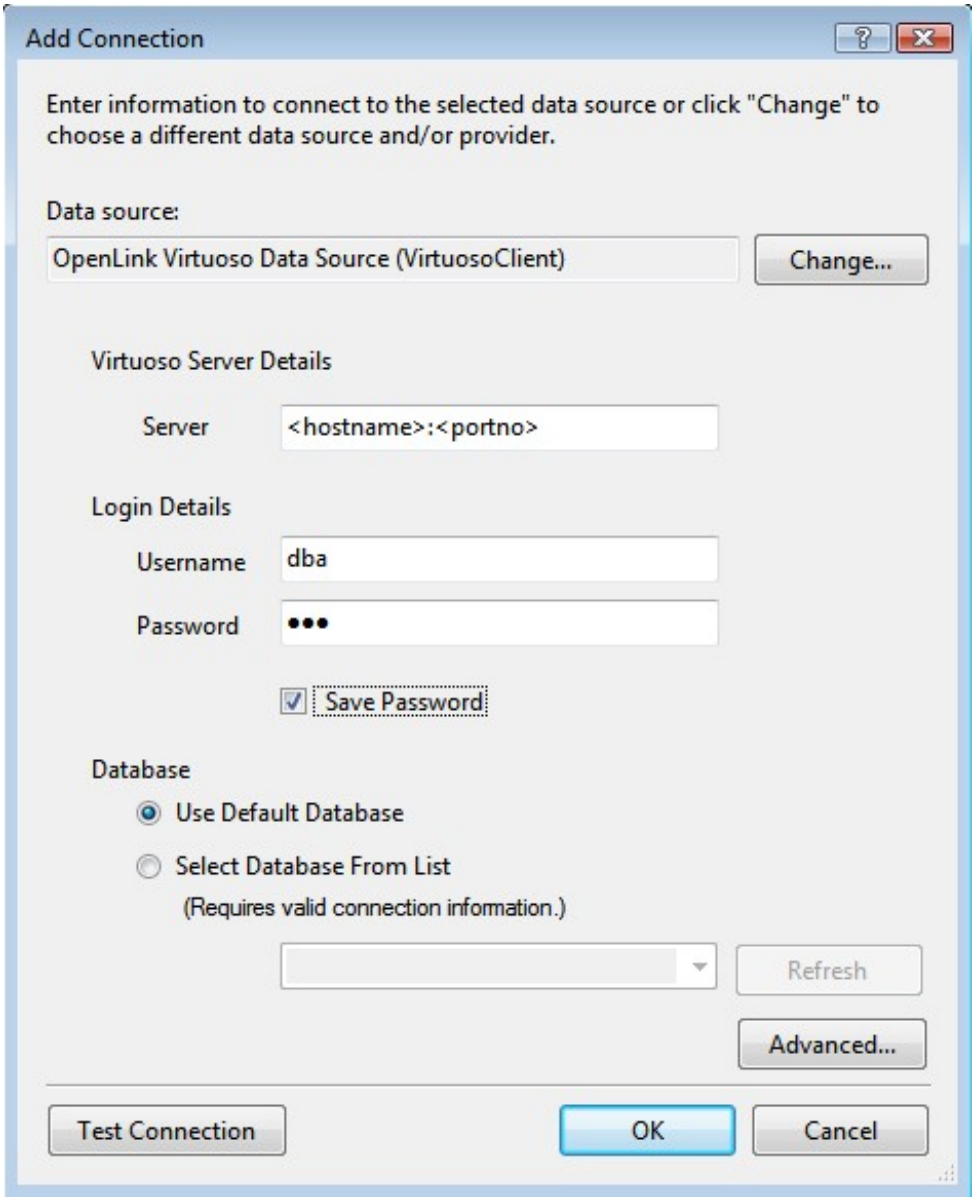
    Add Connection

    dialog, specify the

    hostname, portno, username and password

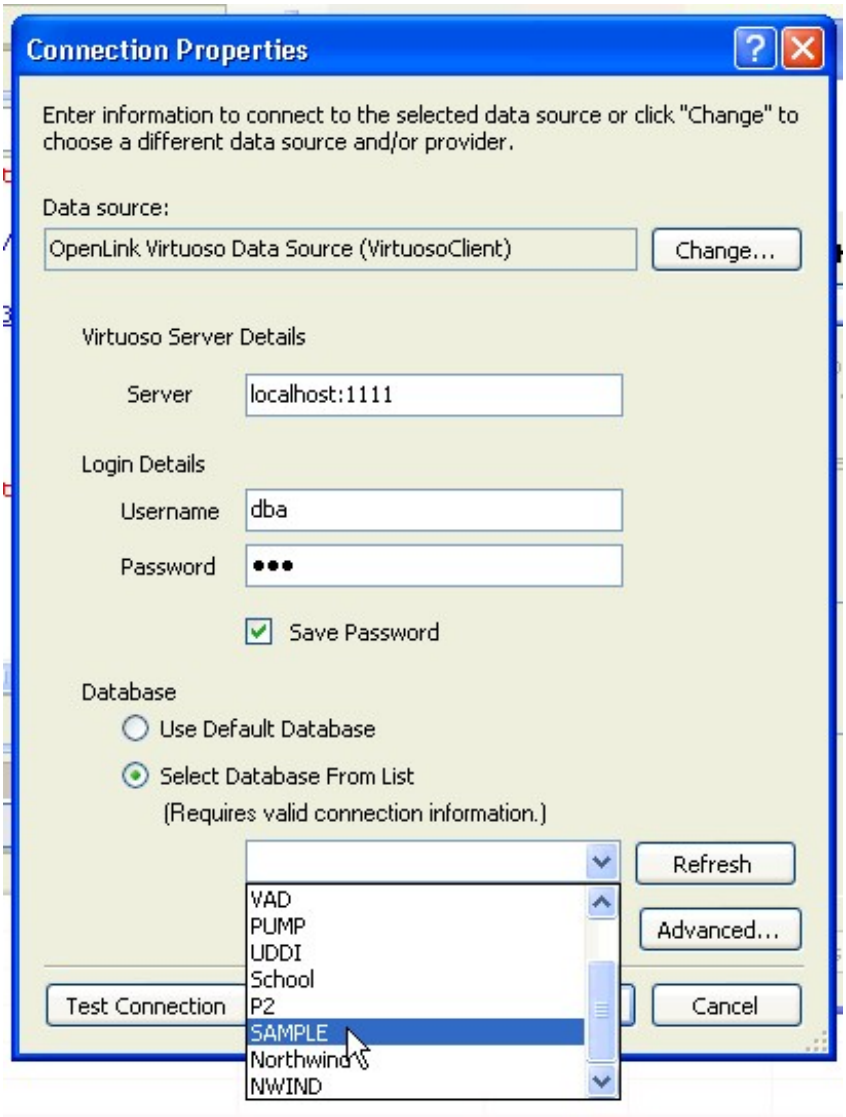
    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.295. Connection Properties



13. Select the Select Database From List radio button and choose SAMPLE from the drop down list. Click OK.

Figure 8.296. Add connection

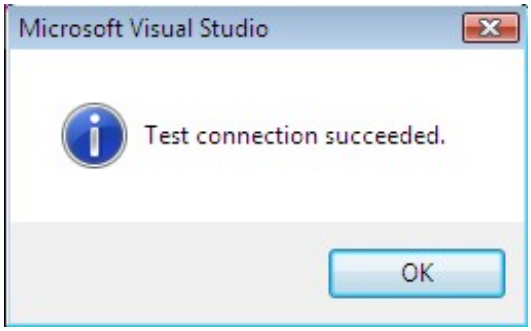


14. Press the

    Test Connection

    dialog to verify that the database is accessible.

    Figure 8.297. Test Connection



15. Set the

    entity connect string

    name to

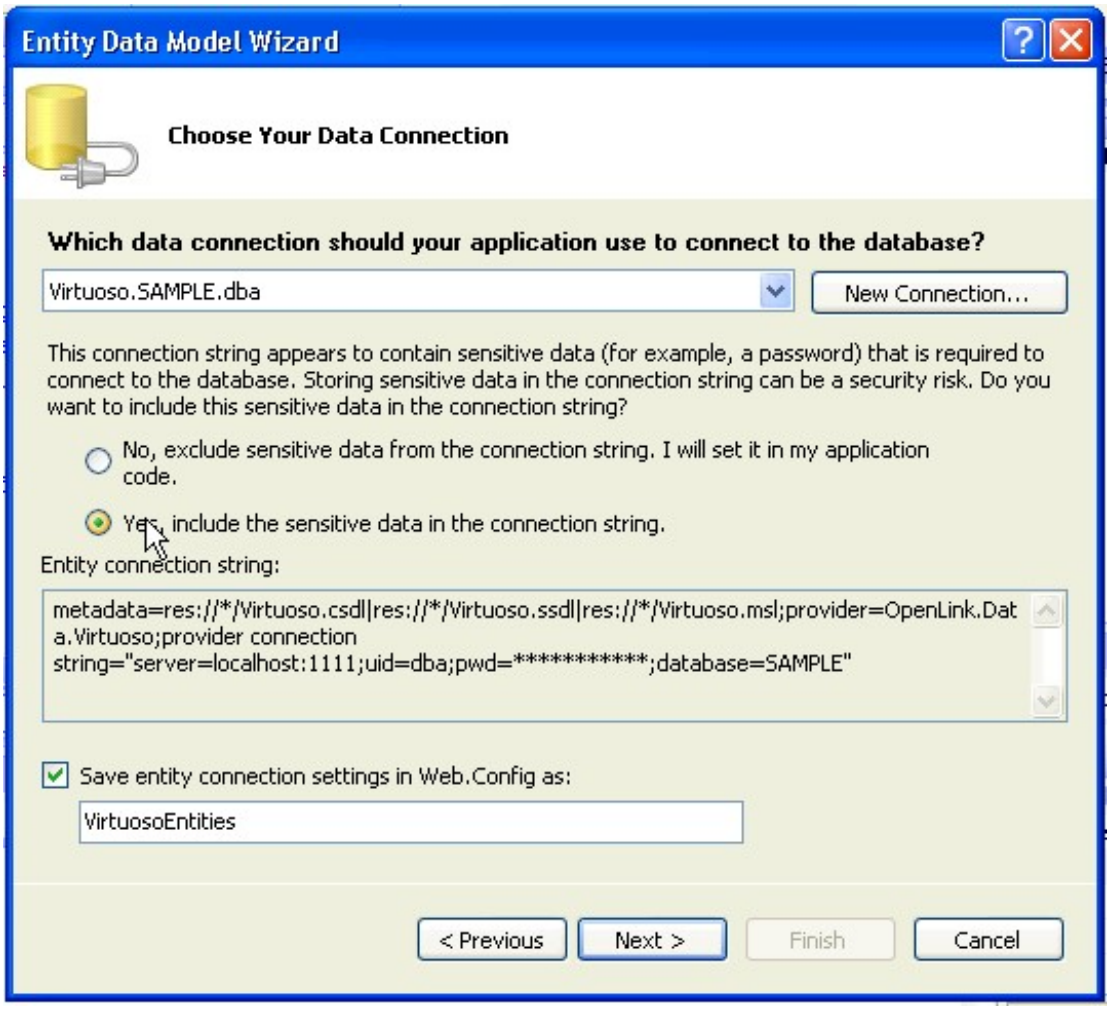
VirtuosoEntities

(note this name as it is required in the section on creating and ADO.Net Data Service) and click

Next

.

Figure 8.298. entity connect string



16. In the

    Choose your Database Objects

    page, tick the

    Tables

    check box to select all tables in the SAMPLE catalog for addition to the Entity Data Model. Set the

    Model Namespace

    to

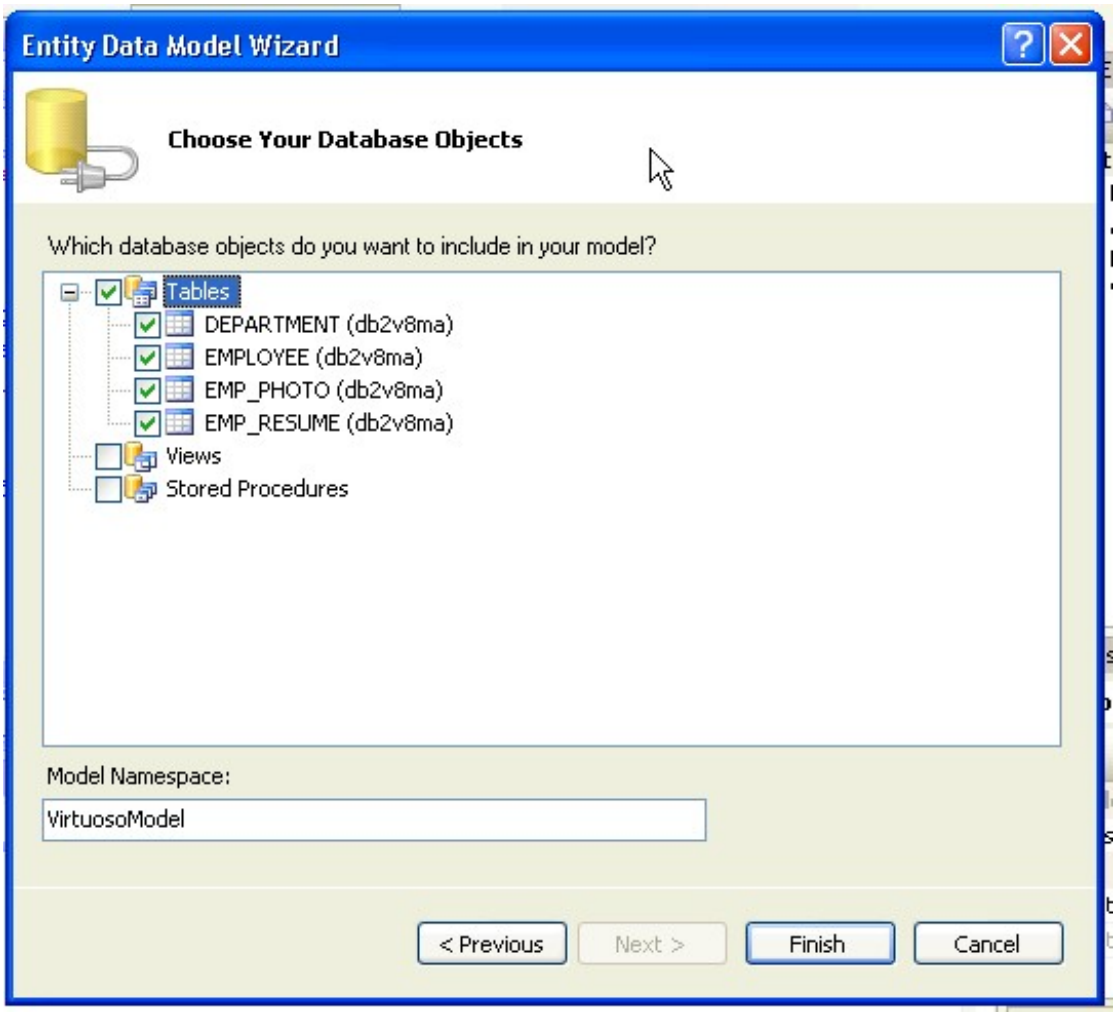
    VirtuosoModel

    and click

    Finish

.

Figure 8.299. Database Objects

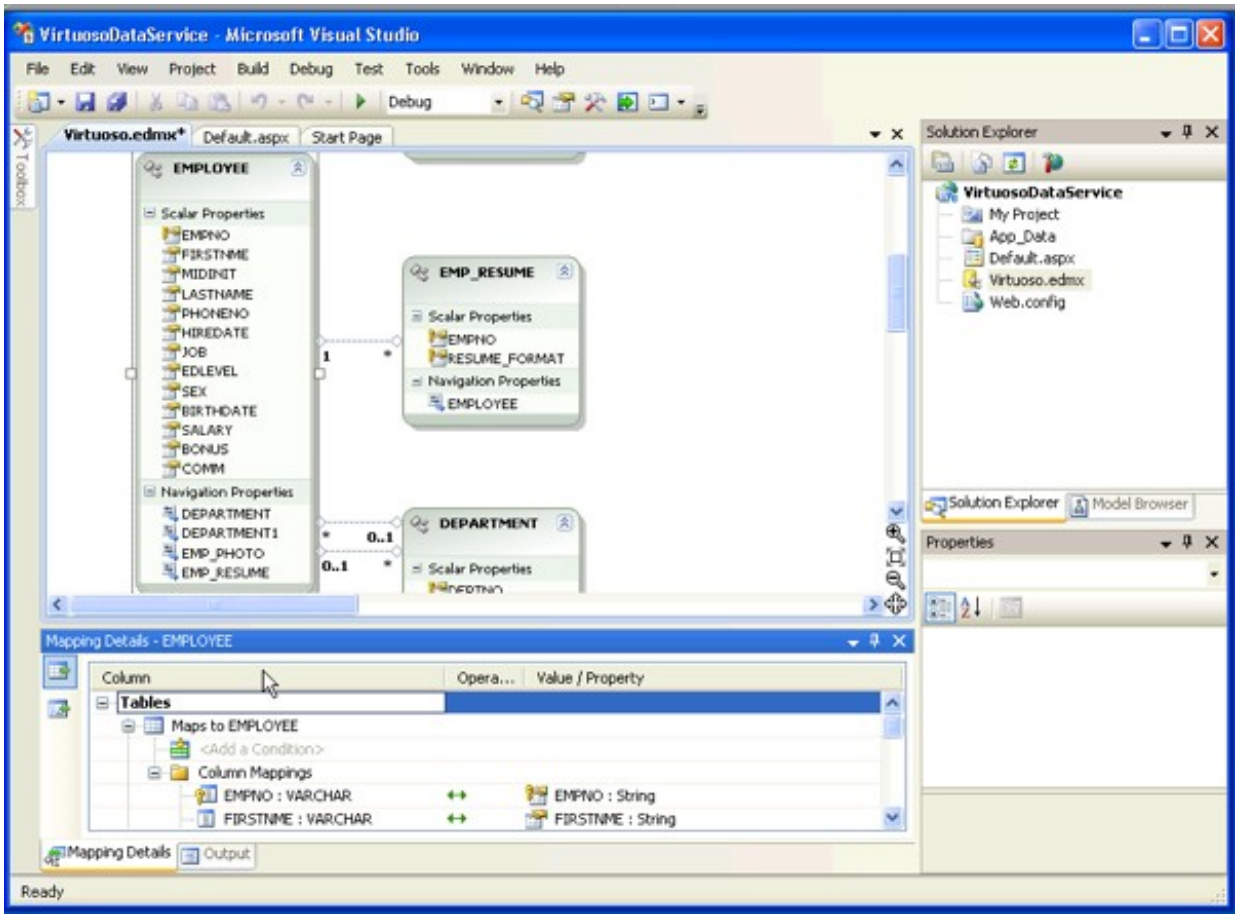


17. The

    Virtuoso.edmx

    EDM will be created with the tables and relationships displayed in the Visual Studio IDE

    Figure 8.300. Virtuoso.edmx



Creation for the Entity Data Model for the DB2 Samples database is now complete.

8.6.5. Using EDM to create Entity Framework based applications

Now that a Microsoft Entity Data Model has been created for the DB2 Samplef database, Entity Framework applications can be created to make use of it.

Entity Frameworks based ADO.NET Data Service

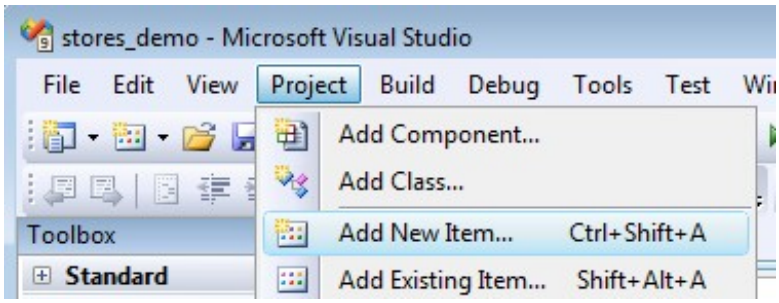
An ADO.Net Data Service for the DB2 tables can be created using the Entity Data Model created in the Creating EDM in Visual Studio 2008 section .

1. Open the

   VirtuosoDataService

   project created in the Creating EDM in Visual Studio 2008 section .
2. Select the Project -> Add New Item menu option.

Figure 8.301. VirtuosoDataService



3. The

   Add New Item

   dialog will appear. Choose the

   ADO.NET Data Service template

   . Give it the name

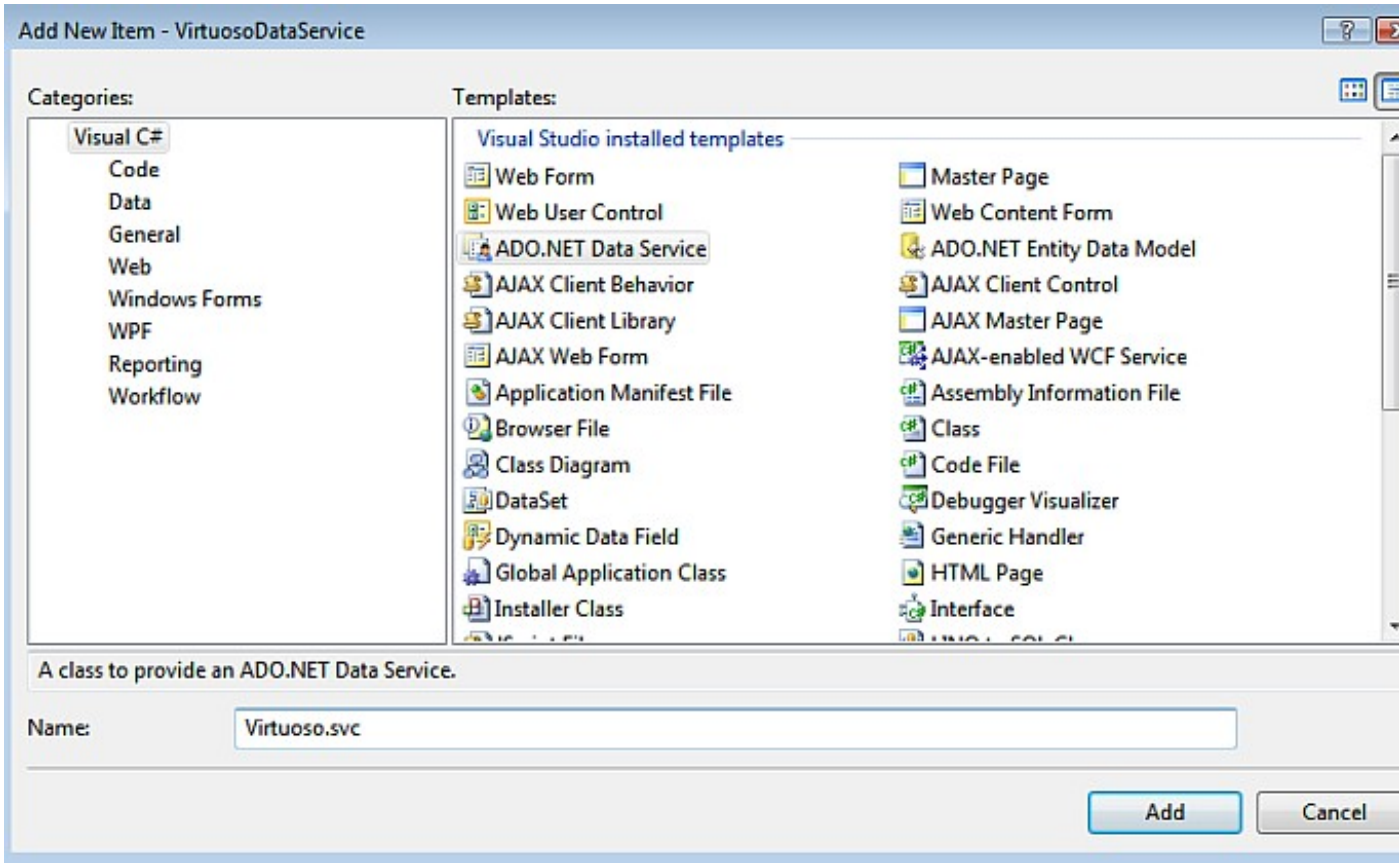
   Virtuoso.svc

   and click

   Add

   to create the ADO.Net Data Service.

   Figure 8.302. Add New Item



4. In the newly created

   Virtuoso.svc.cs

   Data Service file, add the data source class name of

   VirtuosoEntities

   (note this is the name set in the Creating EDM in Visual Studio 2008 section) as the

   DataService

name. Enable the access to the Data Service by adding the entry

config.SetEntitySetAccessRule("", EntitySetRights.All);*

to the

InitializeService

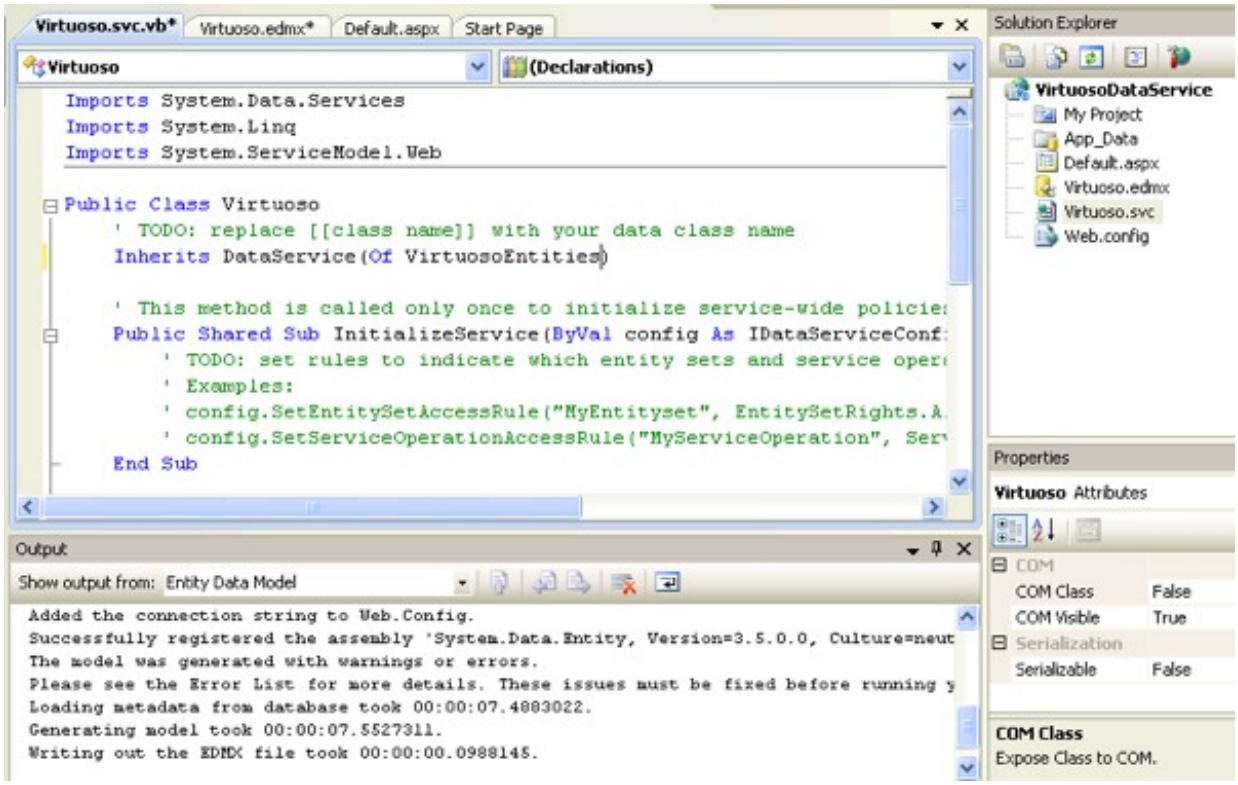
method.

```
// C#

using System;
using System.Web;
using System.Collections.Generic;
using System.ServiceModel.Web;
using System.Linq;
using System.Data.Services;

namespace SimpleDataService
{
    public class Northwind : DataService<VirtuosoDemoEntities>
    {
        public static void InitializeService(IDataServiceConfiguration  config)
        {
            config.SetEntitySetAccessRule("*", EntitySetRights.All);
        }
    }
}
```

Figure 8.303. Virtuoso.svc.cs

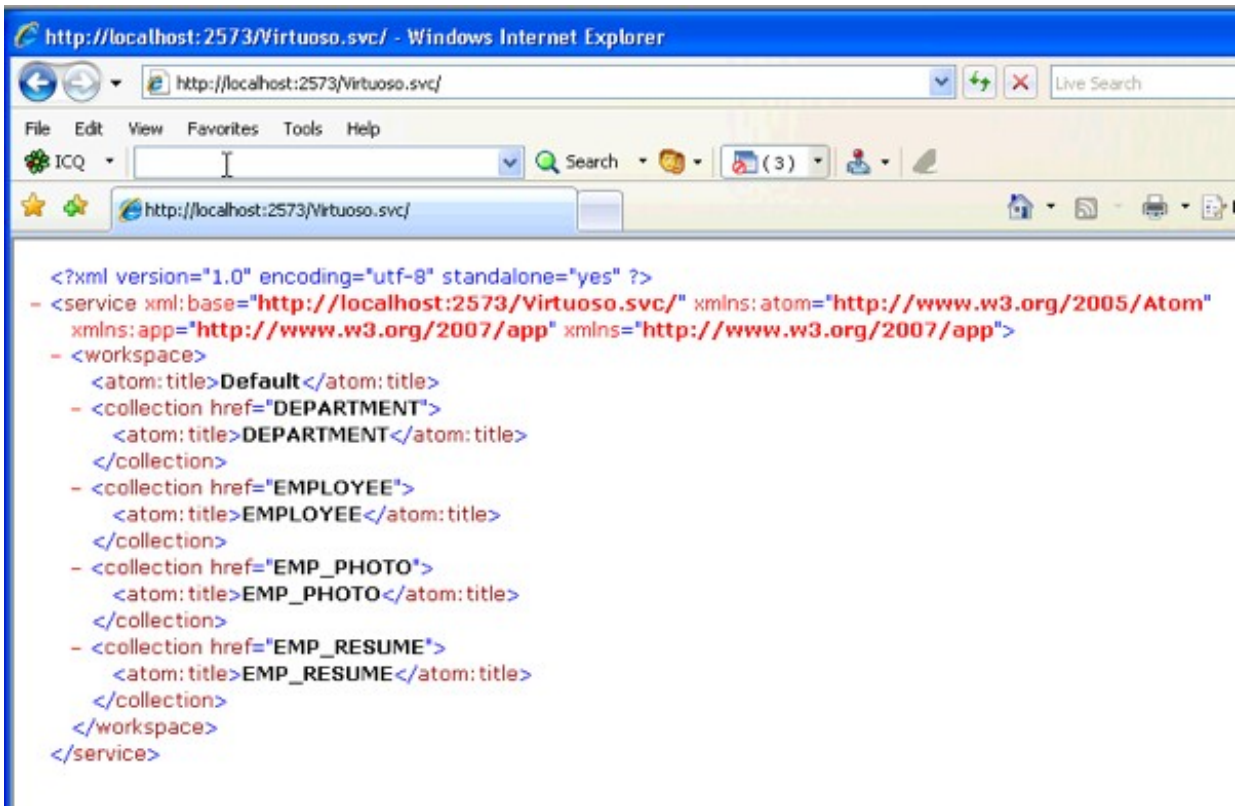


5. To test the Data Service, simply hit

   Ctrl+F5

   within Visual Studio. This will start the development web server, run the Data Services server inside, and load a Web browser page displaying the list of available tables/entities for the SAMPLE database catalog.

Figure 8.304. Data Service test



6. To access a specific entity instance like the

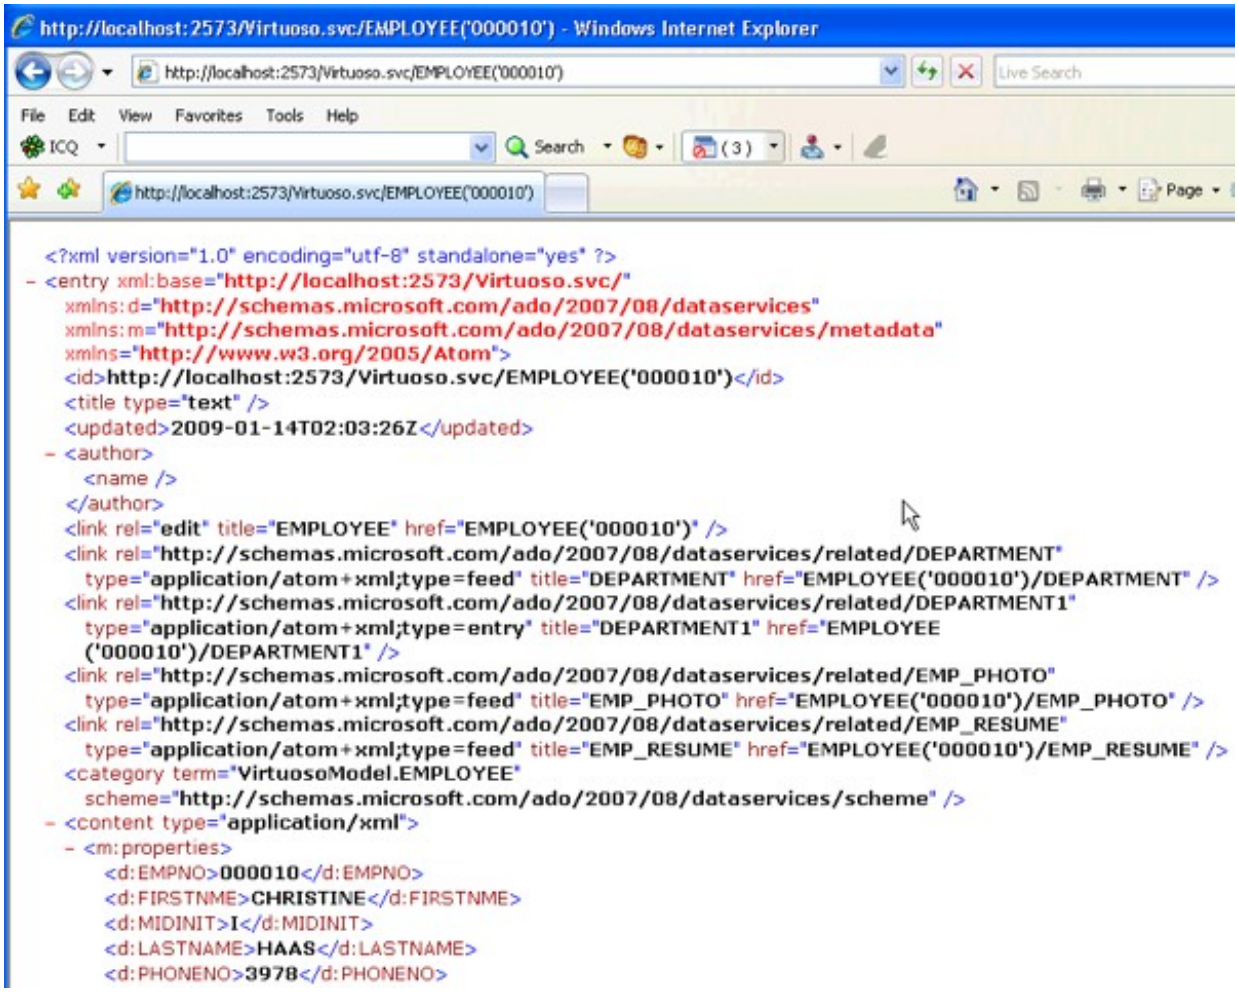
   EMPLOYEES

   table employee number

   000010

   record, use this convention http://host/vdir/Virtuoso.svc/EMPLOYEES("000010") .

   Figure 8.305. EMPLOYEES



Notes:

1. *Important*

   - To view

   Atom

   (the default format returned by an ADO.NET Data Service) in Internet Explorer, you must first ensure that

   Feed Reading View

   is turned

   off

   . This can be done on the

   Content tab

   of

   Tools in Internet Options

   .
2. If a Data Services entity instance URI page fails to load you can turn

   Verbose

errors on by adding

config.UseVerboseErrors = true;

in the

virtuoso.svc.cs InitializeService

method to obtain more detailed information from the server as to why the page failed to load:

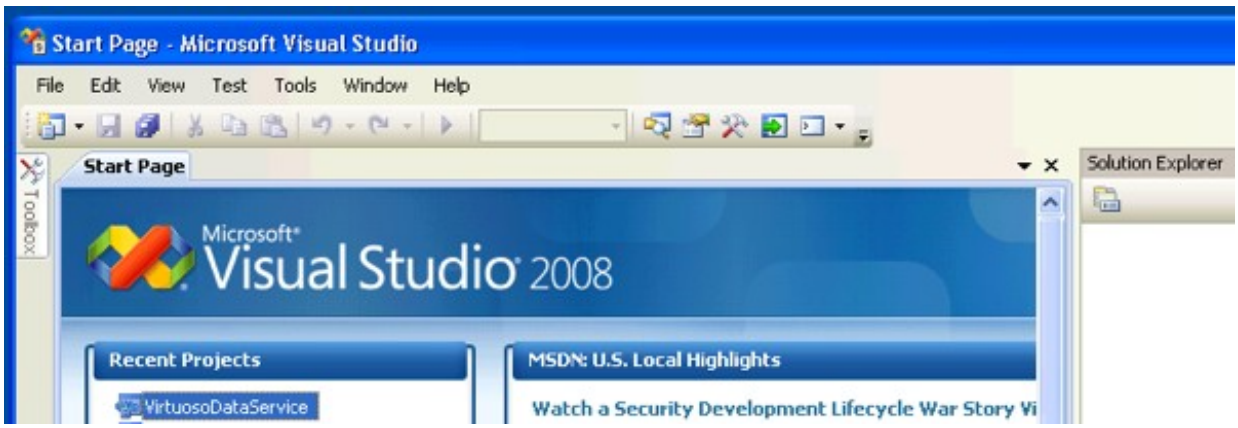
```
public static void InitializeService(IDataServiceConfiguration config)
{
config.UseVerboseErrors = true;
config.SetEntitySetAccessRule("*", EntitySetRights.All);
}
```

Visual Studio Windows DataGrid Form Application

This section details the steps required to create a simple Visual Studio 2008 Windows Form application, with associated DataGridView control for displaying data in selected tables from the target database.

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.306. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

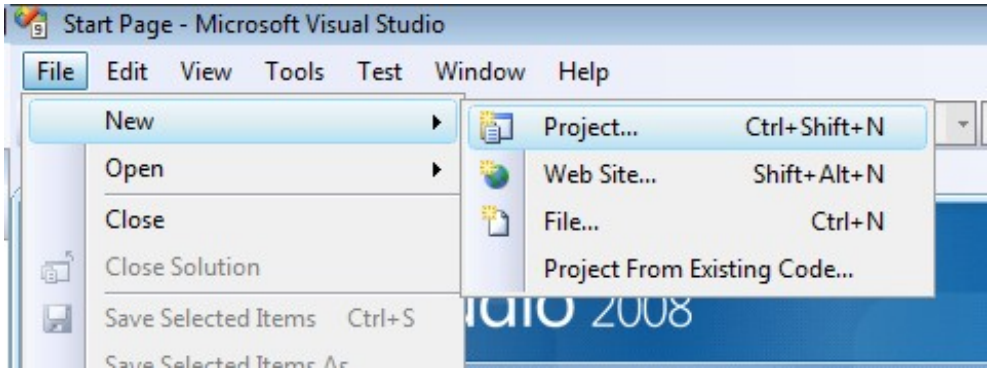
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.307. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Windows

   and select

   Windows Form Application

   from the right-hand panel.
5. Choose a name for the project, for example

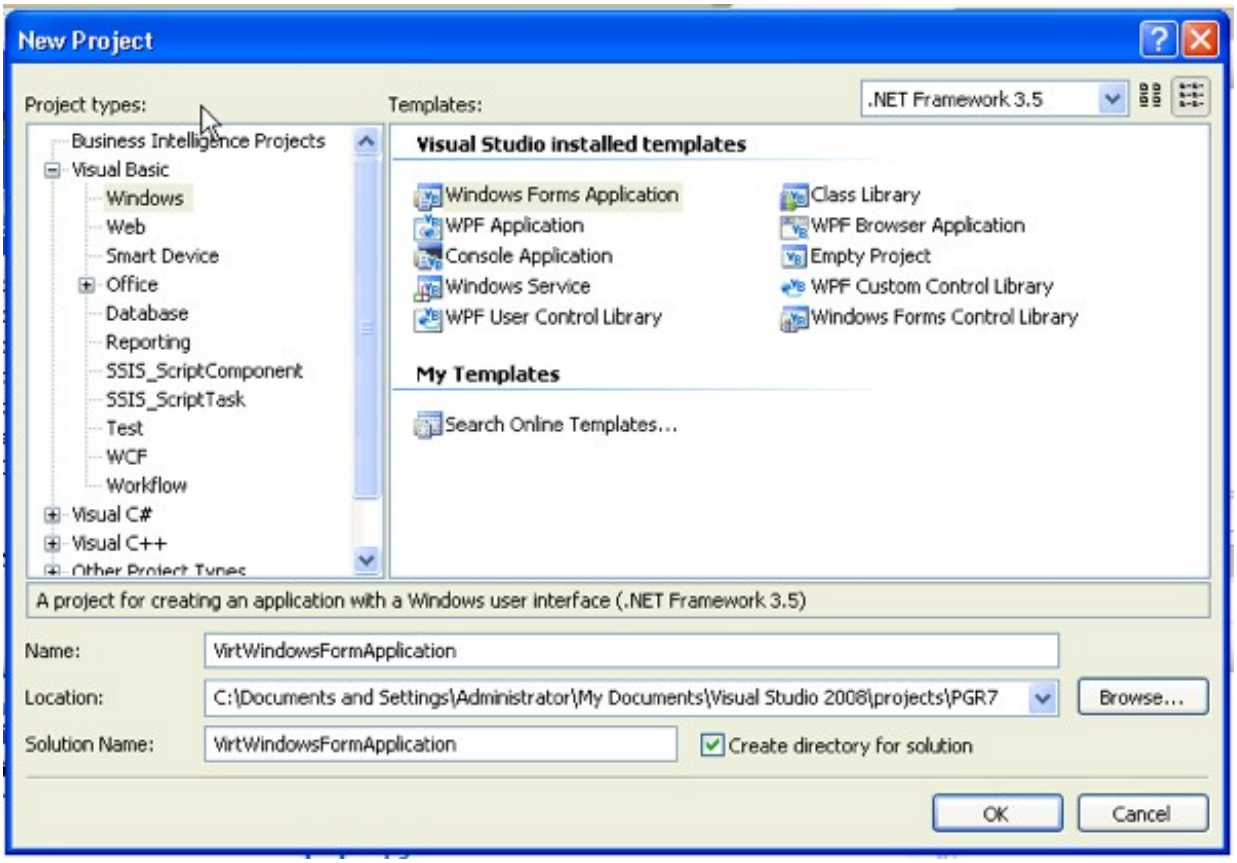
   VirtWindowsFormApplication

   , and click

   OK

   .

   Figure 8.308. Web Application



6. In the

   Toolbox

   , expand

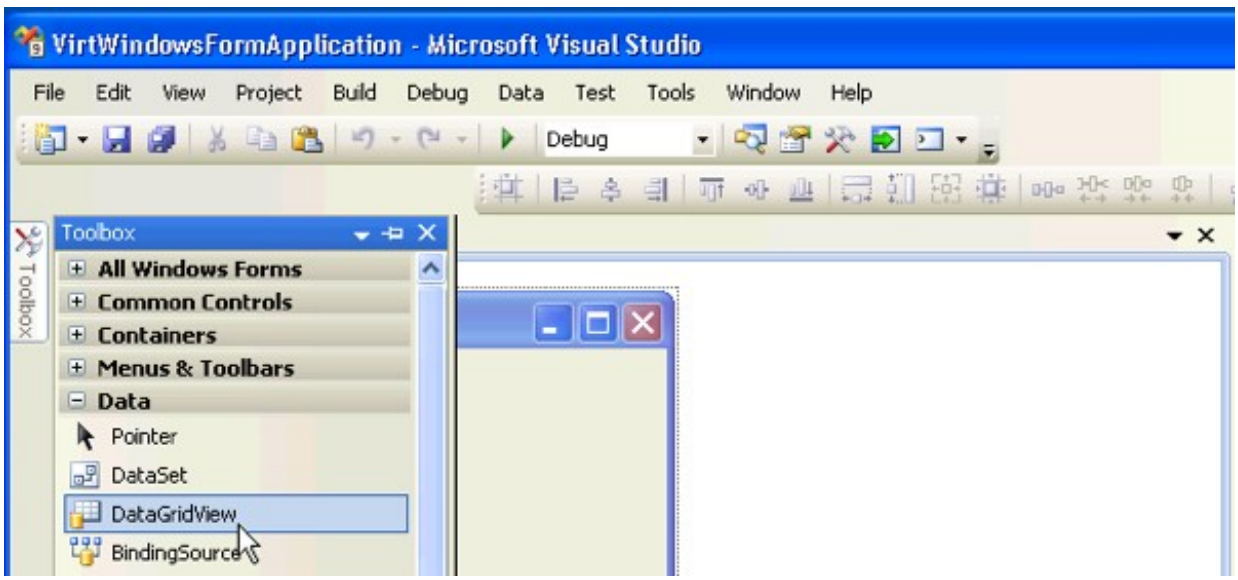
   Data Controls

   , and drag the

   DataGridView

   control onto the form.

Figure 8.309. Toolbox



7. Click on the little

   arrow

   in the top right of the

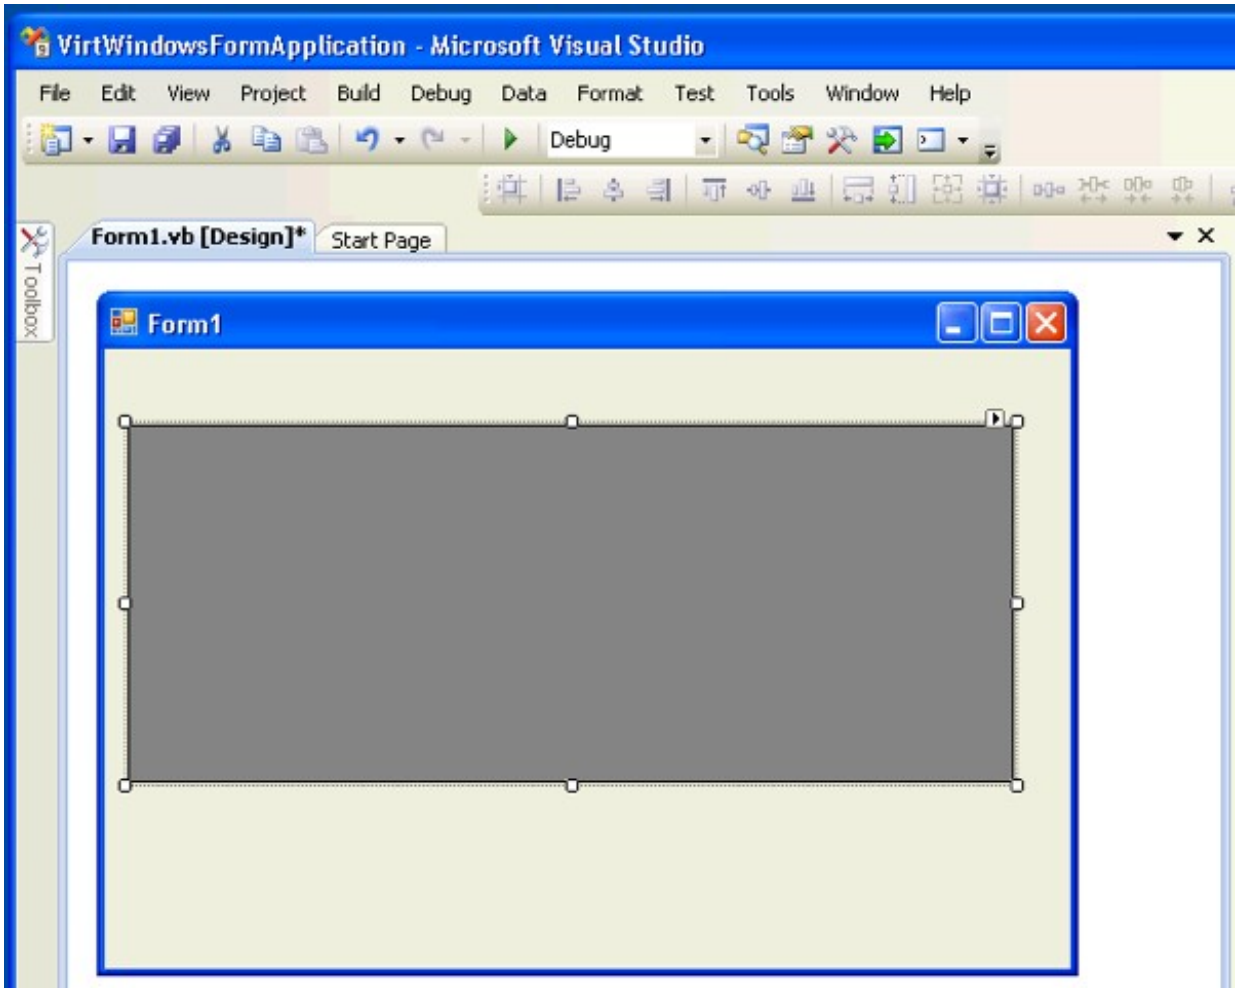
   DataGridView

   control. This loads the

   DataGridView Task

   menu.

   Figure 8.310. DataGridView Task

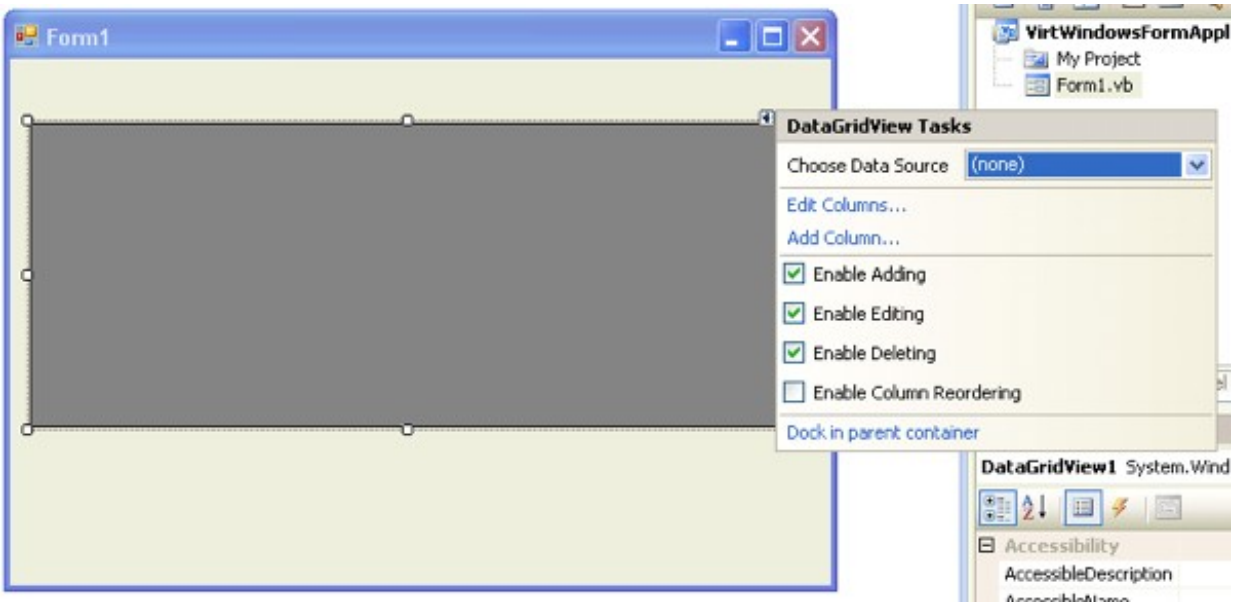


8. Click on the

   Choose Data Source

   list box.

   Figure 8.311. Choose Data Source

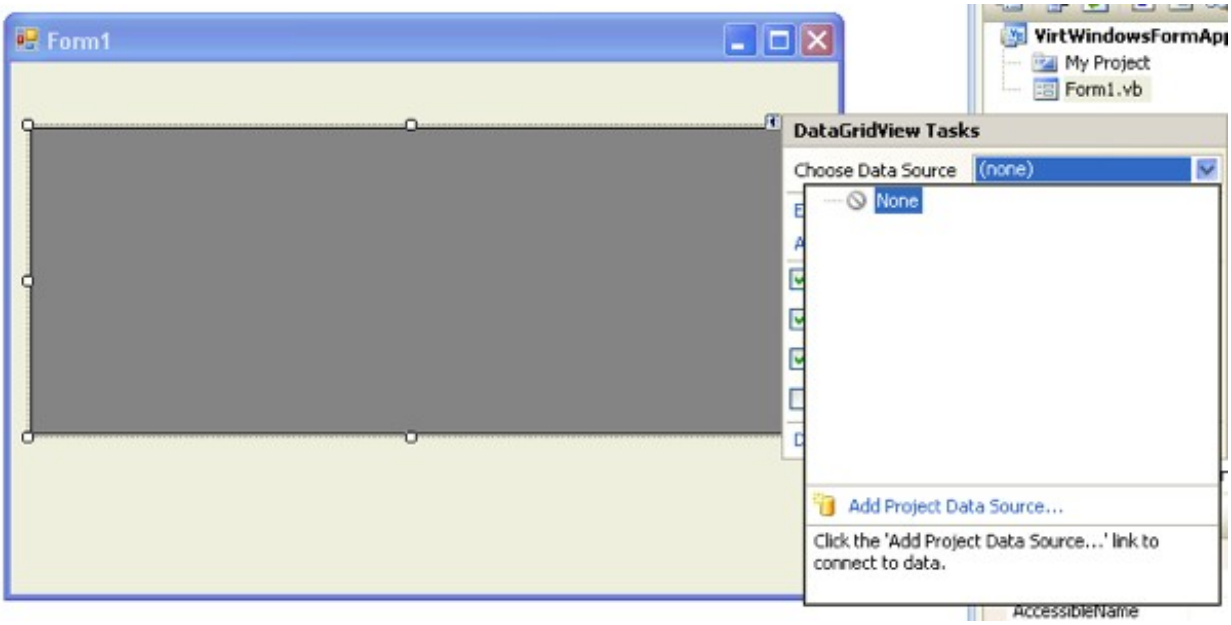


9. Click on the

   Add Project Data Source

   link to connect to a data source.

Figure 8.312. Add Project Data Source



10. In the

    Data Source Configuration Wizard

    dialog

    Choose Data Source Type

    page select the

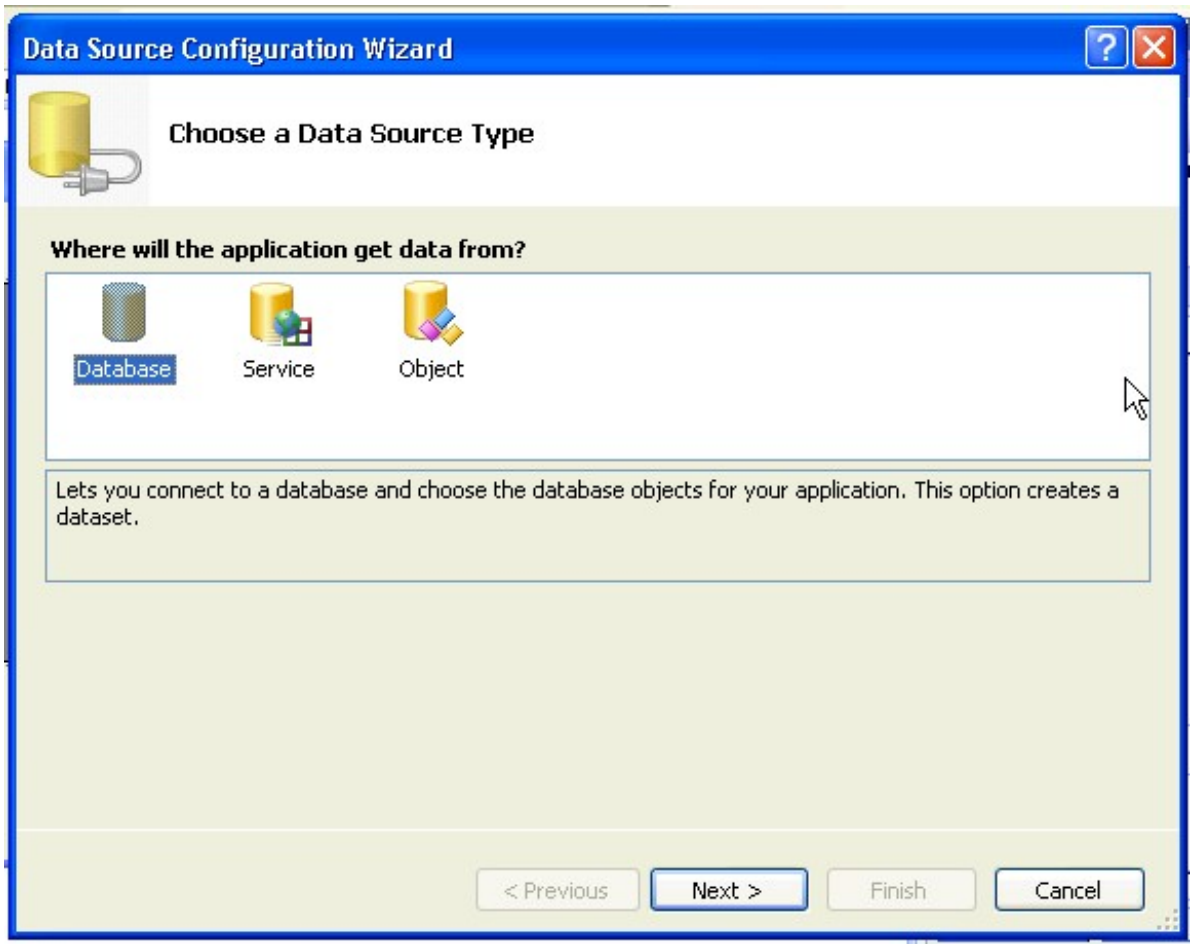
    Database

    data source type and click

Next

.

Figure 8.313. Data Source Type



11. In the

    Data Source Configuration Wizard

    dialog

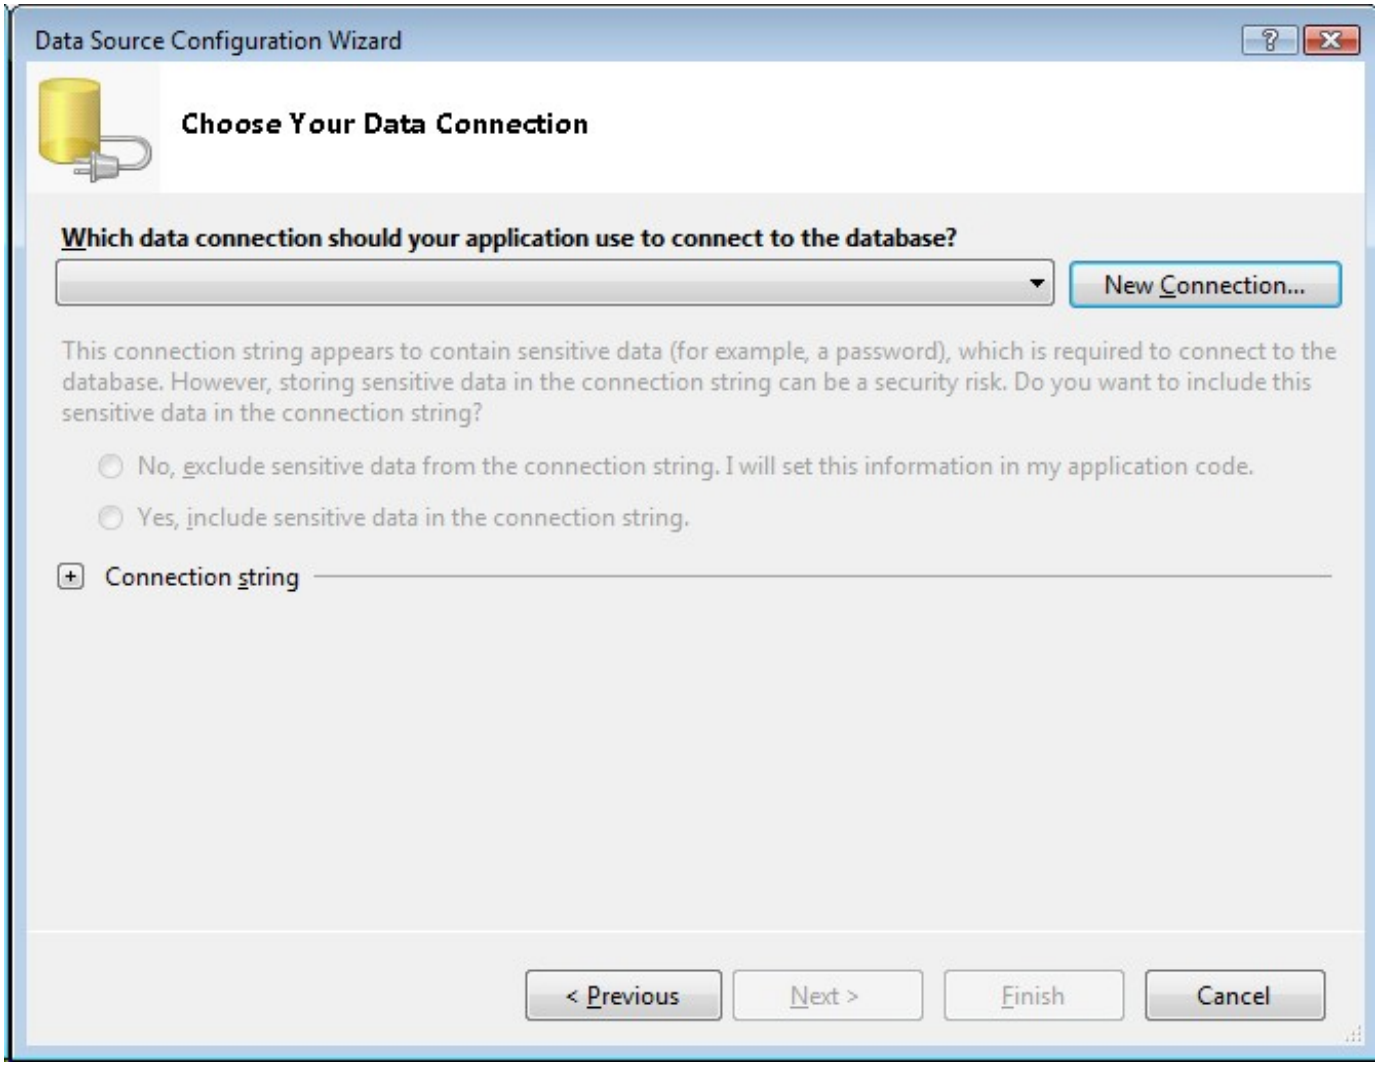
    Choose your Data Connection

    page, select the

    New Connection

    button

Figure 8.314. Data Source Configuration Wizard



12. In the

    Choose Data Source

    dialog, select the OpenLink

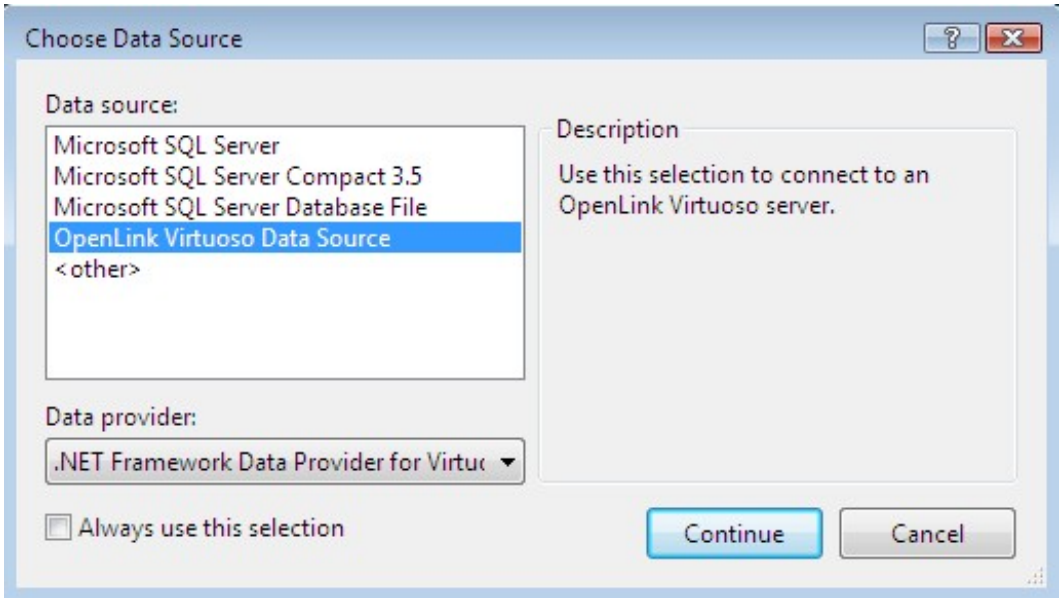
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.315. Data Source



13. In the

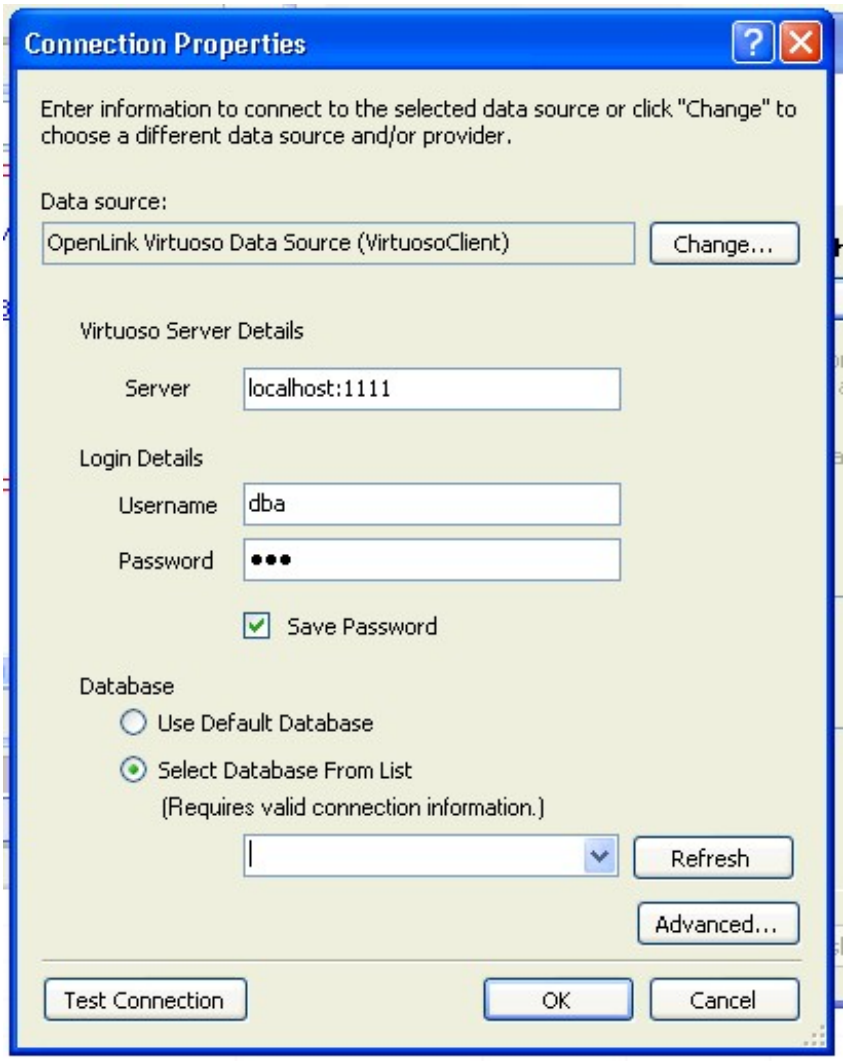
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.316. Connection Properties



14. Select the

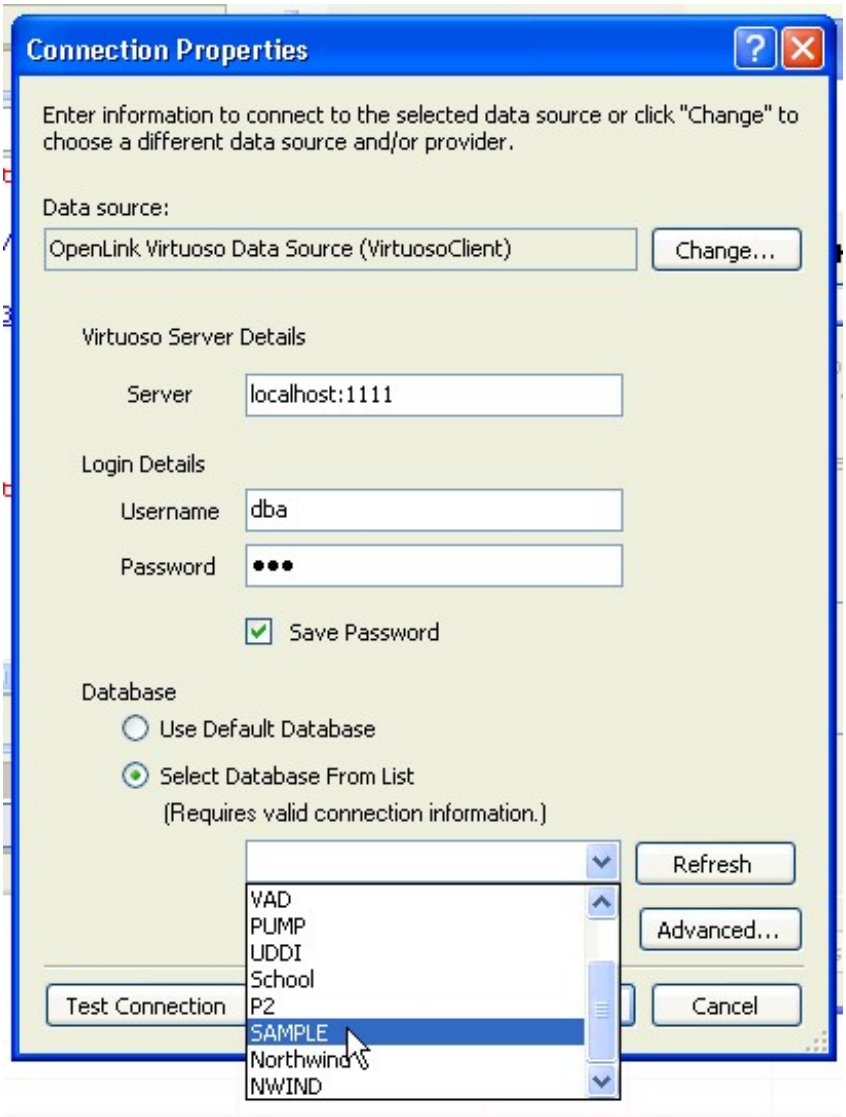
    Select Database From List

    radio button and choose the

    SAMPLE

    database from the drop down list.

Figure 8.317. Add connection

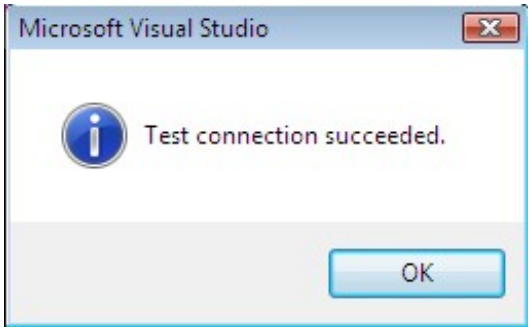


15. Press the

    Test Connection

    dialog to verify that the database is accessible.

    Figure 8.318. Test Connection



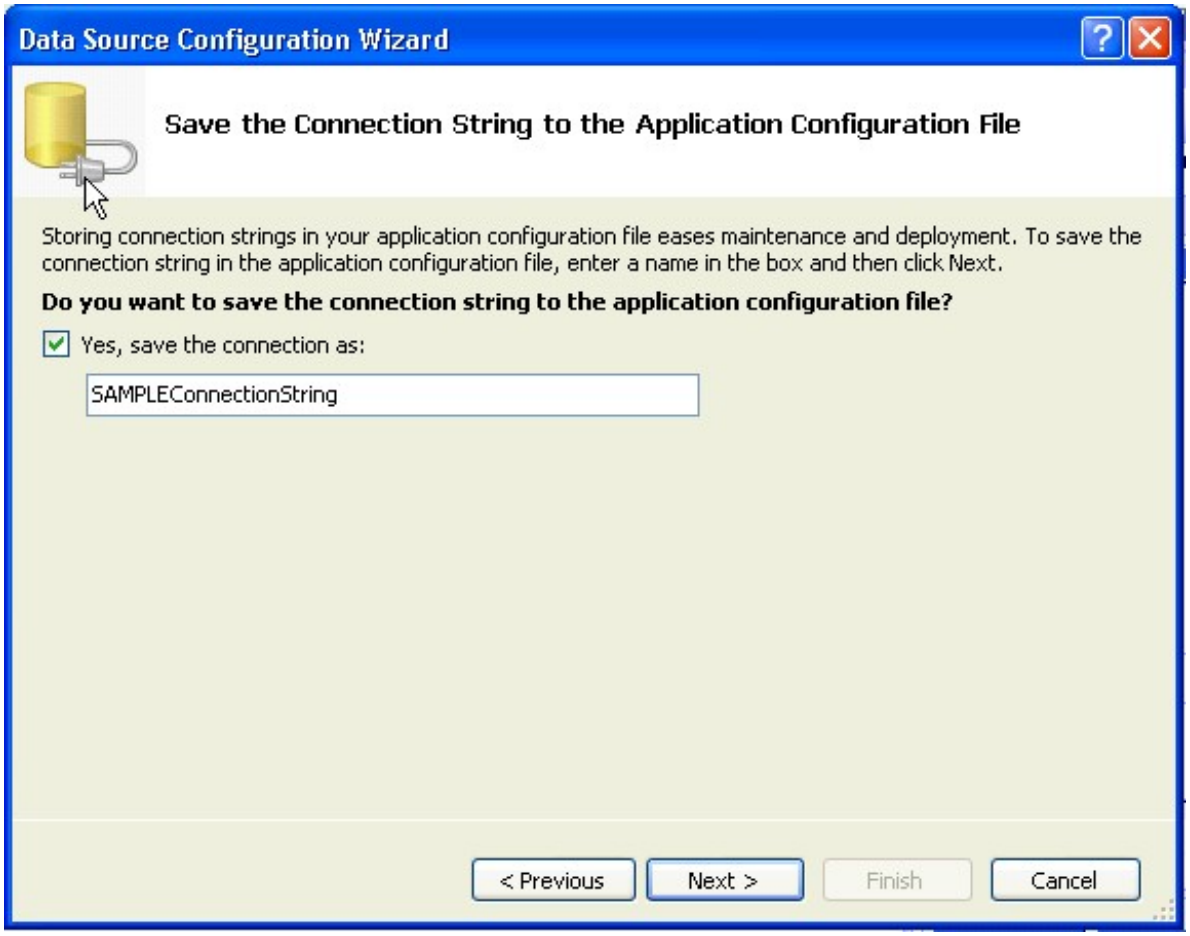
16. Leave the default connect string

    SAMPLEConnectionString

    and click

Next

Figure 8.319. SAMPLEConnectionString



17. From the list of available tables returned for the SAMPLE database select the

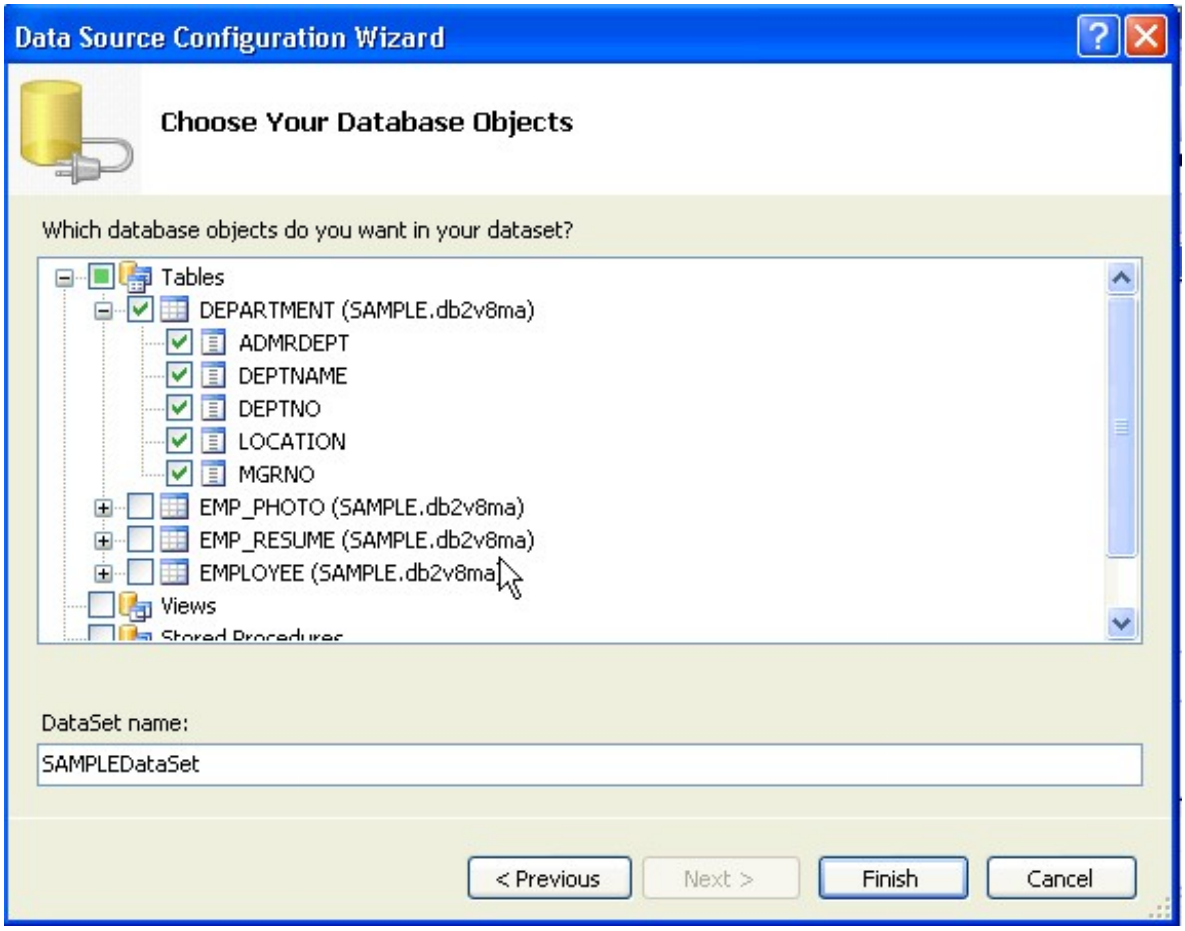
    DEPARTMENT

    table to be associated with the

    DataGridView

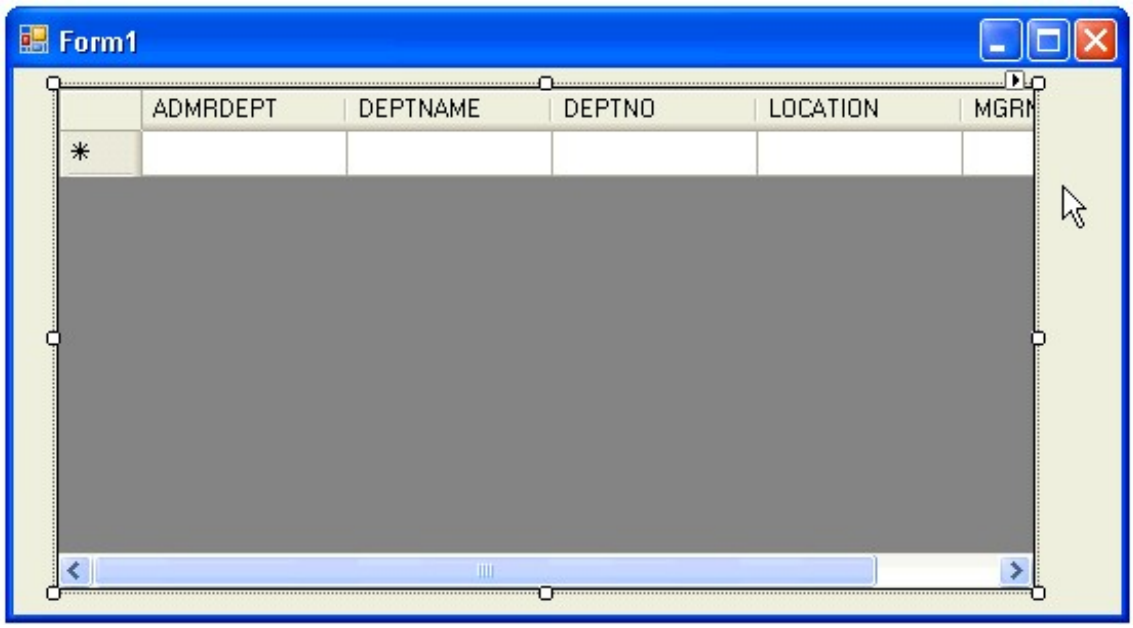
    control

    Figure 8.320. SAMPLE database



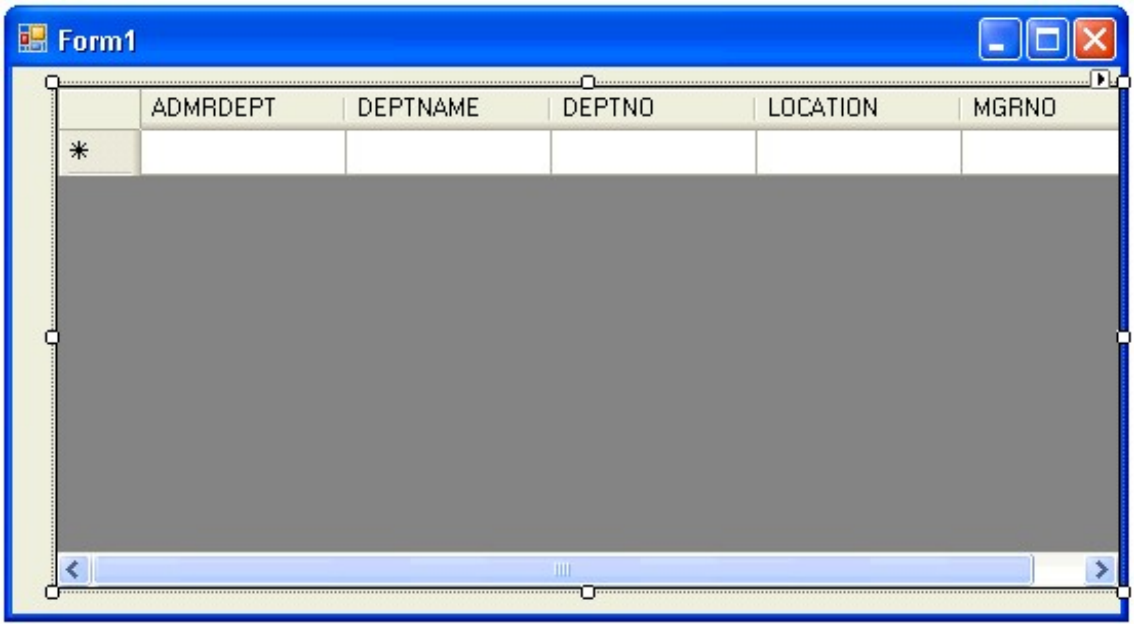
18. The columns names of the select table will be displayed in the DataGridView

Figure 8.321. DataGridView



19. Resize the Form and DataGridView to allow all columns to be visible, if possible.

Figure 8.322. Resize the Form and DataGridView



20. To test the application, simply hit

    Ctrl+F5

    within Visual Studio or select

    Start Debugging

    from the

    Debug

    menu.

    Figure 8.323. Start Debugging

21. The data from the

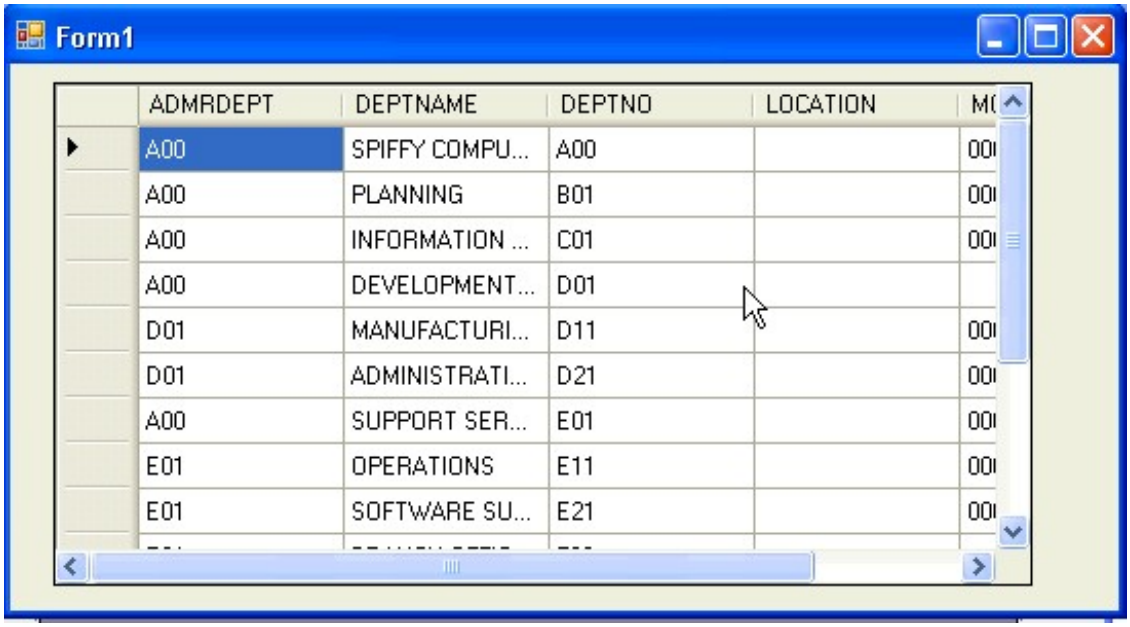
    DEPARTMENT

    table will be displayed in the

    DataGrid

    .

    Figure 8.324. DataGrid



The task is now complete.

8.7. Using Microsoft Entity Frameworks to Access Sybase Schema Objects with Virtuoso

Abstract

This section details the steps required to provide Microsoft Entity Framework access to Sybase Schema Objects using the OpenLink Virtuoso Universal Server. This is achieved by linking the required Sybase Schema objects into Virtuoso using its built in Virtual Database engine, and then using the Virtuoso ADO.NET Entity Framework provider to query the remote Sybase Schema objects linked into the Virtuoso Server.

Prerequisites. The following prerequisites must be in place for this solution to be possible.

Sybase DBMS. An Sybase DBMS hosting the required Schema Objects needs to be available. In this section the *Sybase pubs2 sample* database will be used to demonstrate the process.

An Sybase DBMS hosting the required Schema Objects needs to be available. In this section the *Sybase pubs2 sample* database will be used to demonstrate the process.

ODBC Driver for Sybase. An Sybase ODBC Driver is required for Linking the Sybase Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for Sybase* will be used in this section, for which a functional ODBC Data source name of "syb15ma" will be assumed to exist on the machine hosting the Virtuoso Server.

An Sybase ODBC Driver is required for Linking the Sybase Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for Sybase* will be used in this section, for which a functional ODBC Data source name of "syb15ma" will be assumed to exist on the machine hosting the Virtuoso Server.

Virtuoso Universal Server. An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

Microsoft Visual Studio 2008 SP1. Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Tasks

Ensure Sybase Primary Keys (PKs) are not nullable. The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the Sybase database schema before attempting to generate an EDM. In the case of the Sybase pubs2 database all tables are not nullable, thus this should not be an issue in this case.

The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the Sybase database schema before attempting to generate an EDM. In the case of the Sybase pubs2 database all tables are not nullable, thus this should not be an issue in this case.

8.7.1. Install and configure OpenLink ODBC Driver for Sybase

The Virtuoso Virtual Database engine uses ODBC as the connectivity mechanism for linking remote database objects into its local schema. Thus an Sybase ODBC Driver must be available with a suitably configured DSN for connecting to the target database. The OpenLink ODBC Drivers for Sybase have been used in this section, although in theory any Sybase ODBC Driver can be used.

Installation instructions for the OpenLink ODBC Driver for Sybase are available from:

- Product Installation & Basic Configuration (ODBC)

8.7.2. Install and configure OpenLink Virtuoso Universal Server

- Install and configure OpenLink Virtuoso Universal Server

8.7.3. Linking Sybase tables into OpenLink Virtuoso

1. Start the Virtuoso Web User Interface

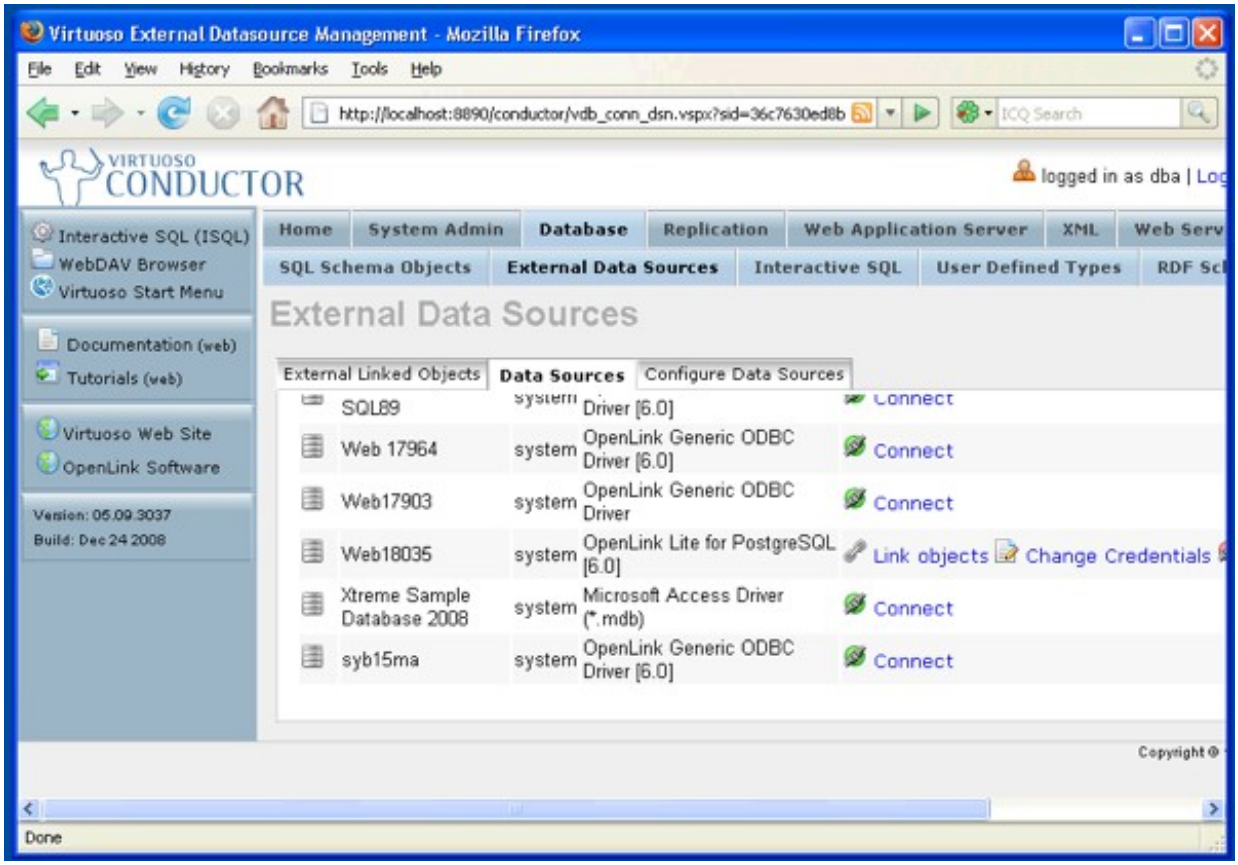
   Figure 8.325. Start

2. Select the "Conductor" link in the Left Frame and Login as the "dba" user.

Figure 8.326. Conductor

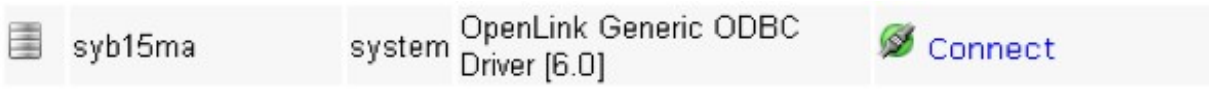
3. Select the "Databases" -> "External Data Source" -> "Data Sources" tab menu items

Figure 8.327. Databases



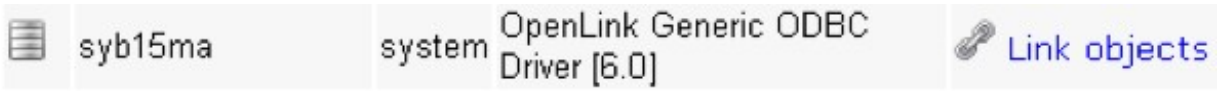
4. Select the "Connect" button for the "syb15ma" Sybase DSN.

Figure 8.328. Connect



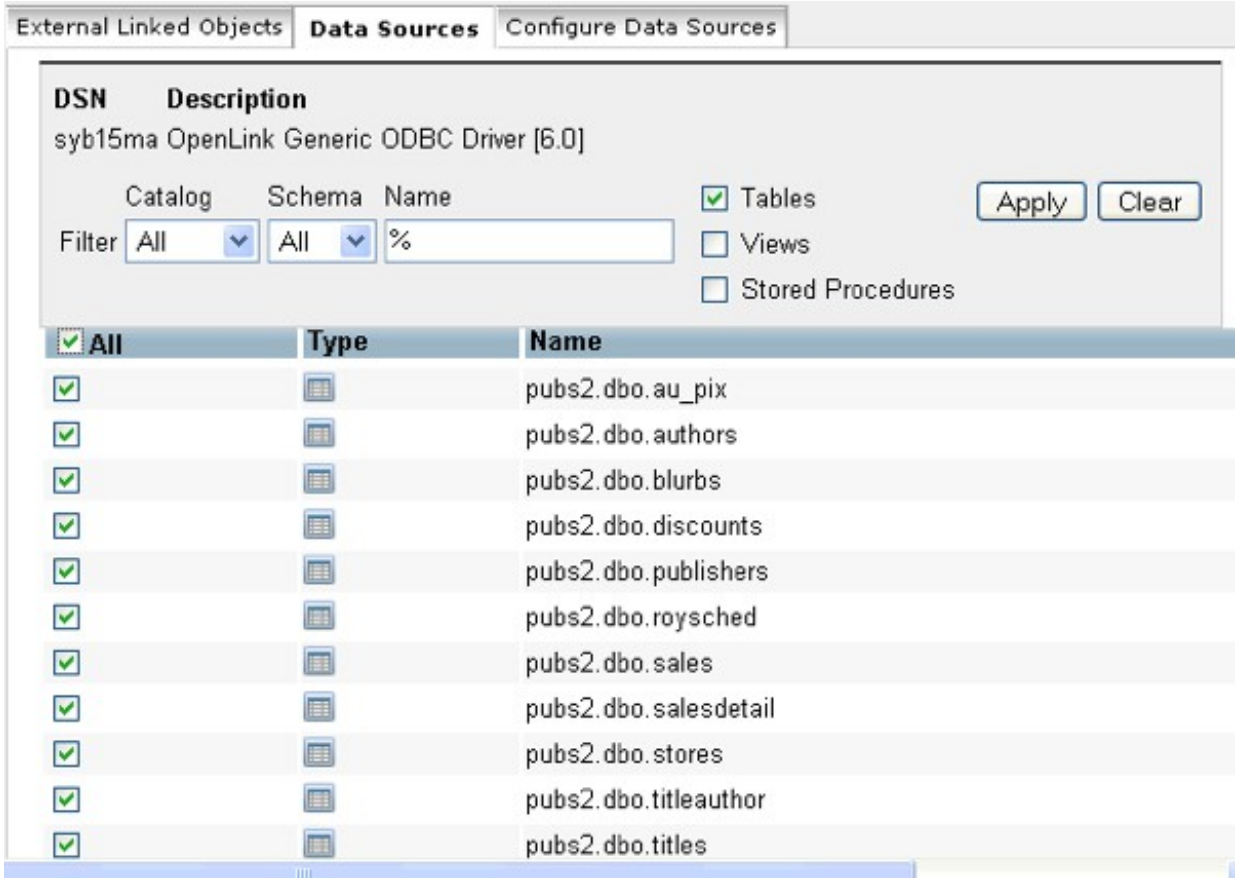
5. On successful connection Select the "Link Objects" button to obtain a list of available tables

Figure 8.329. Link Objects



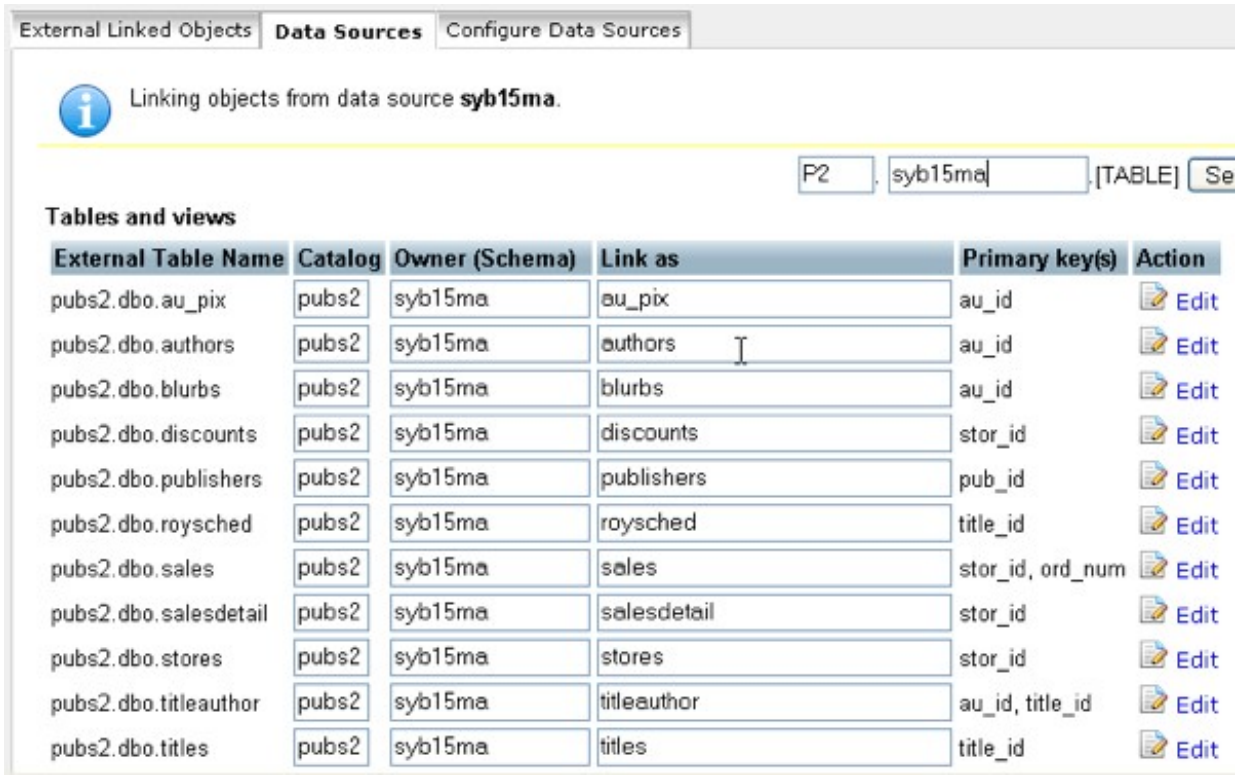
6. Select all the tables that are part of the "pubs2" catalog.

Figure 8.330. Select tables



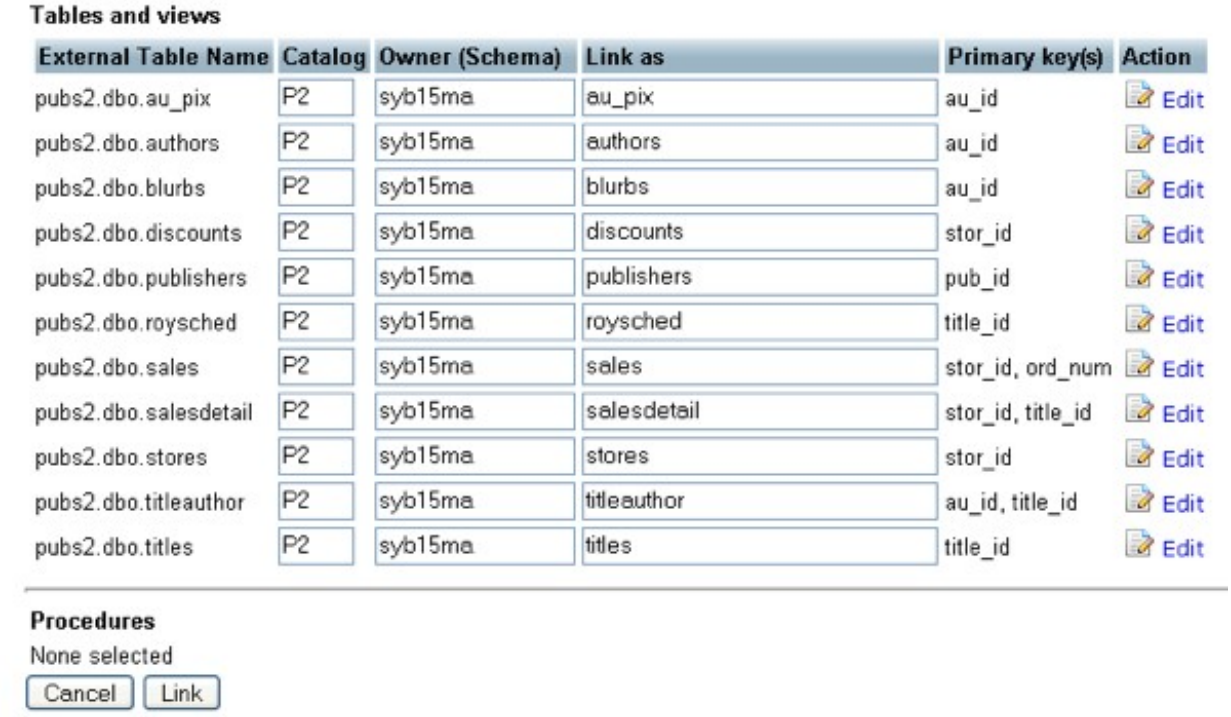
7. Change the Catalog for each table to be "P2" using the "Set All" button.

Figure 8.331. Catalog



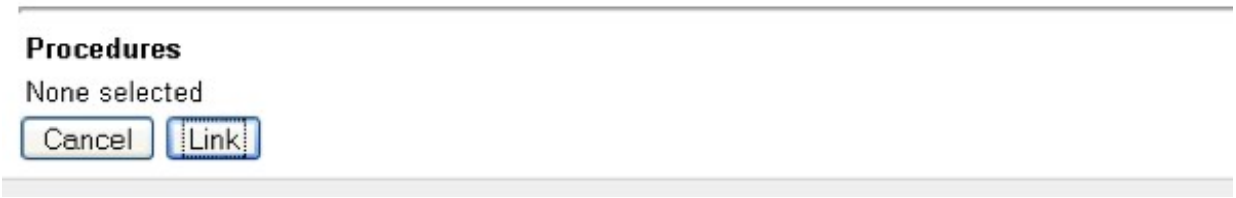
8. All the catalog names are changed to be "P2".

Figure 8.332. catalog names



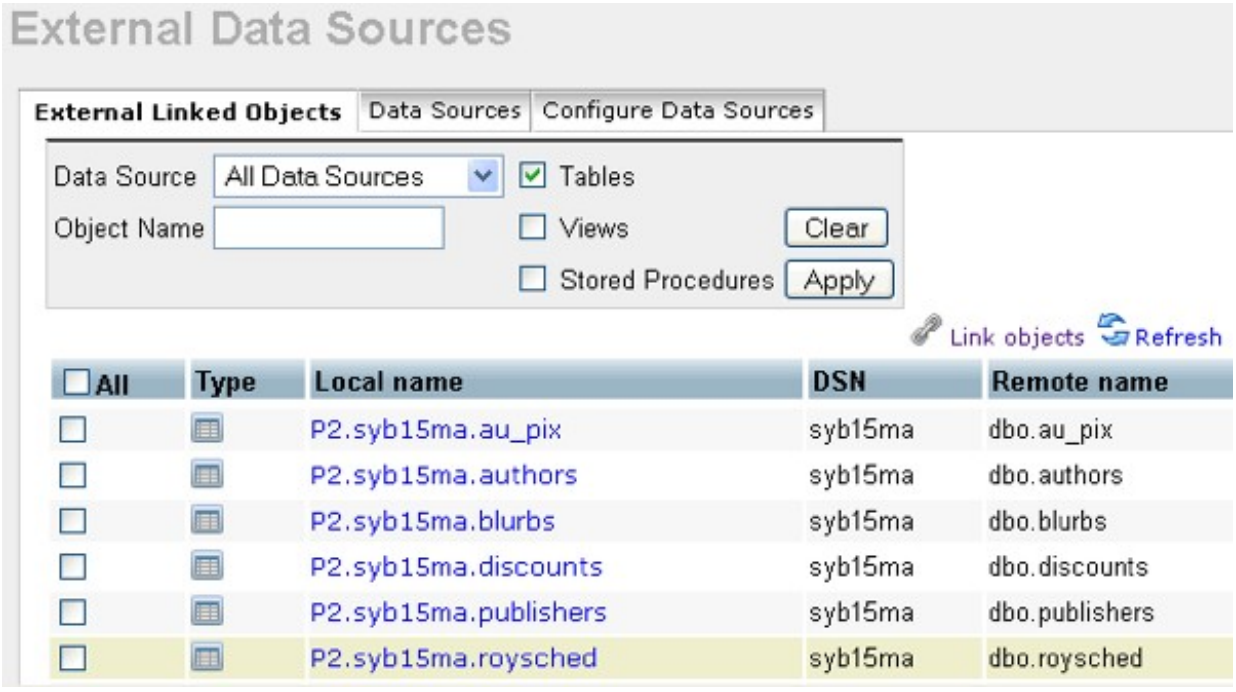
9. Select the "Link" button to link the selected tables into Virtuoso

Figure 8.333. "Link" button



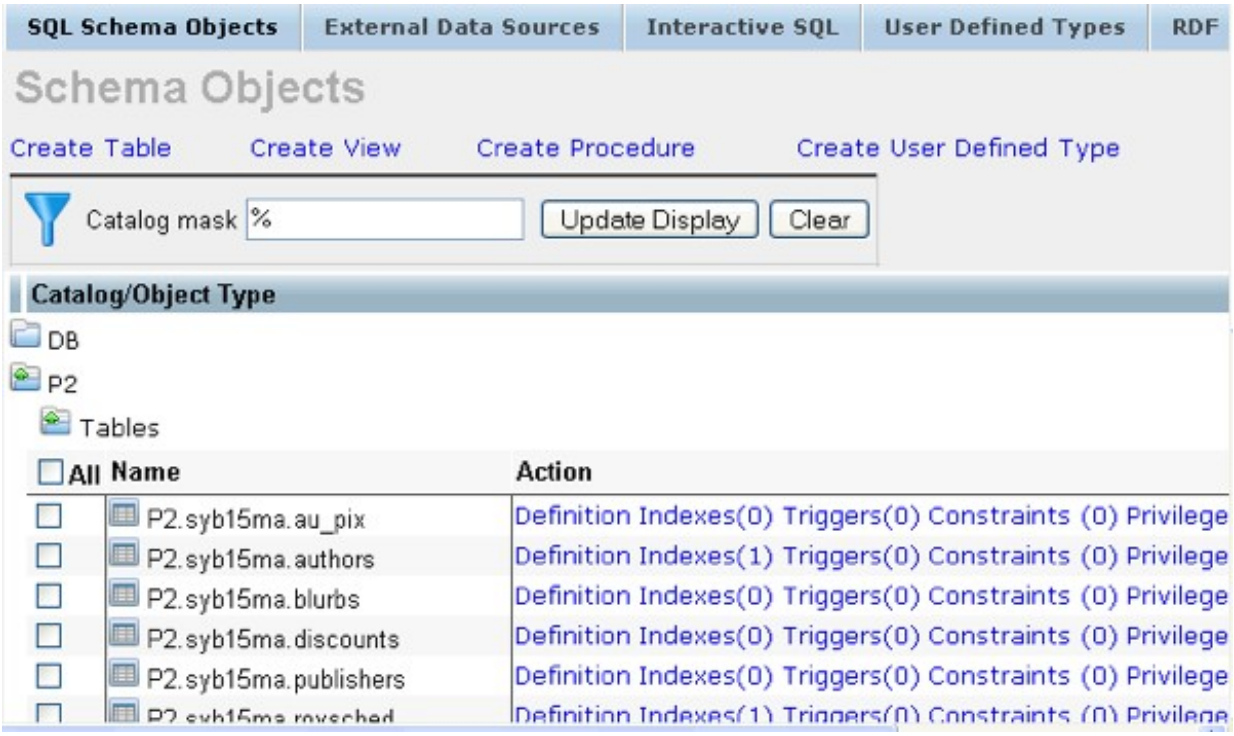
10. On completion of the Link process the tables will be displayed in the "External Linked Objects" tab.

Figure 8.334. Completion



11. The tables can also be viewed as part of the Virtuoso "SQL Schema Objects" under the "P2" catalog name.

Figure 8.335. view tables



The Link process is now complete enabling the tables to be queried as if part of the Virtuoso Schema.

8.7.4. Creating EDM in Visual Studio 2008

The following steps can be used to create an Entity Data Model (EDM) for the Sybase pubs2 database:

1. Launch the Visual Studio 2008 SP1 IDE.

Figure 8.336. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

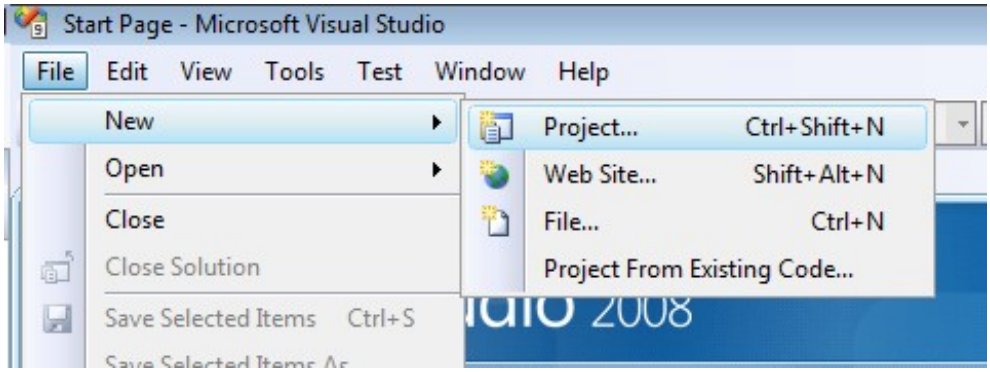
   File

menu in Visual Studio and choosing

New Project

.

Figure 8.337. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Web

   and select

   ASP.NET Web Application

   from the right-hand panel.
5. Choose a name for the project, for example

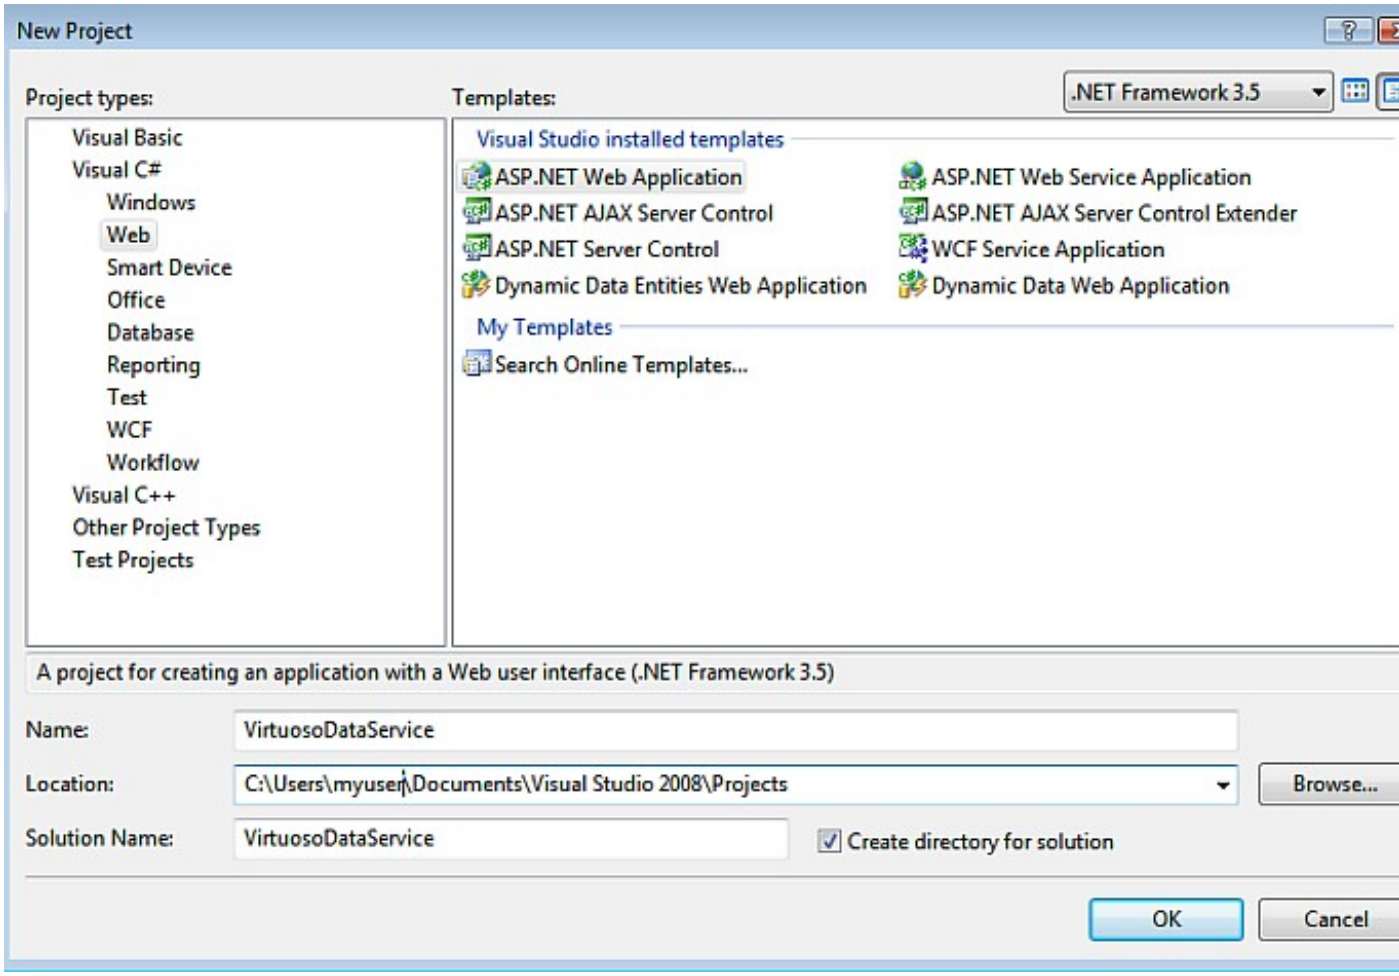
   VirtuosoDataService

   , and click

   OK

   .

Figure 8.338. name for the project

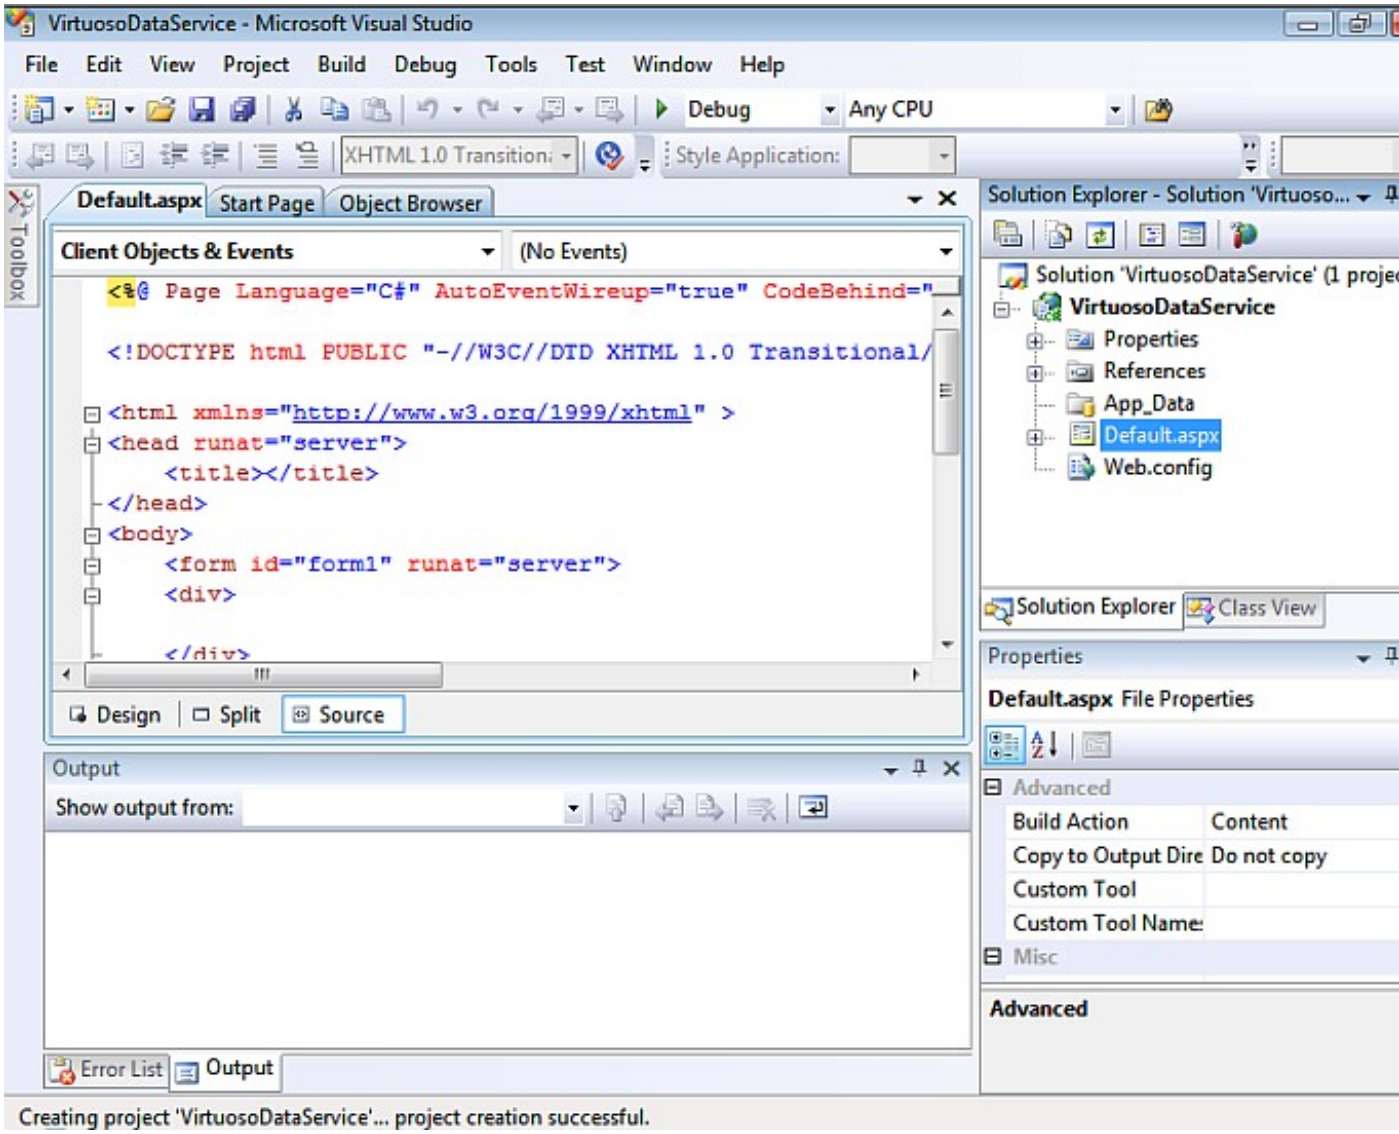


6. This will create a new project called

   VirtuosoDataService

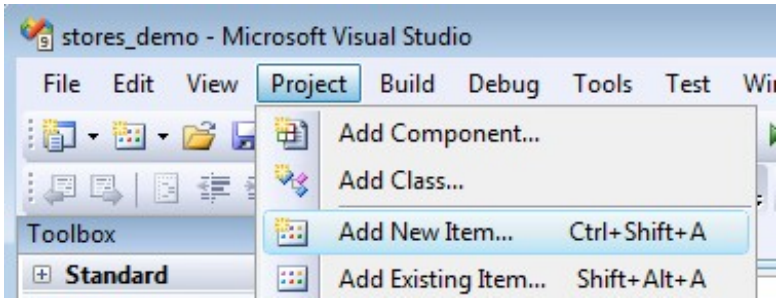
   .

Figure 8.339. create a new project



7. Select the Project -> Add New Item menu option.

Figure 8.340. VirtuosoDataService



8. The

Add New Item

dialog will appear. Choose the

ADO.NET Entity Data Model

template. Give it the name

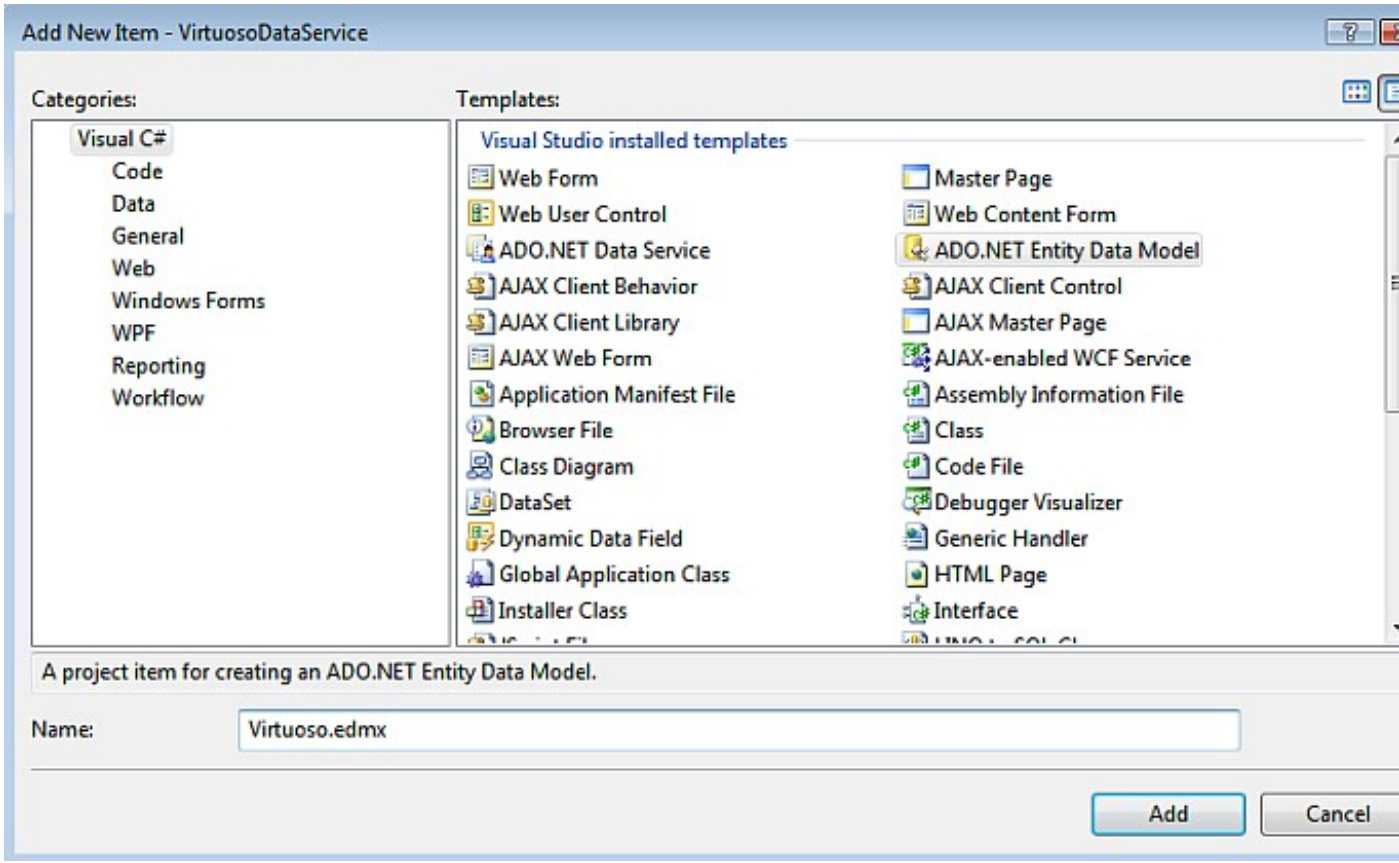
Virtuoso.edmx

and click

Add

to start the creation of the ADO.Net Entity Data Model.

Figure 8.341. Add New Item



9. In the

Entity Data Model Wizard

dialog

Choose Model Contents

page select the

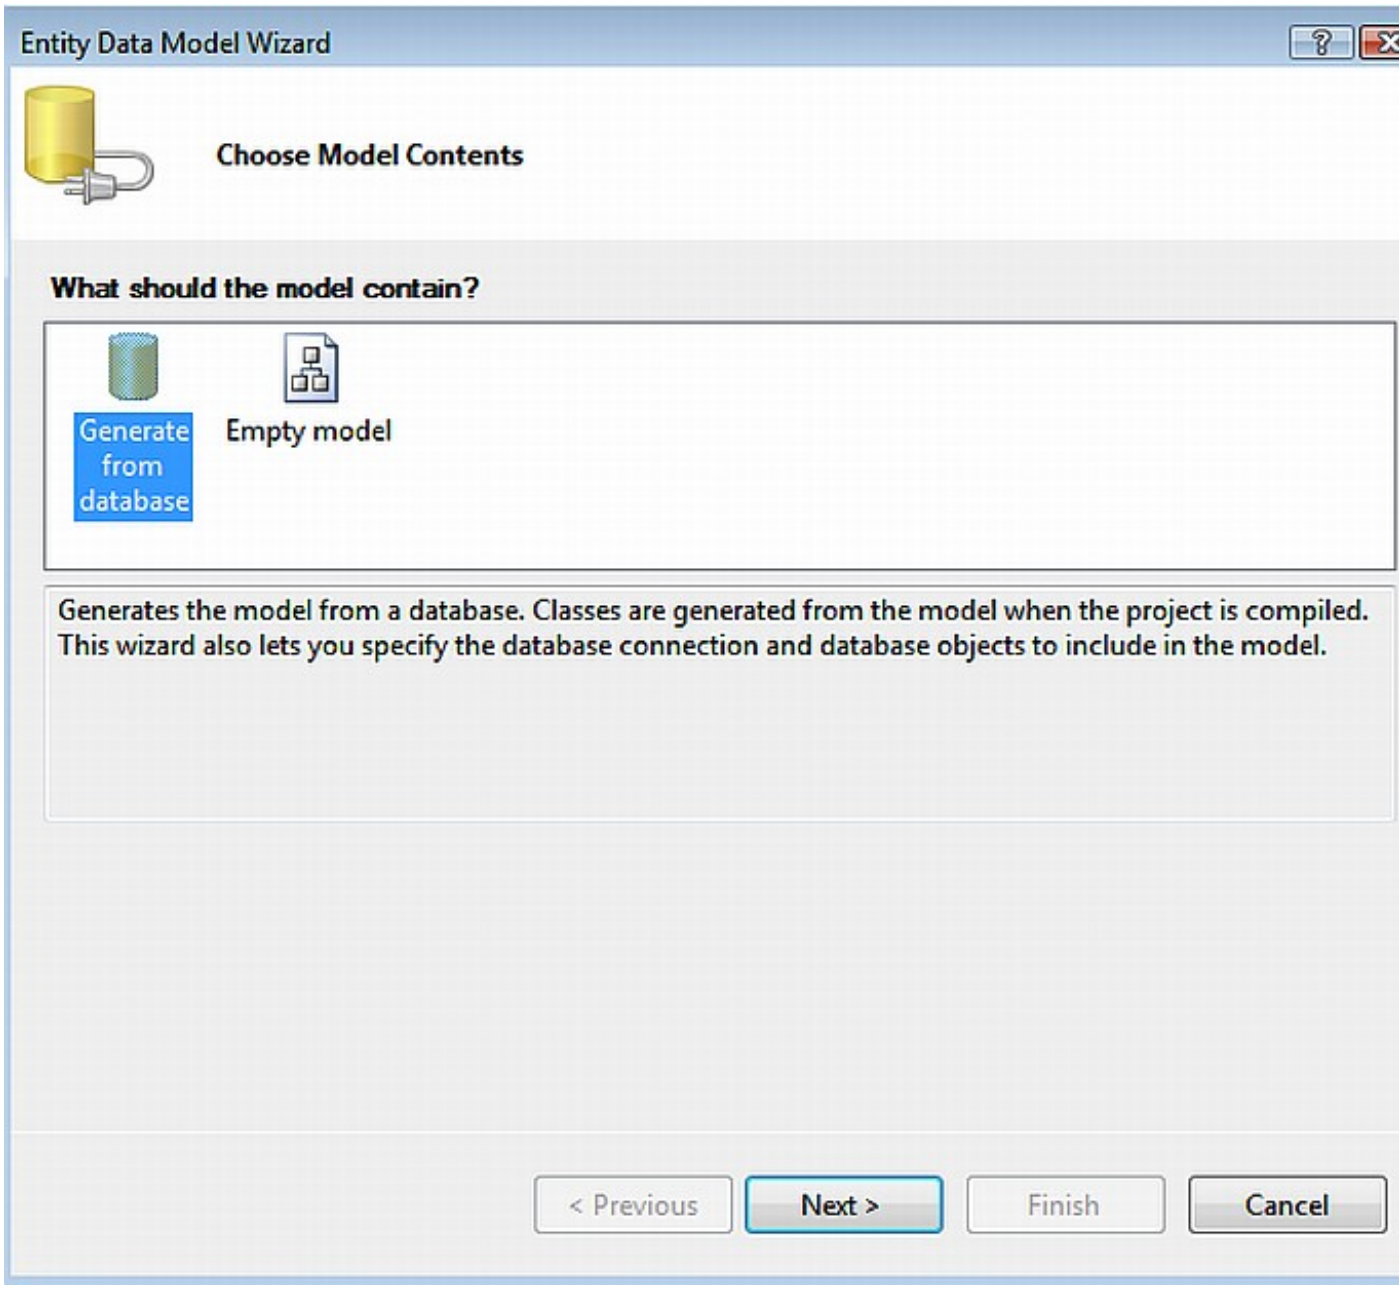
Generate from Database

model type and click

Next

.

Figure 8.342. Choose Model Contents



10. In the

    Entity Data Model Wizard

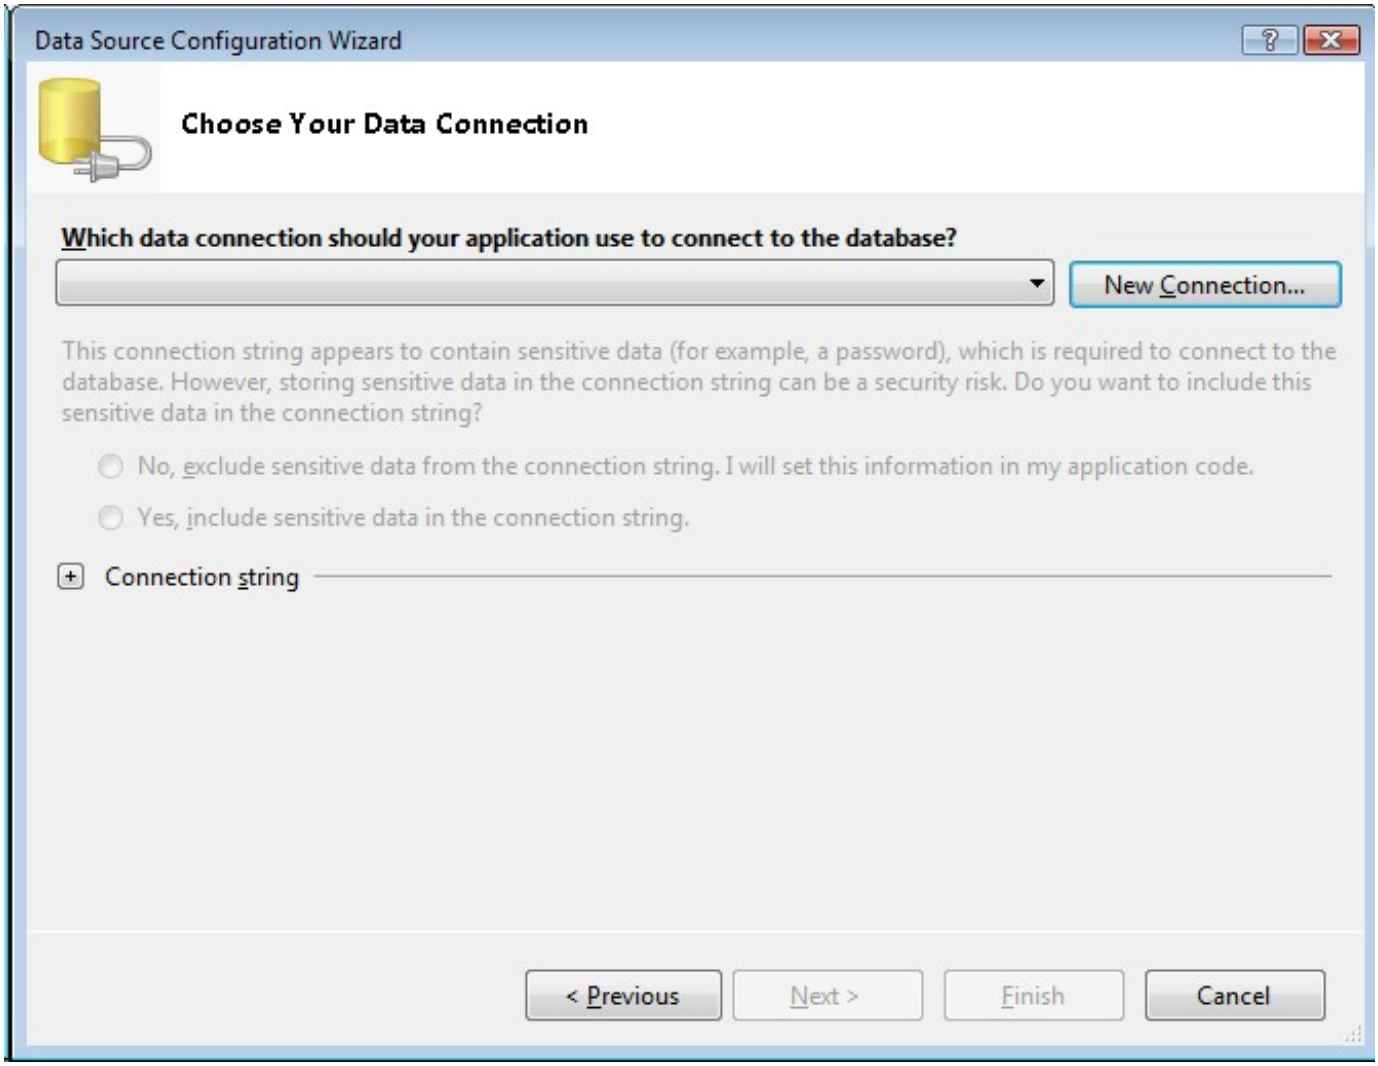
    dialog

    Choose your Data Connection

    page, select the

    New Connection button

Figure 8.343. Entity Data Model Wizard



11. In the

    Choose Data Source

    dialog, select the OpenLink

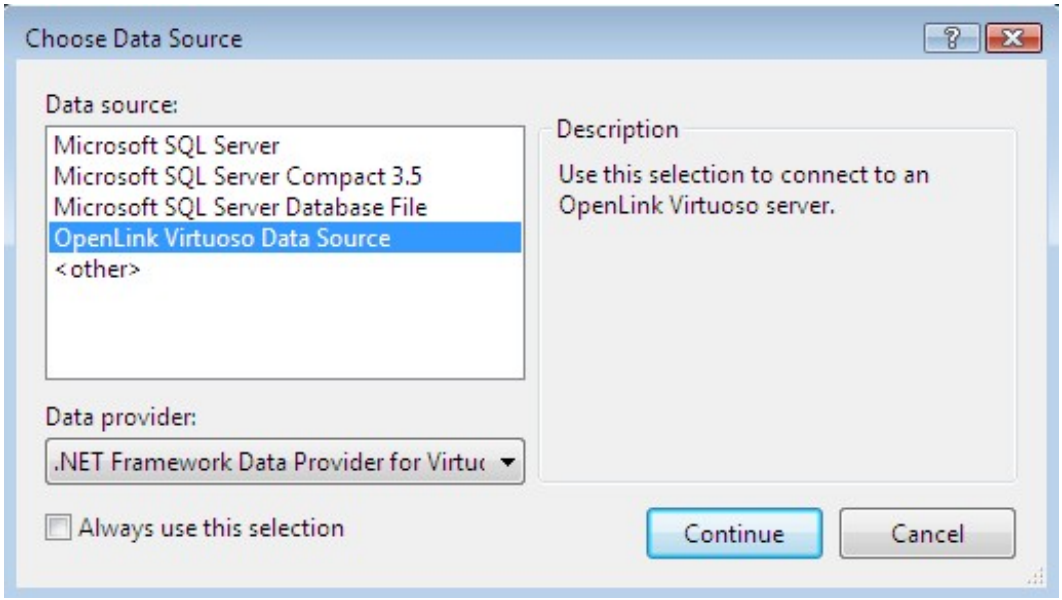
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.344. Choose Data Source



12. In the

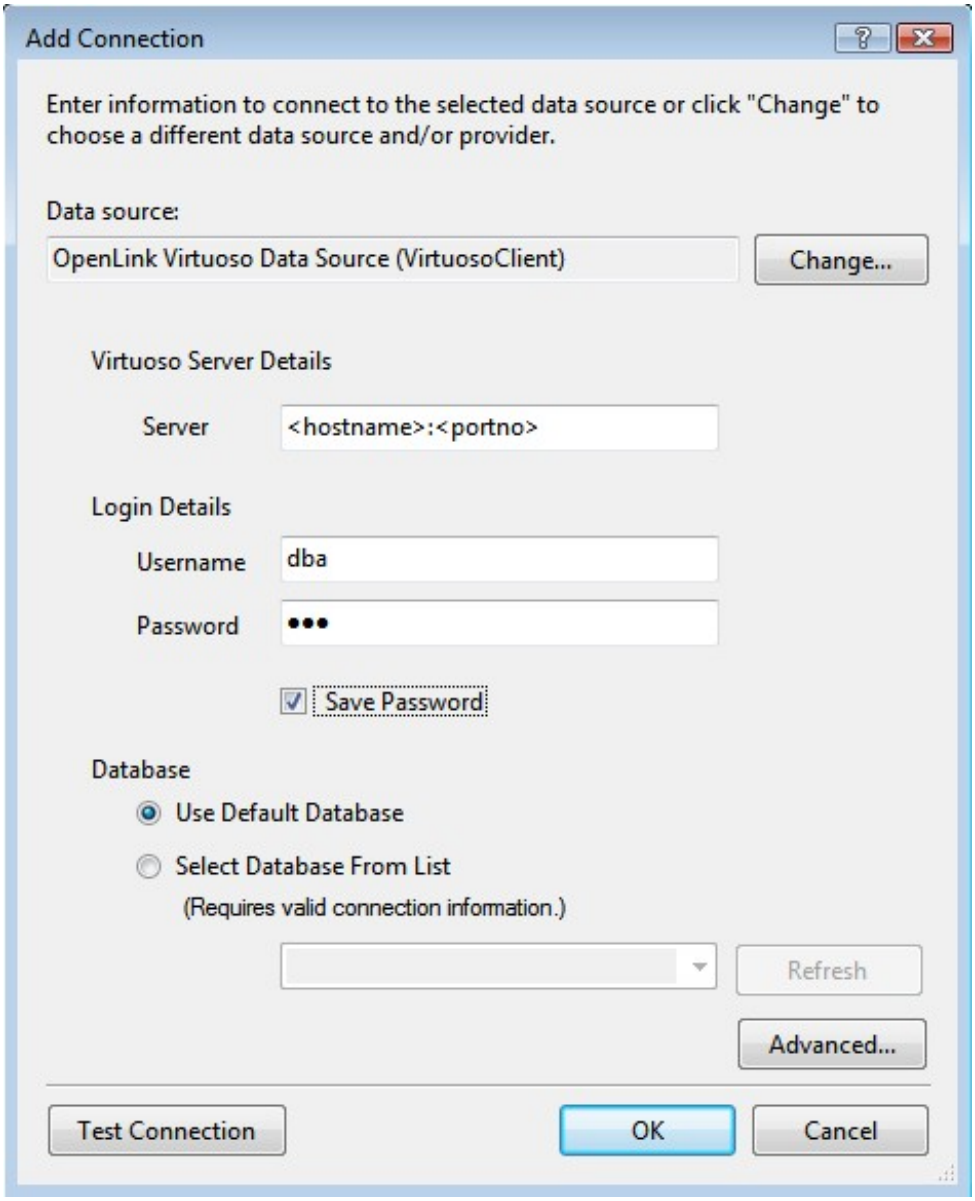
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.345. Connection Properties



13. Select the

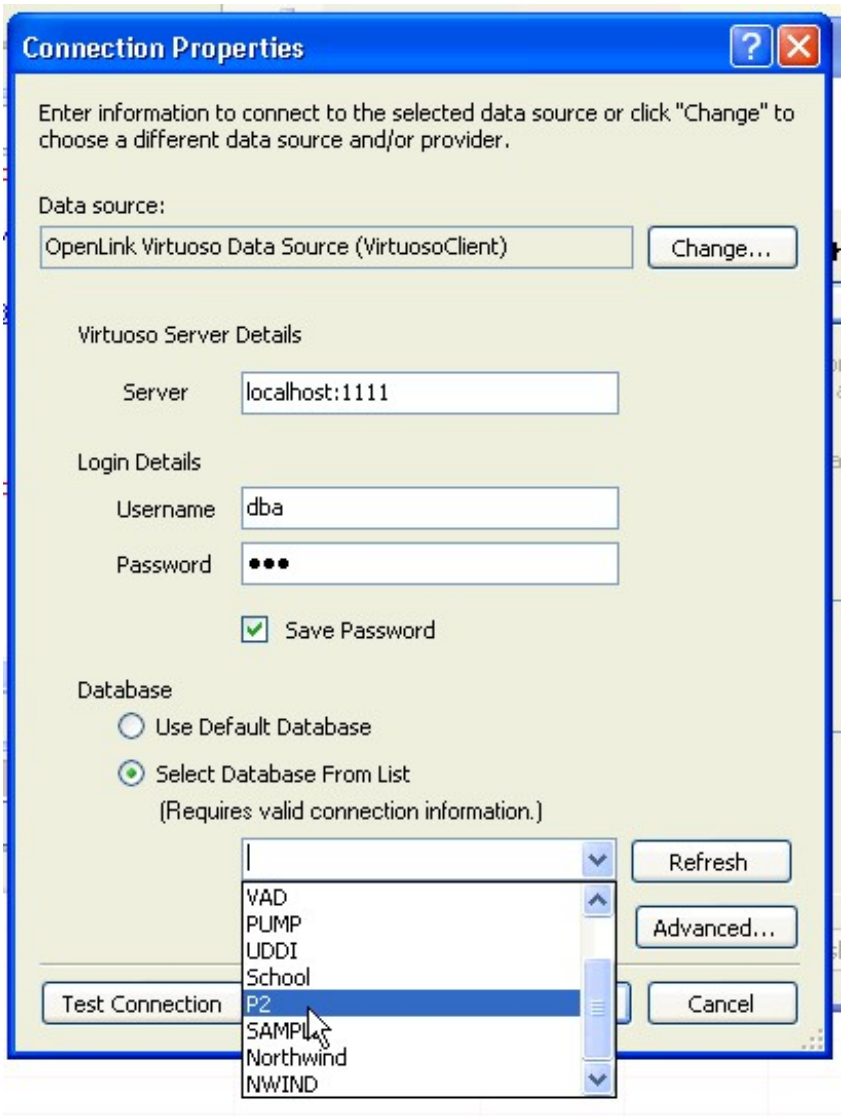
    Select Database From List

    radio button and choose the

    SAMPLE

    database from the drop down list.

Figure 8.346. Add connection

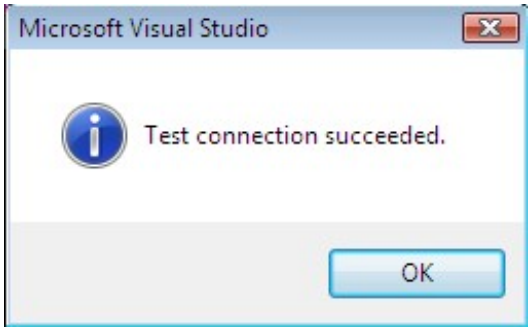


14. Press the

    Test Connection

    dialog to verify that the database is accessible.

    Figure 8.347. Test Connection



15. Set the

    entity connect string

    name to

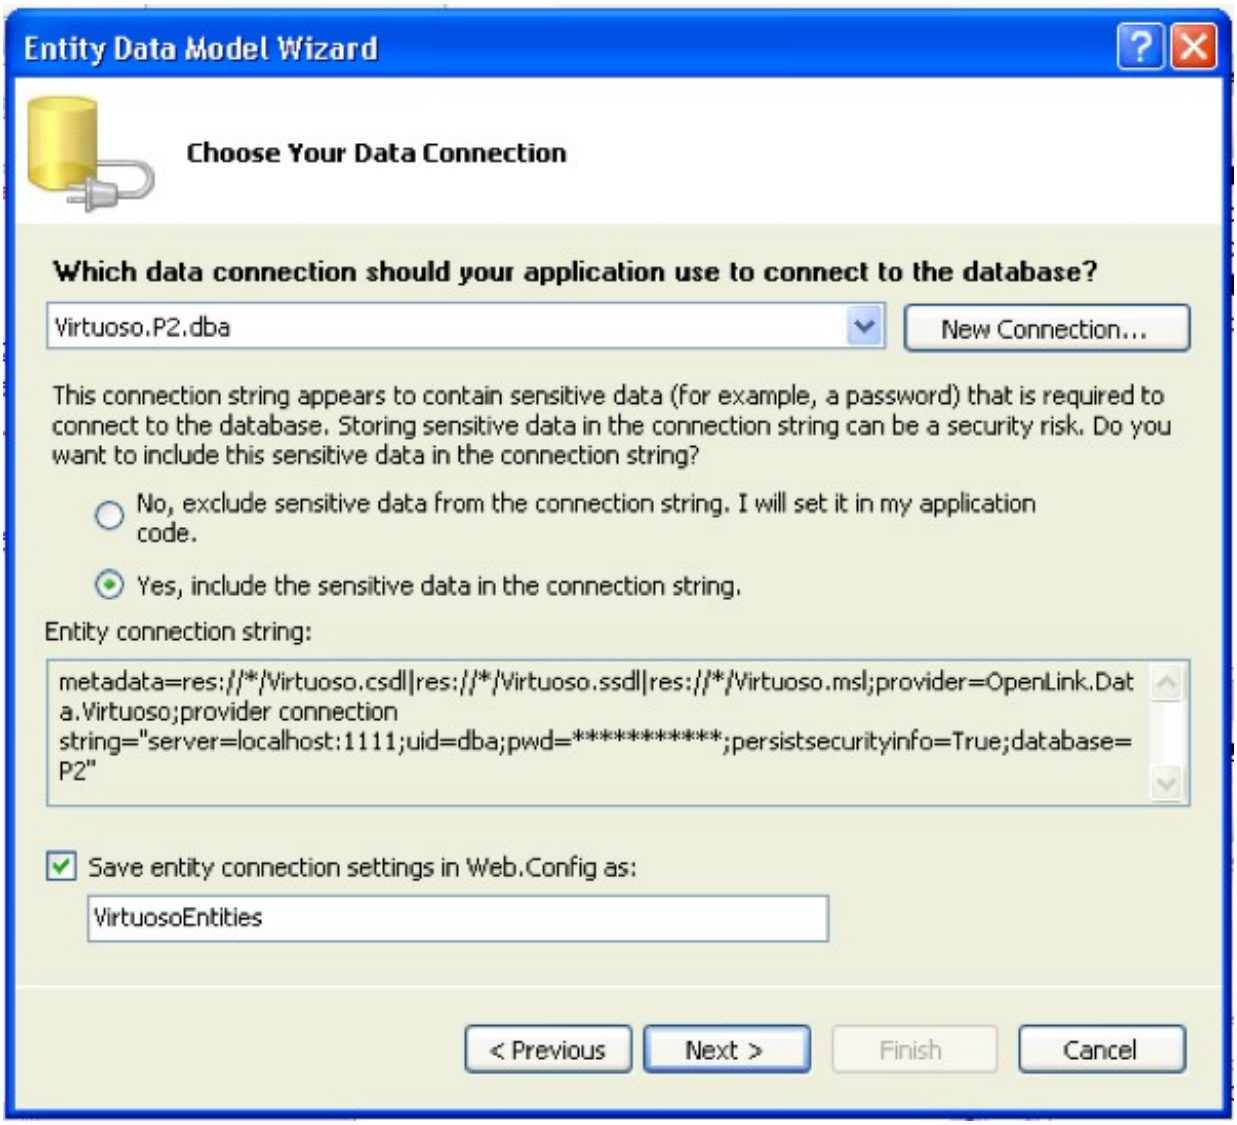
VirtuosoEntities

(note this name as it is required in the section on creating and ADO.Net Data Service) and click

Next

.

Figure 8.348. entity connect string



16. In the

Choose your Database Objects

page select the

Tables

check box to select all tables in the P2 catalog for addition to the Entity Data Model. Set the

Model Namespace

to

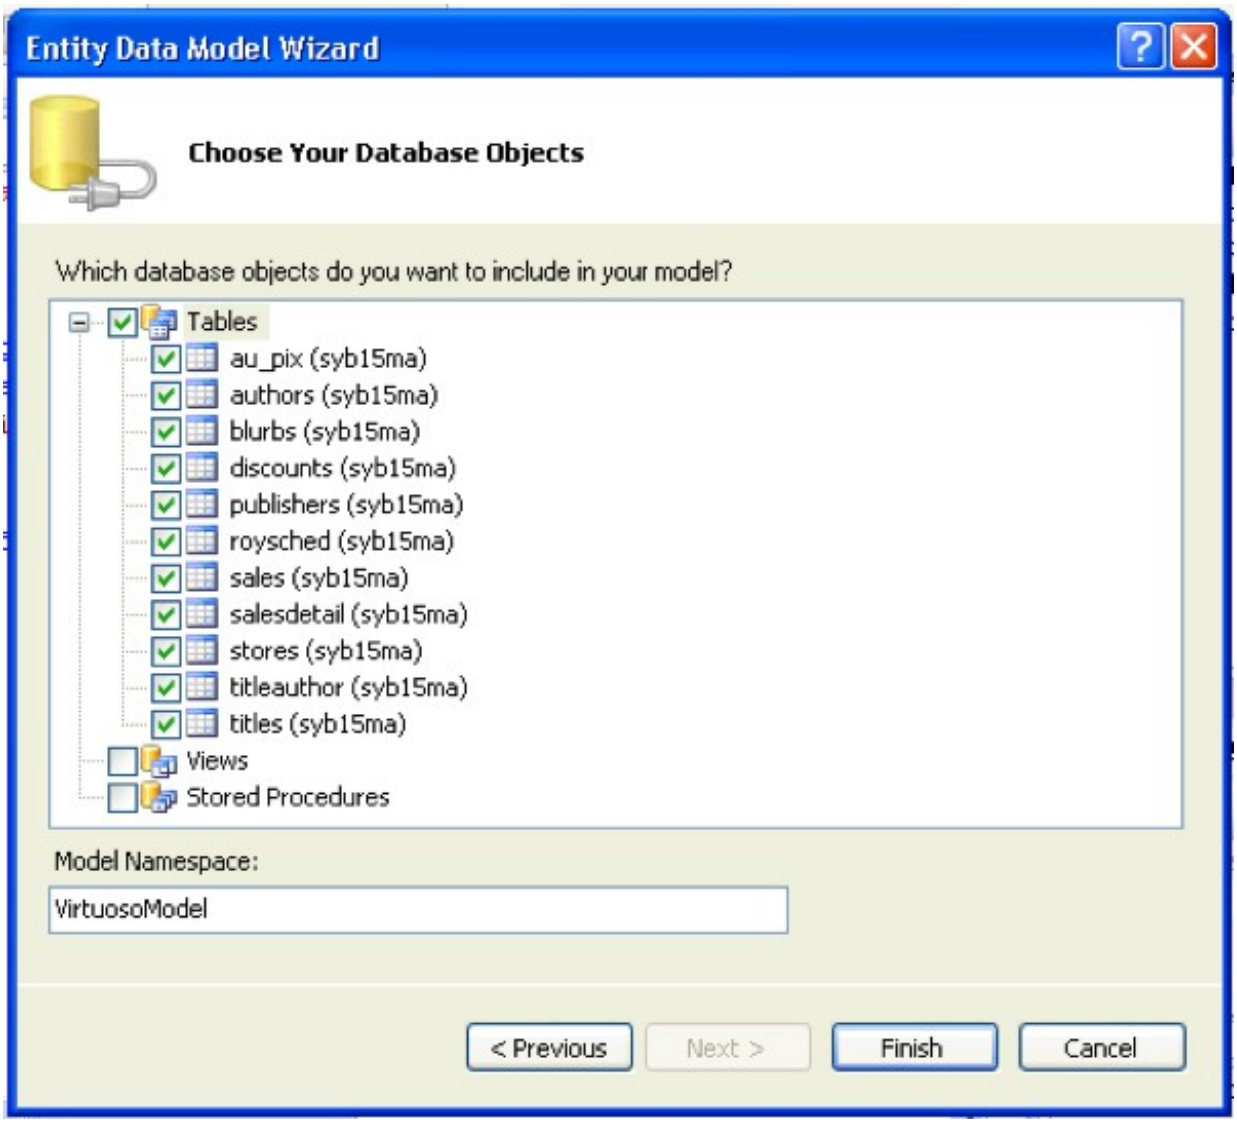
VirtuosoModel

and click

Finish

.

Figure 8.349. Database Objects

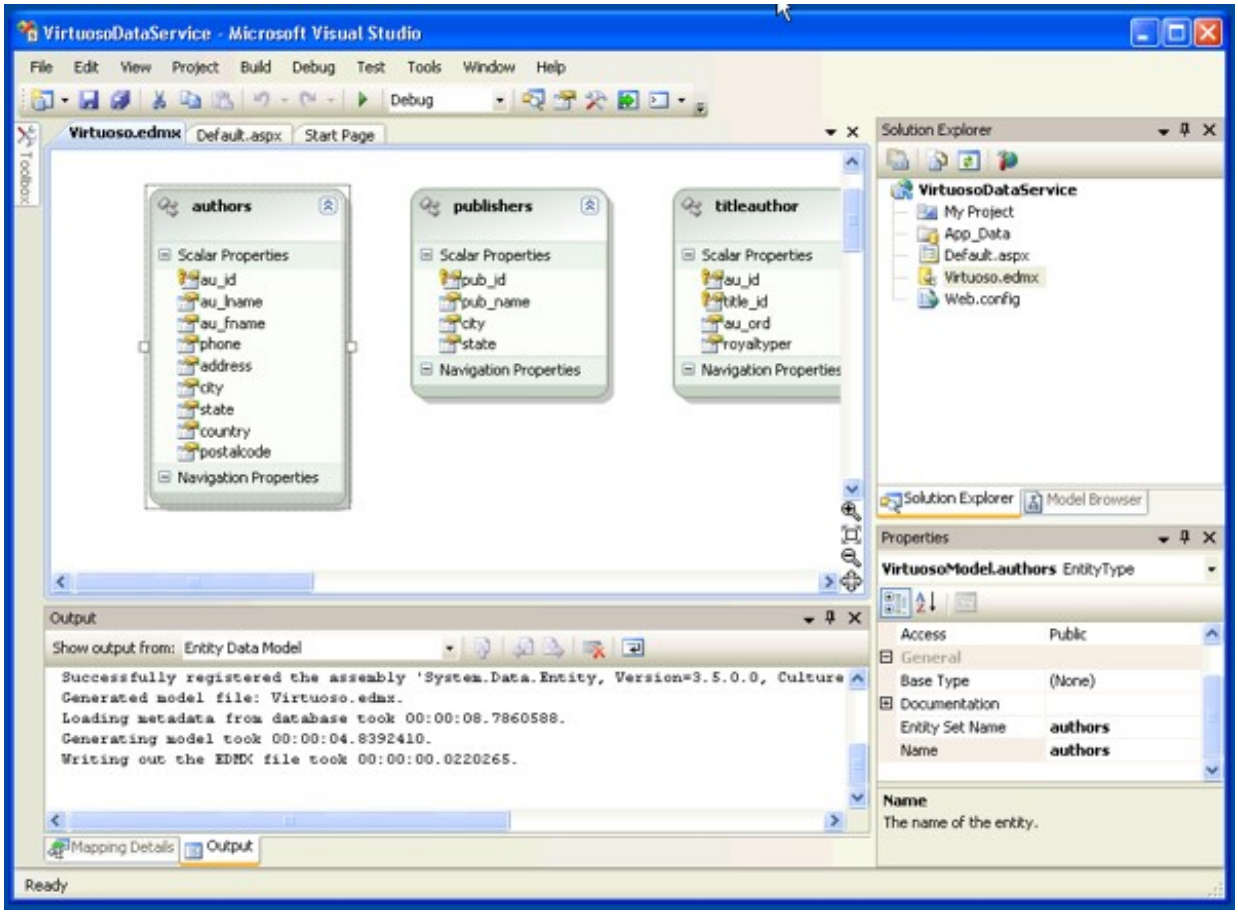


17. The

Virtuoso.edmx

EDM will be created with the tables and relationships displayed in the Visual Studio IDE

Figure 8.350. Virtuoso.edmx



Creation for the Entity Data Model for the Sybase pubs2 database is now complete.

8.7.5. Manually creating EDM Associations (FKs) for the Sybase pubs2 database

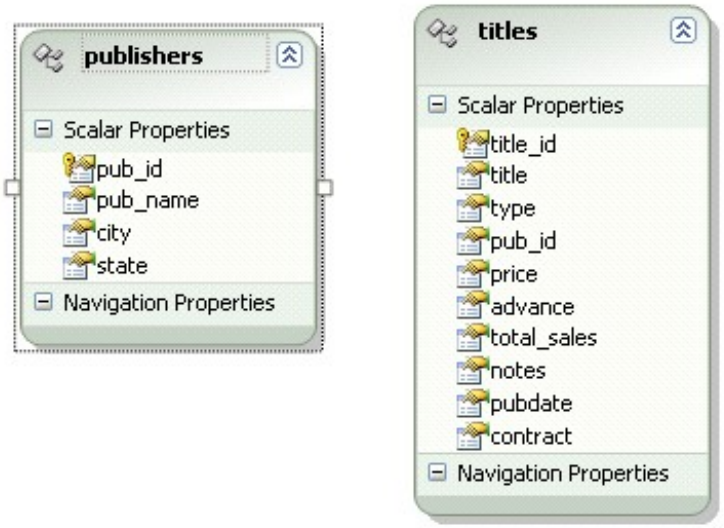
The following steps will detail what is required to manually create "Associations" in your Entity Data Model.

You will need to determine where these associations exist and their multiplicity (one-to-one, one-to-many, etc.) before commencing with the following steps.

Note: These steps will need to be repeated for each association.

1. The first Association will deal with is the relationship between publishers and titles, identified by the presence of the scalar property pub_id in both entities. This is a one-to-many relationship, as a Customer may have any number of Invoices.

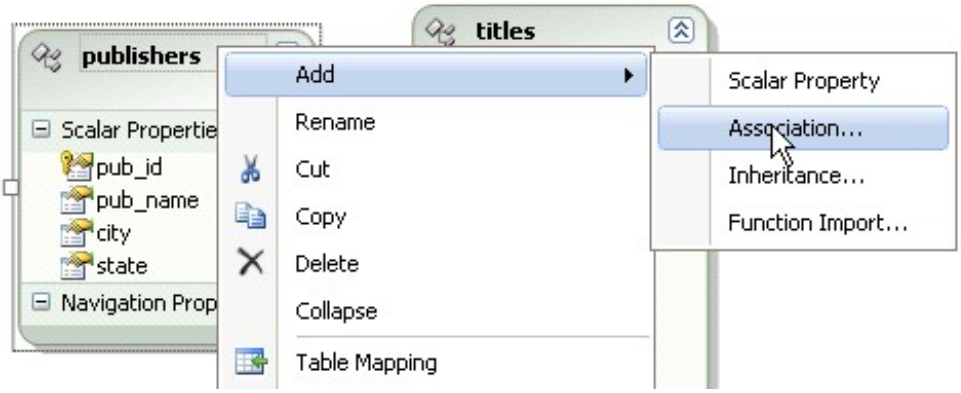
   Figure 8.351. Association



This is a one to many relationship insomuch that publishers may have zero or many titles.

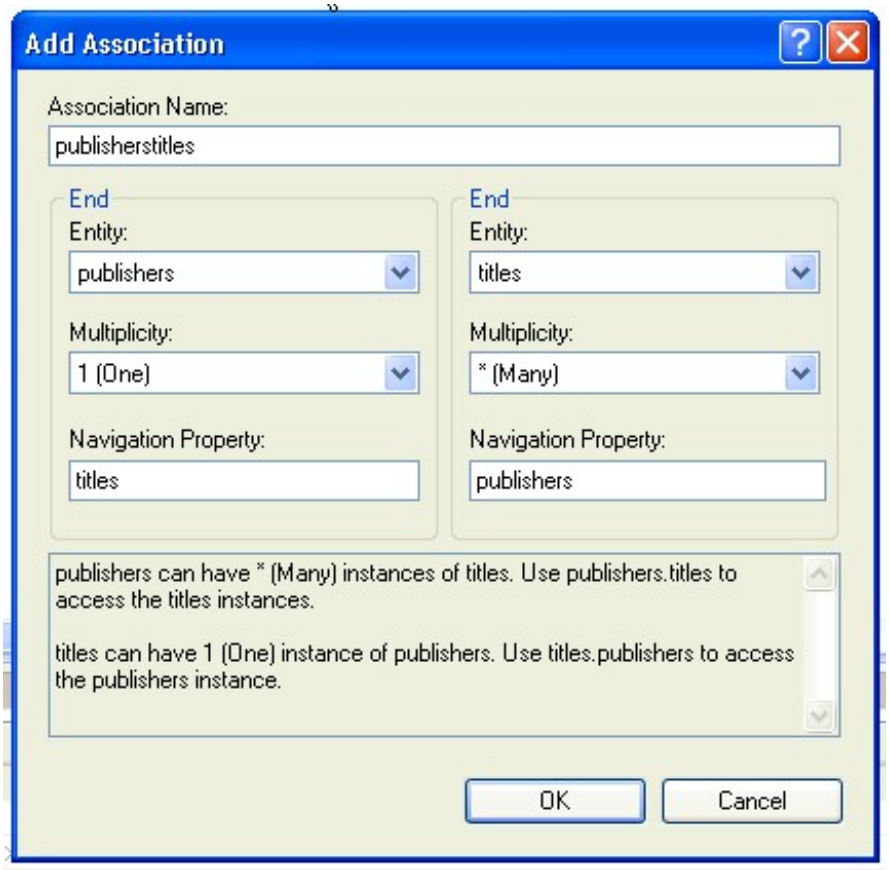
2. To add the Association, right click on the publishers entity then Add -> Association.

Figure 8.352. add the Association



3. You will now see the Add Association dialog.

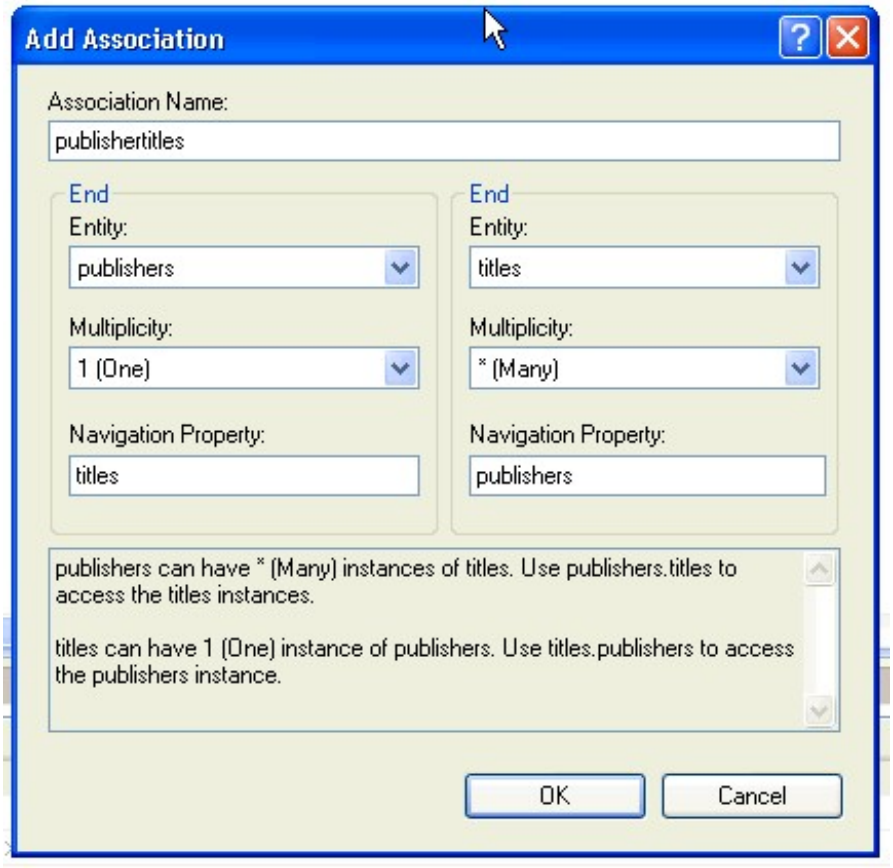
Figure 8.353. Add Association dialog



4. For this association the only thing that needs changing is the name of the Navigation Property from publishers to publisher on the publishers end of the association.

   This more correctly reflects the multiplicity of the association such that a publisher is associated with zero or many titles (plural).

   Figure 8.354. Navigation Property name

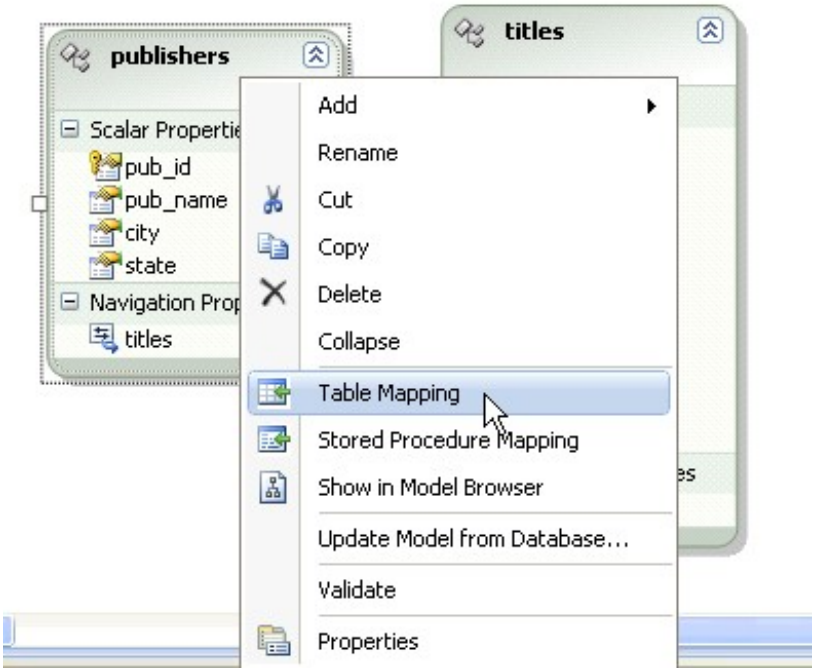


5. Once you then hit OK the diagram is refreshed to include the newly created association.

Figure 8.355. diagram

6. You now need to edit the mappings associated with the newly created association, so right-click the association on the diagram, and select Table Mapping to display the Mapping Details pane.

Figure 8.356. Table Mapping

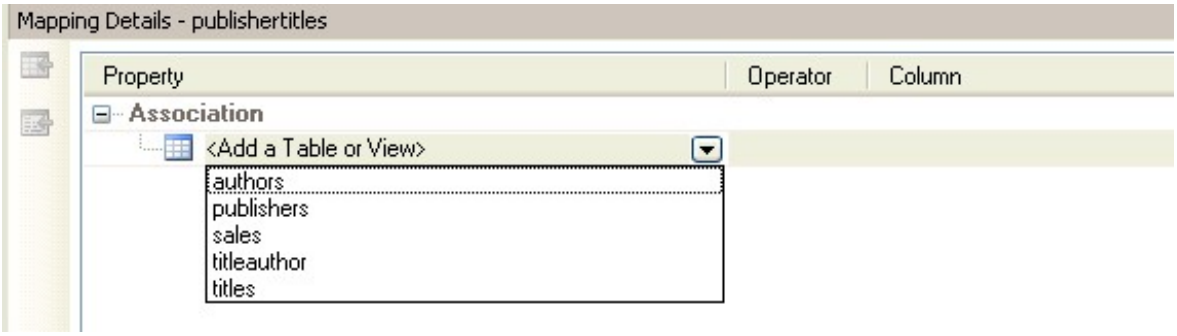


7. Click that line reading <Add a Table or View> to reveal a drop down list of all entities.

Figure 8.357. Add a Table or View

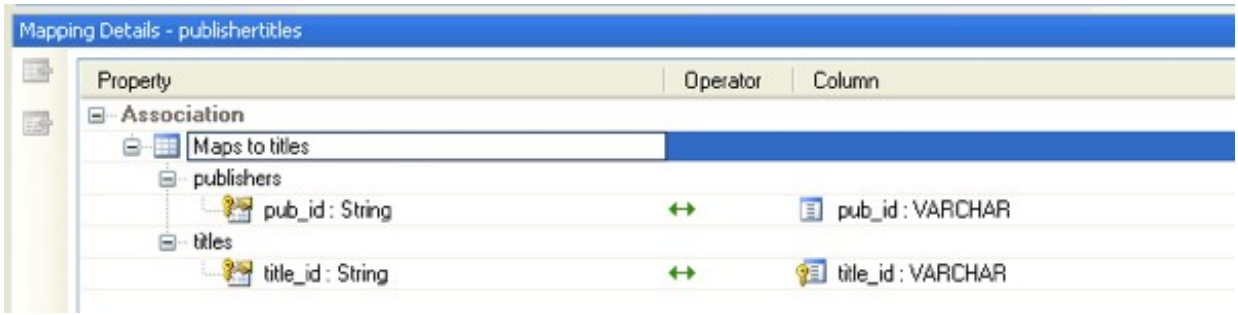
8. Here you need to select the entity on the right/far side of the association (the entity where the foreign key exists). In this example, it is the titles entity.

Figure 8.358. Entity



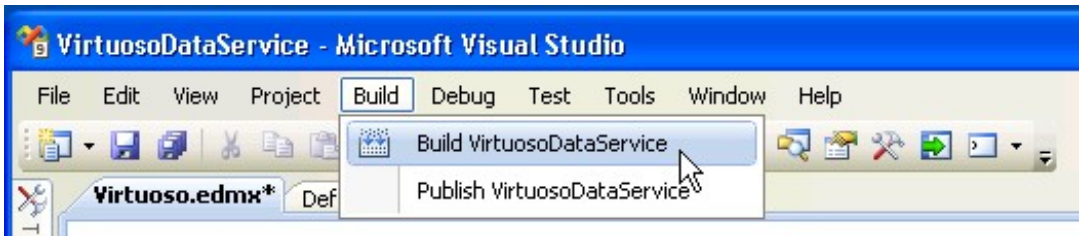
9. The Mapping Details pane now refreshes to display both ends of the association, requiring that you provide relevant target store data types in the Column column for the key fields, as depicted here.

Figure 8.359. Mapping Details



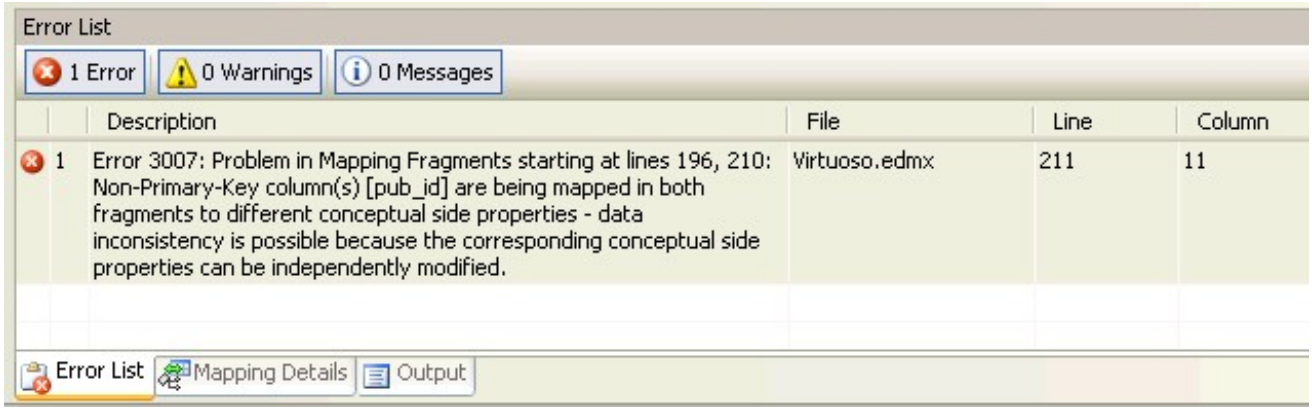
10. Once the mapping is complete, you can build the project using Build -> Build Solution. NOTE: It is worthwhile building as each association is made, since the error messages can be a little confusing.

Figure 8.360. Build the project



11. This should result in the following error:

Figure 8.361. Error

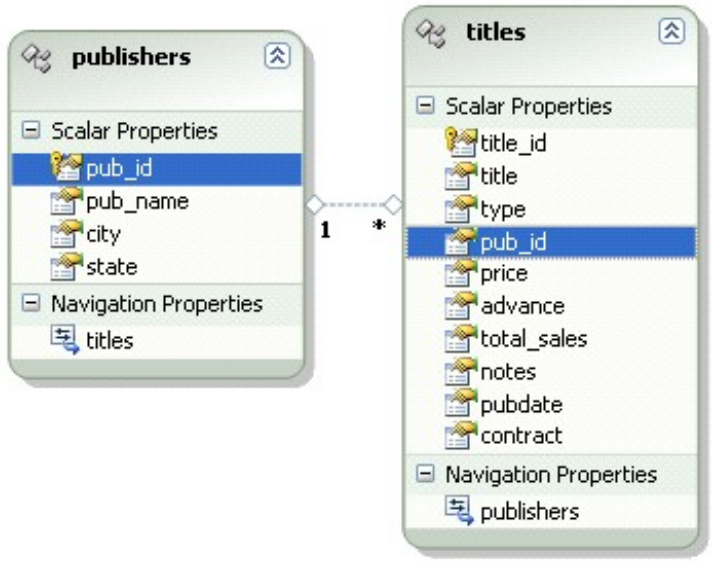


It seems that this error is attempting to say that there are two mappings which map to the same target source column.

In this case it is the target column titles.pub_id.

That is, the scalar property pub_id and the Navigation Property publishers in the Invoice entity, both map to the Sybase table column titles.pub_id - which is not supported

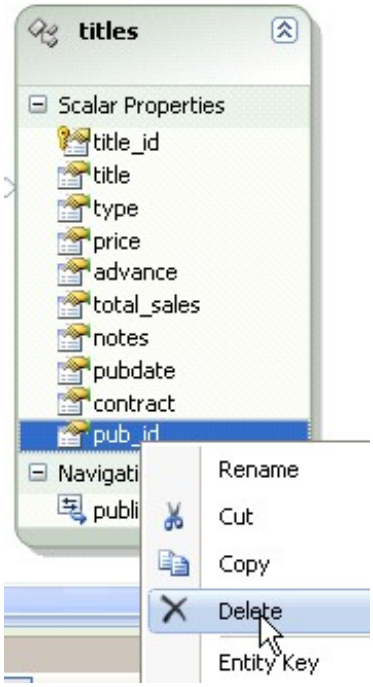
Figure 8.362. Error



12. The solution is simple! Simply delete the scalar property titles.pub_id since its purpose is only to hold data representing a relationship/association (it is a Foreign Key) which has already been represented by the newly created association and resulting Navigation Property publishers.

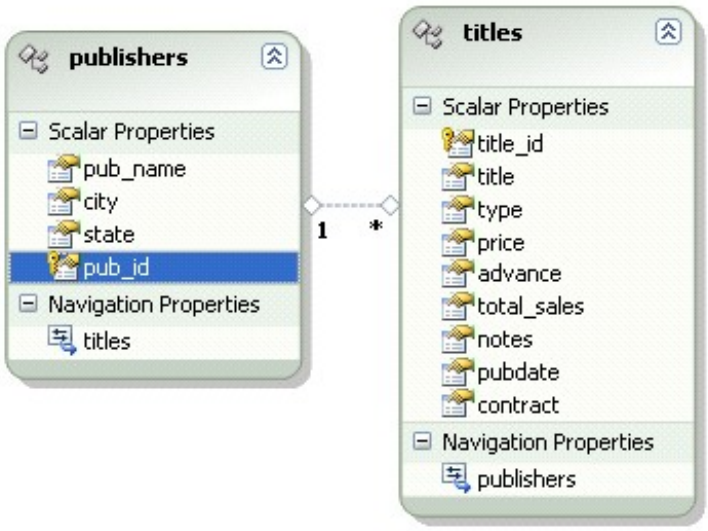
    Right click on titles.pub_id then Delete.

    Figure 8.363. delete the mapping



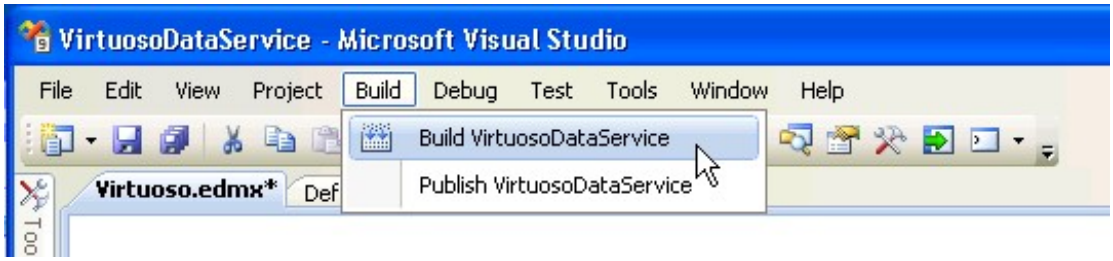
13. The model diagram will refresh to reflect this change.

    Figure 8.364. Model Diagram



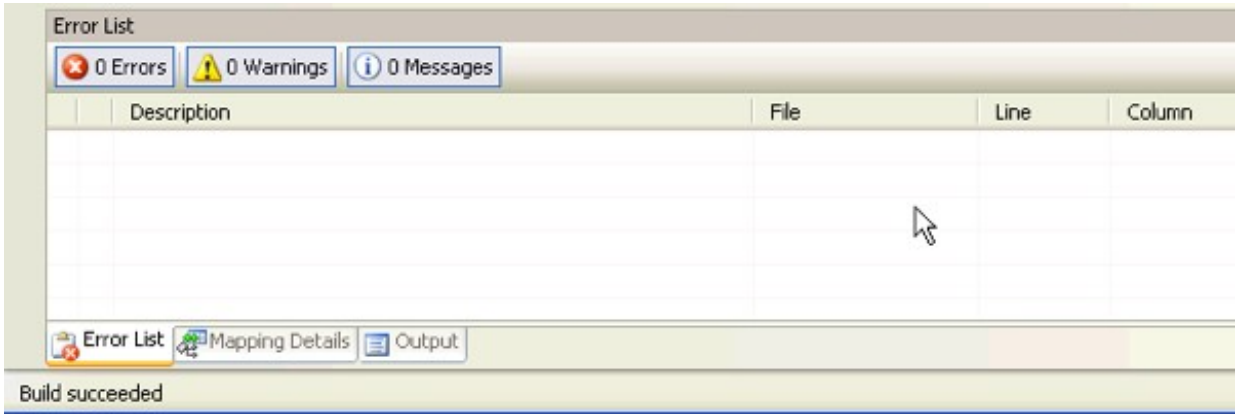
14. Build the project, again, using Build -> Build Solution.

Figure 8.365. Build project



15. The project should now be fine.

Figure 8.366. Build Project



You will need to repeat these steps for each association until you have a completed Entity Data Model.

Figure 8.367. Entity Data Model

8.7.6. Using EDM to create Entity Framework based applications

Now that a Microsoft Entity Data Model has been created for the Sybase pubs2 database, Entity Framework applications can be created to make use of it.

Entity Frameworks based ADO.NET Data Service

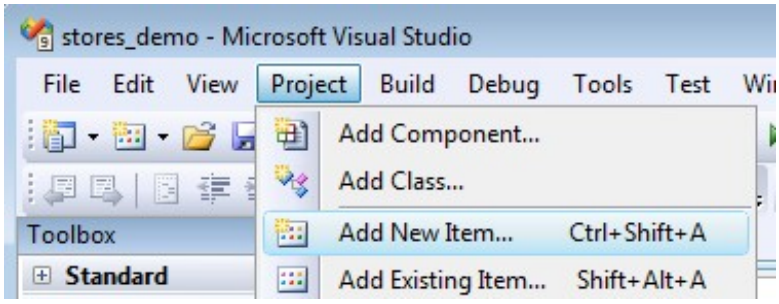
An ADO.Net Data Service for the Sybase tables can be created using the Entity Data Model created in the Creating EDM in Visual Studio 2008 section .

1. Open the

   VirtuosoDataService

   project created in the Creating EDM in Visual Studio 2008 section .
2. Select the Project -> Add New Item menu option.

   Figure 8.368. VirtuosoDataService

3. The

   Add New Item

   dialog will appear. Choose the

   ADO.NET Data Service template

   . Give it the name

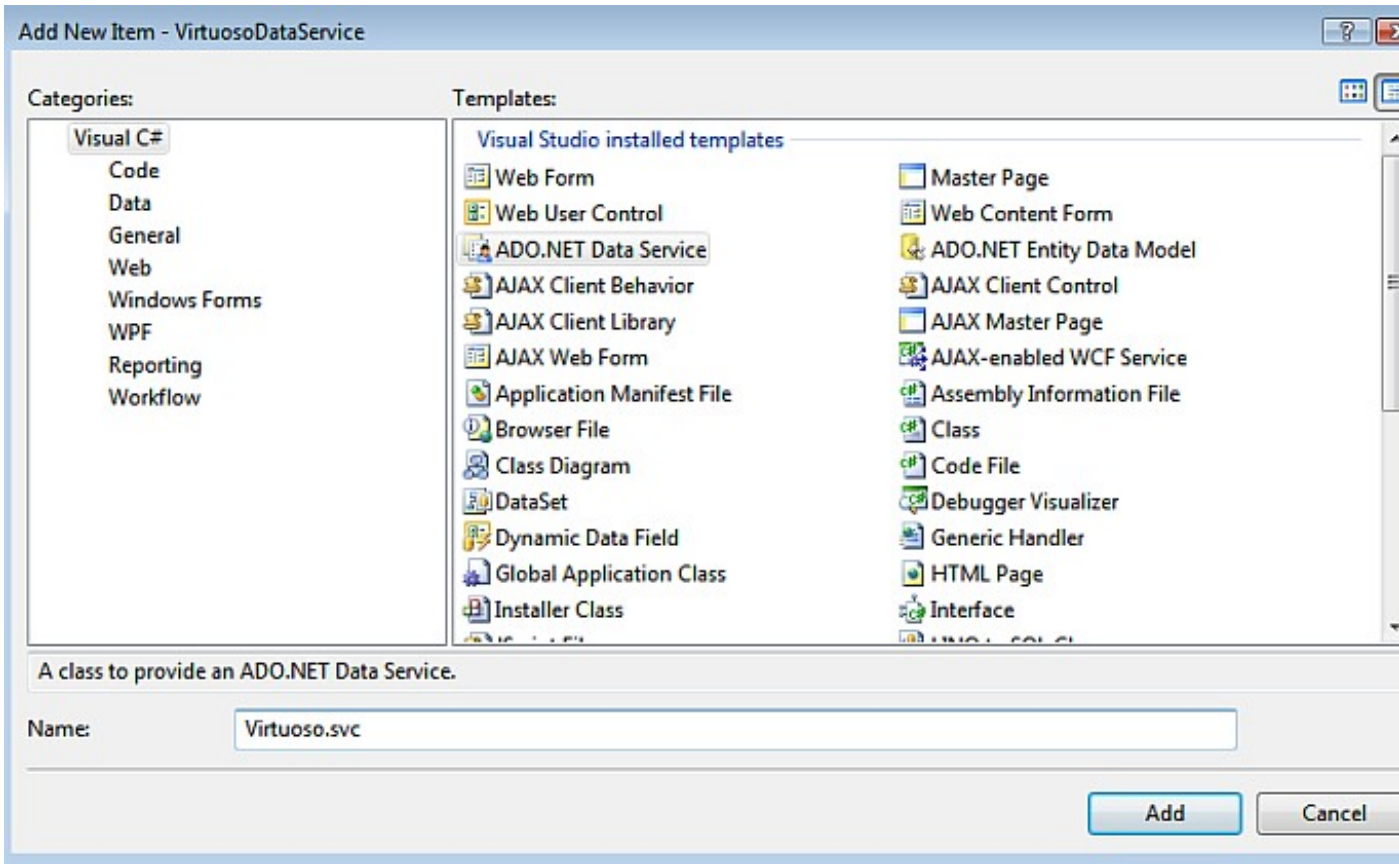
   Virtuoso.svc

   , and click

Add

to create the ADO.Net Data Service.

Figure 8.369. Add New Item



4. In the newly created

   Virtuoso.svc.cs

   Data Service file, add the data source class name of

   VirtuosoEntities

   (note this is the name set in the Creating EDM in Visual Studio 2008 section) as the

   DataService

   name. Enable the access to the Data Service by adding the entry

   config.SetEntitySetAccessRule("", EntitySetRights.All);*

   in the

   InitializeService

   method.

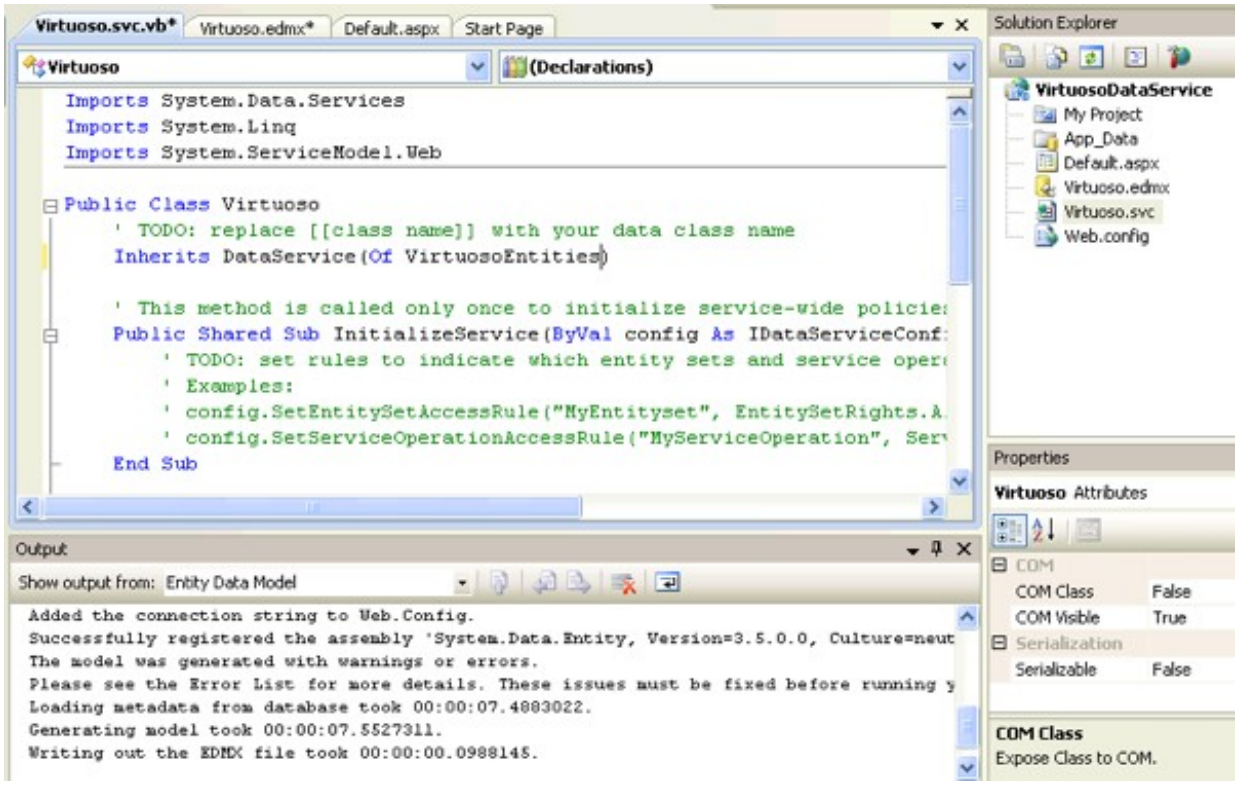
```
// C#

using System;
using System.Web;
using System.Collections.Generic;
using System.ServiceModel.Web;
using System.Linq;
```

```
using System.Data.Services;

namespace SimpleDataService
{
    public class Northwind : DataService<VirtuosoDemoEntities>
    {
        public static void InitializeService(IDataServiceConfiguration  config)
        {
            config.SetEntitySetAccessRule("*", EntitySetRights.All);
        }
    }
}
```

Figure 8.370. Virtuoso.svc.cs

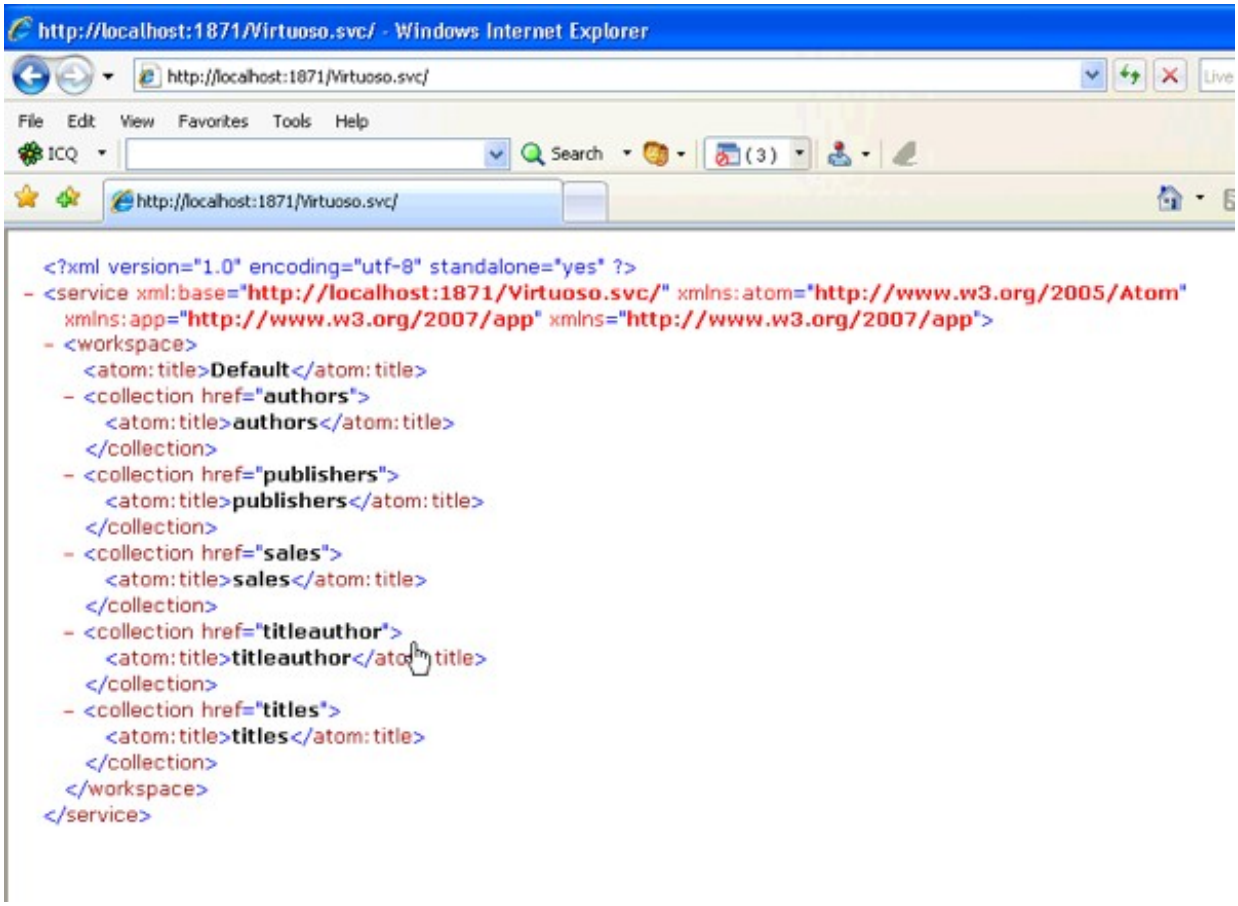


5. To test the Data Service, simply hit

   Ctrl+F5

   within Visual Studio. This will start the development web server, run the Data Services server inside and load a Web browser page displaying the list of available tables/entities for the P2 database catalog.

Figure 8.371. Data Service test



6. To access a specific entity instance like the

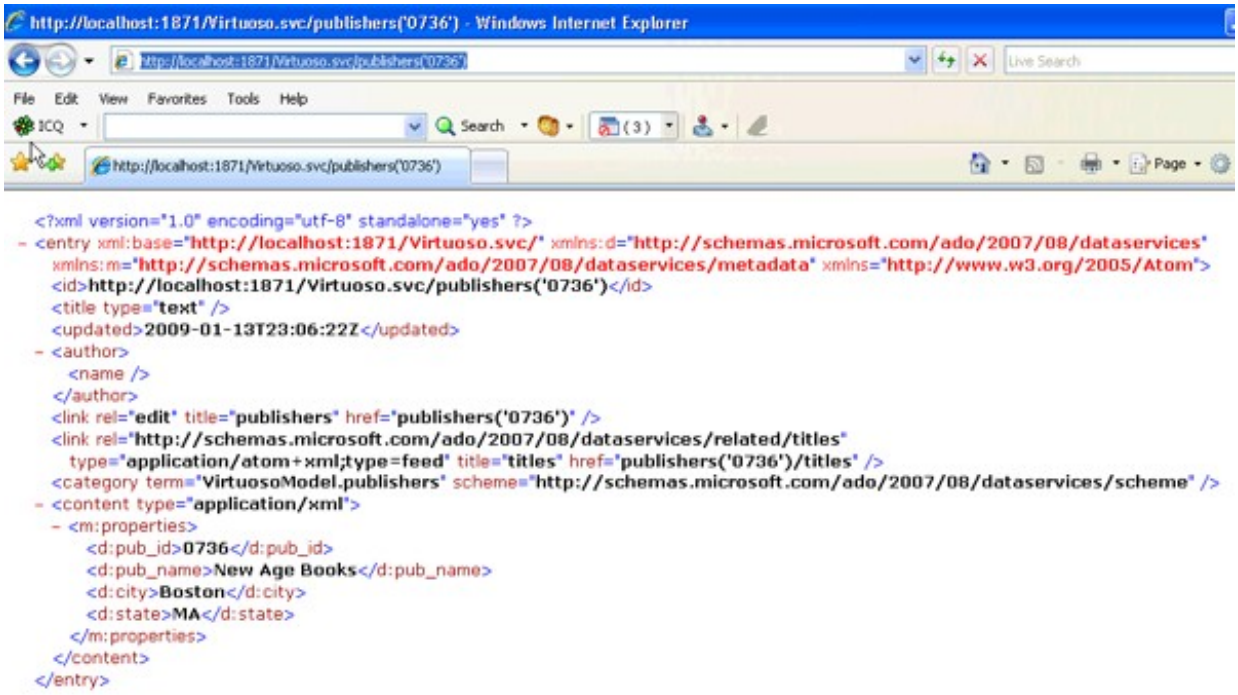
   publisher

   table publisher number

   0736

   record, use this convention http://host/vdir/Virtuoso.svc/publishers("0736") .

   Figure 8.372. publisher



Notes:

1. *Important*

   - To view

   Atom

   (the default format returned by an ADO.NET Data Service) in Internet Explorer, you must first ensure that

   Feed Reading View

   is turned

   off

   . This can be done on the

   Content tab

   of

   Tools in Internet Options

   .
2. If a Data Services entity instance URI page fails to load you can turn

   Verbose

   errors on by adding

   config.UseVerboseErrors = true;

in the

virtuoso.svc.cs InitializeService

method to obtain more detailed information from the server as to why the page failed to load:

```
public static void InitializeService(IDataServiceConfiguration config)
{
config.UseVerboseErrors = true;
config.SetEntitySetAccessRule("*", EntitySetRights.All);
}
```

Visual Studio Windows DataGrid Form Application

This section details the steps required to create a simple Visual Studio 2008 Windows Form application, with associated DataGridView control for displaying data in selected tables from the target database.

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.373. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

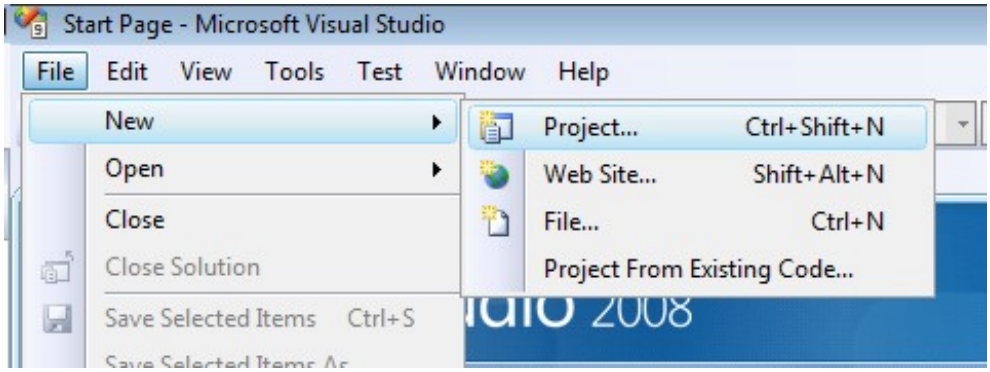
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.374. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Windows

   and select

   Windows Form Application

   from the right-hand panel.
5. Choose a name for the project, for example

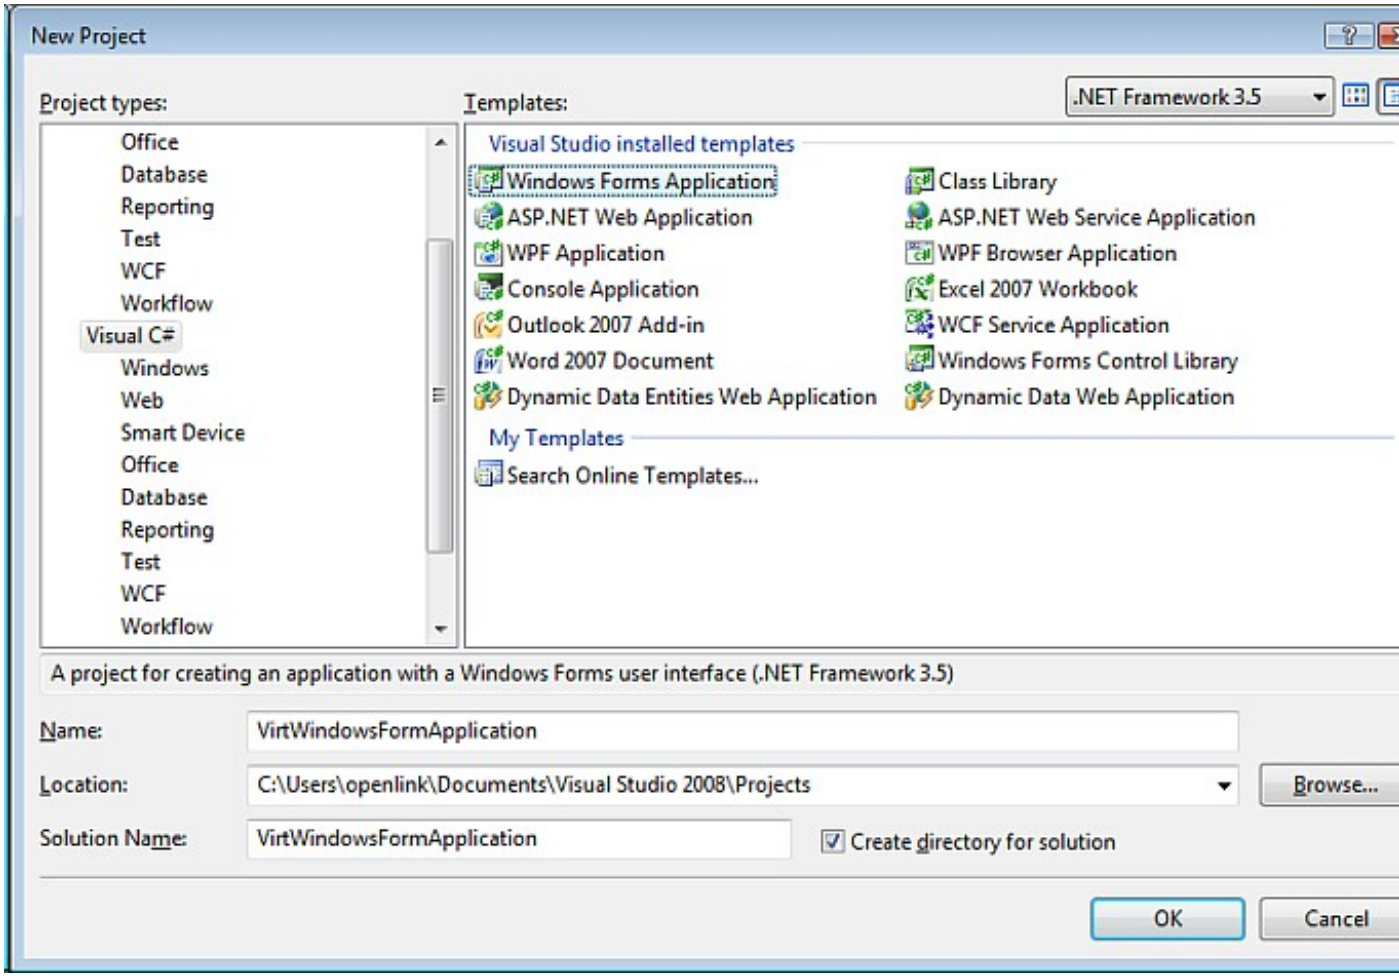
   VirtWindowsFormApplication

   , and click

   OK

   .

   Figure 8.375. Web Application



6. In the

   Toolbox

   , expand

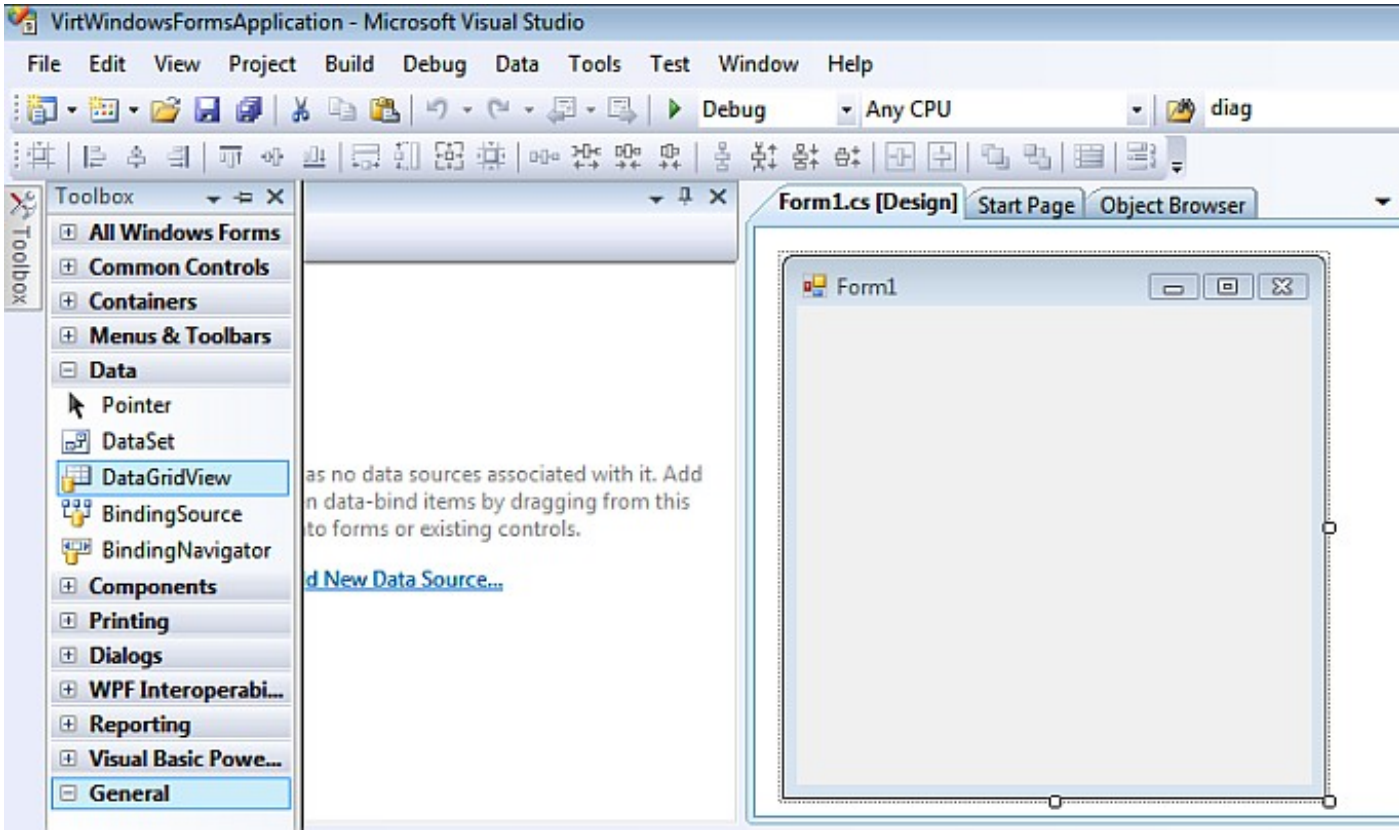
   Data Controls

   , and drag the

   DataGridView

   control onto the form.

   Figure 8.376. Toolbox



7. Click on the little

   arrow

   in the top right of the

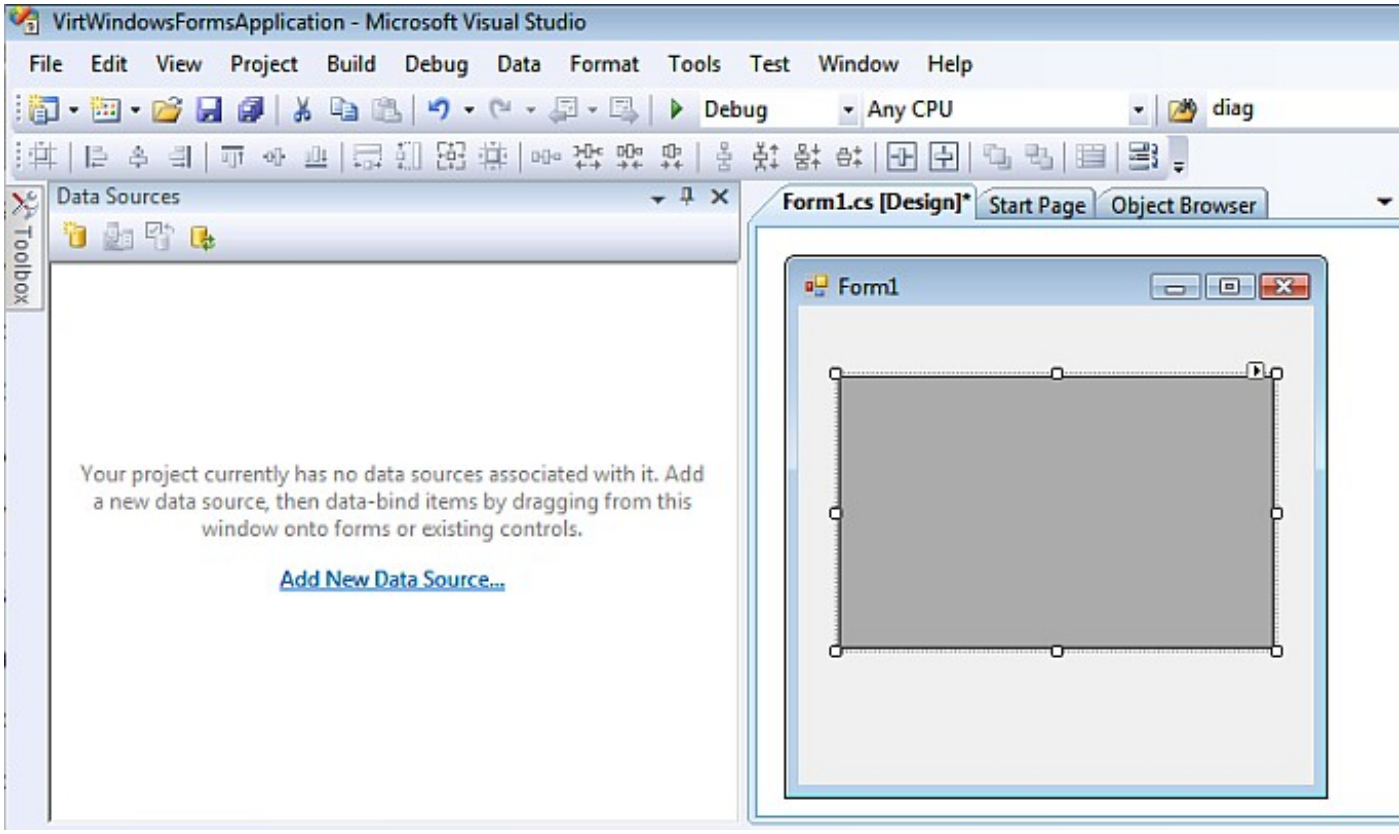
   DataGridView

   control. This loads the

   DataGridView Task

   menu.

Figure 8.377. DataGridView Task

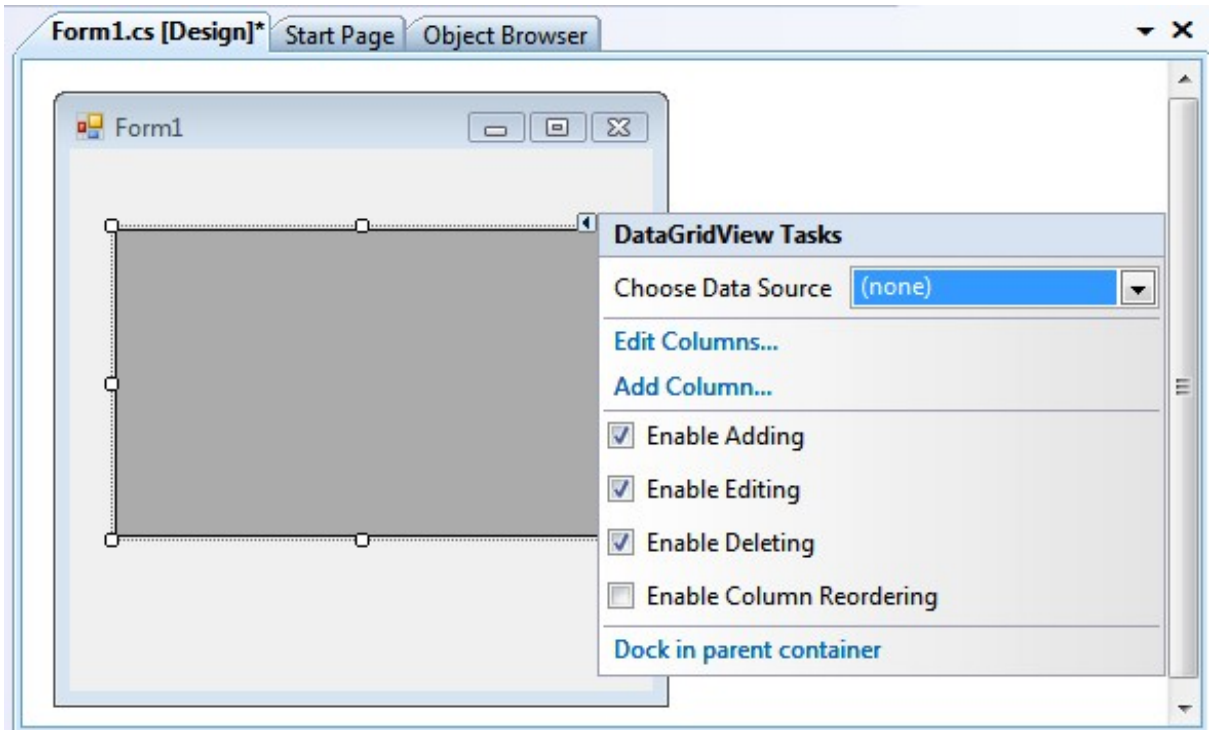


8. Click on the

   Choose Data Source

   list box.

   Figure 8.378. Choose Data Source

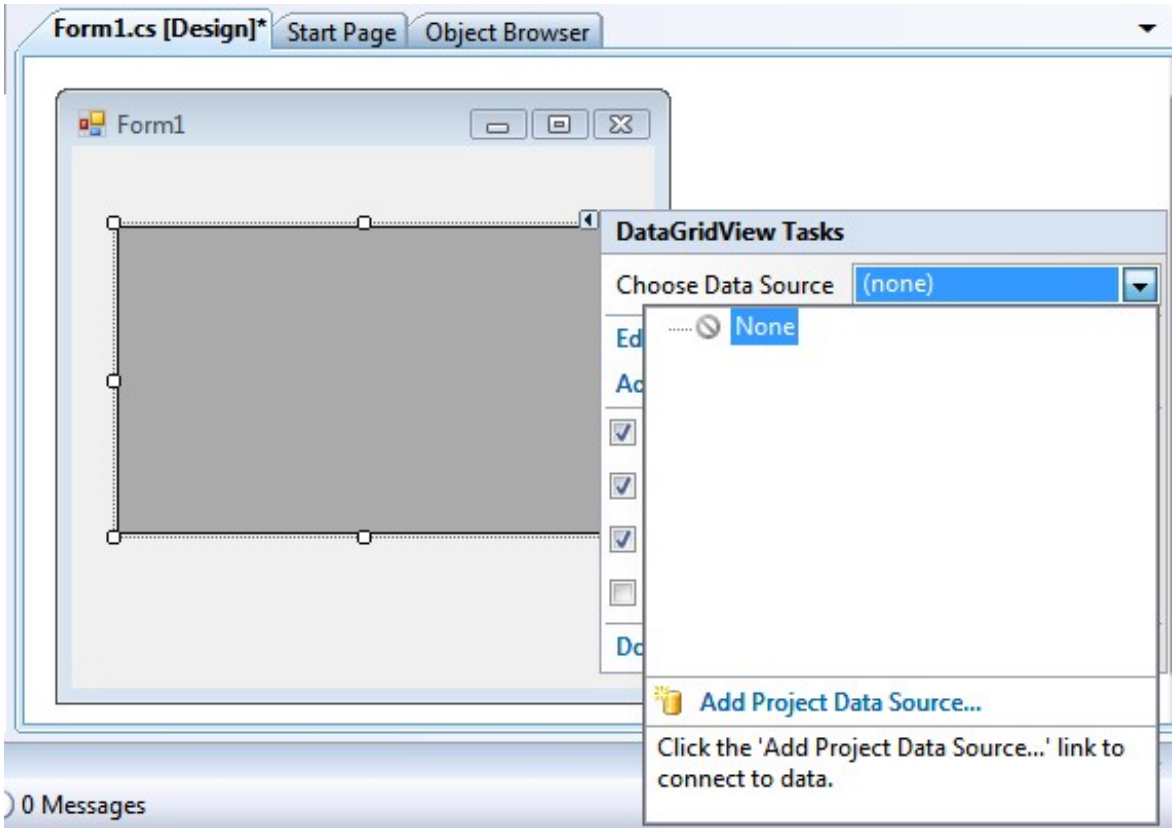


9. Click on the

   Add Project Data Source

link to connect to a data source.

Figure 8.379. Add Project Data Source



10. In the

    Data Source Configuration Wizard

    dialog

    Choose Data Source Type

    page select the

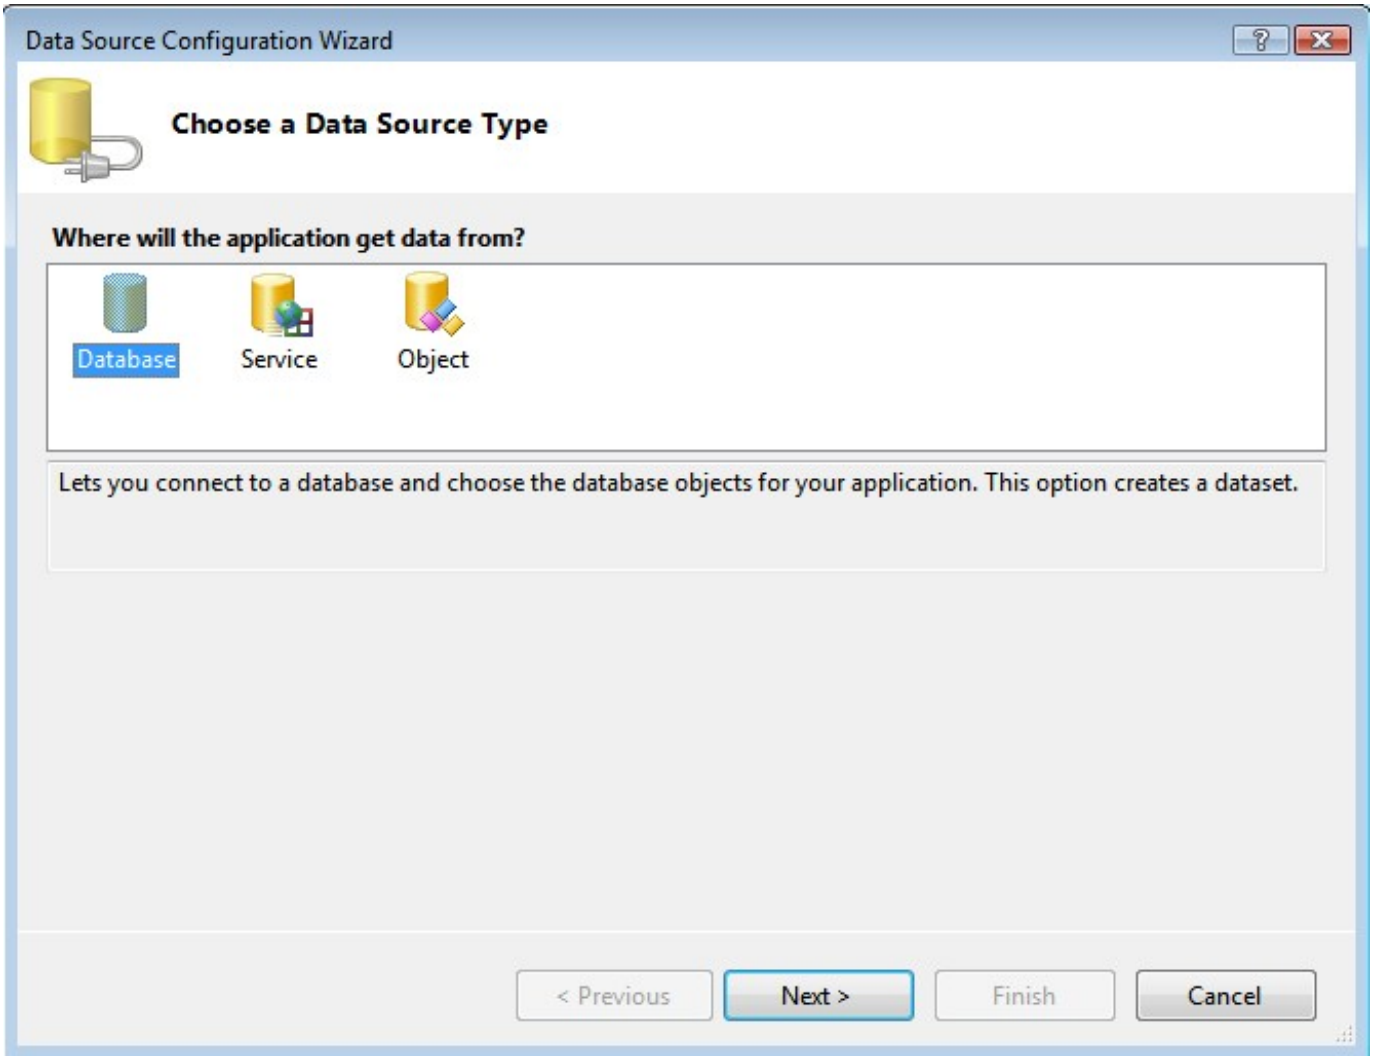
    Database

    data source type and click

    Next

    .

Figure 8.380. Data Source Type



11. In the

    Data Source Configuration Wizard

    dialog

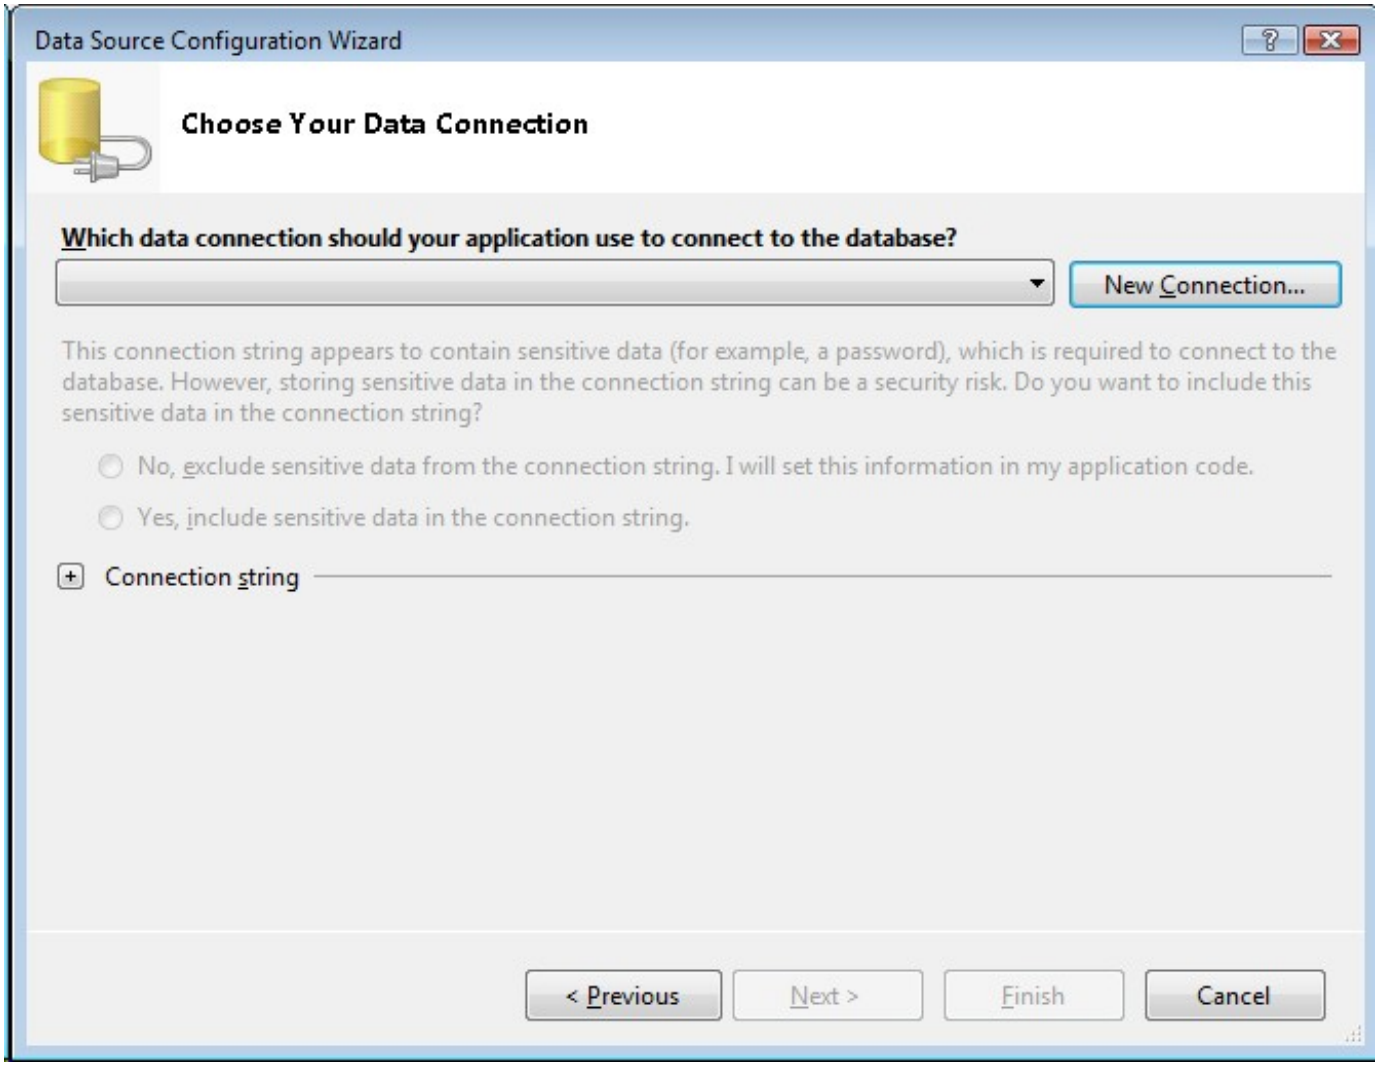
    Choose your Data Connection

    page, select the

    New Connection

    button

Figure 8.381. Data Source Configuration Wizard



12. In the

    Choose Data Source

    dialog, select the OpenLink

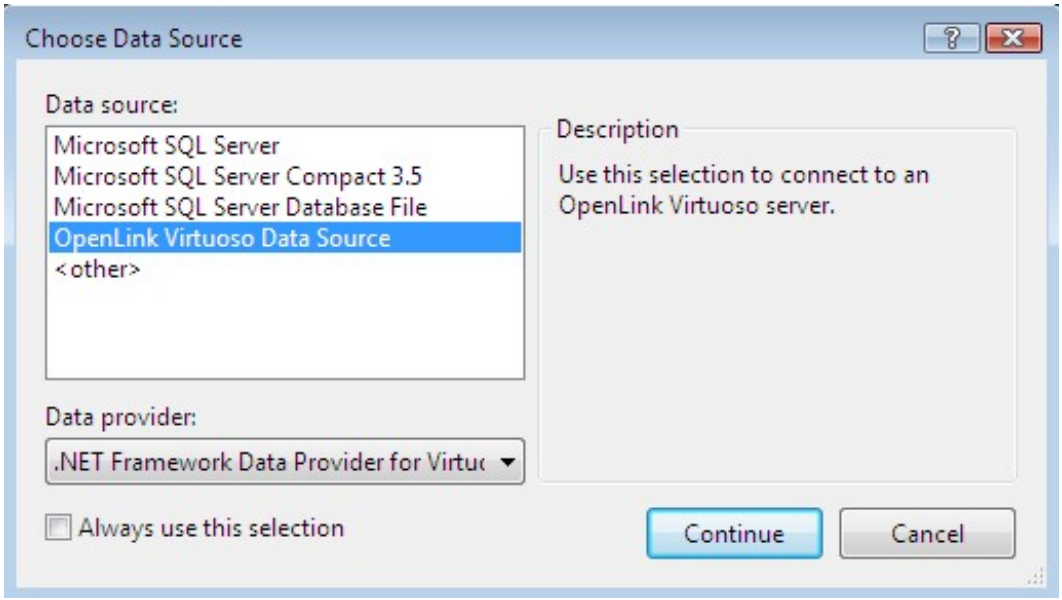
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.382. Data Source



13. In the

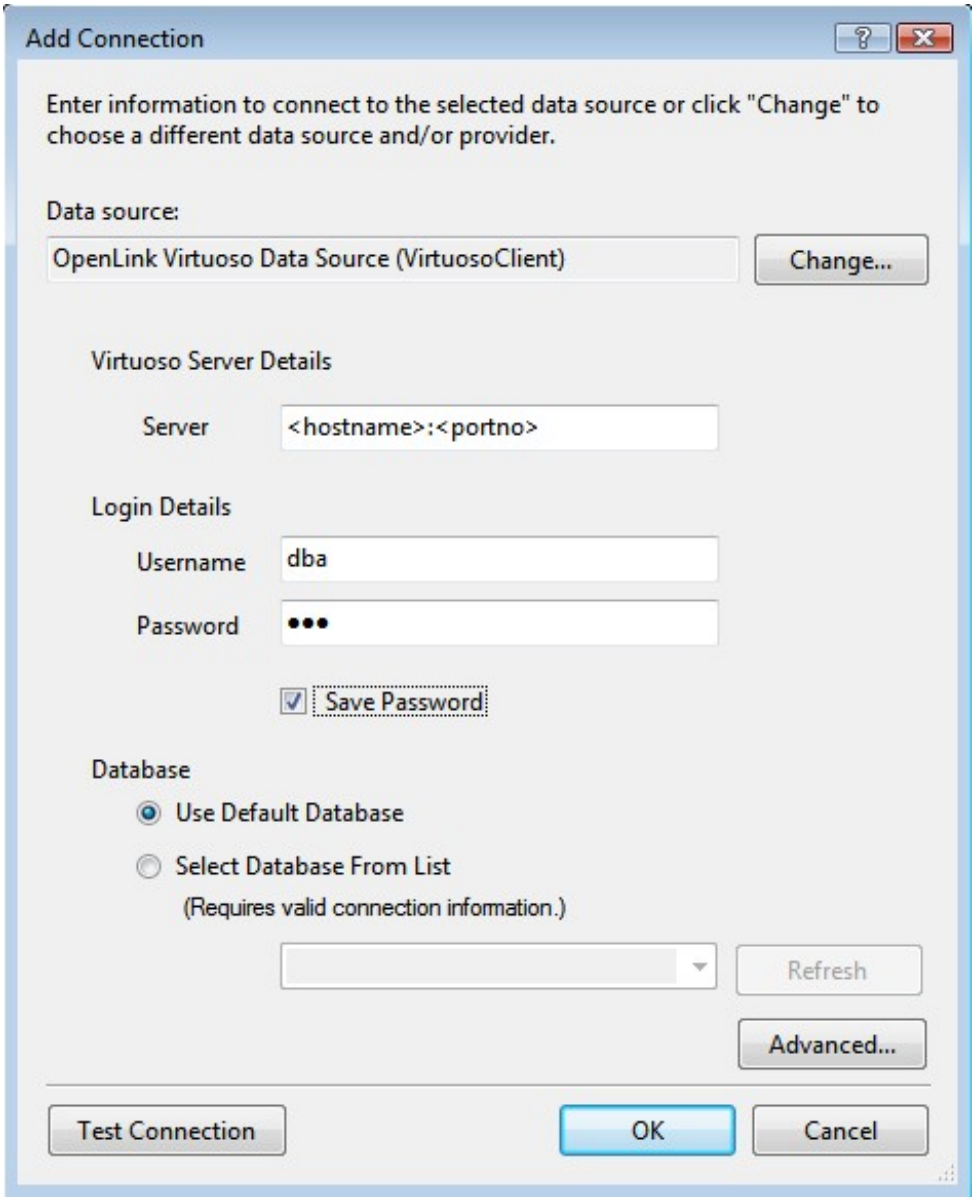
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.383. Connection Properties



14. Select the

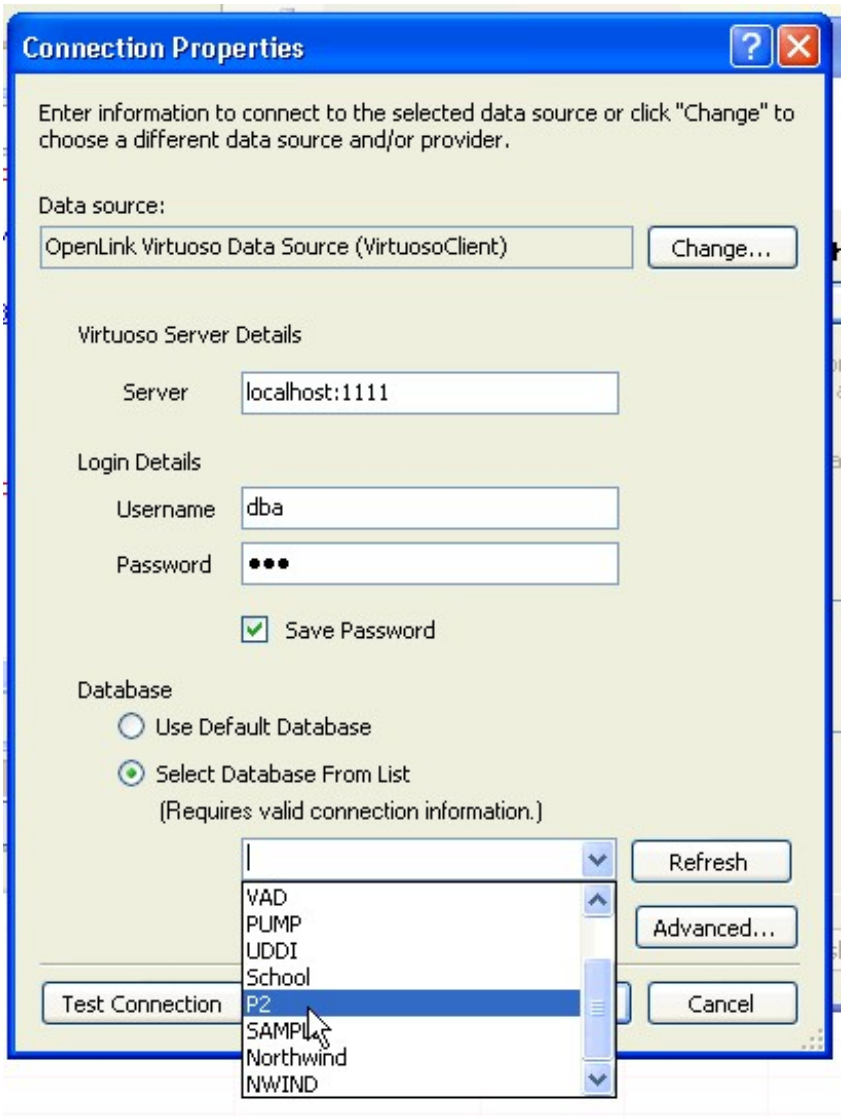
    Select Database From List

    radio button and choose the

    P2

    database from the drop down list.

Figure 8.384. Add connection

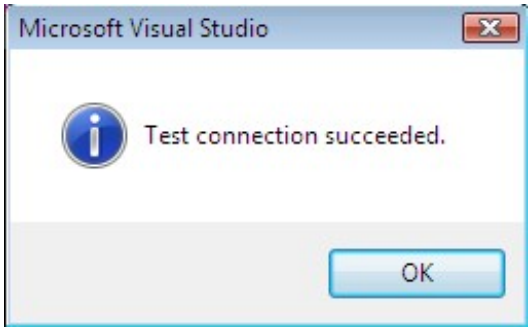


15. Press the

    Test Connection

    dialog to verify that the database is accessible.

    Figure 8.385. Test Connection



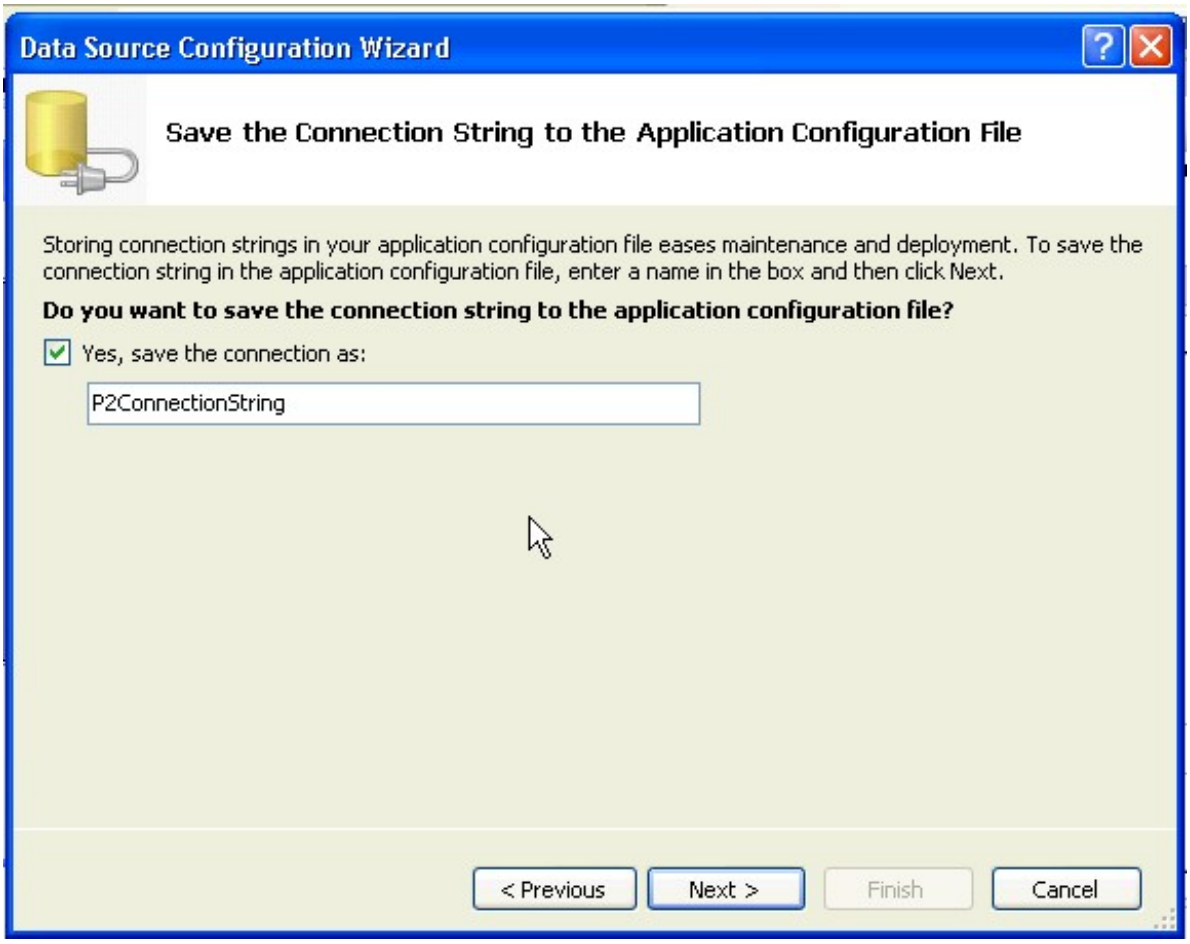
16. Leave the default connect string

    P2ConnectionString

    and click

Next

Figure 8.386. P2ConnectionString



17. From the list of available tables returned for the P2 database, select the

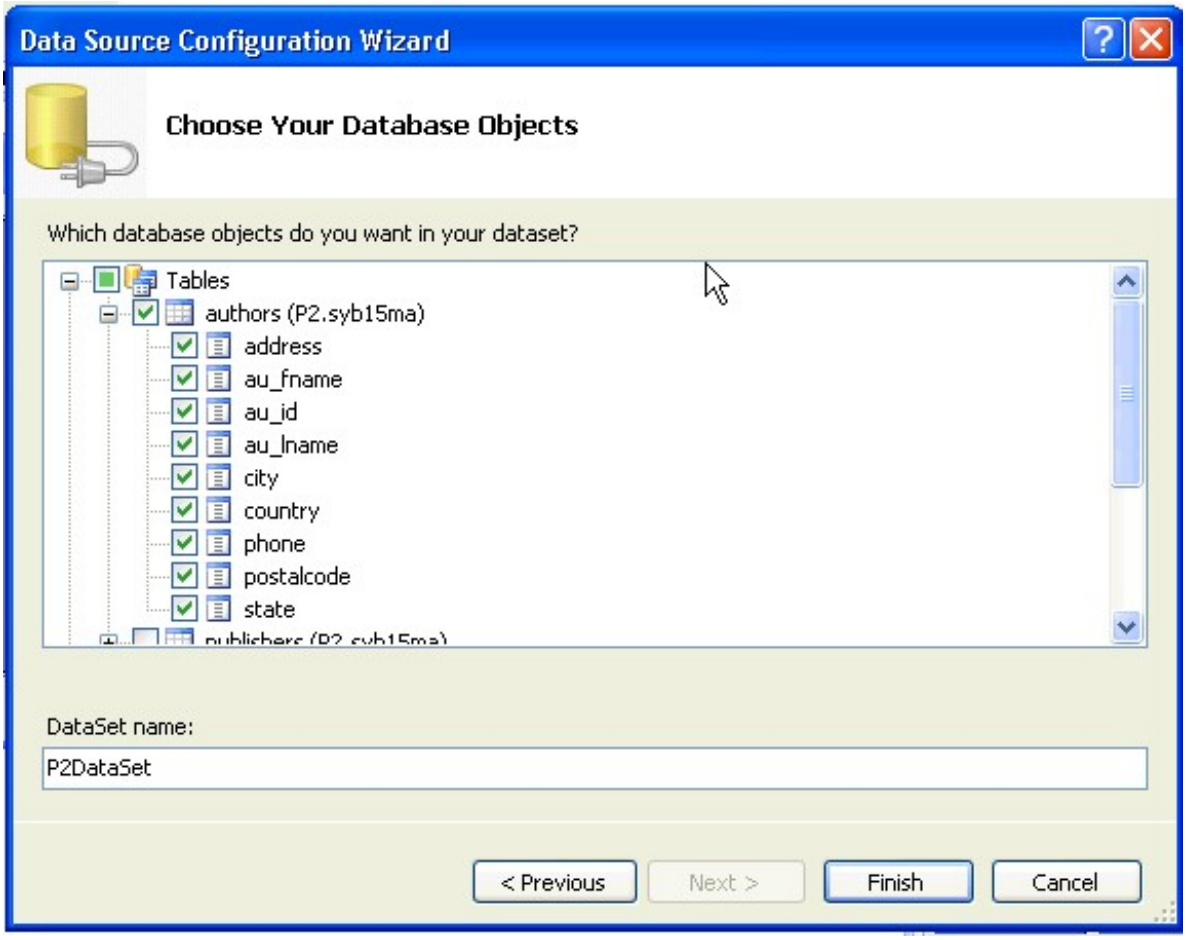
    authors

    table to be associated with the

    DataGridView

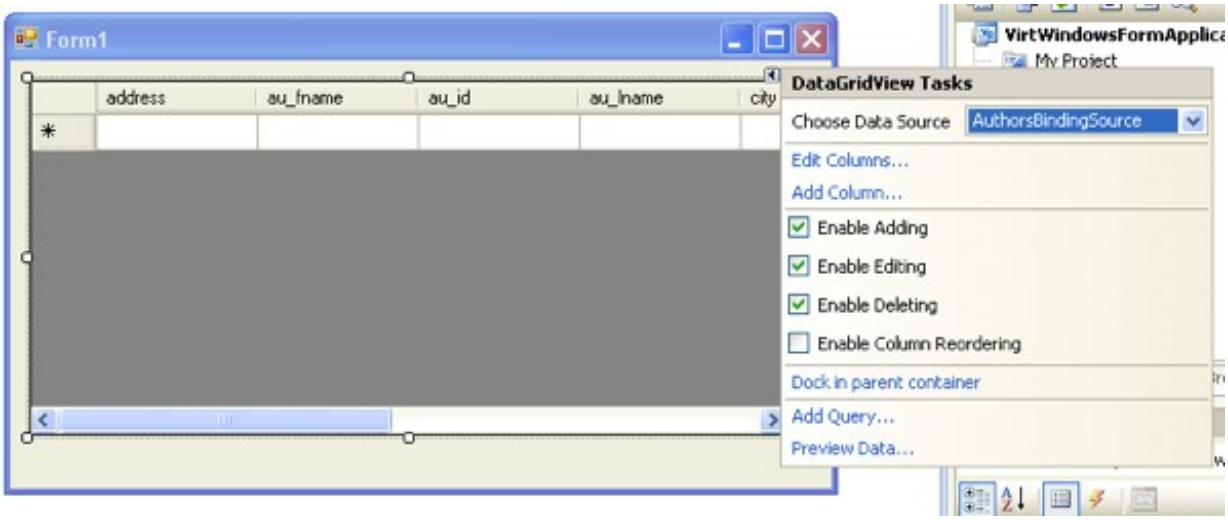
    control.

Figure 8.387. P2 database



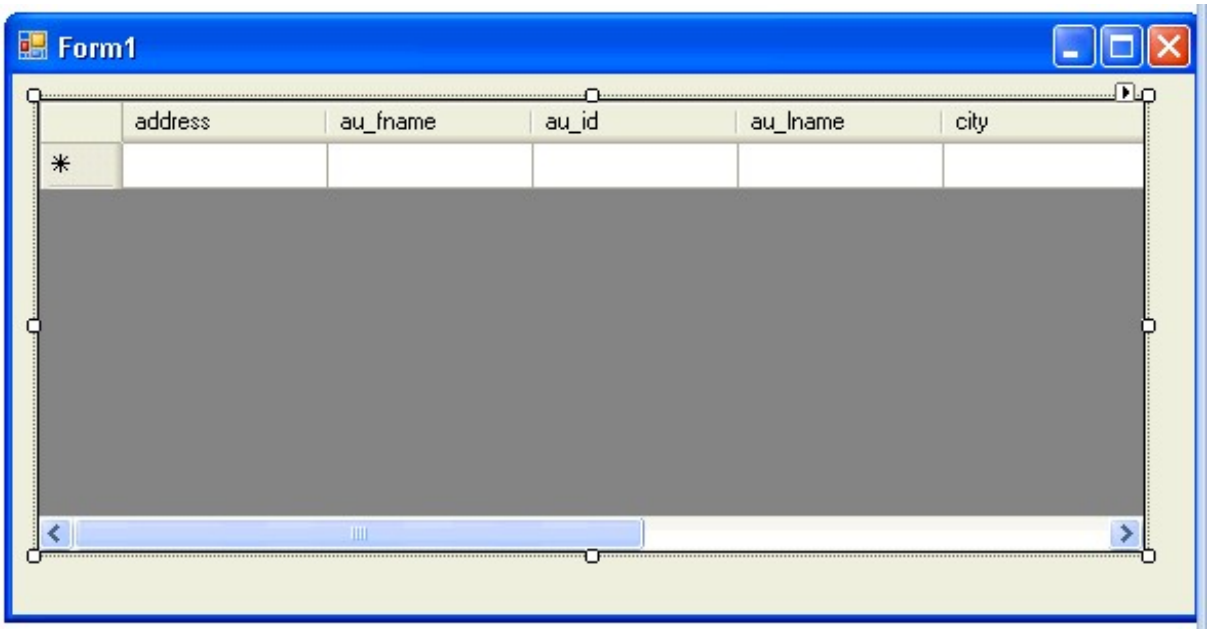
18. The columns names of the select table will be displayed in the DataGridView.

Figure 8.388. DataGridView



19. Resize the Form and DataGridView to allow all columns to be visible, if possible.

Figure 8.389. Resize the Form and DataGridView



20. To test the application, simply hit

    Ctrl+F5

    within Visual Studio or select

    Start Debugging

    from the

    Debug

    menu.

    Figure 8.390. Start Debugging

21. The data from the

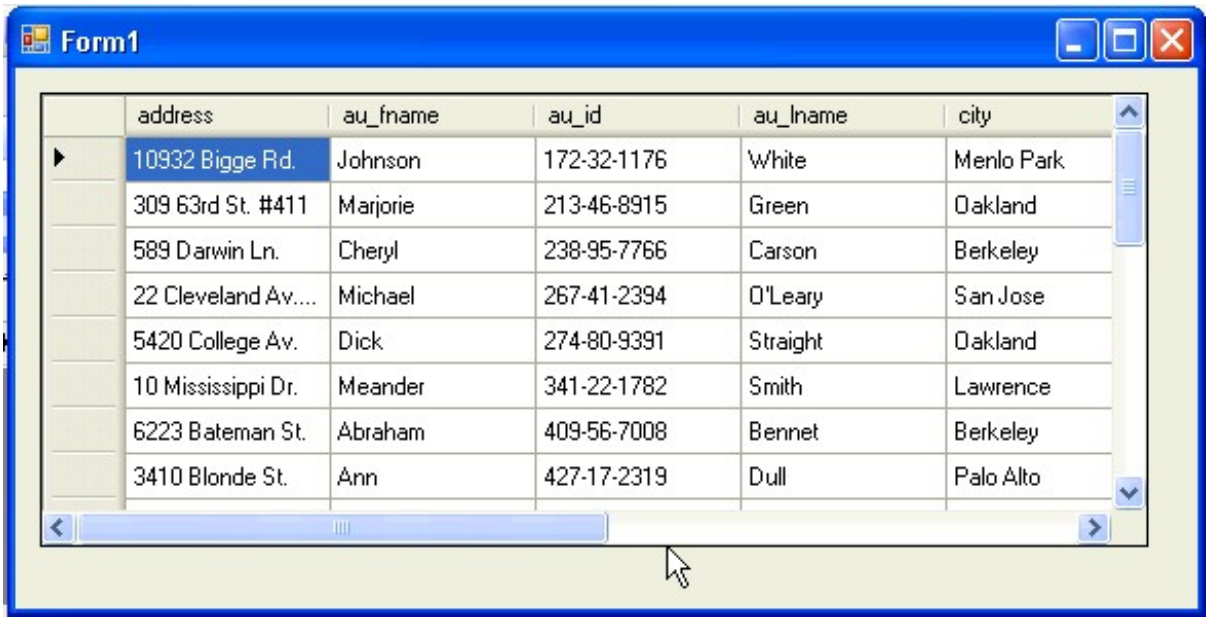
    authors

    table will be displayed in the

    DataGrid

    .

    Figure 8.391. DataGrid



The task is now complete.

8.8. Using Microsoft Entity Frameworks to Access MySQL Schema Objects with Virtuoso

Abstract

This section details the steps required to provide Microsoft Entity Framework access to MySQL Schema Objects using the OpenLink Virtuoso Universal Server. This is achieved by linking the required MySQL Schema objects into Virtuoso using its built in Virtual Database engine, and then using the Virtuoso ADO.NET Entity Framework provider to query the remote MySQL Schema objects linked into the Virtuoso Server.

Prerequisites. The following prerequisites must be in place for this solution to be possible.

MySQL DBMS. An MySQL DBMS hosting the required Schema Objects needs to be available. In this section the *Northwind sample* database will be used to demonstrate the process.

An MySQL DBMS hosting the required Schema Objects needs to be available. In this section the *Northwind sample* database will be used to demonstrate the process.

ODBC Driver for MySQL. An MySQL ODBC Driver is required for Linking the MySQL Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for MySQL* will be used in this section, for which a functional ODBC Data source name of "mysqlma" will be assumed to exist on the machine hosting the Virtuoso Server.

An MySQL ODBC Driver is required for Linking the MySQL Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for MySQL* will be used in this section, for which a functional ODBC Data source name of "mysqlma" will be assumed to exist on the machine hosting the Virtuoso Server.

Virtuoso Universal Server. An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

Microsoft Visual Studio 2008 SP1. Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Tasks

Ensure MySQL Primary Keys (PKs) are not nullable. The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the MySQL database schema before attempting to generate an EDM. In the case of the Northwind database all tables are not nullable, thus this should not be an issue in this case.

The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the MySQL database schema before attempting to generate an EDM. In the case of the Northwind database all tables are not nullable, thus this should not be an issue in this case.

8.8.1. Install and configure OpenLink ODBC Driver for MySQL

The Virtuoso Virtual Database engine uses ODBC as the connectivity mechanism for linking remote database objects into its local schema. Thus an MySQL ODBC Driver must be available with a suitably configured DSN for connecting to the target database. The OpenLink ODBC Drivers for MySQL have been used in this section, although in theory any MySQL ODBC Driver can be used.

Installation instructions for the OpenLink ODBC Driver for MySQL are available from:

- Product Installation & Basic Configuration (ODBC)

8.8.2. Install and configure OpenLink Virtuoso Universal Server

- Install and configure OpenLink Virtuoso Universal Server

8.8.3. Linking MySQL tables into OpenLink Virtuoso

1. Start the Virtuoso Web User Interface

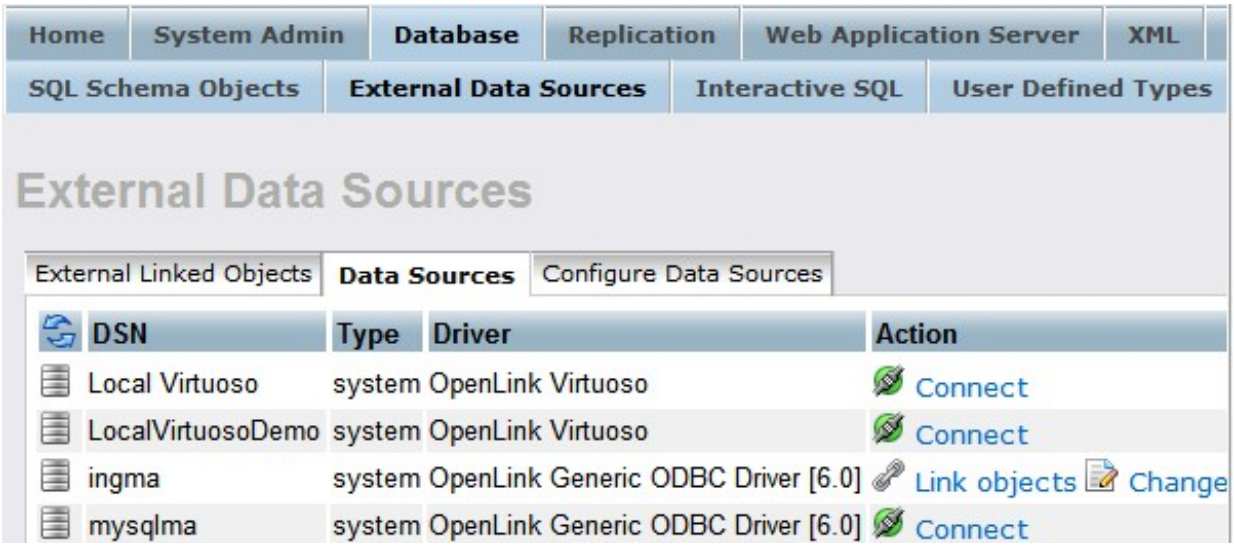
   Figure 8.392. Start

2. Select the "Conductor" link in the Left Frame and Login as the "dba" user.

Figure 8.393. Conductor

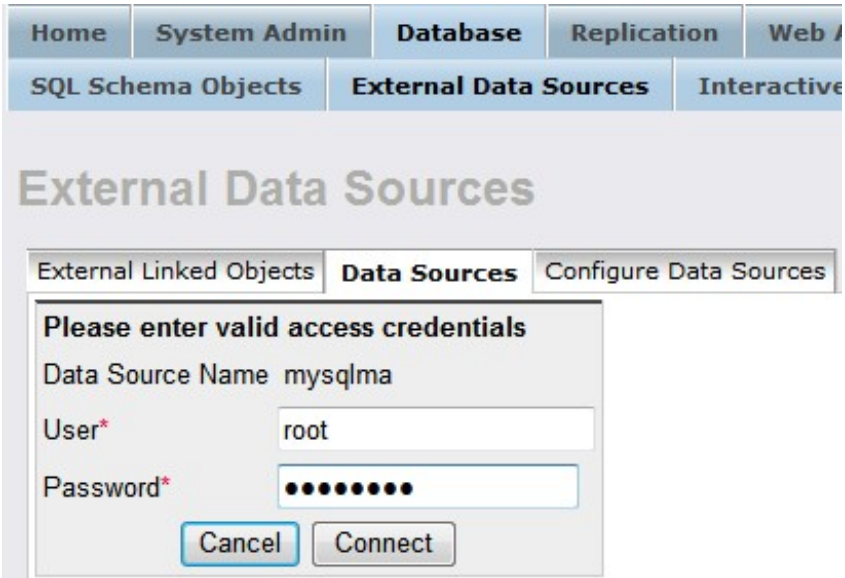
3. Select the "Databases" -> "External Data Source" -> "Data Sources" tab menu items

Figure 8.394. Databases



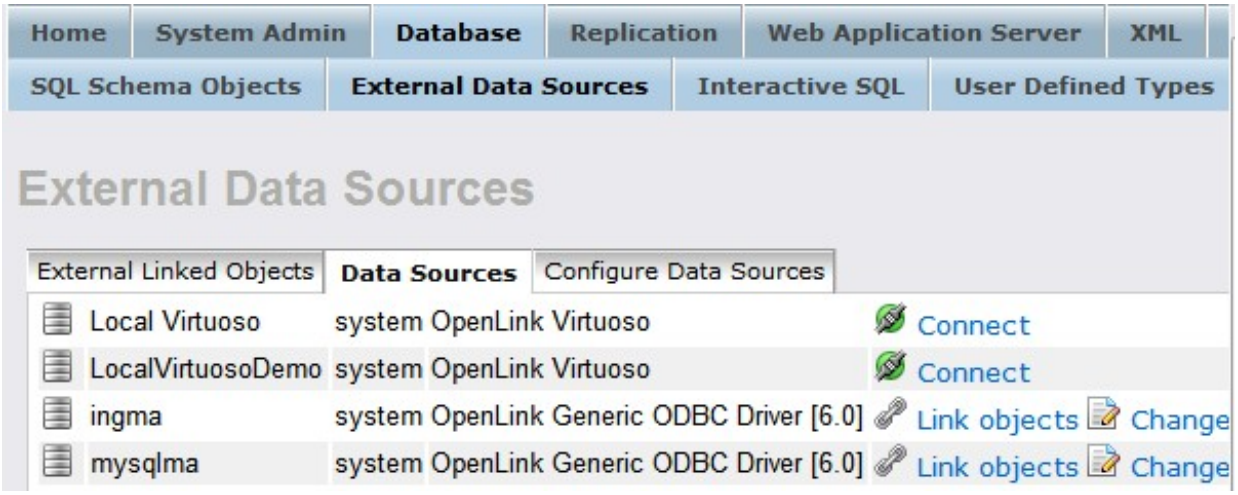
4. Select the "Connect" button for the "mysqlma" MySQL DSN.

Figure 8.395. Connect



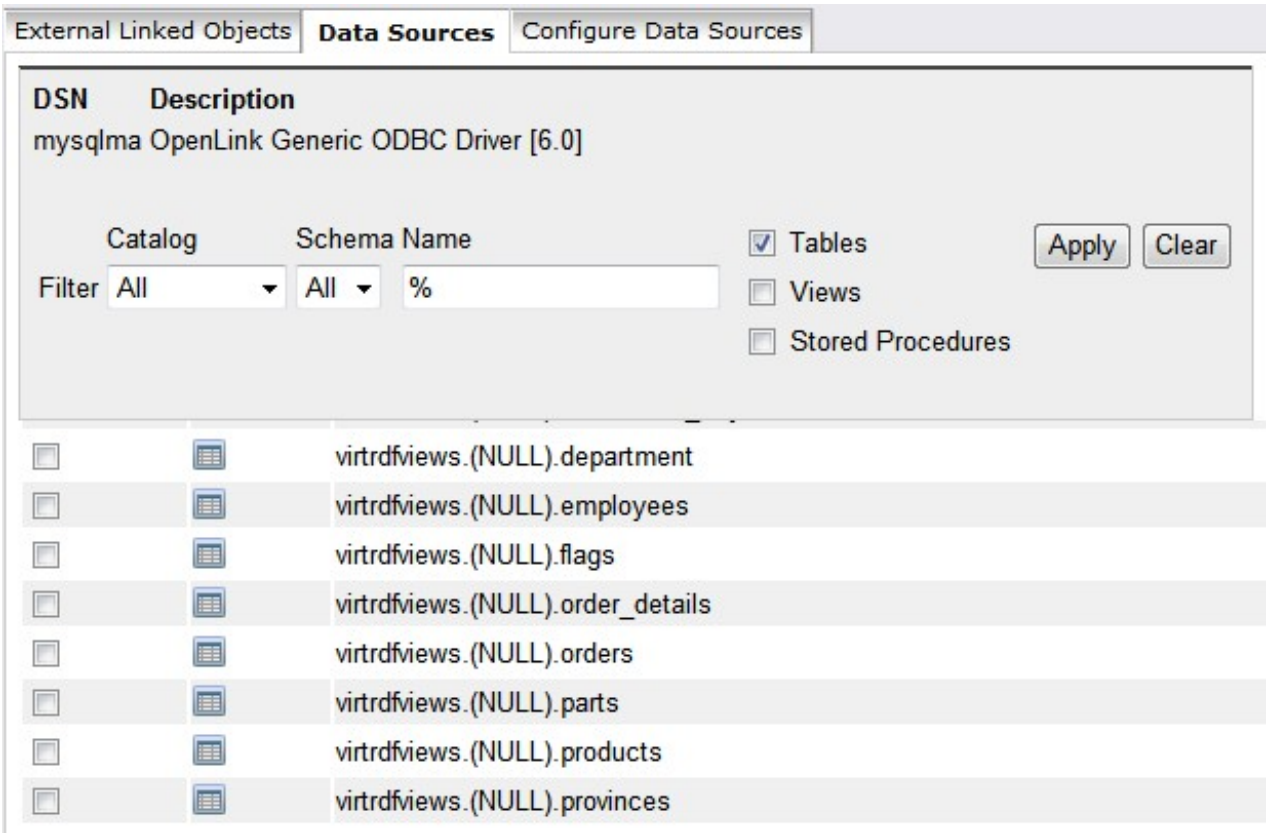
5. On successful connection Select the "Link Objects" button to obtain a list of available tables

Figure 8.396. Link Objects



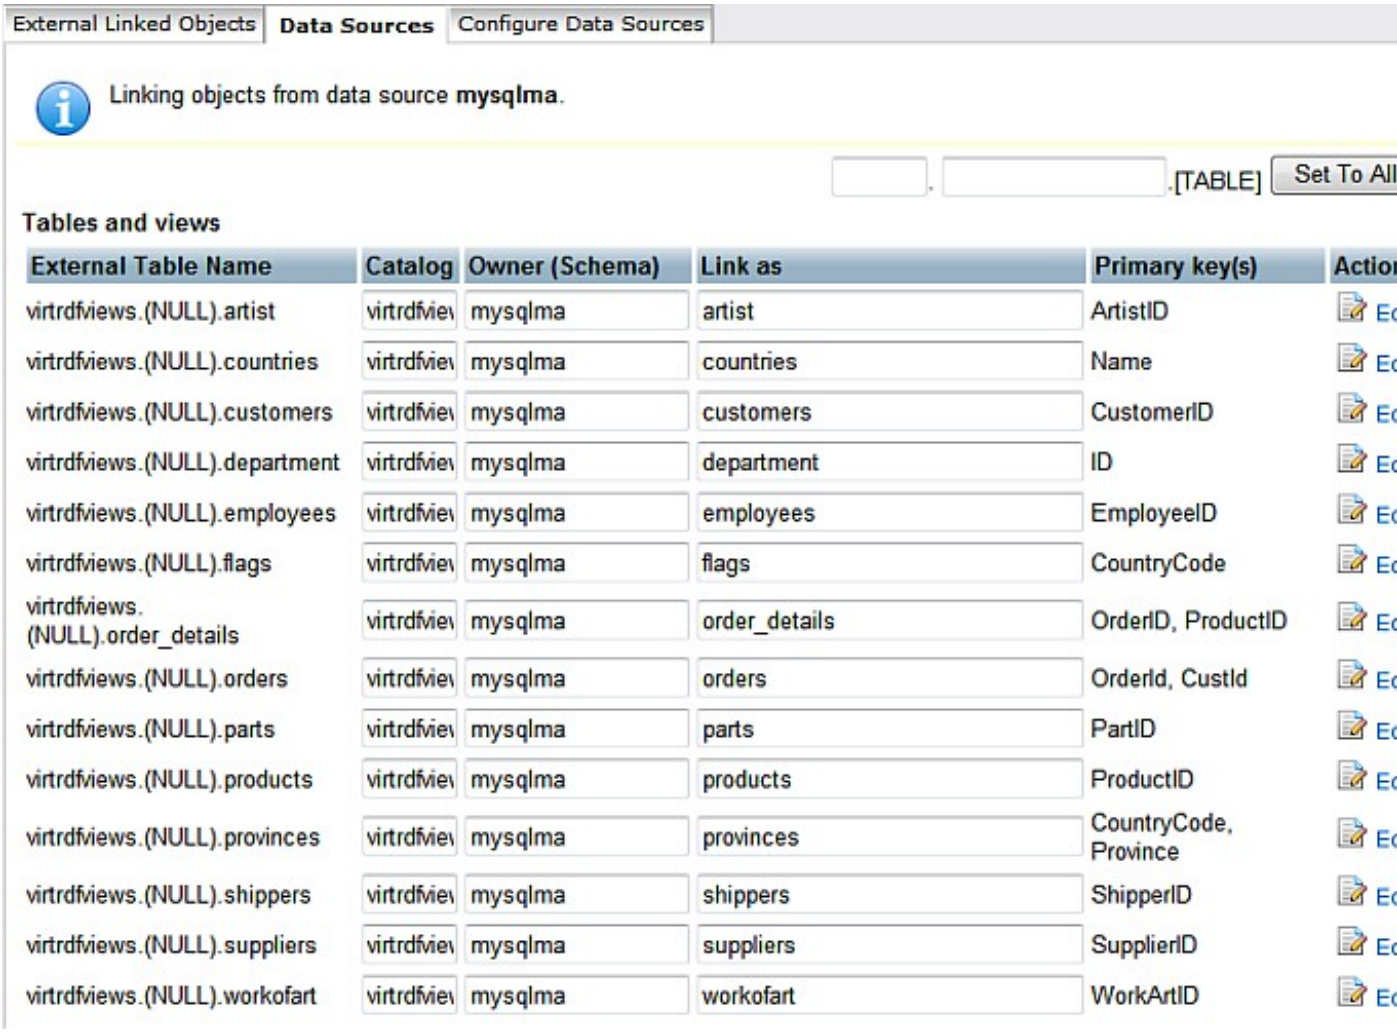
6. Select all the tables that are part of the "mysql" catalog.

Figure 8.397. Select tables



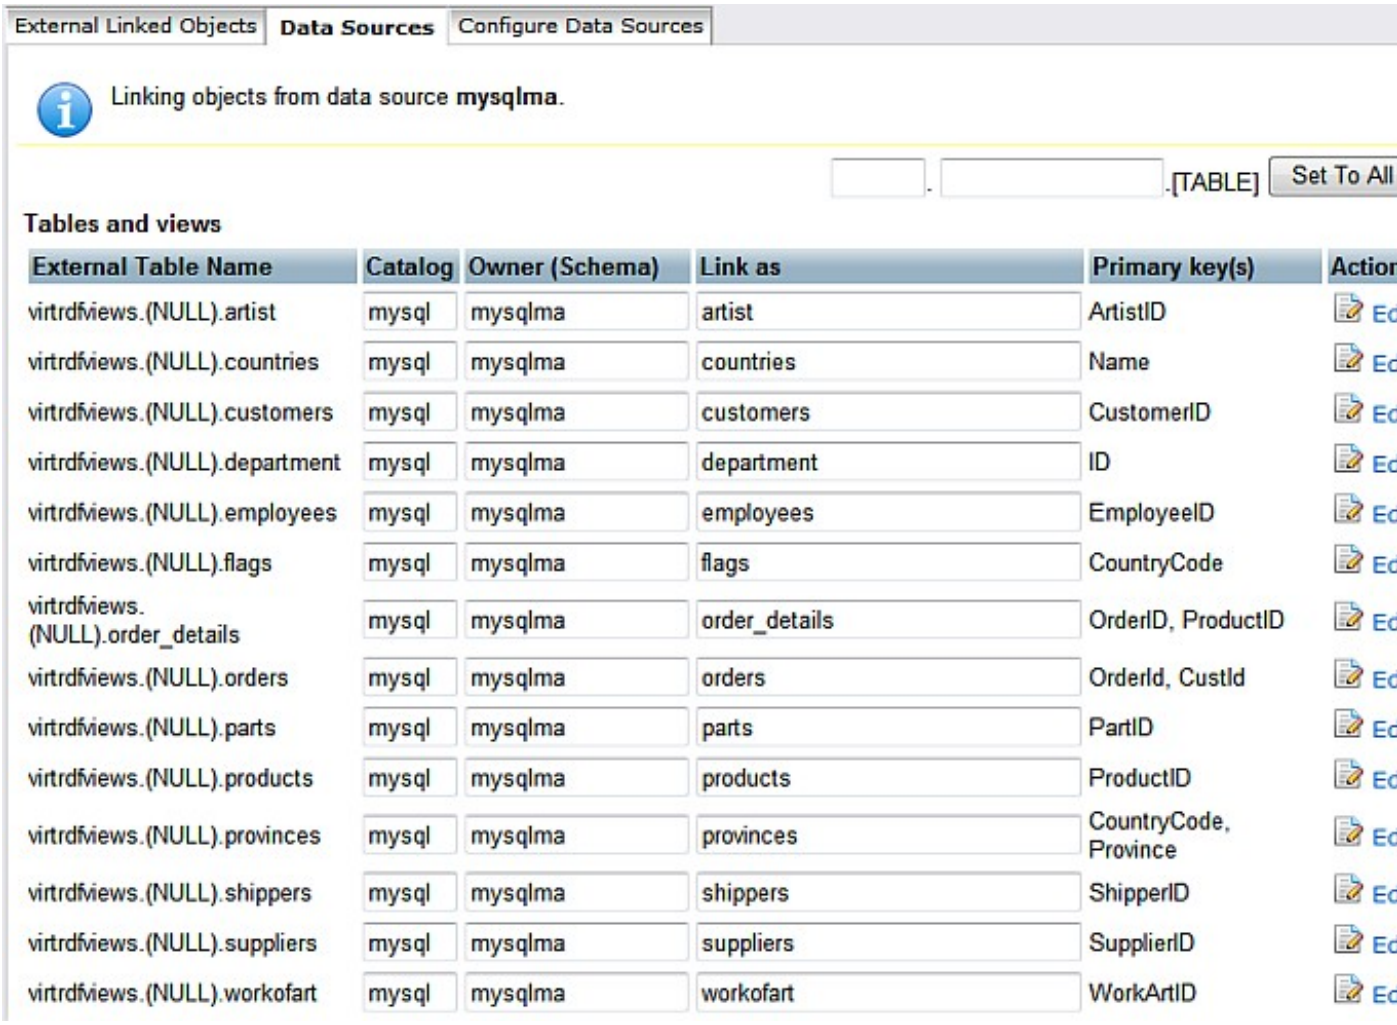
7. Ensure a primary key is assigned to all table that are to be used in the EDM generation phase.

Figure 8.398. Catalog



8. Change the Catalog for each table to be "mysql" using the "Set All" button.
9. Select the "Link" button to link the selected tables into Virtuoso

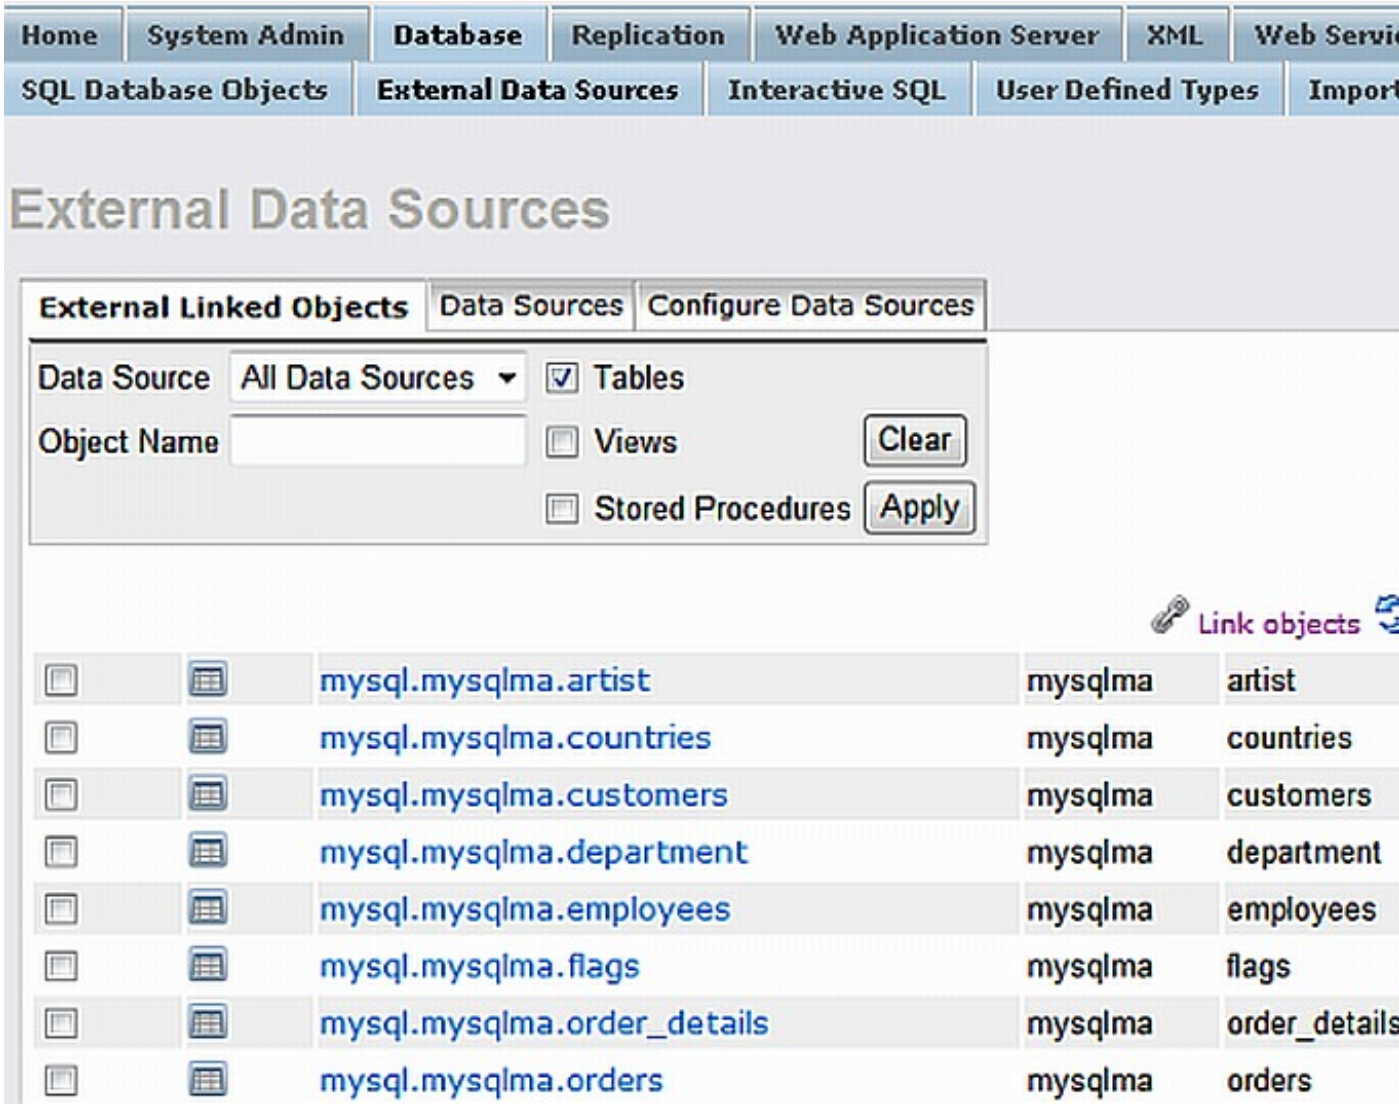
Figure 8.399. "Link" button



External Table Name	Catalog	Owner (Schema)	Link as	Primary key(s)	Action
virtrdfviews.(NULL).artist	mysql	mysqlma	artist	ArtistID	Ed
virtrdfviews.(NULL).countries	mysql	mysqlma	countries	Name	Ed
virtrdfviews.(NULL).customers	mysql	mysqlma	customers	CustomerID	Ed
virtrdfviews.(NULL).department	mysql	mysqlma	department	ID	Ed
virtrdfviews.(NULL).employees	mysql	mysqlma	employees	EmployeeID	Ed
virtrdfviews.(NULL).flags	mysql	mysqlma	flags	CountryCode	Ed
virtrdfviews.(NULL).order_details	mysql	mysqlma	order_details	OrderID, ProductID	Ed
virtrdfviews.(NULL).orders	mysql	mysqlma	orders	OrderId, CustId	Ed
virtrdfviews.(NULL).parts	mysql	mysqlma	parts	PartID	Ed
virtrdfviews.(NULL).products	mysql	mysqlma	products	ProductID	Ed
virtrdfviews.(NULL).provinces	mysql	mysqlma	provinces	CountryCode, Province	Ed
virtrdfviews.(NULL).shippers	mysql	mysqlma	shippers	ShipperID	Ed
virtrdfviews.(NULL).suppliers	mysql	mysqlma	suppliers	SupplierID	Ed
virtrdfviews.(NULL).workofart	mysql	mysqlma	workofart	WorkArtID	Ed

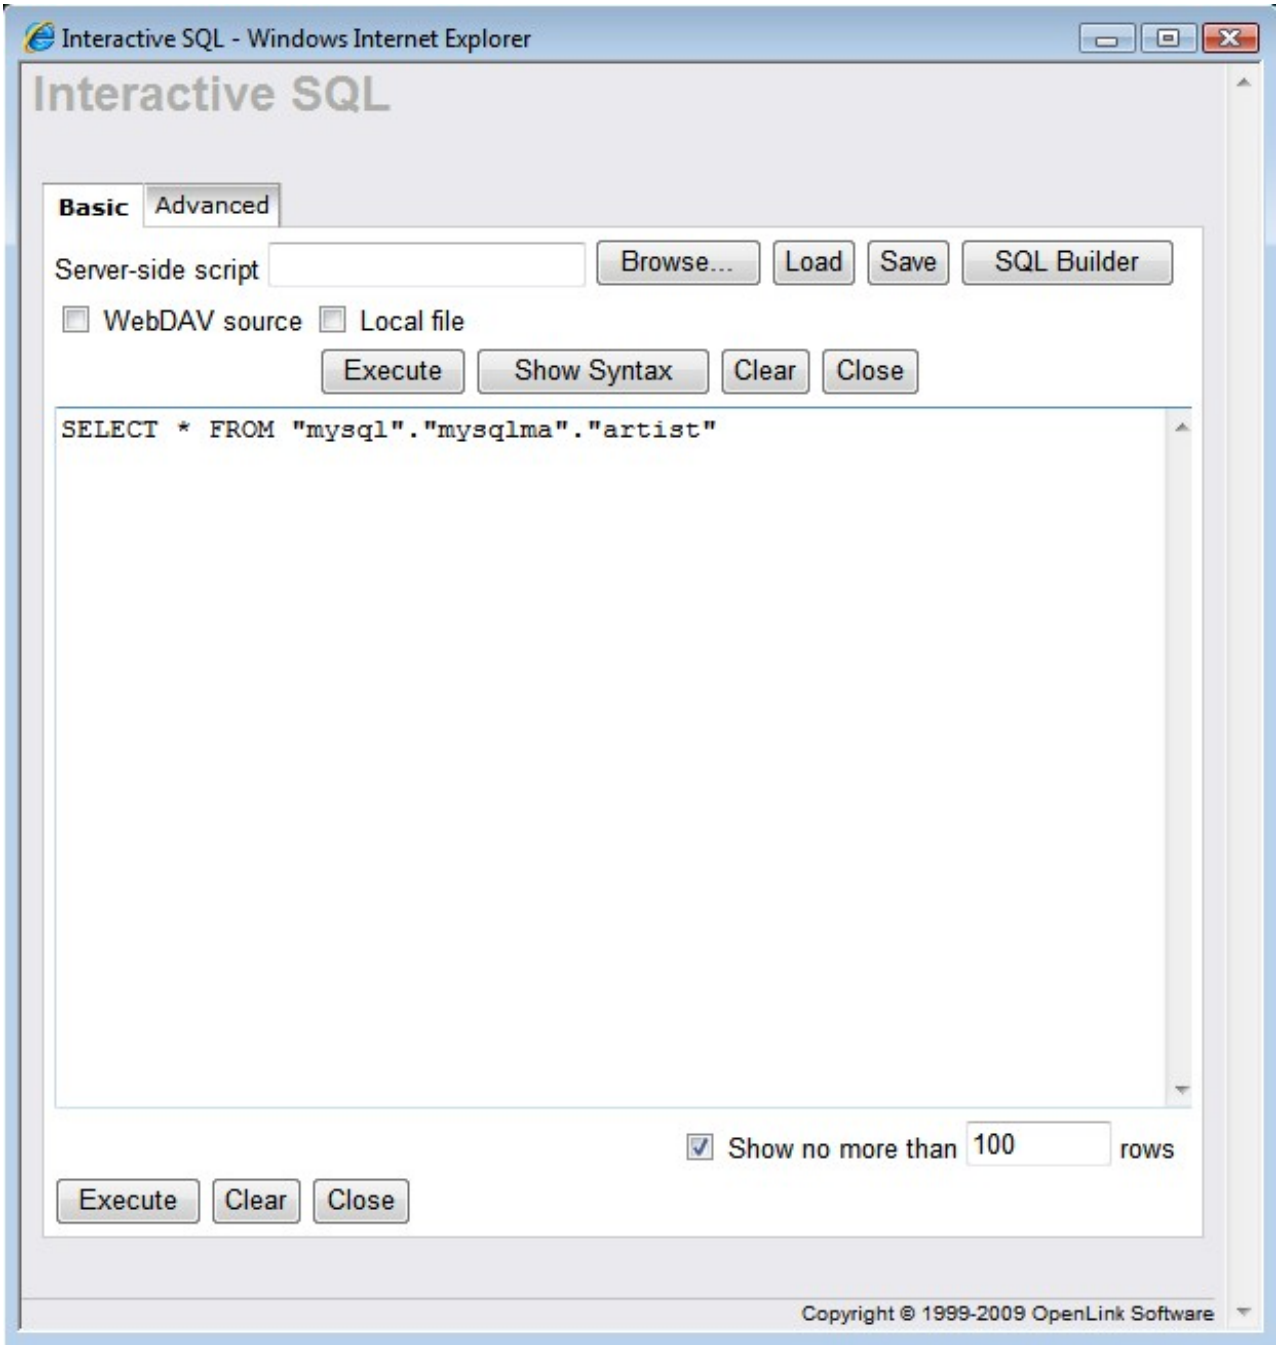
10. On completion of the Link process the tables will be displayed in the "External Linked Objects" tab.

Figure 8.400. Completion



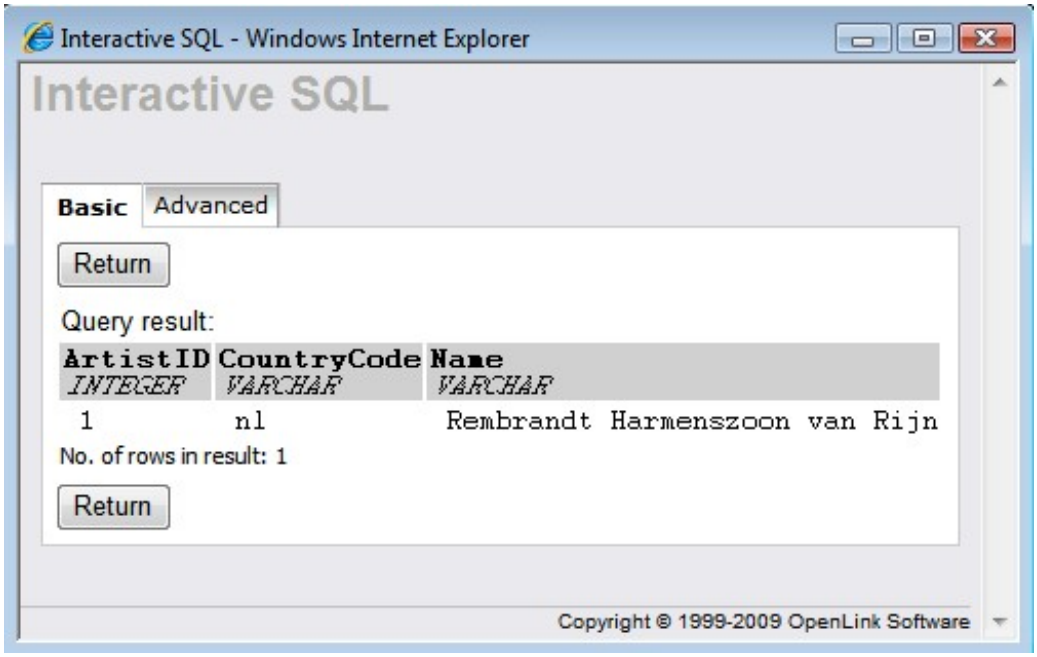
11. The linked tables can be queried by clicking on the hyperlink in the "Local Name" column of the "External Linked Objects" tab above, which loads the Virtuoso "Interactive SQL" interface with the required SQL "Select" for retrieving the remote table data . We shall use the "mysql.mysqlma.artist" table to demonstrate this.

Figure 8.401. Completion



12. Then click the "Execute" button to run the query and retrieve the results from the remote table.

Figure 8.402. Completion



13. The tables can also be viewed as part of the Virtuoso "SQL Schema Objects" under the "mysql" catalog name.

Figure 8.403. view tables

The Link process is now complete enabling the tables to be queried as if part of the Virtuoso Schema.

8.8.4. Creating EDM in Visual Studio 2008

The following steps can be used to create an Entity Data Model (EDM) for the MySQL Northwind database:

1. Launch the Visual Studio 2008 SP1 IDE.

Figure 8.404. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

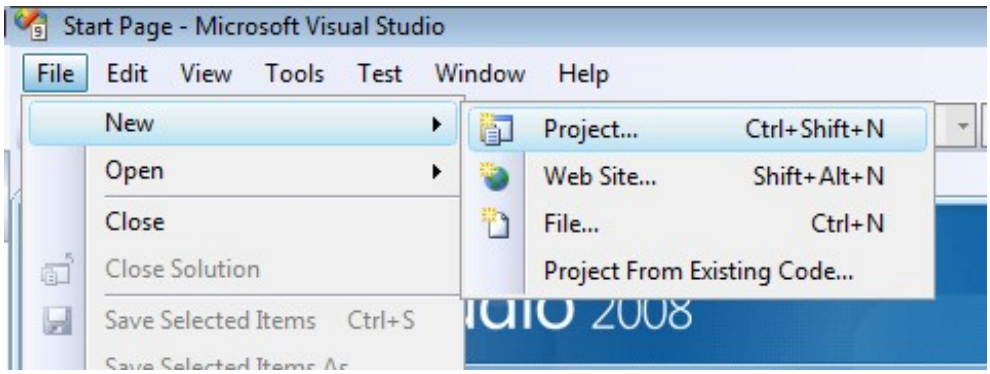
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.405. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Web

   and select

   ASP.NET Web Application

from the right-hand panel.

5. Choose a name for the project, for example

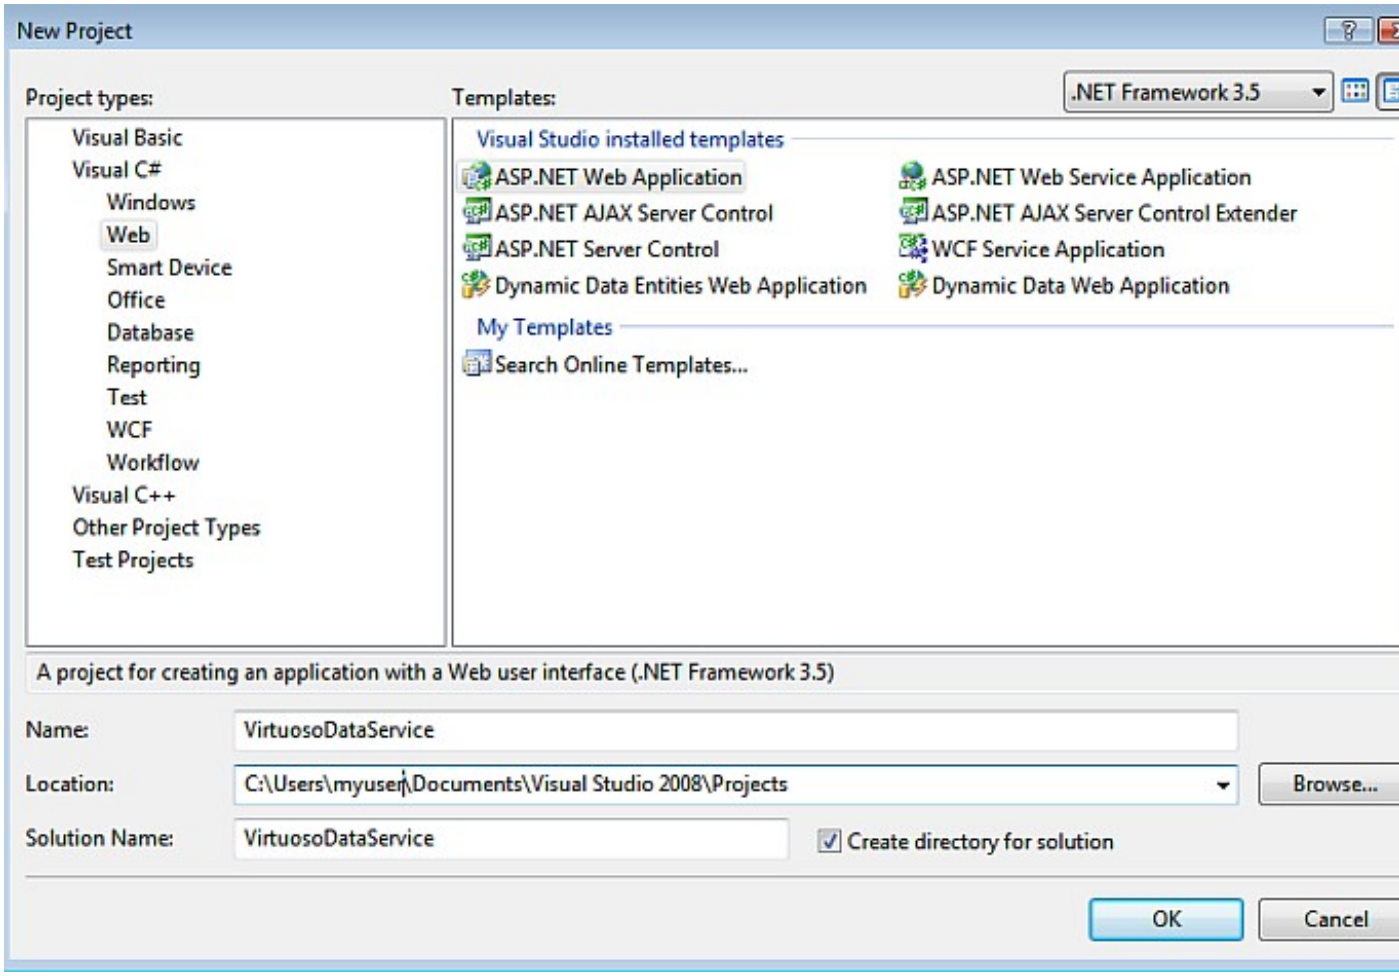
   VirtuosoDataService

   , and click

   OK

   .

   Figure 8.406. name for the project

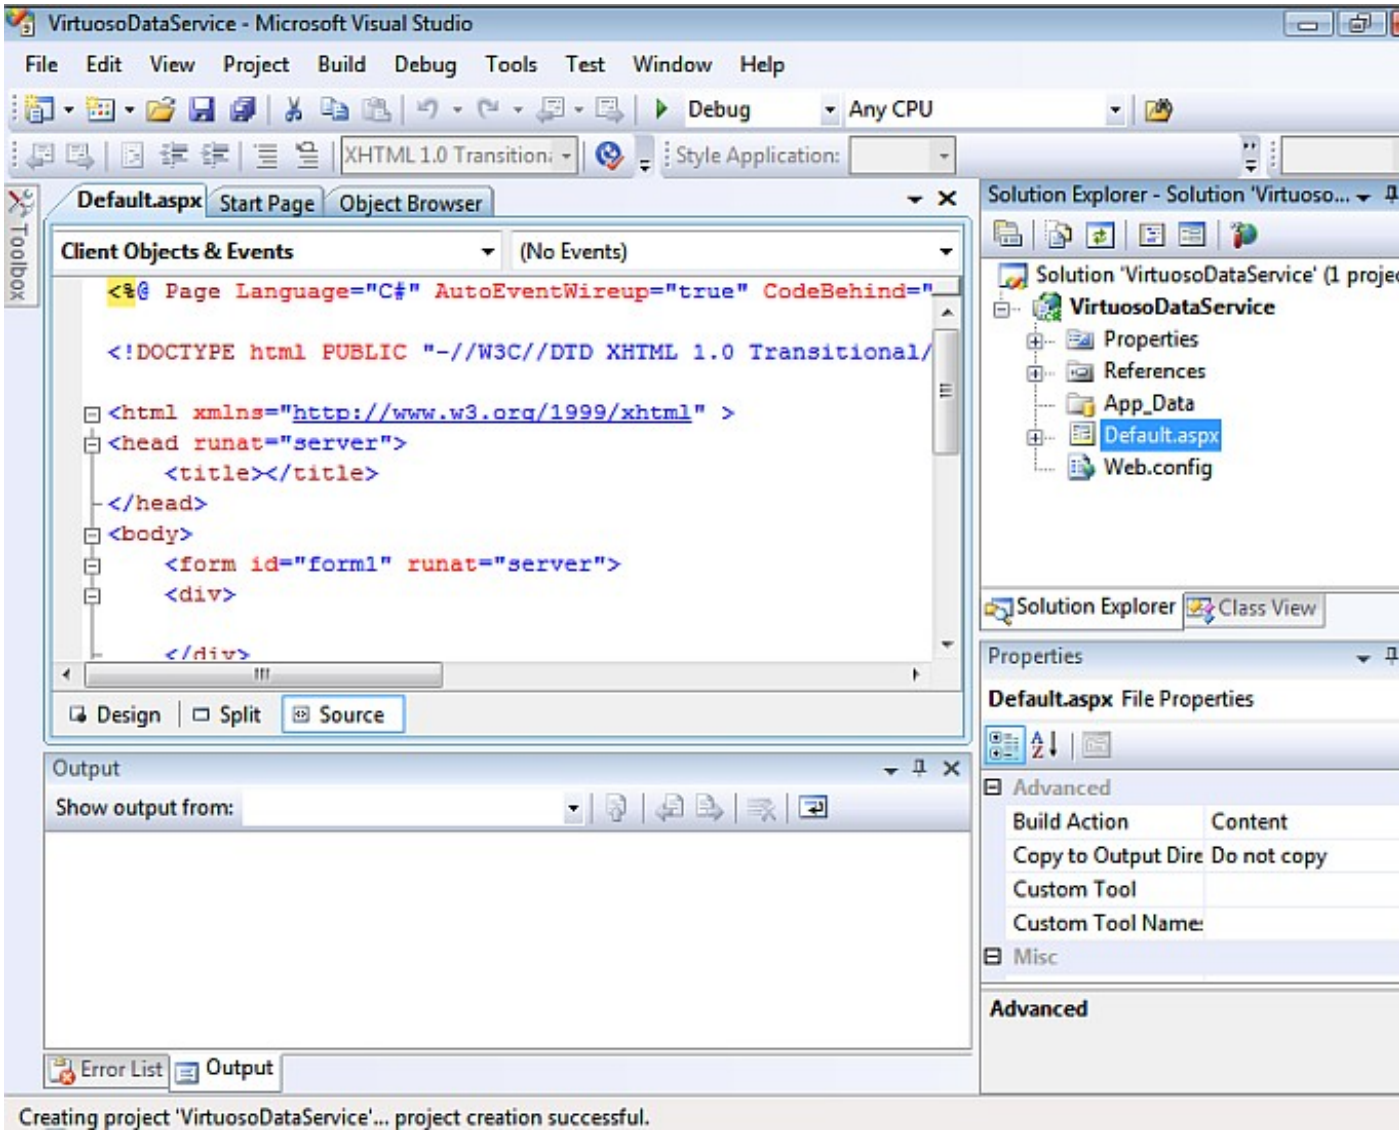


6. This will create a new project called

   VirtuosoDataService

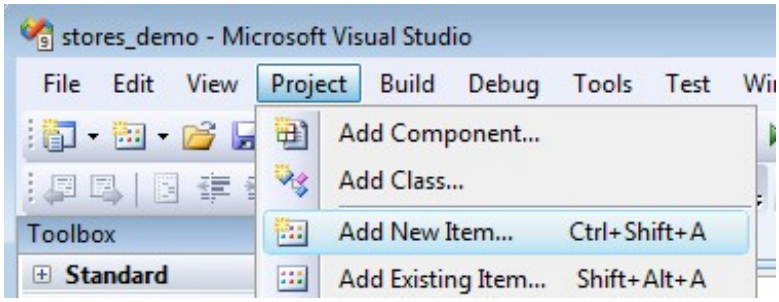
   .

   Figure 8.407. create a new project



7. Select the Project -> Add New Item menu option.

Figure 8.408. VirtuosoDataService



8. The

Add New Item

dialog will appear. Choose the

ADO.NET Entity Data Model

template. Give it the name

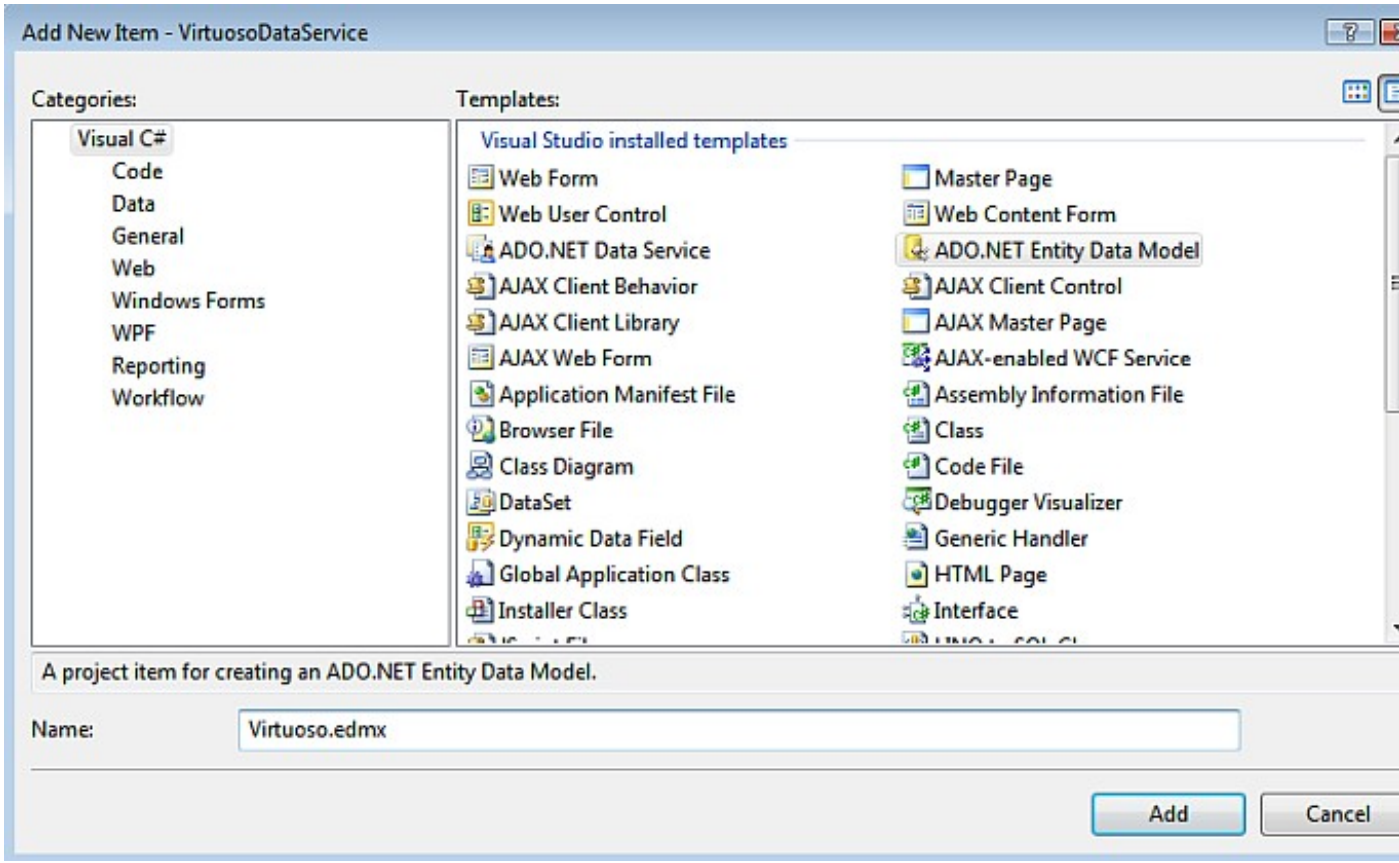
Virtuoso.edmx

and click

Add

to start the creation of the ADO.Net Entity Data Model.

Figure 8.409. Add New Item



9. In the

Entity Data Model Wizard

dialog

Choose Model Contents

page select the

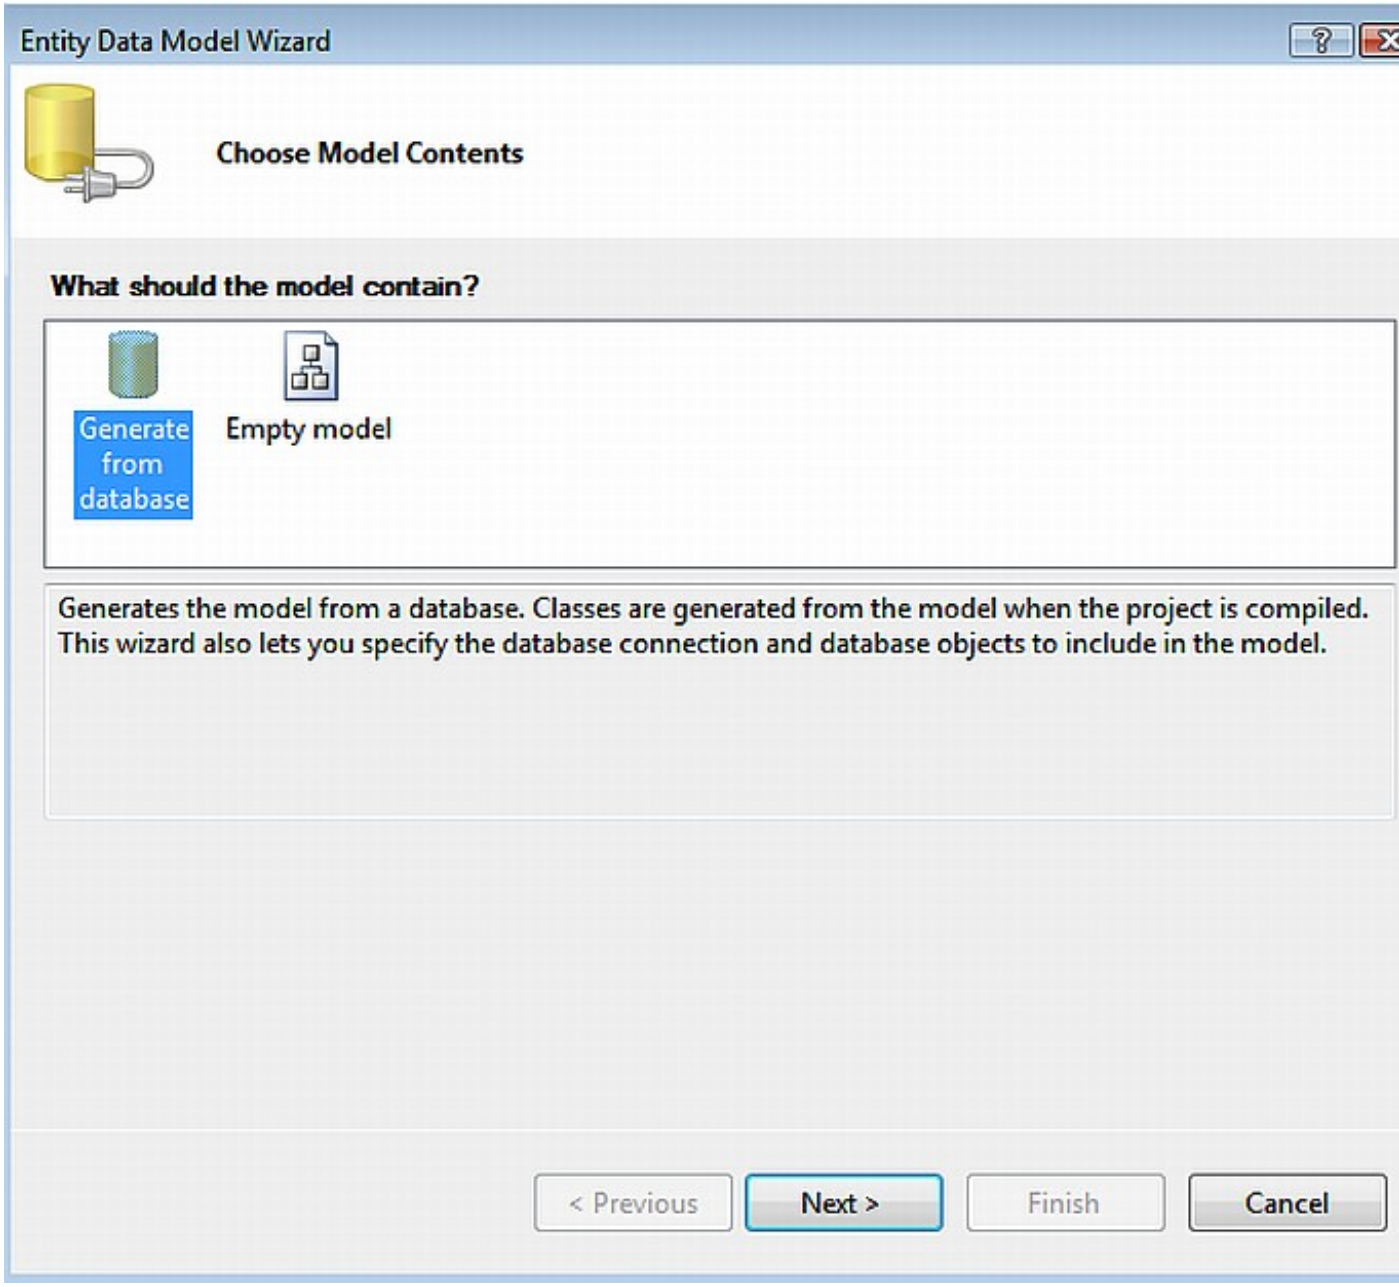
Generate from Database

model type and click

Next

.

Figure 8.410. Choose Model Contents



10. In the

    Entity Data Model Wizard

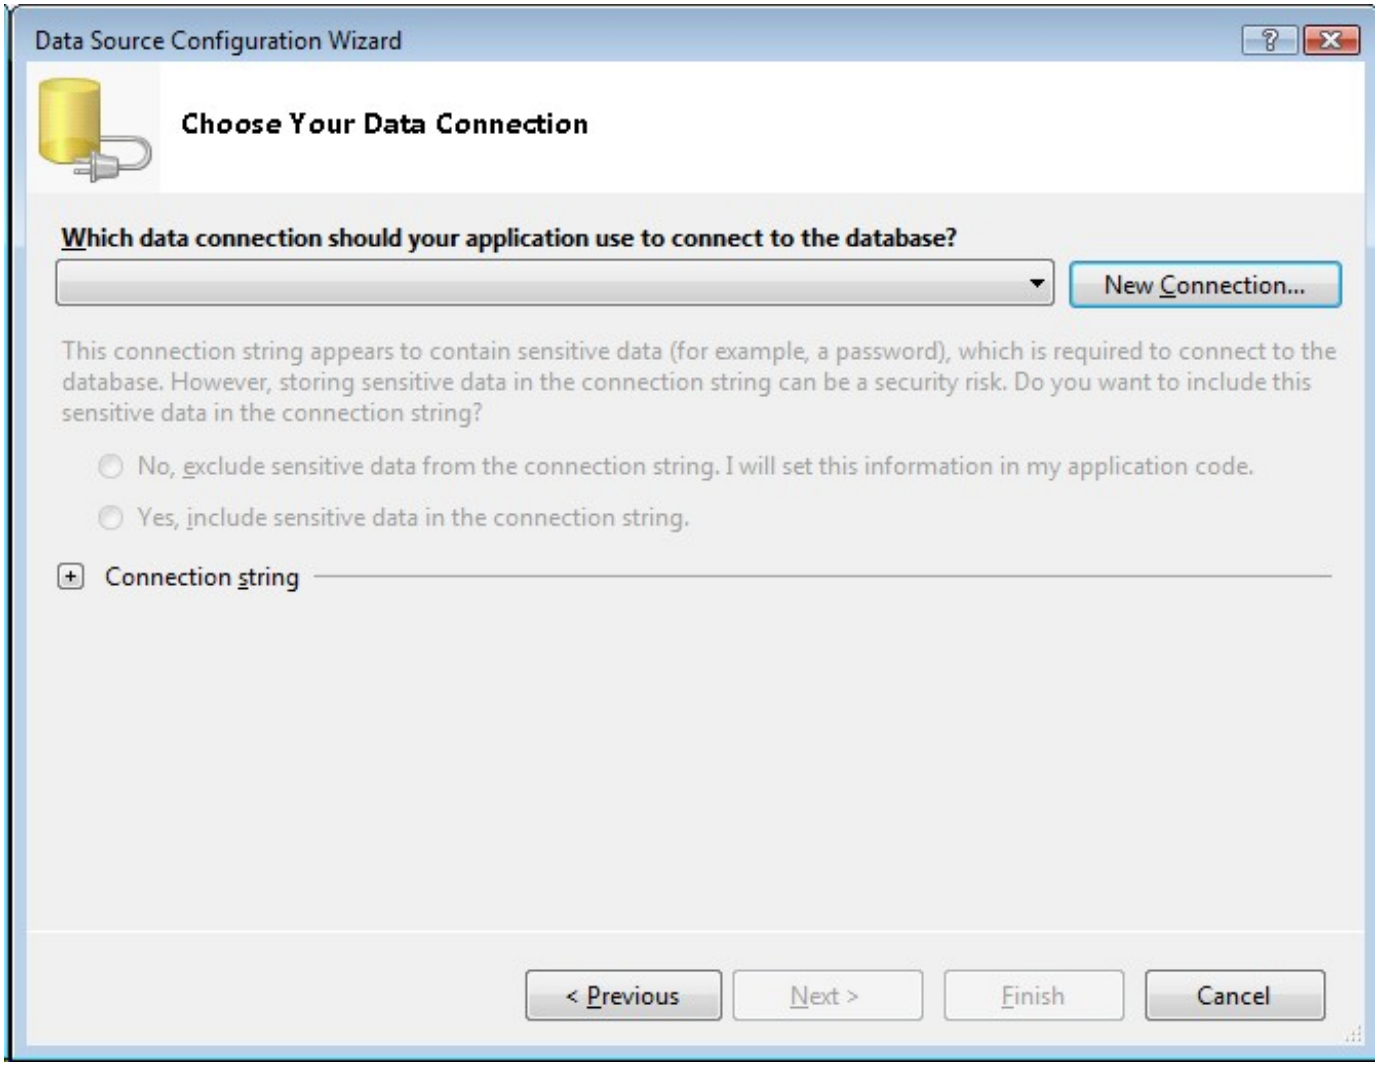
    dialog

    Choose your Data Connection

    page, select the

    New Connection button

Figure 8.411. Entity Data Model Wizard



11. In the

    Choose Data Source

    dialog, select the OpenLink

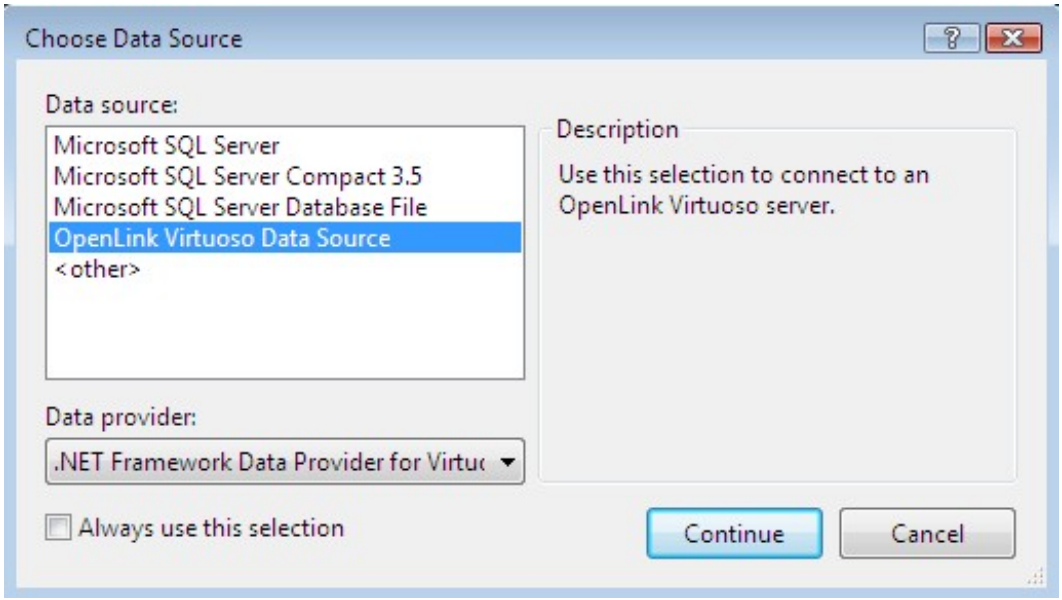
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.412. Choose Data Source



12. In the

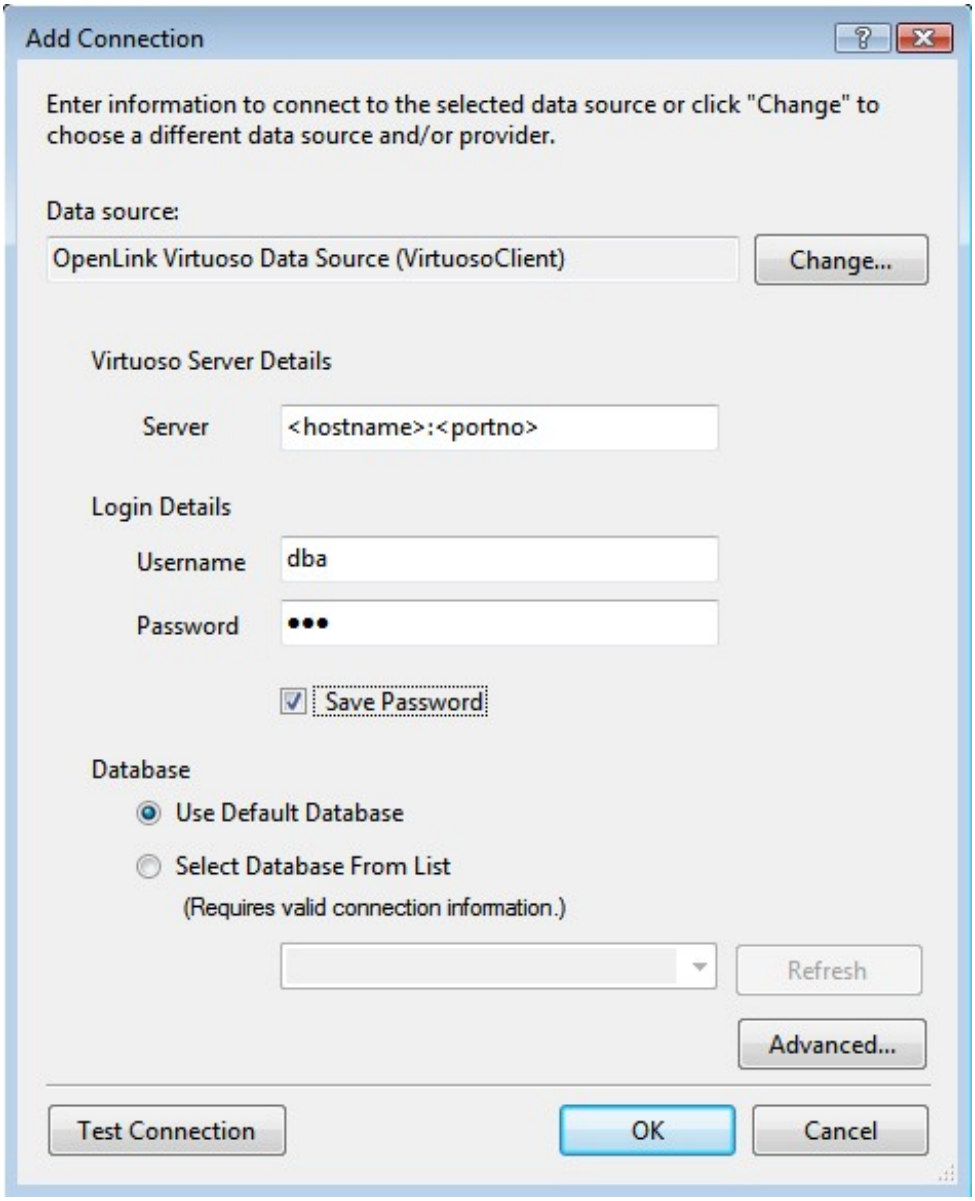
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.413. Connection Properties



13. Select the

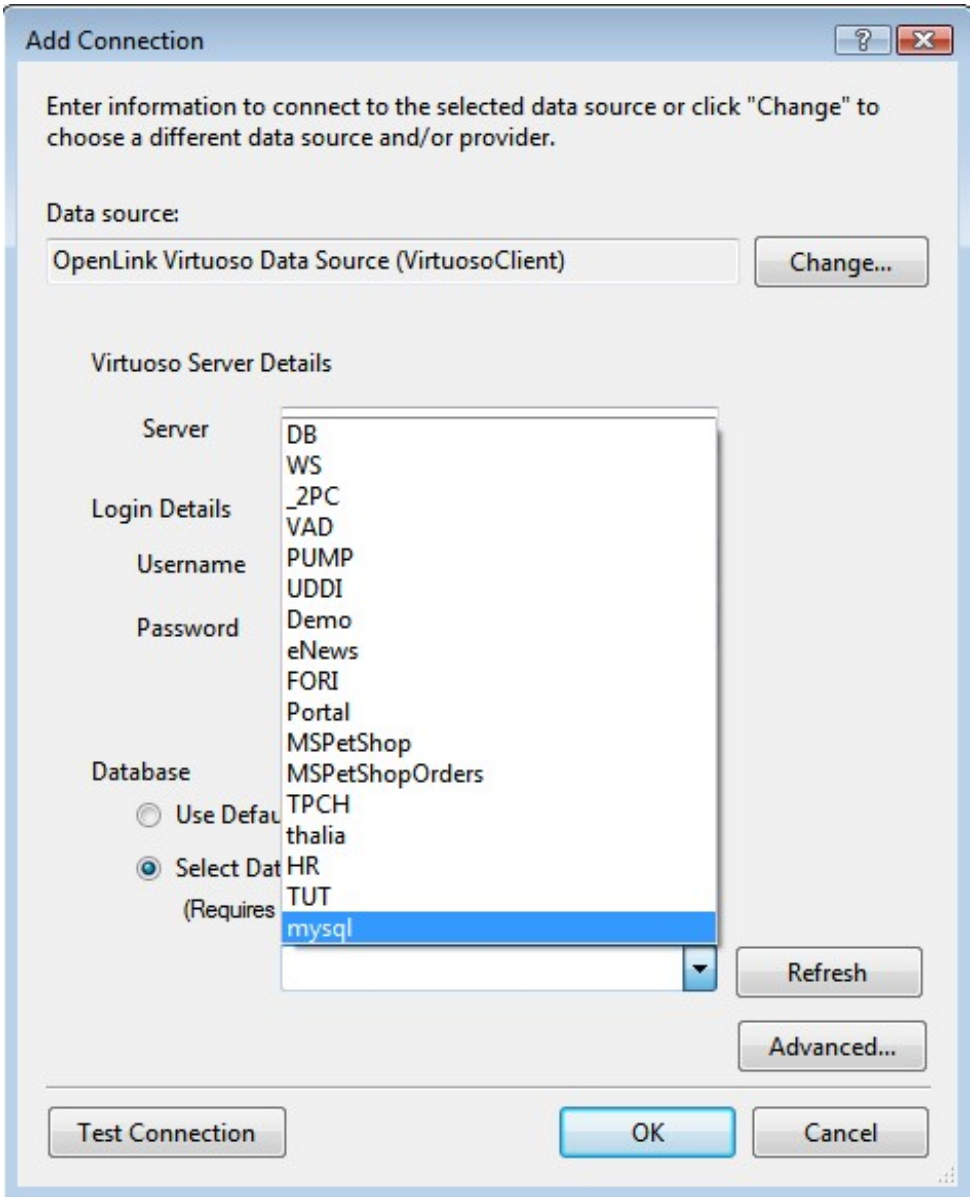
    Select Database From List

    radio button and choose the

    mysql

    database from the drop down list.

Figure 8.414. Add connection

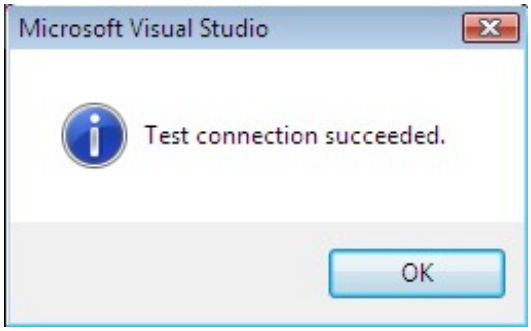


14. Press the

    Test Connection

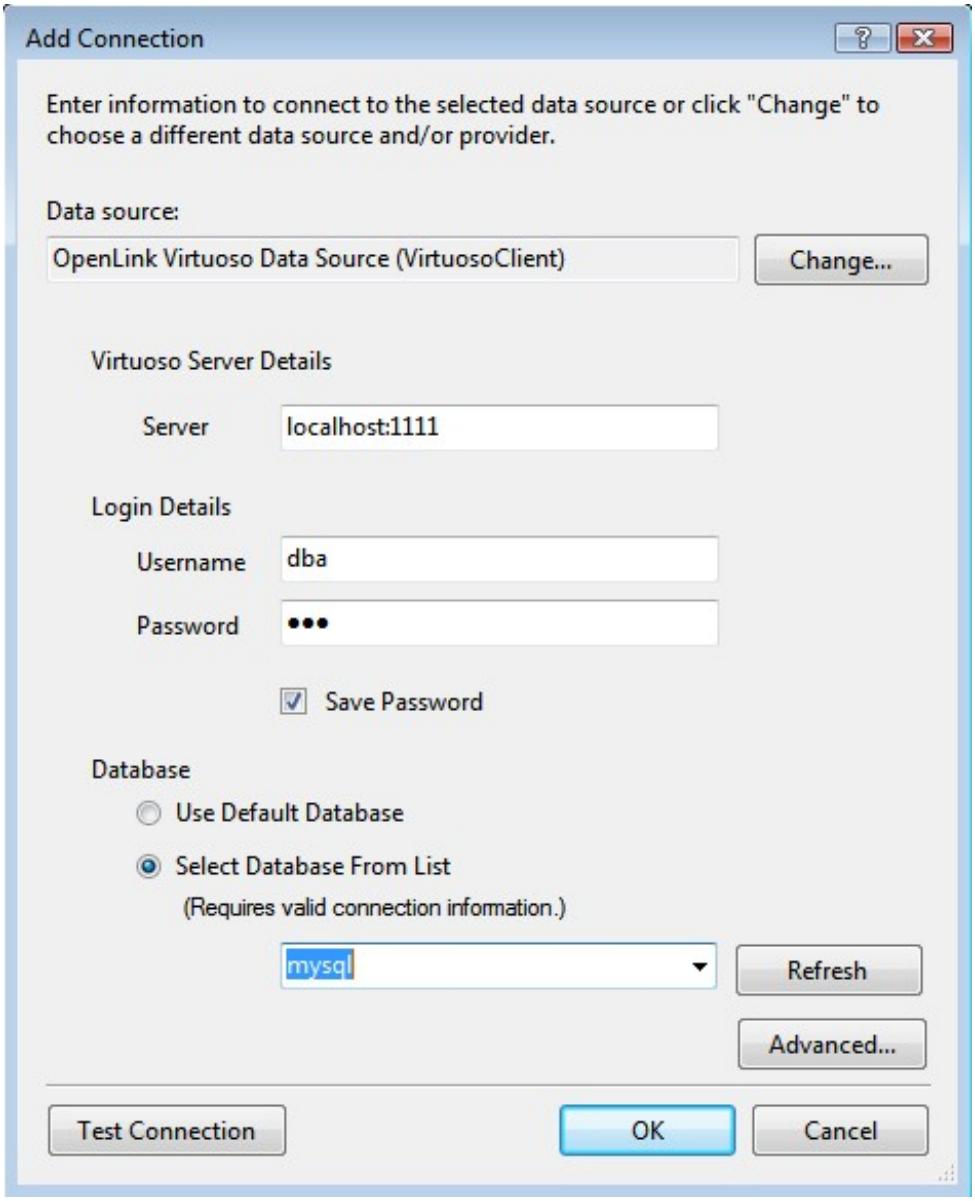
    dialog to verify that the database is accessible.

Figure 8.415. Test Connection



15. Click OK to add the connection.

Figure 8.416. Test Connection



16. Set the

    entity connect string

    name to

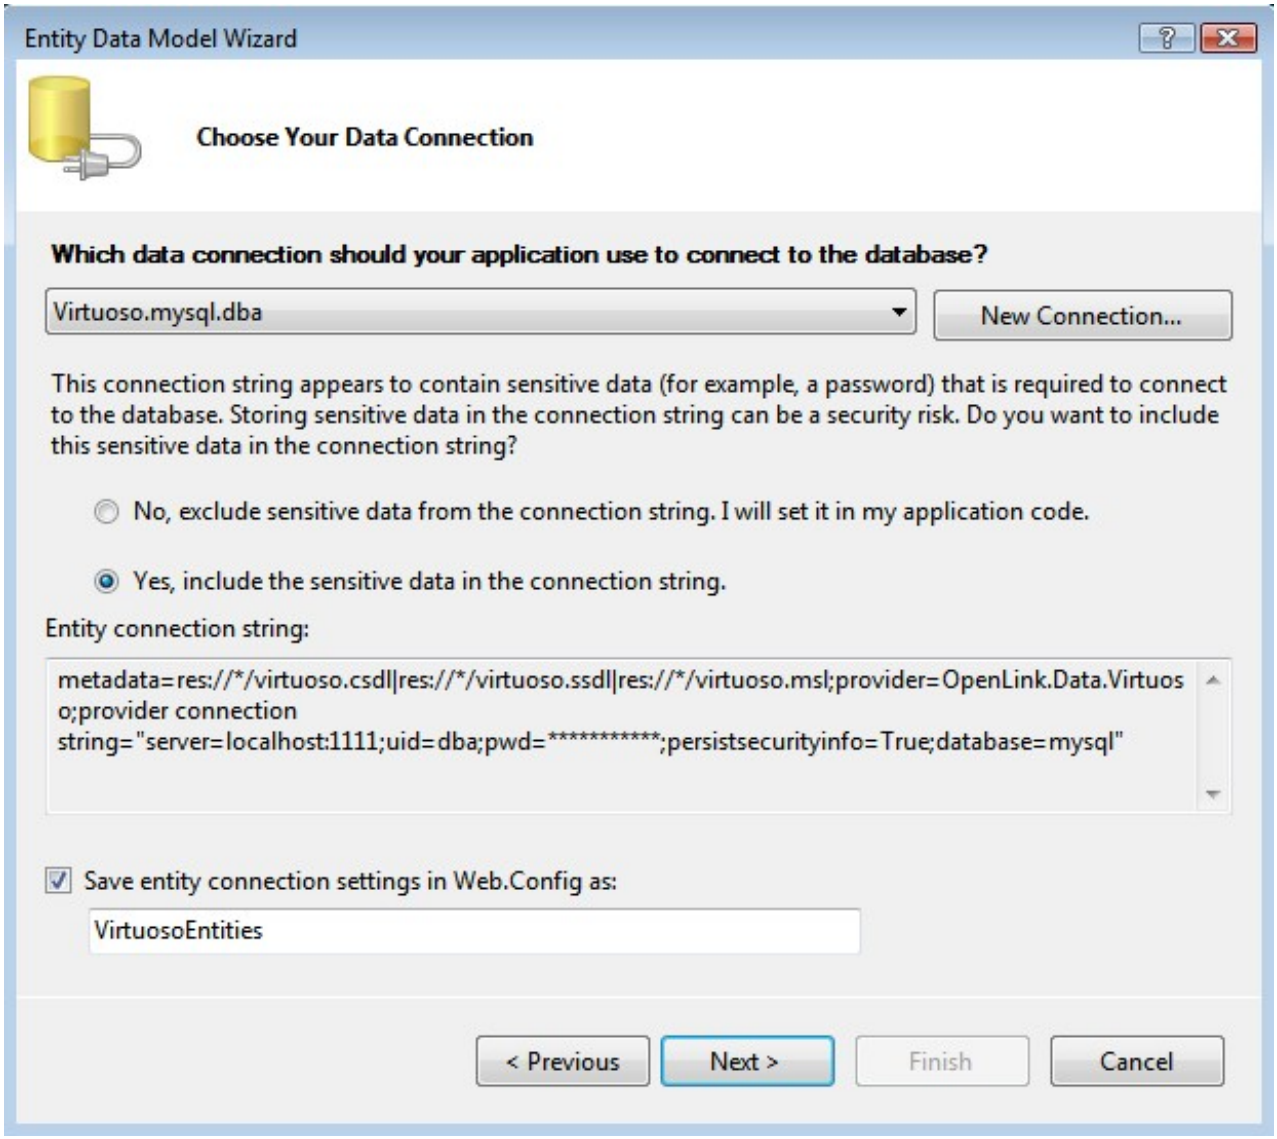
    VirtuosoEntities

    (note this name as it is required in the section on creating and ADO.Net Data Service) and click

    Next

    .

    Figure 8.417. entity connect string



17. In the

    Choose your Database Objects

    page tick the

    Tables

    check box to select all tables in the mysql catalog for addition to the Entity Data Model. Set the

    Model Namespace

    to

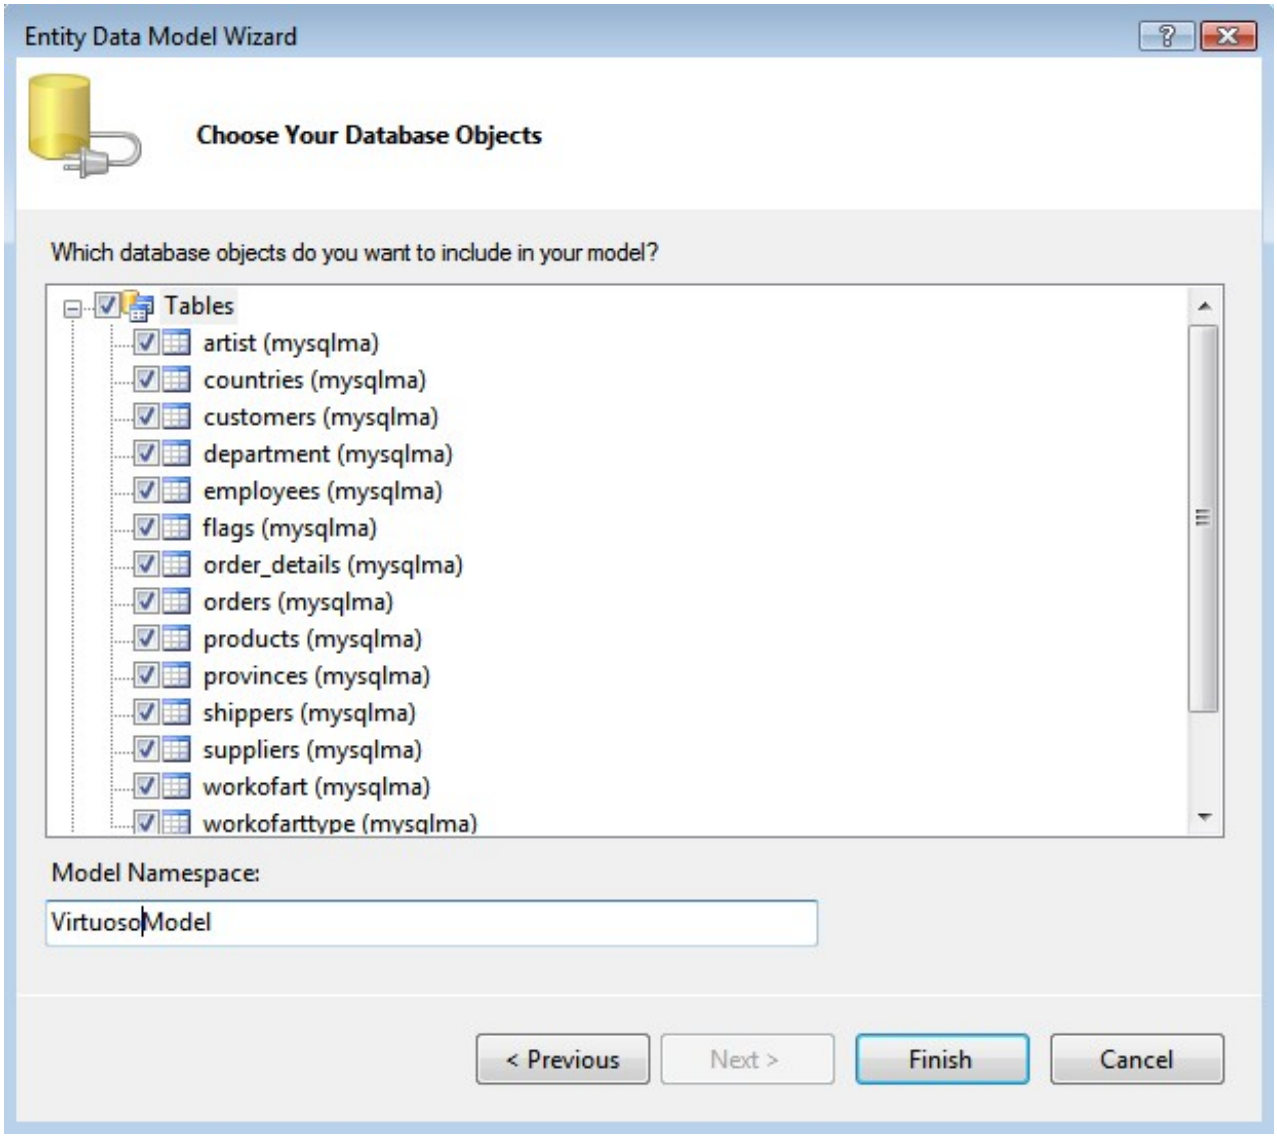
    VirtuosoModel

    and click

    Finish

    .

Figure 8.418. Database Objects

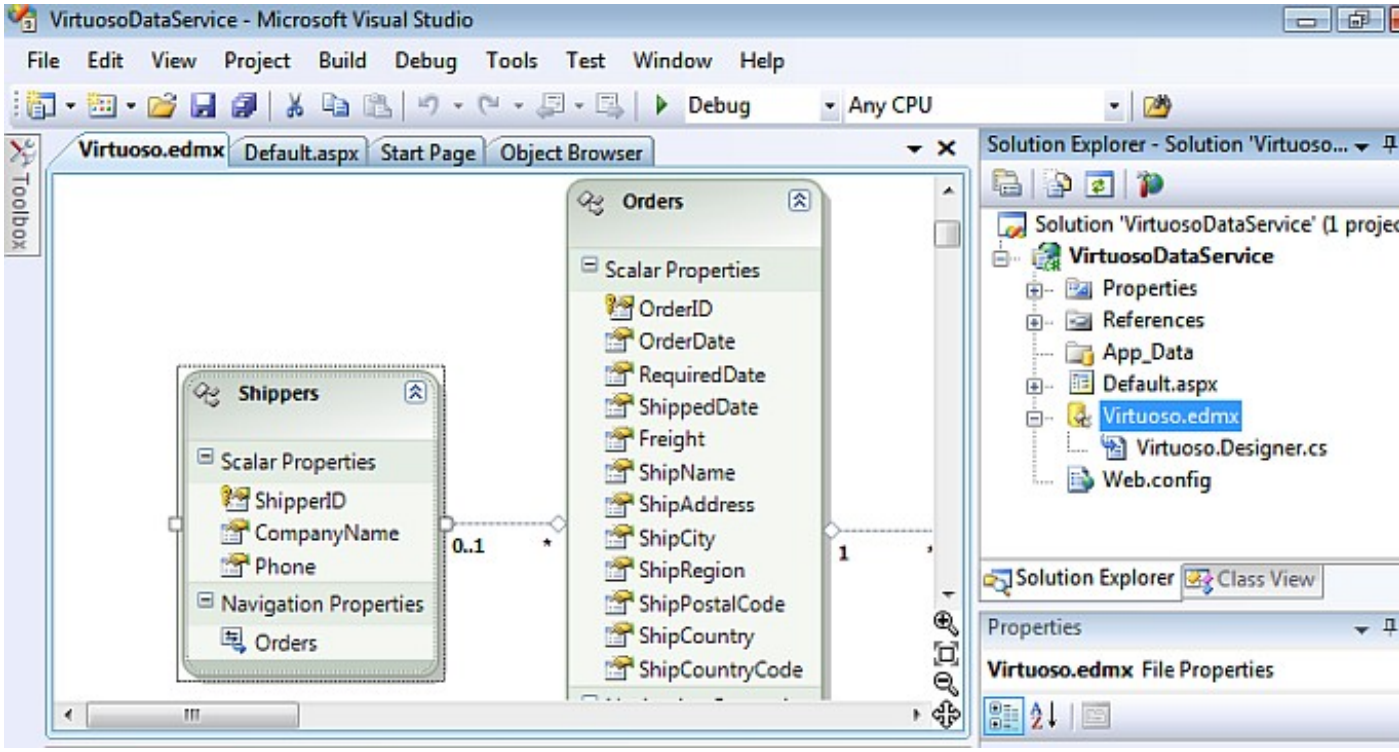


18. The

    Virtuoso.edmx

    EDM will be created with the tables and relationships displayed in the Visual Studio IDE

    Figure 8.419. Virtuoso.edmx



Creation for the Entity Data Model for the MySQL Northwind database is now complete.

8.8.5. Using EDM to create Entity Framework based applications

Now that a Microsoft Entity Data Model has been created for the Northwind database, Entity Framework applications can be created to make use of it.

Entity Frameworks based ADO.NET Data Service

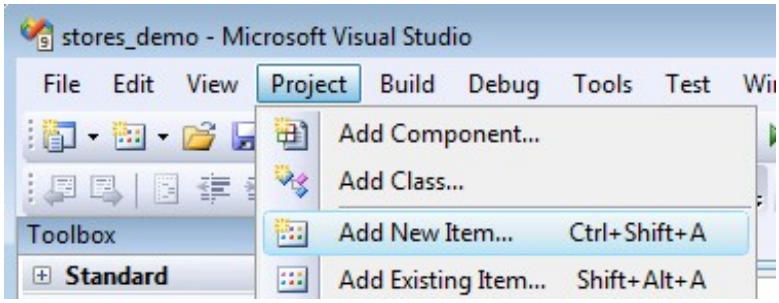
An ADO.Net Data Service for the MySQL tables can be created using the Entity Data Model created in the Creating EDM in Visual Studio 2008 section .

1. Open the

   VirtuosoDataService

   project created in the Creating EDM in Visual Studio 2008 section .
2. Select the Project -> Add New Item menu option.

   Figure 8.420. VirtuosoDataService



3. The

   Add New Item

dialog will appear. Choose the

ADO.NET Data Service template

. Give it the name

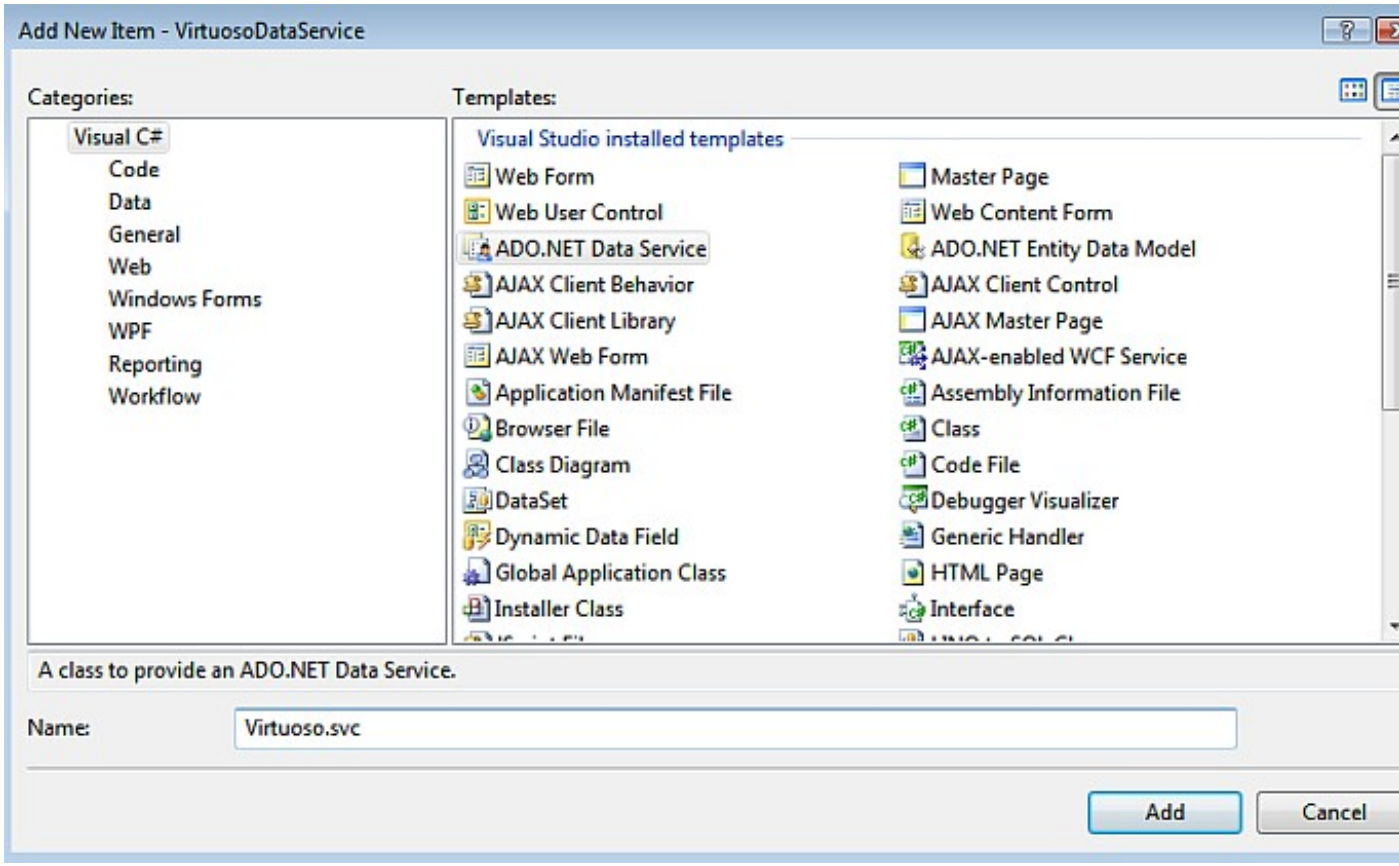
Virtuoso.svc

, and click

Add

to create the ADO.Net Data Service.

Figure 8.421. Add New Item



4. In the newly created

Virtuoso.svc.cs

Data Service file, add the data source class name of

VirtuosoEntities

(note this is the name set in the Creating EDM in Visual Studio 2008 section) as the

DataService

name. Enable the access to the Data Service by adding the entry

config.SetEntitySetAccessRule("", EntitySetRights.All);*

in the

InitializeService

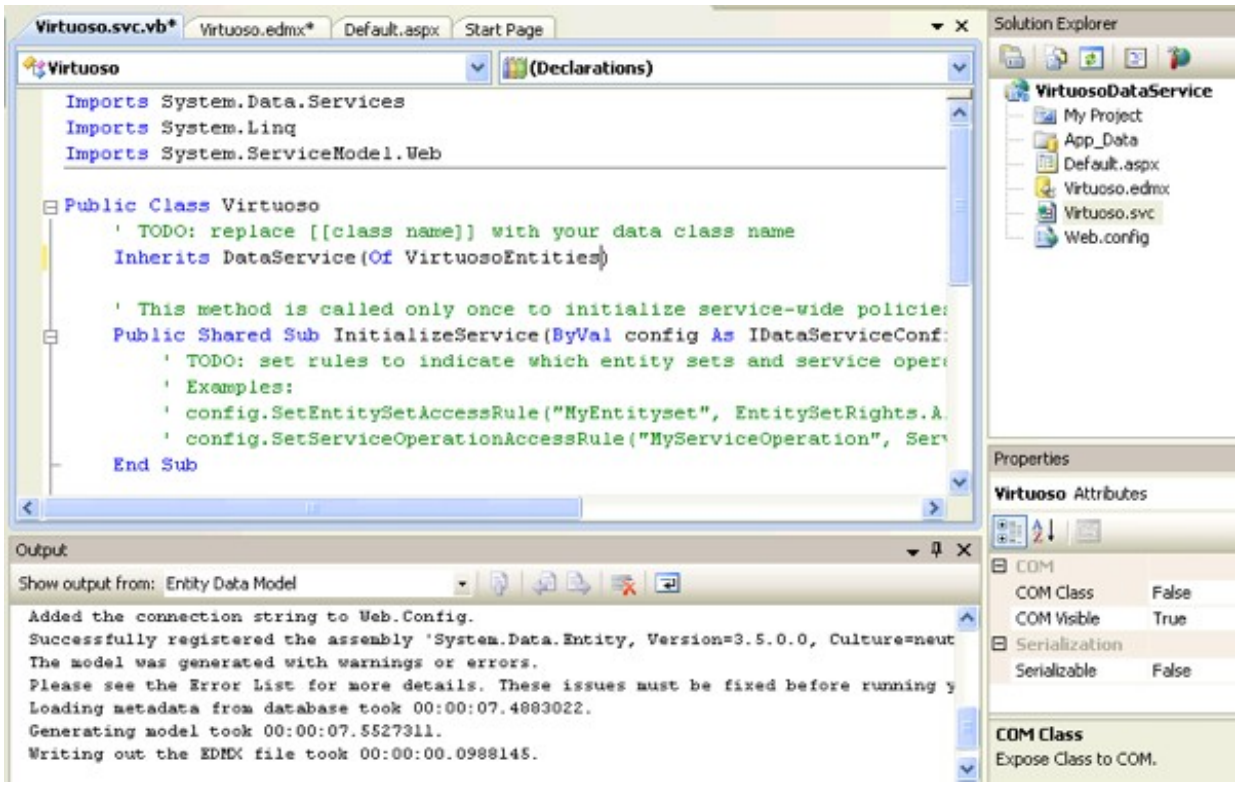
method.

```
// C#

using System;
using System.Web;
using System.Collections.Generic;
using System.ServiceModel.Web;
using System.Linq;
using System.Data.Services;

namespace SimpleDataService
{
    public class Northwind: DataService<VirtuosoDemoEntities>
    {
        public static void InitializeService(IDataServiceConfiguration  config)
        {
            config.SetEntitySetAccessRule("*", EntitySetRights.All);
        }
    }
}
```

Figure 8.422. Virtuoso.svc.cs

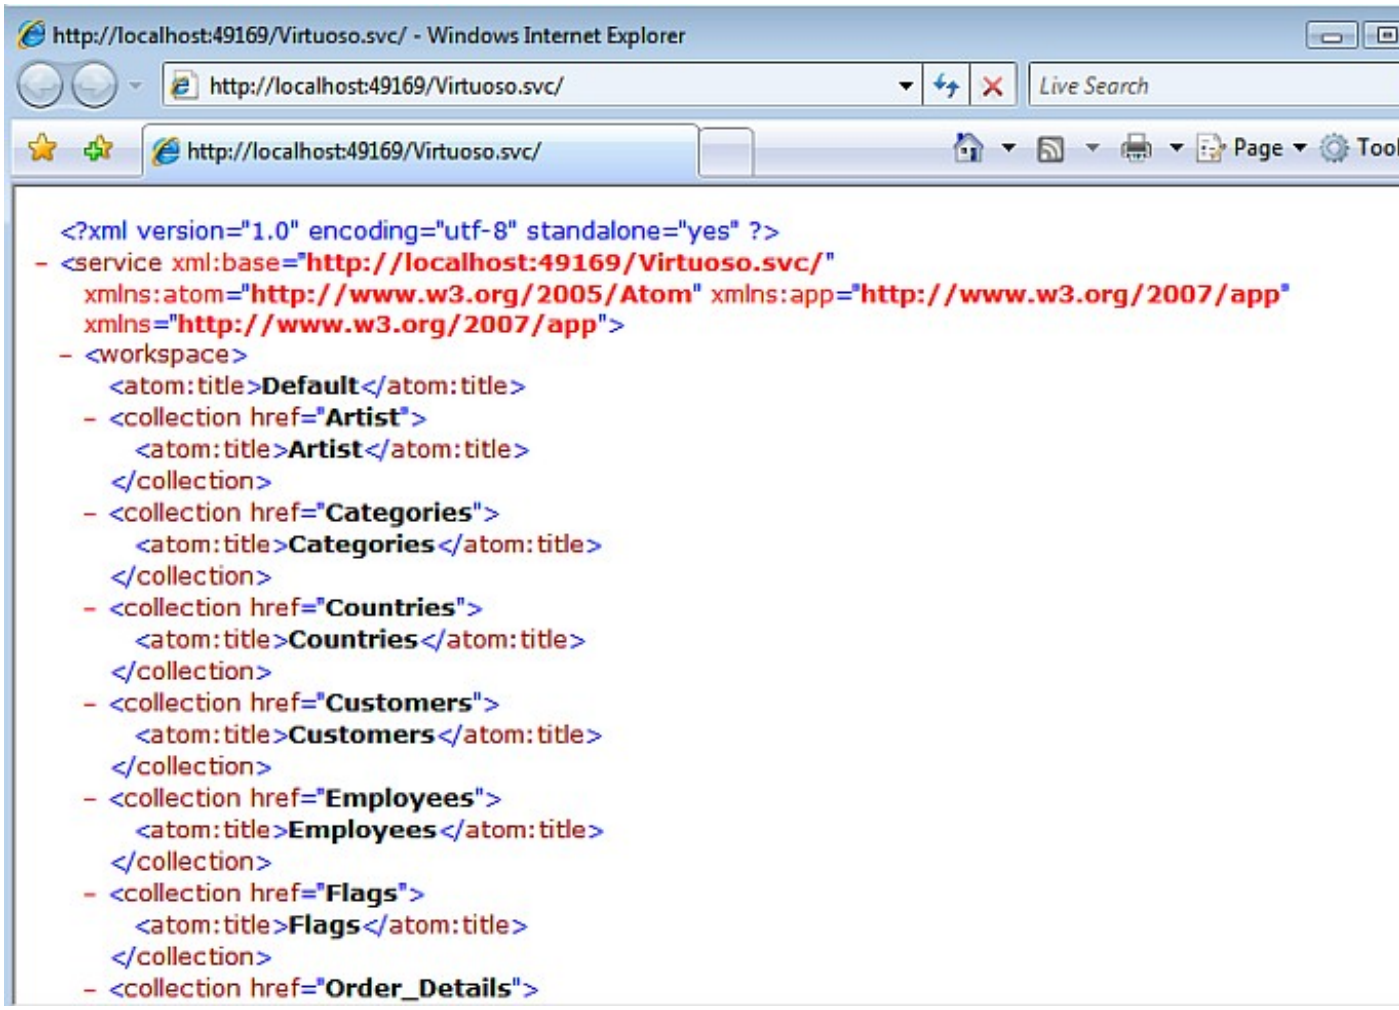


5. To test the Data Service, simply hit

   Ctrl+F5

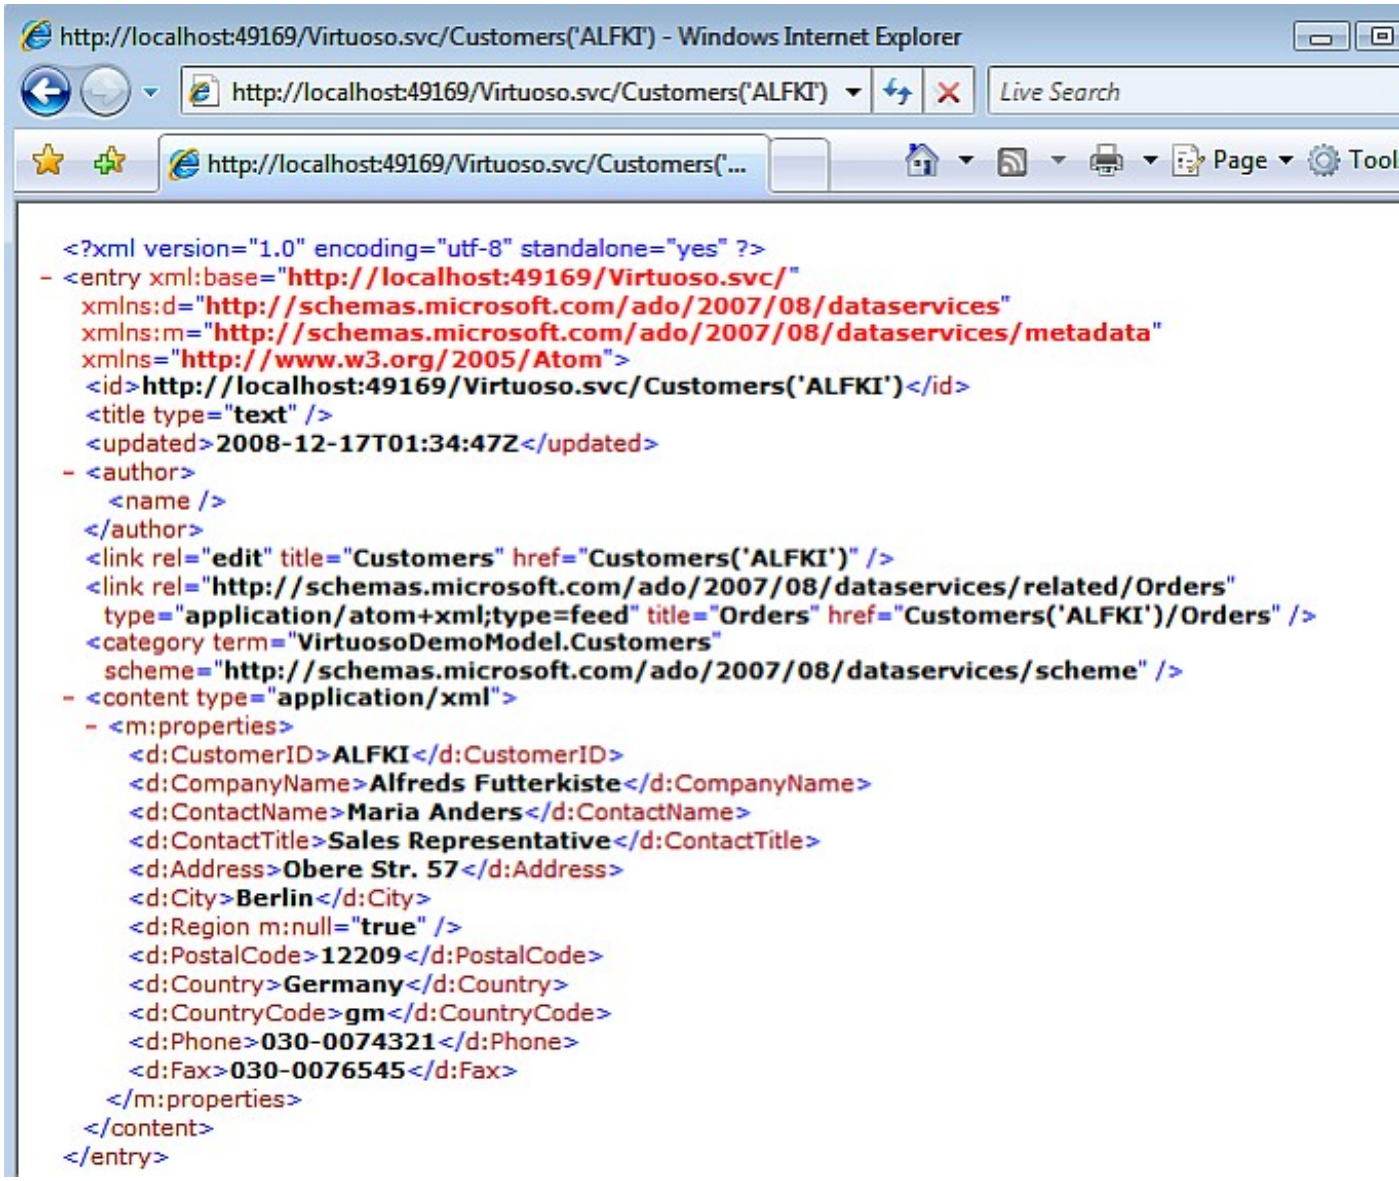
   within Visual Studio. This will start the development web server, run the Data Services server inside and load a Web browser page displaying the list of available tables/entities for the mysql Northwind database catalog.

Figure 8.423. Data Service test



6. To access a specific entity instance like the Customers table ALFKI record, use this convention: http://host/vdir/Virtuoso.svc/Customers('ALFKI') .

Figure 8.424. Customers



Notes:

1. *Important*

   - To view

   Atom

   (the default format returned by an ADO.NET Data Service) in Internet Explorer, you must first ensure that

   Feed Reading View

   is turned

   off

   . This can be done on the

   Content tab

   of

Tools in Internet Options

.

2. If a Data Services entity instance URI page fails to load you can turn

   Verbose

   errors on by adding

   config.UseVerboseErrors = true;

   in the

   virtuoso.svc.cs InitializeService

   method to obtain more detailed information from the server as to why the page failed to load:

```
public static void InitializeService(IDataServiceConfiguration config)
{
config.UseVerboseErrors = true;
config.SetEntitySetAccessRule("*", EntitySetRights.All);
}
```

Visual Studio Windows DataGrid Form Application

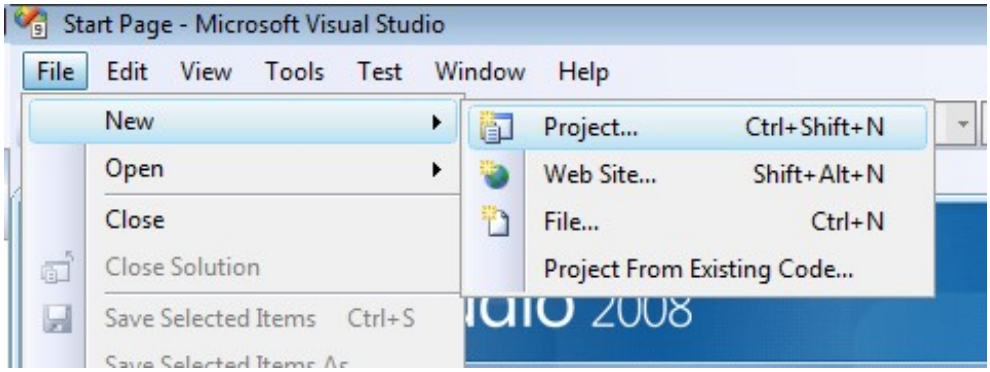
This section details the steps required to create a simple Visual Studio 2008 Windows Form application, with associated DataGridView control for displaying data in selected tables from the target database.

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.425. Visual Studio 2008 SP1 IDE

2. Create a *Web Application* project by going to the *File* menu in Visual Studio and choosing *New Project* .

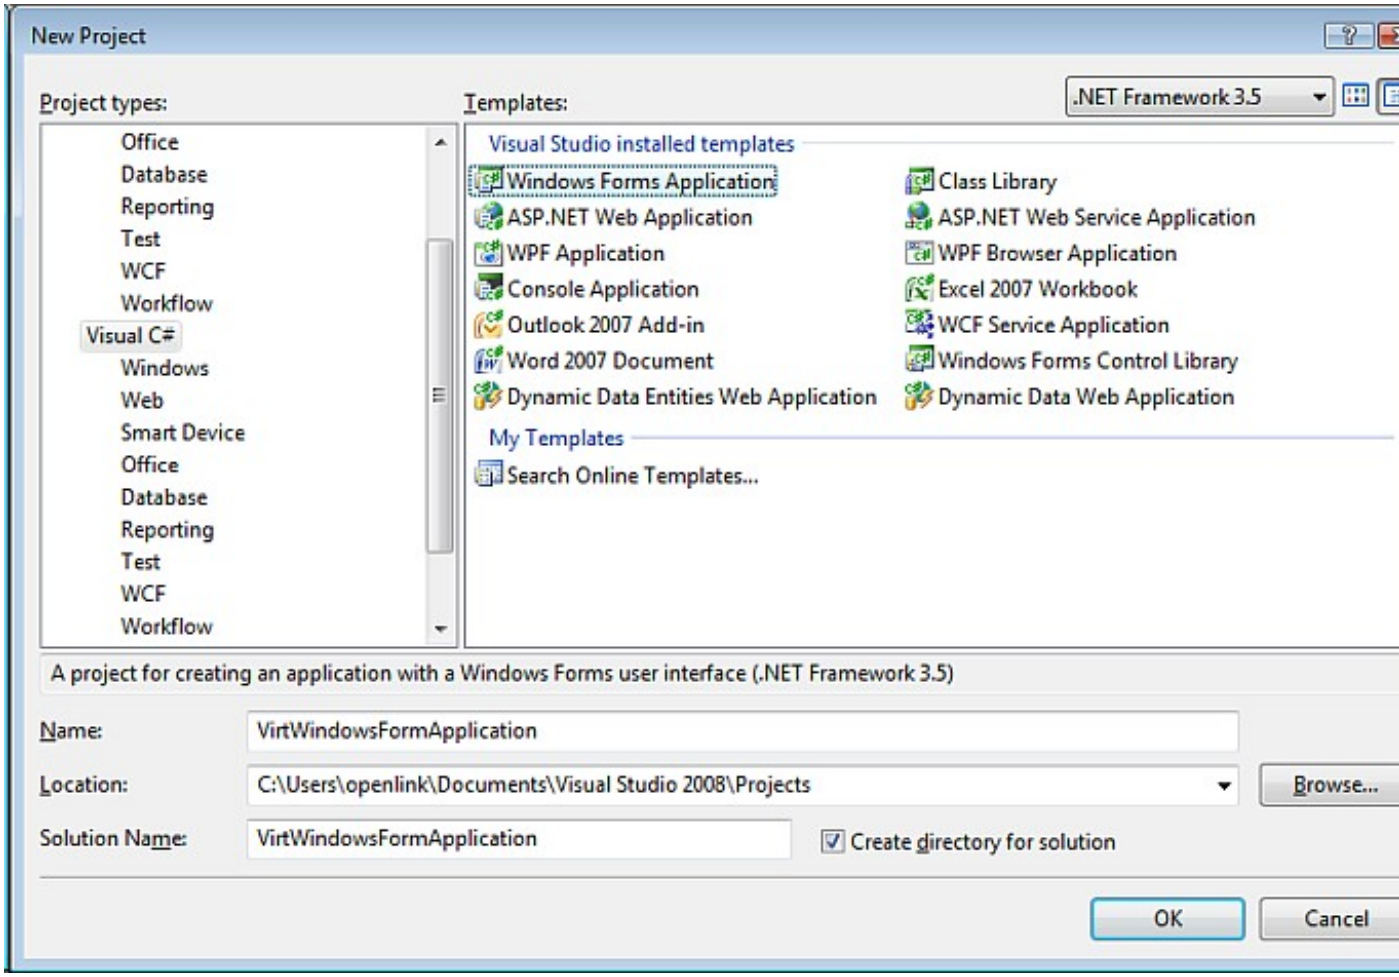
   Figure 8.426. Web Application



3. When the New Project window appears, choose either

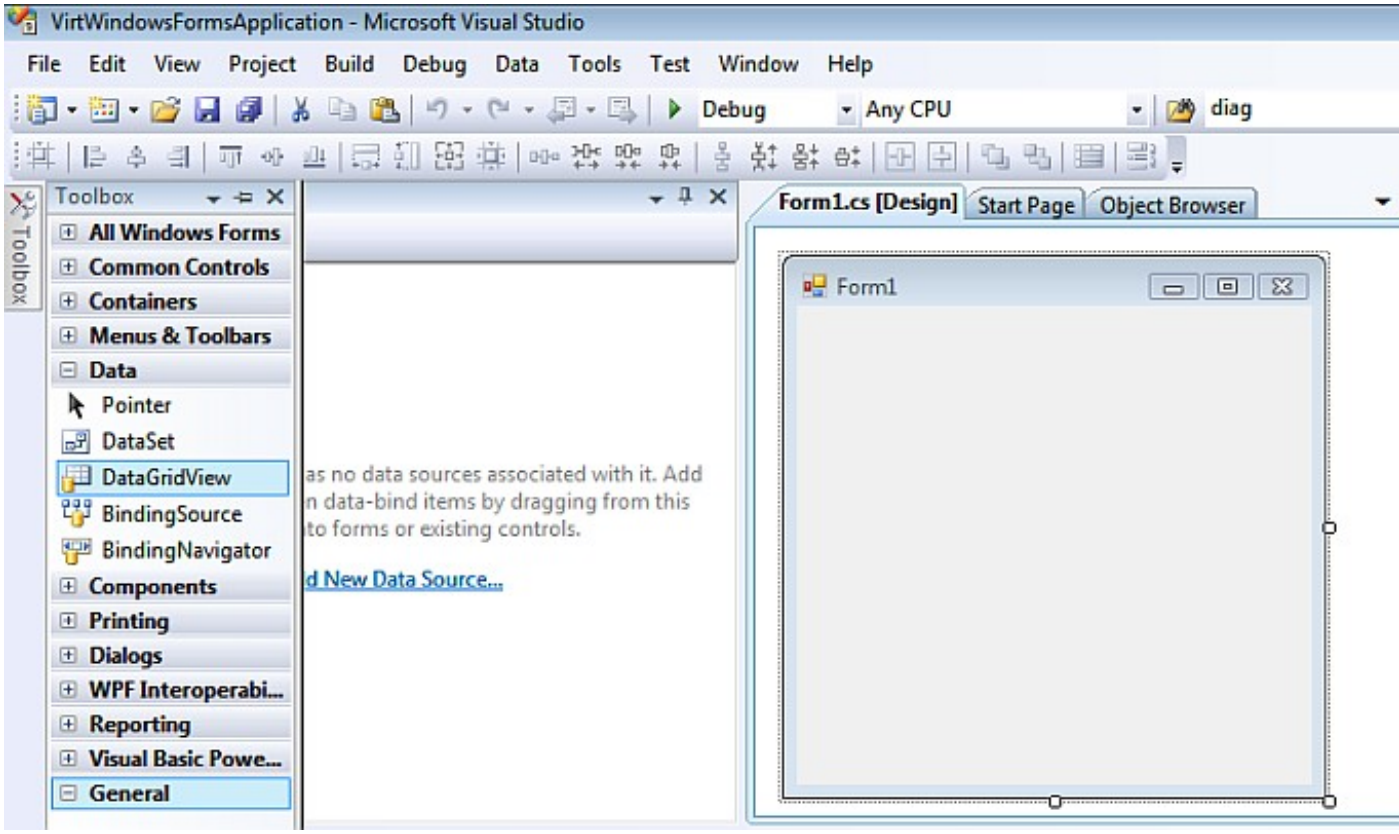
   Visual Basic or *Visual C#* as your programming language.
4. Within the language category, click on *Windows* and select *Windows Form Application* from the right-hand panel.
5. Choose a name for the project, for example *VirtWindowsFormApplication* , and click *OK* .

Figure 8.427. Web Application



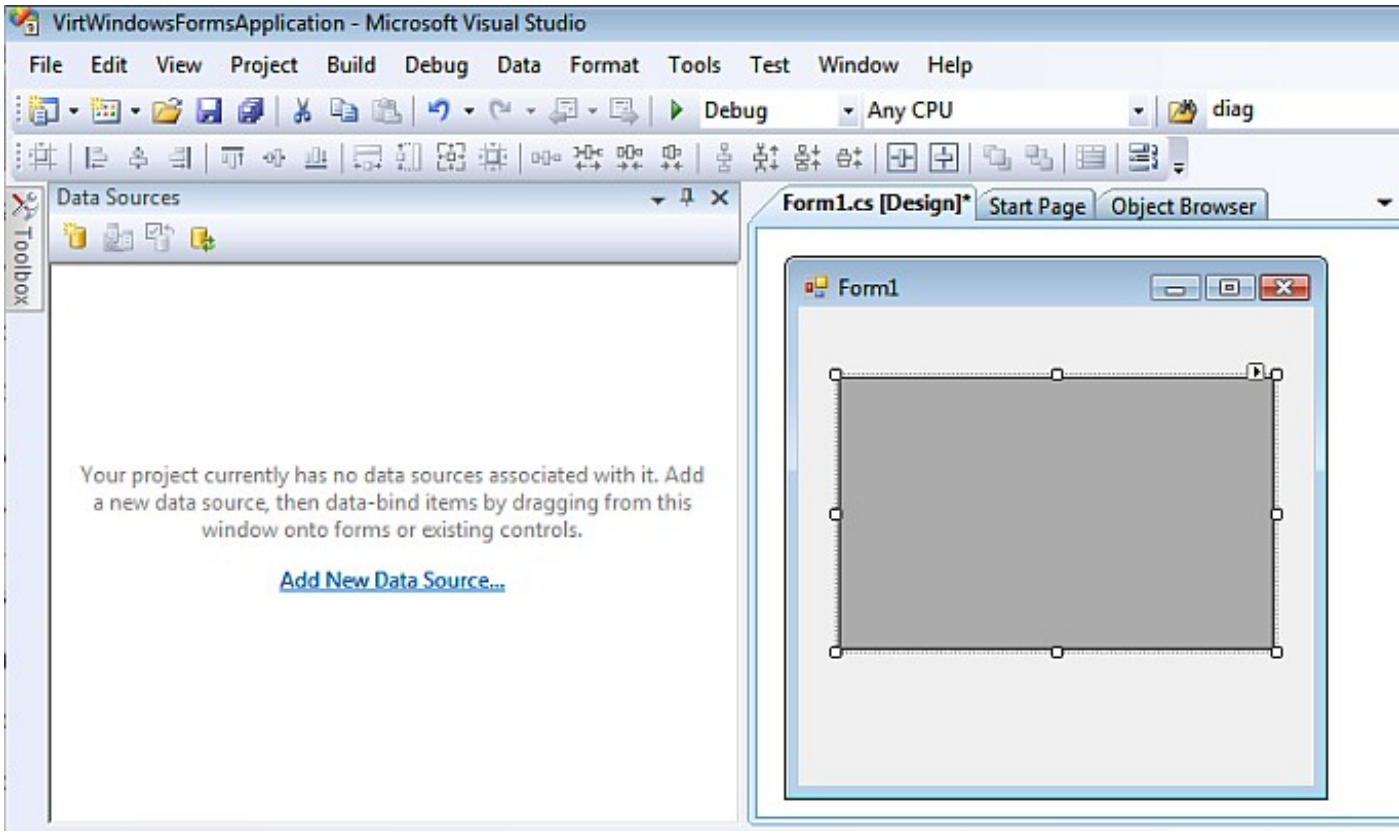
6. In the *Toolbox* , expand *Data Controls* , and drag the *DataGridView* control onto the form.

Figure 8.428. Toolbox



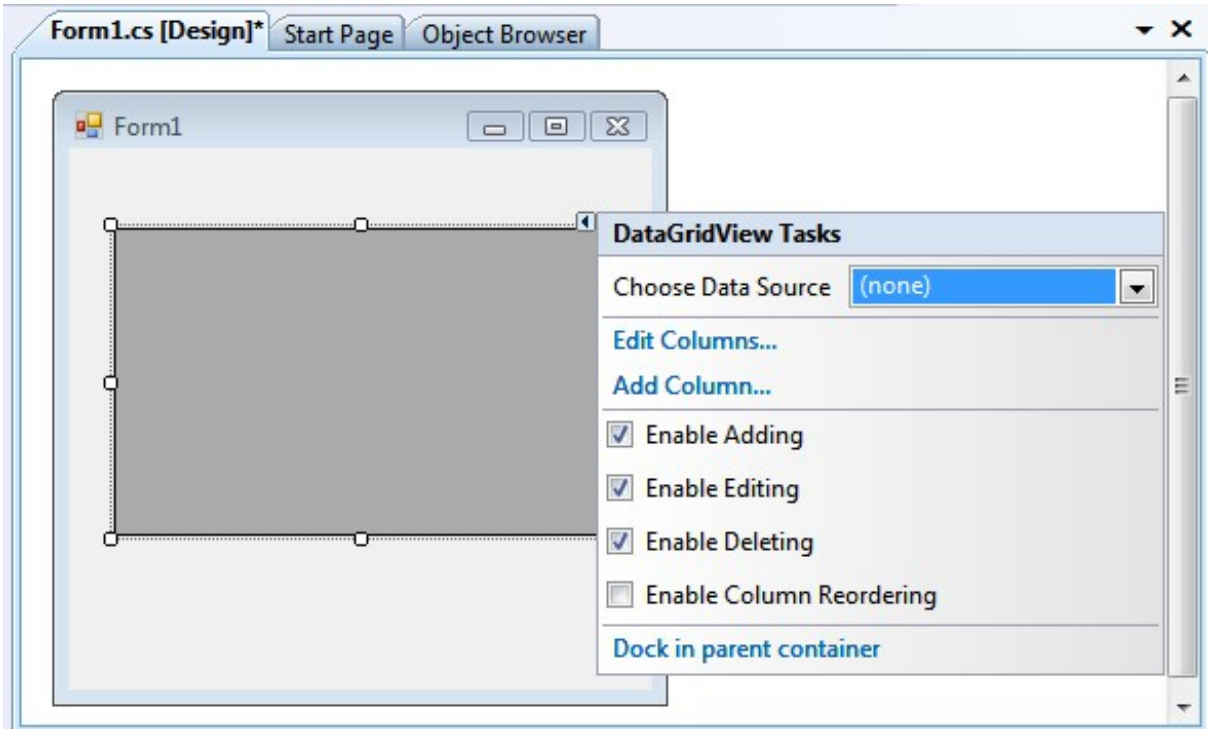
7. Click on the little *arrow* in the top right of the *DataGridView* control. This loads the *DataGridView Task* menu.

Figure 8.429. DataGridView Task



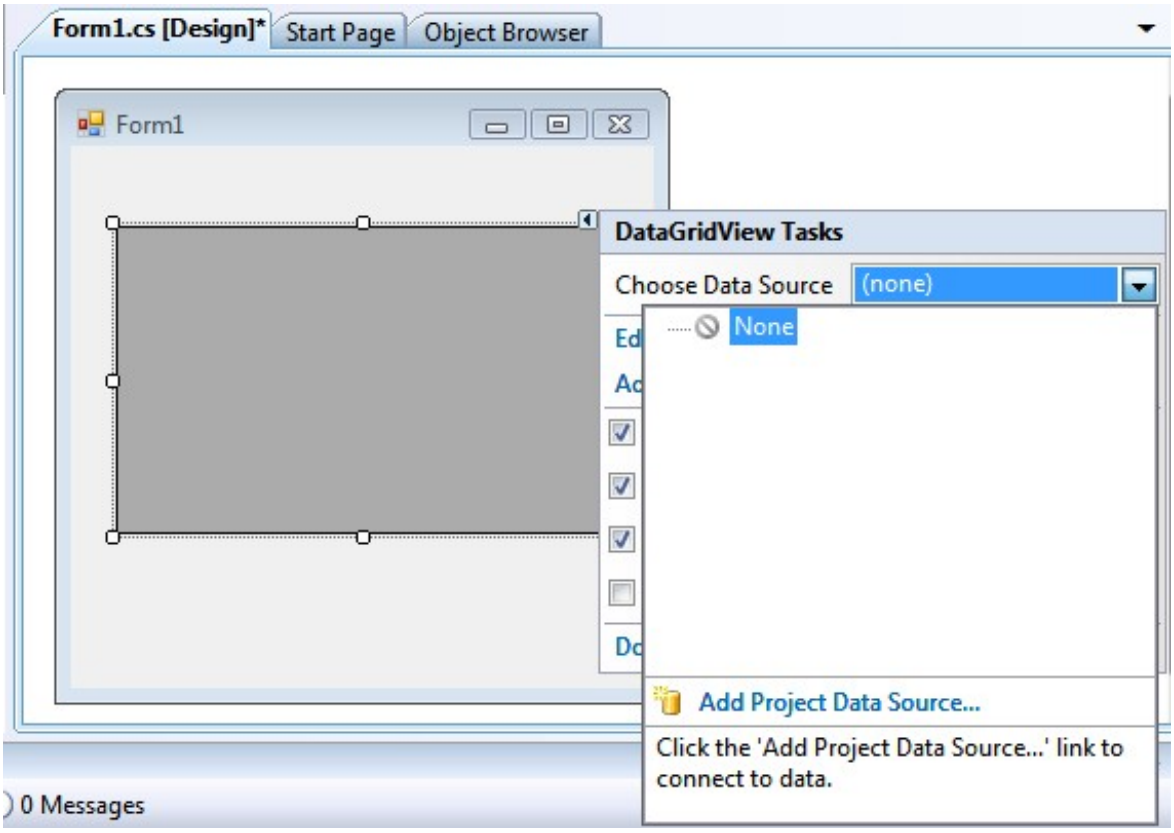
8. Click on the *Choose Data Source* list box.

Figure 8.430. Choose Data Source



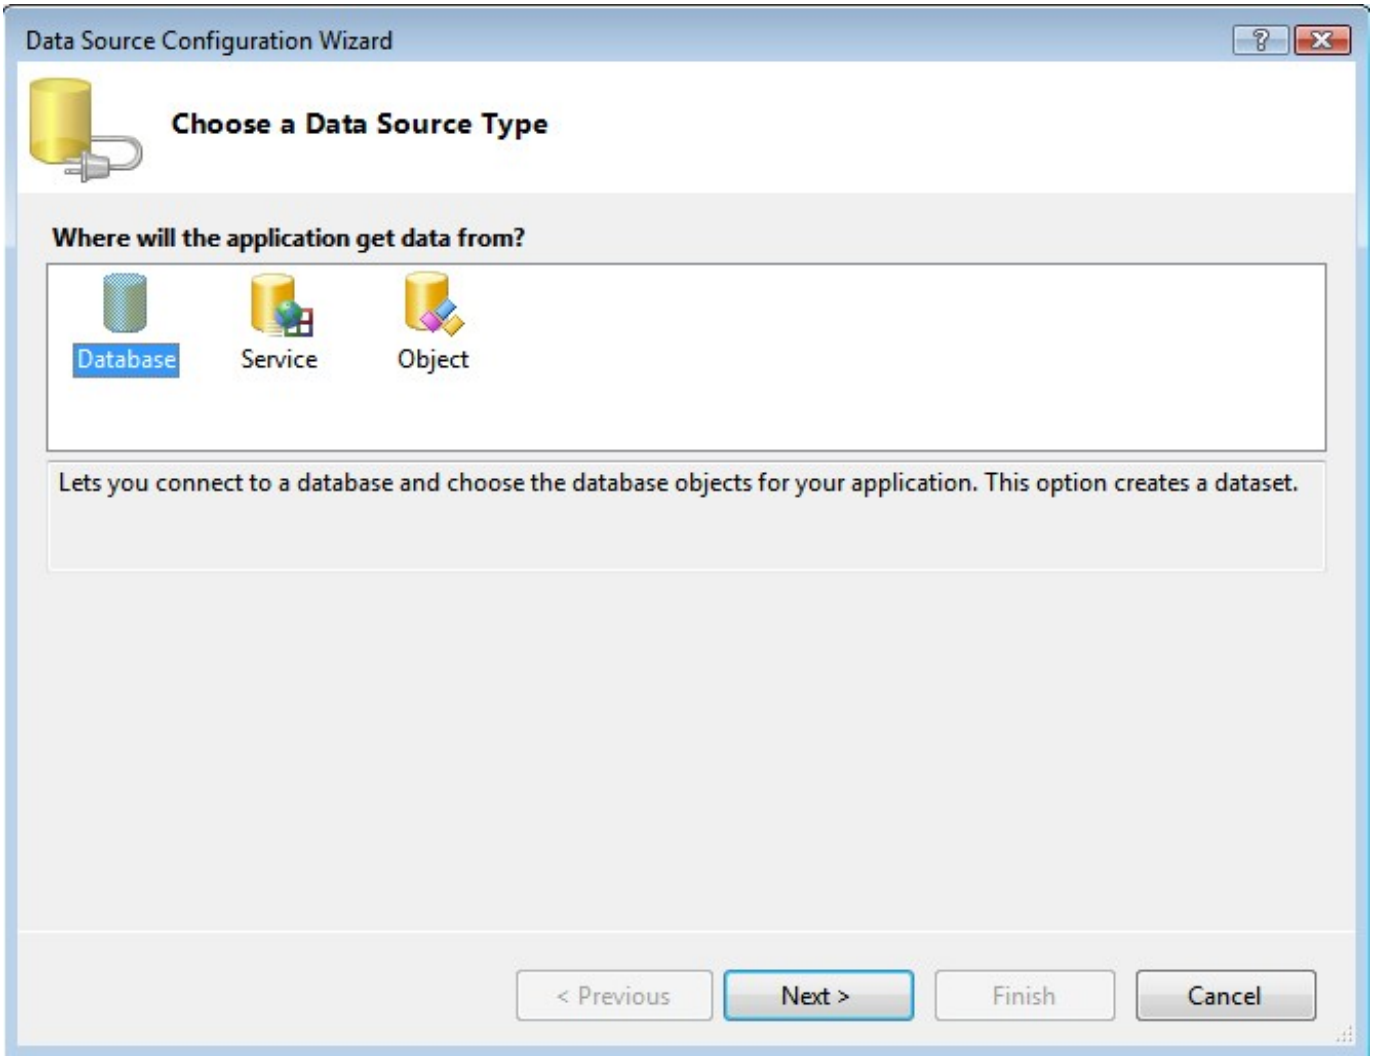
9. Click on the *Add Project Data Source* link to connect to a data source.

Figure 8.431. Add Project Data Source



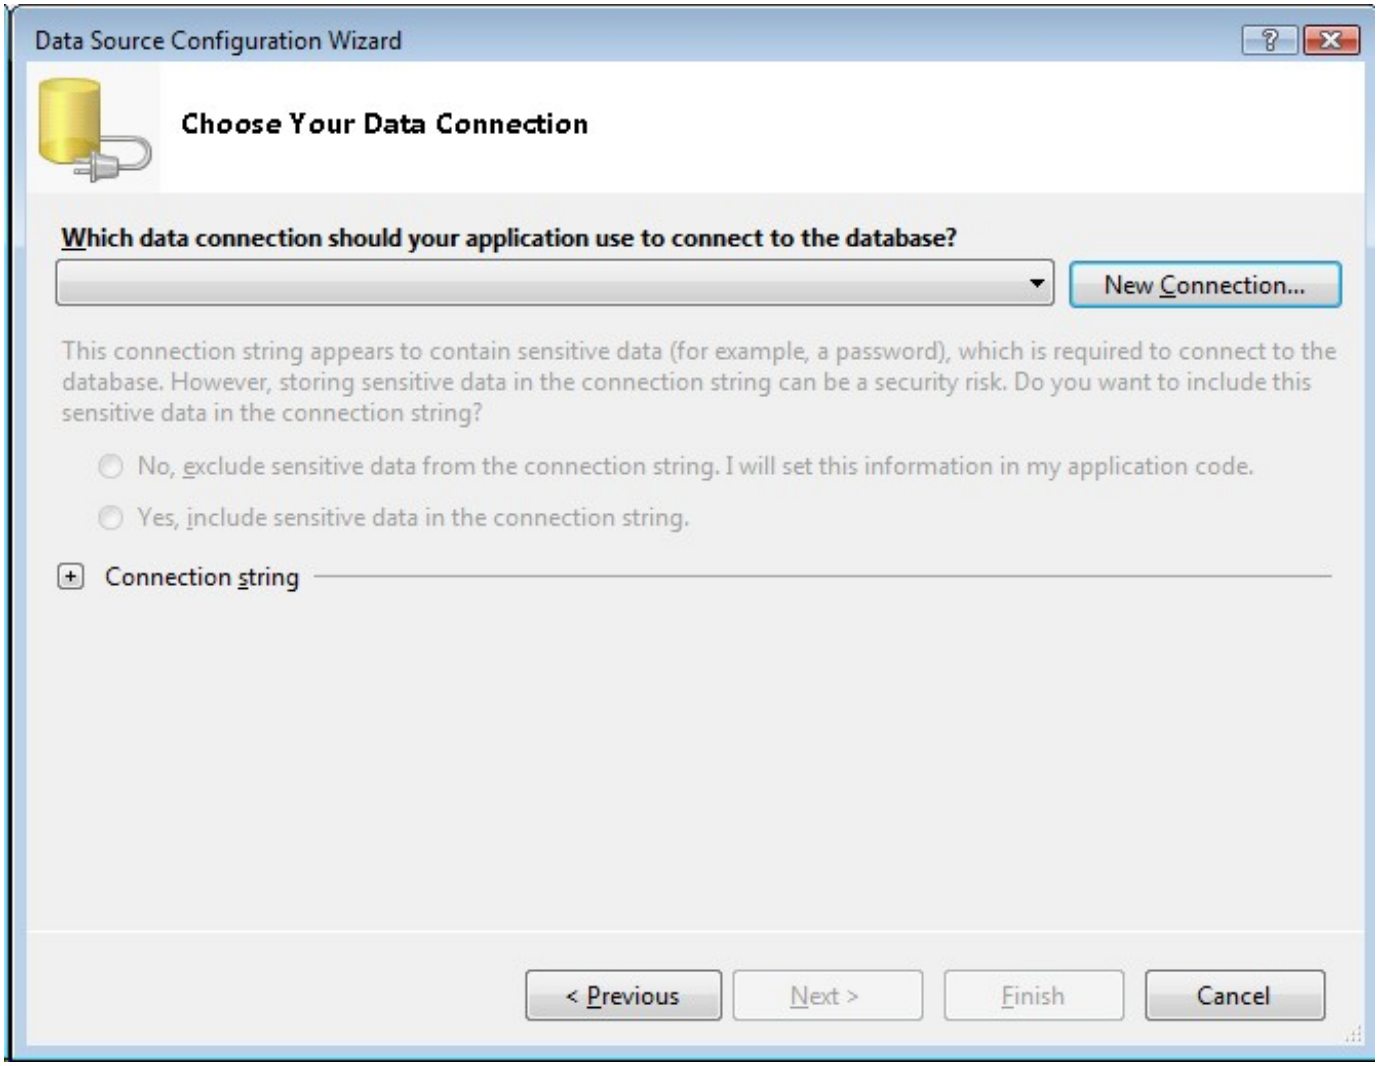
10. In the *Data Source Configuration Wizard* dialog *Choose Data Source Type* page select the *Database* data source type and click *Next* .

Figure 8.432. Data Source Type



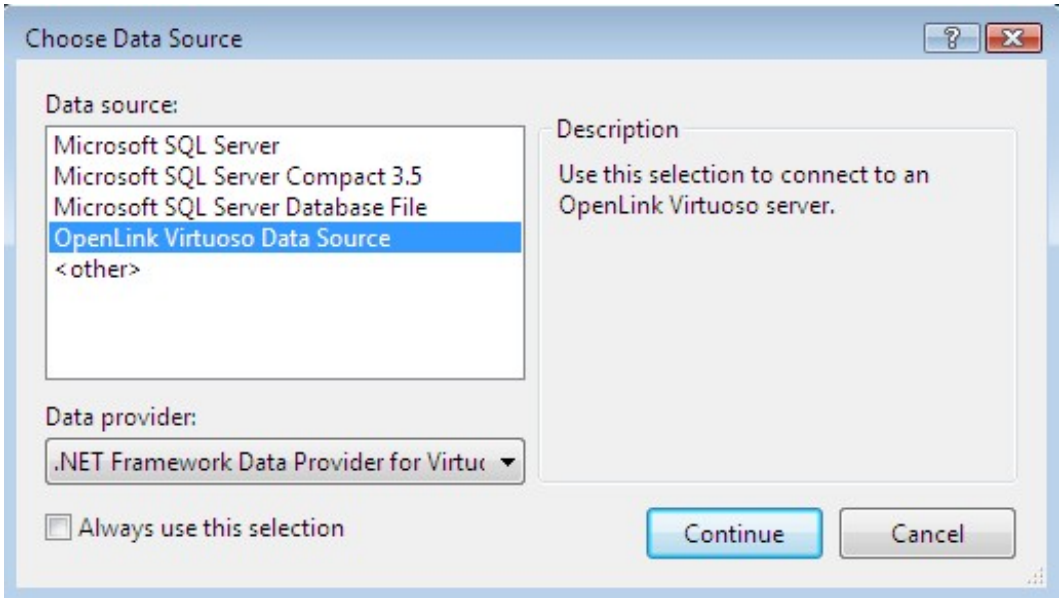
11. In the *Data Source Configuration Wizard* dialog *Choose your Data Connection* page, select the *New Connection* button

Figure 8.433. Data Source Configuration Wizard



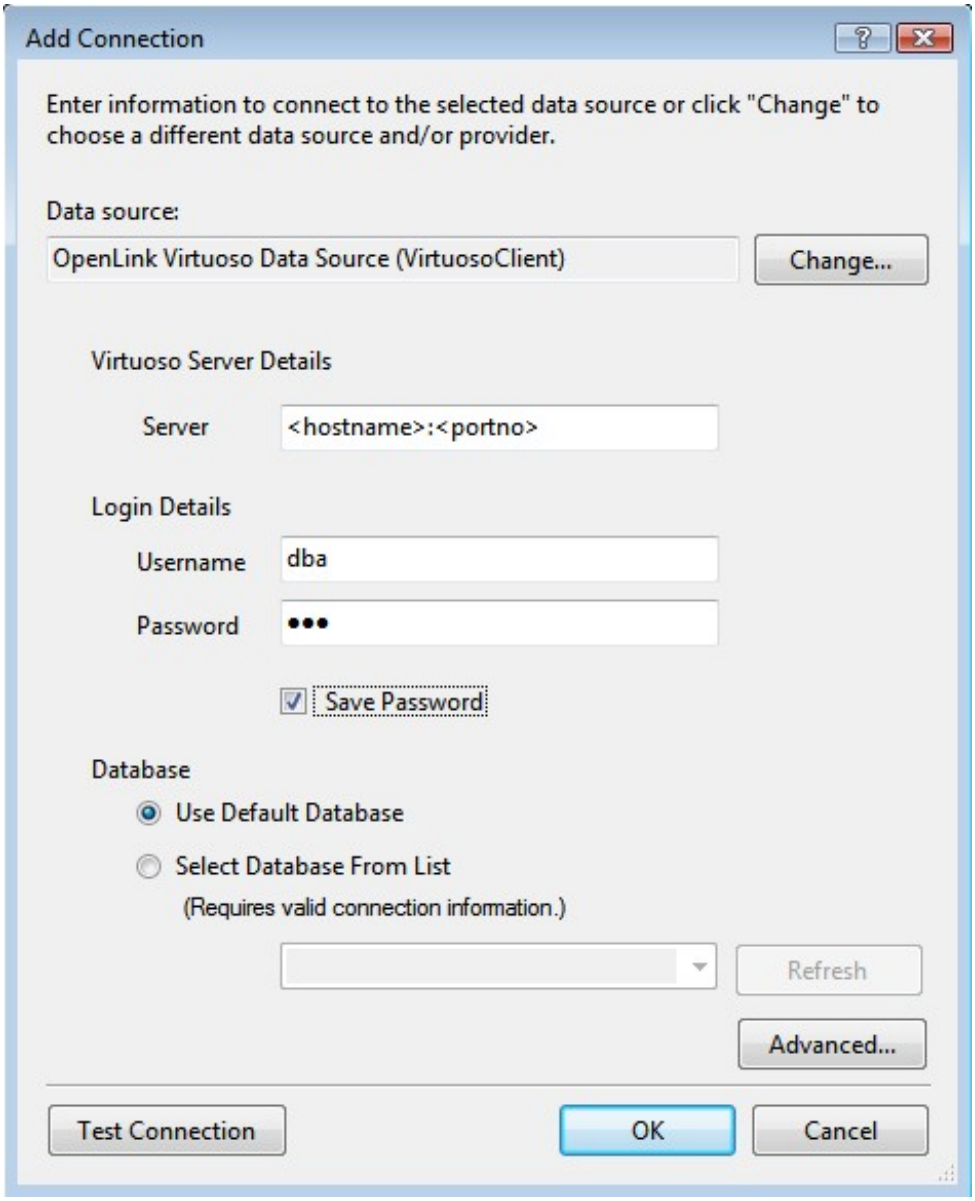
12. In the *Choose Data Source* dialog, select the OpenLink *Virtuoso Data Source* from the list and click *Continue* .

Figure 8.434. Data Source



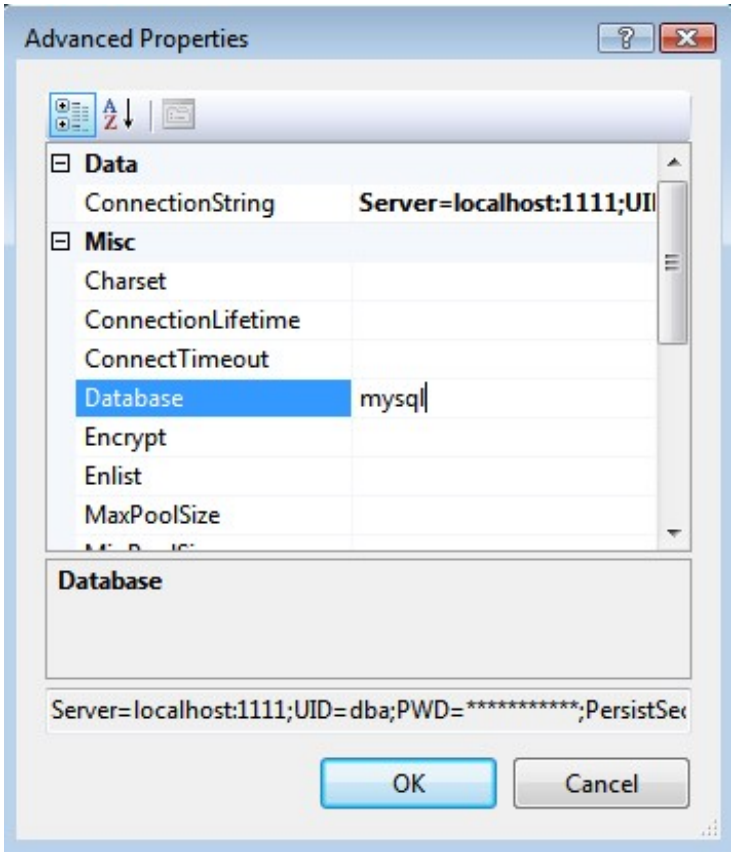
13. In the *Add Connection* dialog, specify the *hostname, portno, username and password* for the target Virtuoso Server and check the Save Password check box.

Figure 8.435. Connection Properties



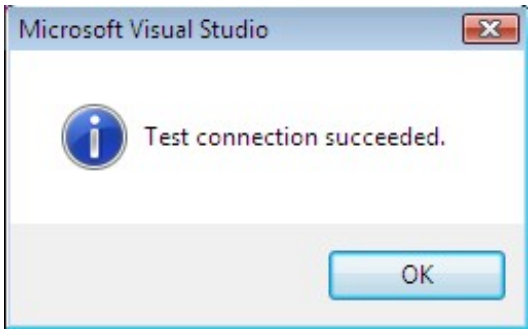
14. Select the *Select Database From List* radio button and choose the *mysql* database from the drop down list.

Figure 8.436. Add connection



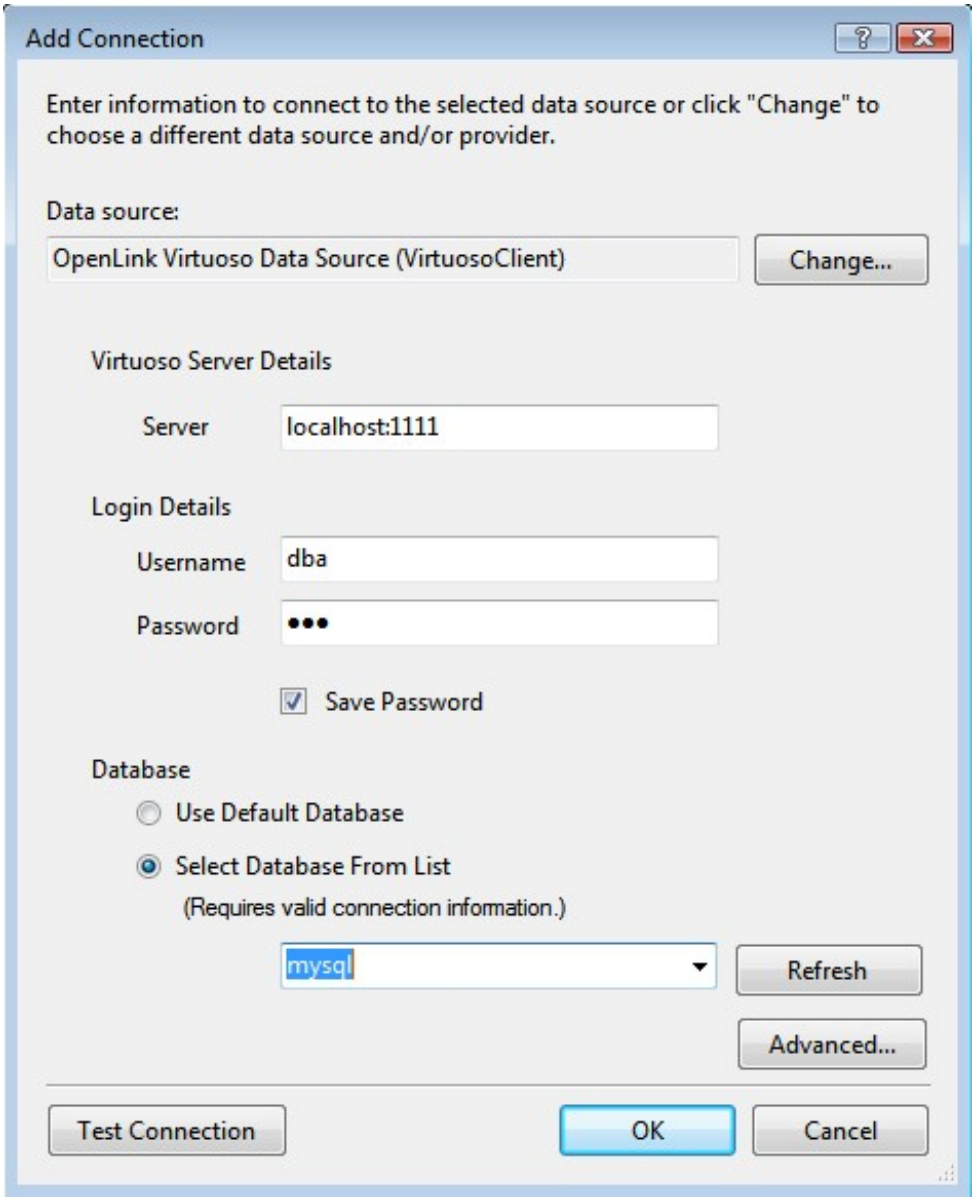
15. Press the *Test Connection* dialog to verify that the database is accessible.

Figure 8.437. Test Connection



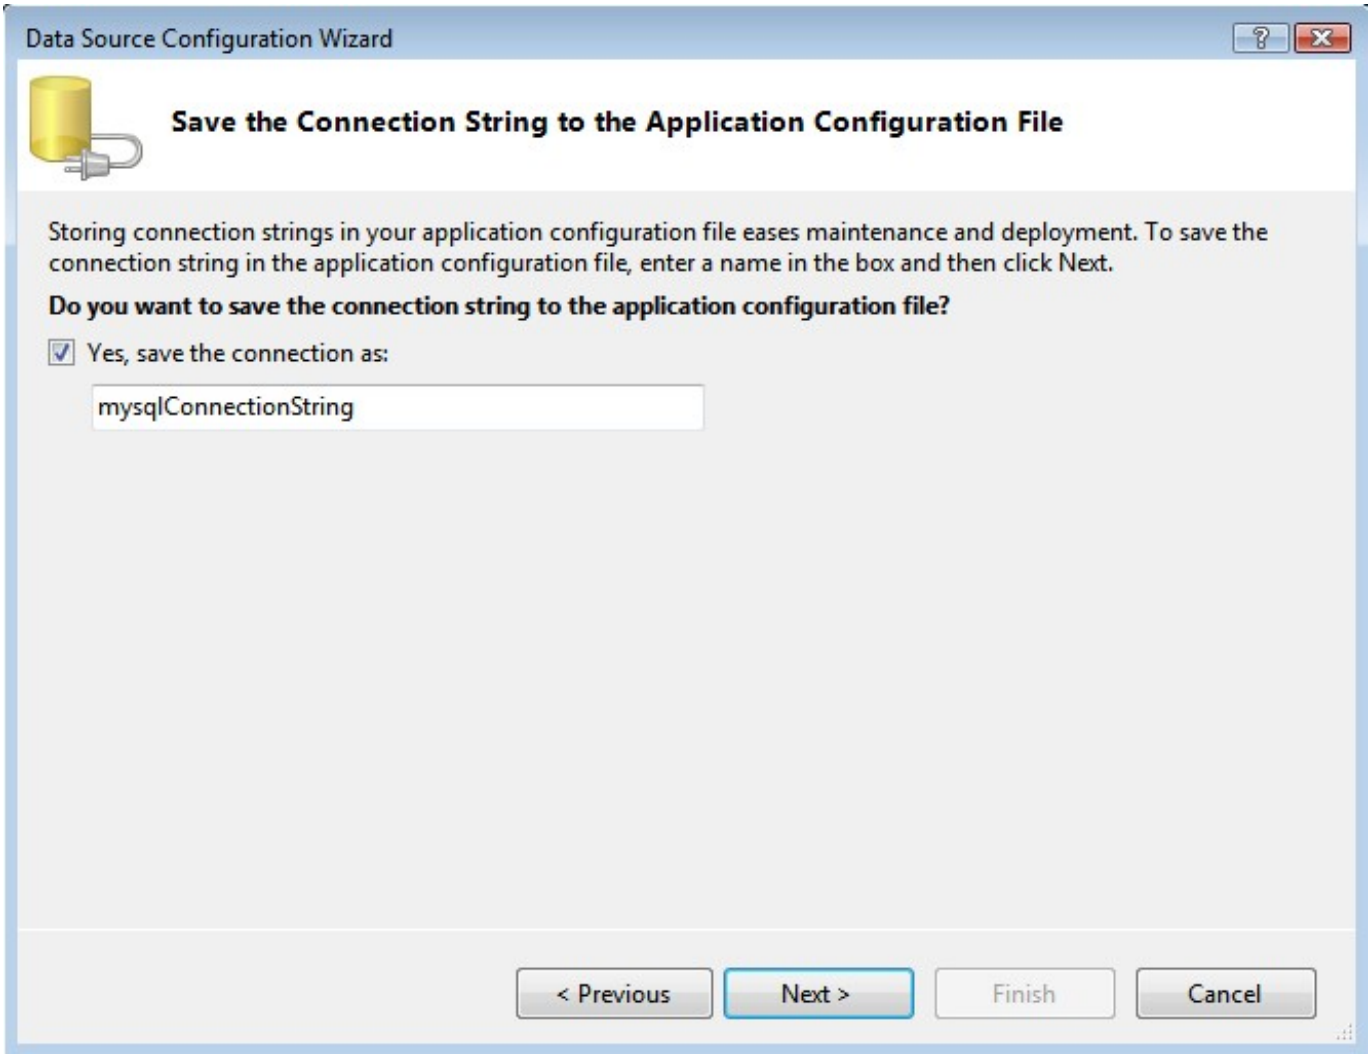
16. Click OK to add the connection.

Figure 8.438. Test Connection



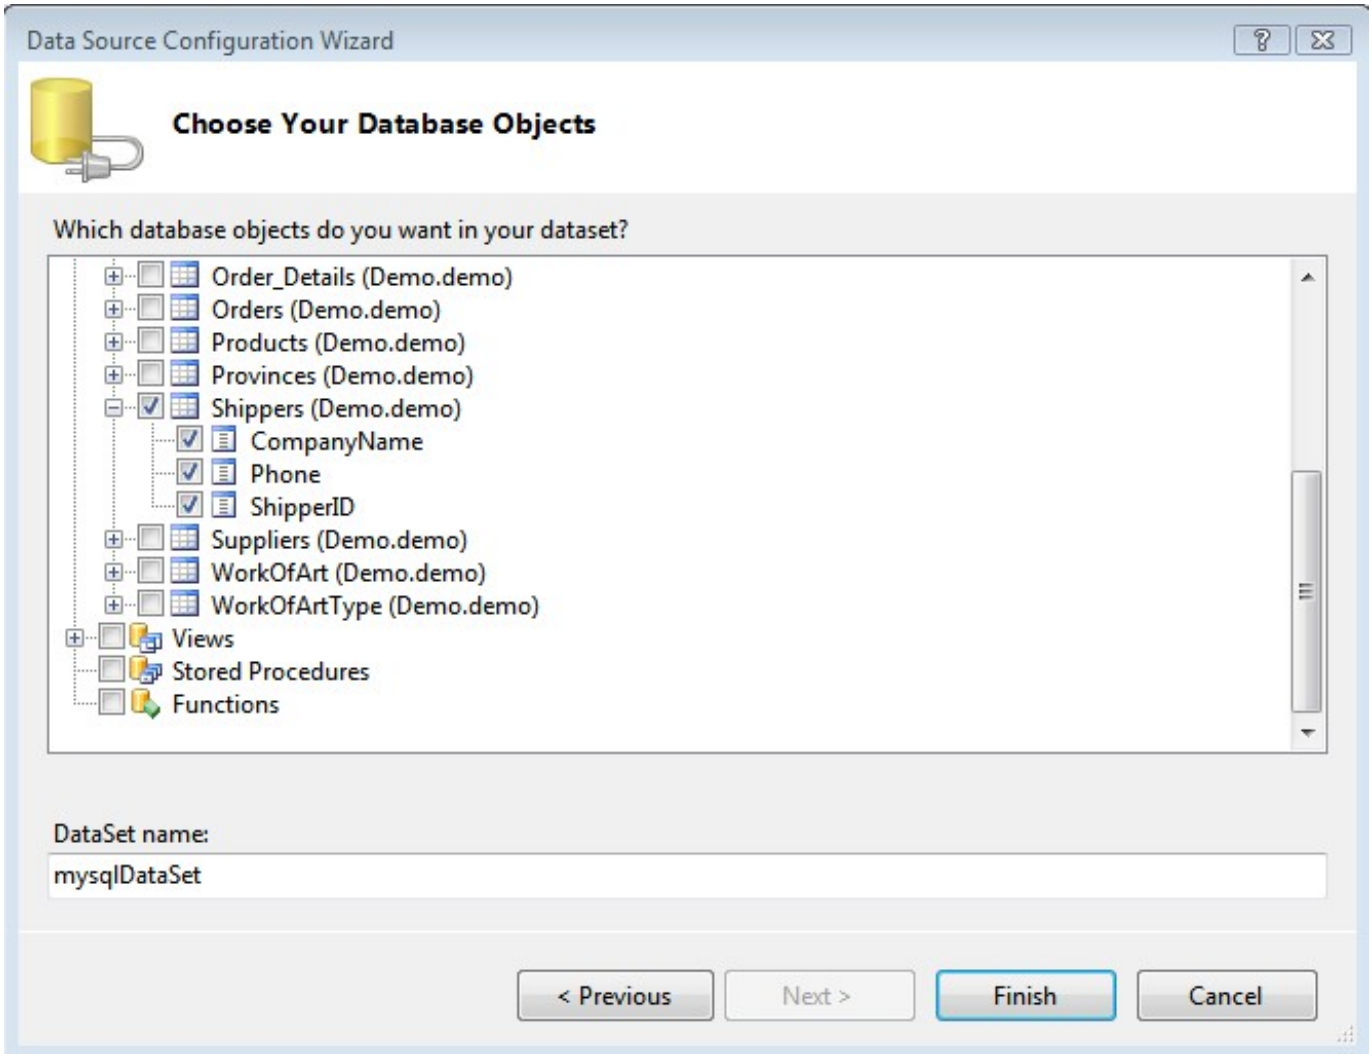
17. Leave the default connect string name*mysqlConnectionString* and click *Next* .

Figure 8.439. mysqlConnectionString



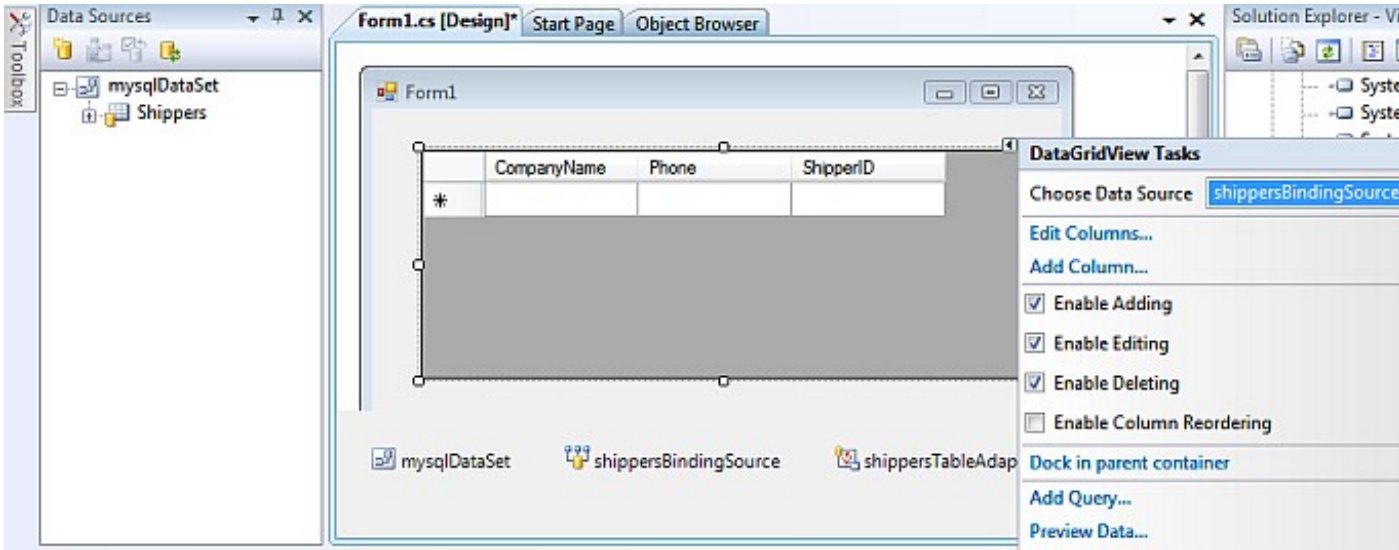
18. From the list of available tables returned for the mysql database, select the *Shippers* table to be associated with the *DataGridView* control.

Figure 8.440. mysql database



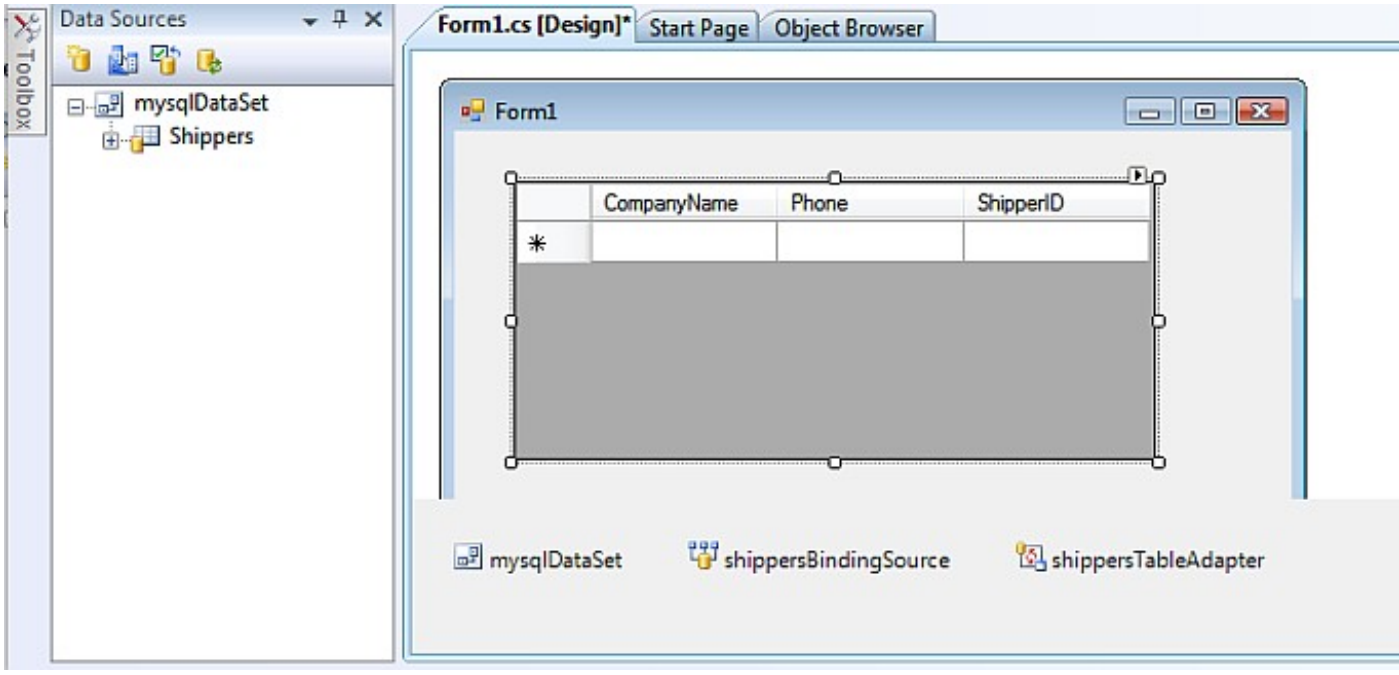
19. The columns names of the select table will be displayed in the DataGridView.

Figure 8.441. DataGridView



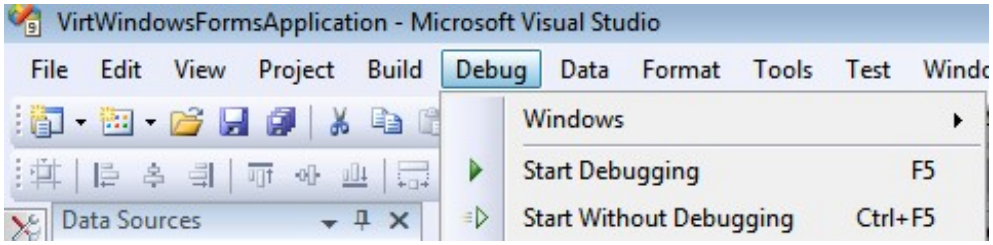
20. Resize the Form and DataGridView to allow all columns to be visible, if possible.

Figure 8.442. Resize the Form and DataGridView



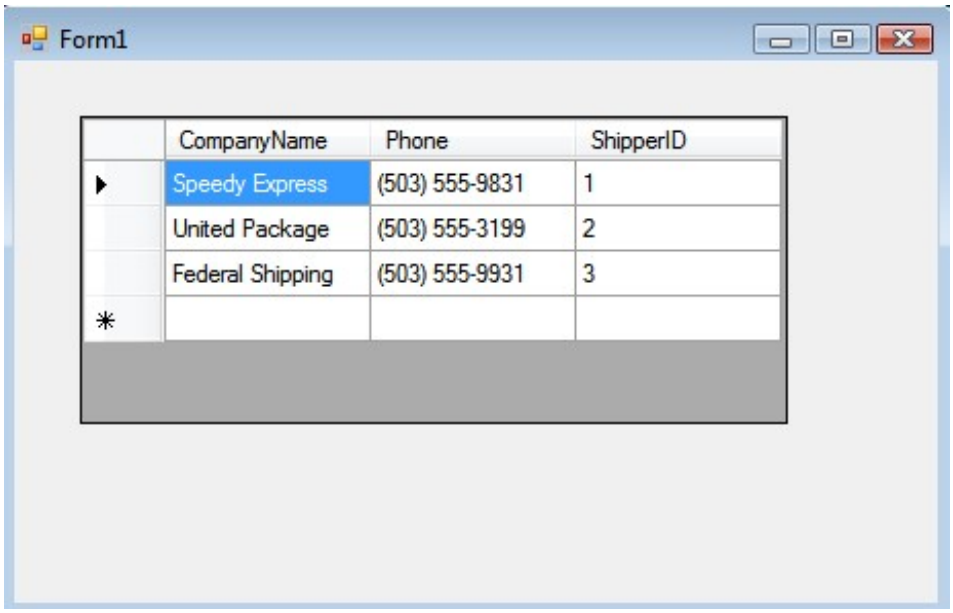
21. To test the application, simply hit *Ctrl+F5* within Visual Studio or select *Start Debugging* from the *Debug* menu.

Figure 8.443. Start Debugging



22. The data from the *Shippers* table will be displayed in the *DataGrid* .

Figure 8.444. DataGrid



The task is now complete.

8.9. Using Microsoft Entity Frameworks to Access PostgreSQL Schema Objects with Virtuoso

Abstract

This document details the steps required to provide Microsoft Entity Framework access to PostgreSQL Schema Objects using the OpenLink Virtuoso Universal Server. This is achieved by linking the required PostgreSQL Schema objects into Virtuoso using its built in Virtual Database engine, and then using the Virtuoso ADO.NET Entity Framework provider to query the remote PostgreSQL Schema objects linked into the Virtuoso Server.

Prerequisites. The following prerequisites must be in place for this solution to be possible.

PostgreSQL DBMS. An PostgreSQL DBMS hosting the required Schema Objects needs to be available. In this section the *PostgreSQL* sample database will be used to demonstrate the process.

An PostgreSQL DBMS hosting the required Schema Objects needs to be available. In this section the *PostgreSQL* sample database will be used to demonstrate the process.

ODBC Driver for PostgreSQL. An PostgreSQL ODBC Driver is required for Linking the PostgreSQL Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for PostgreSQL* will be used in this section, for which a functional ODBC Data source name of "ora10ma" will be assumed to exist on the machine hosting the Virtuoso Server.

An PostgreSQL ODBC Driver is required for Linking the PostgreSQL Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for PostgreSQL* will be used in this section, for which a functional ODBC Data source name of "ora10ma" will be assumed to exist on the machine hosting the Virtuoso Server.

Virtuoso Universal Server. An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

Microsoft Visual Studio 2008 SP1. Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Tasks

Ensure PostgreSQL Primary Keys (PKs) are not nullable. The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the PostgreSQL database schema before attempting to generate an EDM. In the case of the PostgreSQL database all tables are not nullable, thus this should not be an issue in this case.

The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the PostgreSQL database schema before attempting to generate an EDM. In the case of the PostgreSQL database all tables are not nullable, thus this should not be an issue in this case.

8.9.1. Install and configure OpenLink ODBC Driver for PostgreSQL

The Virtuoso Virtual Database engine uses ODBC as the connectivity mechanism for linking remote database objects into its local schema. Thus an PostgreSQL ODBC Driver must be available with a suitably configured DSN for connecting to the target database. The OpenLink ODBC Drivers for PostgreSQL have been used in this section, although in theory any PostgreSQL ODBC Driver can be used.

Installation instructions for the OpenLink ODBC Driver for PostgreSQL are available from:

- Product Installation & Basic Configuration (ODBC)

8.9.2. Install and configure OpenLink Virtuoso Universal Server

- Install and configure OpenLink Virtuoso Universal Server

8.9.3. Linking PostgreSQL tables into OpenLink Virtuoso

1. Start the Virtuoso Web User Interface

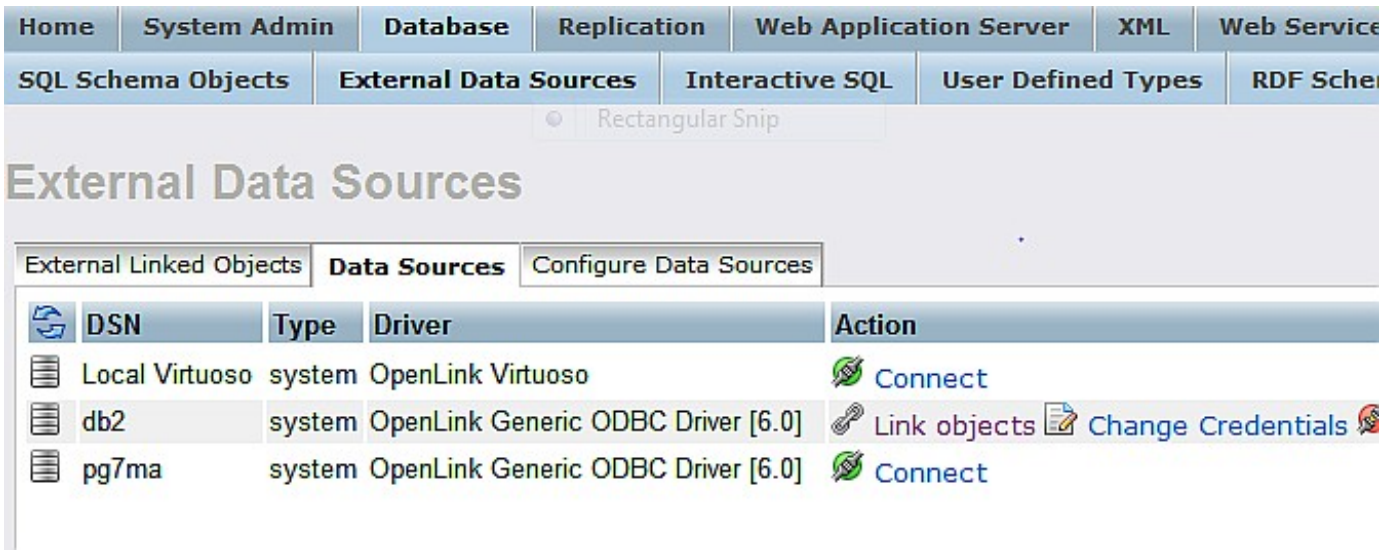
Figure 8.445. Start

2. Select the "Conductor" link in the Left Frame and Login as the "dba" user.

Figure 8.446. Conductor

3. Select the "Databases" -> "External Data Source" -> "Data Sources" tab menu items

Figure 8.447. Databases



4. Select the "Connect" button for the "pg7ma" PostgreSQL DSN.

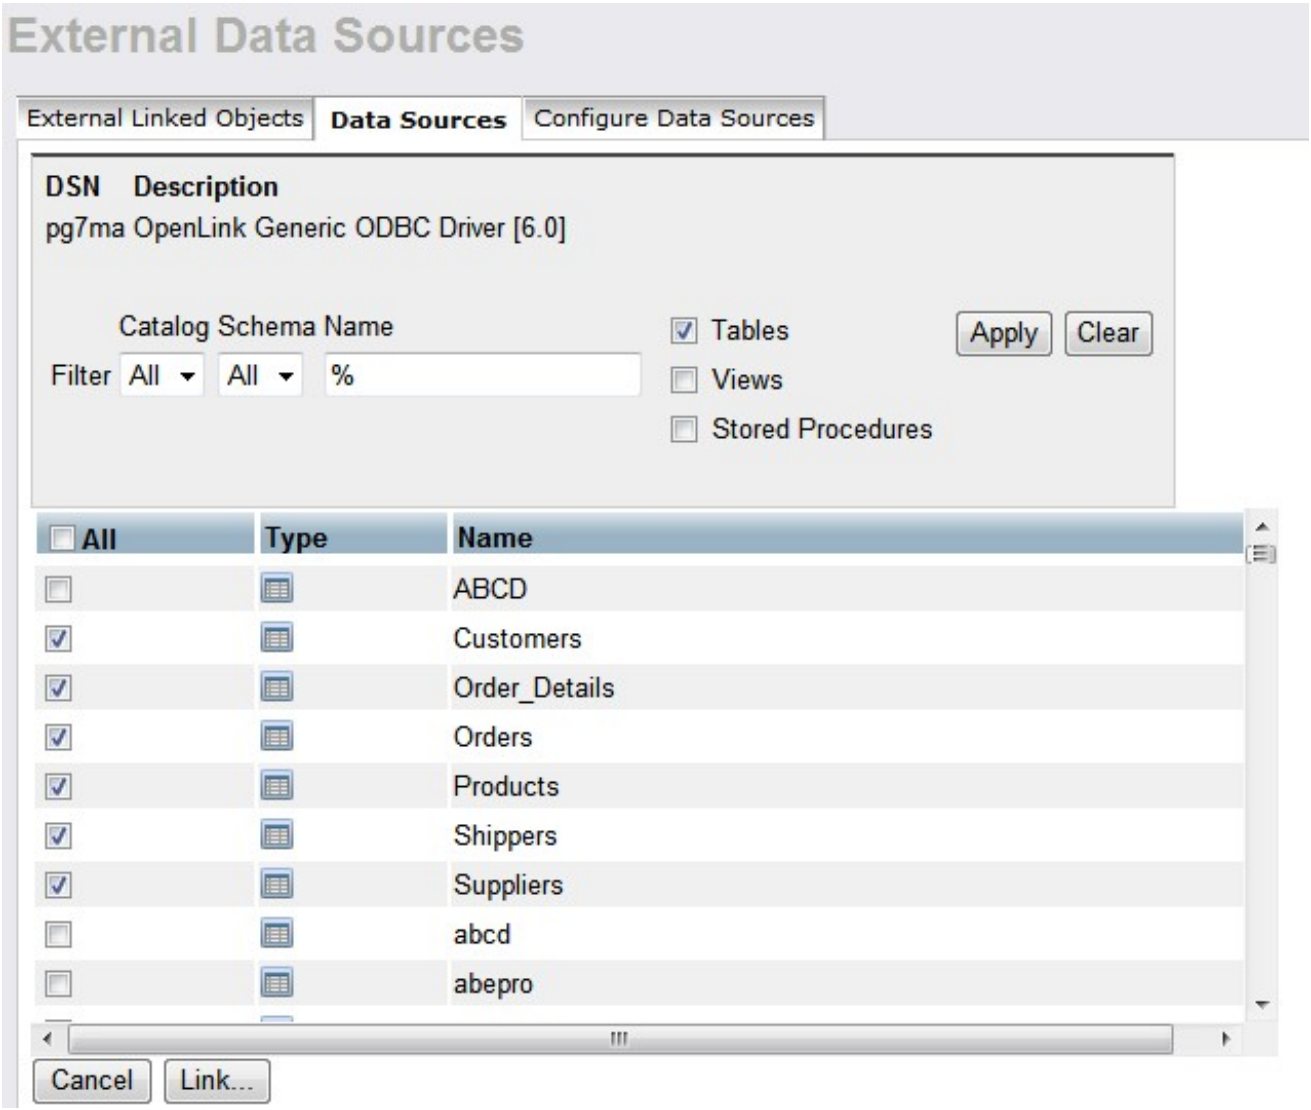
Figure 8.448. Connect

5. On successful connection Select the "Link Objects" button to obtain a list of available tables

Figure 8.449. Link Objects

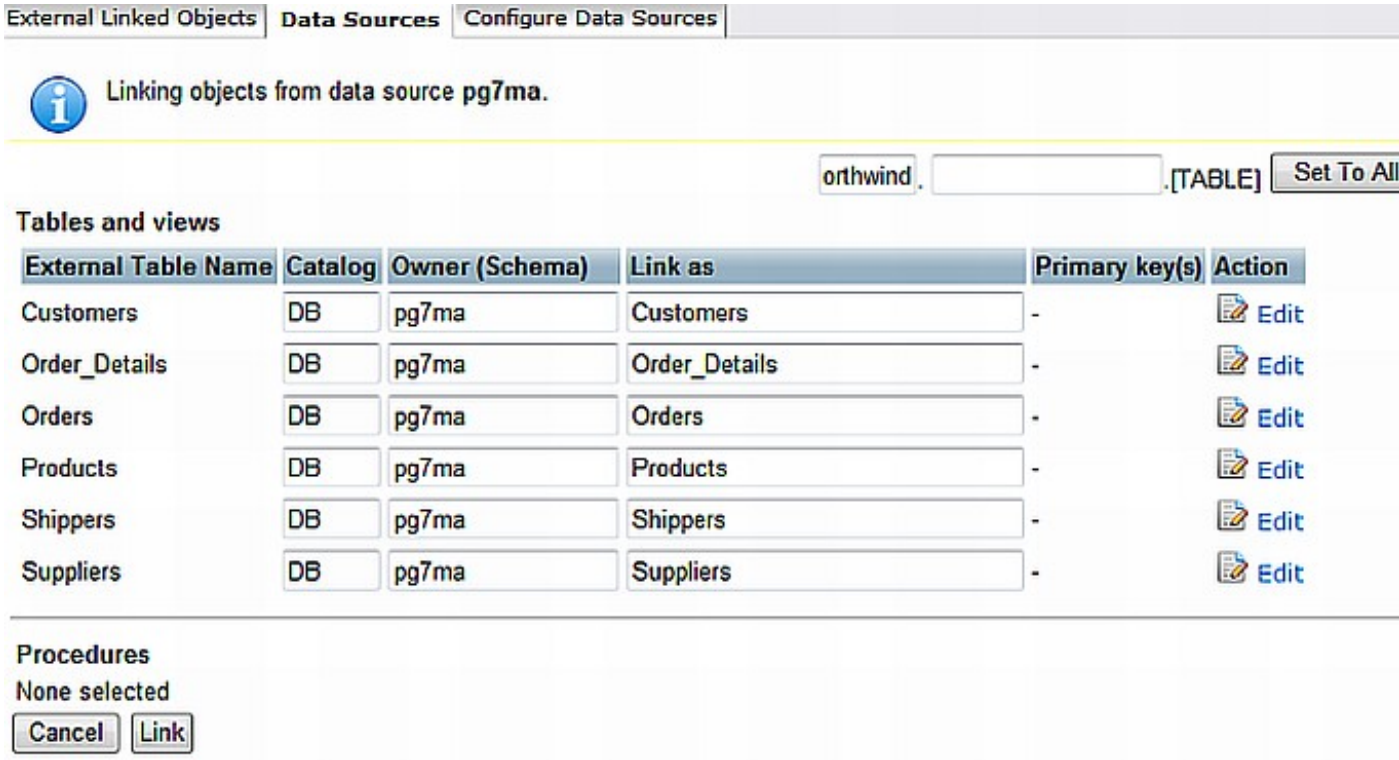
6. Select all the tables that you would like to link.

Figure 8.450. Select all tables



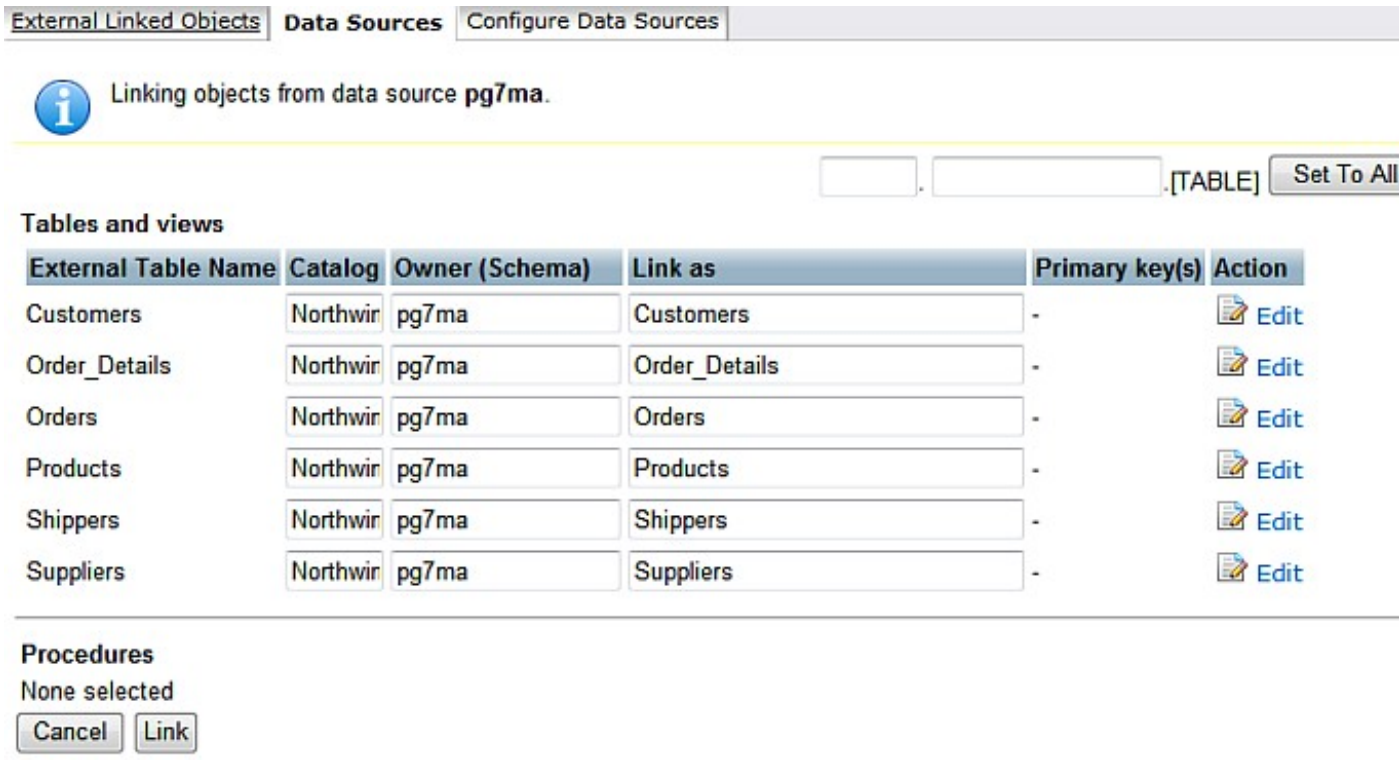
7. Change the Catalog for each table to be "Northwind" using the "Set All" button.

Figure 8.451. Catalog



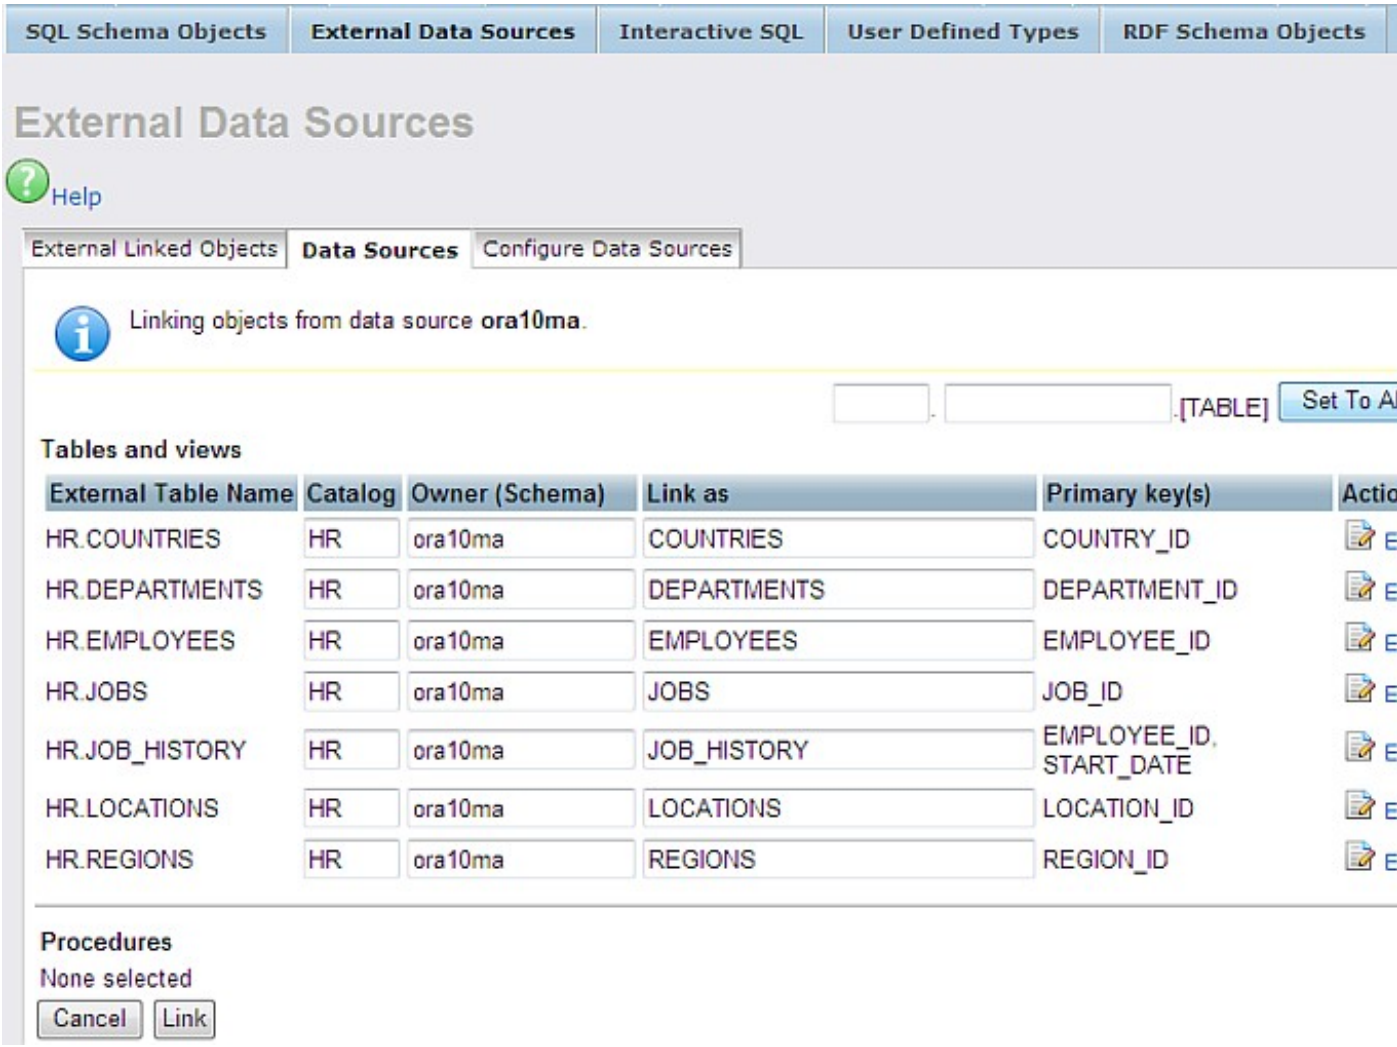
8. All the catalog names are changed to be "Northwind".

Figure 8.452. Catalog



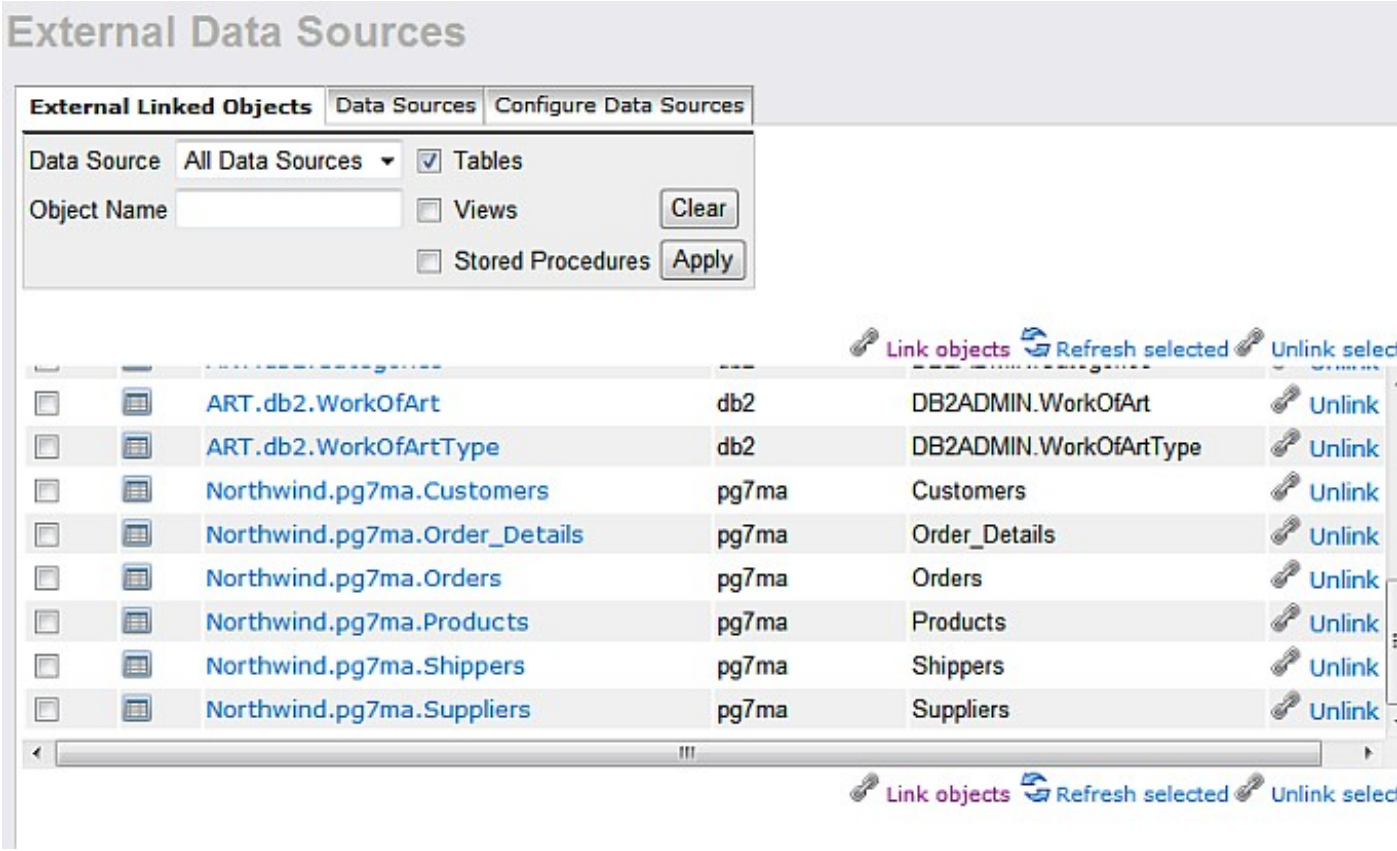
9. Select the "Link" button to link the selected tables into Virtuoso

Figure 8.453. "Link" button



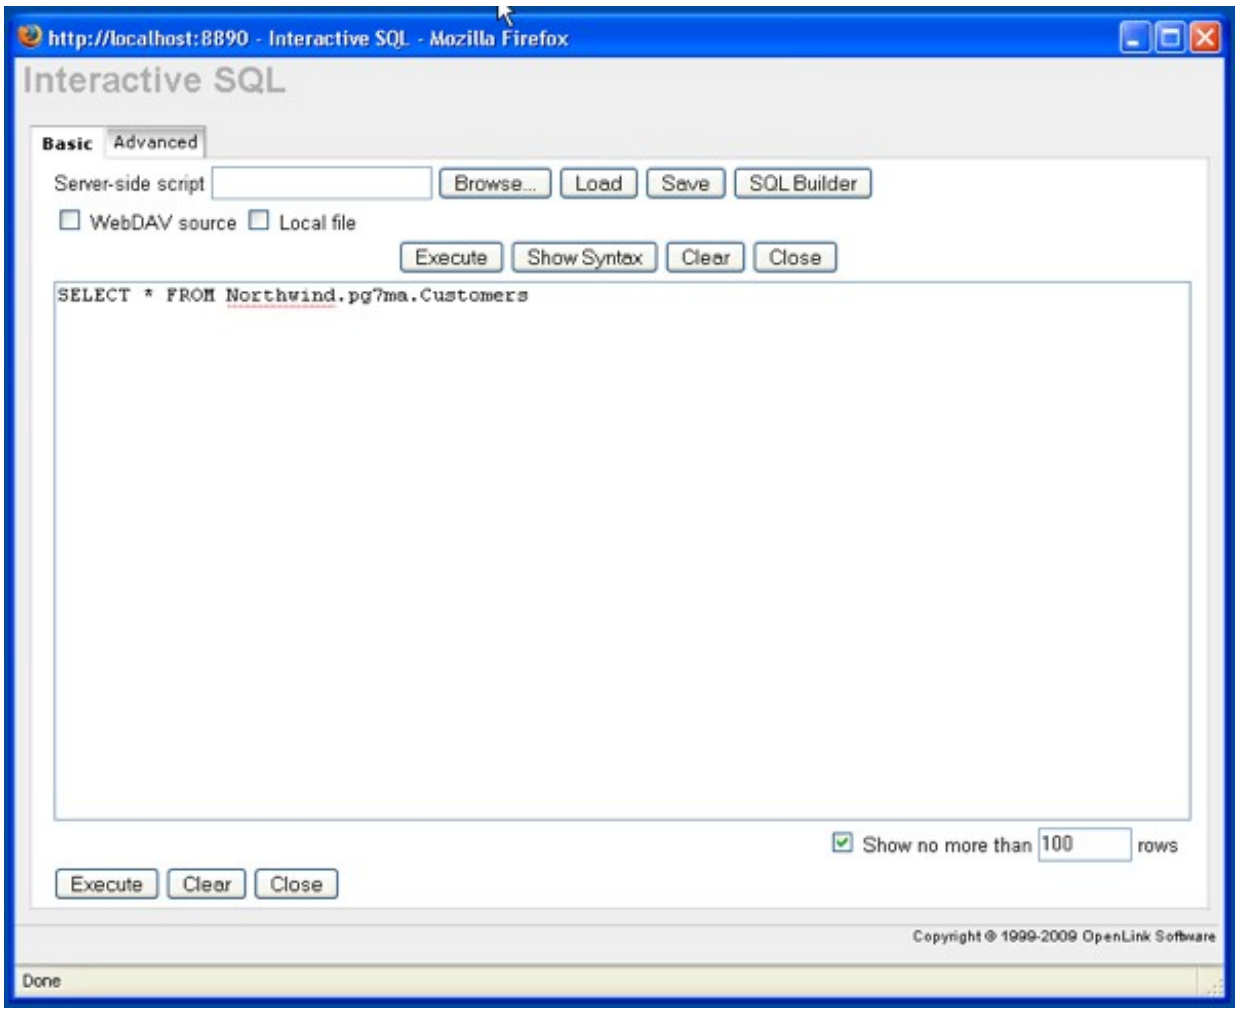
10. On completion of the Link process the tables will be displayed in the "External Linked Objects" tab.

Figure 8.454. Completion



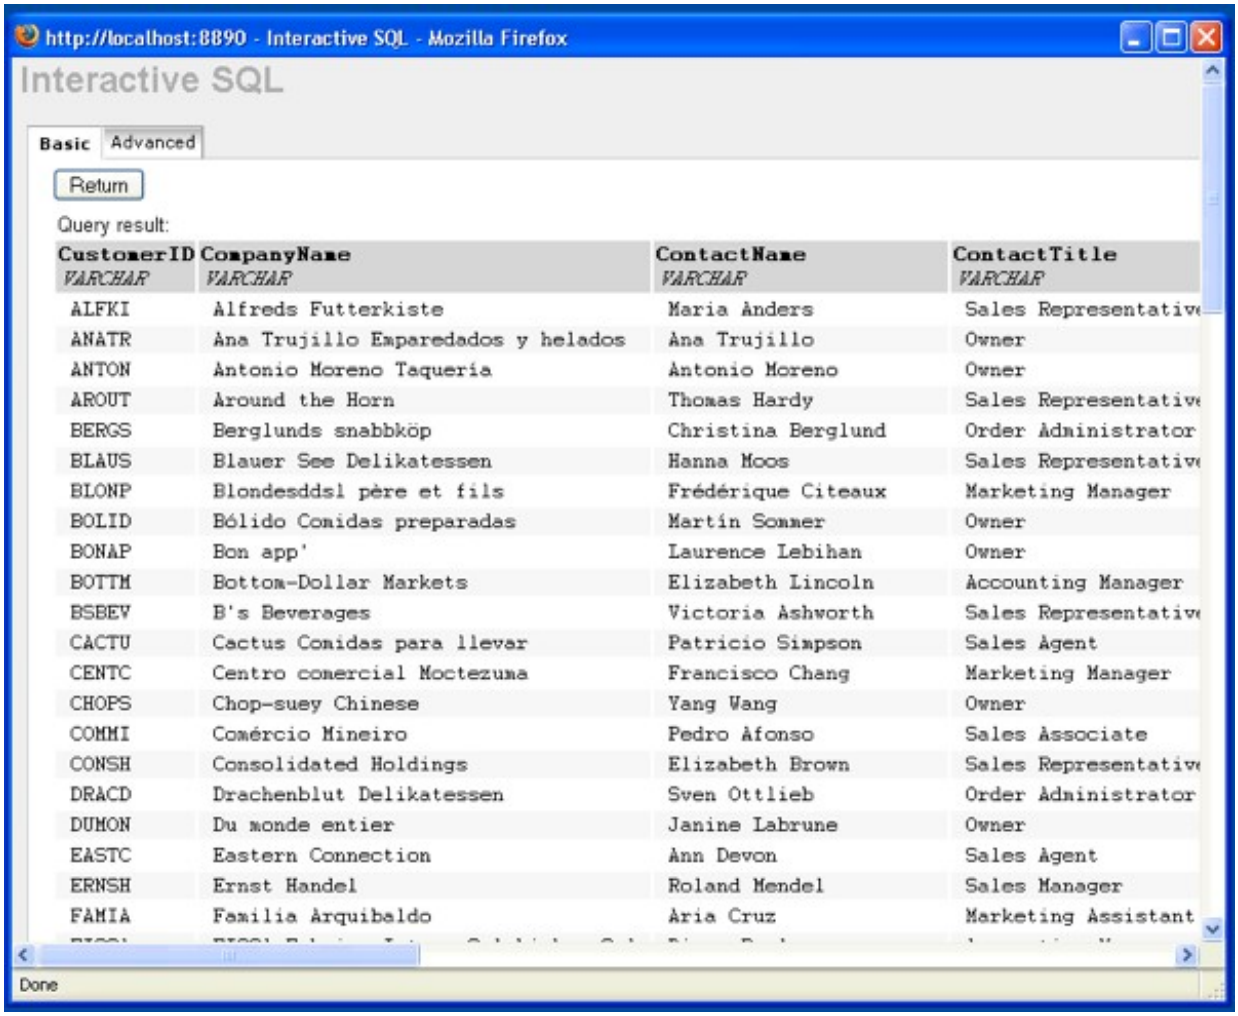
11. The linked tables can be queried by clicking on the hyperlink in the "Local Name" column of the "External Linked Objects" tab above, which loads the Virtuoso "Interactive SQL" interface with the required SQL "Select" for retrieving the remote table data . We shall use the "Northwind.pg7ma.Customers" table to demonstrate this.

Figure 8.455. Querying



12. Then click the "Execute" button to run the query and retrieve the results from the remote table.

Figure 8.456. Execute



CustomerID VARCHAR	CompanyName VARCHAR	ContactName VARCHAR	ContactTitle VARCHAR
ALFKI	Alfreds Futterkiste	Maria Anders	Sales Representative
ANATR	Ana Trujillo Emparedados y helados	Ana Trujillo	Owner
ANTON	Antonio Moreno Taquería	Antonio Moreno	Owner
AROUT	Around the Horn	Thomas Hardy	Sales Representative
BERGS	Berglunds snabbköp	Christina Berglund	Order Administrator
BLAUS	Blauer See Delikatessen	Hanna Moos	Sales Representative
BLONP	Blondesddsl père et fils	Frédérique Citeaux	Marketing Manager
BOLID	Bólido Comidas preparadas	Martín Sommer	Owner
BONAP	Bon app'	Laurence Lebihan	Owner
BOTTM	Bottom-Dollar Markets	Elizabeth Lincoln	Accounting Manager
BSBEV	B's Beverages	Victoria Ashworth	Sales Representative
CACTU	Cactus Comidas para llevar	Patricio Simpson	Sales Agent
CENTC	Centro comercial Moctezuma	Francisco Chang	Marketing Manager
CHOPS	Chop-suey Chinese	Yang Wang	Owner
COMMI	Comércio Mineiro	Pedro Afonso	Sales Associate
CONSH	Consolidated Holdings	Elizabeth Brown	Sales Representative
DRACD	Drachenblut Delikatessen	Sven Ottlieb	Order Administrator
DUMON	Du monde entier	Janine Labrune	Owner
EASTC	Eastern Connection	Ann Devon	Sales Agent

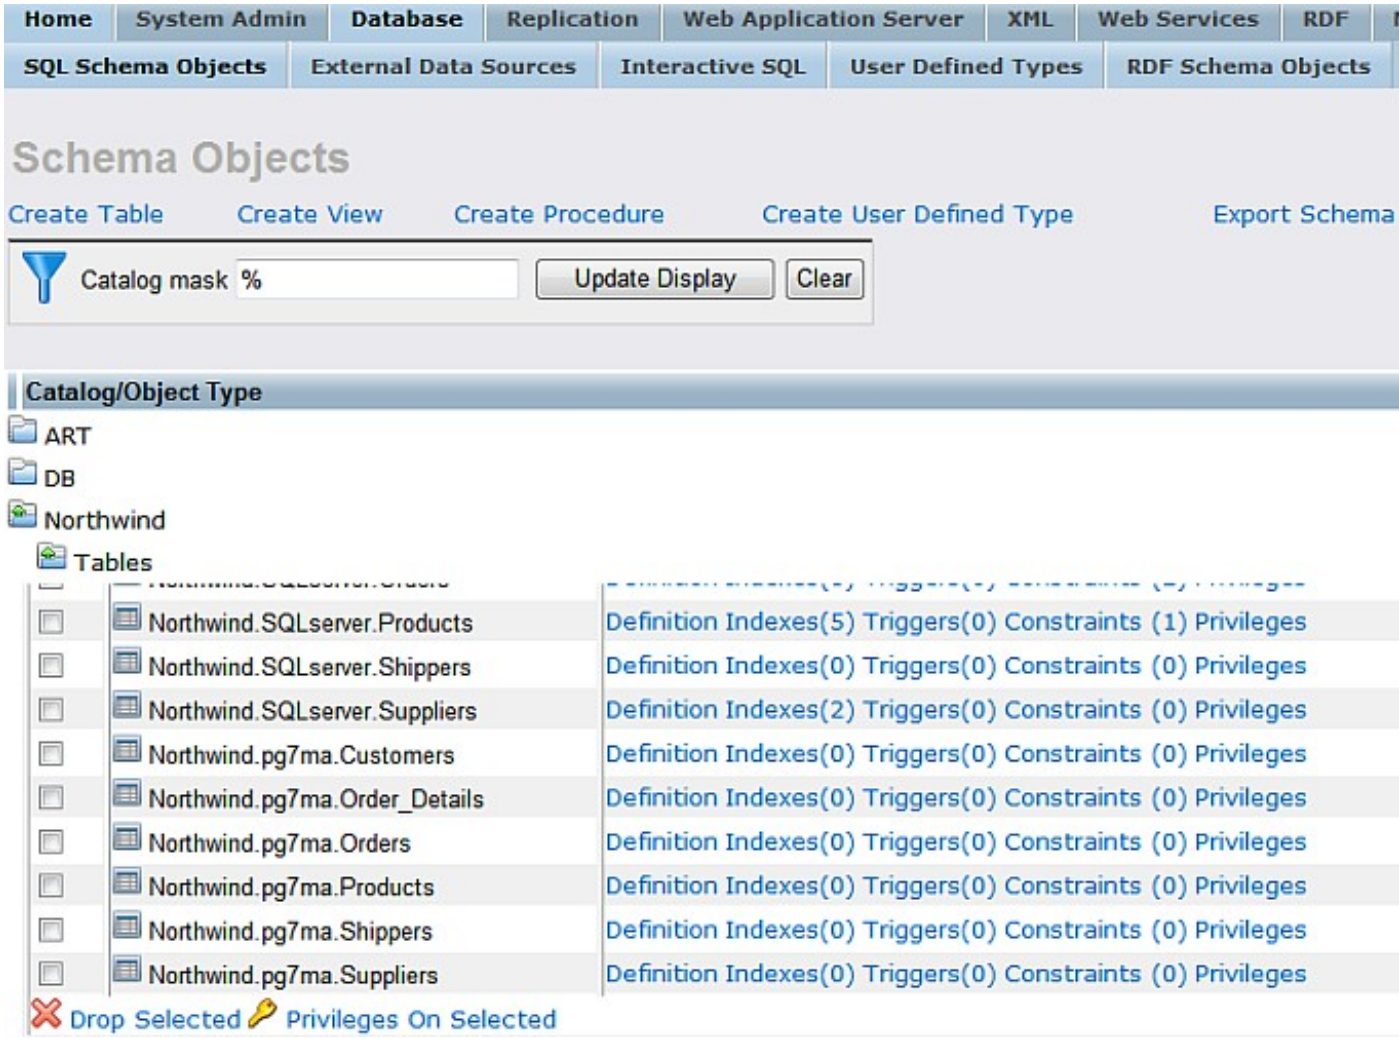
FAMIA	Familia Arquibaldo	Aria Cruz	Marketing Assistant

13. The tables can also be viewed as part of the Virtuoso "SQL Schema Objects" under the "Northwind" catalog name.

Figure 8.457. SQL Schema Objects



The Link process is now complete enabling the tables to be queried as if part of the Virtuoso Schema.

8.9.4. Creating EDM in Visual Studio 2008

The following steps can be used to create an Entity Data Model (EDM) for the PostgreSQL Northwind database:

1. Launch the Visual Studio 2008 SP1 IDE.

Figure 8.458. Visual Studio 2008 SP1 IDE

2. Create a

Web Application

project by going to the

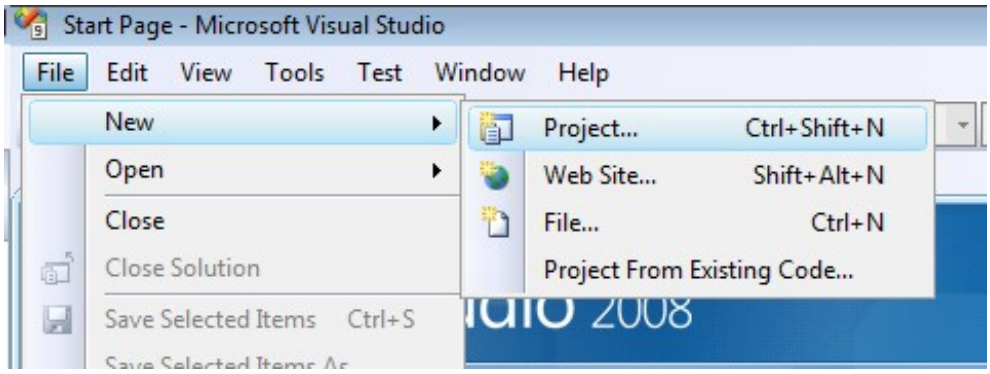
File

menu in Visual Studio and choosing

New Project

.

Figure 8.459. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Web

   , and select

   ASP.NET Web Application

   from the right-hand panel.
5. Choose a name for the project, for example

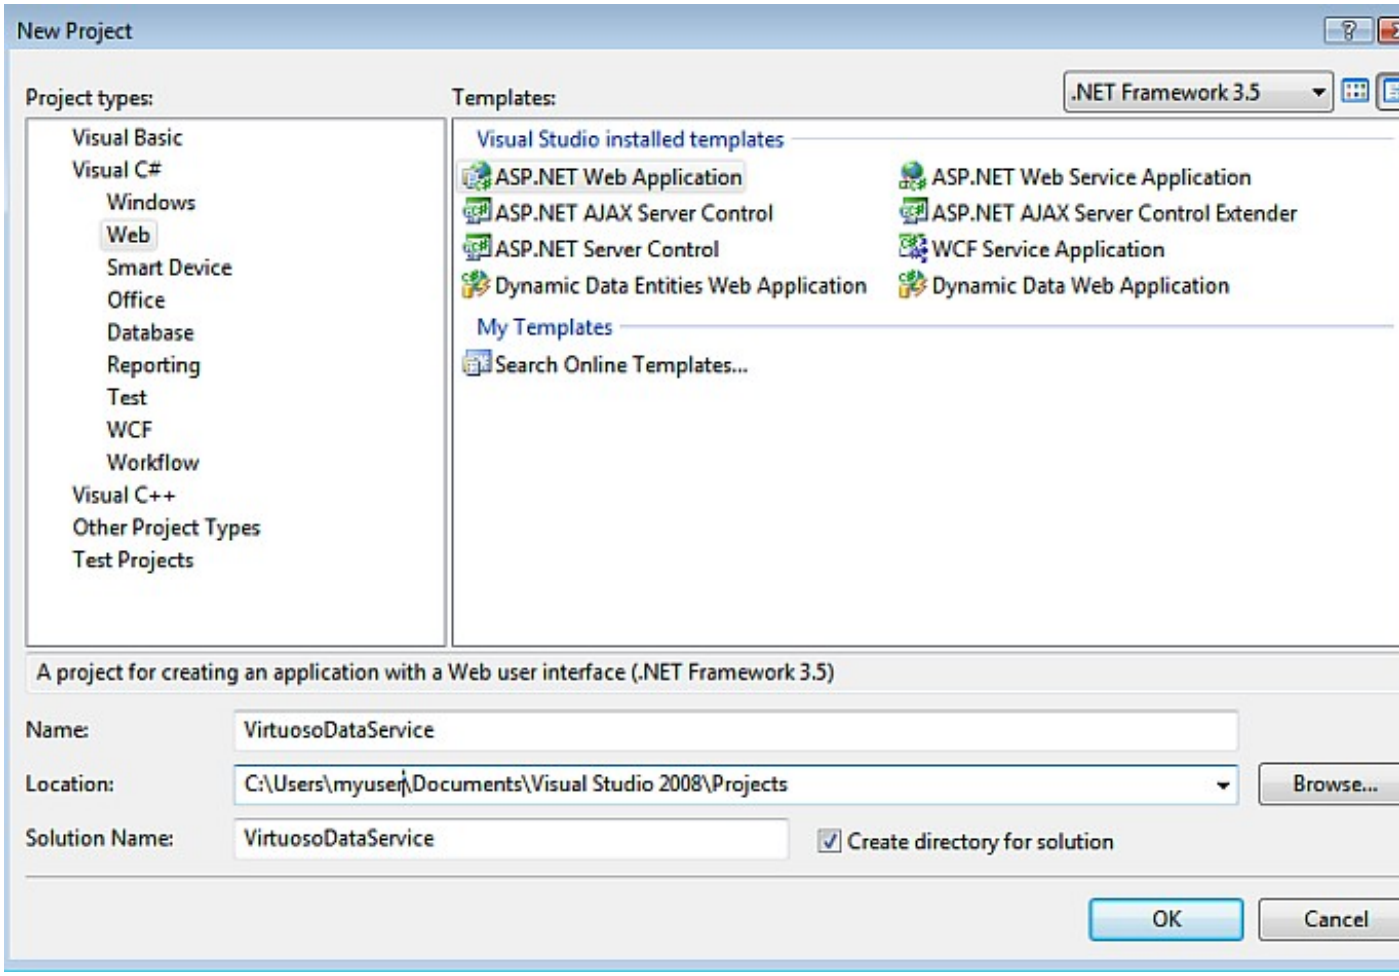
   VirtuosoDataService

   , and click

   OK

   .

Figure 8.460. name for the project

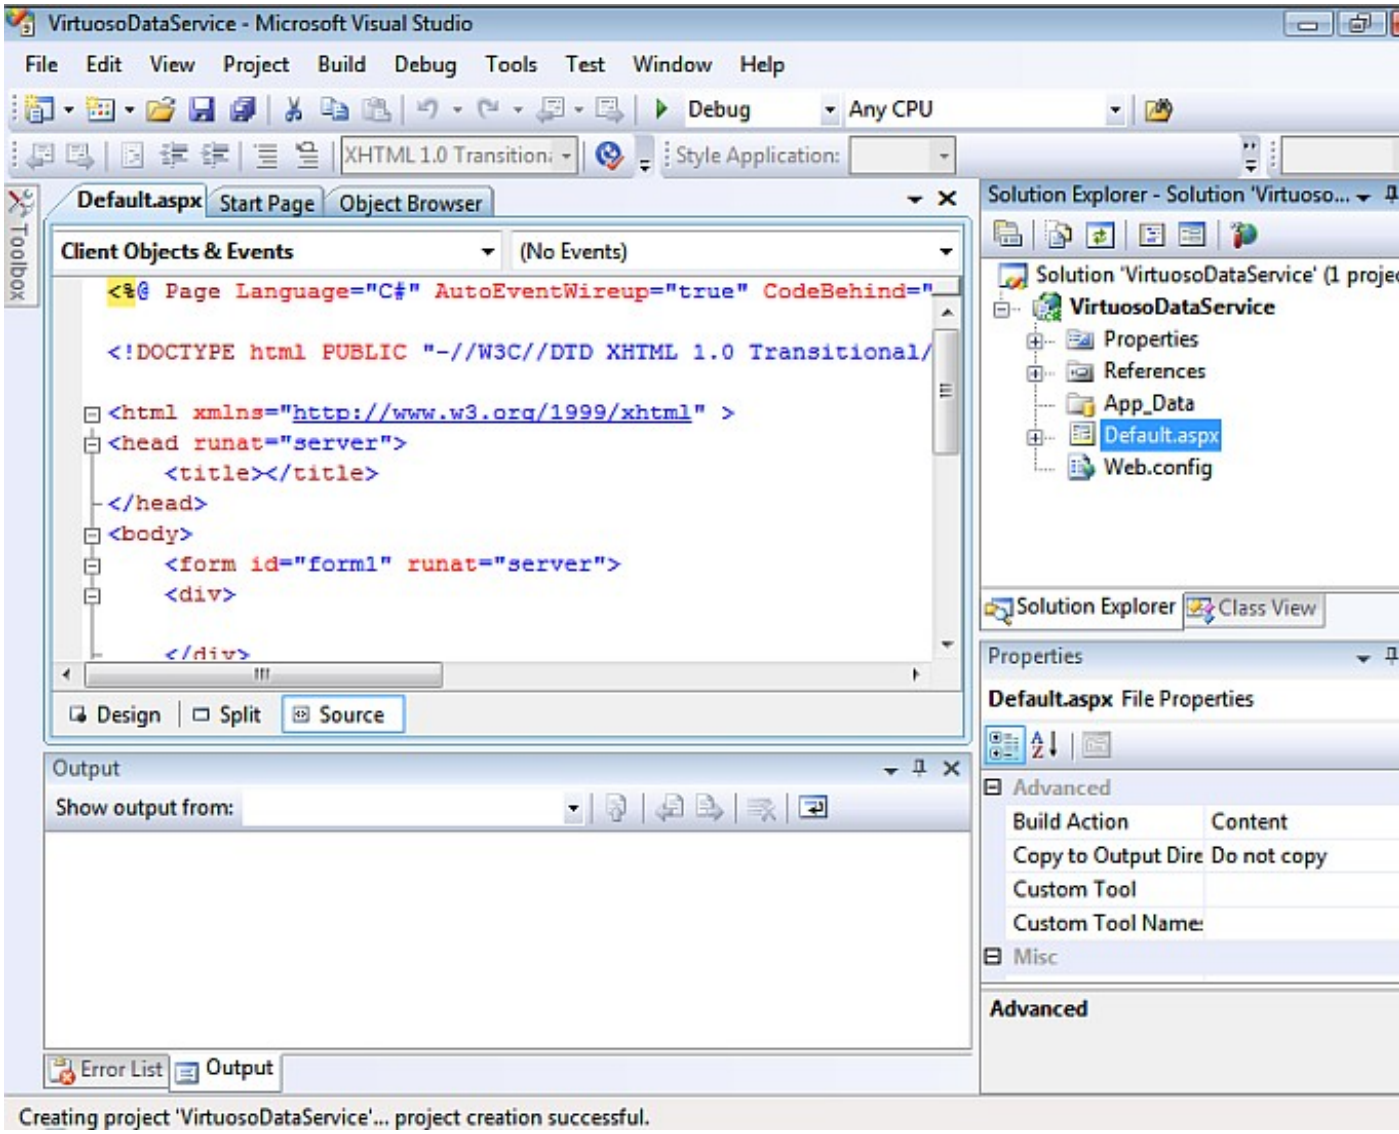


6. This will create a new project called

   VirtuosoDataService

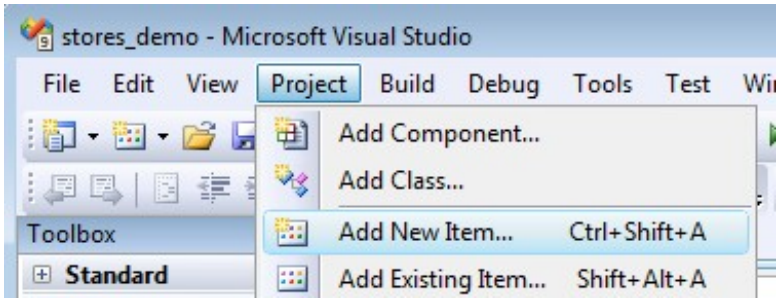
   .

Figure 8.461. create a new project



7. Select the Project -> Add New Item menu option.

Figure 8.462. VirtuosoDataService



8. The

Add New Item

dialog will appear. Choose the

ADO.NET Entity Data Model

template. Give it the name

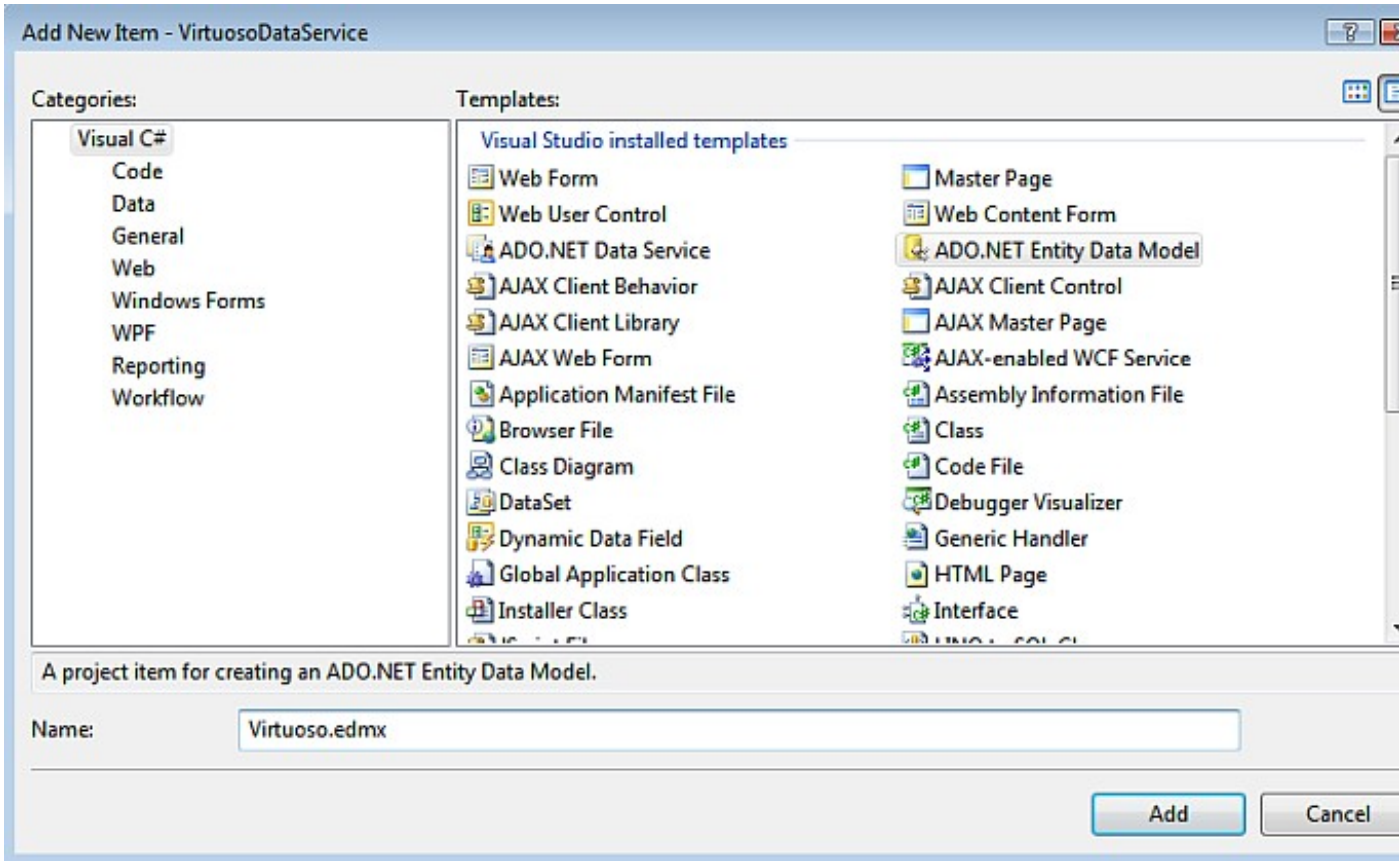
Virtuoso.edmx

and click

Add

to start the creation of the ADO.Net Entity Data Model.

Figure 8.463. Add New Item



9. In the

Entity Data Model Wizard

dialog

Choose Model Contents

page select the

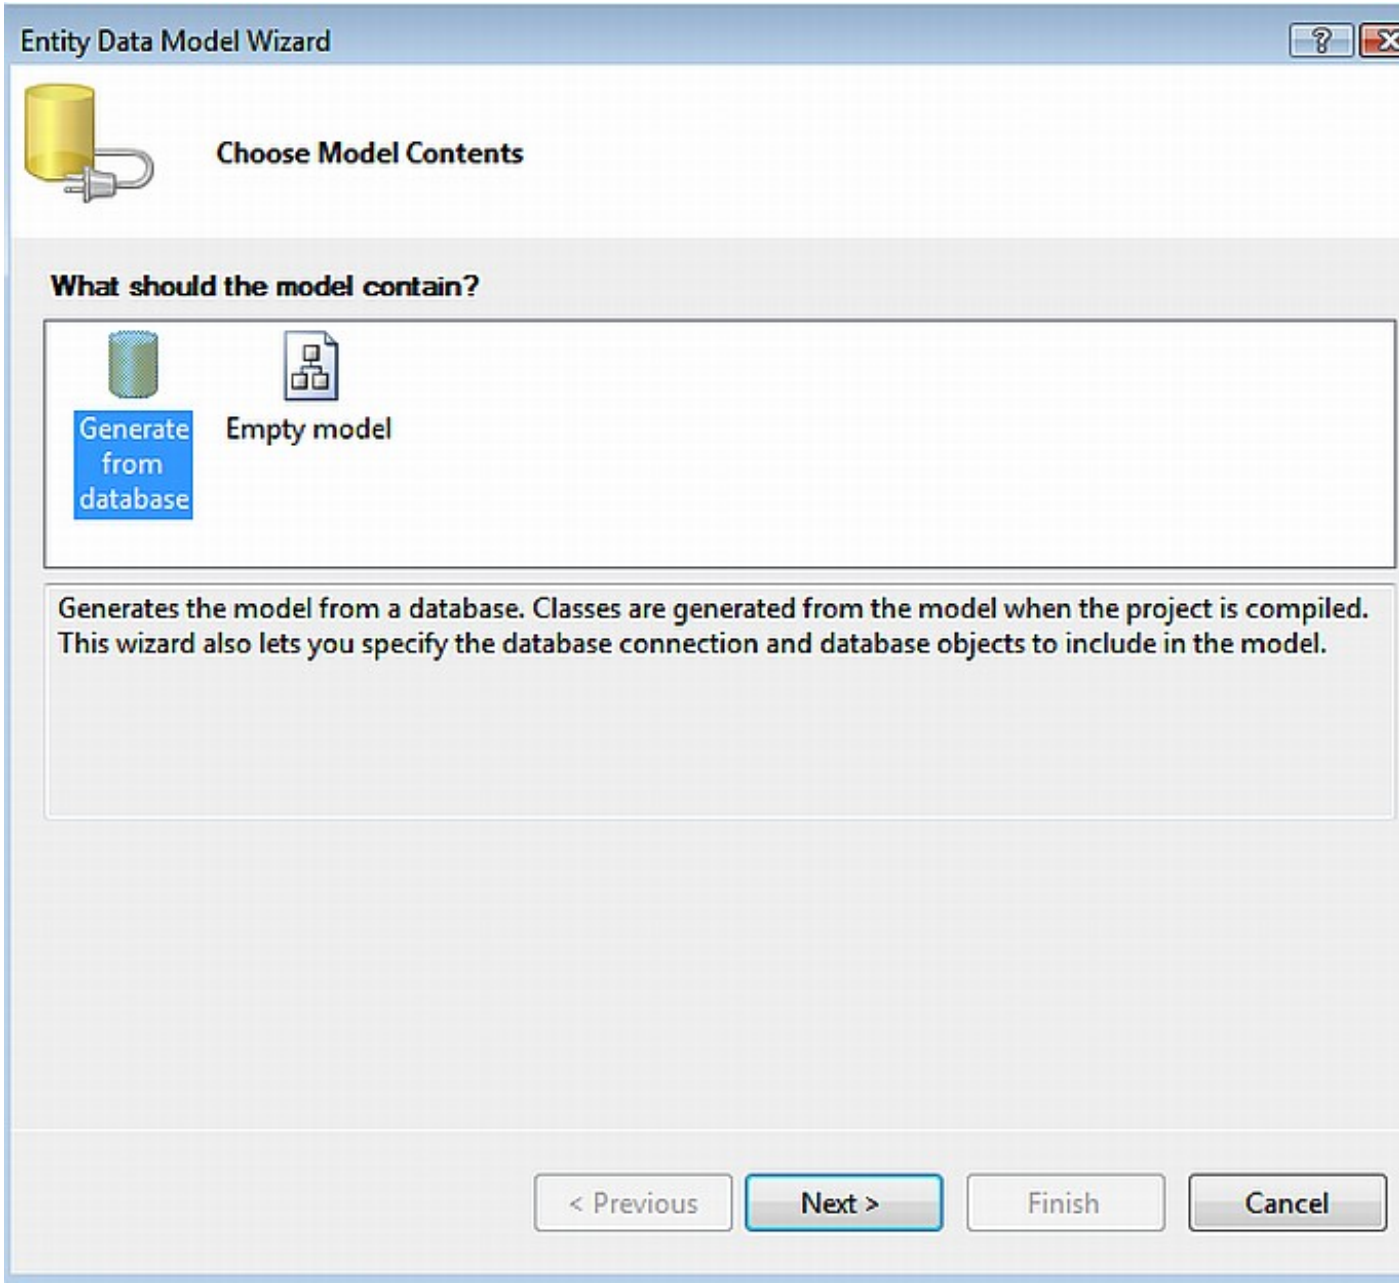
Generate from Database

model type and click

Next

.

Figure 8.464. Choose Model Contents



10. In the

    Entity Data Model Wizard

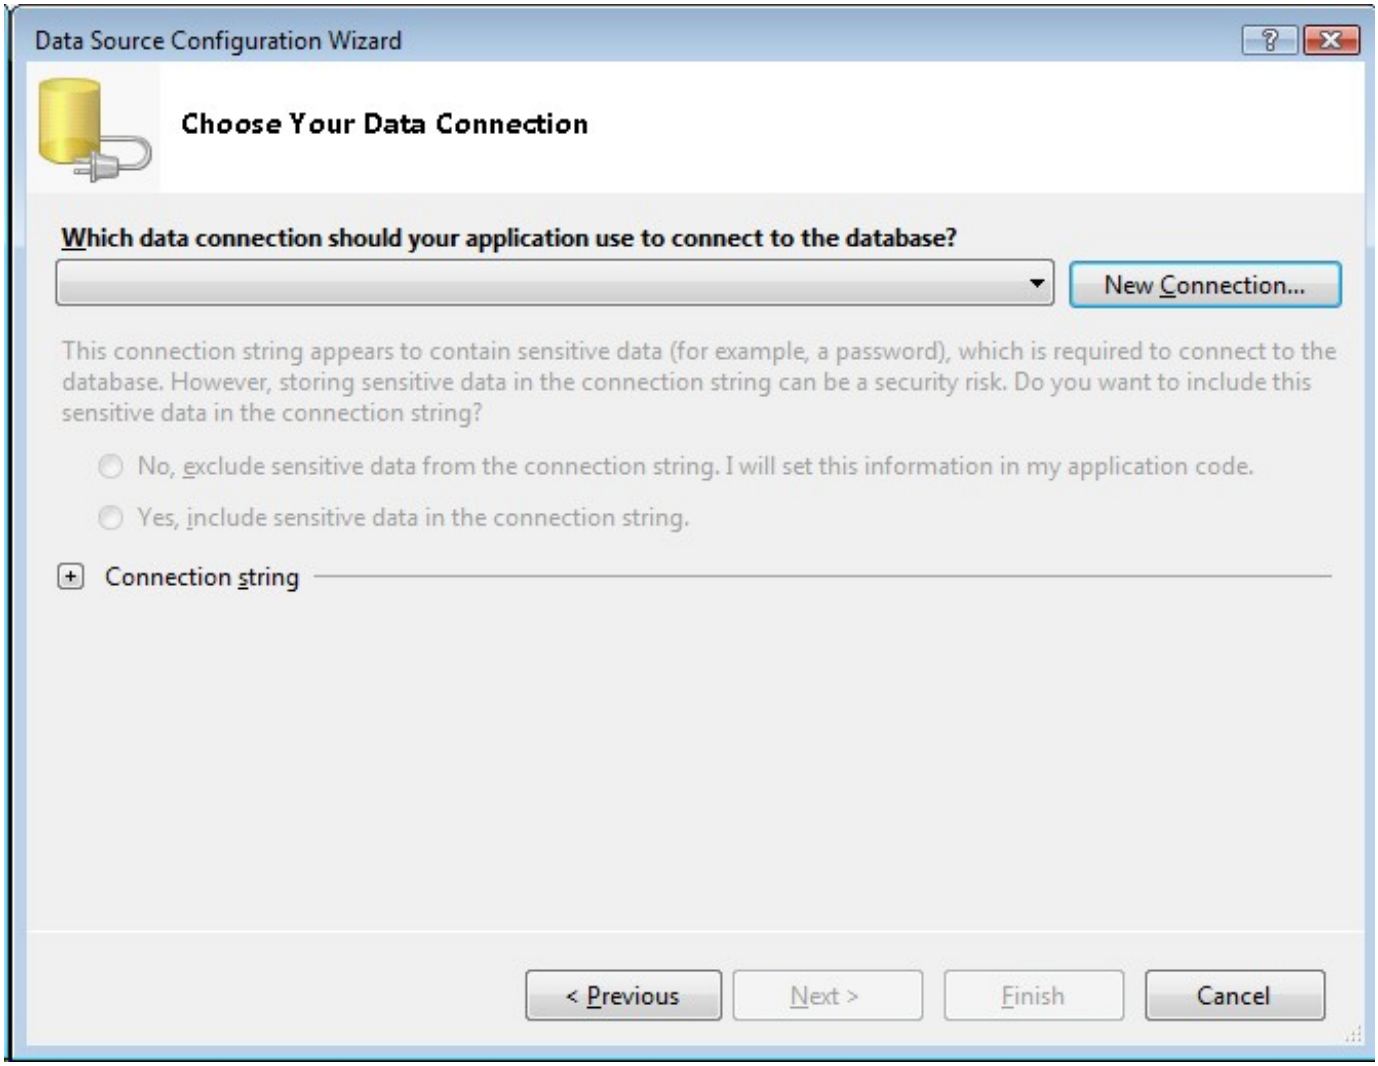
    dialog

    Choose your Data Connection

    page, select the

    New Connection button

Figure 8.465. Entity Data Model Wizard



11. In the

    Choose Data Source

    dialog, select the OpenLink

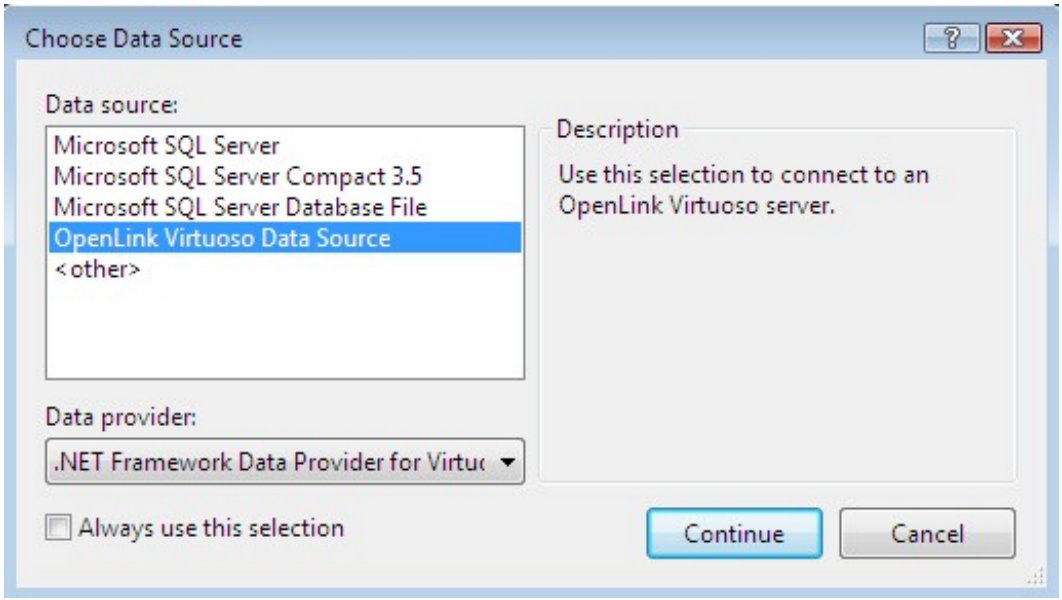
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.466. Choose Data Source



12. In the

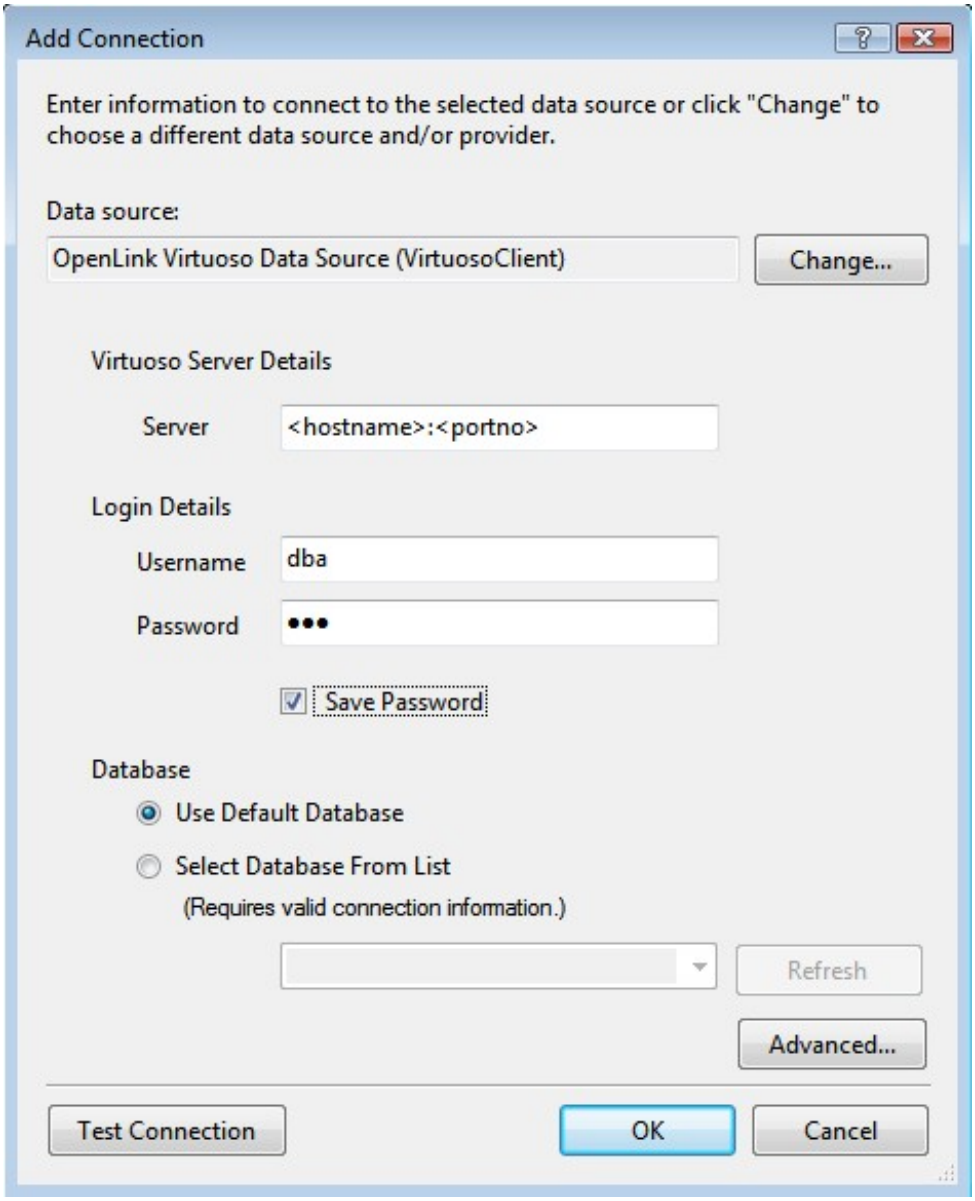
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.467. Connection Properties



13. Select the

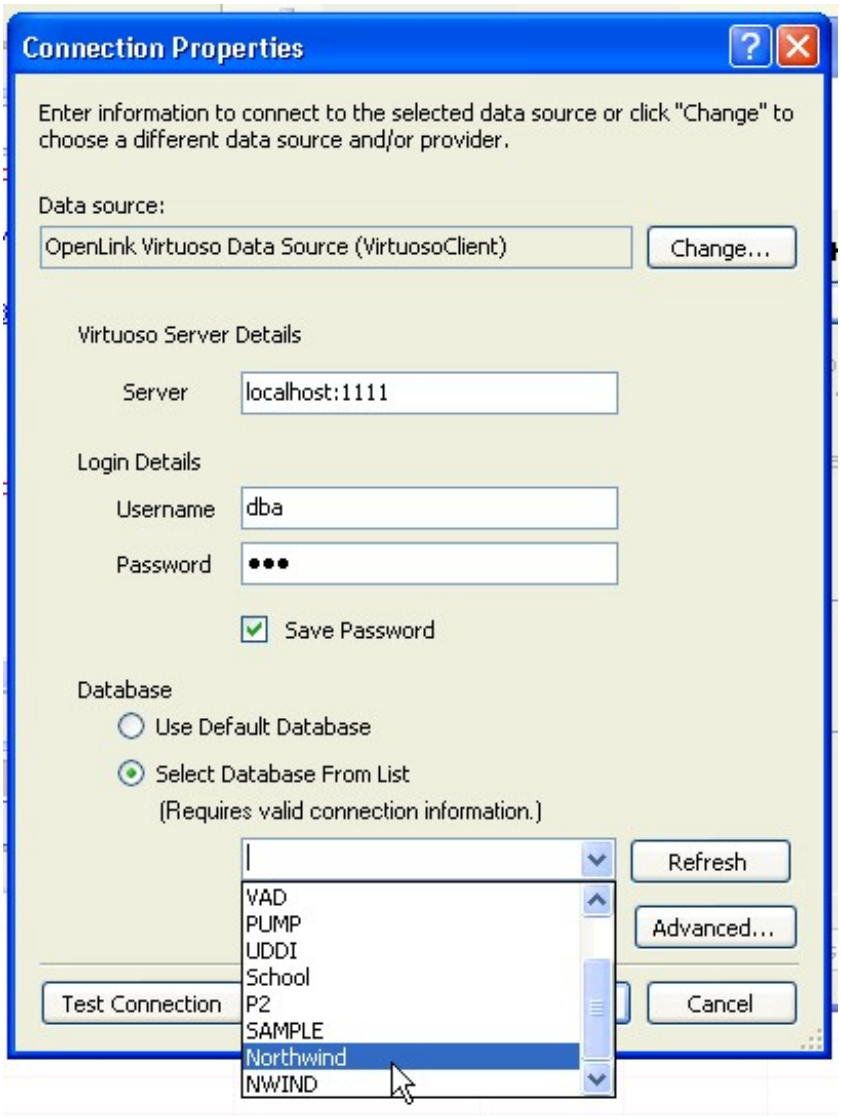
    Select Database From List

    radio button and choose the

    Northwind

    database from the drop down list.

Figure 8.468. Add connection

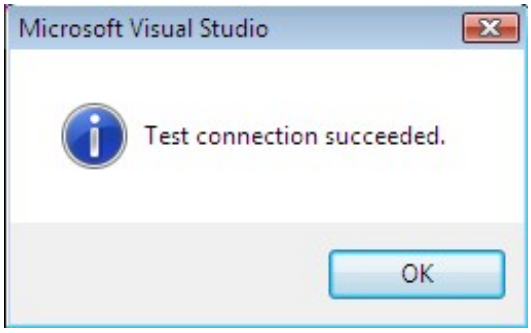


14. Press the

    Test Connection

    dialog to verify that the database is accessible.

    Figure 8.469. Test Connection



15. Set the

    entity connect string

    name to

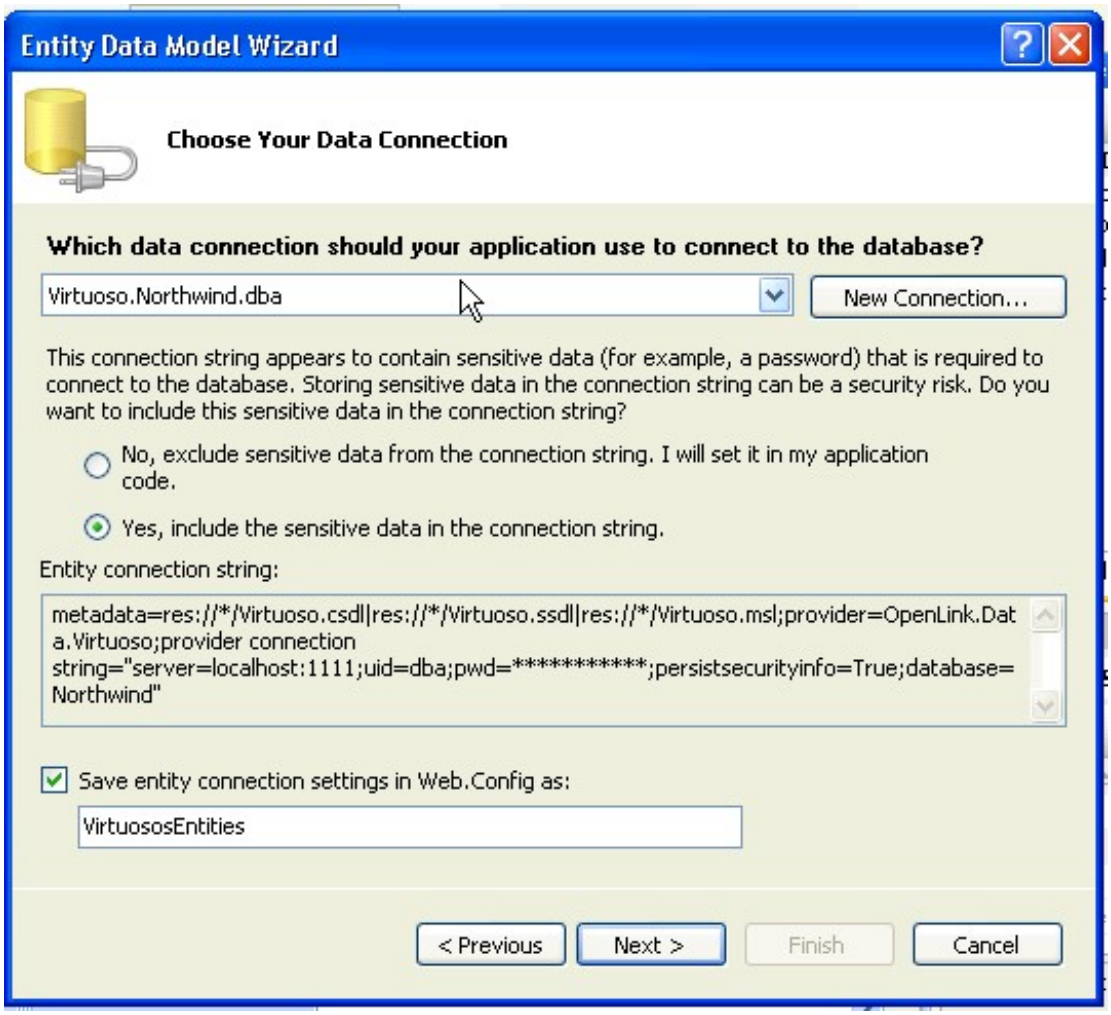
VirtuosoEntities

(note this name as it is required in the section on creating and ADO.Net Data Service) and click

Next

.

Figure 8.470. entity connect string



16. In the

    Choose your Database Objects

    page select the

    Tables

    check box to select all tables in the Northwind catalog for addition to the Entity Data Model. Set the

    Model Namespace

    to

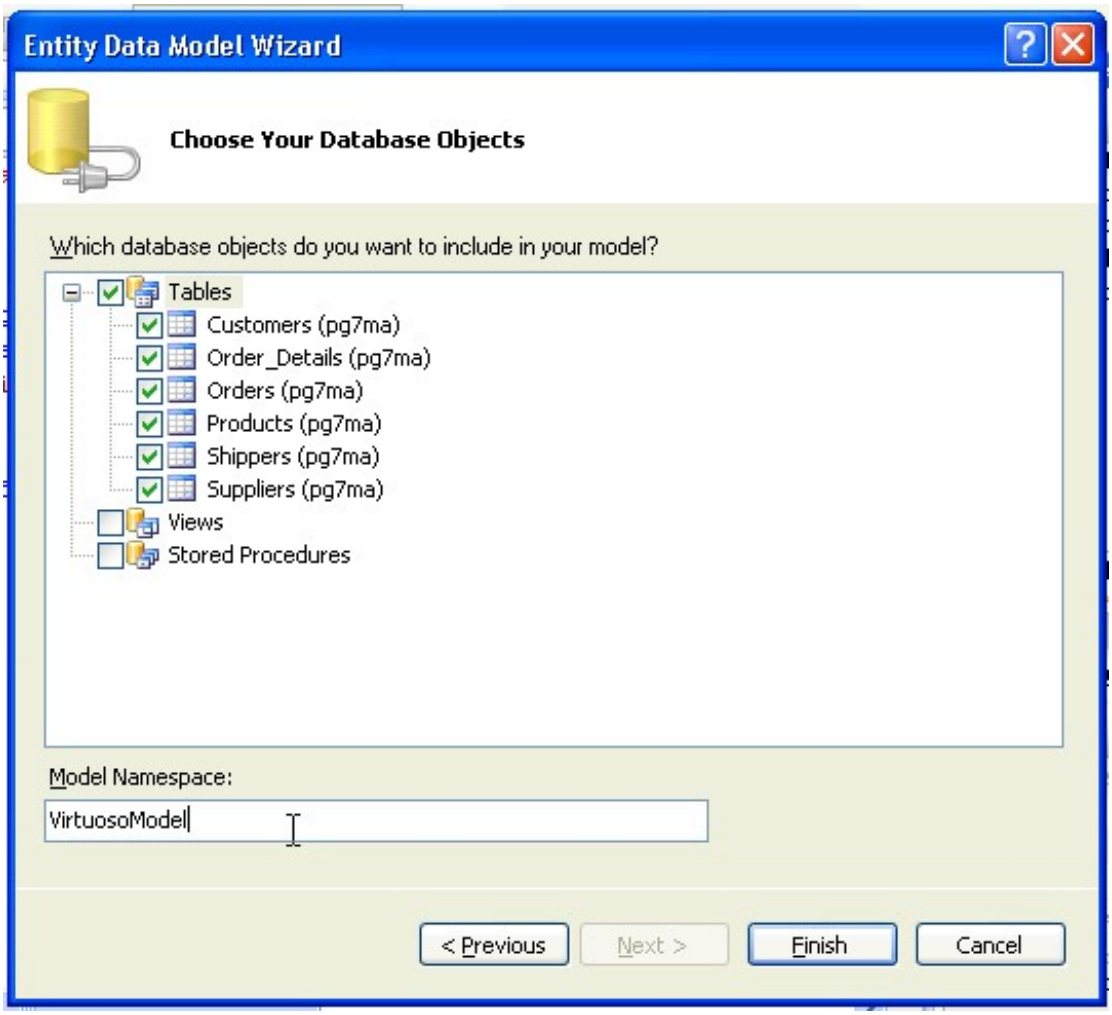
    VirtuosoModel

    and click

    Finish

.

Figure 8.471. Database Objects

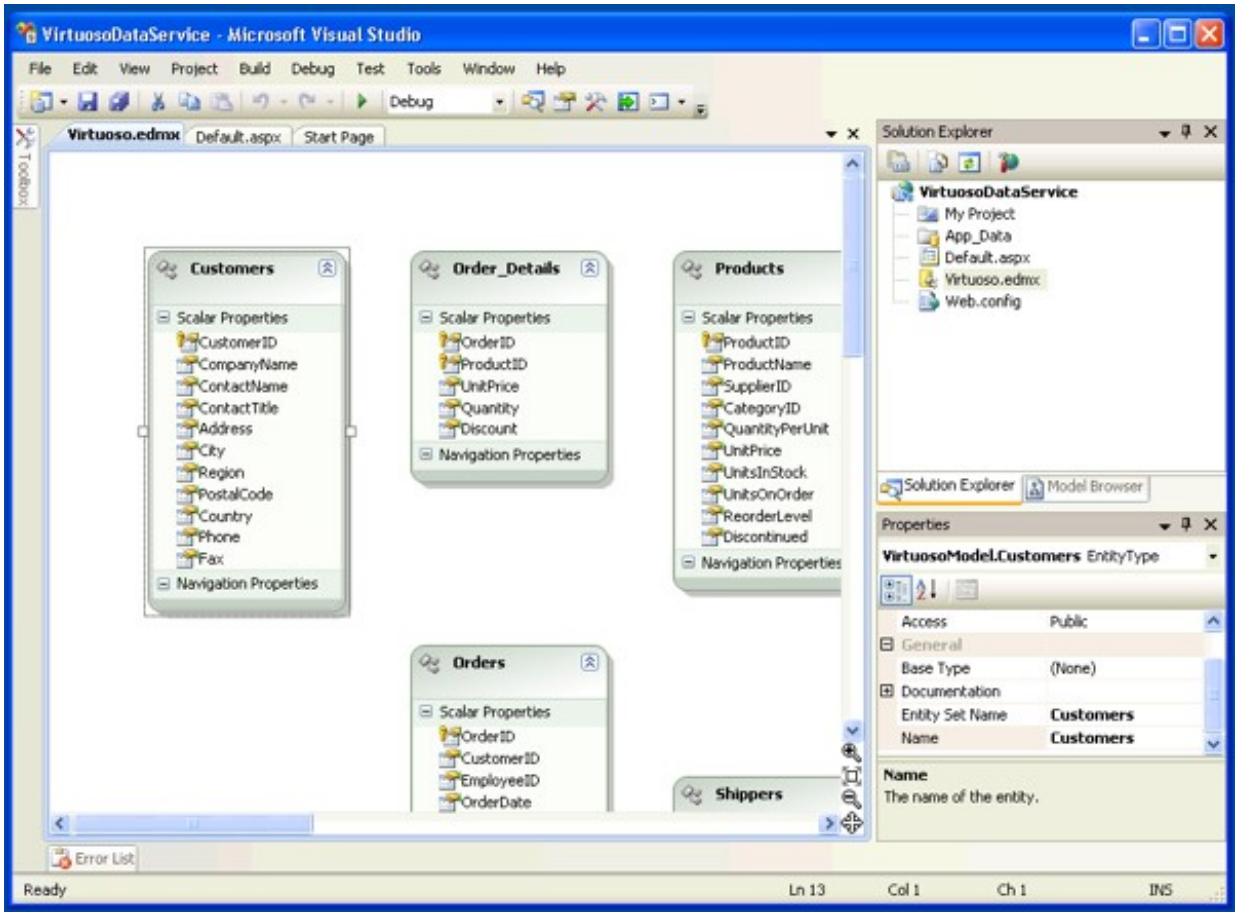


17. The

    Virtuoso.edmx

    EDM will be created with the tables and relationships displayed in the Visual Studio IDE

Figure 8.472. Virtuoso.edmx



Creation for the Entity Data Model for the PostgreSQL Northwind database is now complete.

8.9.5. Using EDM to create Entity Framework based applications

Now that a Microsoft Entity Data Model has been created for the PostgreSQL database, Entity Framework applications can be created to make use of it.

Visual Studio Windows DataGrid Form Application

This section details the steps required to create a simple Visual Studio 2008 Windows Form application, with associated DataGridView control for displaying data in selected tables from the target database.

1. Launch the Visual Studio 2008 SP1 IDE.

Figure 8.473. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

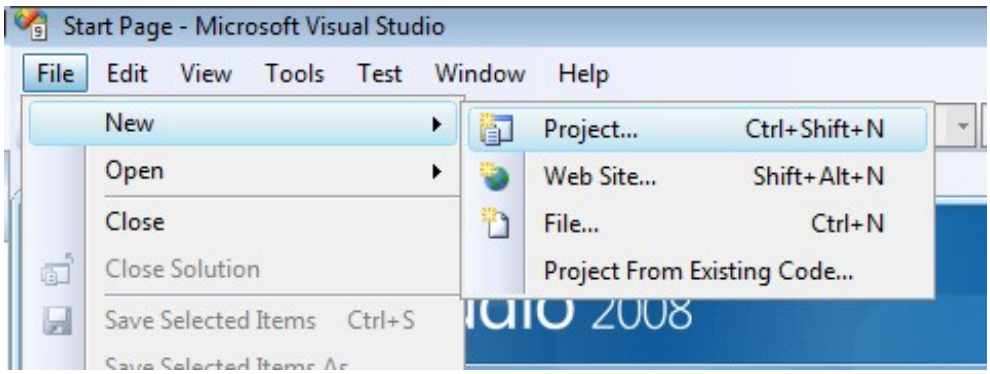
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.474. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Windows

   and select

   Windows Form Application

from the right-hand panel.

5. Choose a name for the project, for example

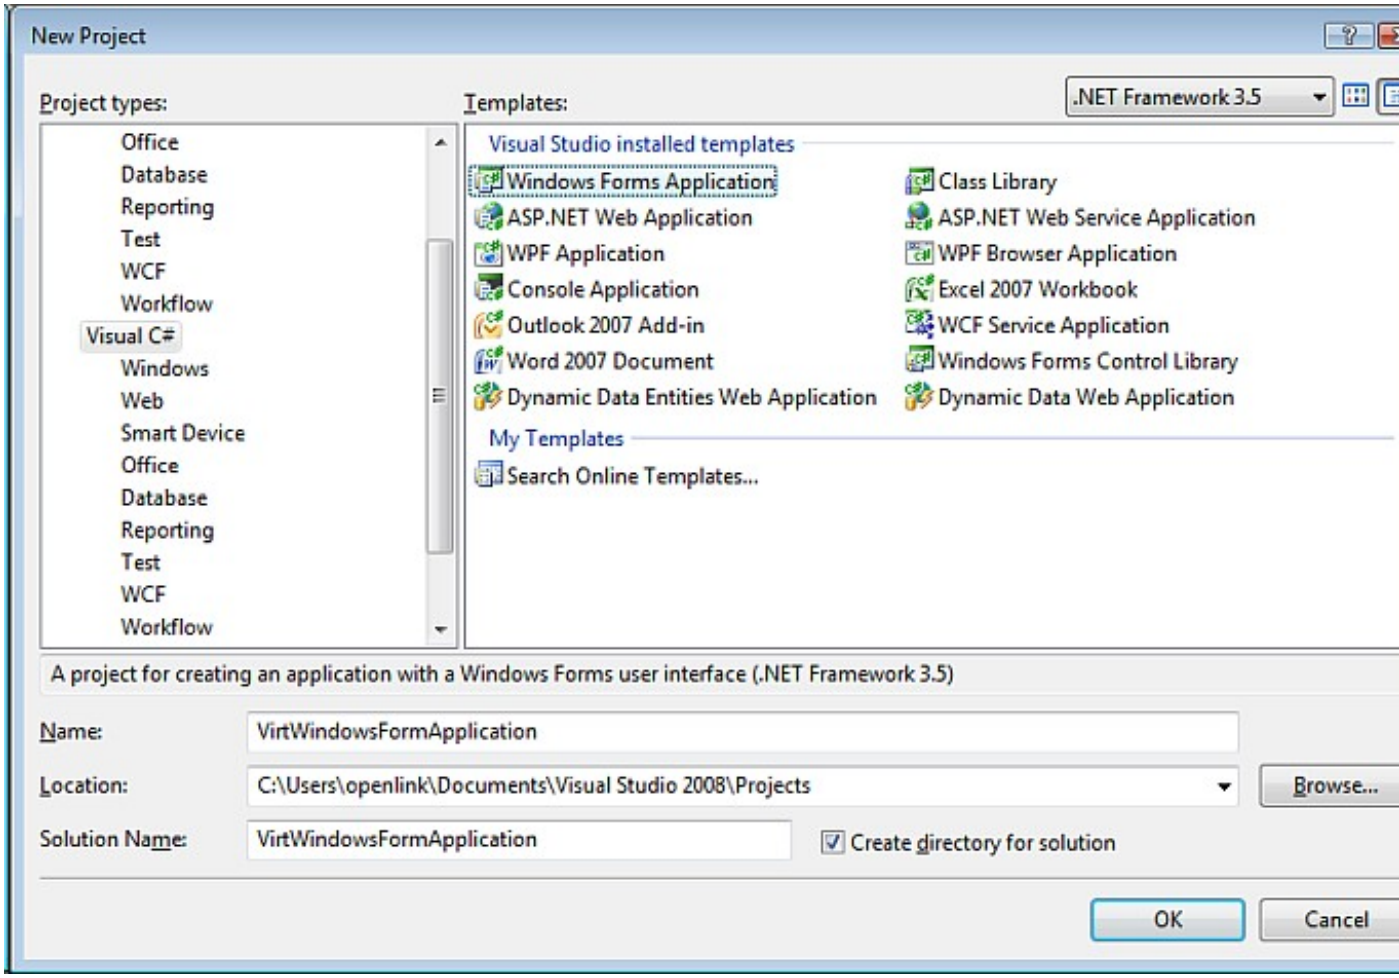
   VirtWindowsFormApplication

   , and click

   OK

   .

   Figure 8.475. Web Application



6. In the

   Toolbox

   , expand

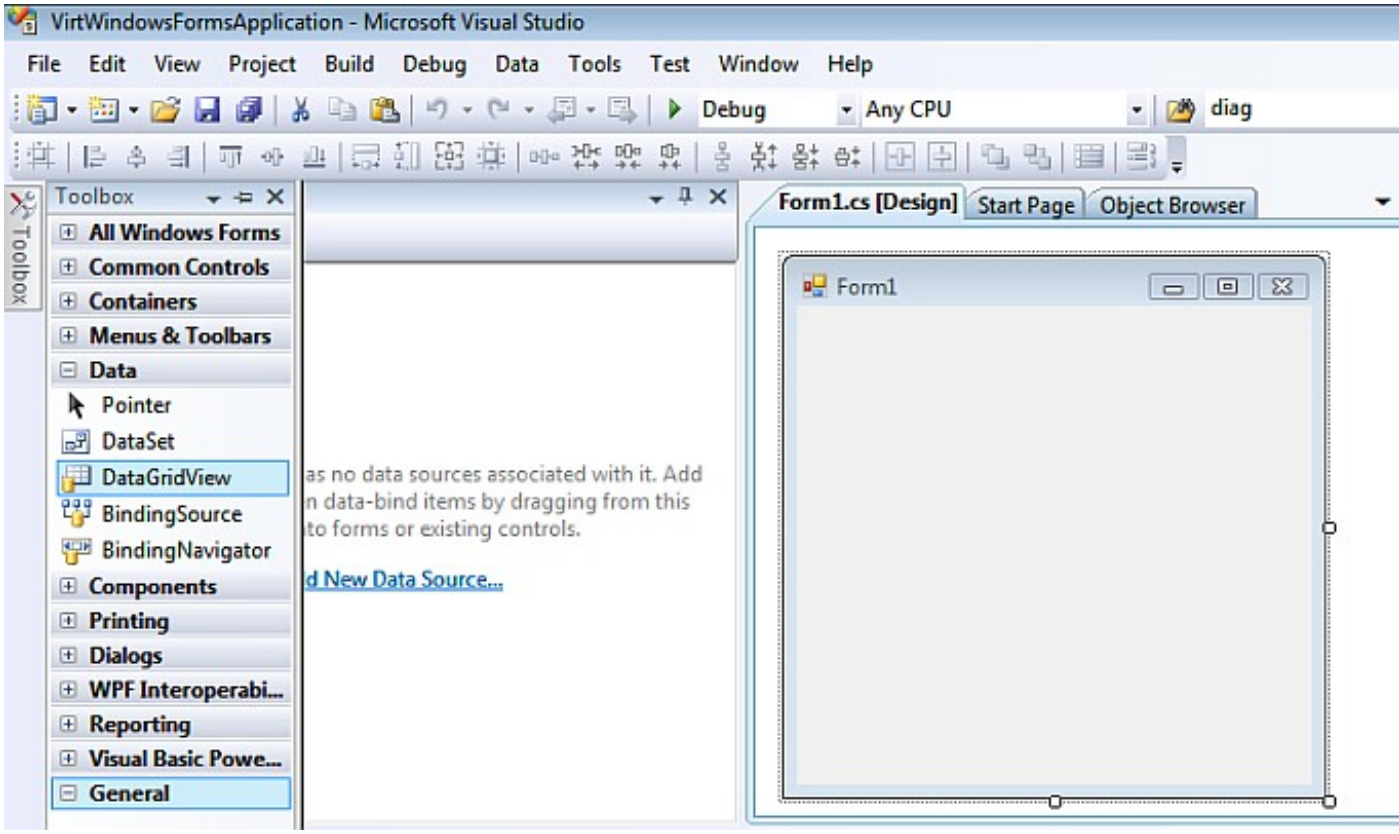
   Data Controls

   , and drag the

   DataGridView

   control onto the form.

   Figure 8.476. Toolbox



7. Click on the little

   arrow

   in the top right of the

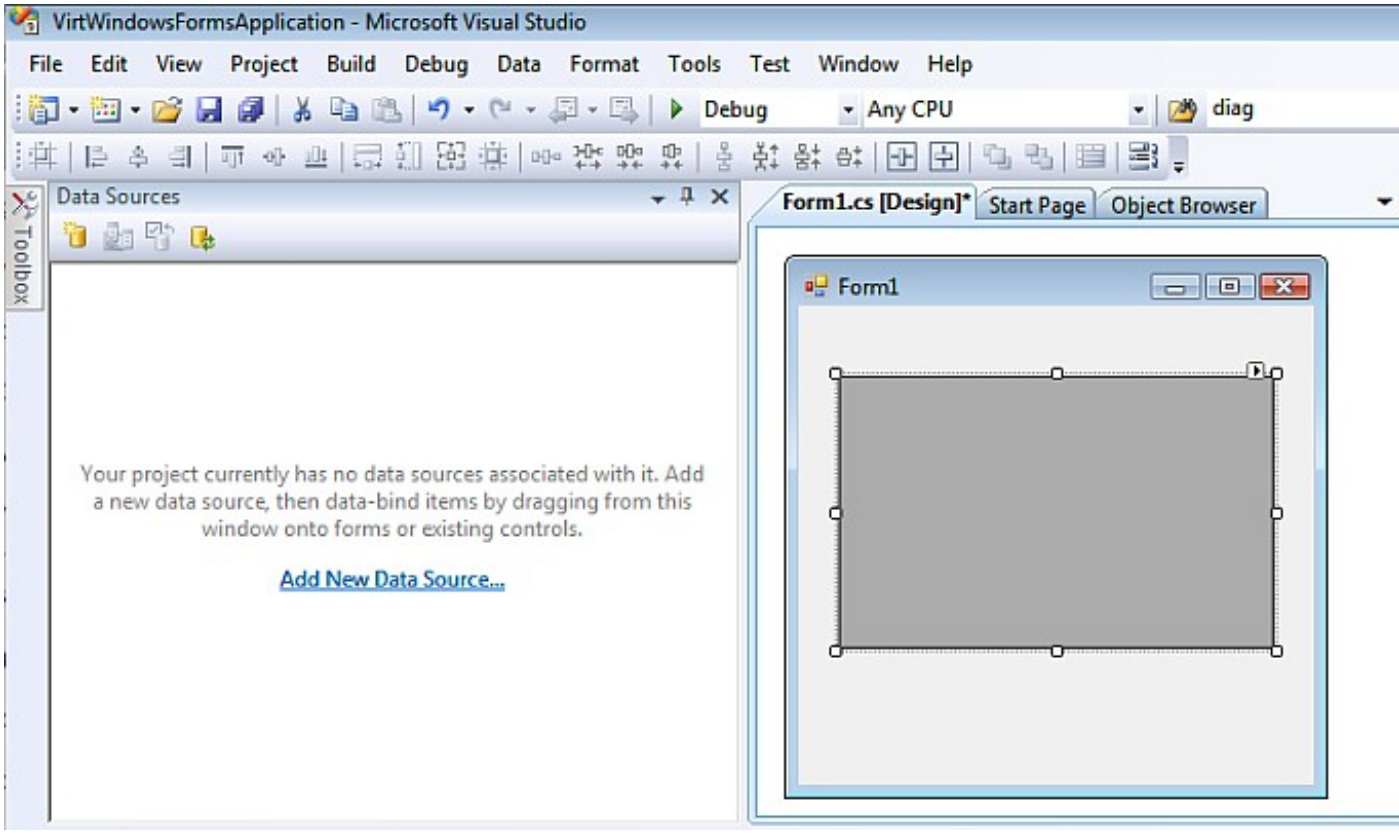
   DataGridView

   control. This loads the

   DataGridView Task

   menu.

Figure 8.477. DataGridView Task

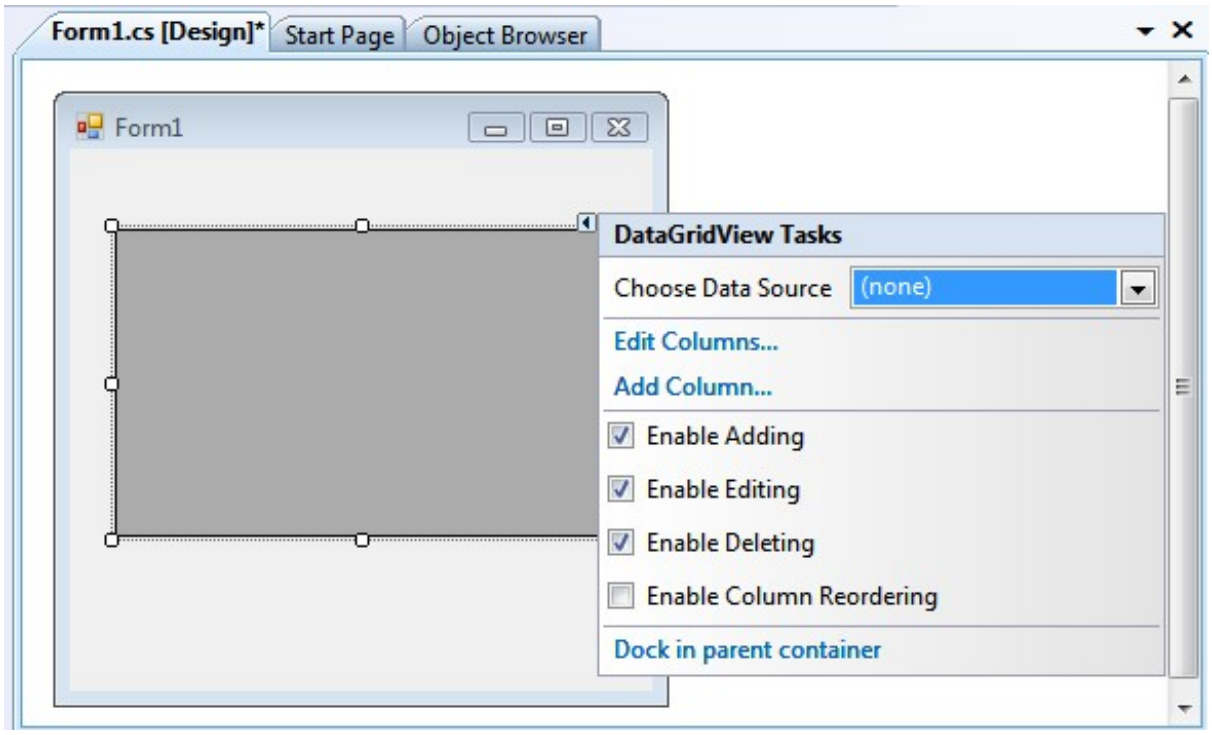


8. Click on the

   Choose Data Source

   list box.

   Figure 8.478. Choose Data Source

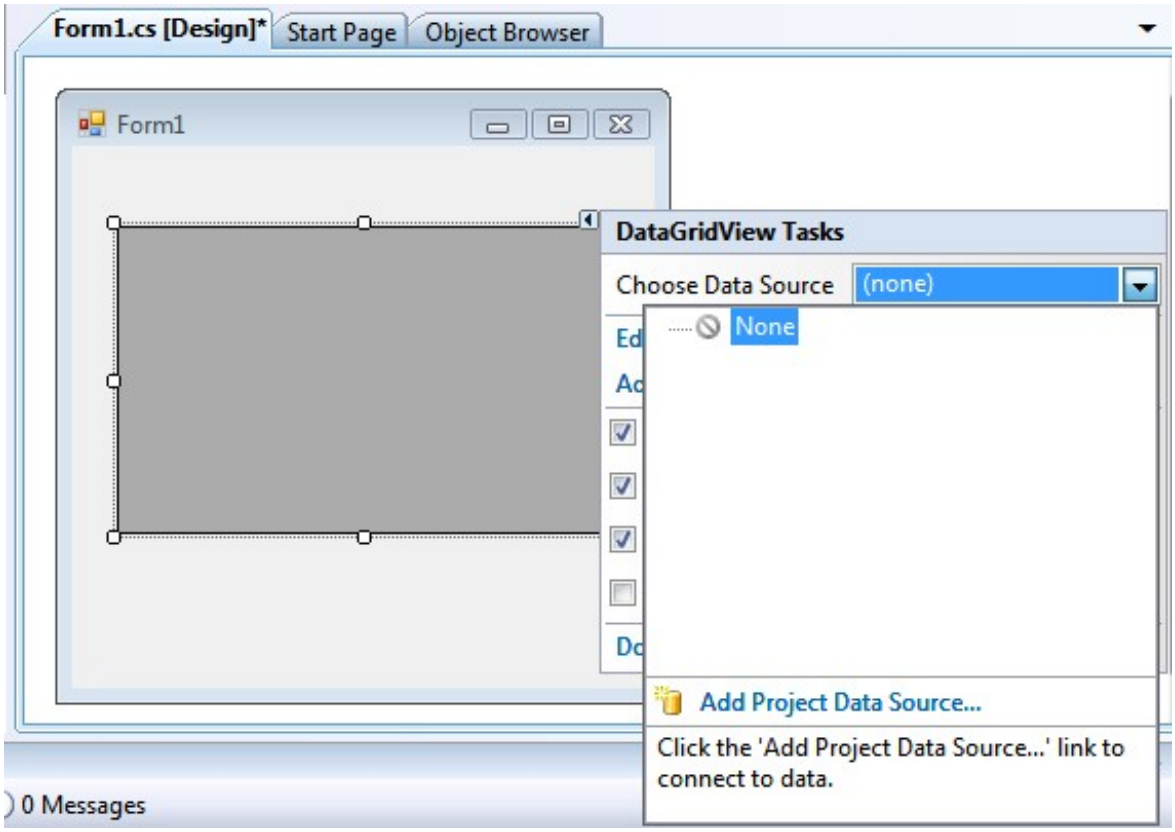


9. Click on the

   Add Project Data Source

link to connect to a data source.

Figure 8.479. Add Project Data Source



10. In the

    Data Source Configuration Wizard

    dialog

    Choose Data Source Type

    page select the

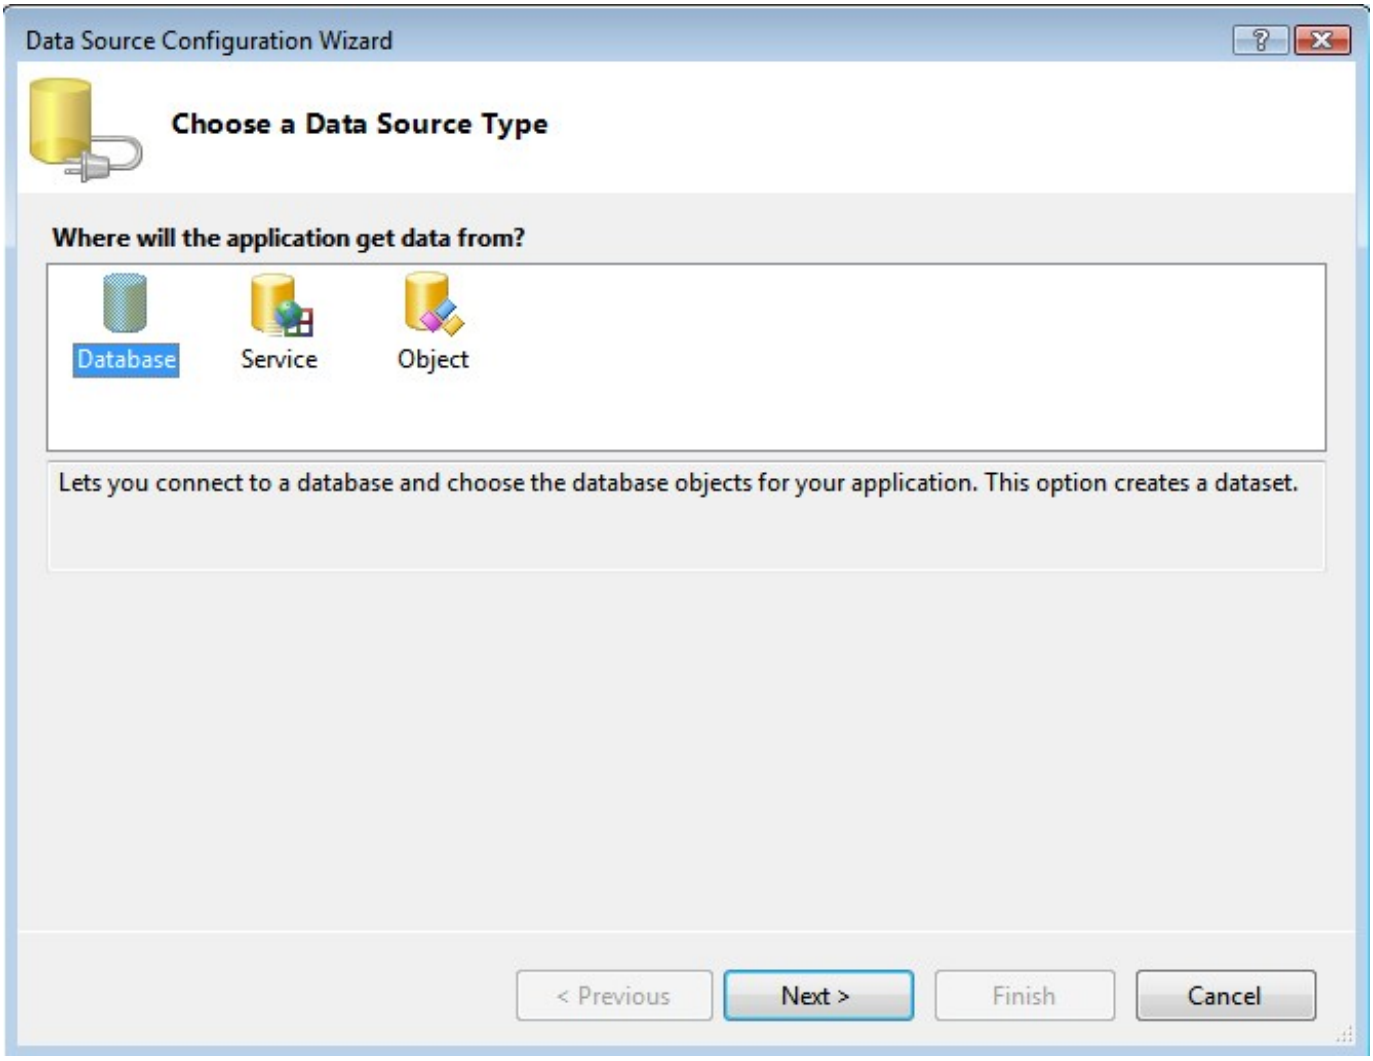
    Database

    data source type and click

    Next

    .

Figure 8.480. Data Source Type



11. In the

    Data Source Configuration Wizard

    dialog

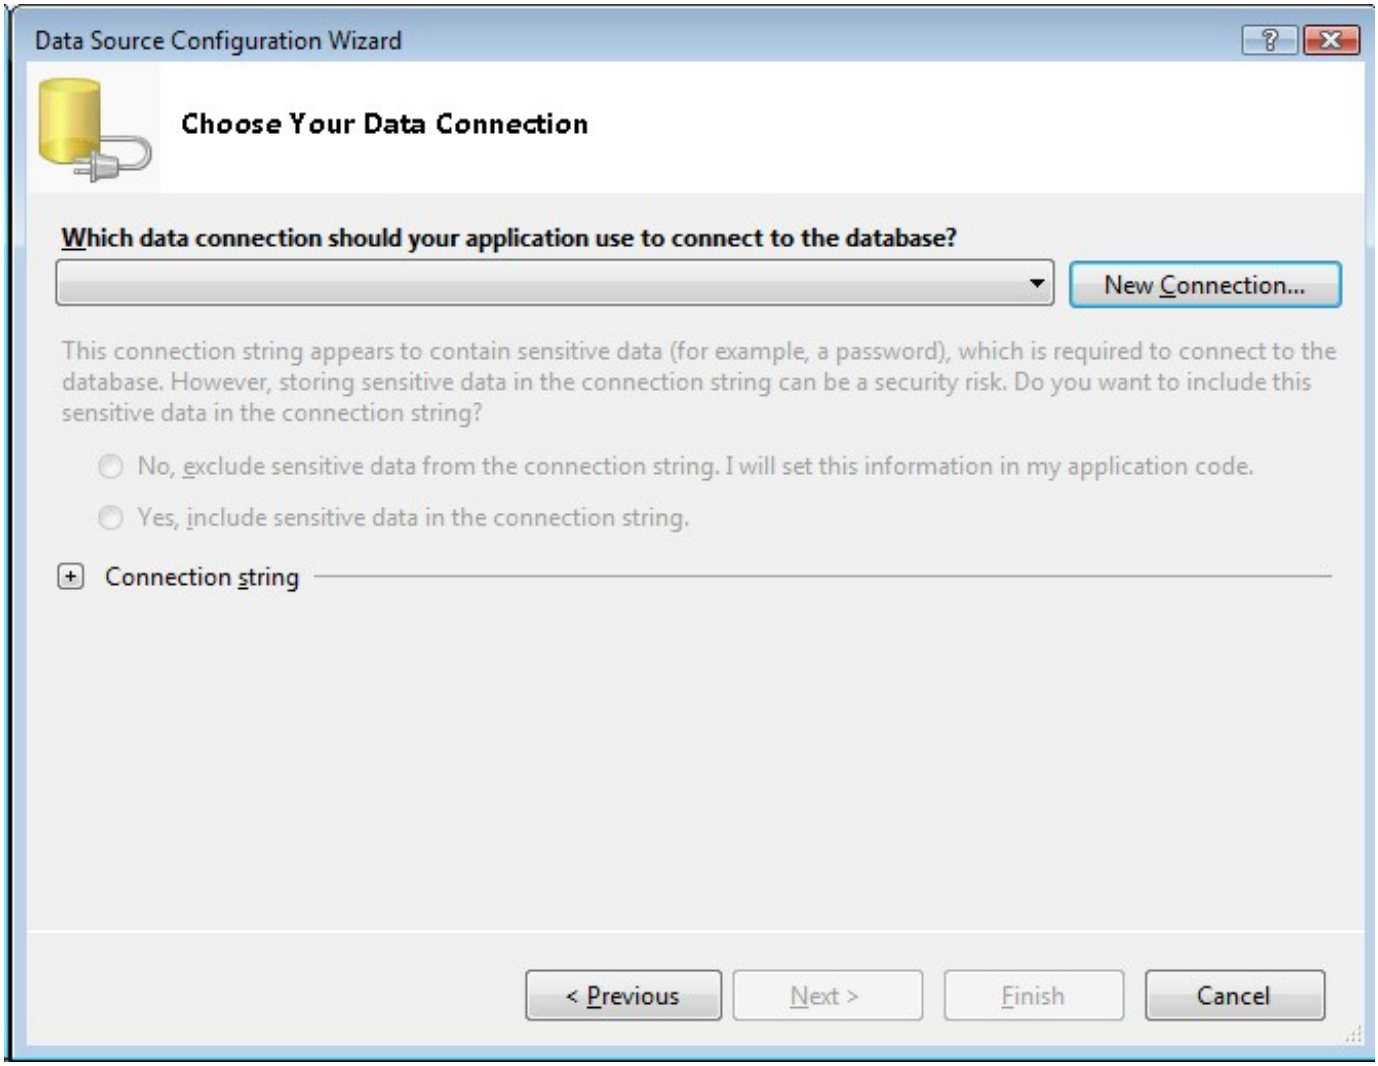
    Choose your Data Connection

    page, select the

    New Connection

    button

Figure 8.481. Data Source Configuration Wizard



12. In the

    Choose Data Source

    dialog, select the OpenLink

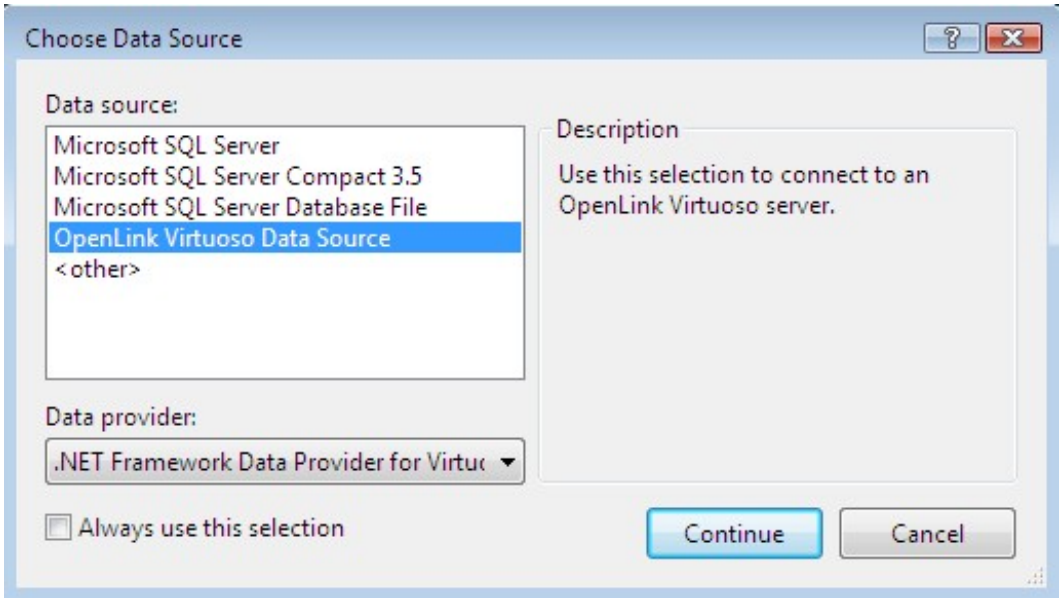
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.482. Data Source



13. In the

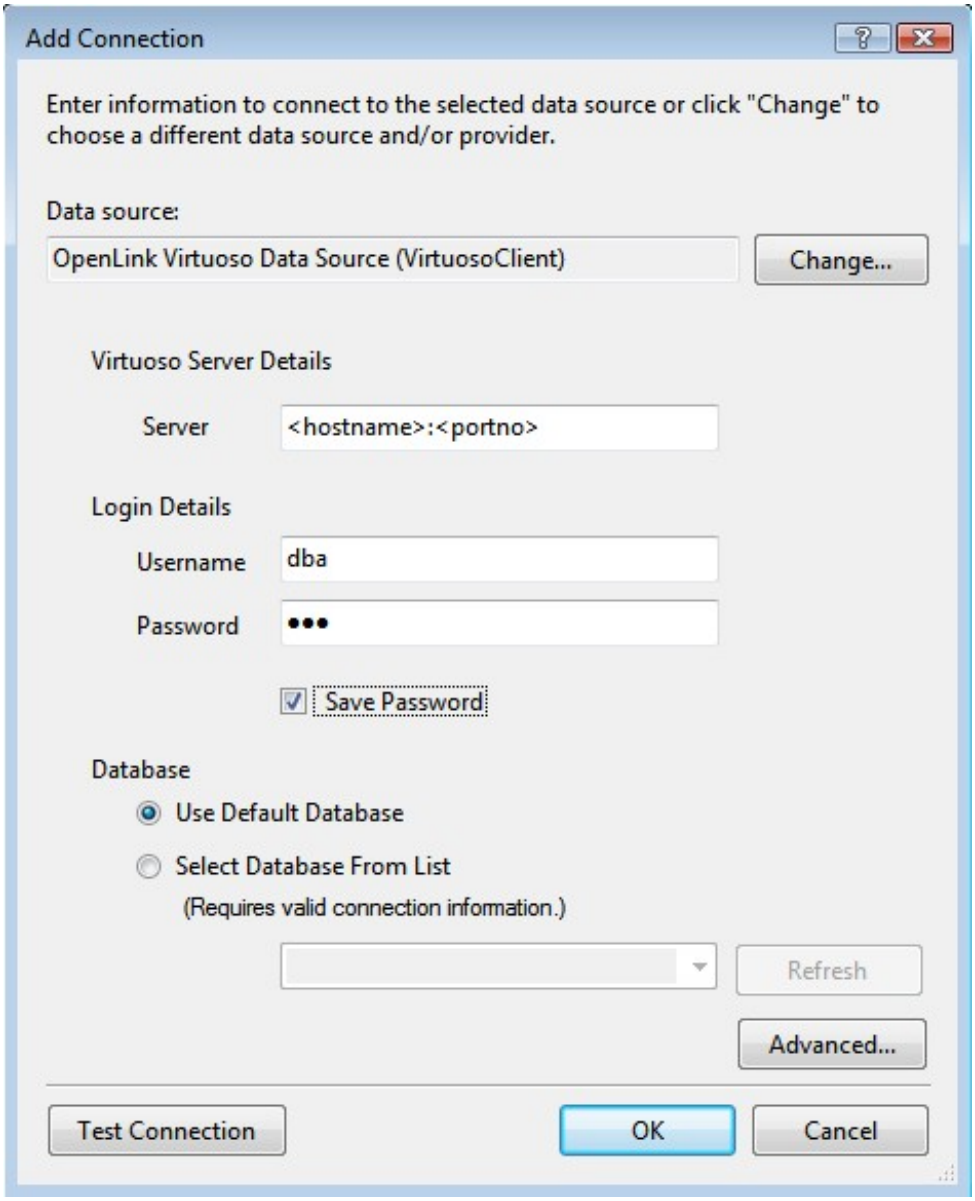
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.483. Connection Properties



14. Select the

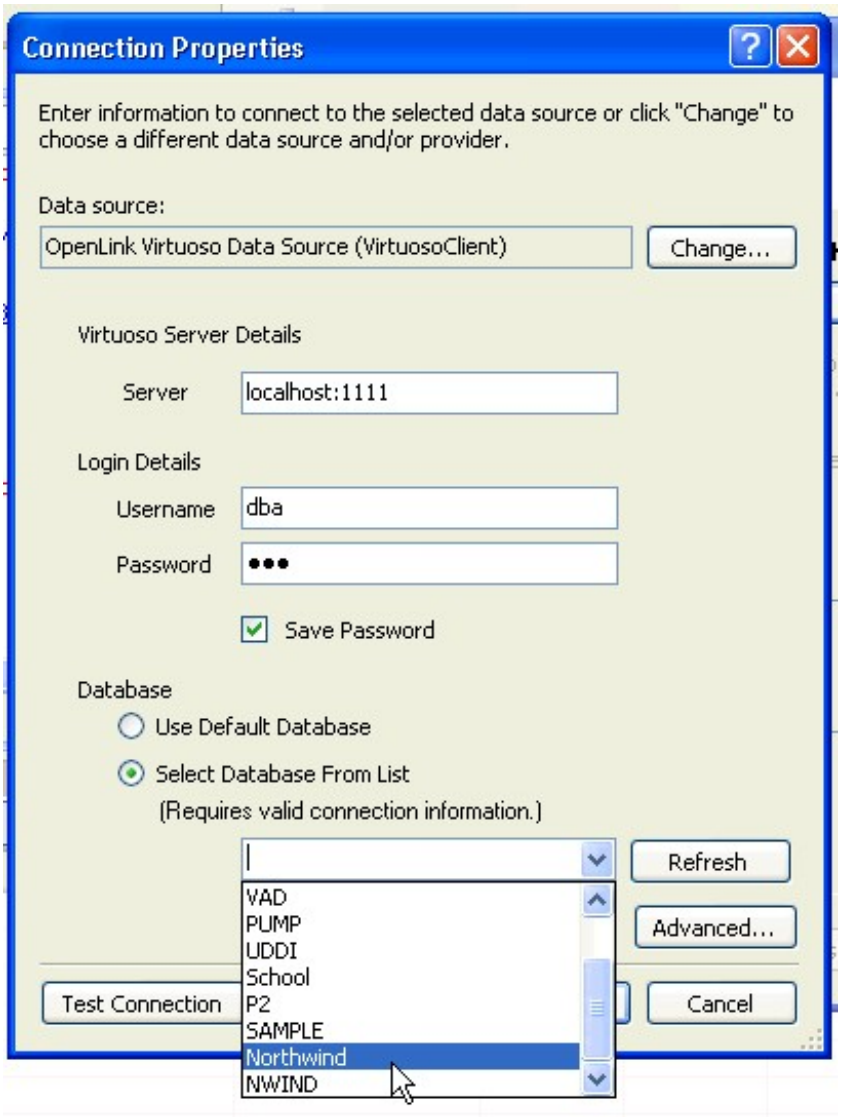
    Select Database From List

    radio button and choose the

    Northwind

    database from the drop down list.

Figure 8.484. Add connection

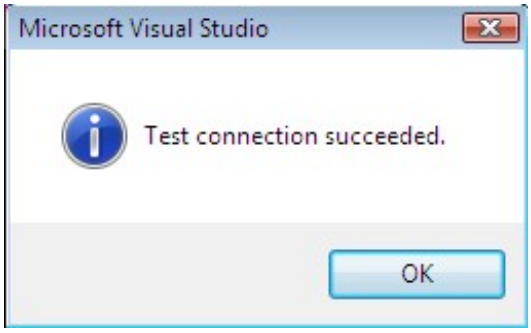


15. Press the

    Test Connection

    dialog to verify that the database is accessible.

    Figure 8.485. Test Connection



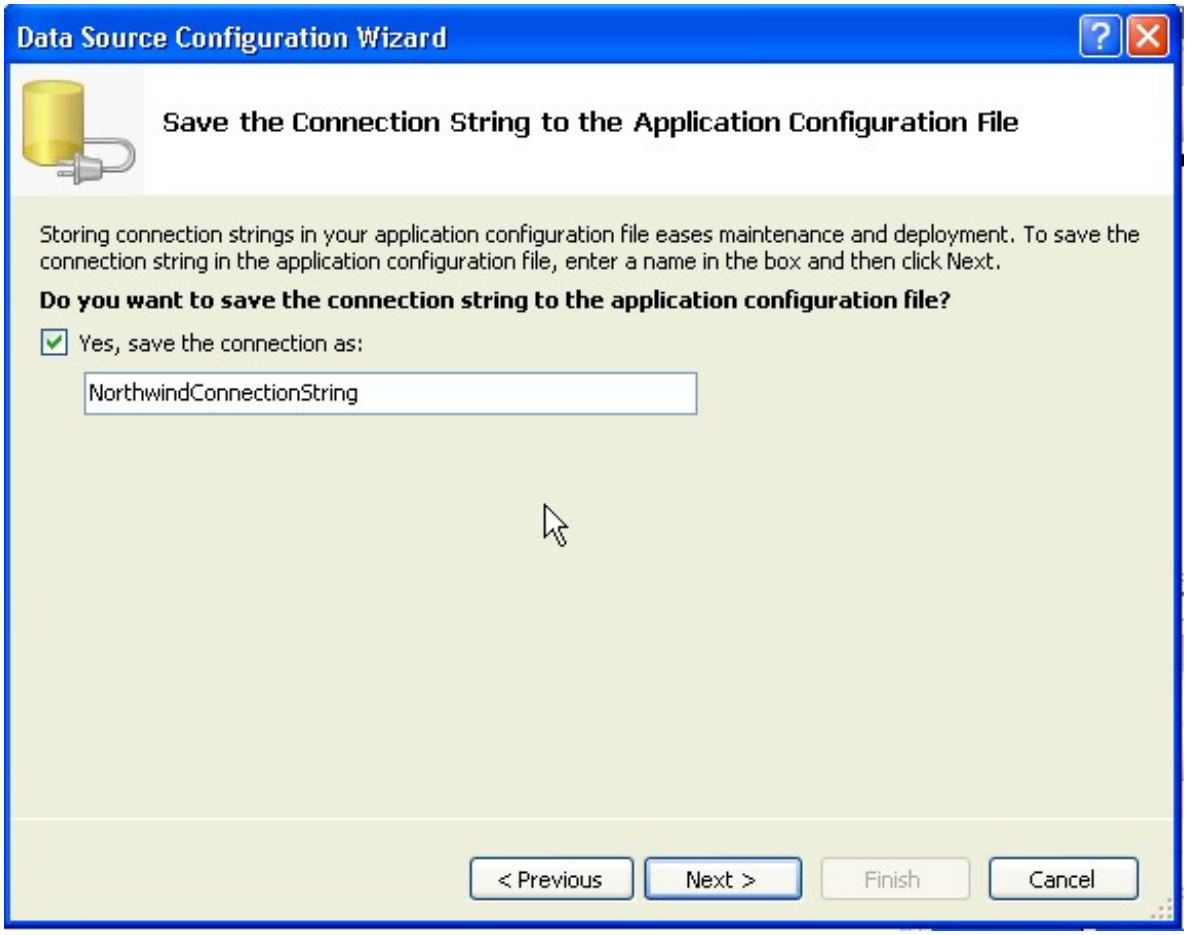
16. Leave the default connect string

    NorthwindConnectionString

    and click

Next

Figure 8.486. NorthwindConnectionString



17. From the list of available tables returned for the Northwind database, select the

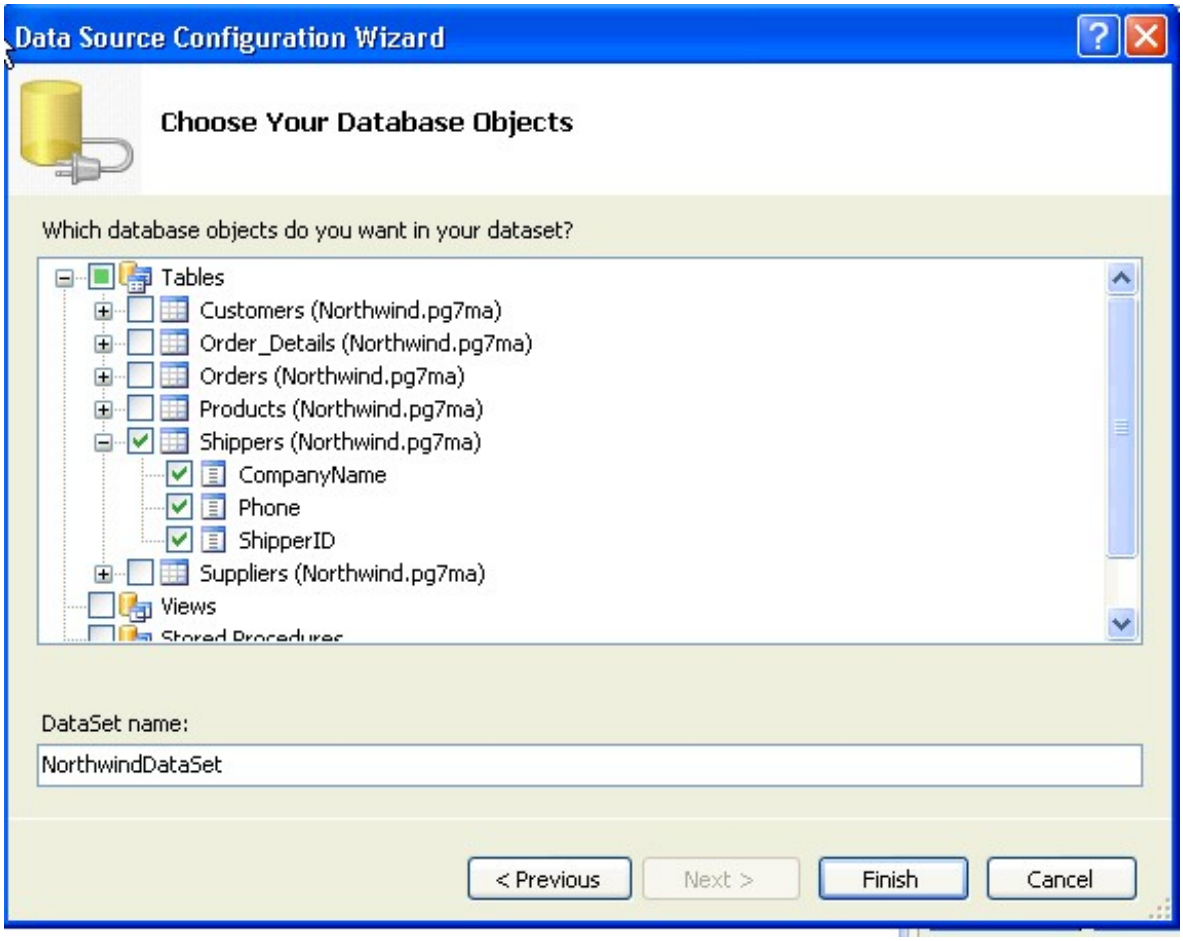
    Shippers

    table to be associated with the

    DataGridView

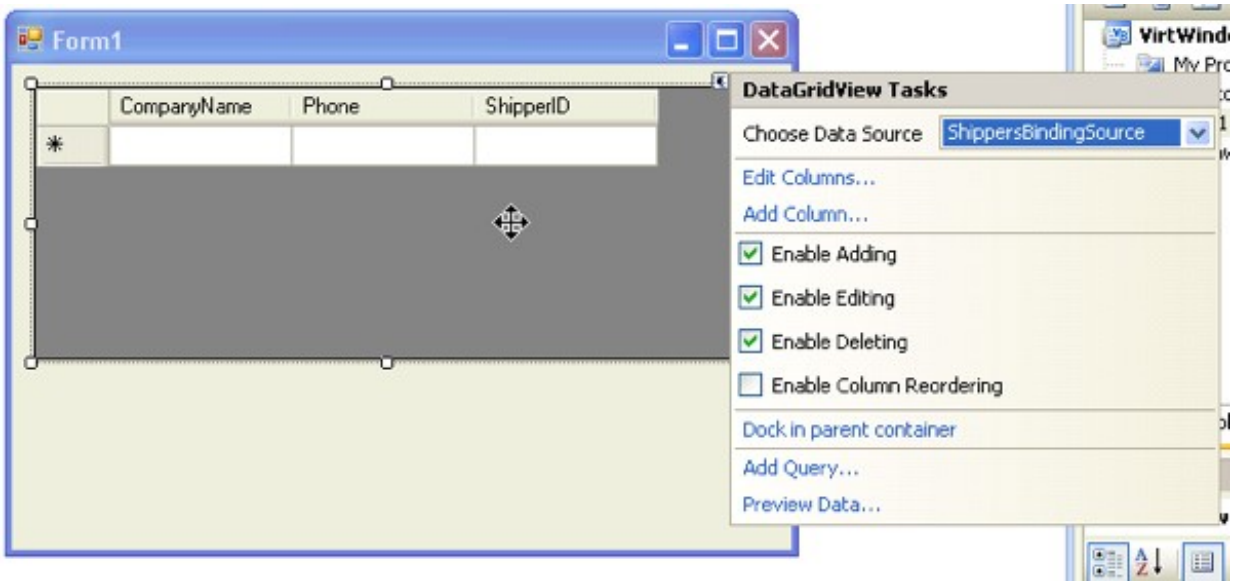
    control.

    Figure 8.487. Northwind database



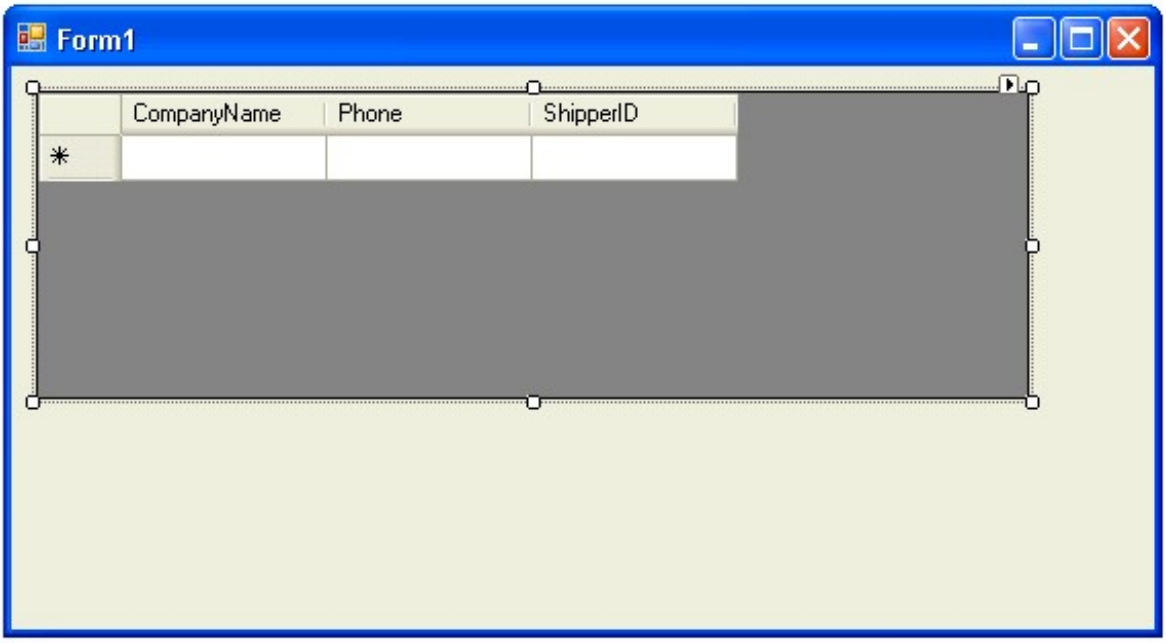
18. The columns names of the select table will be displayed in the DataGridView.

Figure 8.488. DataGridView



19. Resize the Form and DataGridView to allow all columns to be visible, if possible.

Figure 8.489. Resize the Form and DataGridView



20. To test the application, simply hit

    Ctrl+F5

    within Visual Studio or select

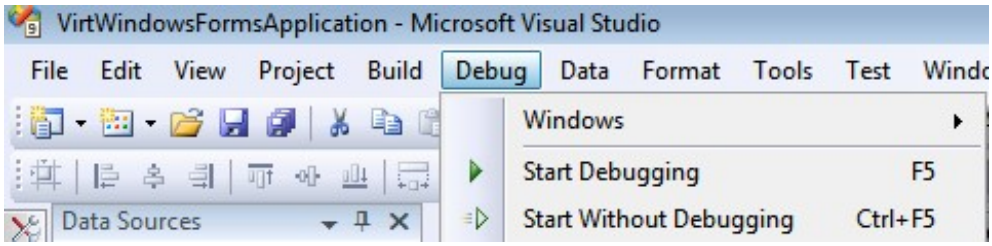
    Start Debugging

    from the

    Debug

    menu.

    Figure 8.490. Start Debugging



21. The data from the

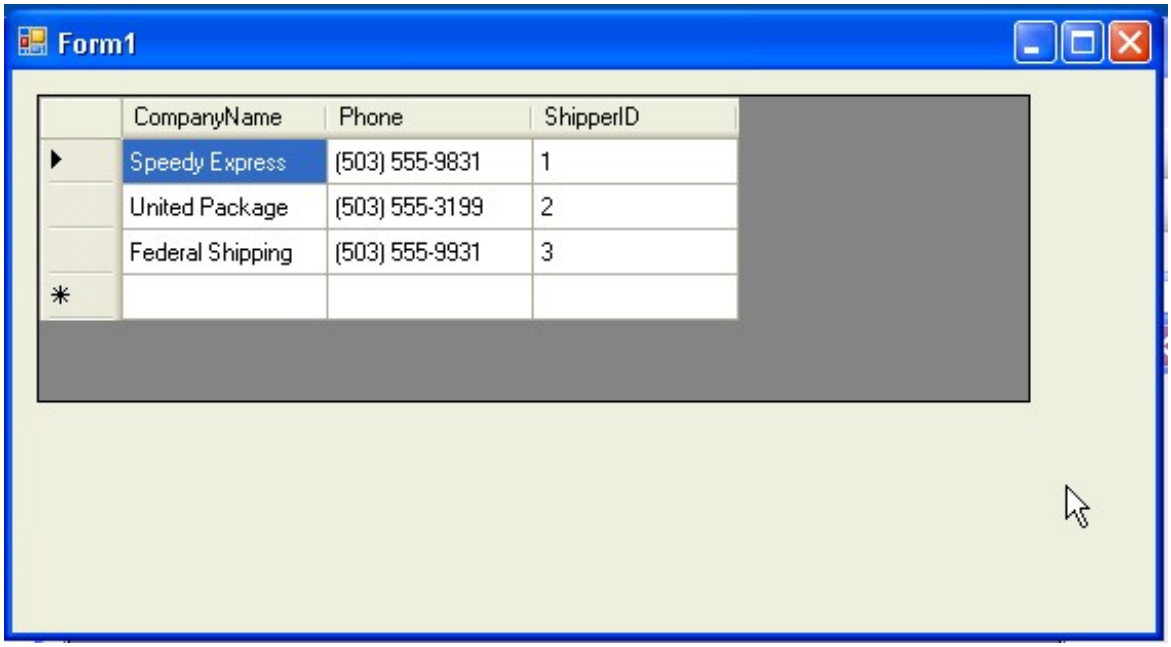
    Shippers

    table will be displayed in the

    DataGrid

    .

    Figure 8.491. DataGrid



The task is now complete.

8.10. Using Microsoft Entity Frameworks to Access ODBC to JDBC Bridge Schema Objects with Virtuoso

Abstract

This section details the steps required to provide Microsoft Entity Framework access to ODBC to JDBC Bridge Schema Objects using the OpenLink Virtuoso Universal Server. This is achieved by linking the required ODBC to JDBC Bridge Schema objects into Virtuoso using its built in Virtual Database engine, and then using the Virtuoso ADO.NET Entity Framework provider to query the remote ODBC to JDBC Bridge Schema objects linked into the Virtuoso Server.

Prerequisites. The following prerequisites must be in place for this solution to be possible.

ODBC to JDBC Bridge DBMS. An ODBC to JDBC Bridge DBMS hosting the required Schema Objects needs to be available. In this section we shall make and ODBC to JDBC bridge connection to another *Virtuoso Northwind Demo* database to demonstrate the process.

An ODBC to JDBC Bridge DBMS hosting the required Schema Objects needs to be available. In this section we shall make and ODBC to JDBC bridge connection to another *Virtuoso Northwind Demo* database to demonstrate the process.

ODBC to JDBC Bridge Driver. An ODBC to JDBC Bridge Driver is required for Linking the ODBC to JDBC Bridge Schema Objects into the Virtuoso Server. The *OpenLink ODBC to JDBC Bridge Driver* will be used in this section, for which a functional ODBC Data source name of "jdbcma" will be assumed to exist on the machine hosting the Virtuoso Server.

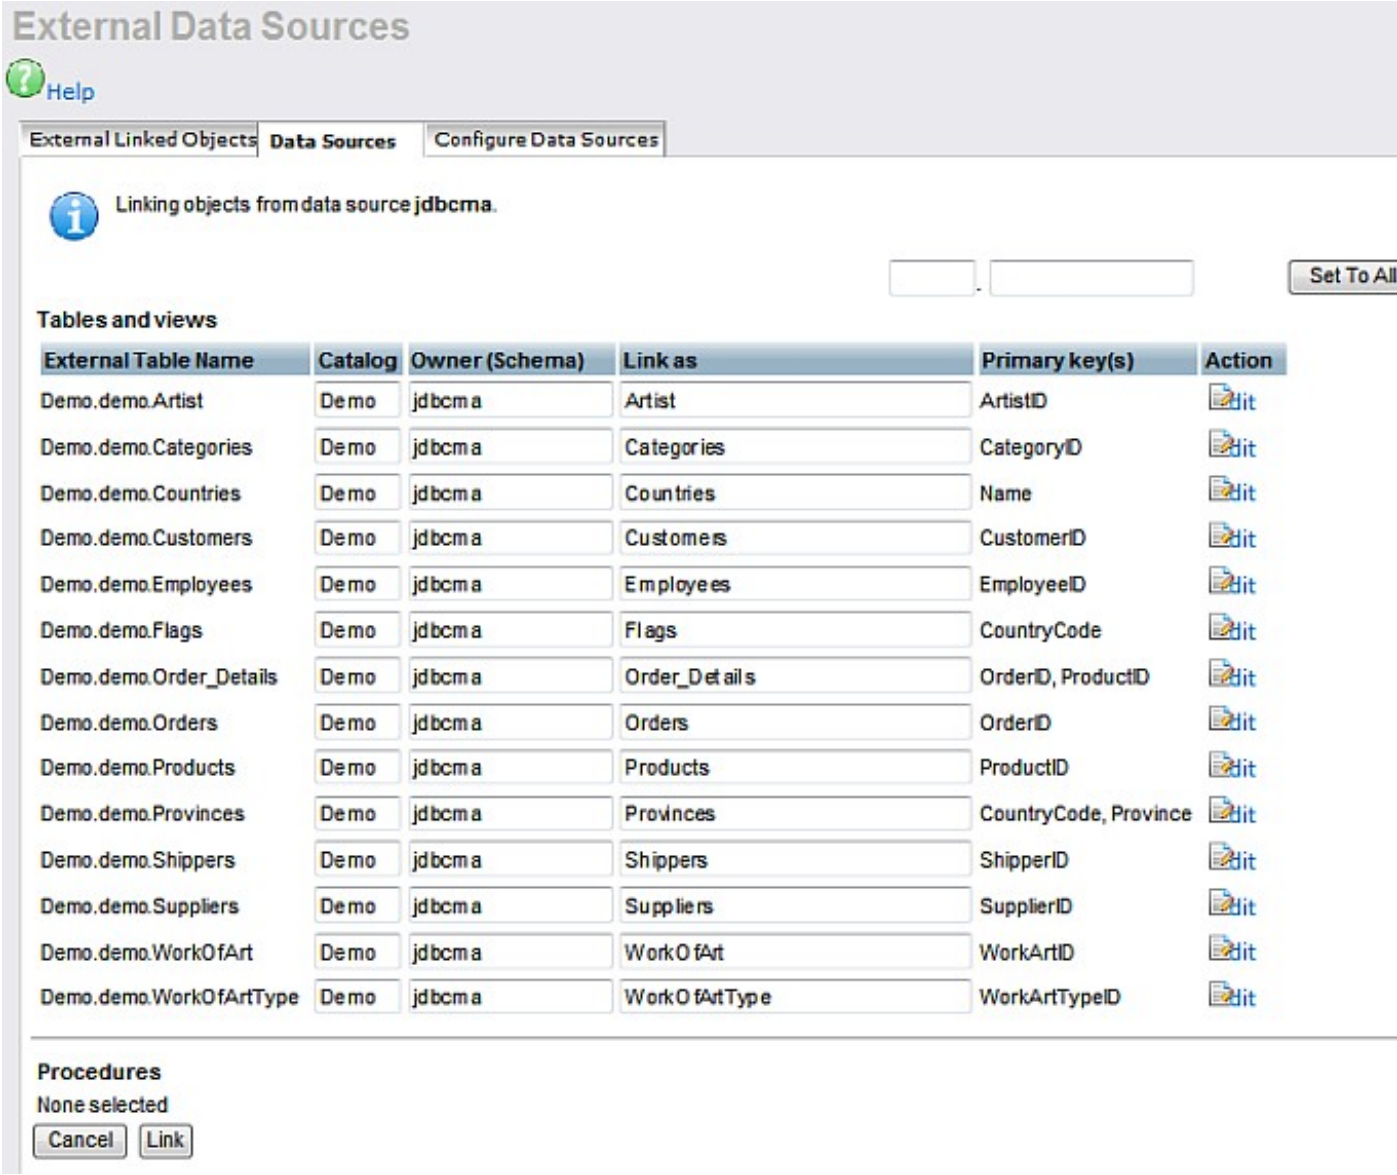
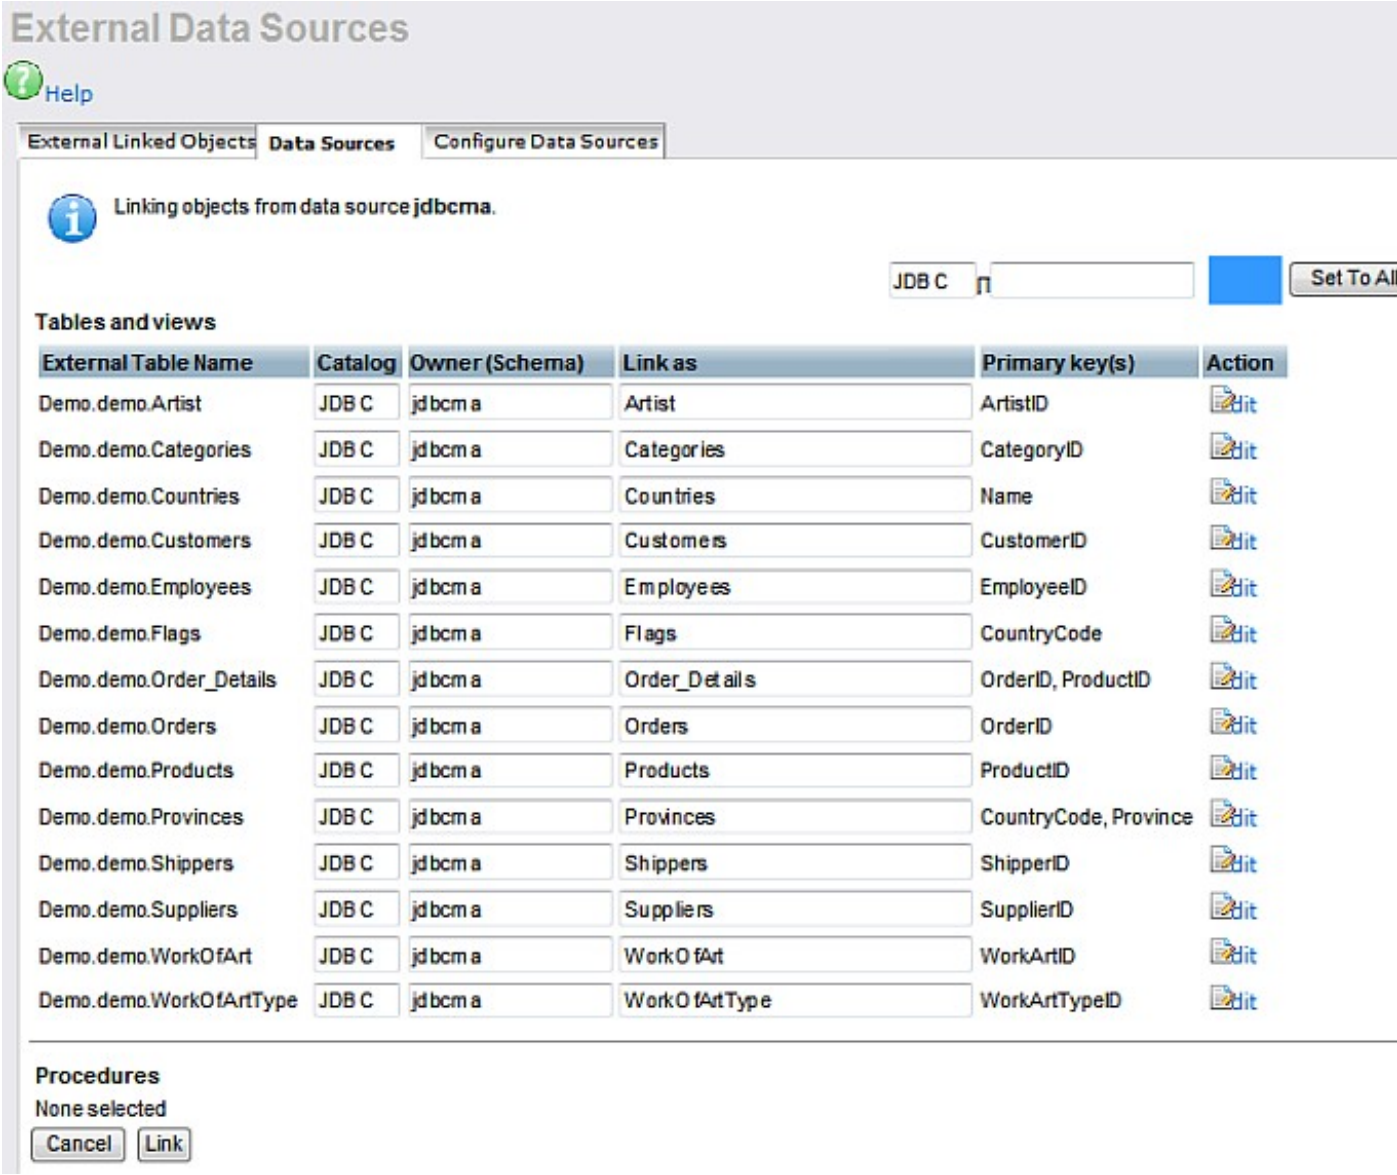
8. Change the Catalog for each table to be "JDBC" using the "Set All" button.

Figure 8.499. "Link" button



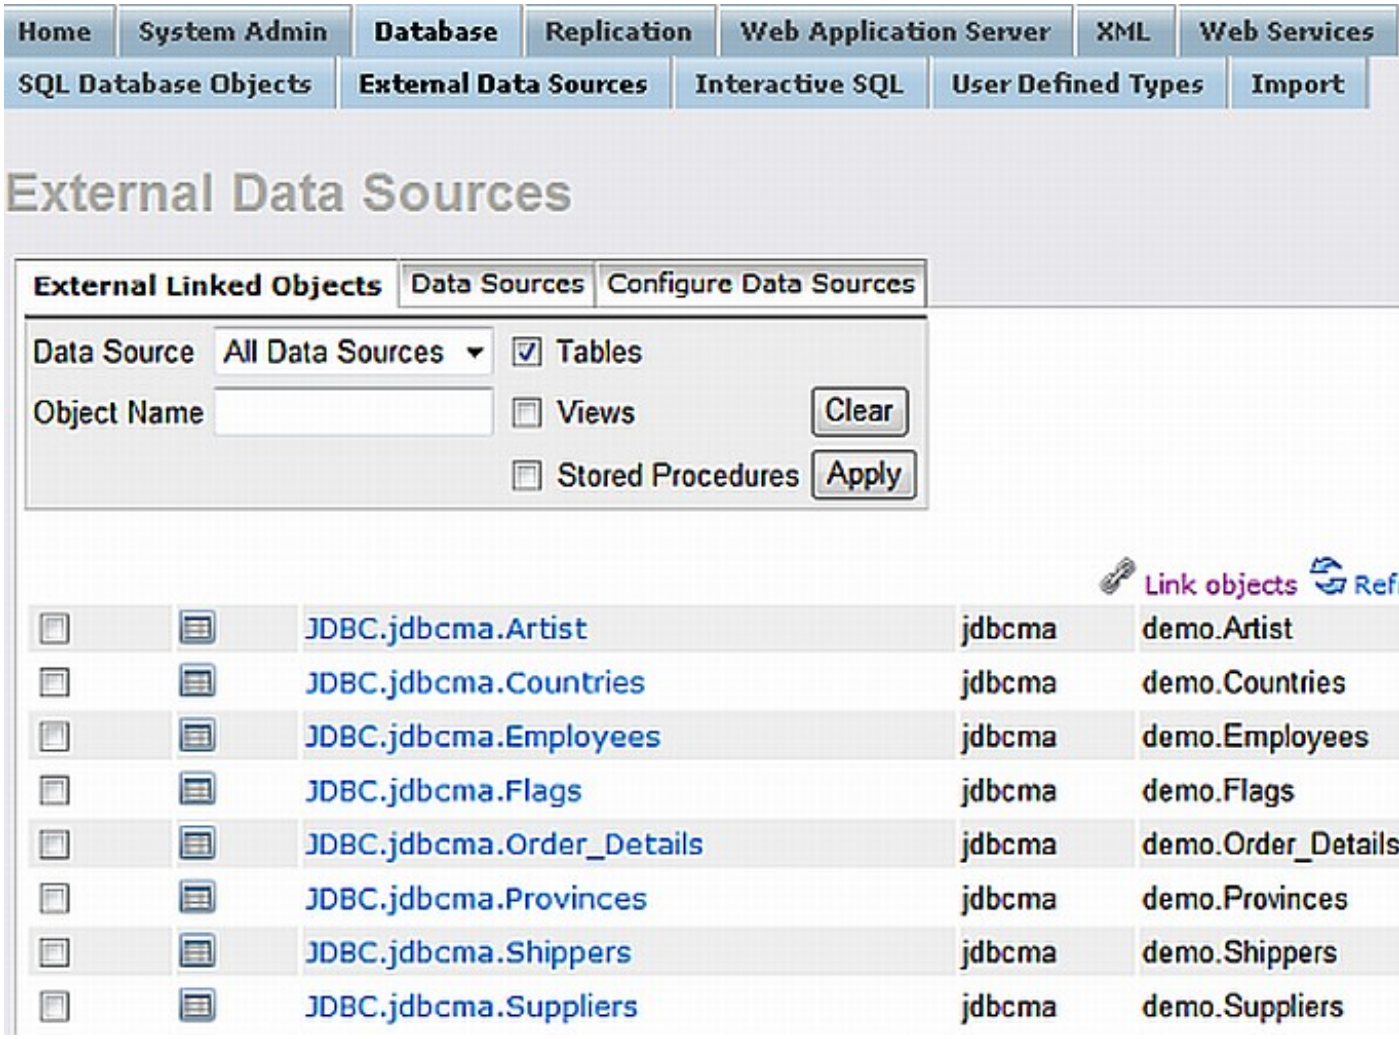
9. Select the "Link" button to link the selected tables into Virtuoso

Figure 8.500. "Link" button



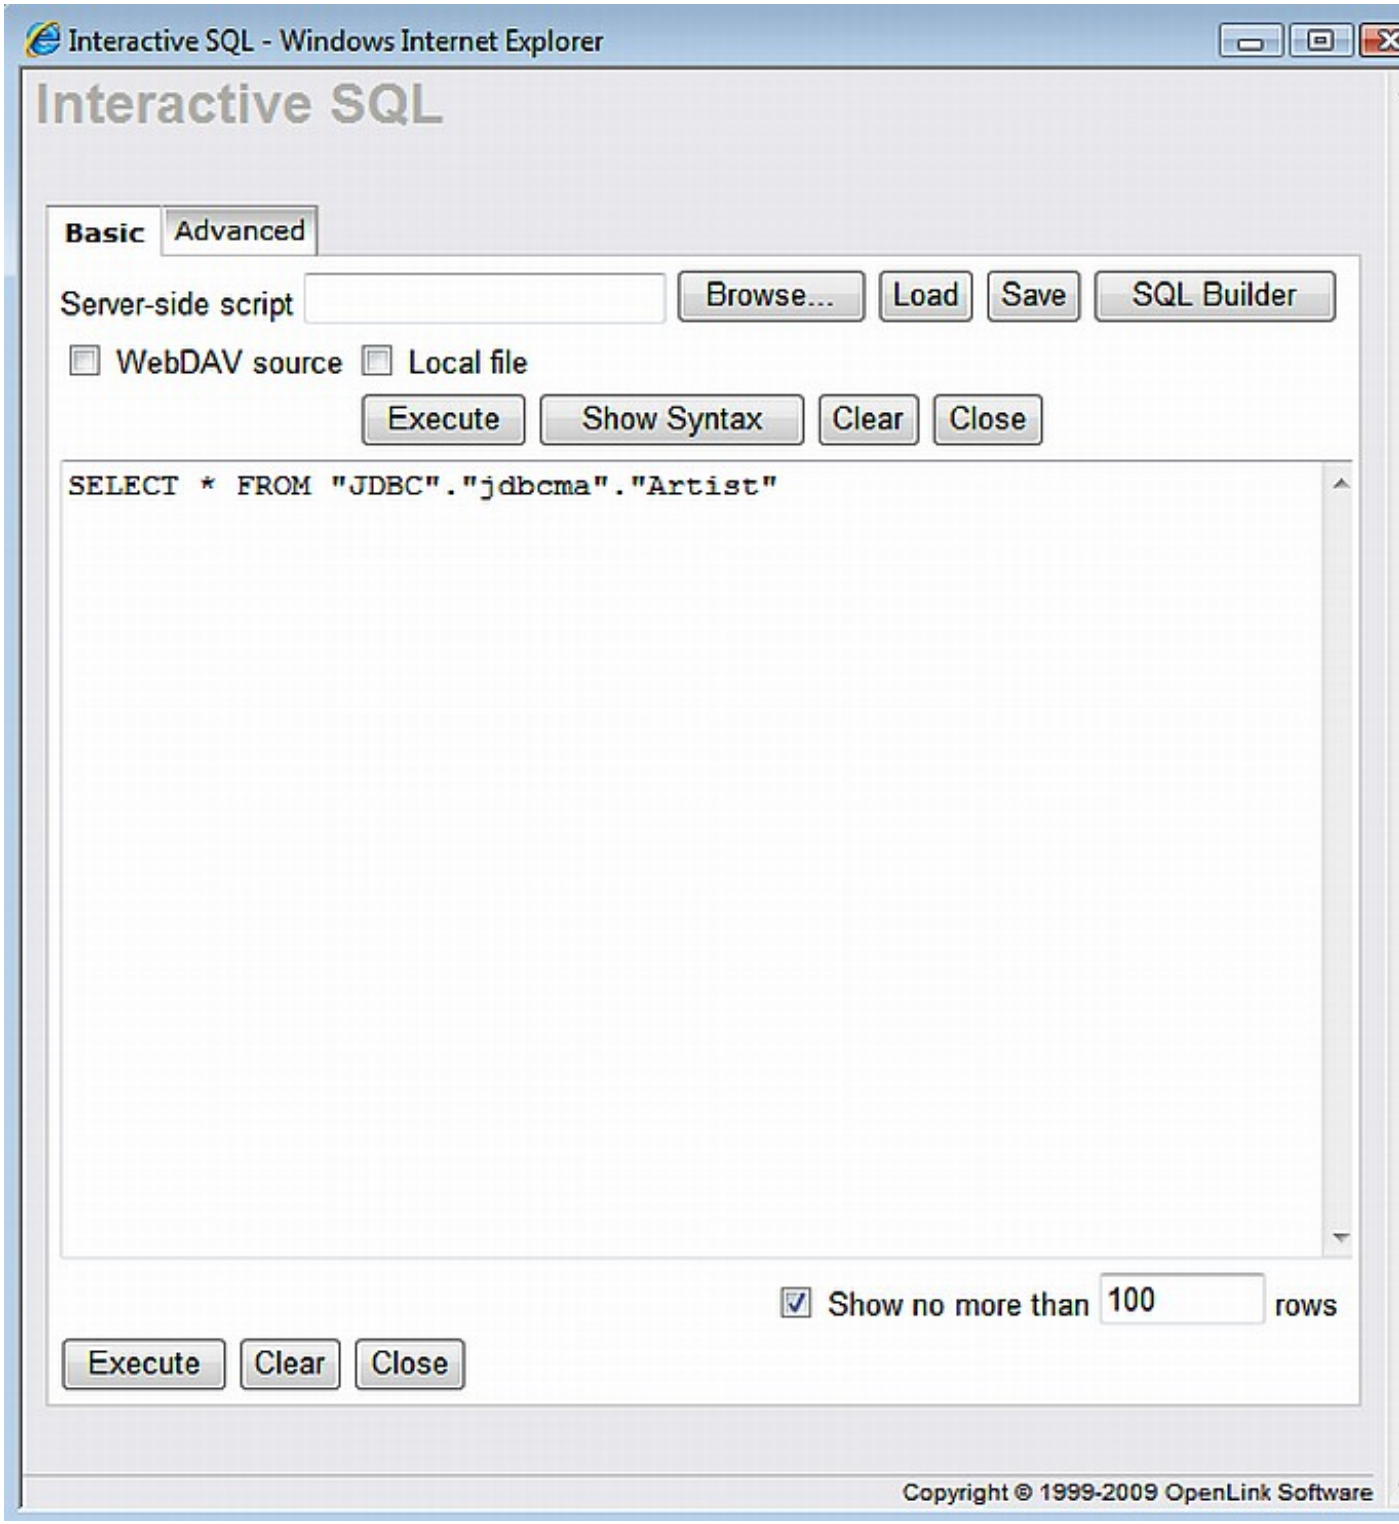
10. On completion of the Link process the tables will be displayed in the "External Linked Objects" tab.

Figure 8.501. Completion



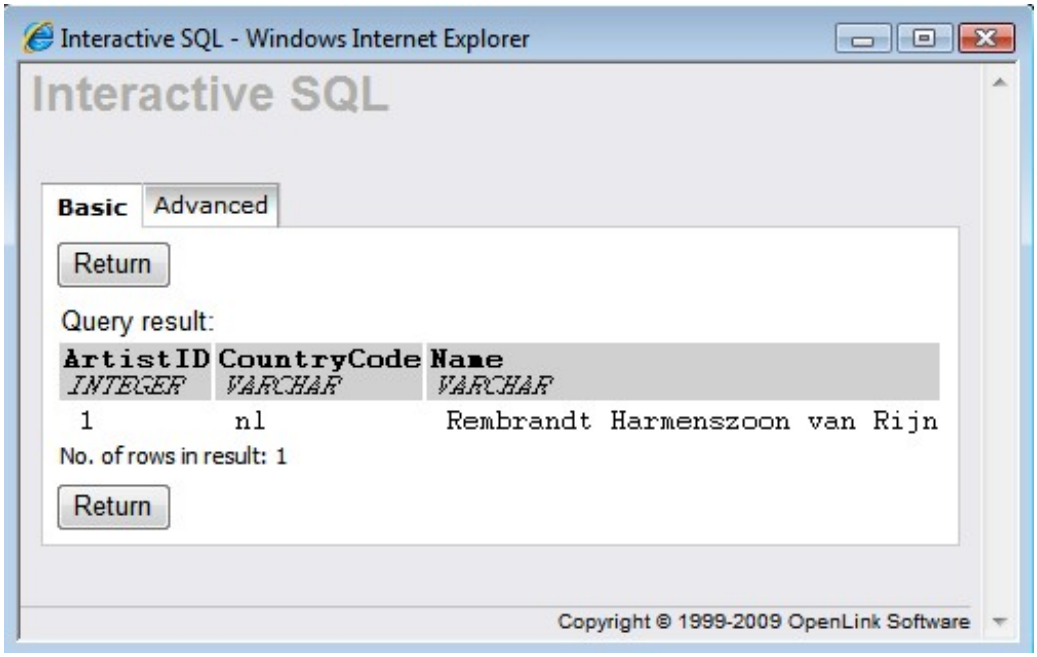
11. The linked tables can be queried by clicking on the hyperlink in the "Local Name" column of the "External Linked Objects" tab above, which loads the Virtuoso "Interactive SQL" interface with the required SQL "Select" for retrieving the remote table data. We shall use the "JDBC.jdbcma.Artist" table to demonstrate this.

Figure 8.502. Completion



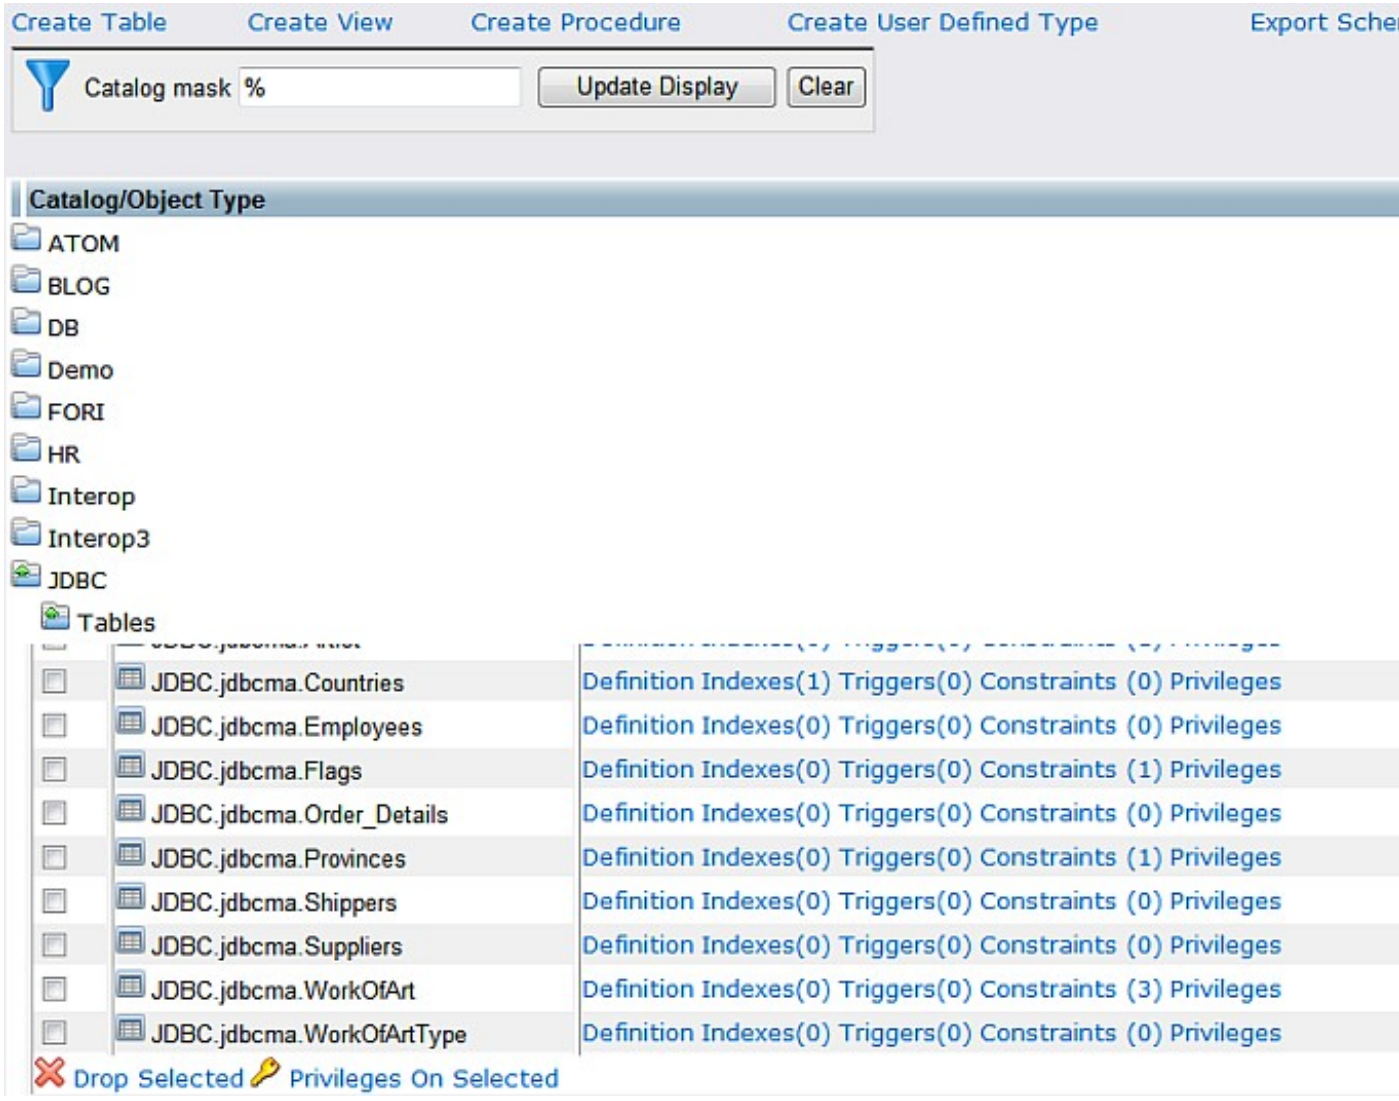
12. Then click the "Execute" button to run the query and retrieve the results from the remote table.

Figure 8.503. Completion



13. The tables can also be viewed as part of the Virtuoso "SQL Schema Objects" under the "JDBC" catalog name.

Figure 8.504. view tables



The Link process is now complete enabling the tables to be queried as if part of the Virtuoso Schema.

8.10.4. Creating EDM in Visual Studio 2008

The following steps can be used to create an Entity Data Model (EDM) for the ODBC to JDBC Bridge Northwind database:

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.505. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

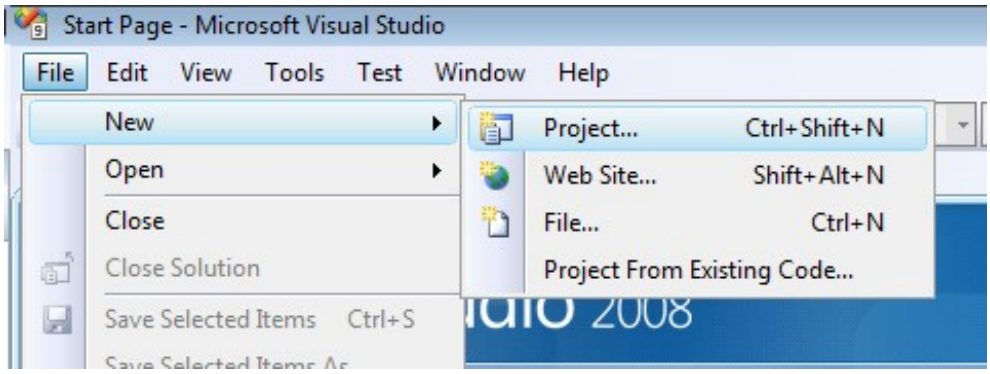
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.506. Web Application

3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

as your programming language.

4. Within the language category, click on

   Web

   and select

   ASP.NET Web Application

   from the right-hand panel.
5. Choose a name for the project, for example

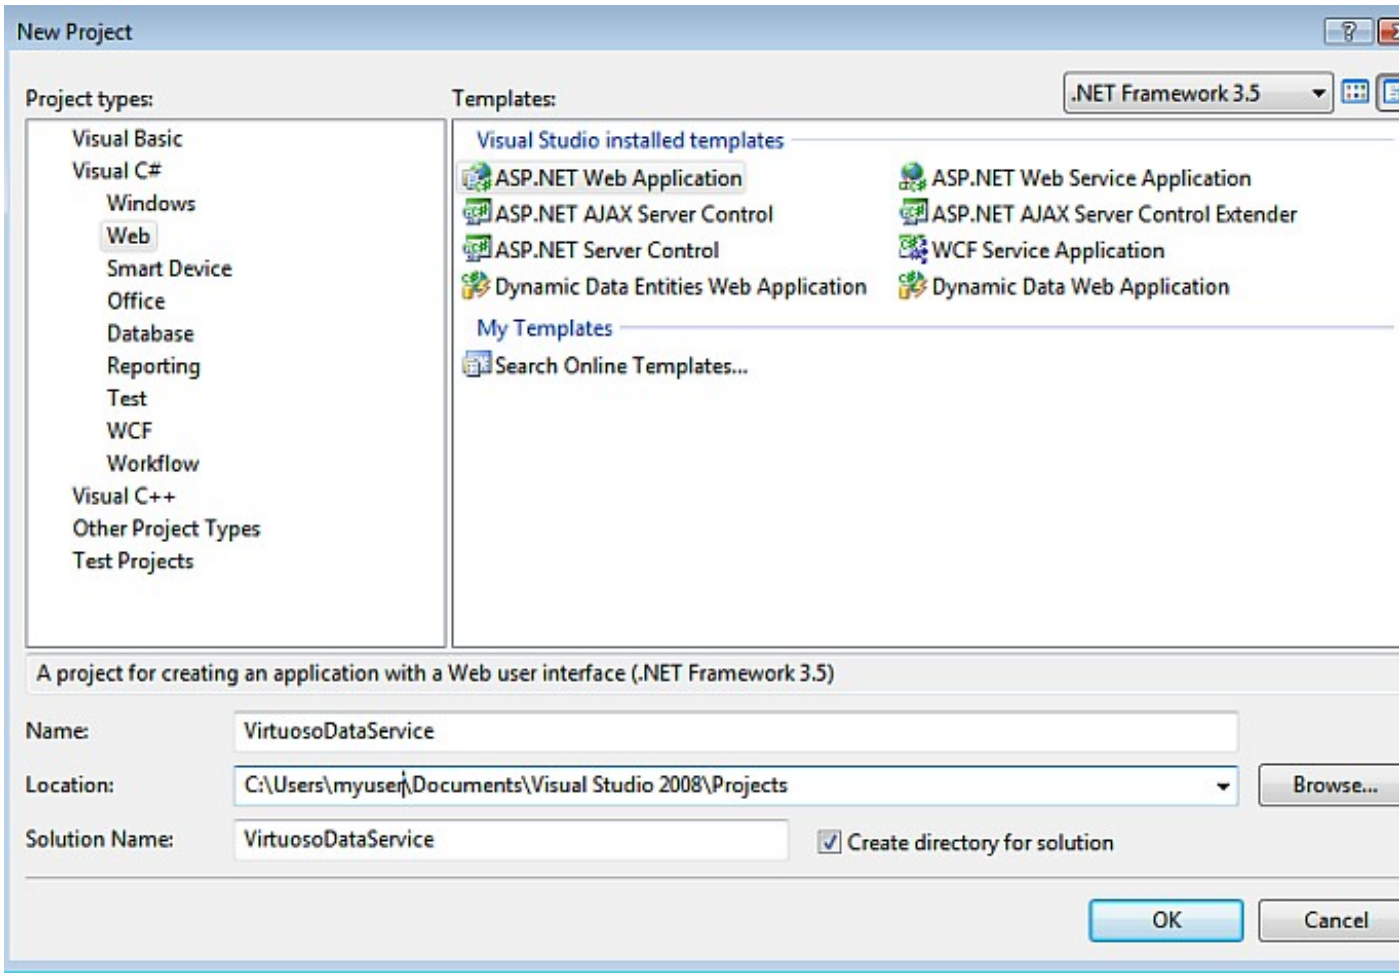
   VirtuosoDataService

   , and click

   OK

   .

Figure 8.507. name for the project

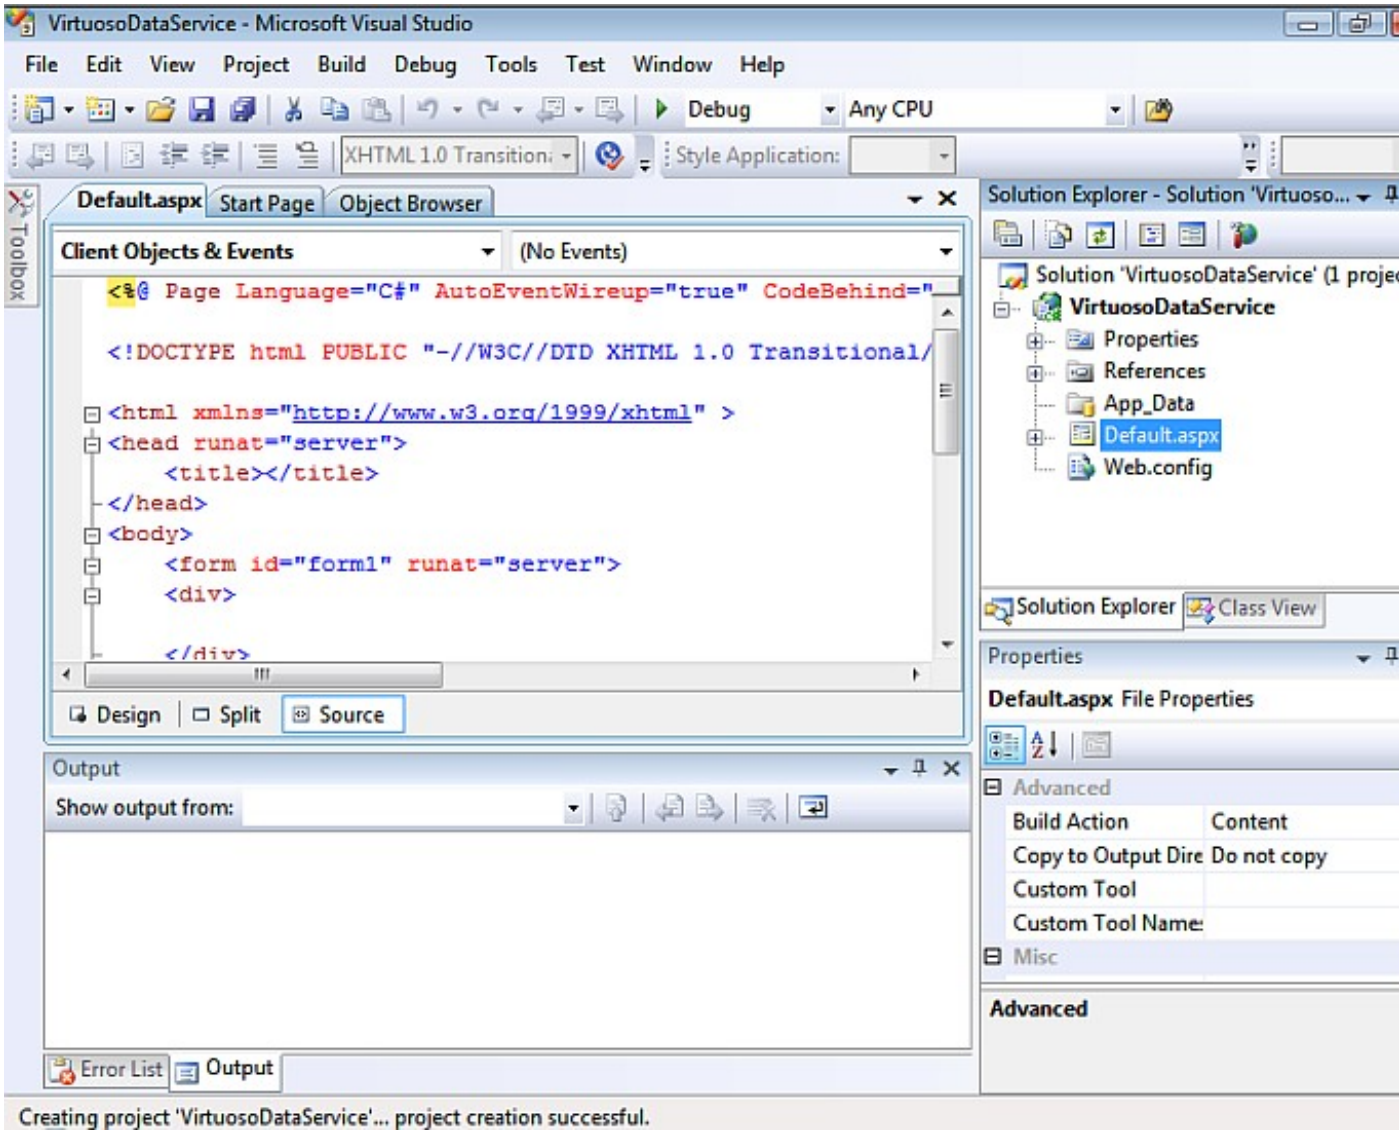


6. This will create a new project called

   VirtuosoDataService

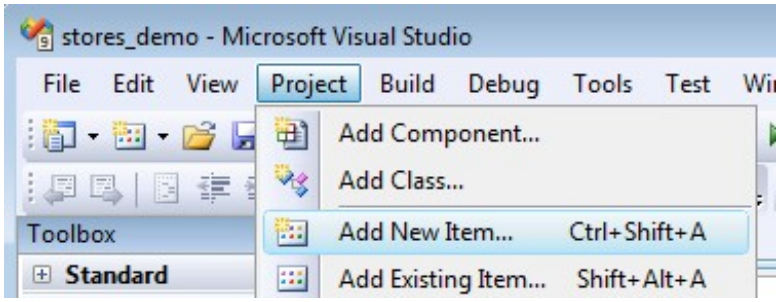
   .

Figure 8.508. create a new project



7. Select the Project -> Add New Item menu option.

Figure 8.509. VirtuosoDataService



8. The

Add New Item

dialog will appear. Choose the

ADO.NET Entity Data Model

template. Give it the name

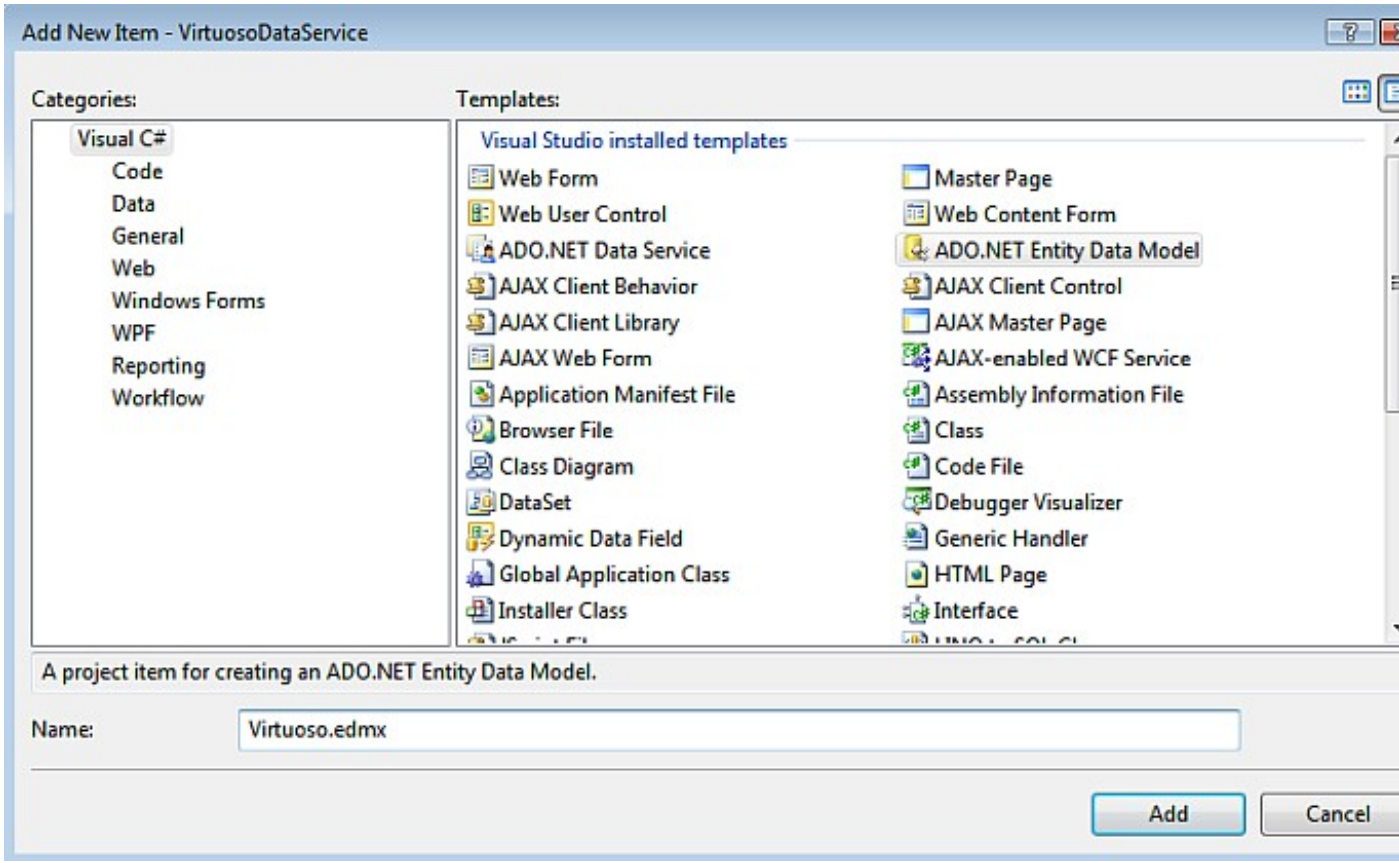
Virtuoso.edmx

and click

Add

to start the creation of the ADO.Net Entity Data Model.

Figure 8.510. Add New Item



9. In the

Entity Data Model Wizard

dialog

Choose Model Contents

page select the

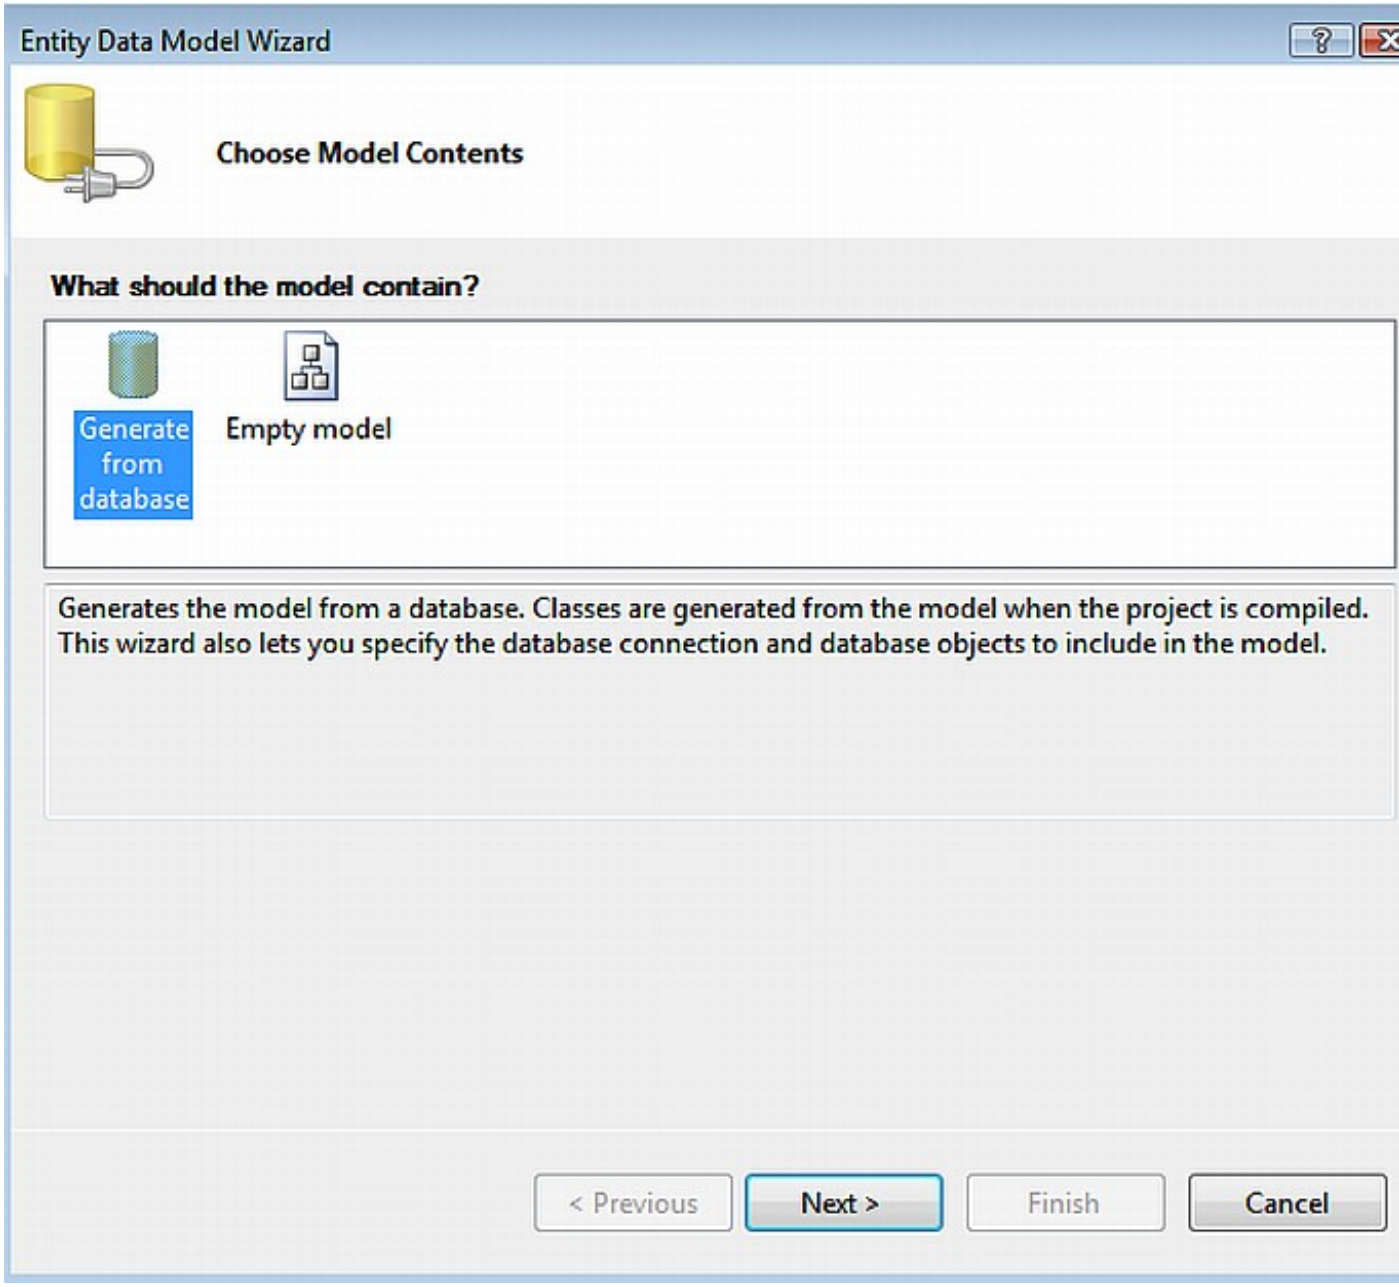
Generate from Database

model type and click

Next

.

Figure 8.511. Choose Model Contents



10. In the

    Entity Data Model Wizard

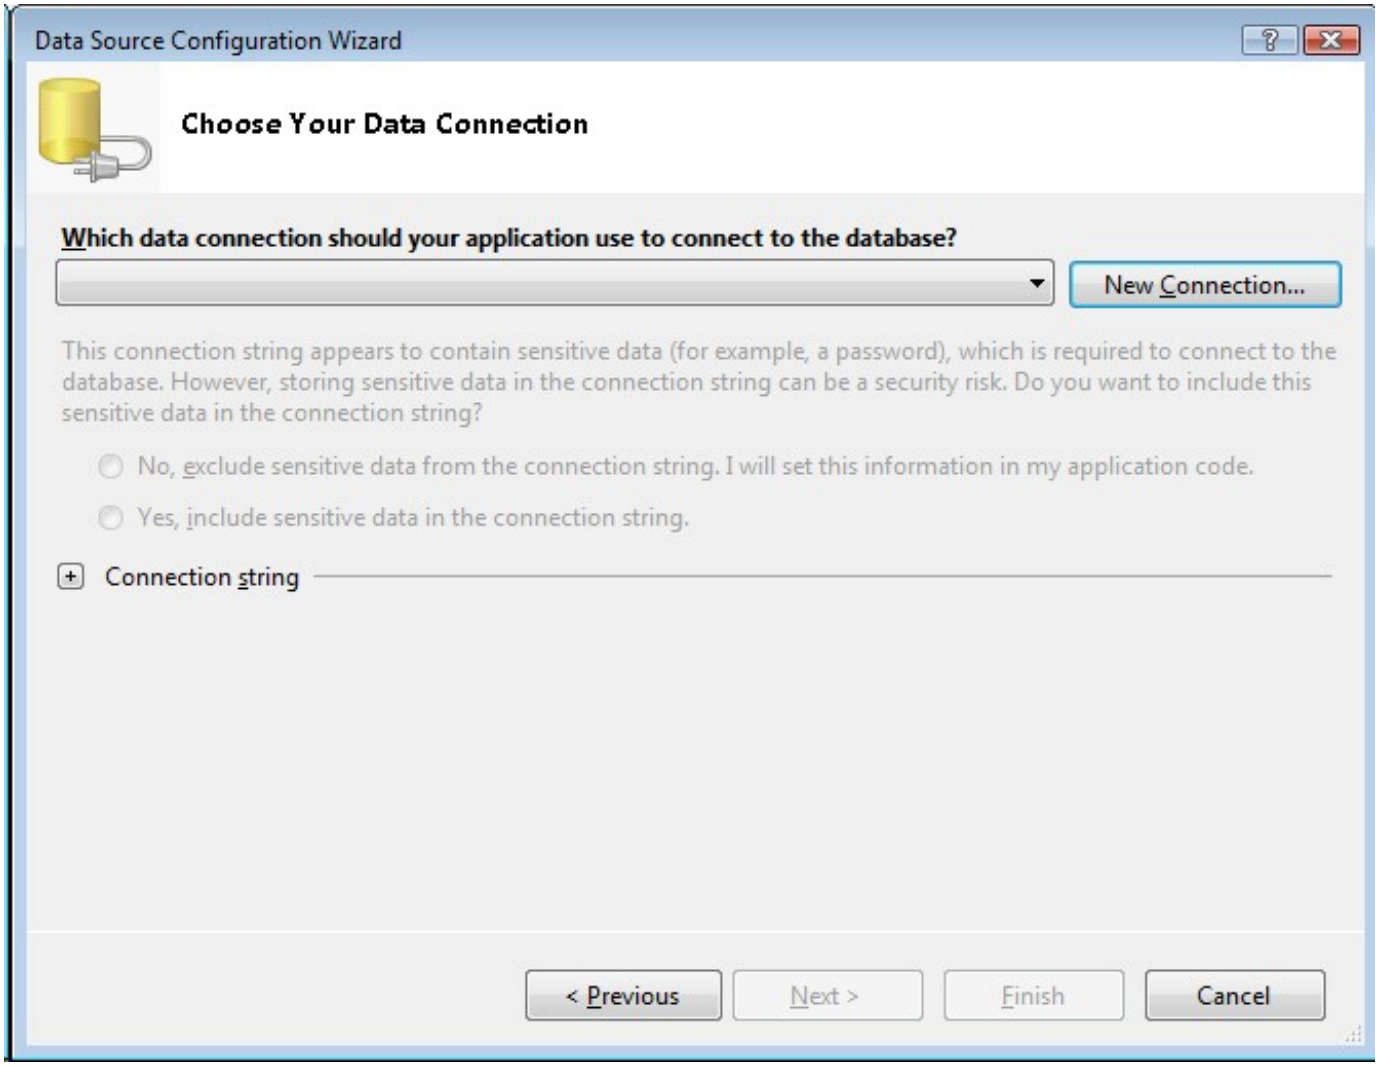
    dialog

    Choose your Data Connection

    page, select the

    New Connection button

Figure 8.512. Entity Data Model Wizard



11. In the

    dialog, select the OpenLink

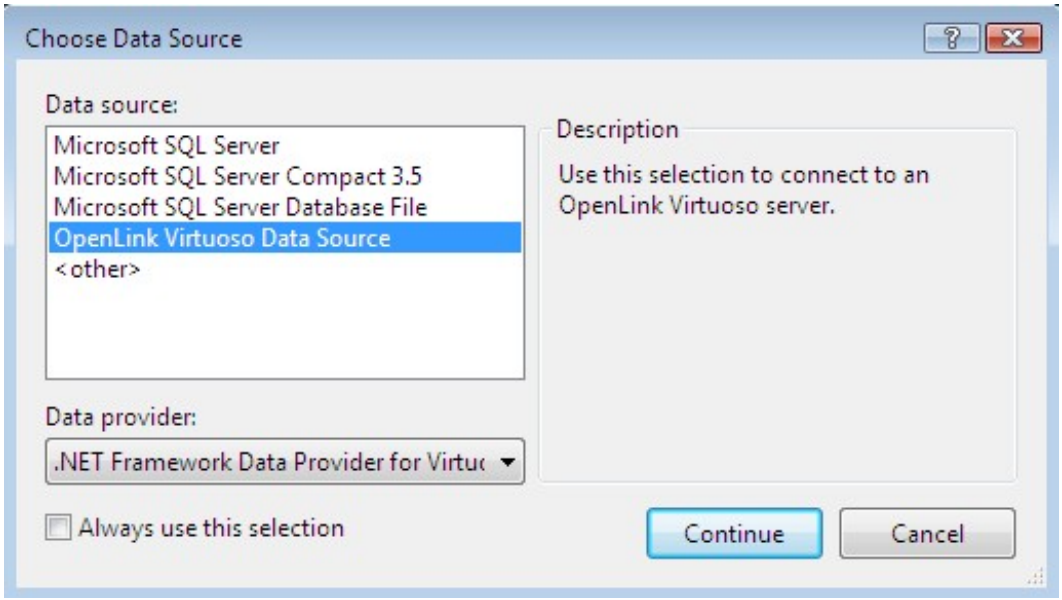
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.513. Choose Data Source



12. In the

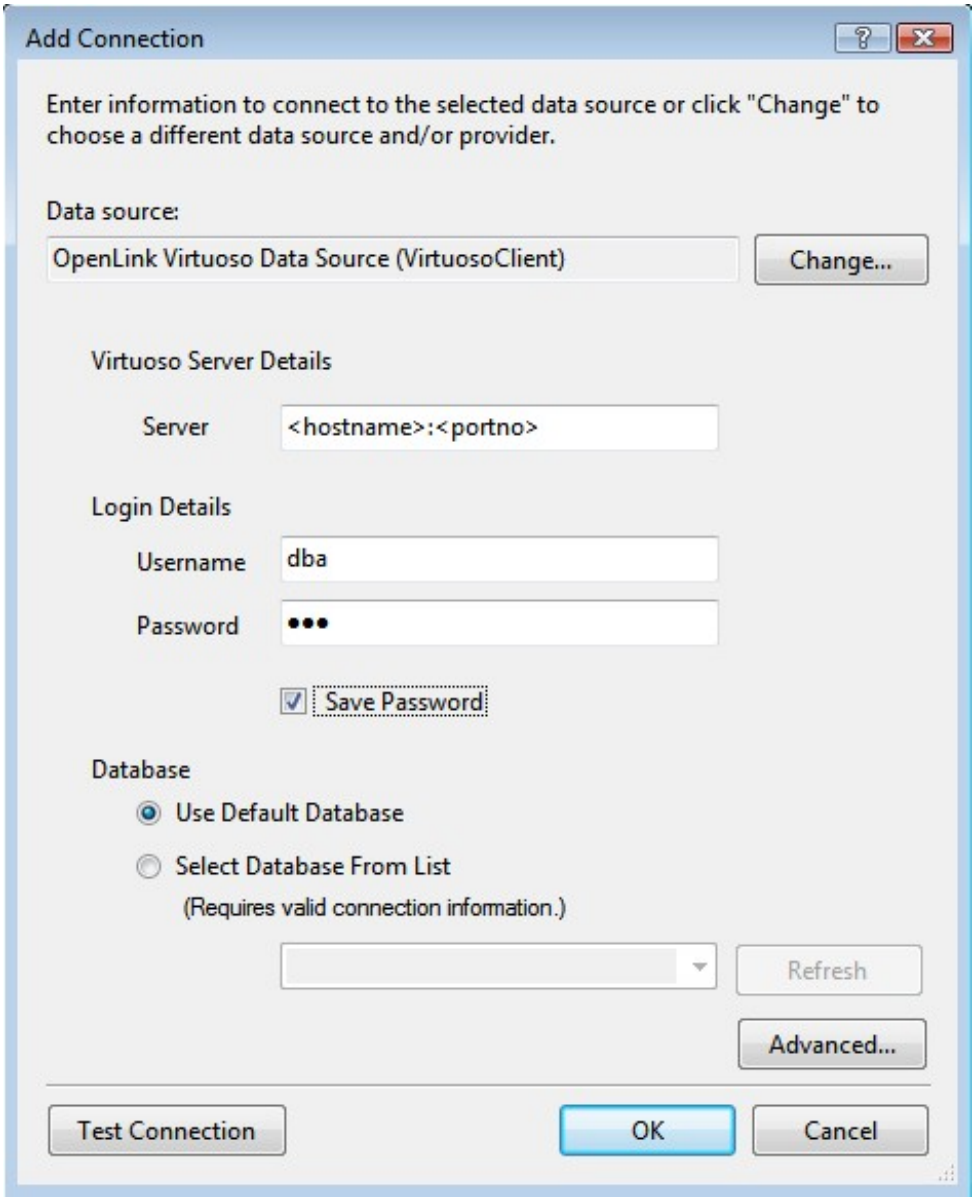
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.514. Connection Properties



13. Select the

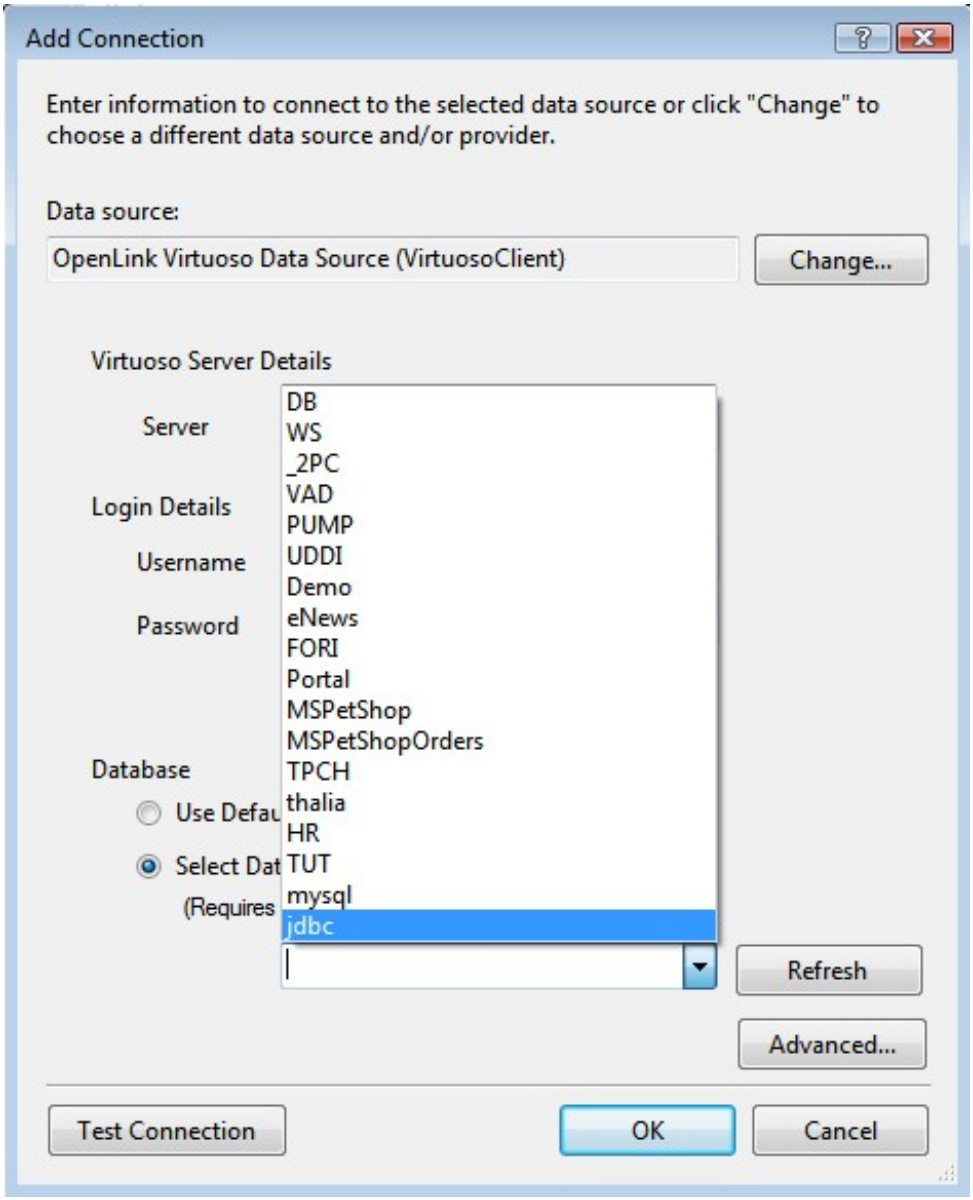
    Select Database From List

    radio button and choose the

    JDBC

    database from the drop down list.

Figure 8.515. Add connection

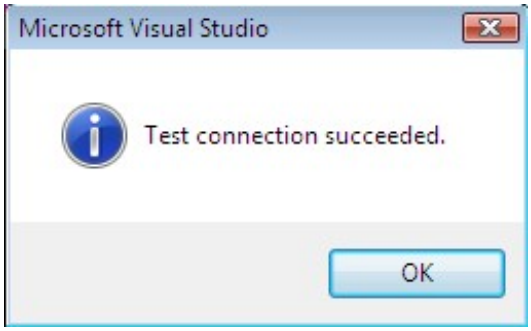


14. Press the

    Test Connection

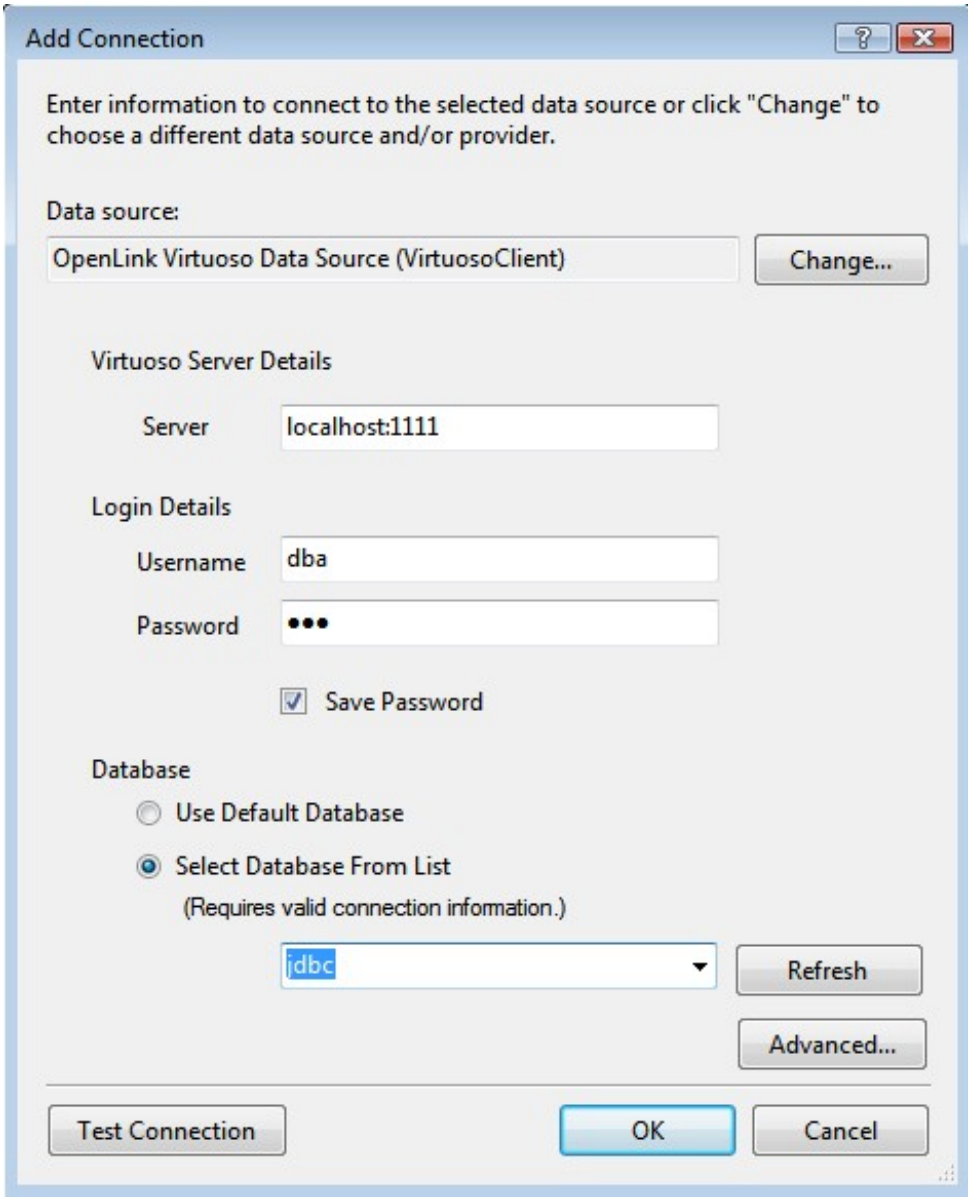
    dialog to verify that the database is accessible.

    Figure 8.516. Test Connection



15. Click OK to add the connection.

    Figure 8.517. Test Connection



16. Set the

    entity connect string

    name to

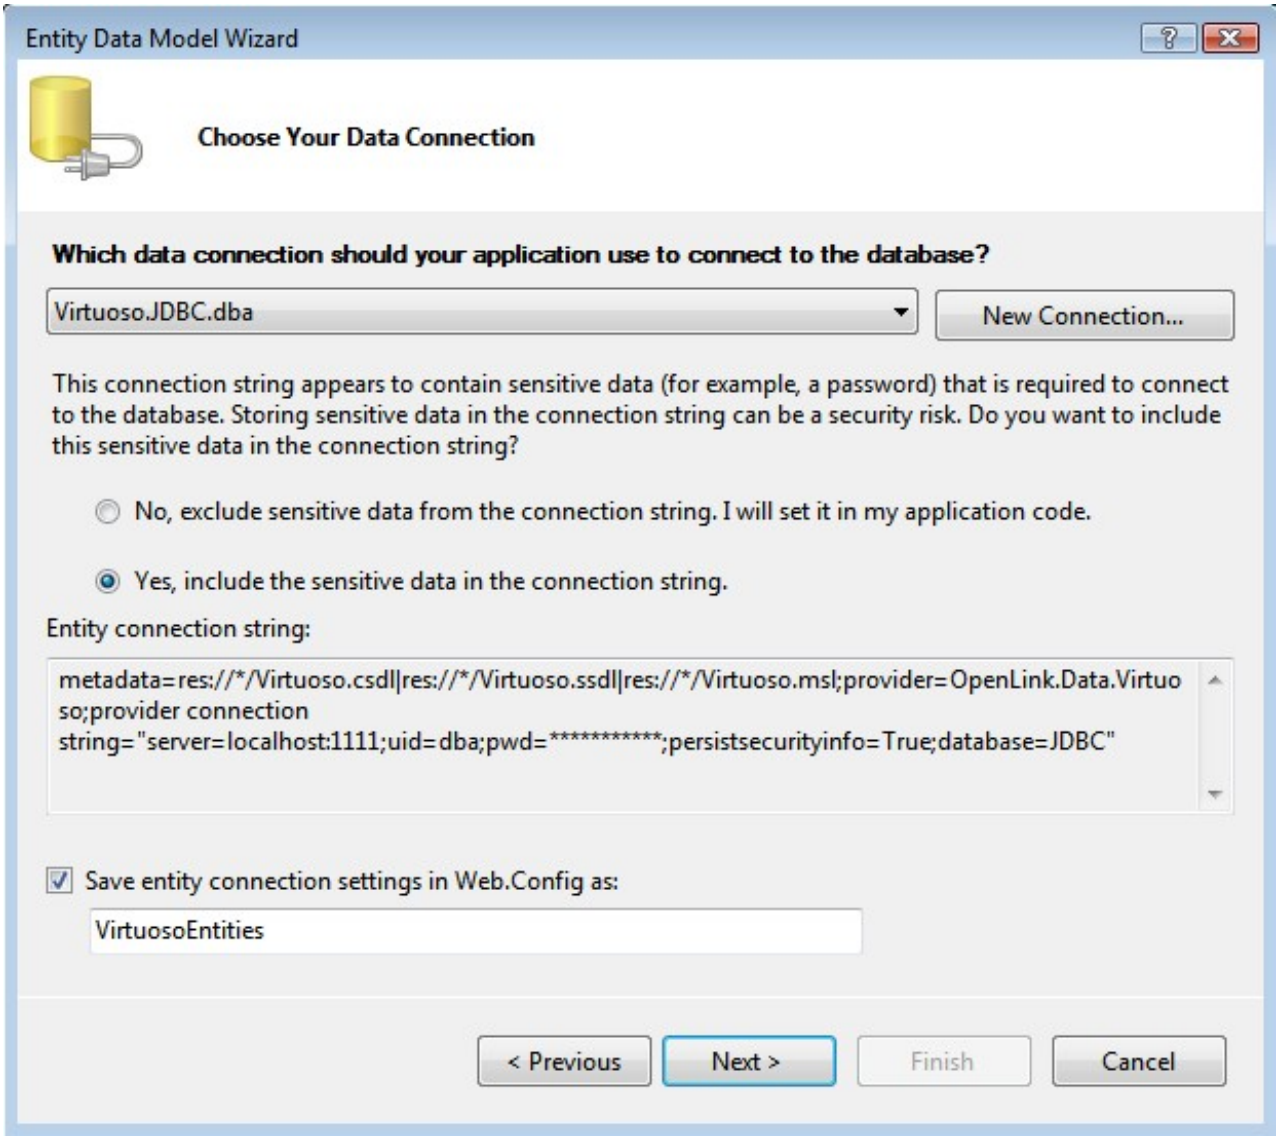
    VirtuosoEntities

    (note this name as it is required in the section on creating and ADO.Net Data Service) and click

    Next

    .

    Figure 8.518. entity connect string



17. In the

    Choose your Database Objects

    page select the

    Tables

    check box to select all tables in the JDBC catalog for addition to the Entity Data Model. Set the

    Model Namespace

    to

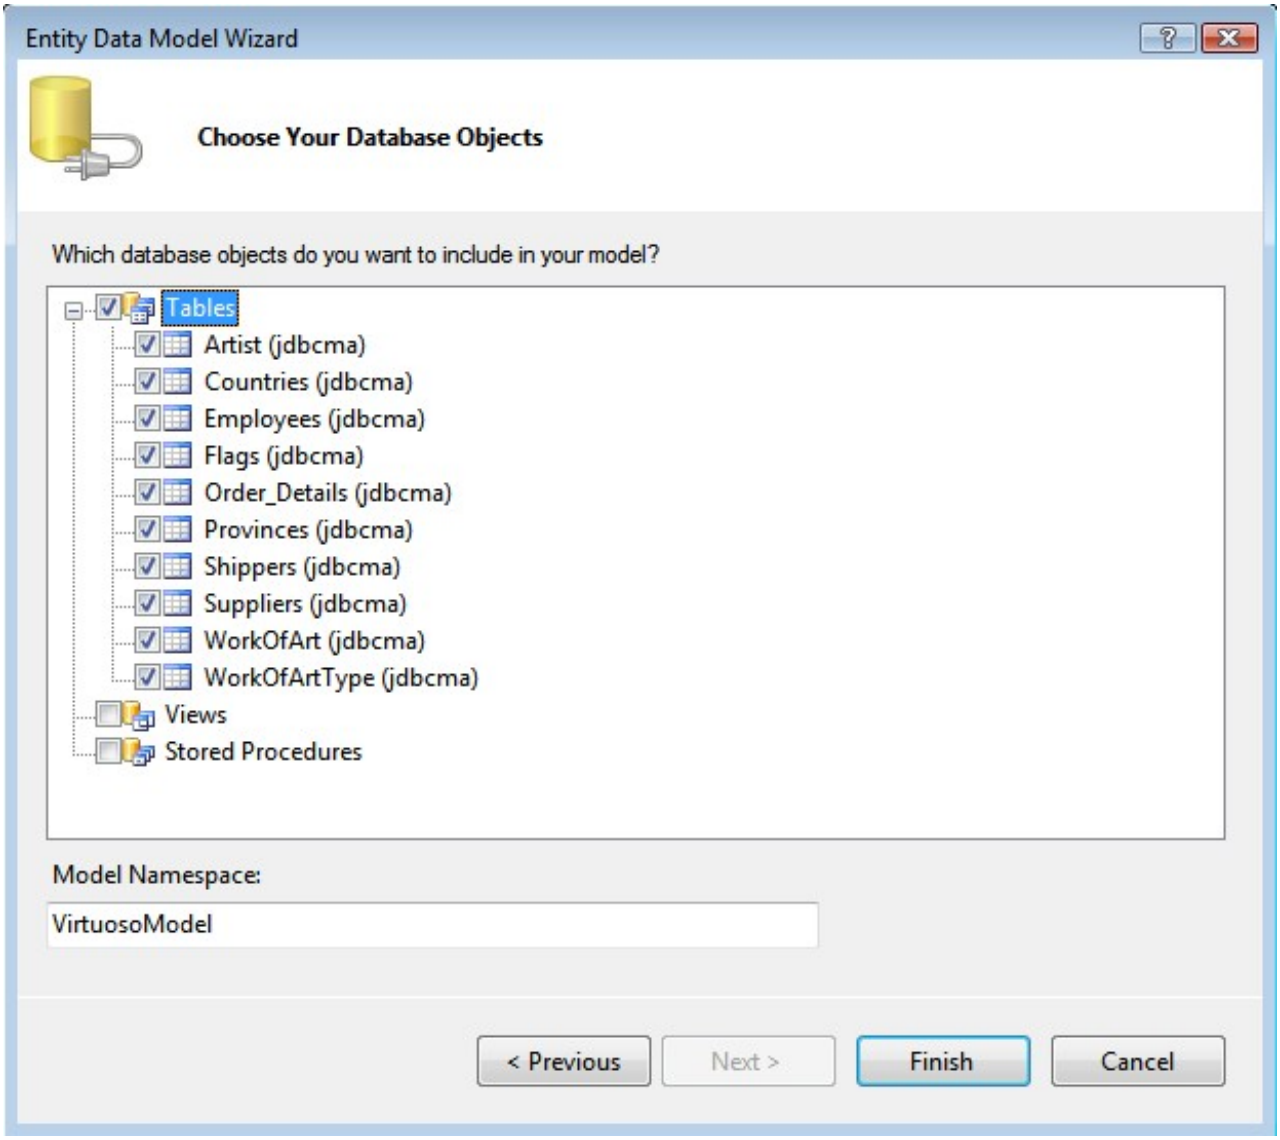
    VirtuosoModel

    and click

    Finish

    .

Figure 8.519. Database Objects

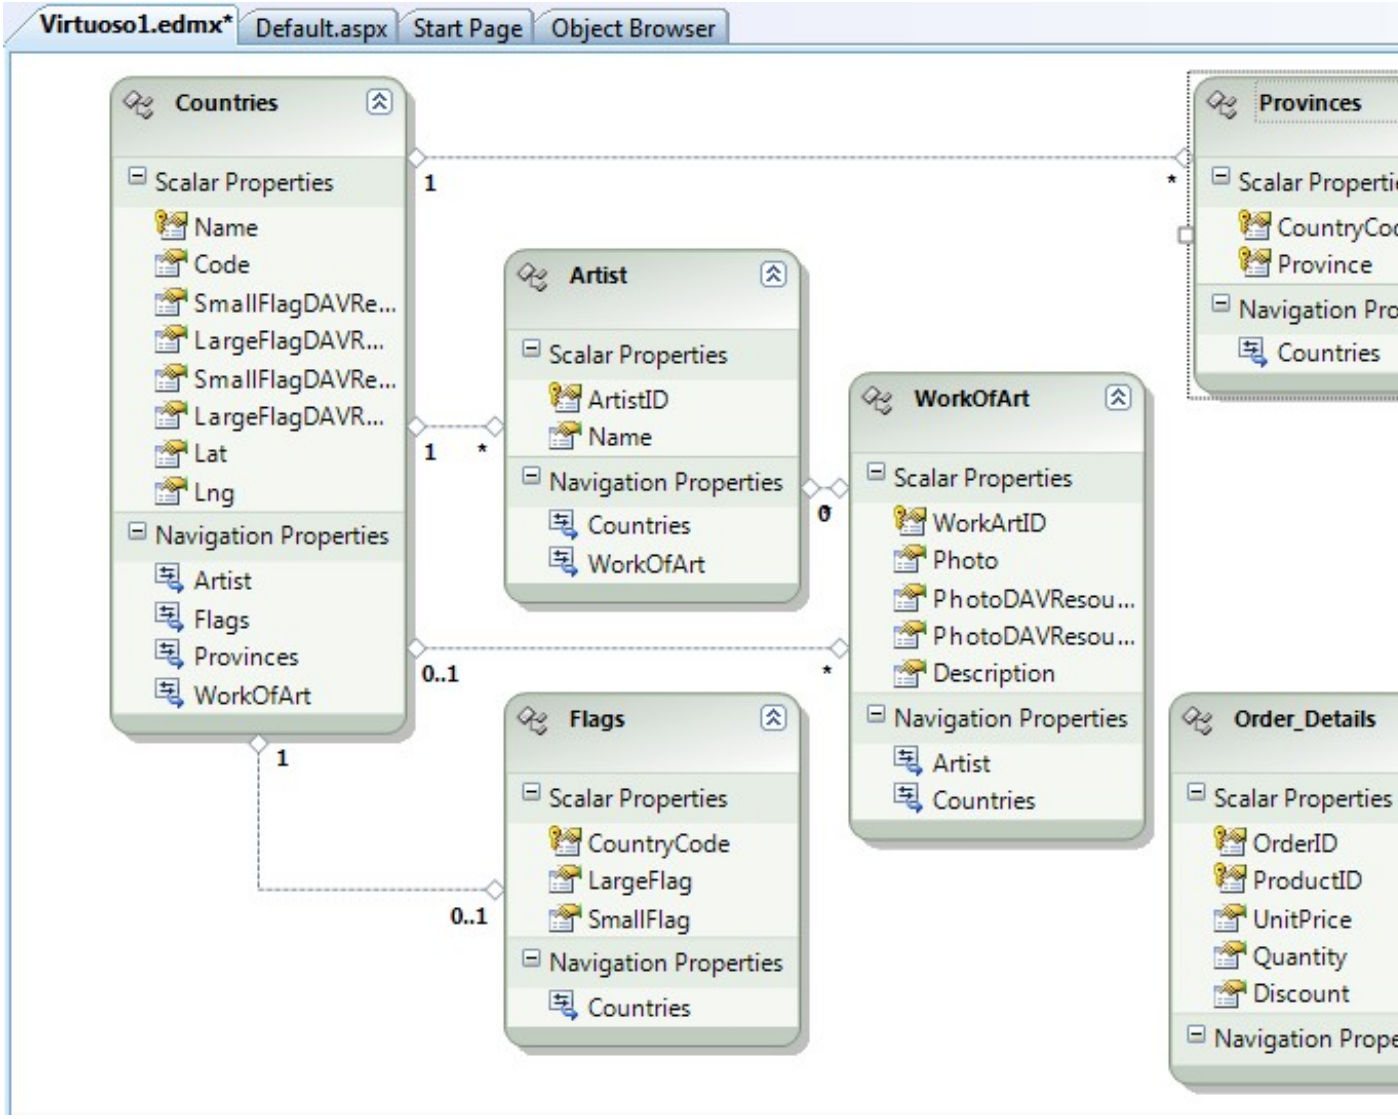


18. The

    Virtuoso.edmx

    EDM will be created with the tables and relationships displayed in the Visual Studio IDE

    Figure 8.520. Virtuoso.edmx



Creation for the Entity Data Model for the ODBC to JDBC Bridge Northwind database is now complete.

8.10.5. Using EDM to create Entity Framework based applications

Now that a Microsoft Entity Data Model has been created for the Northwind database, Entity Framework applications can be created to make use of it.

Entity Frameworks based ADO.NET Data Service

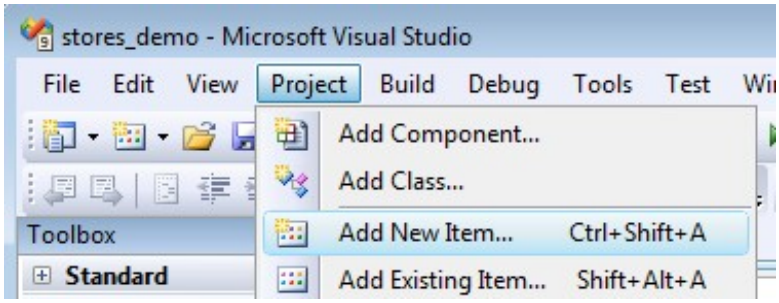
An ADO.Net Data Service for the ODBC to JDBC Bridge tables can be created using the Entity Data Model created in the Creating EDM in Visual Studio 2008 section .

1. Open the

   VirtuosoDataService

   project created in the Creating EDM in Visual Studio 2008 section .
2. Select the Project -> Add New Item menu option.

Figure 8.521. VirtuosoDataService



3. The

   Add New Item

   dialog will appear. Choose the

   ADO.NET Data Service template

   . Give it the name

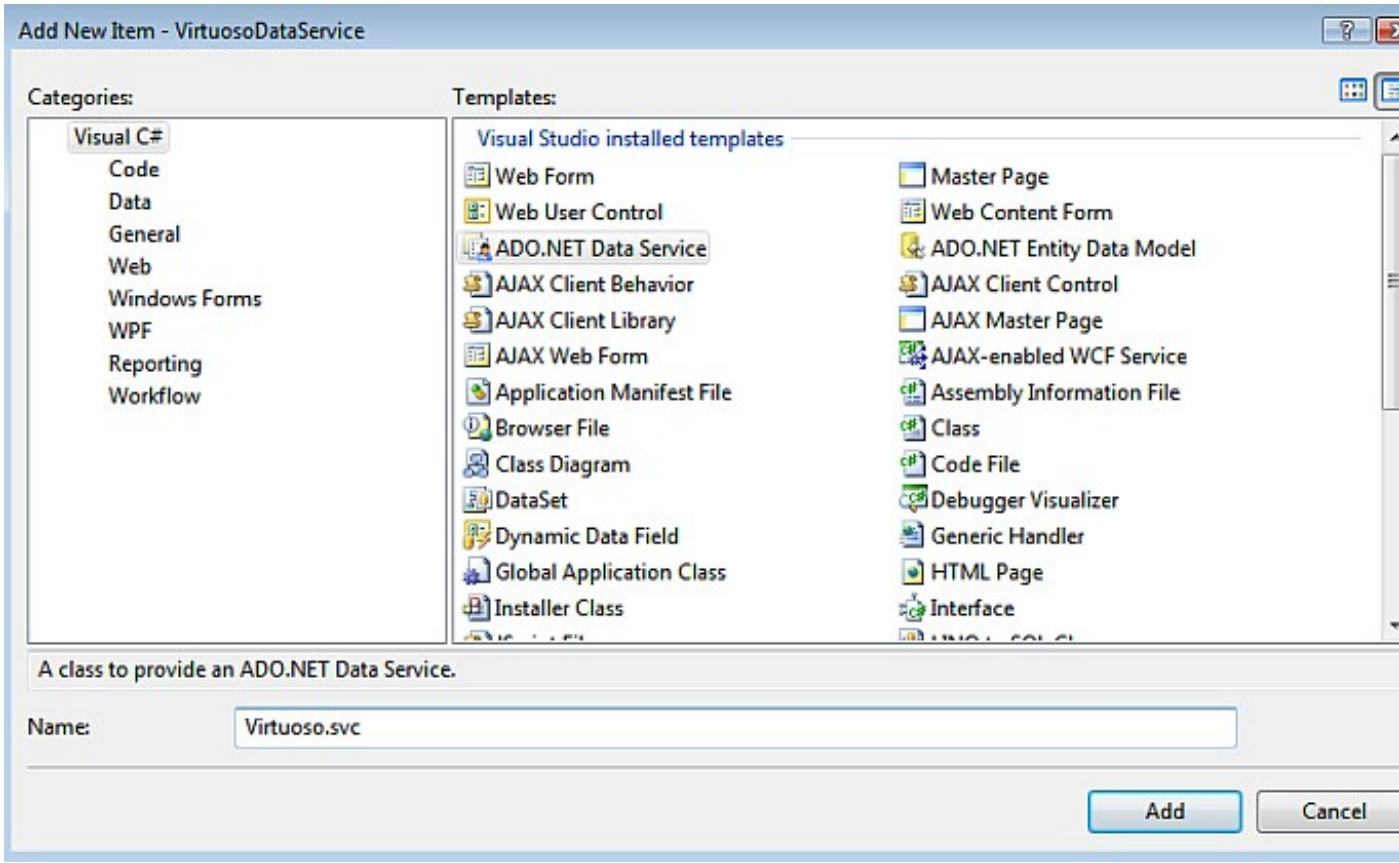
   Virtuoso.svc

   , and click

   Add

   to create the ADO.Net Data Service.

   Figure 8.522. Add New Item



4. In the newly created

   Virtuoso.svc.cs

Data Service file, add the data source class name of

VirtuosoEntities

(note this is the name set in the Creating EDM in Visual Studio 2008 section) as the

DataService

name. Enable the access to the Data Service by adding the entry

config.SetEntitySetAccessRule("", EntitySetRights.All);*

in the

InitializeService

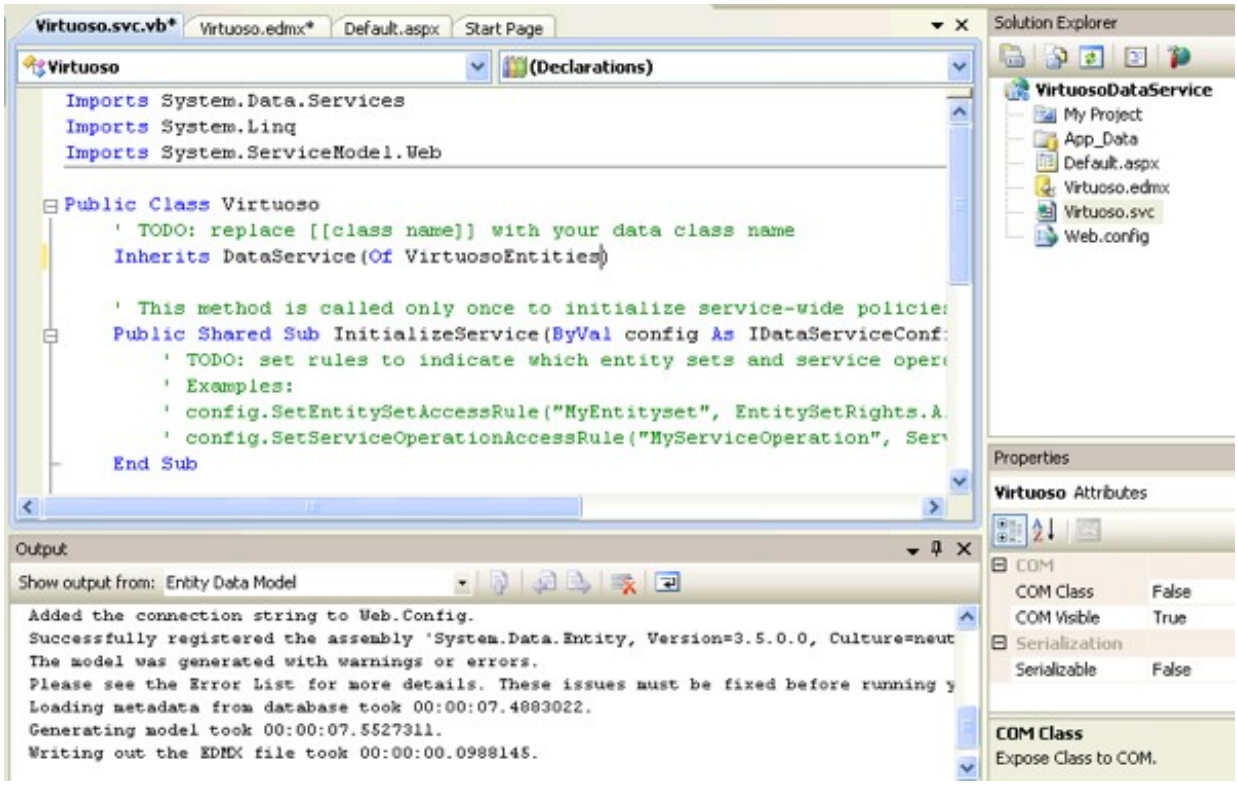
method.

```
// C#

using System;
using System.Web;
using System.Collections.Generic;
using System.ServiceModel.Web;
using System.Linq;
using System.Data.Services;

namespace SimpleDataService
{
    public class Northwind: DataService<VirtuosoDemoEntities>
    {
        public static void InitializeService(IDataServiceConfiguration  config)
        {
            config.SetEntitySetAccessRule("*", EntitySetRights.All);
        }
    }
}
```

Figure 8.523. Virtuoso.svc.cs

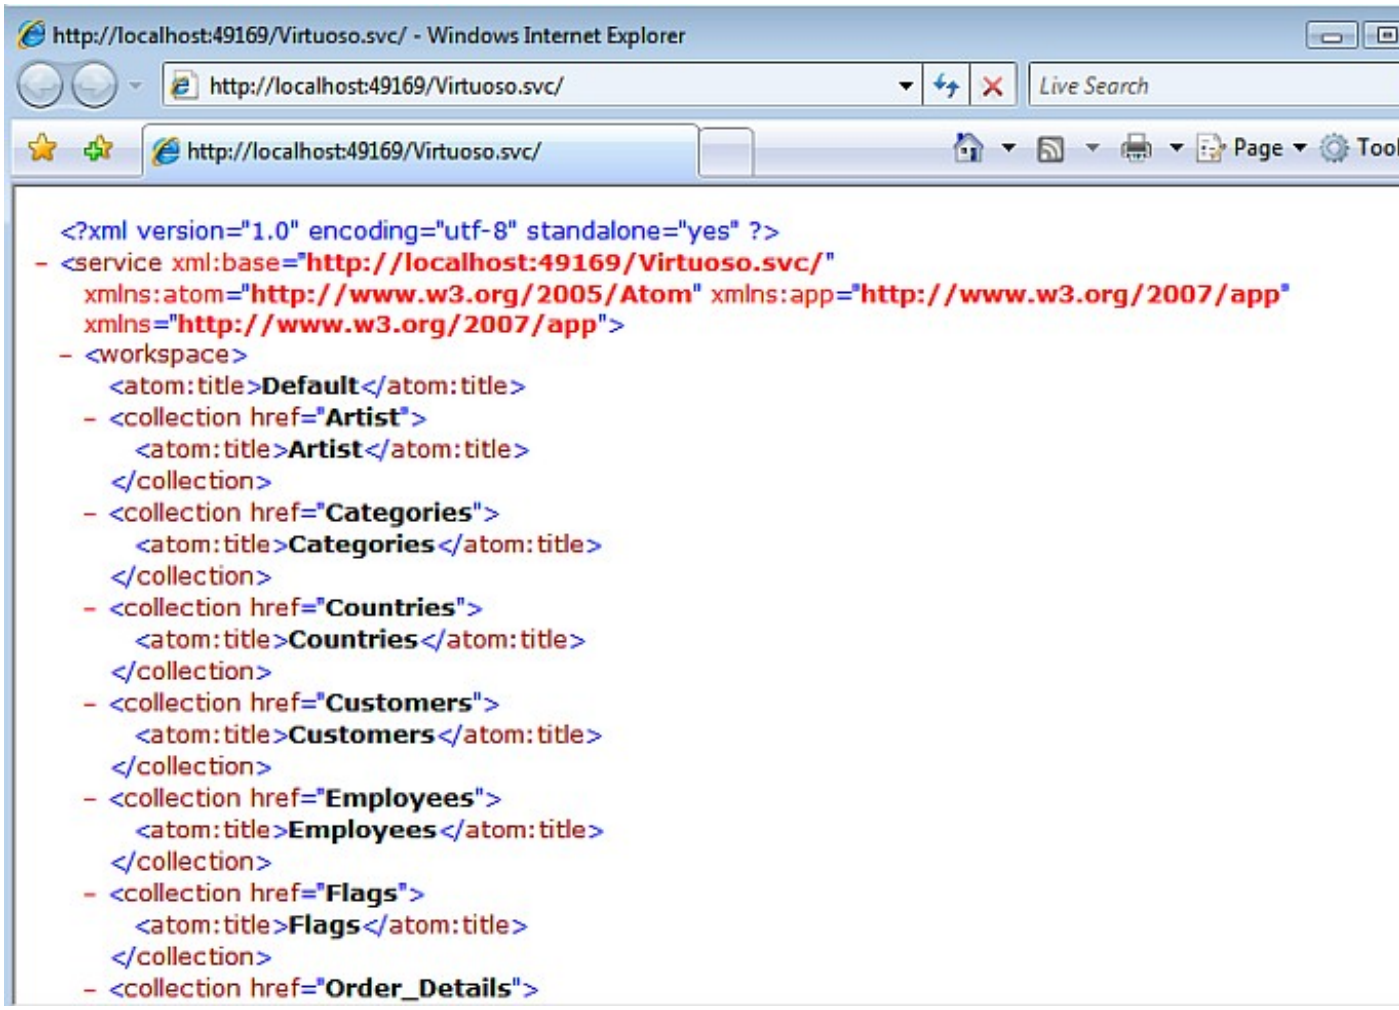


5. To test the Data Service, simply hit

   Ctrl+F5

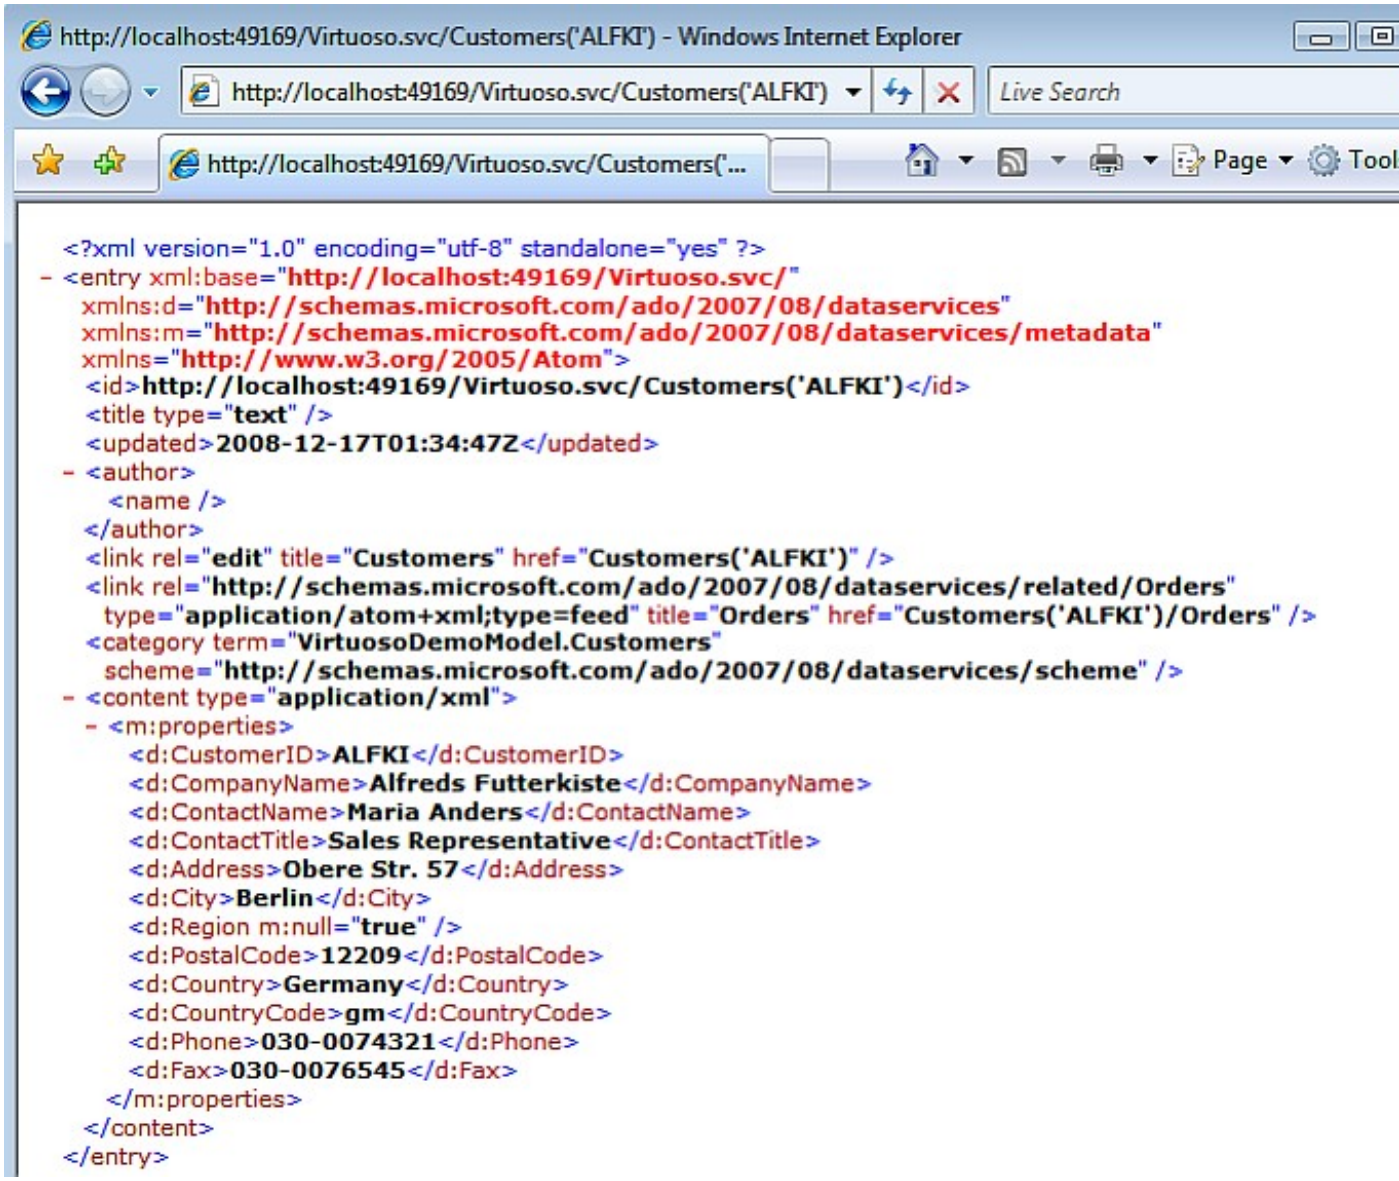
   within Visual Studio. This will start the development web server, run the Data Services server inside and load a Web browser page displaying the list of available tables/entities for the Northwind Demo database catalog.

   Figure 8.524. Data Service test



6. To access a specific entity instance like the Customers table ALFKI record, use this convention http://host/vdir/Virtuoso.svc/Customers('ALFKI') .

   Figure 8.525. Customers



Notes:

1. *Important*

   - To view

   Atom

   (the default format returned by an ADO.NET Data Service) in Internet Explorer, you must first ensure that

   Feed Reading View

   is turned

   off

   . This can be done on the

   Content tab

   of

Tools in Internet Options

.

2. If a Data Services entity instance URI page fails to load you can turn

   Verbose

   errors on by adding

   config.UseVerboseErrors = true;

   in the

   virtuoso.svc.cs InitializeService

   method to obtain more detailed information from the server as to why the page failed to load:

```
public static void InitializeService(IDataServiceConfiguration config)
{
config.UseVerboseErrors = true;
config.SetEntitySetAccessRule("*", EntitySetRights.All);
}
```

Visual Studio Windows DataGrid Form Application

This section details the steps required to create a simple Visual Studio 2008 Windows Form application, with associated DataGridView control for displaying data in selected tables from the target database.

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.526. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

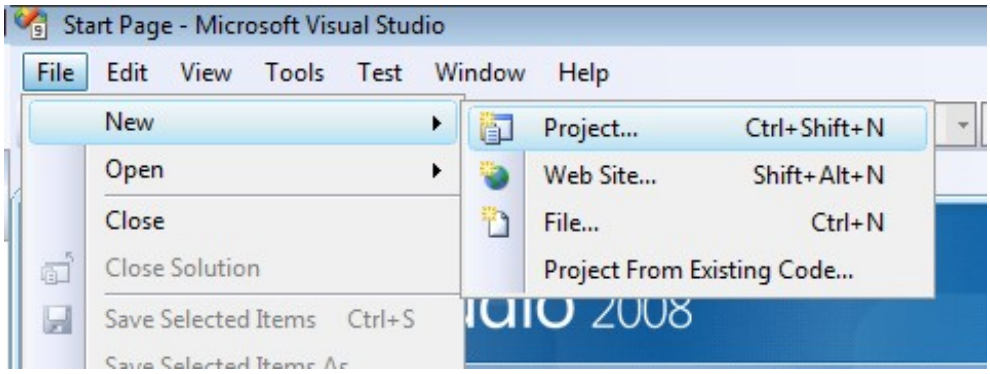
   File

   menu in Visual Studio and choosing

New Project

.

Figure 8.527. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Windows

   and select

   Windows Form Application

   from the right-hand panel.
5. Choose a name for the project, for example

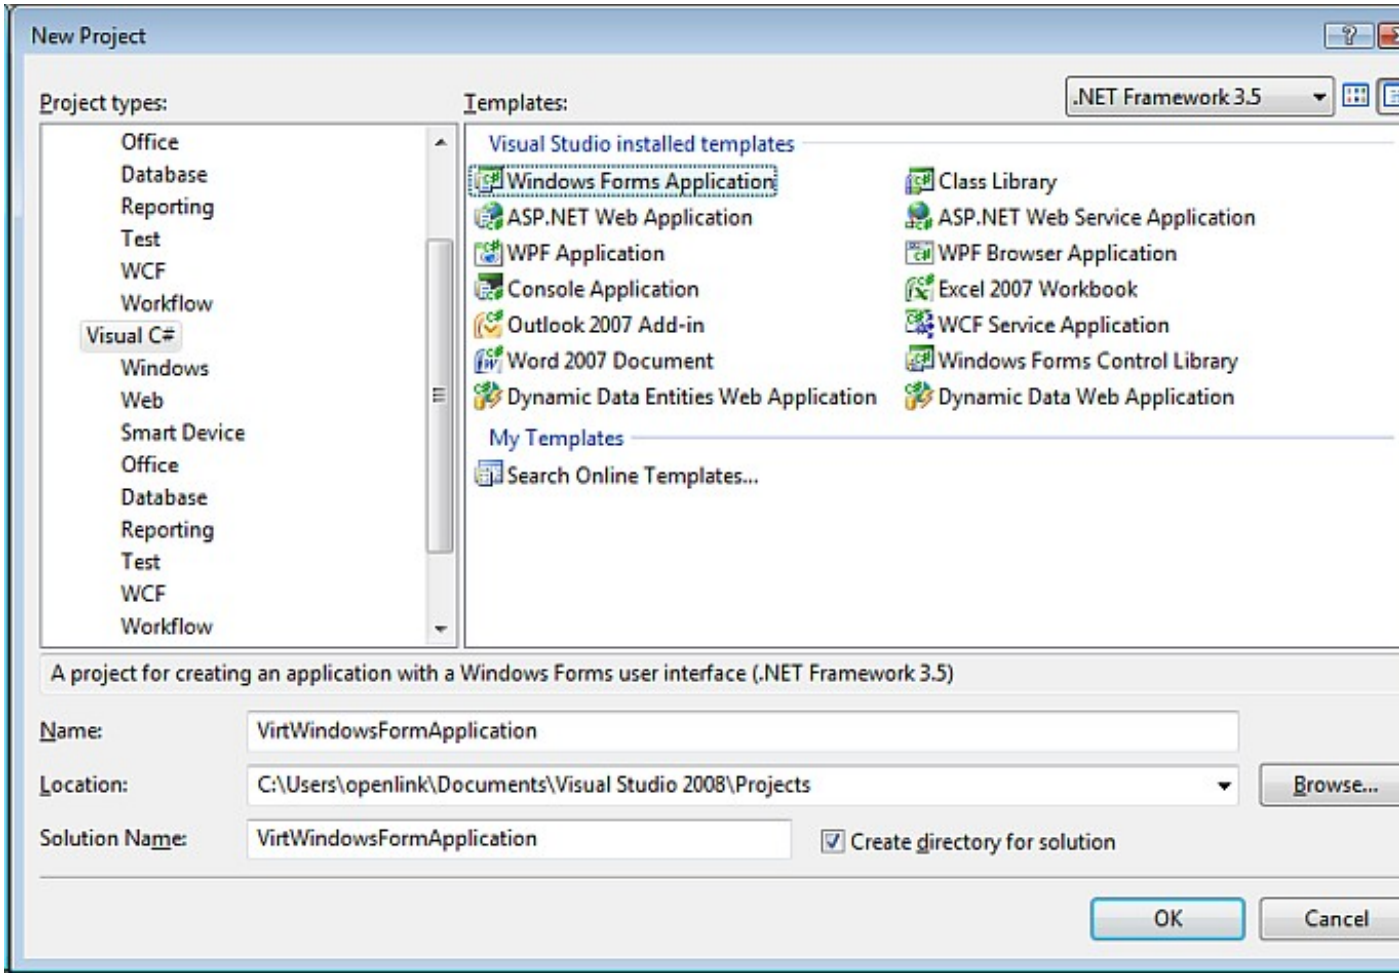
   VirtWindowsFormApplication

   , and click

   OK

   .

Figure 8.528. Web Application



6. In the

   Toolbox

   , expand

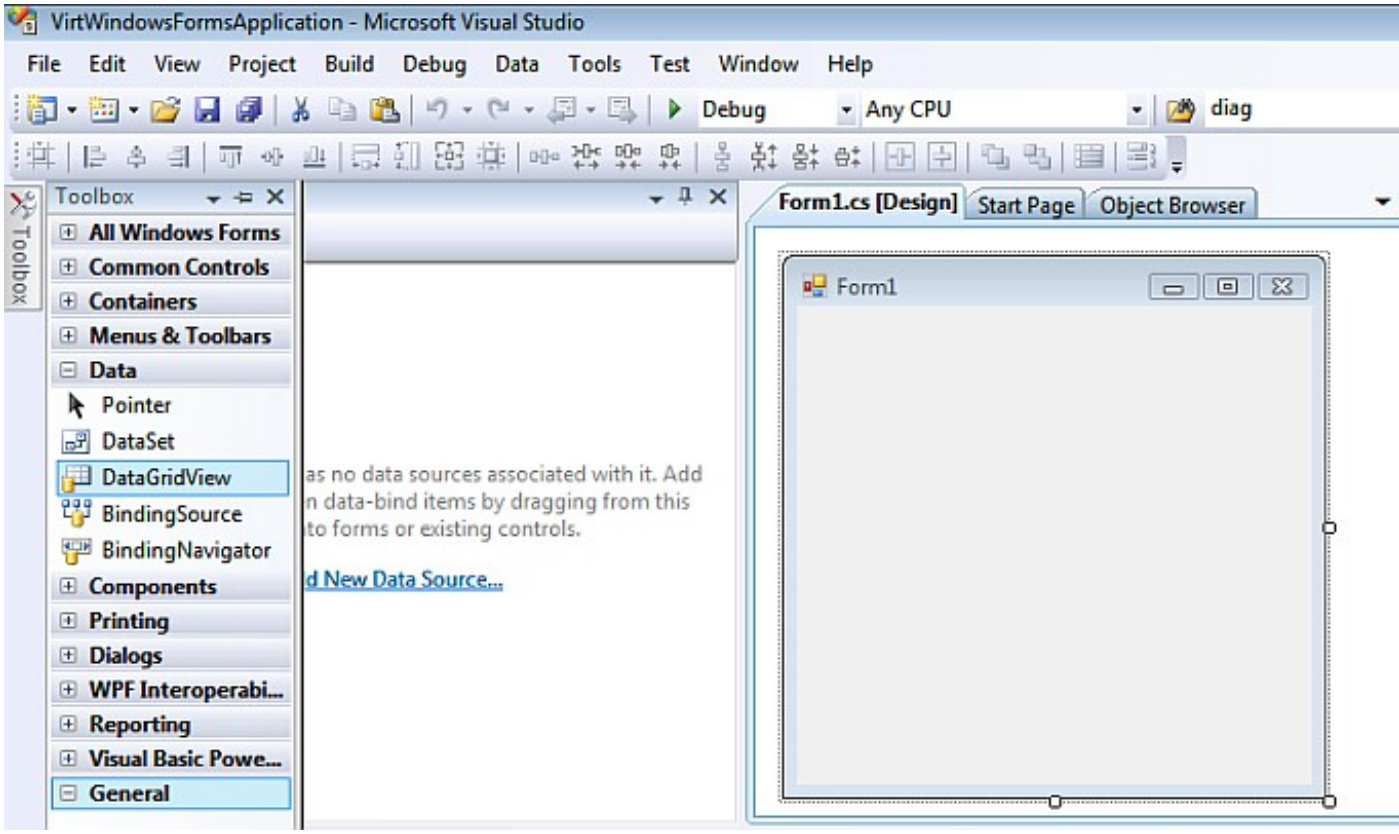
   Data Controls

   , and drag the

   DataGridView

   control onto the form.

   Figure 8.529. Toolbox



7. Click on the little

   arrow

   in the top right of the

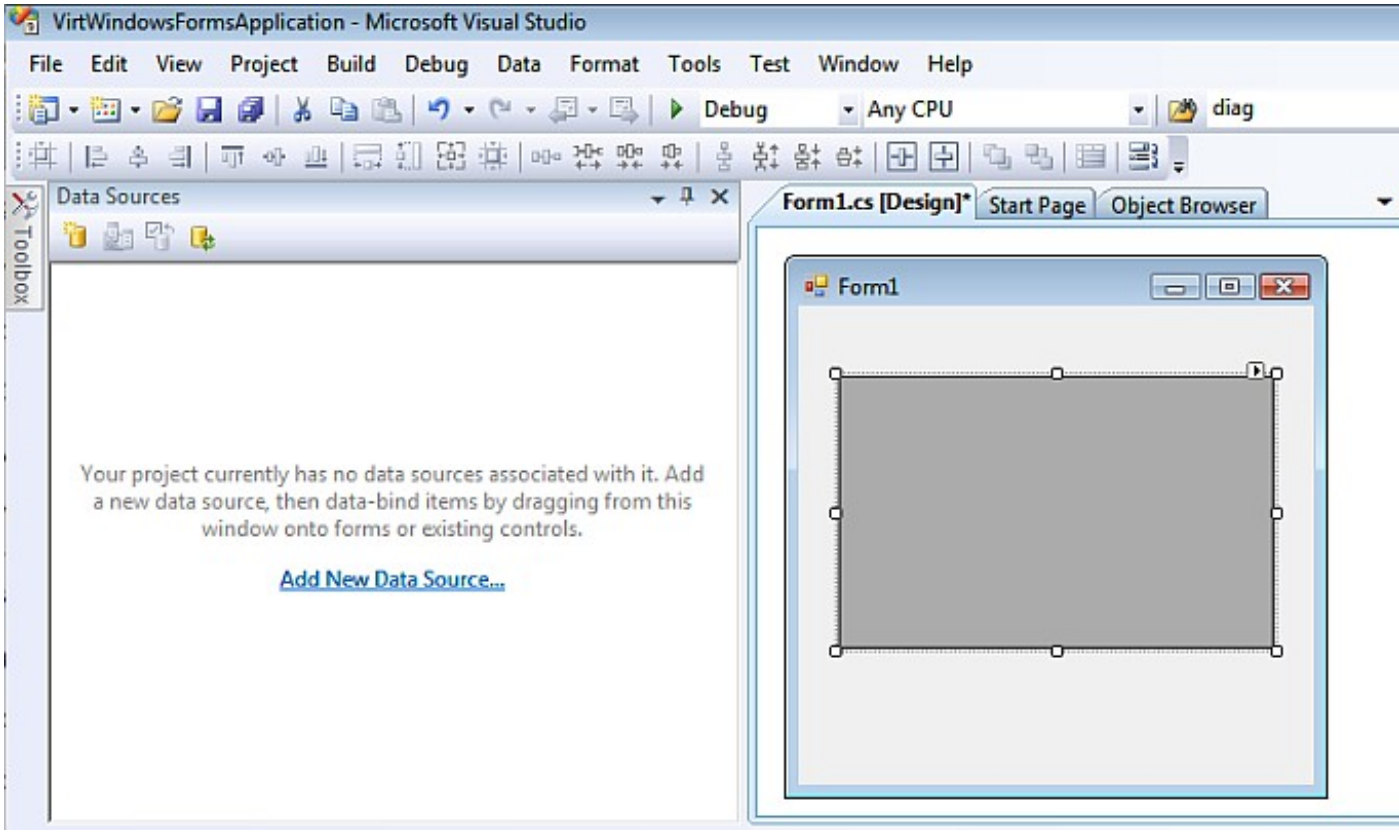
   DataGridView

   control. This loads the

   DataGridView Task

   menu.

Figure 8.530. DataGridView Task

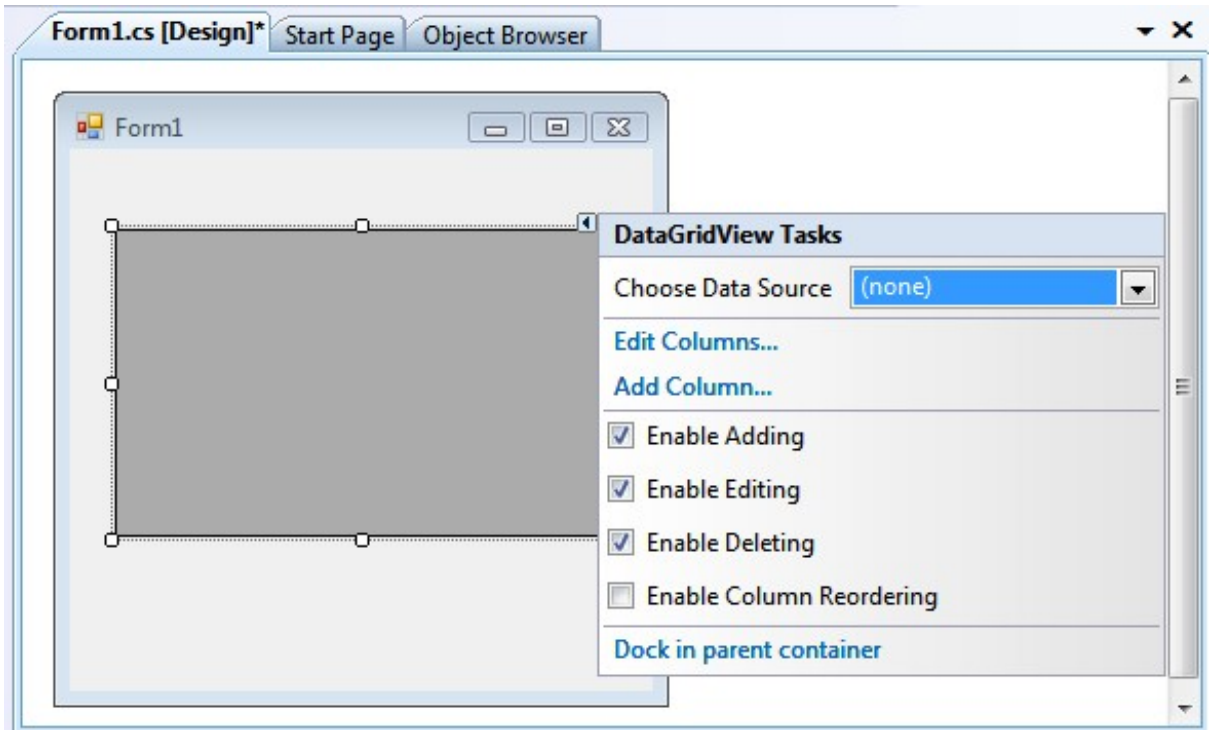


8. Click on the

   Choose Data Source

   list box.

   Figure 8.531. Choose Data Source

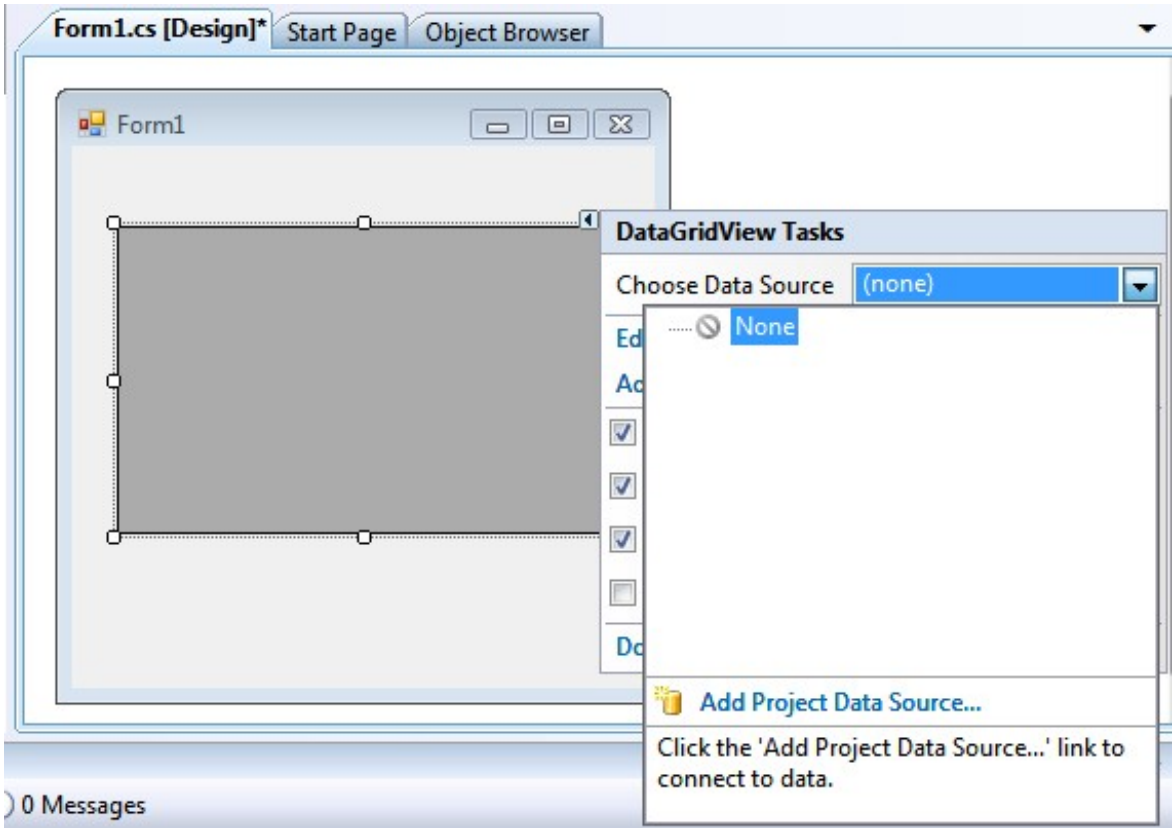


9. Click on the

   Add Project Data Source

link to connect to a data source.

Figure 8.532. Add Project Data Source



10. In the

    Data Source Configuration Wizard

    dialog

    Choose Data Source Type

    page select the

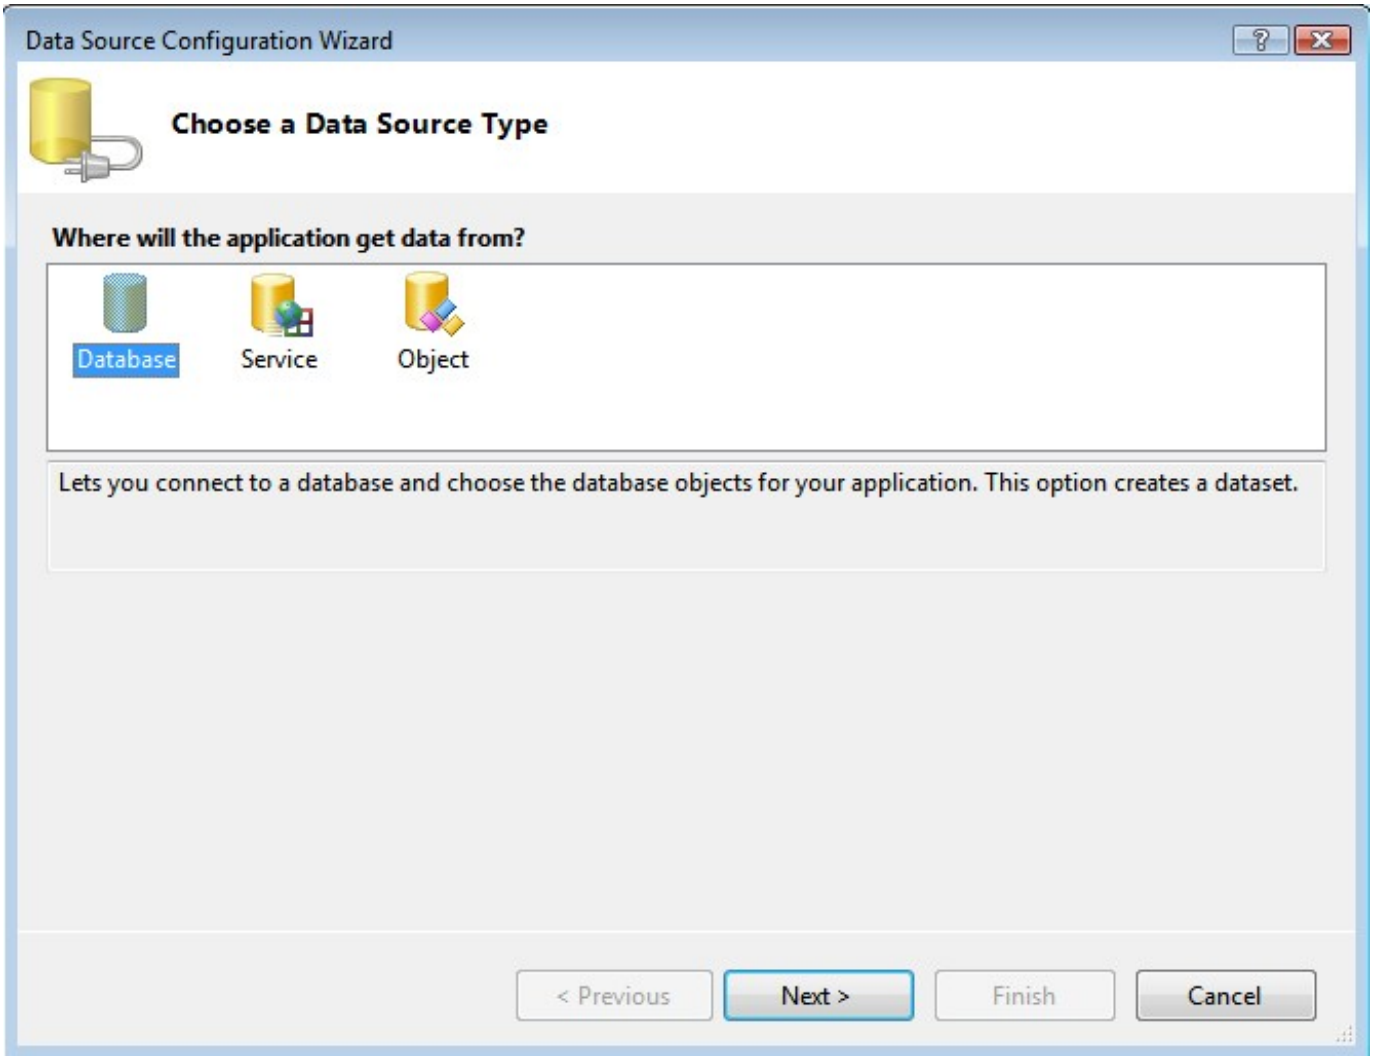
    Database

    data source type and click

    Next

    .

Figure 8.533. Data Source Type



11. In the

    Data Source Configuration Wizard

    dialog

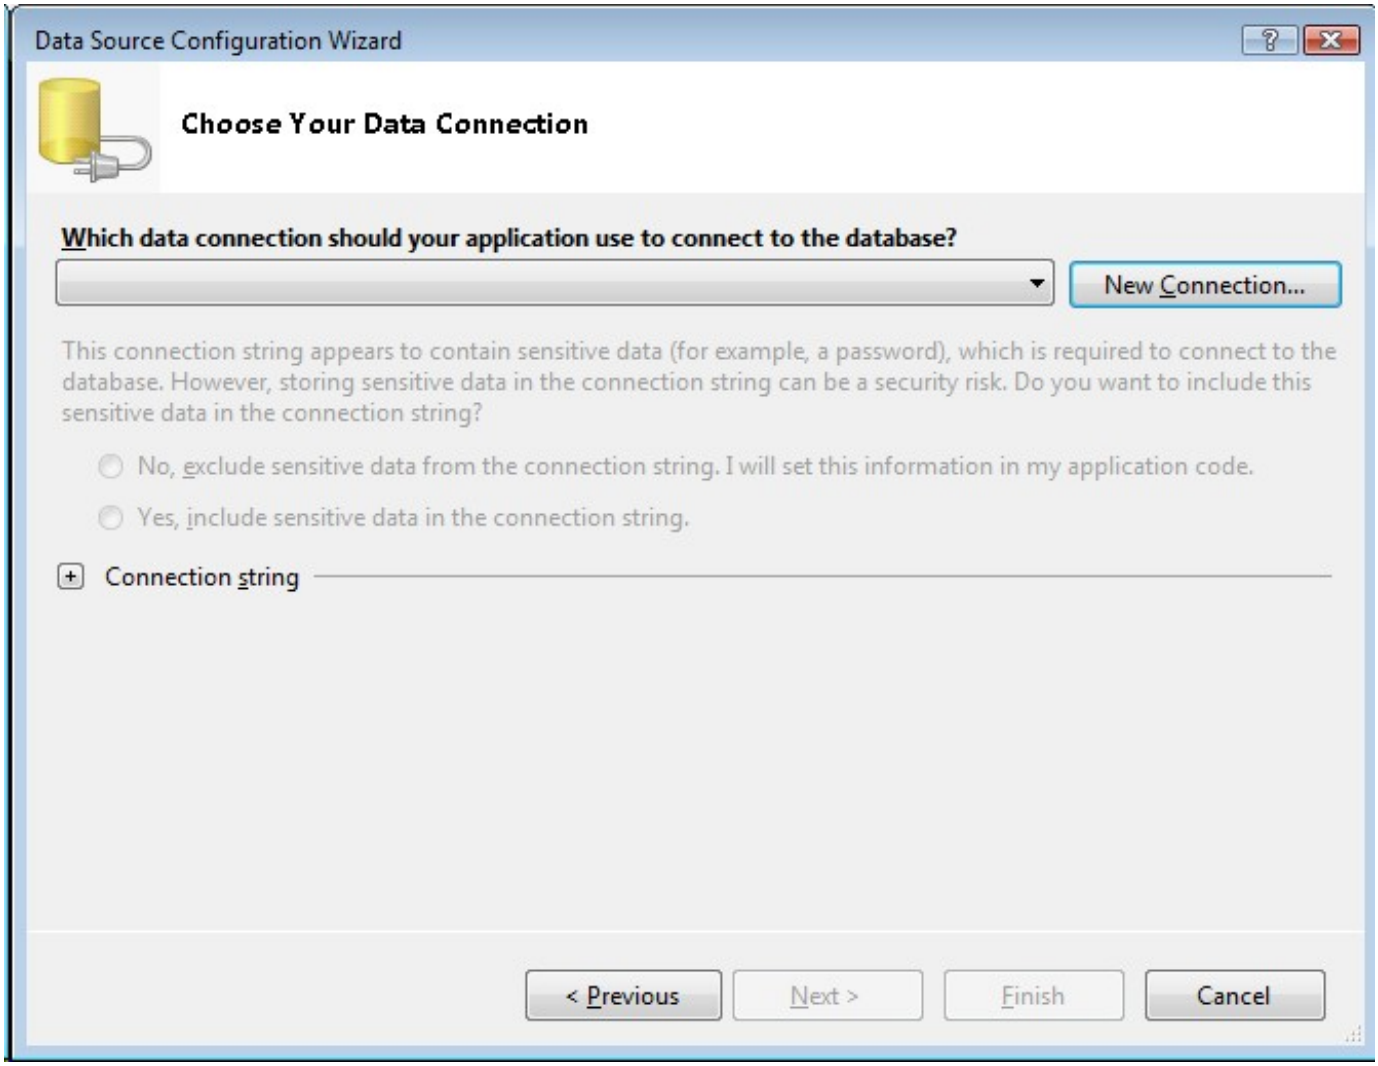
    Choose your Data Connection

    page, select the

    New Connection

    button

Figure 8.534. Data Source Configuration Wizard



12. In the

    Choose Data Source

    dialog, select the OpenLink

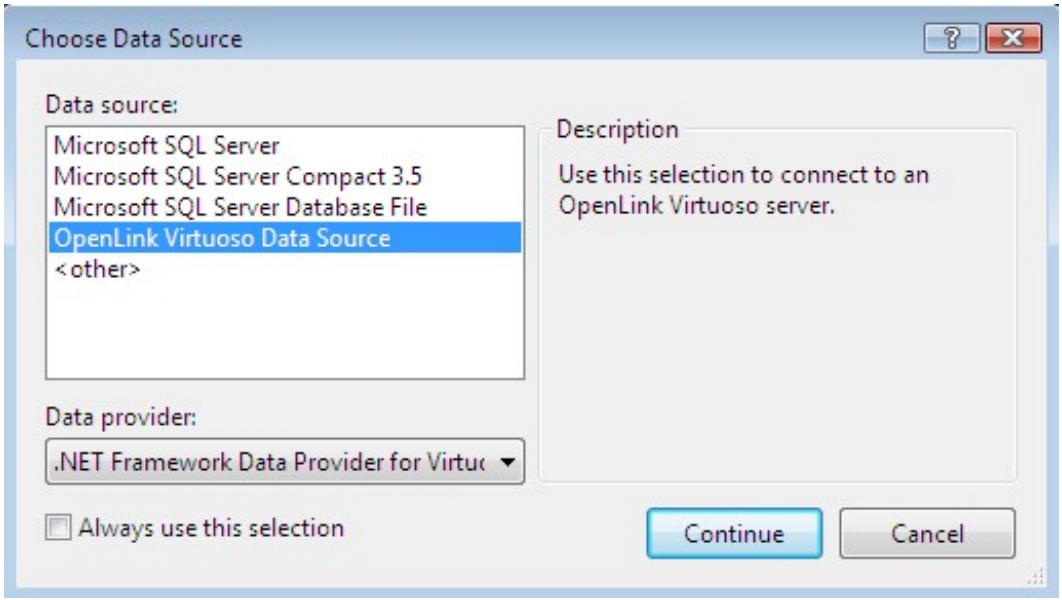
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.535. Data Source



13. In the

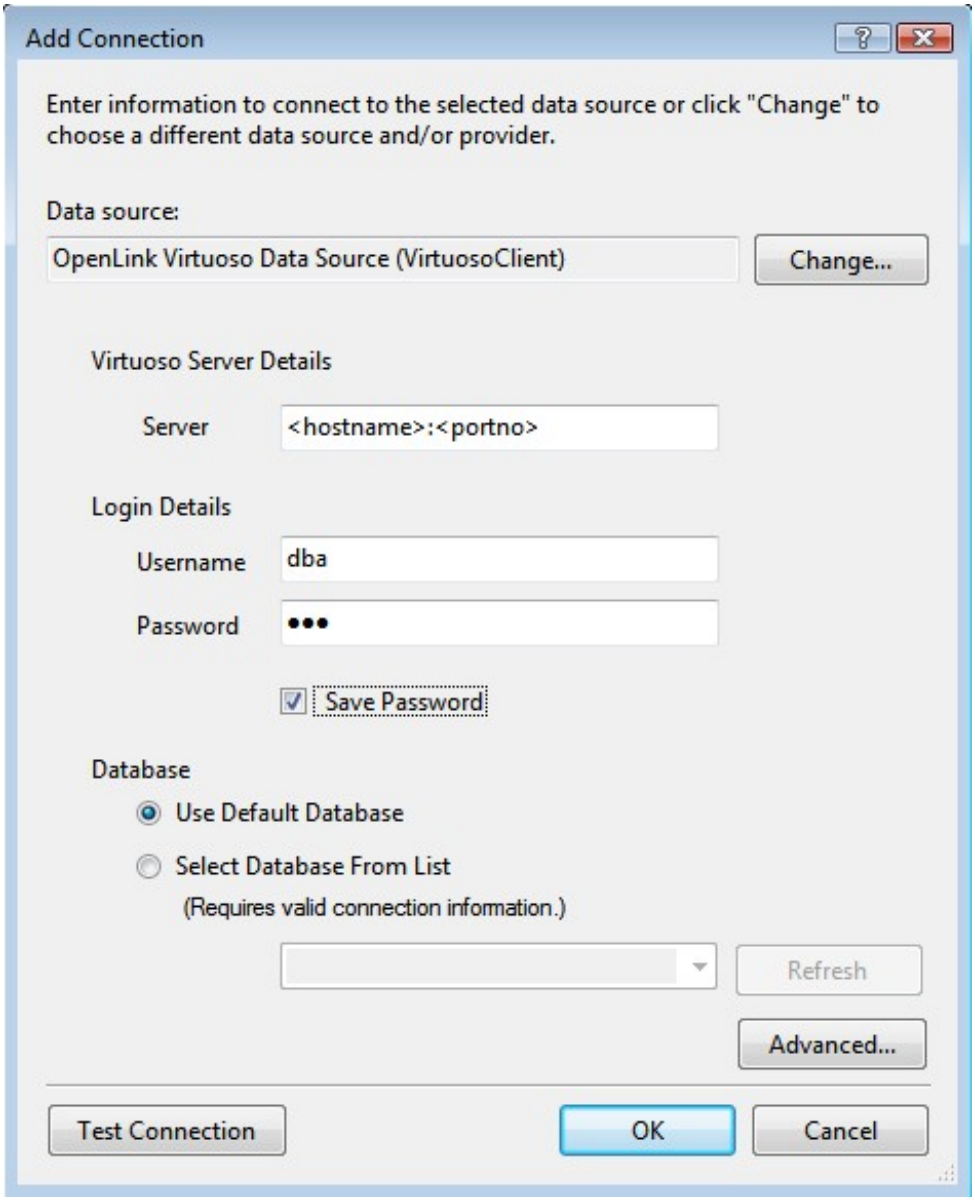
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.536. Connection Properties



14. Select the

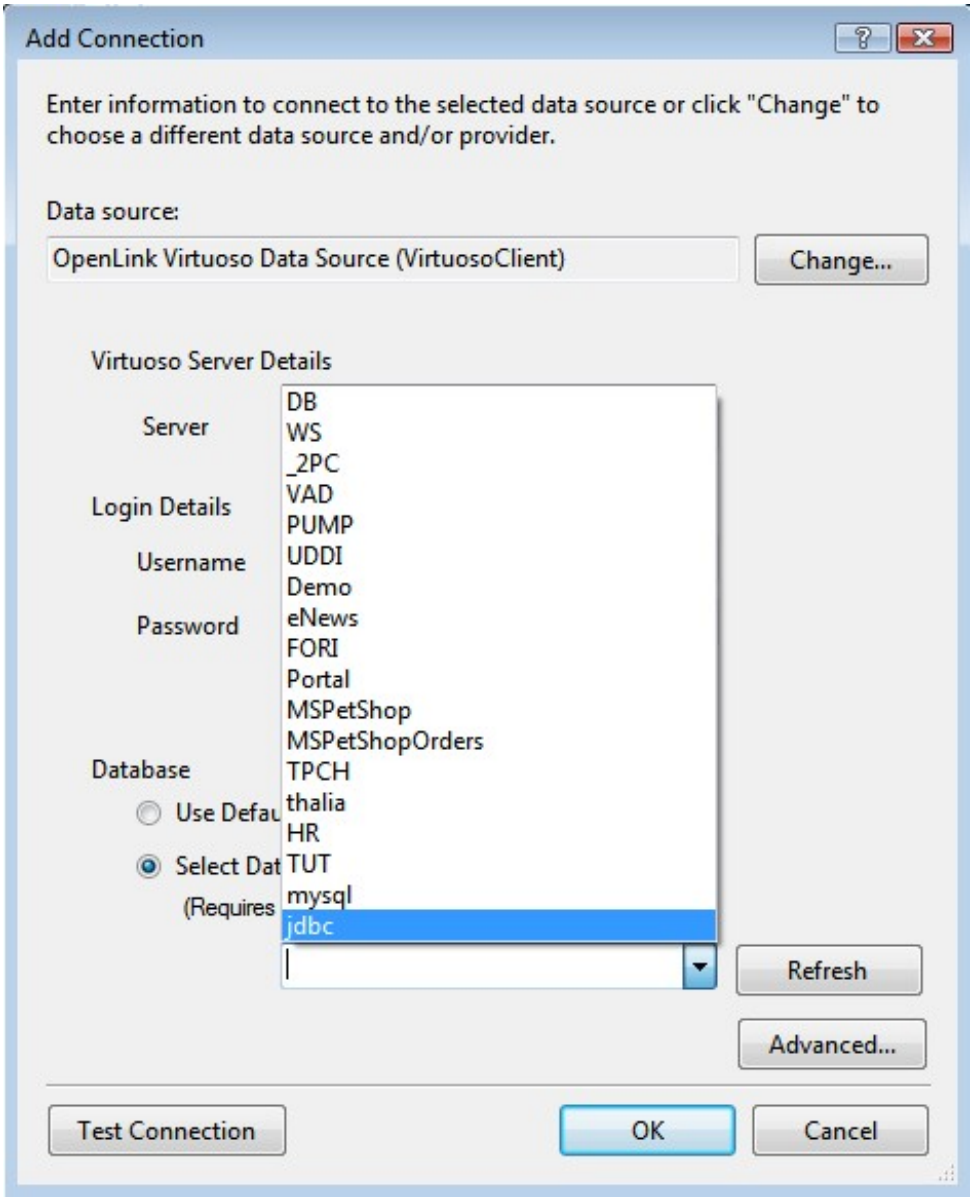
    Select Database From List

    radio button and choose the

    jdbc

    database from the drop down list.

    Figure 8.537. Add connection

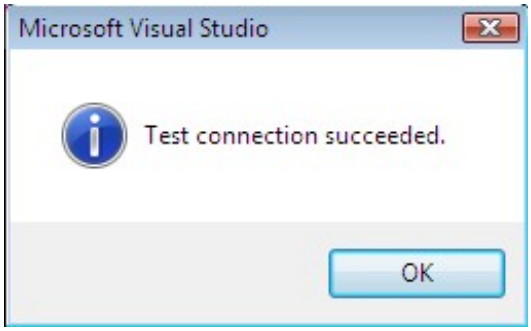


15. Press the

    Test Connection

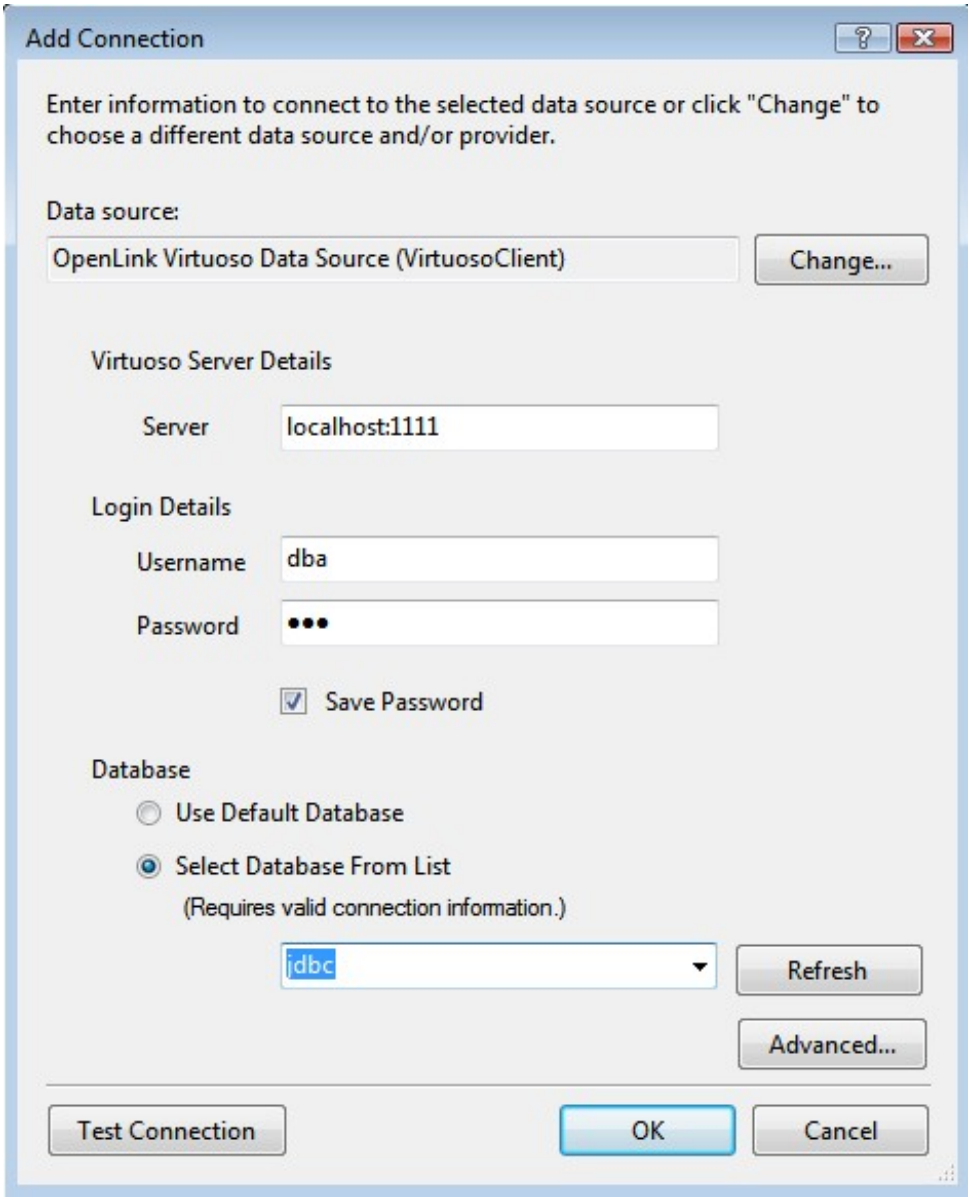
    dialog to verify that the database is accessible.

Figure 8.538. Test Connection



16. Click OK to add the connection.

Figure 8.539. Test Connection



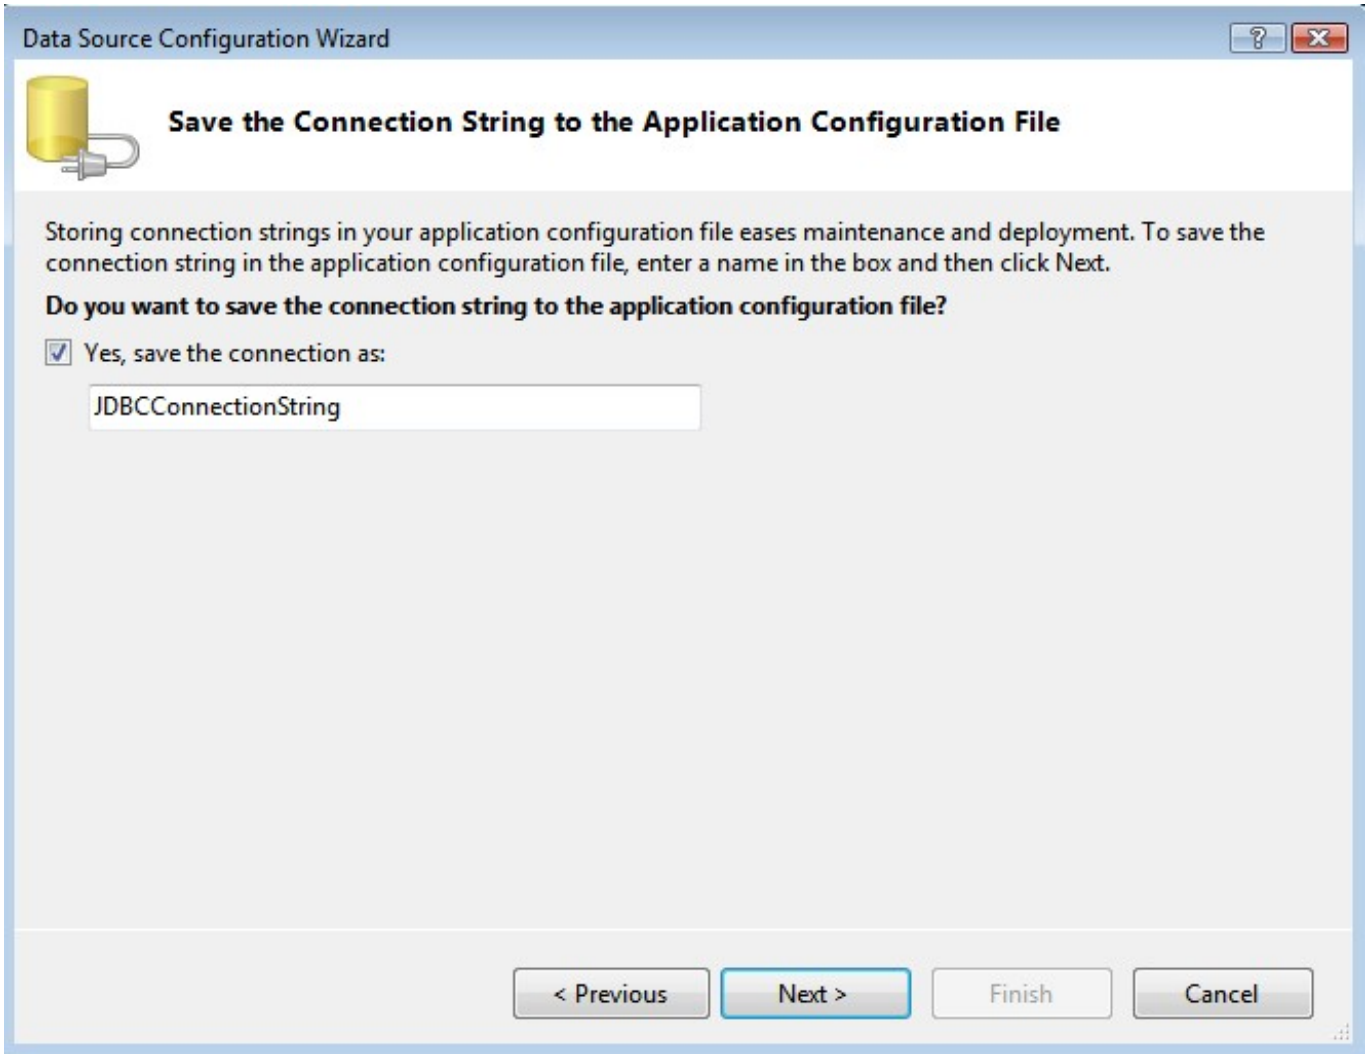
17. Leave the default connect string

    JDBCConnectionString

    and click

    Next

    Figure 8.540. JDBCConnectionString



18. From the list of available tables returned for the JDBC database, select the

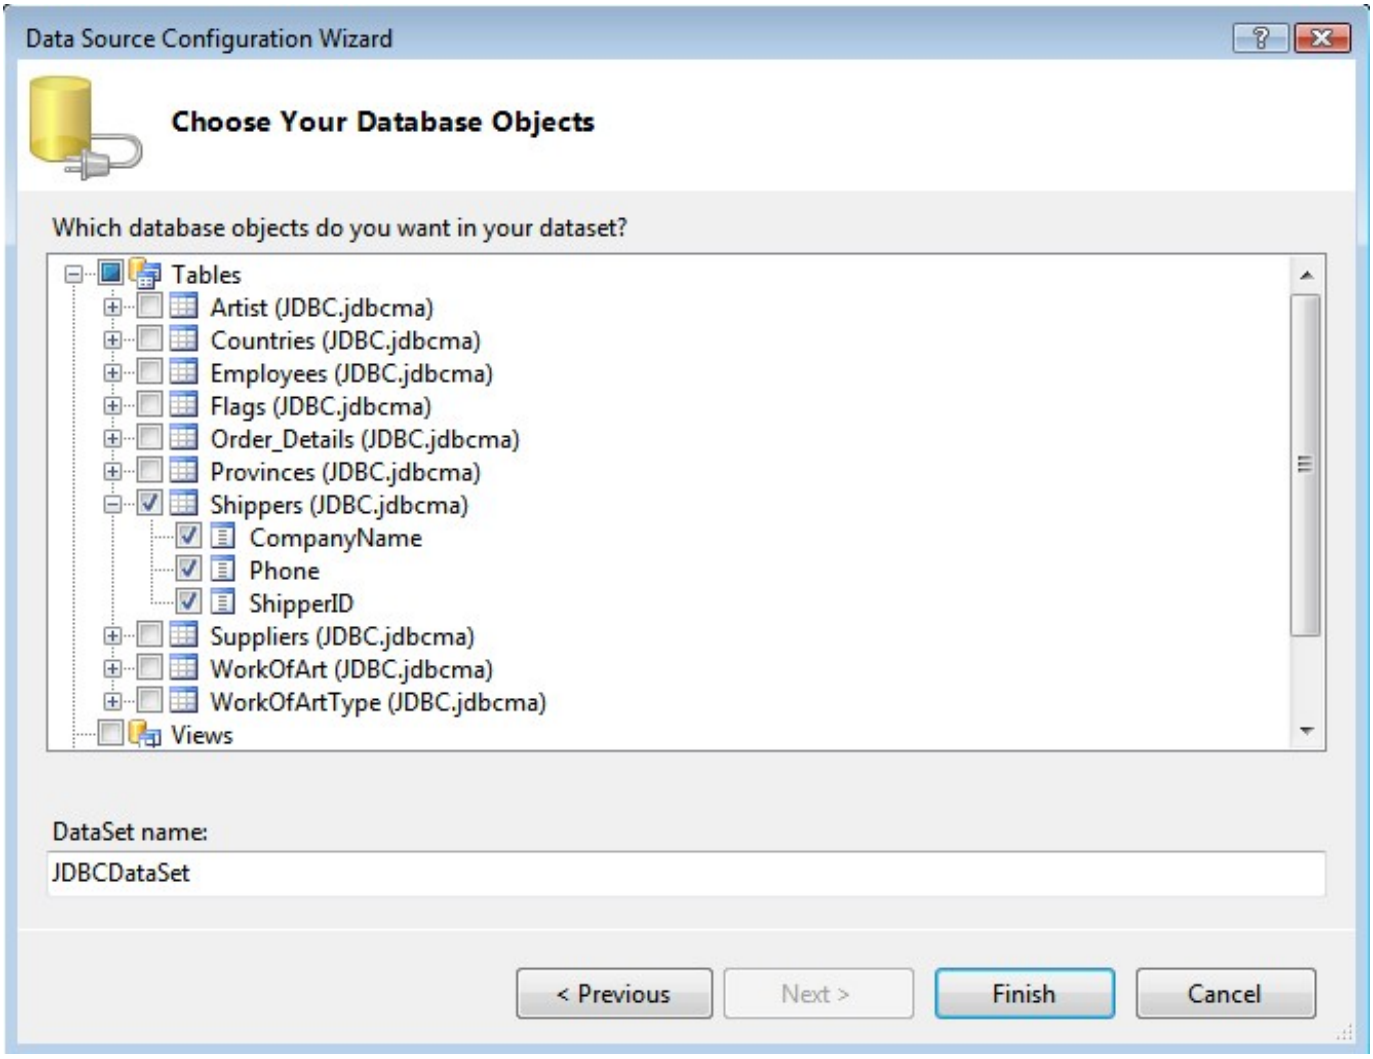
    Shippers

    table to be associated with the

    DataGridView

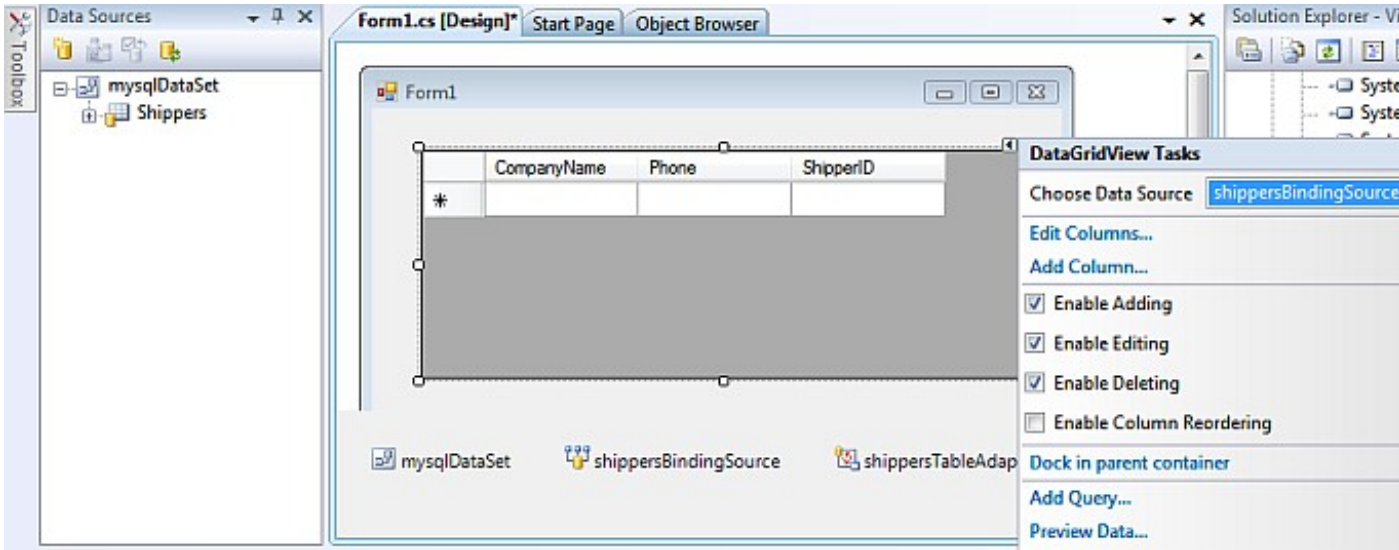
    control.

    Figure 8.541. JDBC database



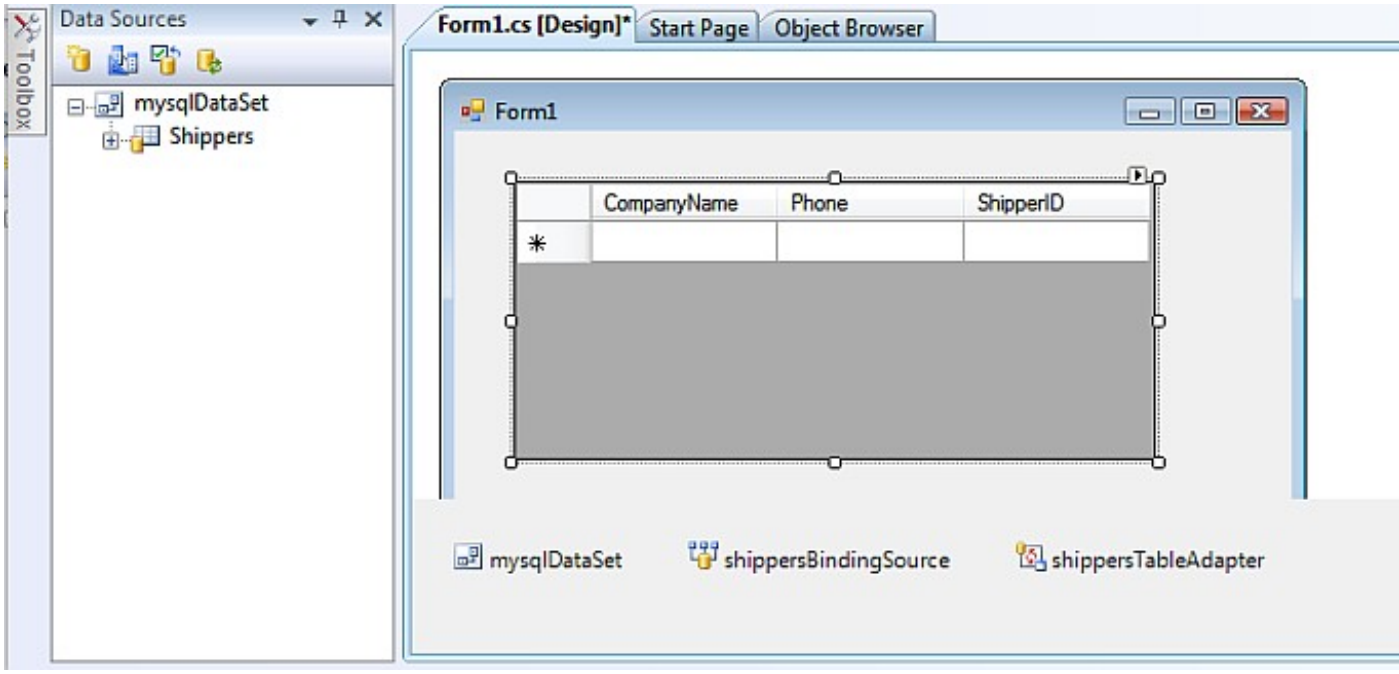
19. The columns names of the select table will be displayed in the DataGridView.

Figure 8.542. DataGridView



20. Resize the Form and DataGridView to allow all columns to be visible, if possible.

Figure 8.543. Resize the Form and DataGridView



21. To test the application, simply hit

    Ctrl+F5

    within Visual Studio or select

    Start Debugging

    from the

    Debug

    menu.

    Figure 8.544. Start Debugging

22. The data from the

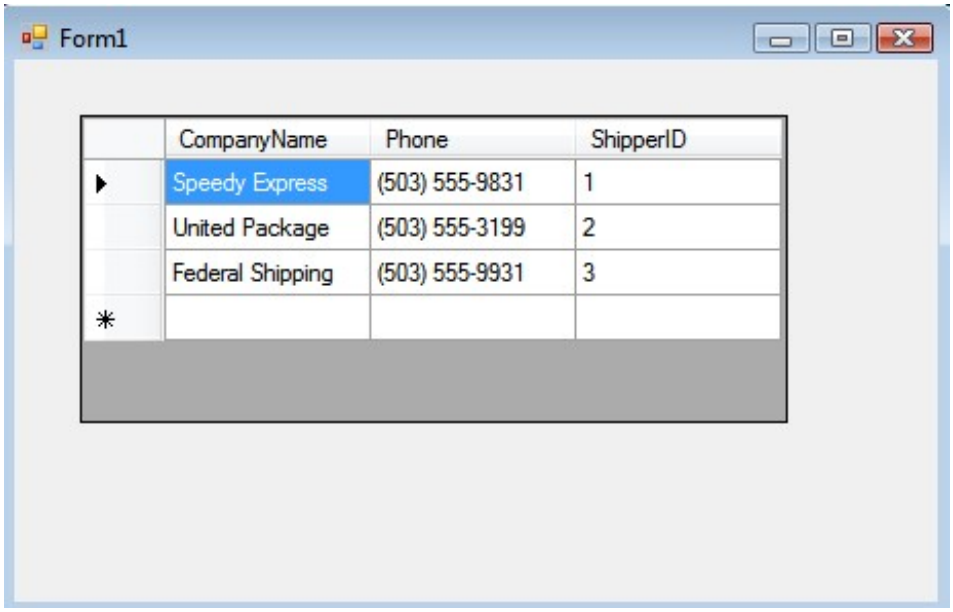
    Shippers

    table will be displayed in the

    DataGrid

    .

    Figure 8.545. DataGrid



The task is now complete.

8.11. Using Microsoft Entity Frameworks to Access ODBC to ODBC Bridge Schema Objects with Virtuoso

Abstract

This section details the steps required to provide Microsoft Entity Framework access to ODBC to ODBC Bridge Schema Objects using the OpenLink Virtuoso Universal Server. This is achieved by linking the required ODBC to ODBC Bridge Schema objects into Virtuoso using its built in Virtual Database engine, and then using the Virtuoso ADO.NET Entity Framework provider to query the remote ODBC to ODBC Bridge Schema objects linked into the Virtuoso Server.

Prerequisites. The following prerequisites must be in place for this solution to be possible.

ODBC to ODBC Bridge DBMS. An ODBC to ODBC Bridge DBMS hosting the required Schema Objects needs to be available. In this section we shall make and ODBC to ODBC bridge connection to another *Virtuoso Northwind Demo* database to demonstrate the process.

An ODBC to ODBC Bridge DBMS hosting the required Schema Objects needs to be available. In this section we shall make and ODBC to ODBC bridge connection to another *Virtuoso Northwind Demo* database to demonstrate the process.

ODBC to ODBC Bridge Driver. An ODBC to ODBC Bridge Driver is required for Linking the ODBC to ODBC Bridge Schema Objects into the Virtuoso Server. The *OpenLink ODBC to ODBC Bridge Driver* will be used in this section, for which a functional ODBC Data source name of "odbcma" will be assumed to exist on the machine hosting the Virtuoso Server.

An ODBC to ODBC Bridge Driver is required for Linking the ODBC to ODBC Bridge Schema Objects into the Virtuoso Server. The *OpenLink ODBC to ODBC Bridge Driver* will be used in this section, for which a functional ODBC Data source name of "odbcma" will be assumed to exist on the machine hosting the Virtuoso Server.

Virtuoso Universal Server. An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

Microsoft Visual Studio 2008 SP1. Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Tasks

Ensure ODBC to ODBC Bridge Primary Keys (PKs) are not nullable. The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the ODBC to ODBC Bridge database schema before attempting to generate an EDM. In the case of the ODBC to ODBC Bridge Virtuoso Northwind Demo database all tables are not nullable, thus this should not be an issue in this case.

The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the ODBC to ODBC Bridge database schema before attempting to generate an EDM. In the case of the ODBC to ODBC Bridge Virtuoso Northwind Demo database all tables are not nullable, thus this should not be an issue in this case.

8.11.1. Install and configure OpenLink ODBC Driver for ODBC to ODBC Bridge

The Virtuoso Virtual Database engine uses ODBC as the connectivity mechanism for linking remote database objects into its local schema. Thus an ODBC to ODBC Bridge Driver must be available with a suitably configured DSN for connecting to the target database. The OpenLink ODBC to ODBC Bridge Drivers have been used in this document, although in theory any ODBC to ODBC Bridge Driver can be used.

Installation instructions for the OpenLink ODBC Driver for ODBC to ODBC Bridge are available from: Product Installation & Basic Configuration (ODBC)

Install and configure OpenLink Virtuoso Universal Server

1. Install and configure OpenLink Virtuoso Universal Server

8.11.2. Linking ODBC to ODBC Bridge tables into OpenLink Virtuoso

1. Start the Virtuoso Web User Interface

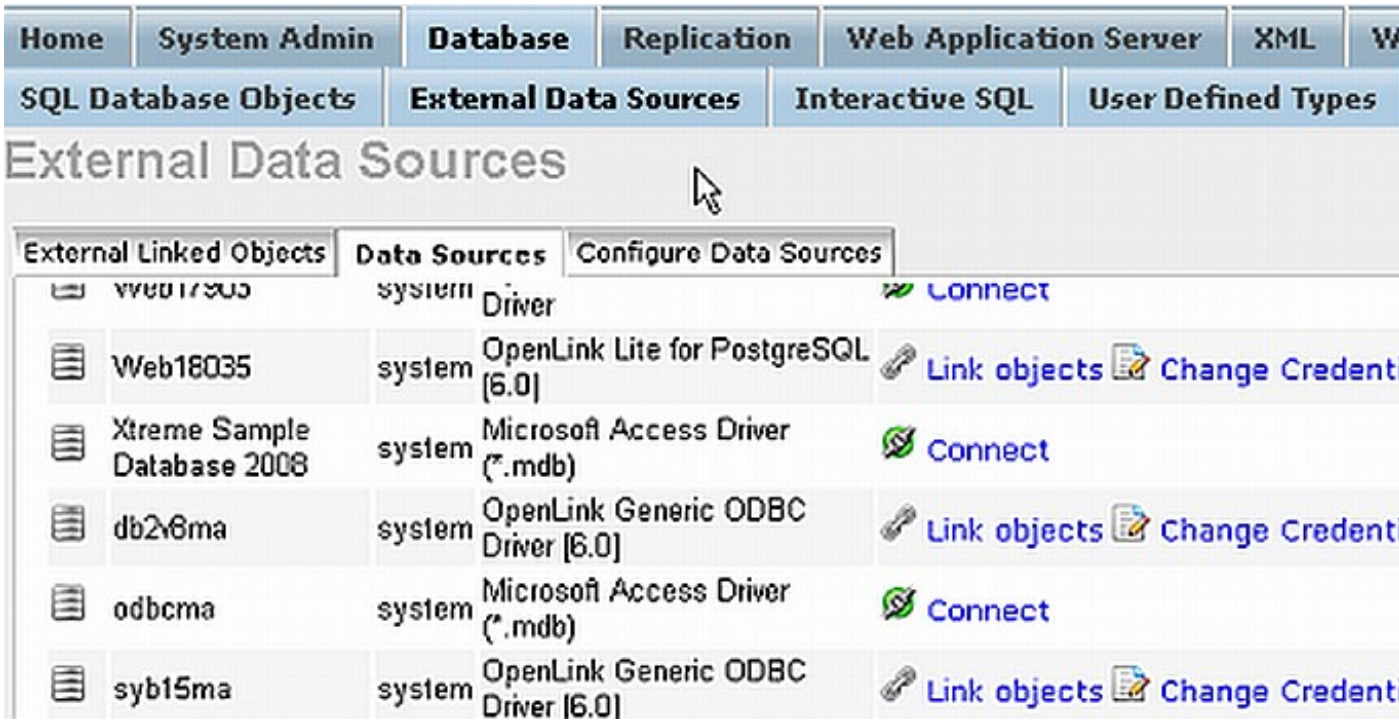
   Figure 8.546. Start

2. Select the "Conductor" link in the Left Frame and Login as the "dba" user.

Figure 8.547. Conductor

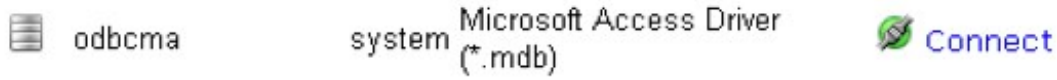
3. Select the "Databases" -> "External Data Source" -> "Data Sources" tab menu items

Figure 8.548. Databases



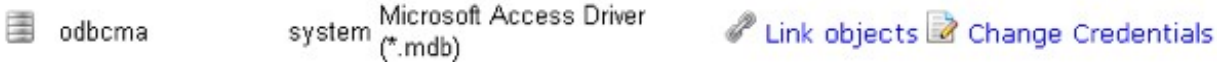
4. Select the "Connect" button for the "odbcma" ODBC to ODBC Bridge DSN.

Figure 8.549. Connect



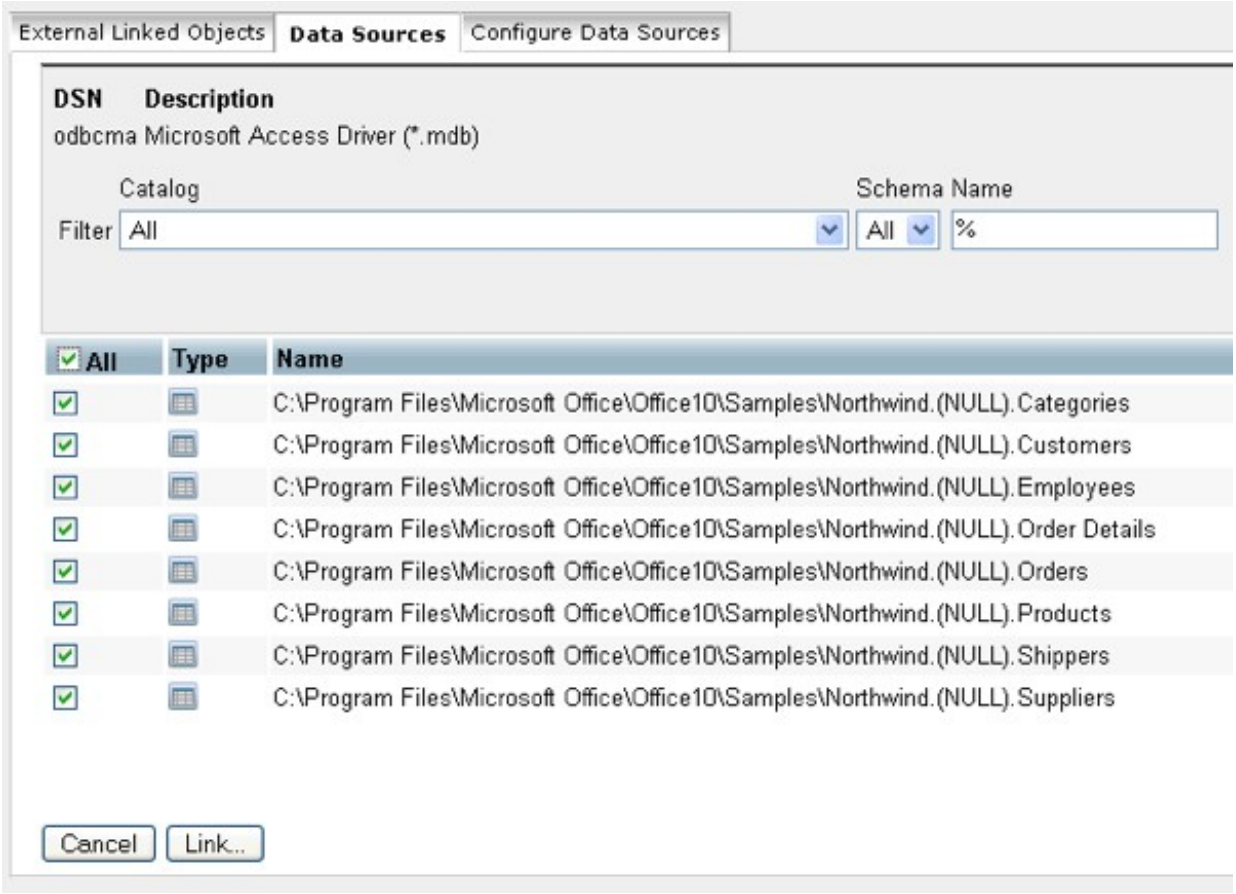
5. On successful connection Select the "Link Objects" button to obtain a list of available tables

Figure 8.550. Link Objects



6. Select all the tables that are part of the "Northwind" catalog.

Figure 8.551. Select tables

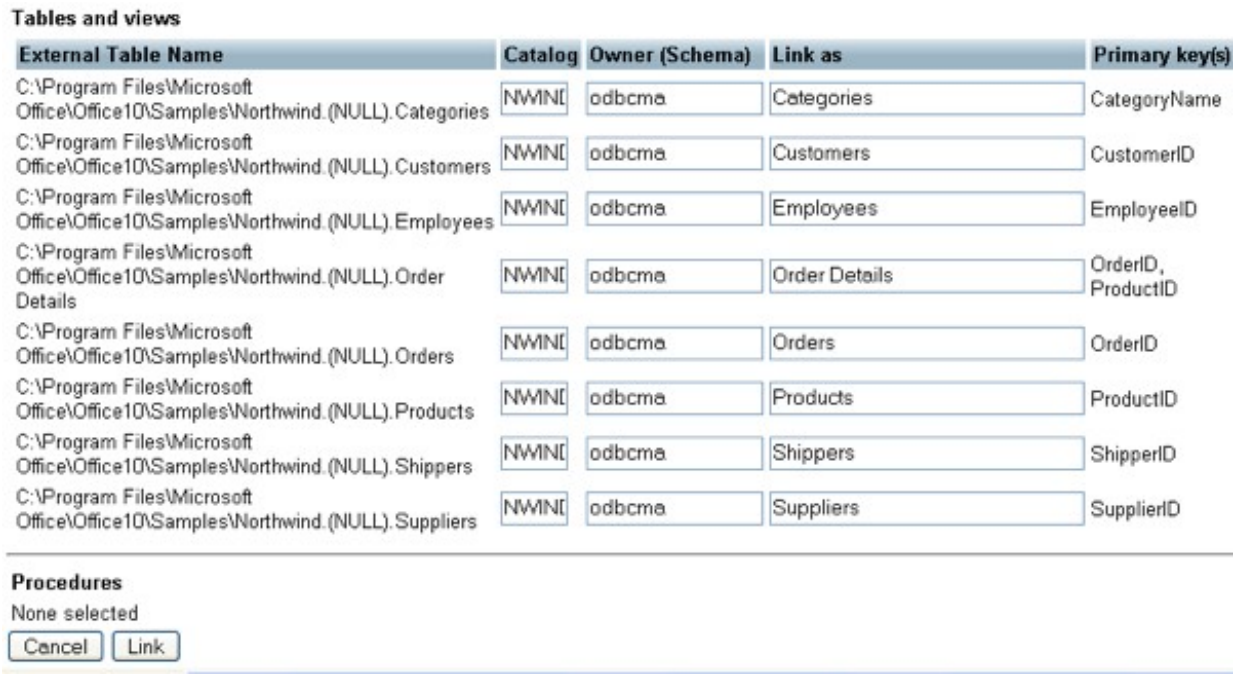


7. Change the Catalog for each table to be "NWIND" using the "Set All" button.

Figure 8.552. "Link" button

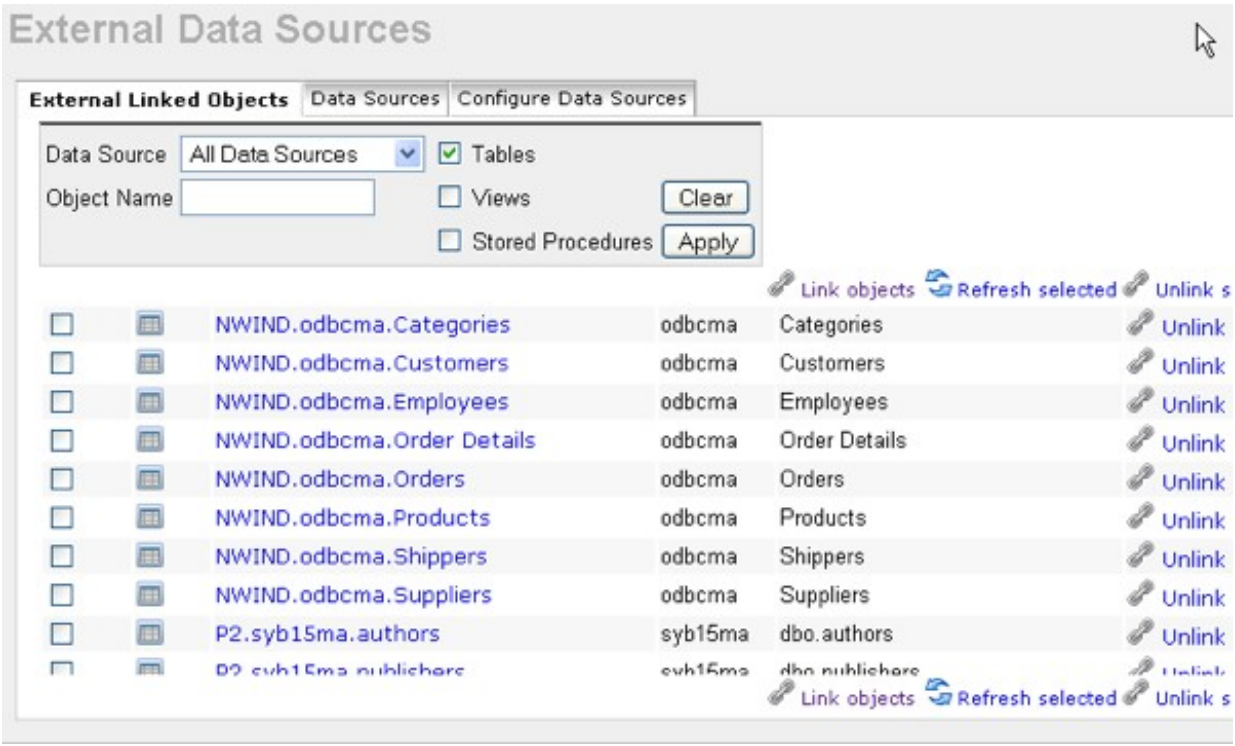
8. All the catalog names are changed to be "NWIND".
9. Select the "Link" button to link the selected tables into Virtuoso

Figure 8.553. "Link" button



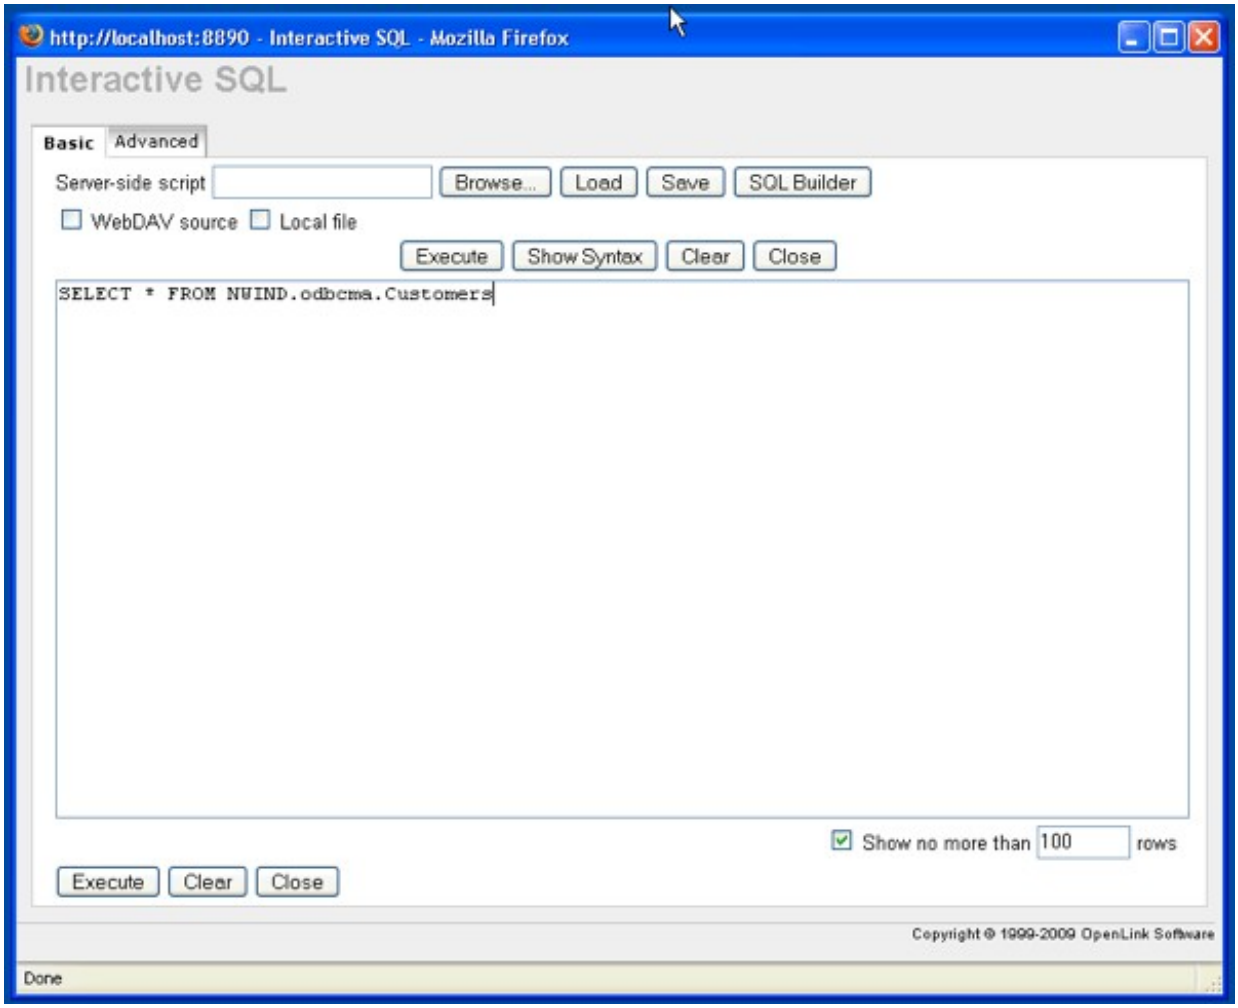
10. On completion of the Link process the tables will be displayed in the "External Linked Objects" tab.

Figure 8.554. Completion



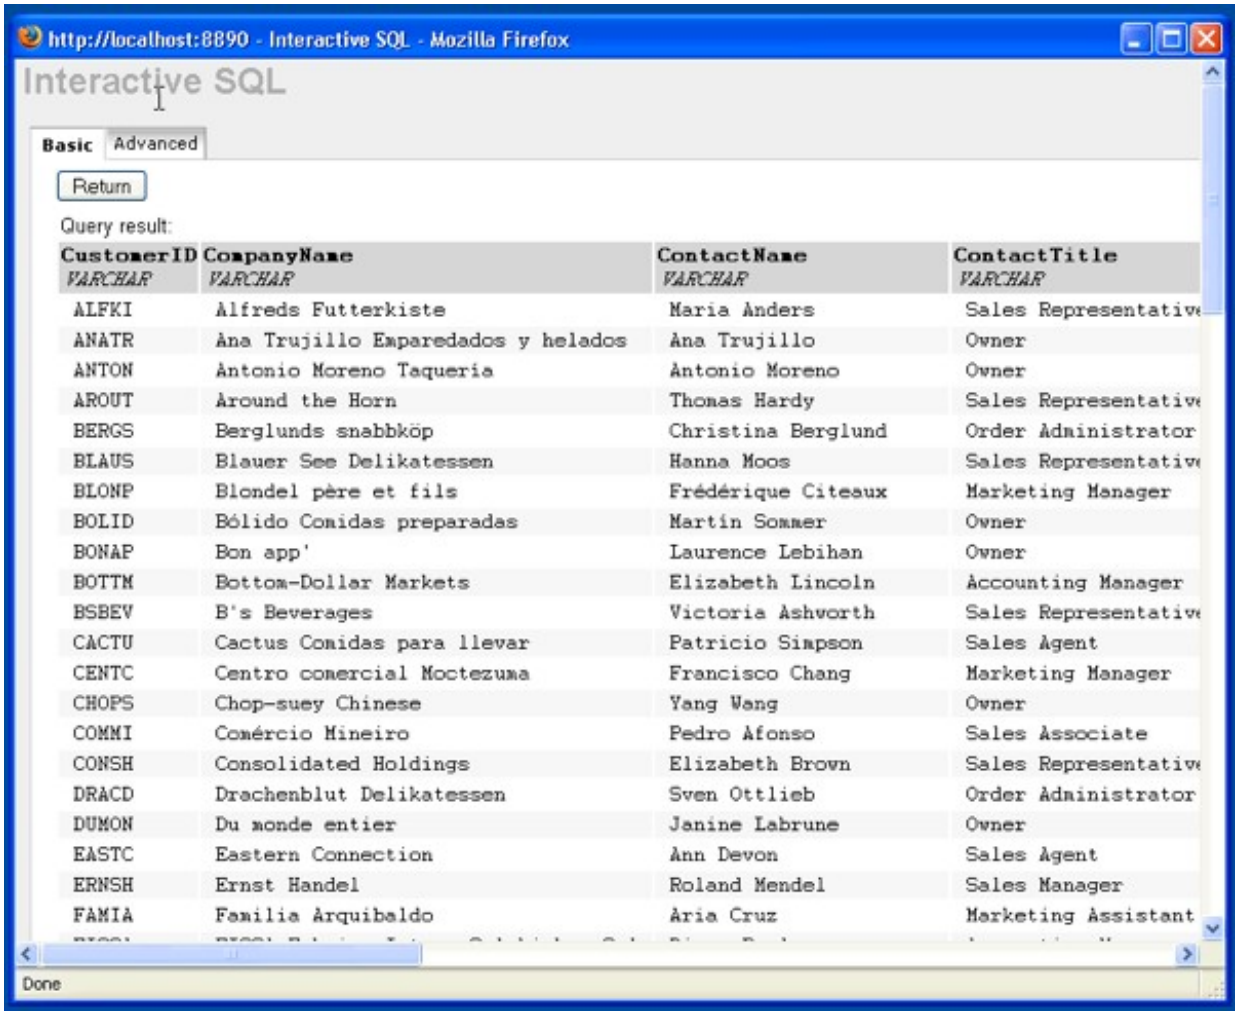
11. The linked tables can be queried by clicking on the hyperlink in the "Local Name" column of the "External Linked Objects" tab above, which loads the Virtuoso "Interactive SQL" interface with the required SQL "Select" for retrieving the remote table data. We shall use the "NWIND.odbcma.Customers" table to demonstrate this.

Figure 8.555. Completion



12. Then click the "Execute" button to run the query and retrieve the results from the remote table.

Figure 8.556. Completion



CustomerID VARCHAR	CompanyName VARCHAR	ContactName VARCHAR	ContactTitle VARCHAR
ALFKI	Alfreds Futterkiste	Maria Anders	Sales Representative
ANATR	Ana Trujillo Emparedados y helados	Ana Trujillo	Owner
ANTON	Antonio Moreno Taqueria	Antonio Moreno	Owner
AROUT	Around the Horn	Thomas Hardy	Sales Representative
BERGS	Berglunds snabbköp	Christina Berglund	Order Administrator
BLAUS	Blauer See Delikatessen	Hanna Moos	Sales Representative

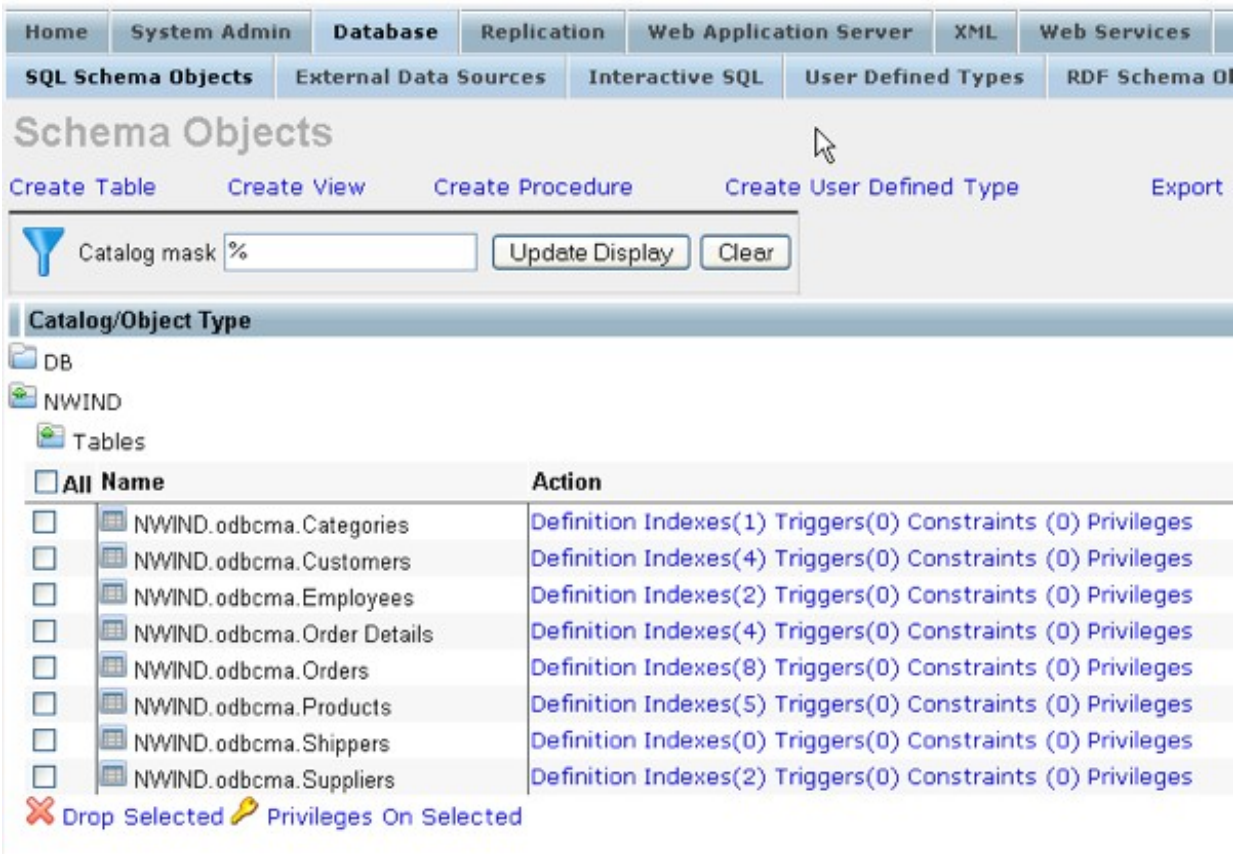
ERNSH	Ernst Handel	Roland Mendel	Sales Manager
FAMIA	Familia Arquibaldo	Aria Cruz	Marketing Assistant

13. The tables can also be viewed as part of the Virtuoso "SQL Schema Objects" under the "NWIND" catalog name.

Figure 8.557. view tables



The Link process is now complete enabling the tables to be queried as if part of the Virtuoso Schema.

8.11.3. Creating EDM in Visual Studio 2008

The following steps can be used to create an Entity Data Model (EDM) for the Microsoft Access Northwind database:

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.558. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

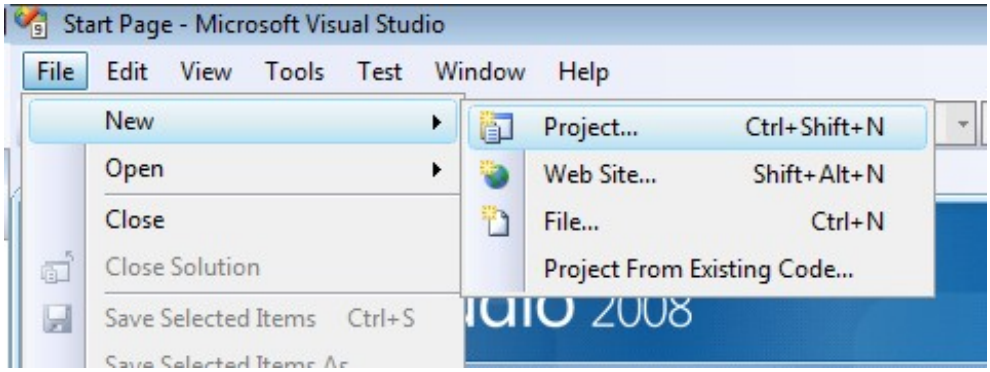
   File

menu in Visual Studio and choosing

New Project

.

Figure 8.559. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Web

   and select

   ASP.NET Web Application

   from the right-hand panel.
5. Choose a name for the project, for example

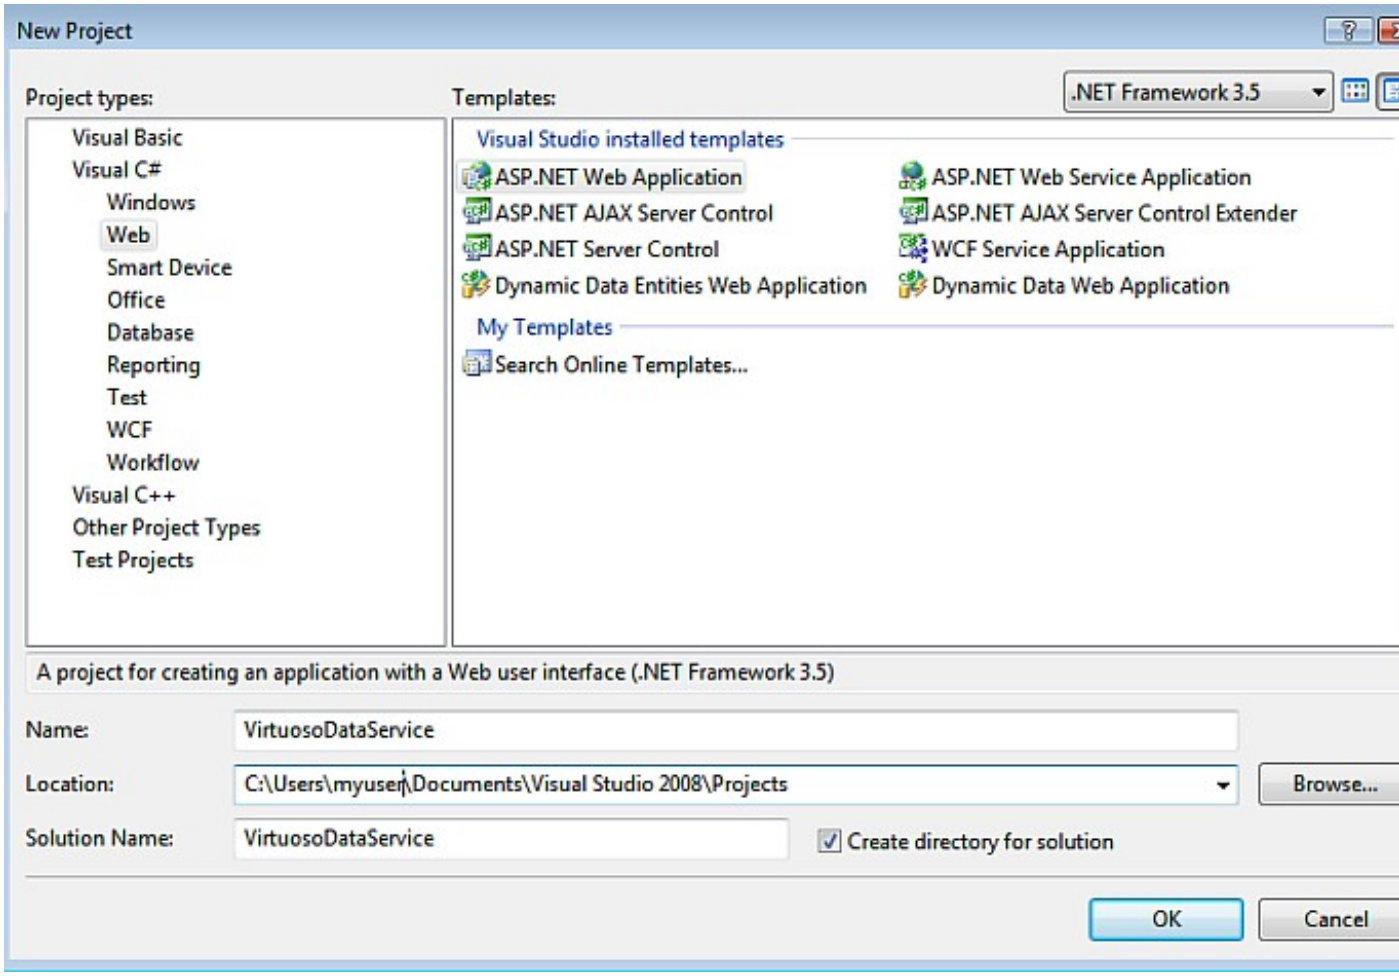
   VirtuosoDataService

   , and click

   OK

   .

Figure 8.560. name for the project

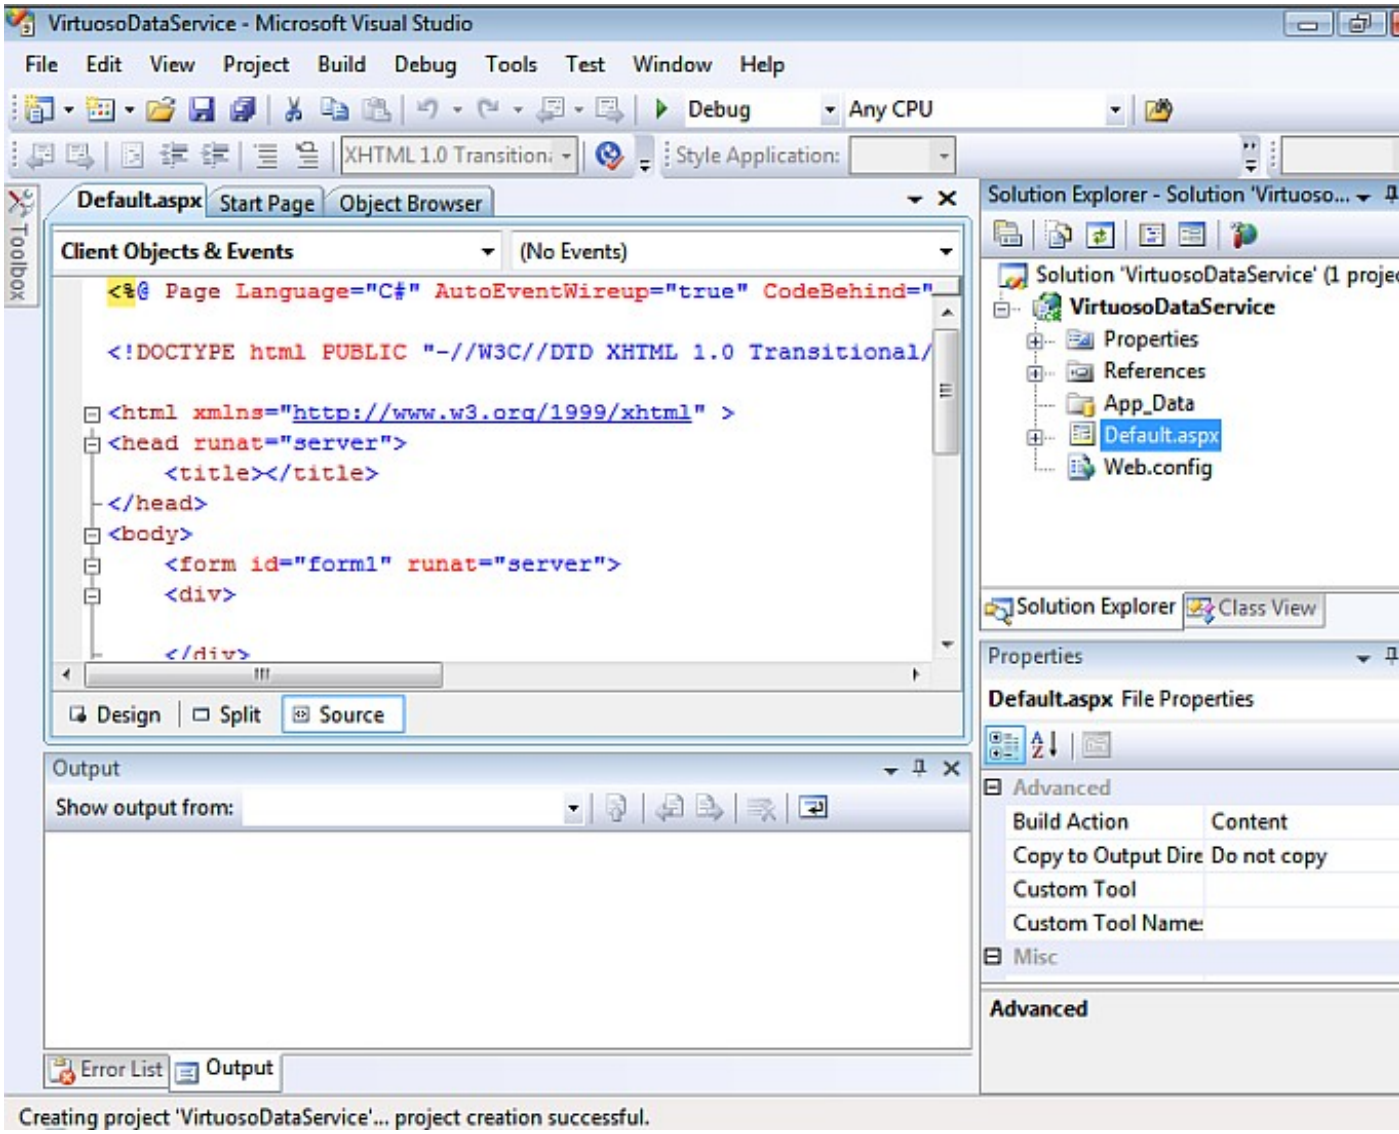


6. This will create a new project called

   VirtuosoDataService

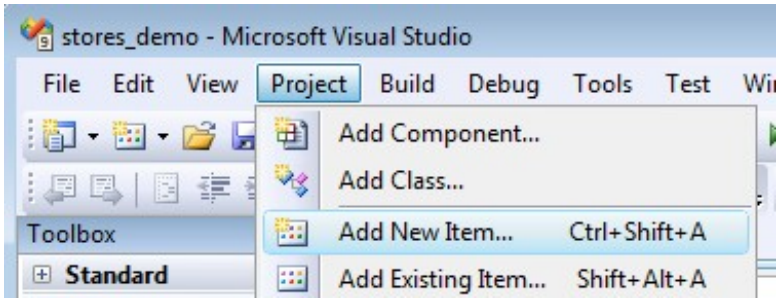
   .

Figure 8.561. create a new project



7. Select the Project -> Add New Item menu option.

Figure 8.562. VirtuosoDataService



8. The

Add New Item

dialog will appear. Choose the

ADO.NET Entity Data Model

template. Give it the name

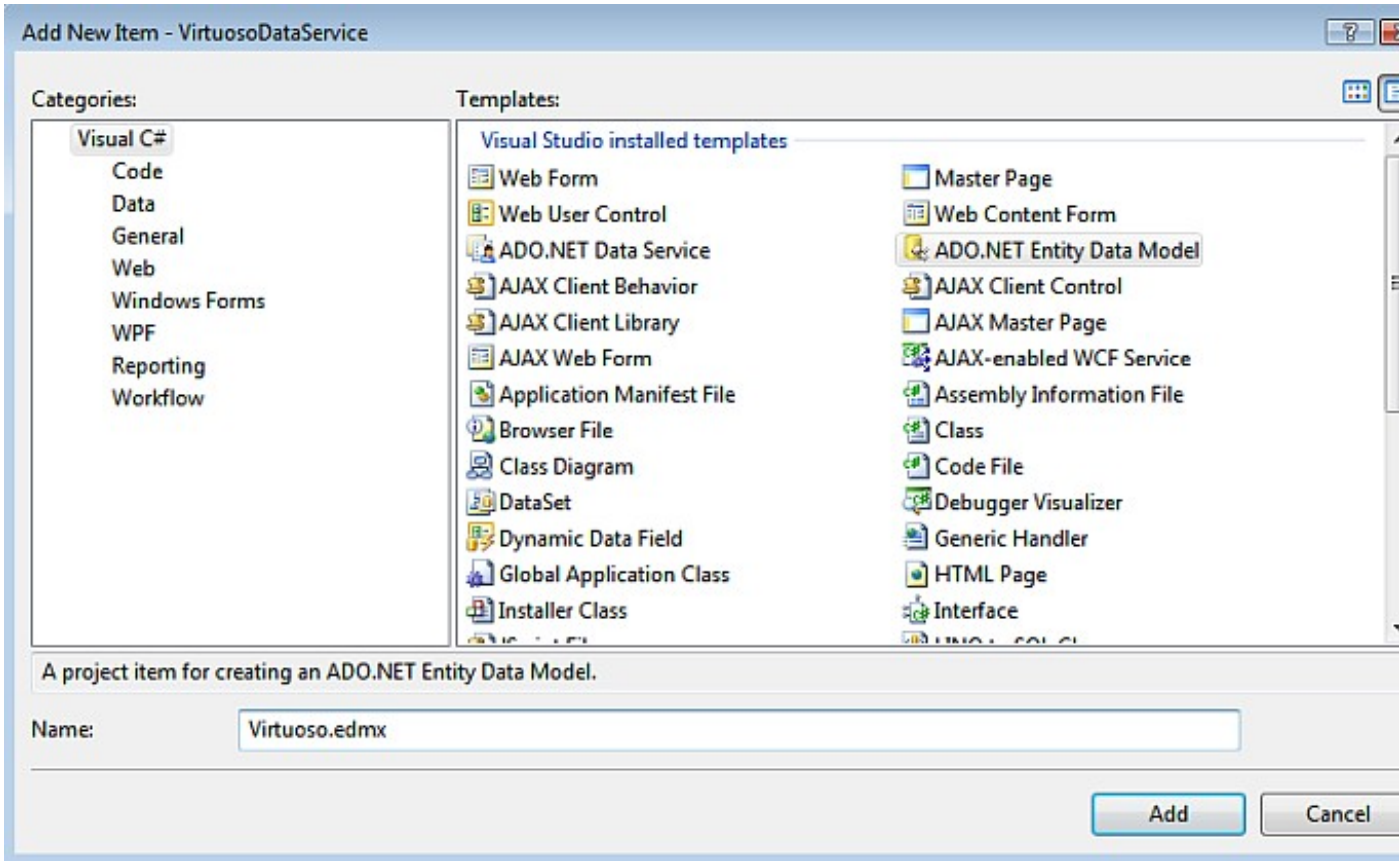
Virtuoso.edmx

and click

Add

to start the creation of the ADO.Net Entity Data Model.

Figure 8.563. Add New Item



9. In the

Entity Data Model Wizard

dialog

Choose Model Contents

page select the

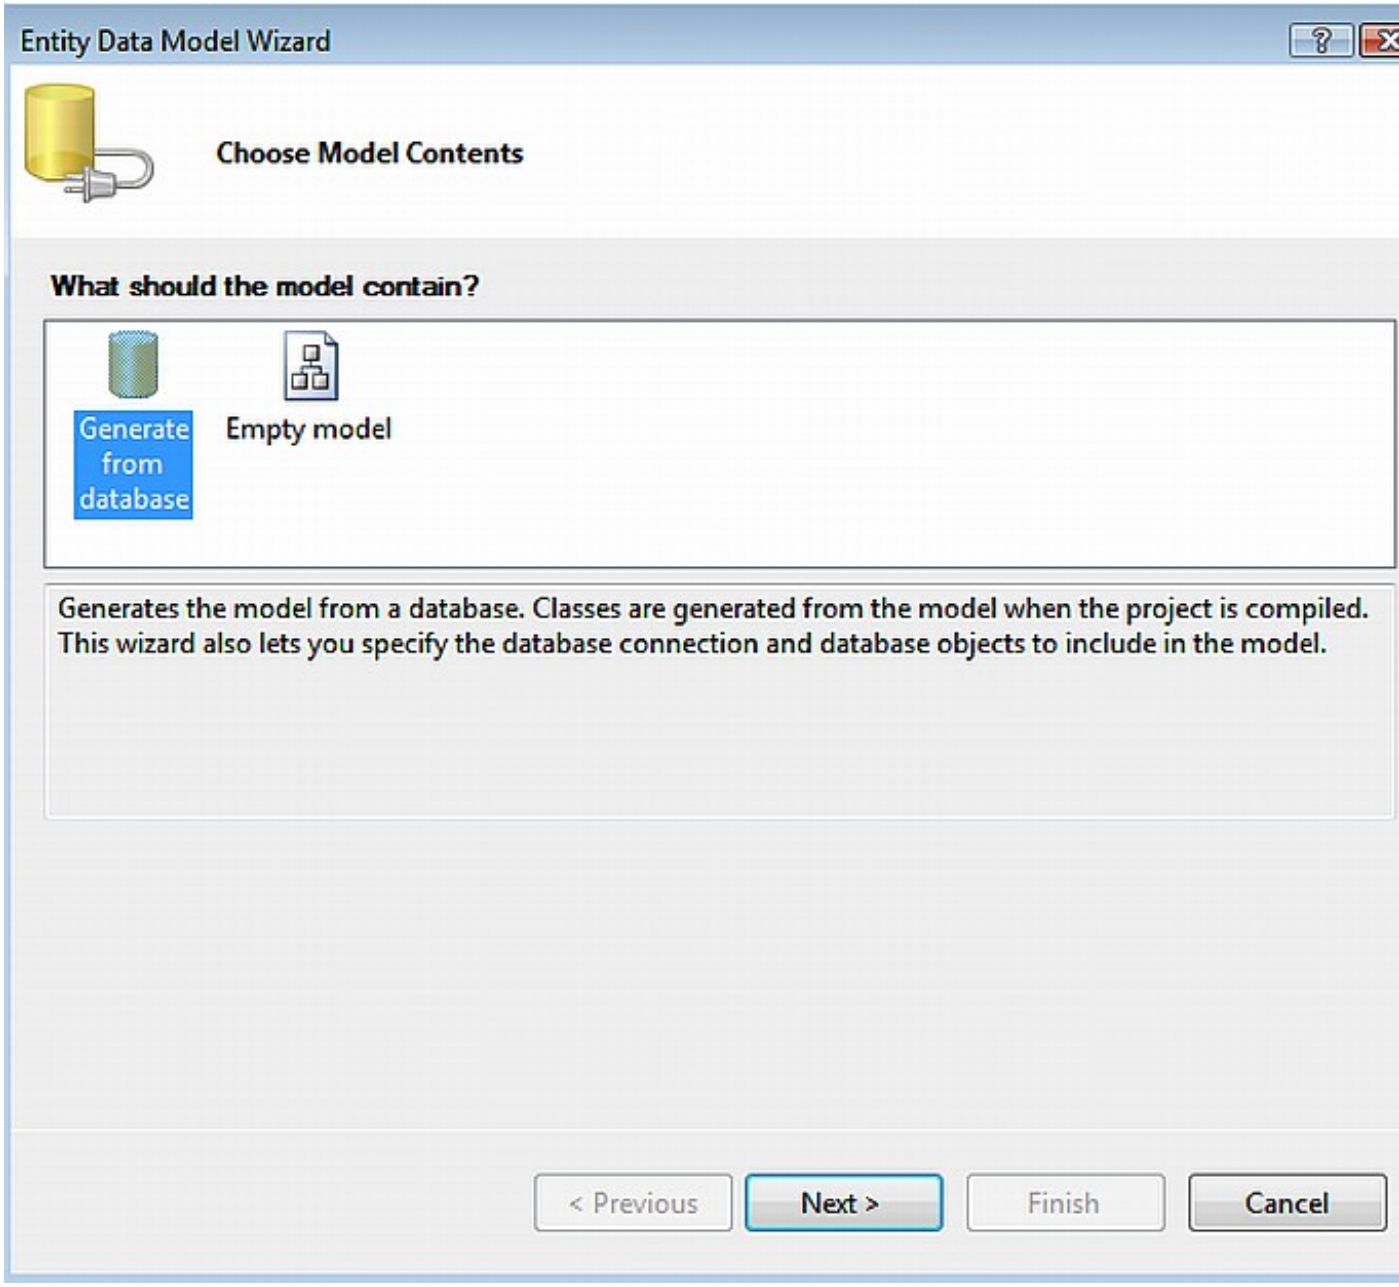
Generate from Database

model type and click

Next

.

Figure 8.564. Choose Model Contents



10. In the

    Entity Data Model Wizard

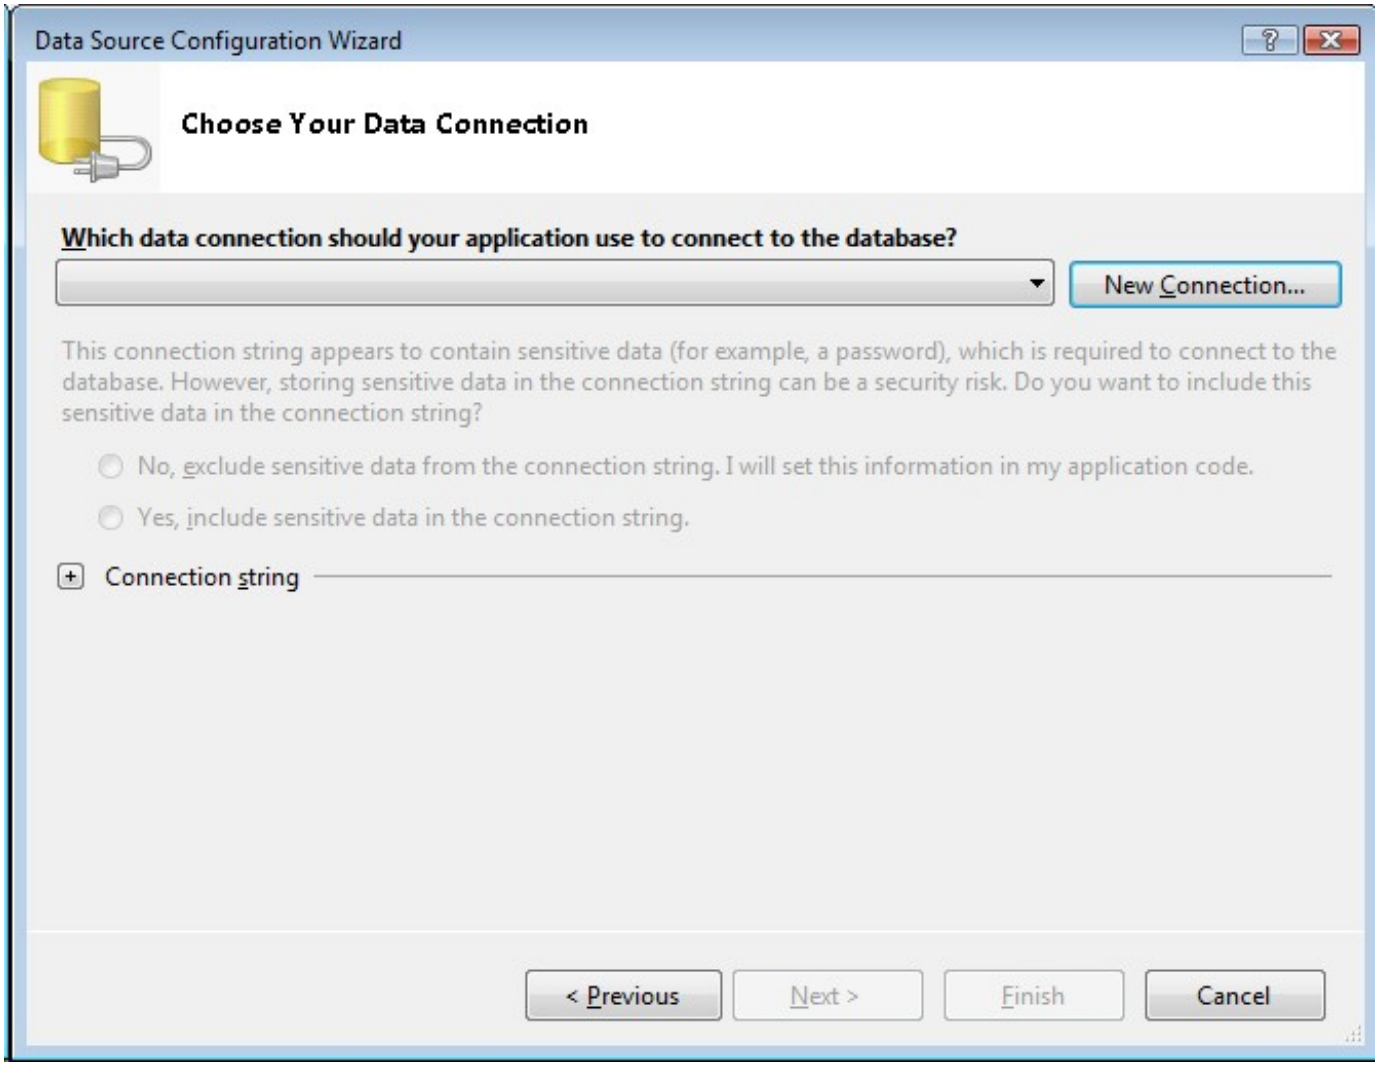
    dialog

    Choose your Data Connection

    page, select the

    New Connection button

Figure 8.565. Entity Data Model Wizard



11. In the

    Choose Data Source

    dialog, select the OpenLink

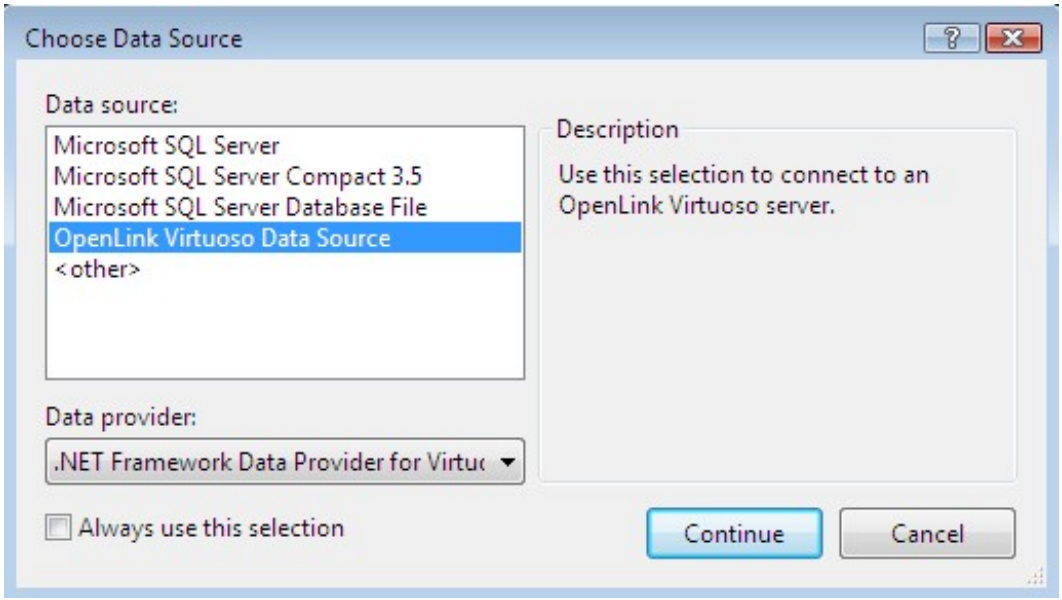
    Virtuoso Data Source

    from the list and click

    Continue

    .

    Figure 8.566. Choose Data Source



12. In the

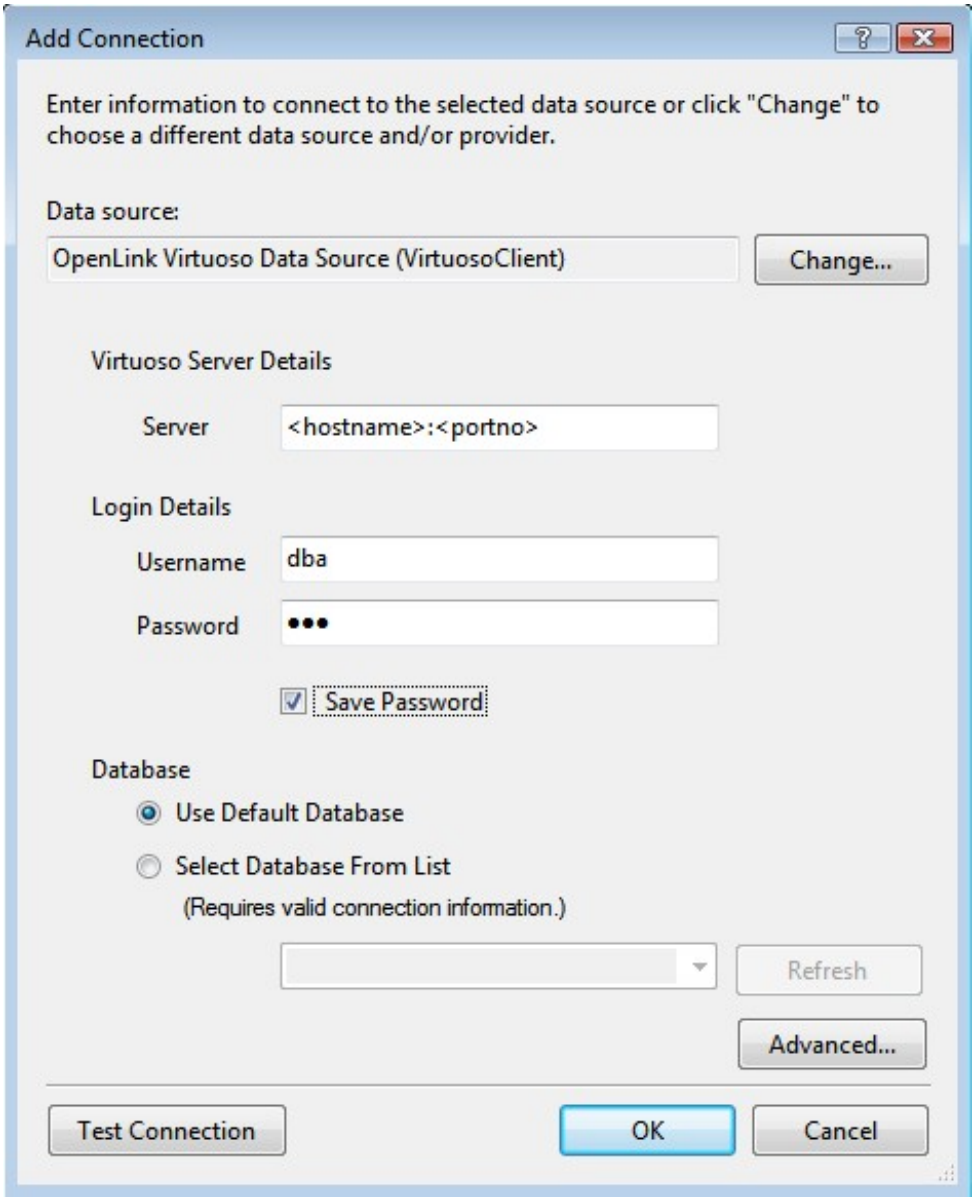
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.567. Connection Properties



13. Select the

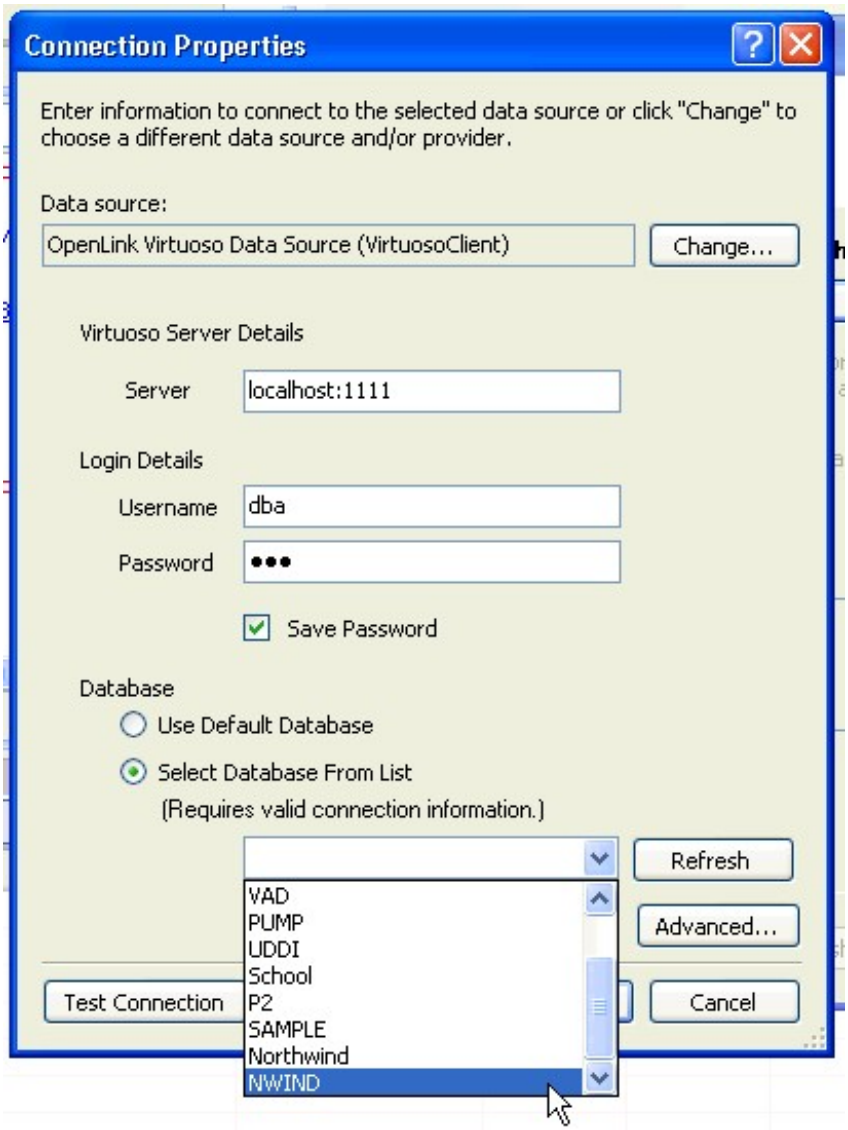
    Select Database From List

    radio button and choose the

    NWIND

    database from the drop down list.

Figure 8.568. Add connection

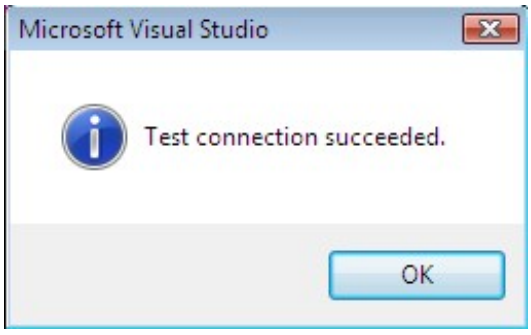


14. Press the

    Test Connection

    dialog to verify that the database is accessible.

    Figure 8.569. Test Connection



15. Set the

    entity connect string

    name to

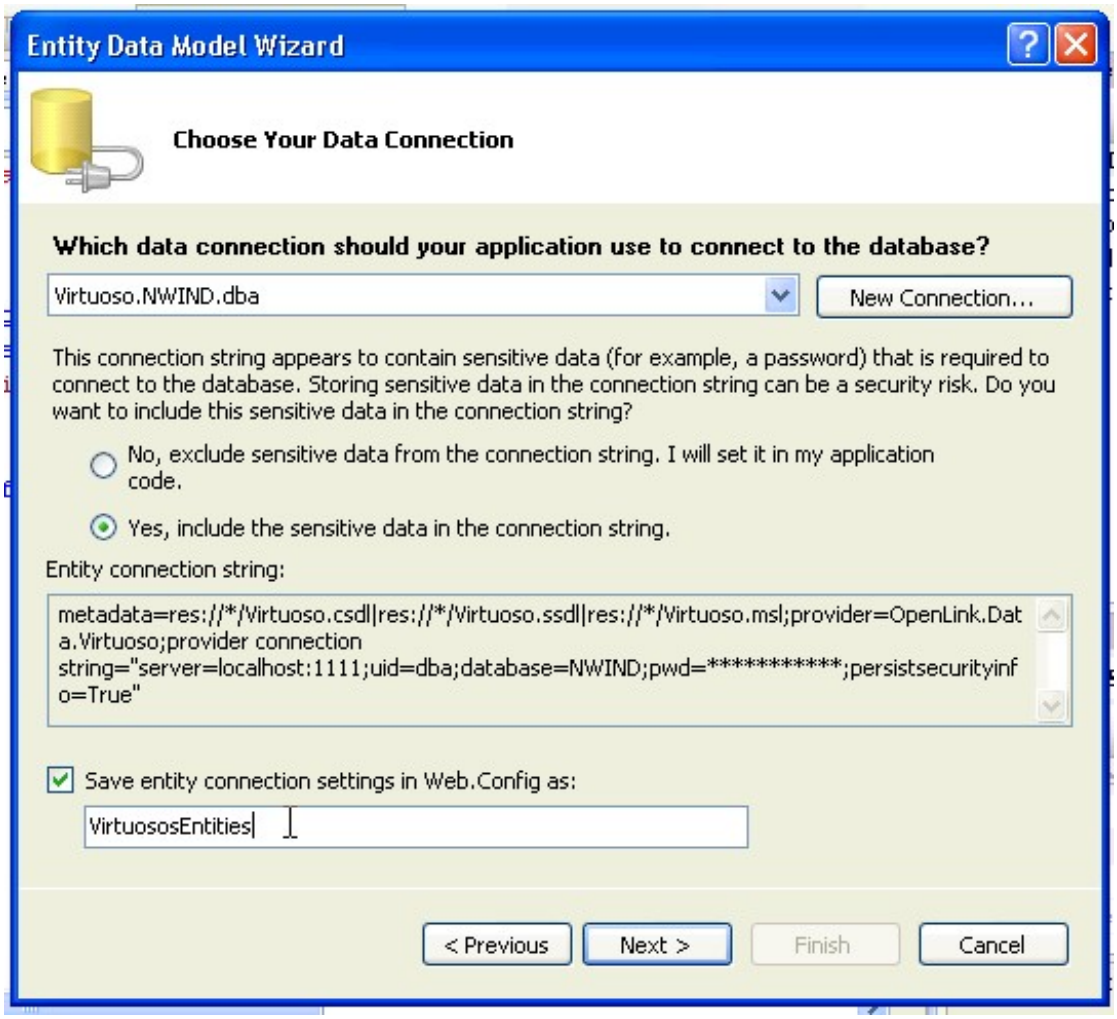
VirtuosoEntities

(note this name as it is required in the section on creating and ADO.Net Data Service) and click

Next

.

Figure 8.570. entity connect string



16. In the

    Choose your Database Objects

    page select the

    Tables

    check box to select all tables in the NWIND catalog for addition to the Entity Data Model. Set the

    Model Namespace

    to

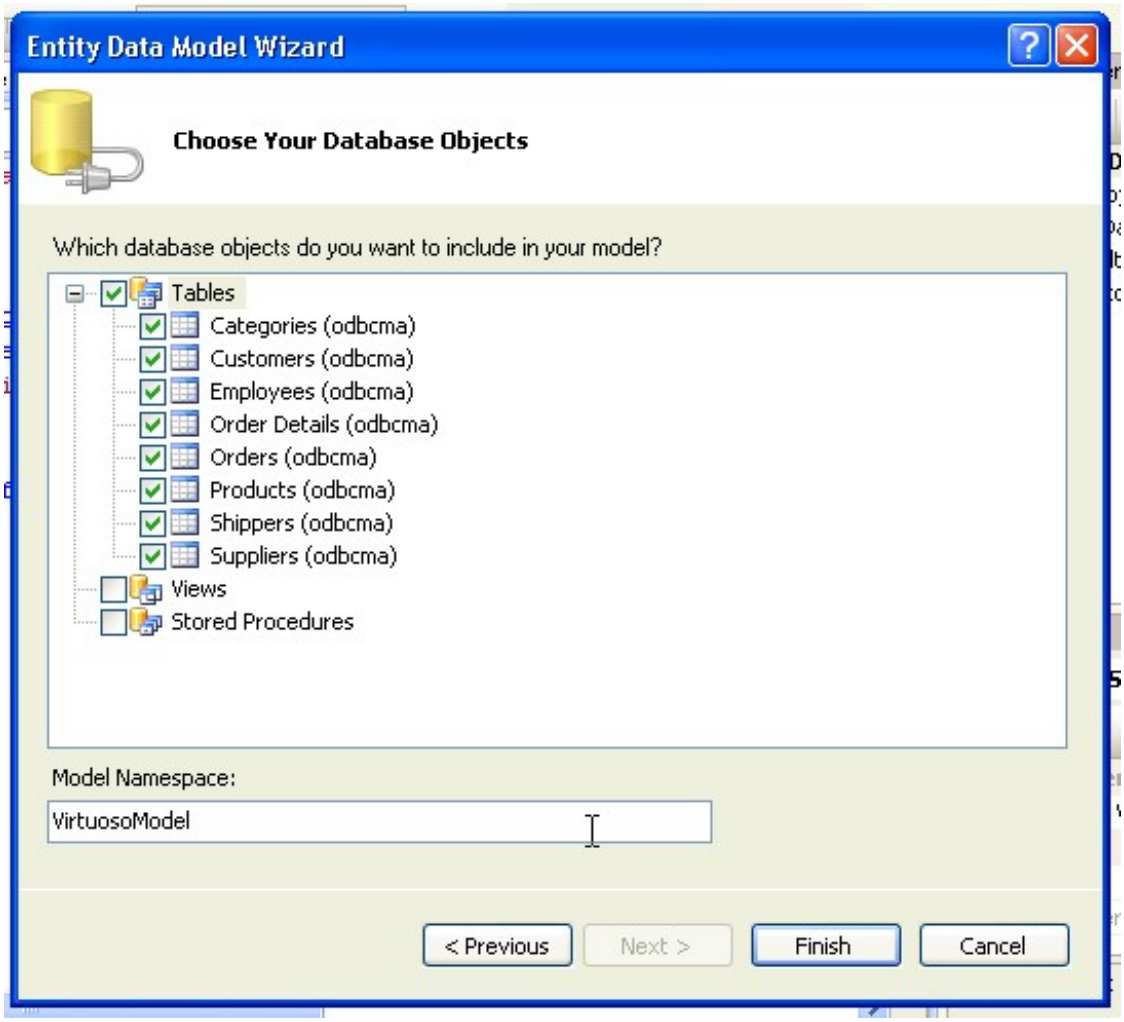
    VirtuosoModel

    and click

Finish

.

Figure 8.571. Database Objects

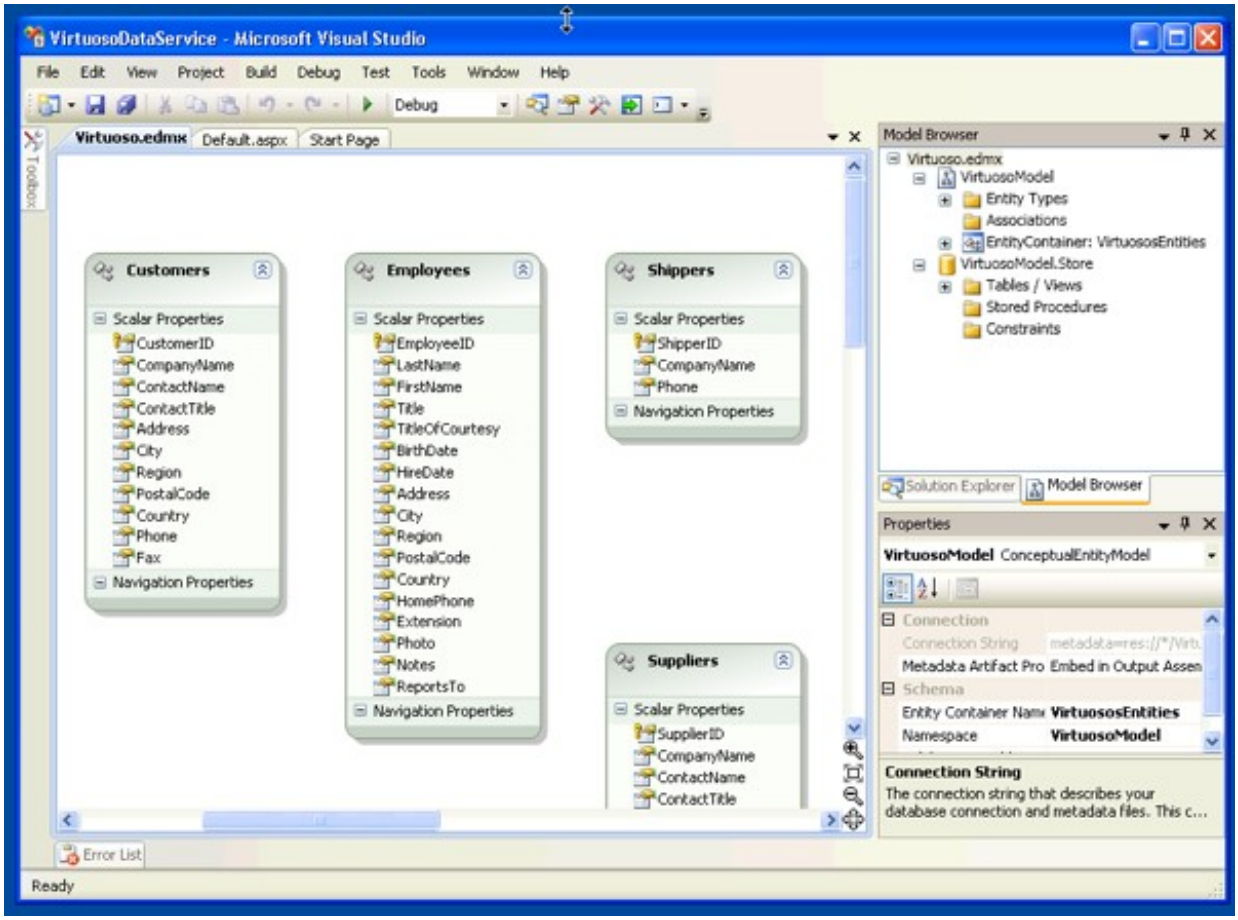


17. The

    Virtuoso.edmx

    EDM will be created with the tables and relationships displayed in the Visual Studio IDE

Figure 8.572. Virtuoso.edmx



Creation for the Entity Data Model for the Microsoft Access Northwind database is now complete.

8.11.4. Using EDM to create Entity Framework based applications

Now that a Microsoft Entity Data Model has been created for the Northwind database, Entity Framework applications can be created to make use of it.

Visual Studio Windows DataGrid Form Application

This section details the steps required to create a simple Visual Studio 2008 Windows Form application, with associated DataGridView control for displaying data in selected tables from the target database.

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.573. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

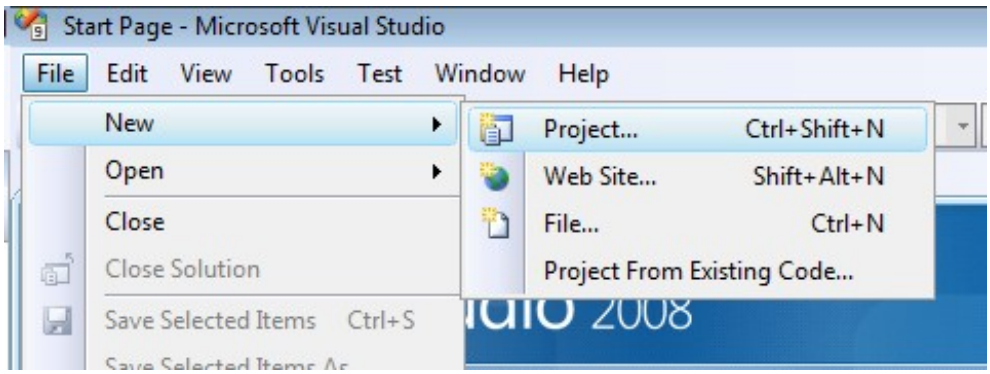
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.574. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Windows

   and select

   Windows Form Application

from the right-hand panel.

5. Choose a name for the project, for example

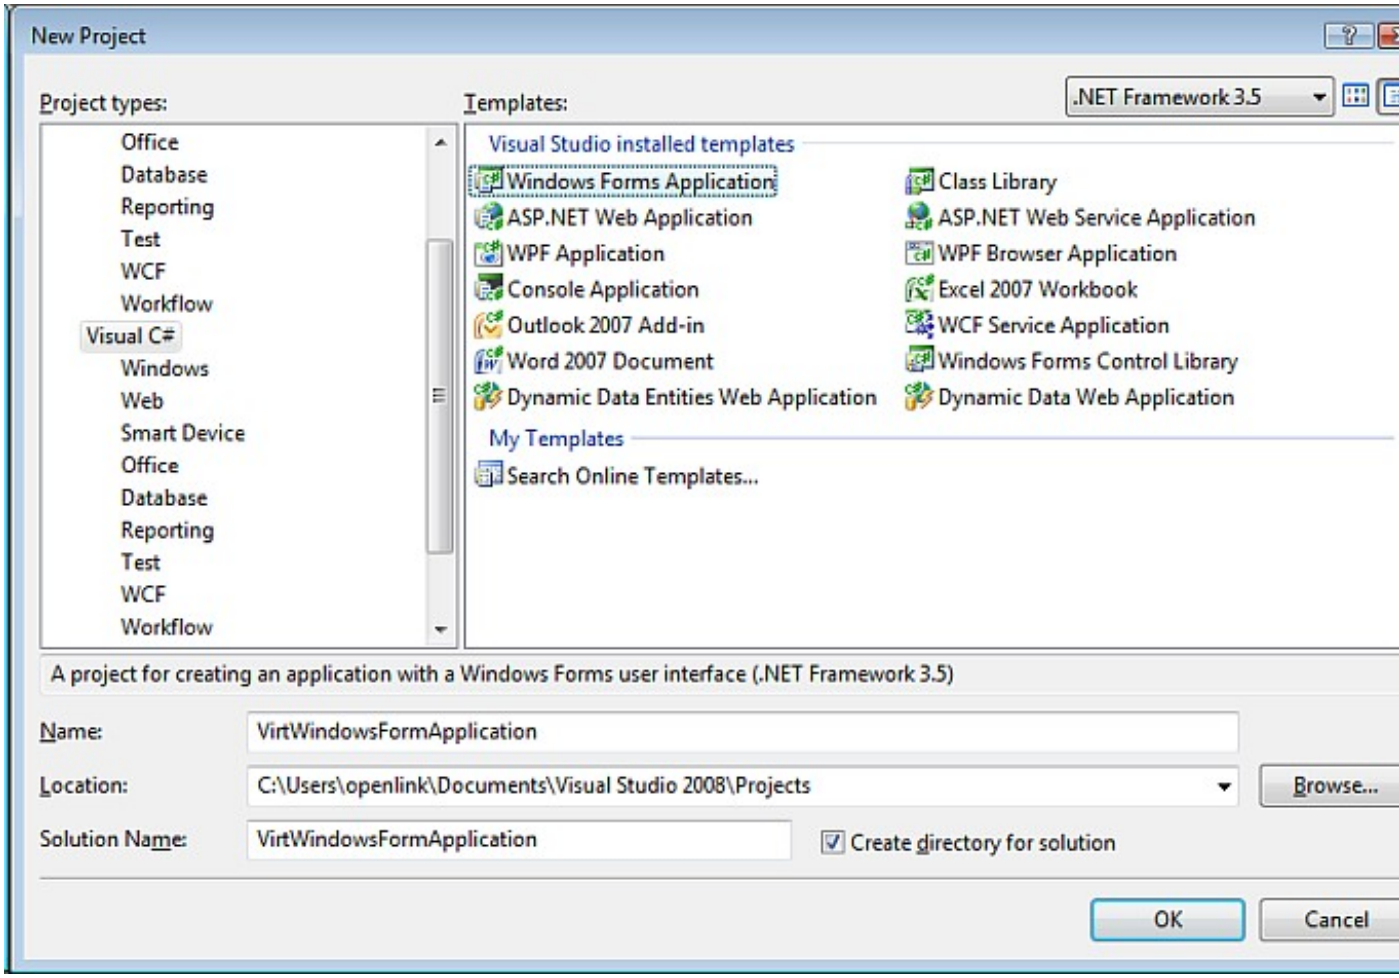
   VirtWindowsFormApplication

   , and click

   OK

   .

   Figure 8.575. Web Application



6. In the

   Toolbox

   , expand

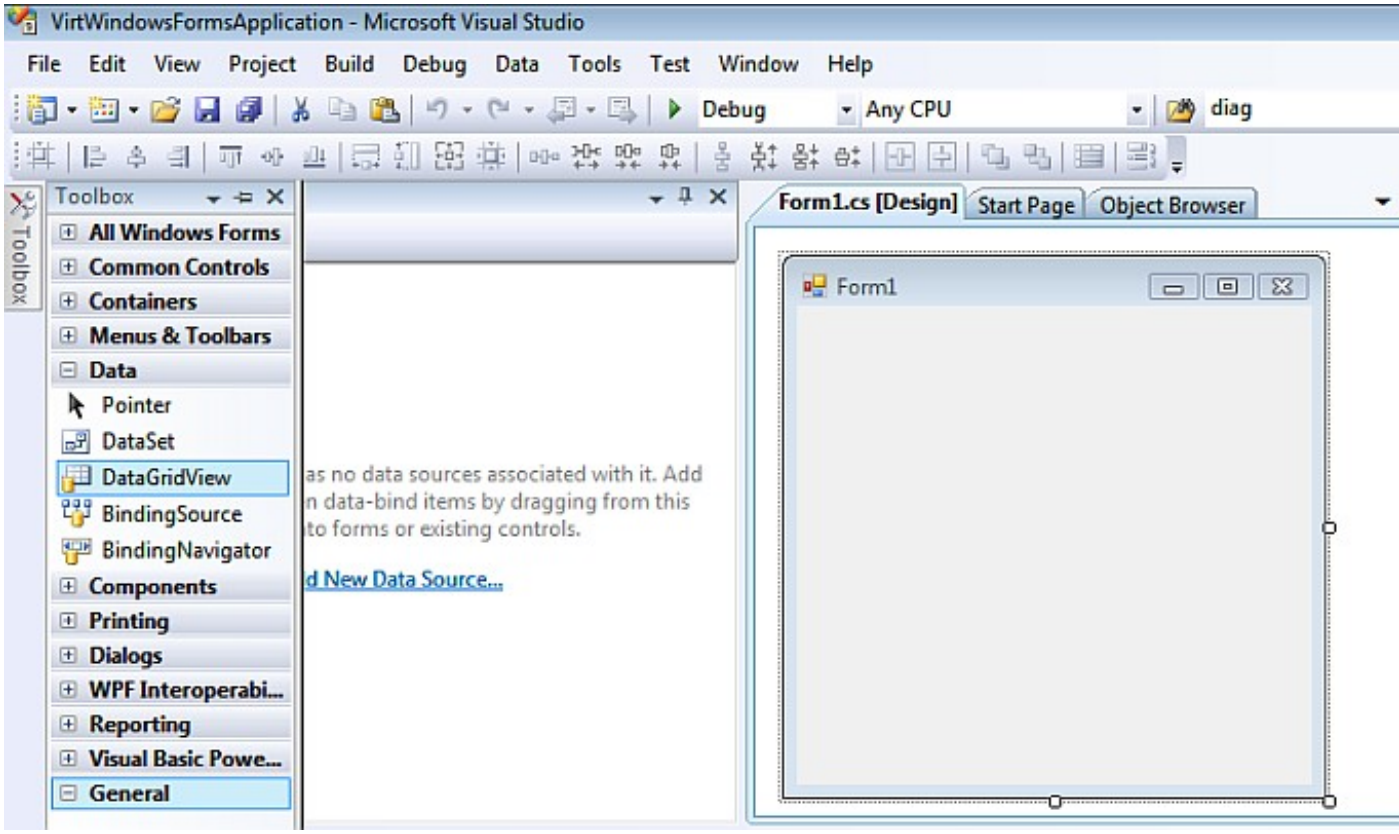
   Data Controls

   , and drag the

   DataGridView

   control onto the form.

   Figure 8.576. Toolbox



7. Click on the little

   arrow

   in the top right of the

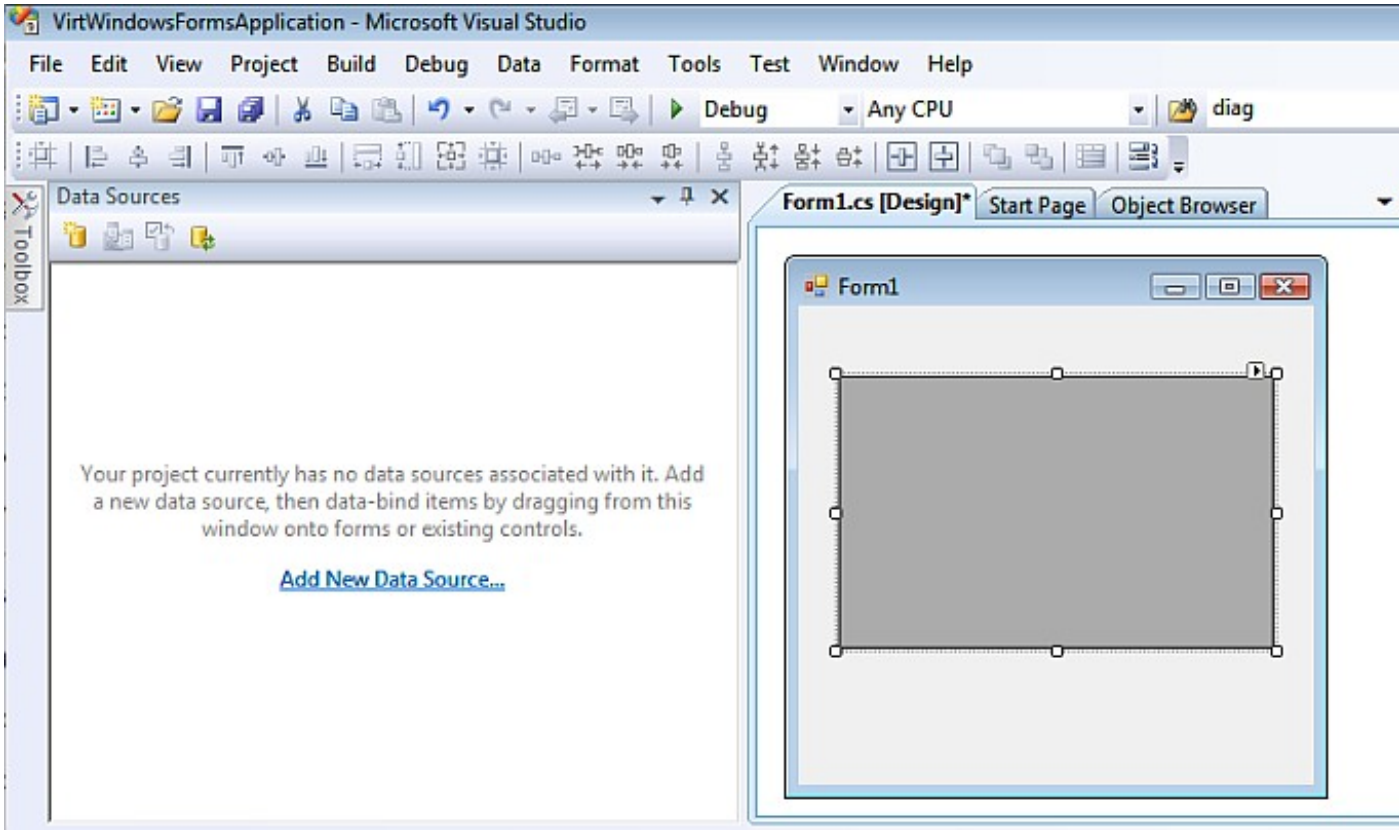
   DataGridView

   control. This loads the

   DataGridView Task

   menu.

Figure 8.577. DataGridView Task

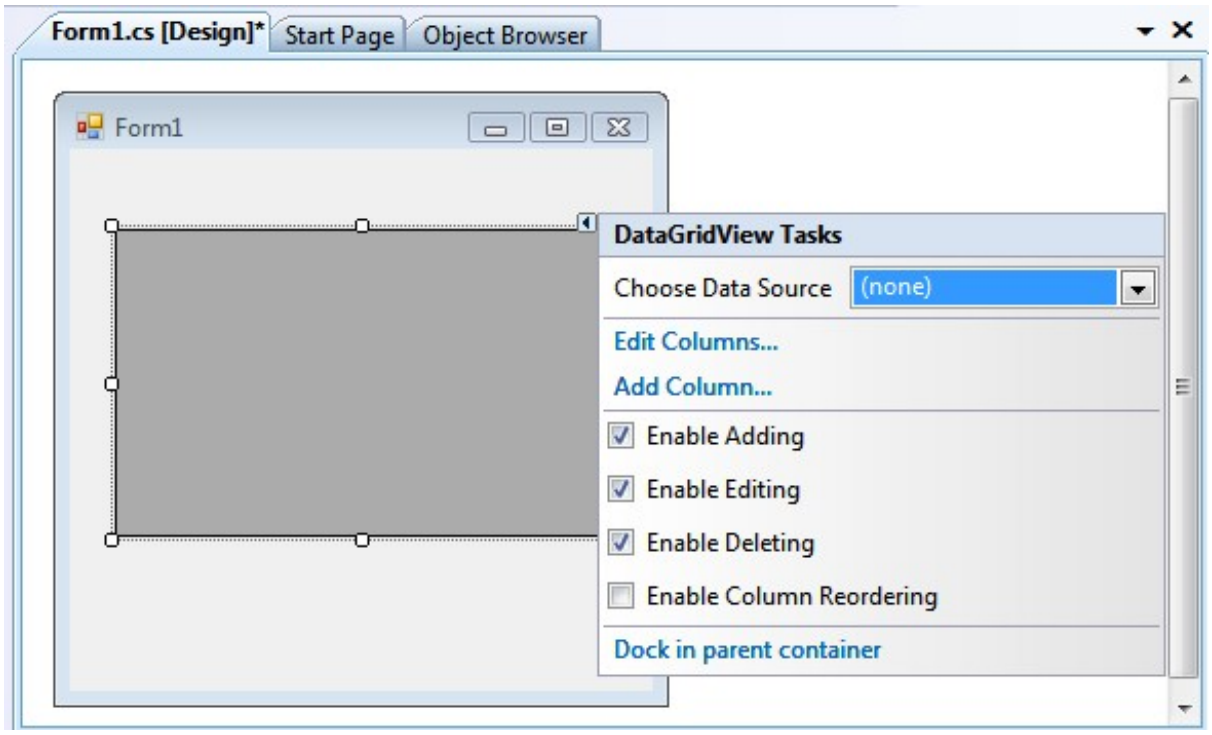


8. Click on the

   Choose Data Source

   list box.

Figure 8.578. Choose Data Source

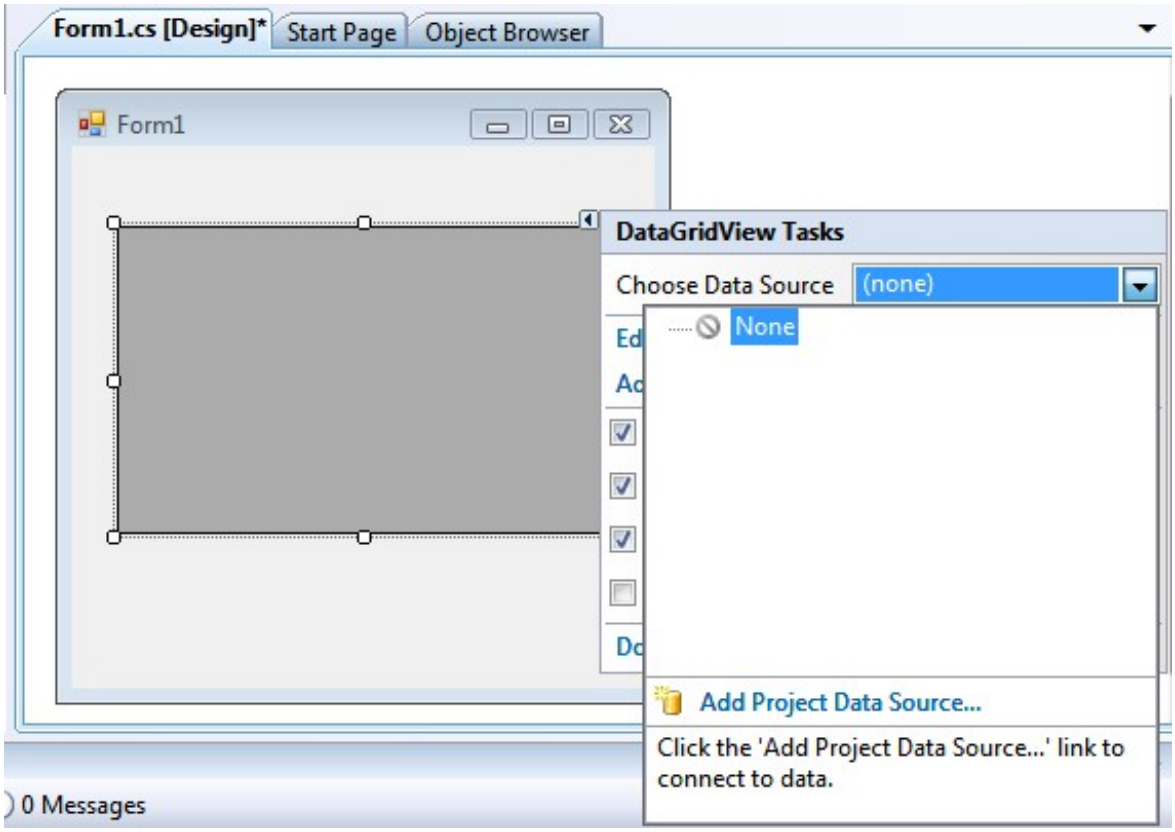


9. Click on the

   Add Project Data Source

link to connect to a data source.

Figure 8.579. Add Project Data Source



10. In the

    Data Source Configuration Wizard

    dialog

    Choose Data Source Type

    page select the

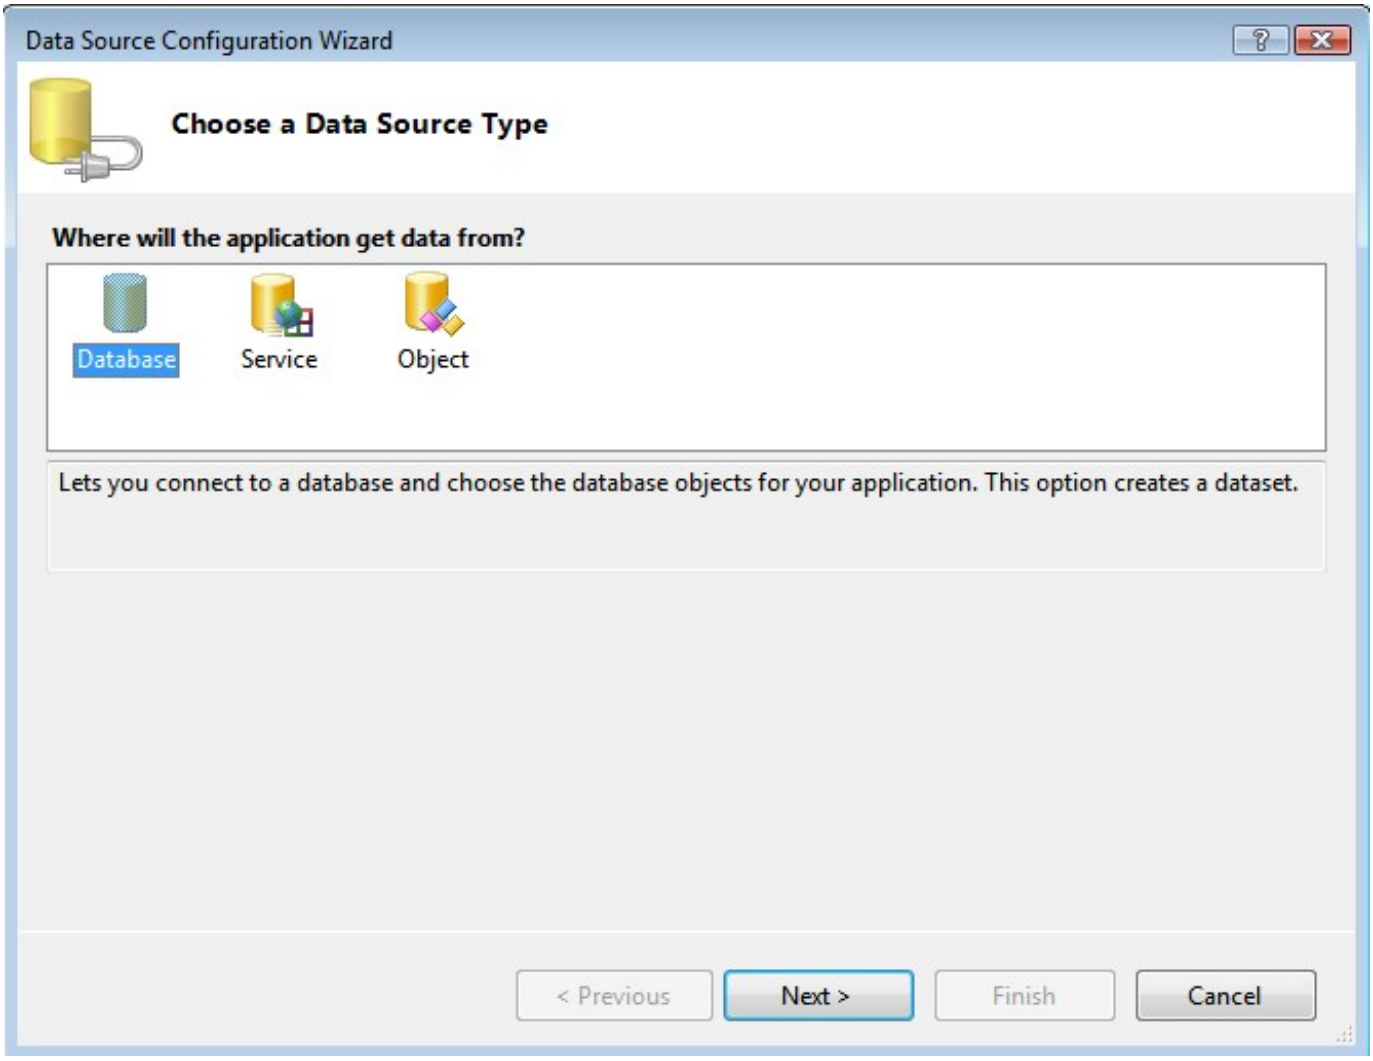
    Database

    data source type and click

    Next

    .

Figure 8.580. Data Source Type



11. In the

    Data Source Configuration Wizard

    dialog

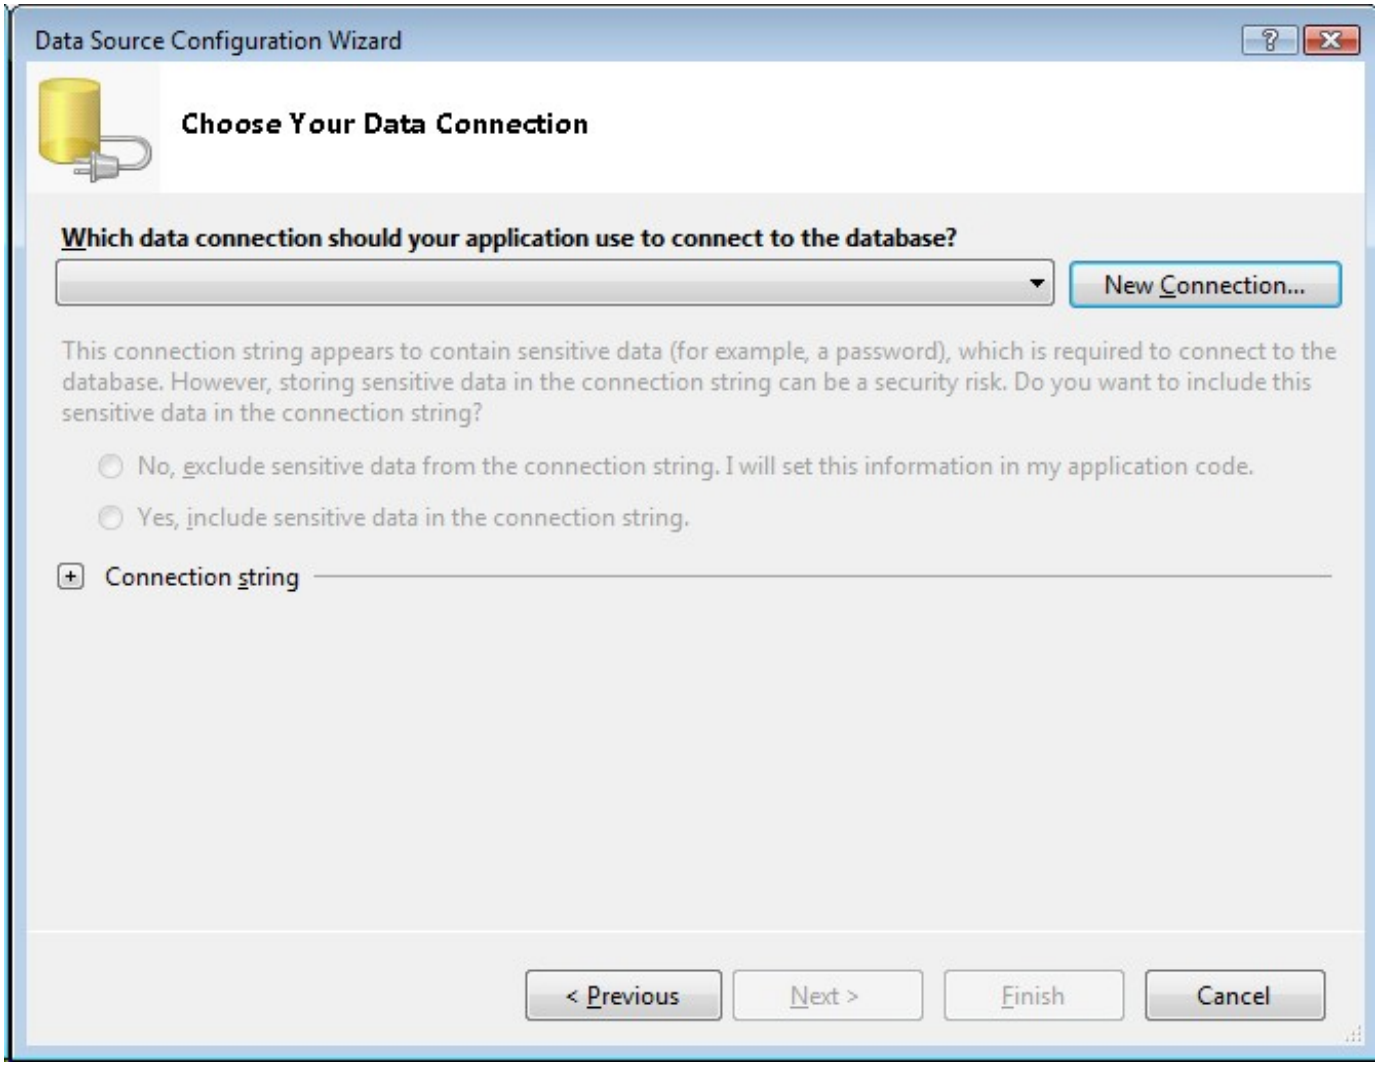
    Choose your Data Connection

    page, select the

    New Connection

    button

Figure 8.581. Data Source Configuration Wizard



12. In the

    Choose Data Source

    dialog, select the OpenLink

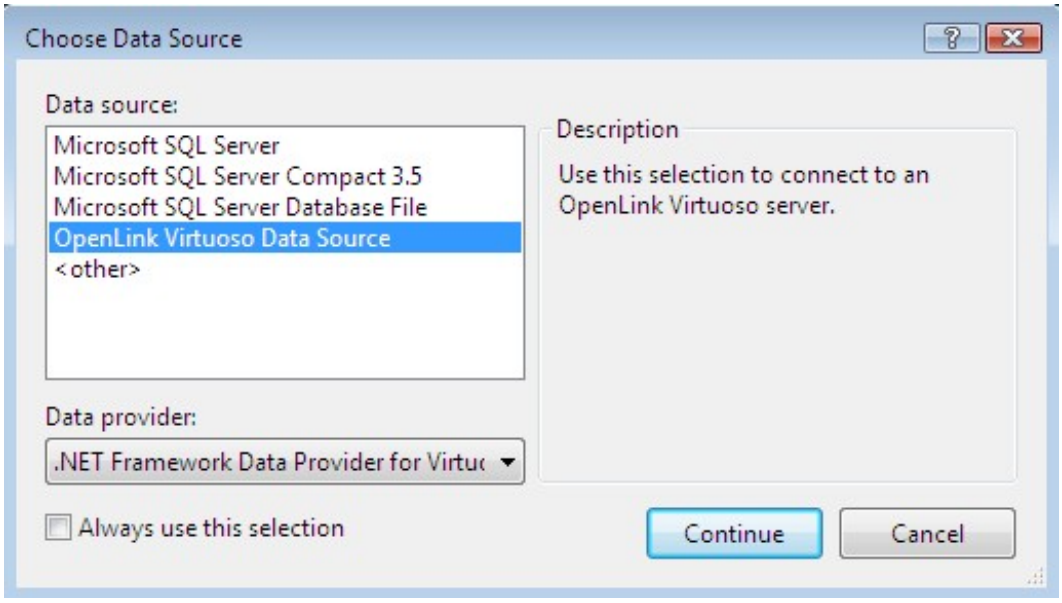
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.582. Data Source



13. In the

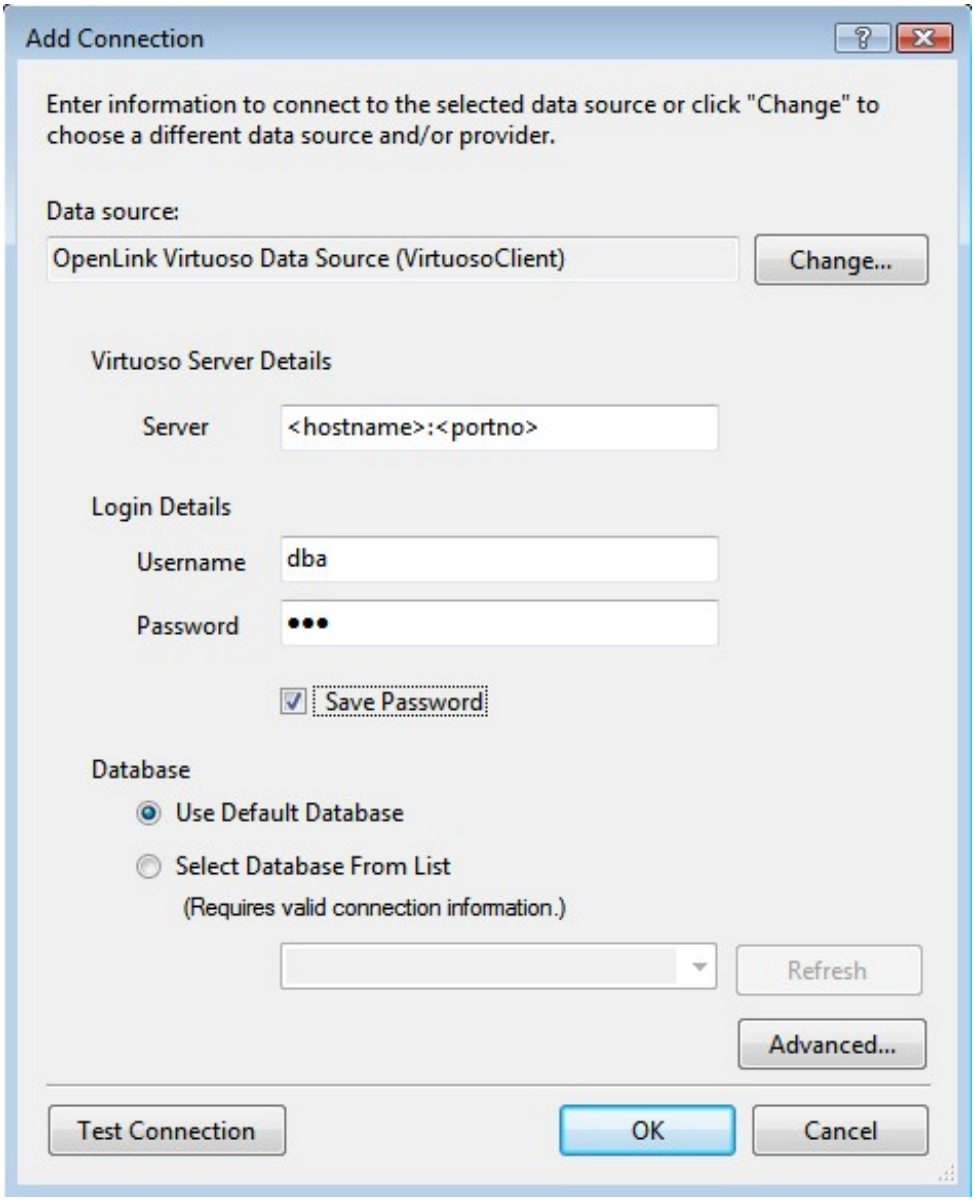
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.583. Connection Properties



14. Select the

8.12.1. Install and configure the Firebird ODBC Driver

The Virtuoso Virtual Database engine uses ODBC as the connectivity mechanism for linking remote database objects into its local schema. Thus a Firebird ODBC Driver must be available with a suitably configured DSN for connecting to the target database.

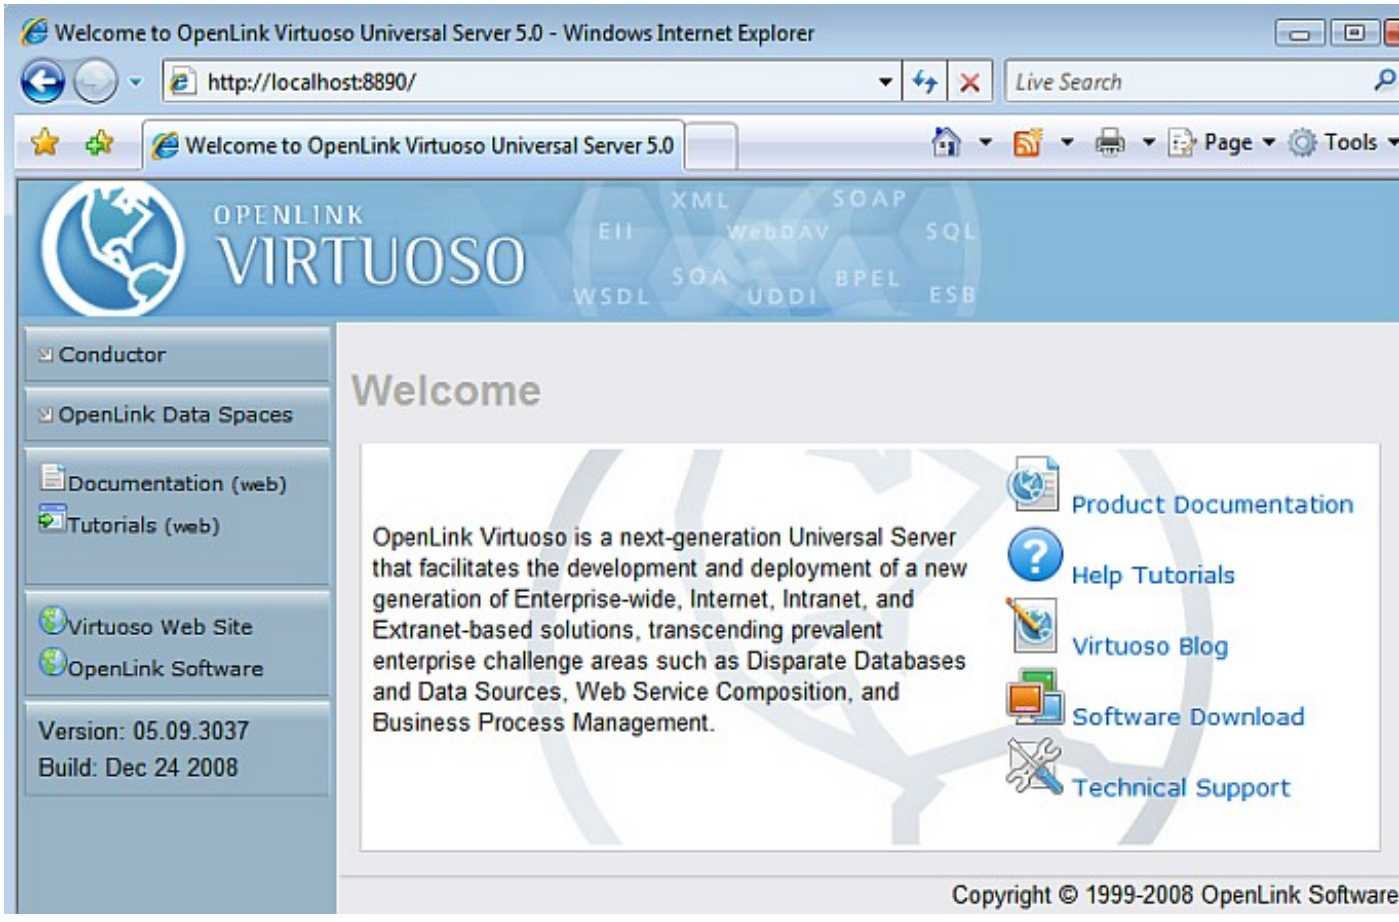
8.12.2. Install and configure OpenLink Virtuoso Universal Server

- Install and configure OpenLink Virtuoso Universal Server

8.12.3. Linking Firebird tables into OpenLink Virtuoso

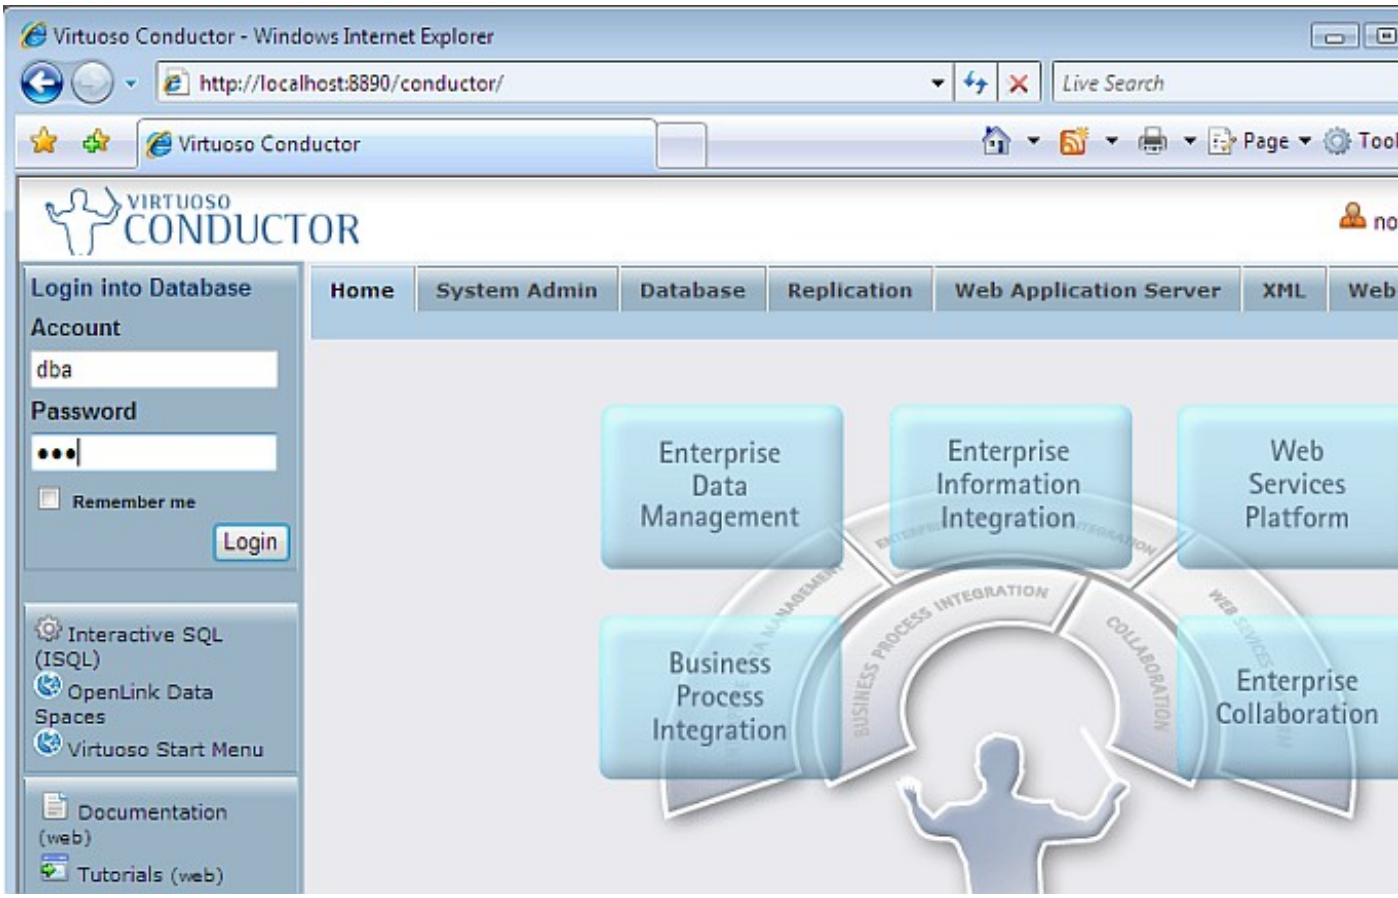
1. Start the Virtuoso Web User Interface

   Figure 8.592. Start



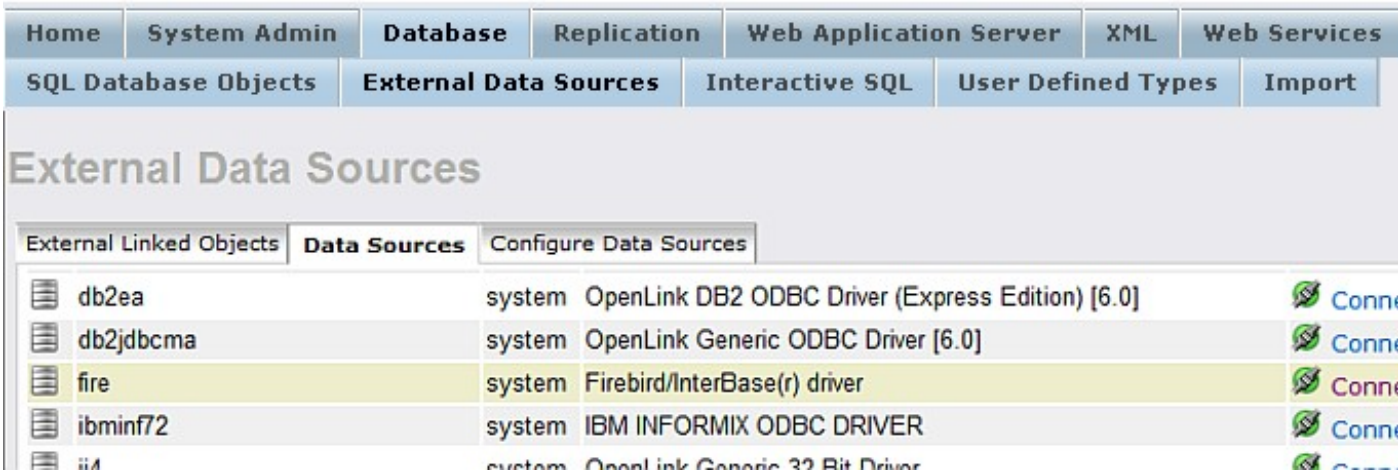
2. Select the "Conductor" link in the Left Frame and Login as the "dba" user.

Figure 8.593. Conductor



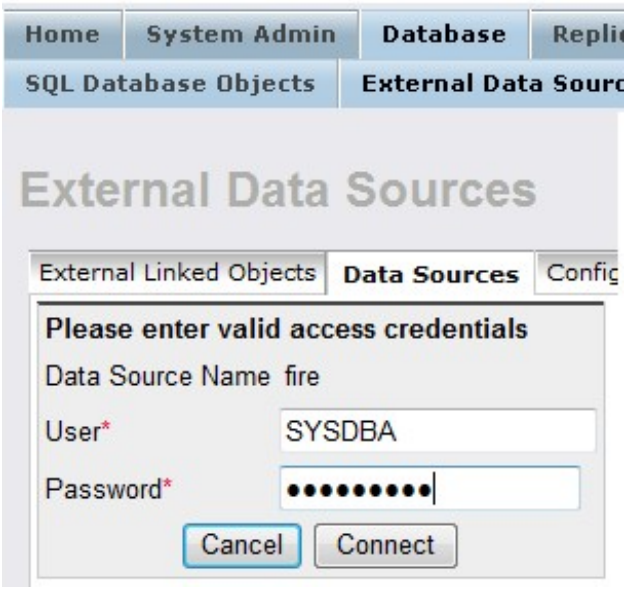
3. Select the "Databases" -> "External Data Source" -> "Data Sources" tab menu items

Figure 8.594. Databases



4. Select the "Connect" button for the "fire" Firebird DSN.

Figure 8.595. Connect

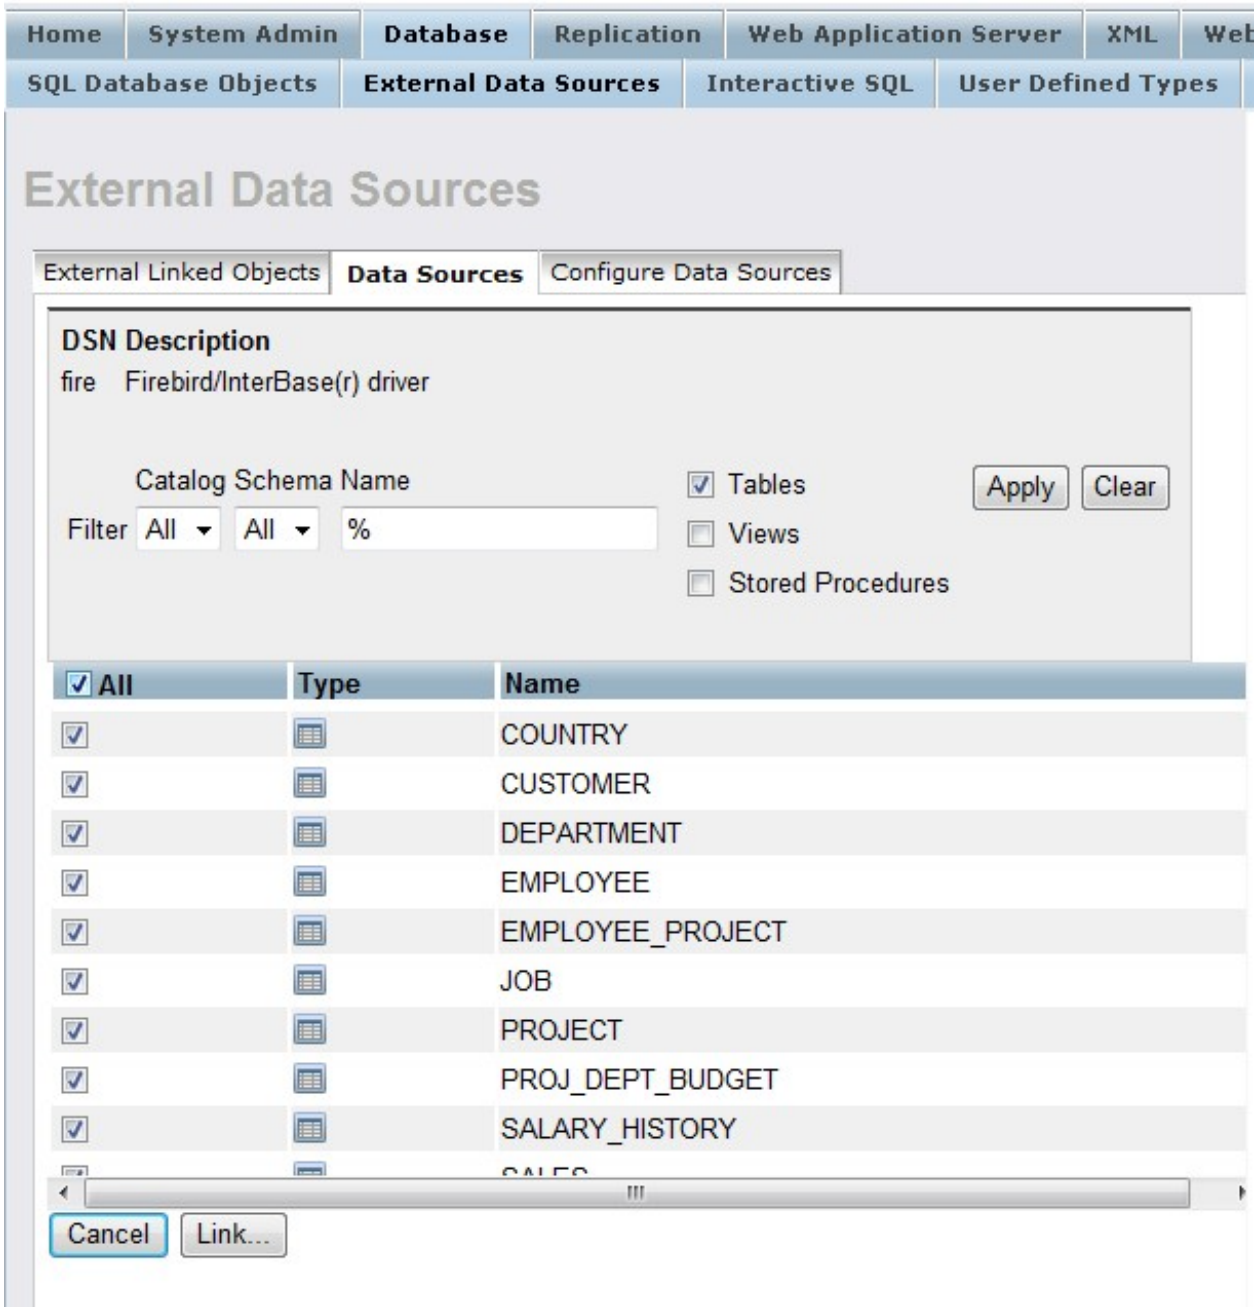


5. On successful connection Select the "Link Objects" button to obtain a list of available tables

Figure 8.596. Link Objects

6. Select all the tables that are part of the "employee" catalog.

Figure 8.597. Select all tables

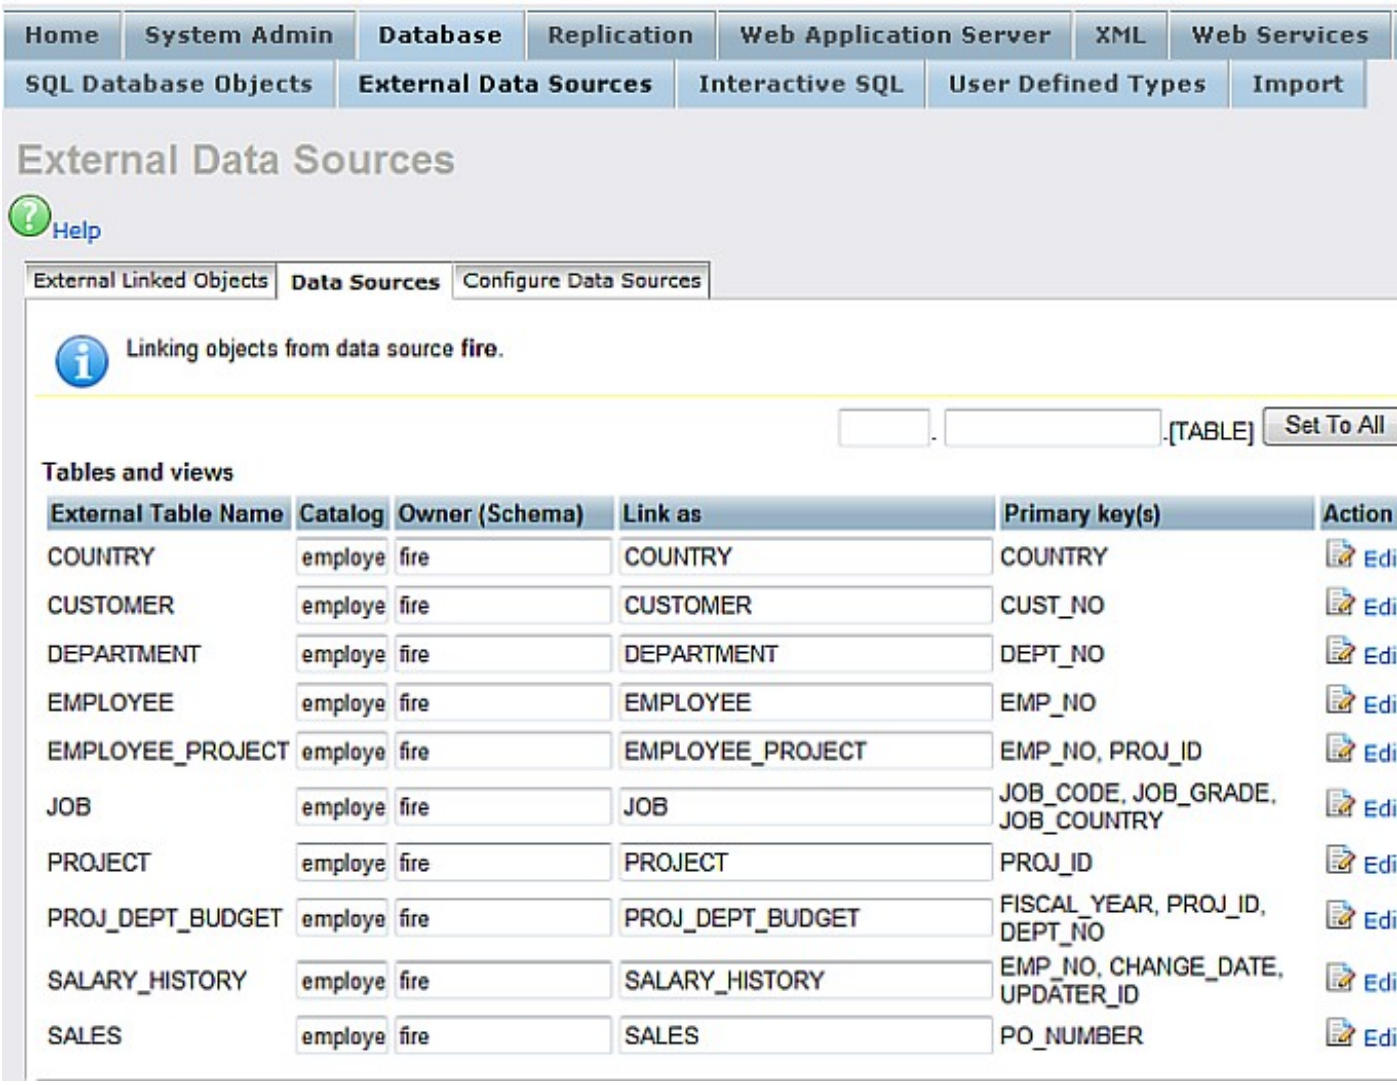


7. Change the Catalog for each table to be "employee" using the "Set All" button.

Figure 8.598. Catalog

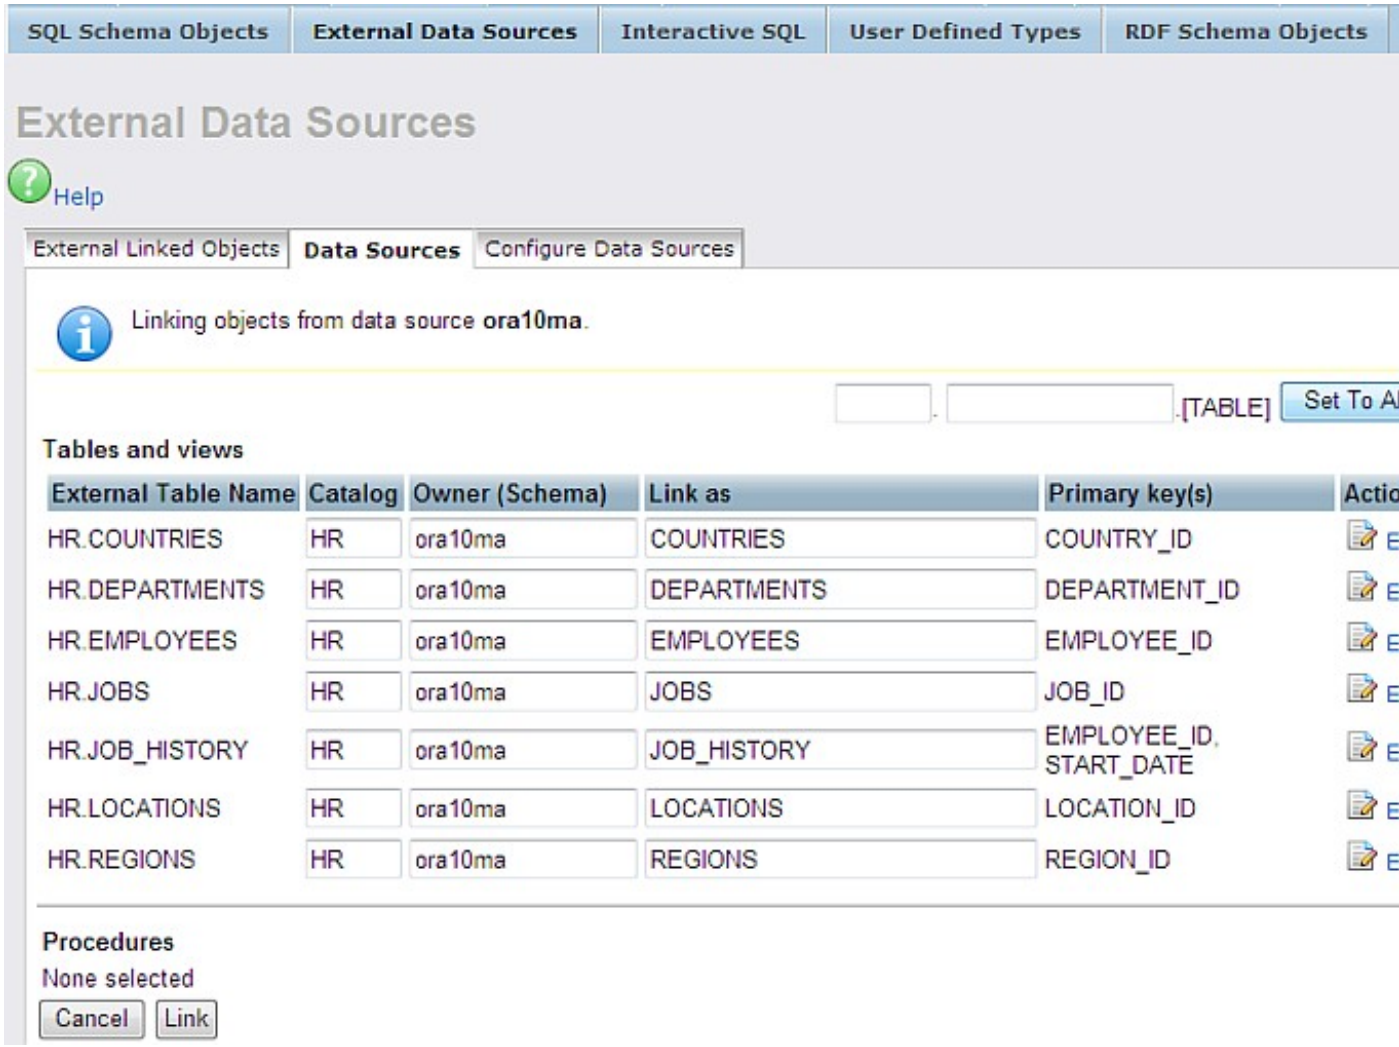
8. All the catalog names are changed to be "employee".

Figure 8.599. catalog names



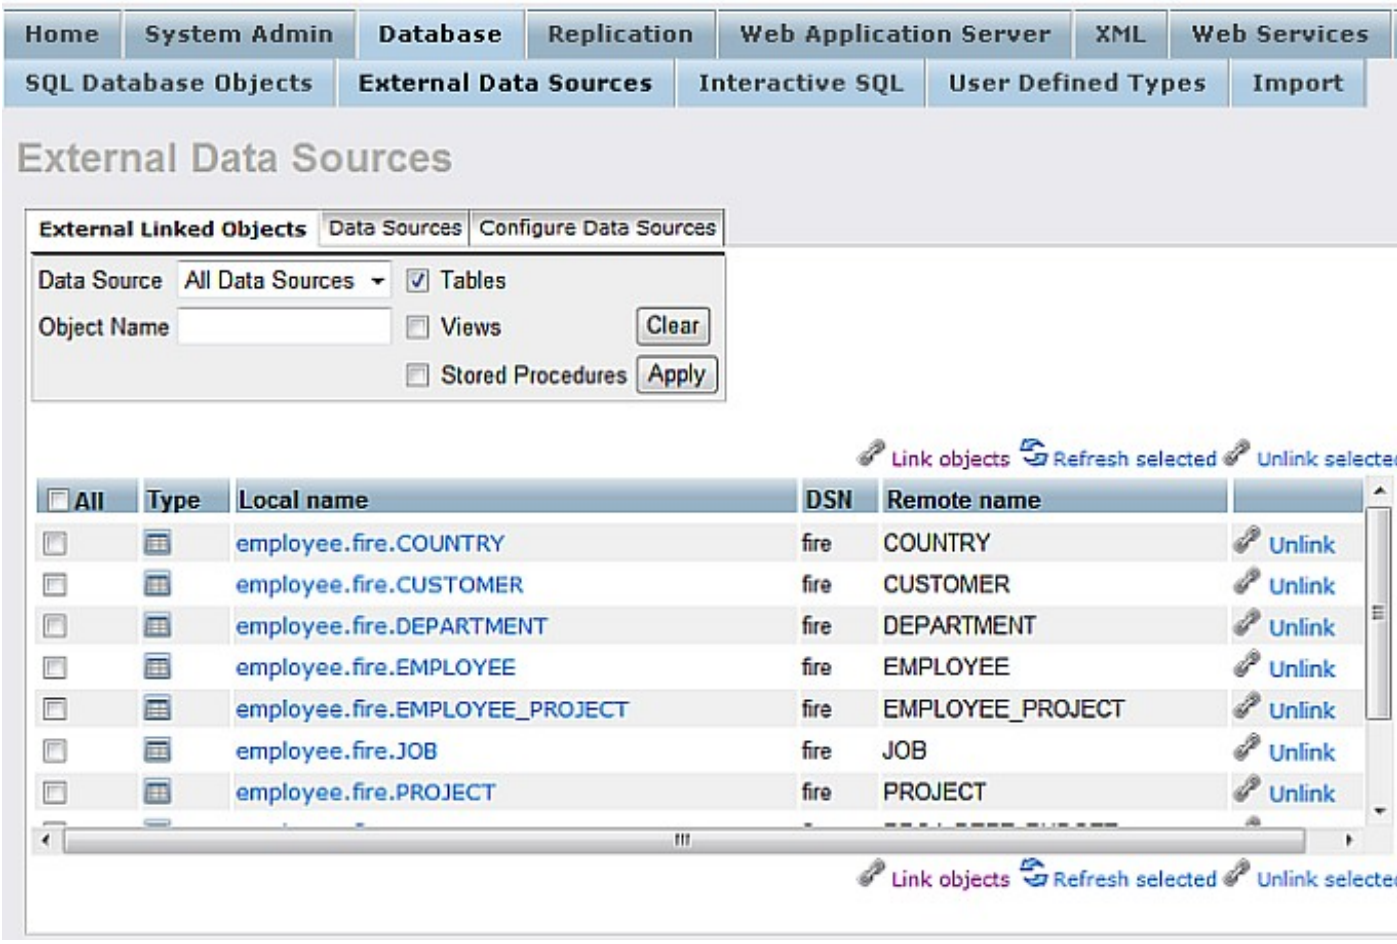
9. Select the "Link" button to link the selected tables into Virtuoso

Figure 8.600. "Link" button



10. On completion of the Link process the tables will be displayed in the "External Linked Objects" tab.

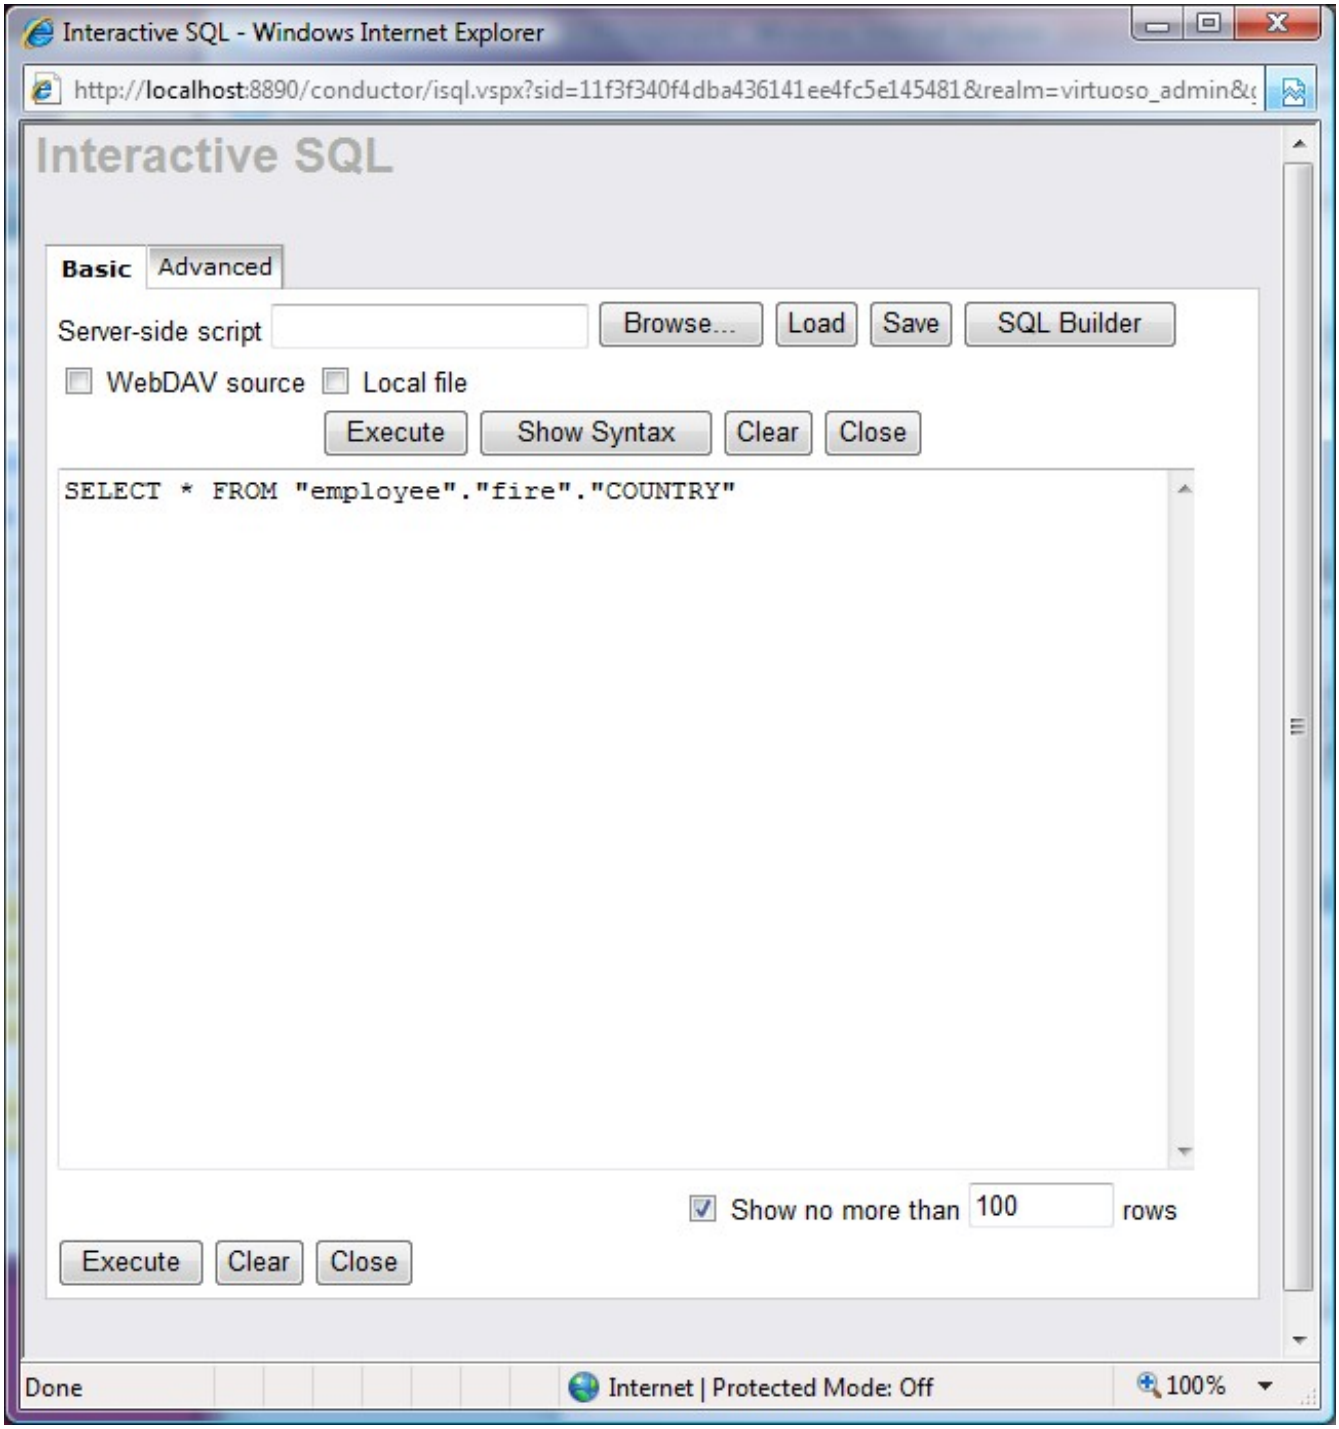
Figure 8.601. Completion



11. At this point you can test the remotely linked tables by clicking on the link that accompanies each table. e.g. employee.fire.COUNTRY.

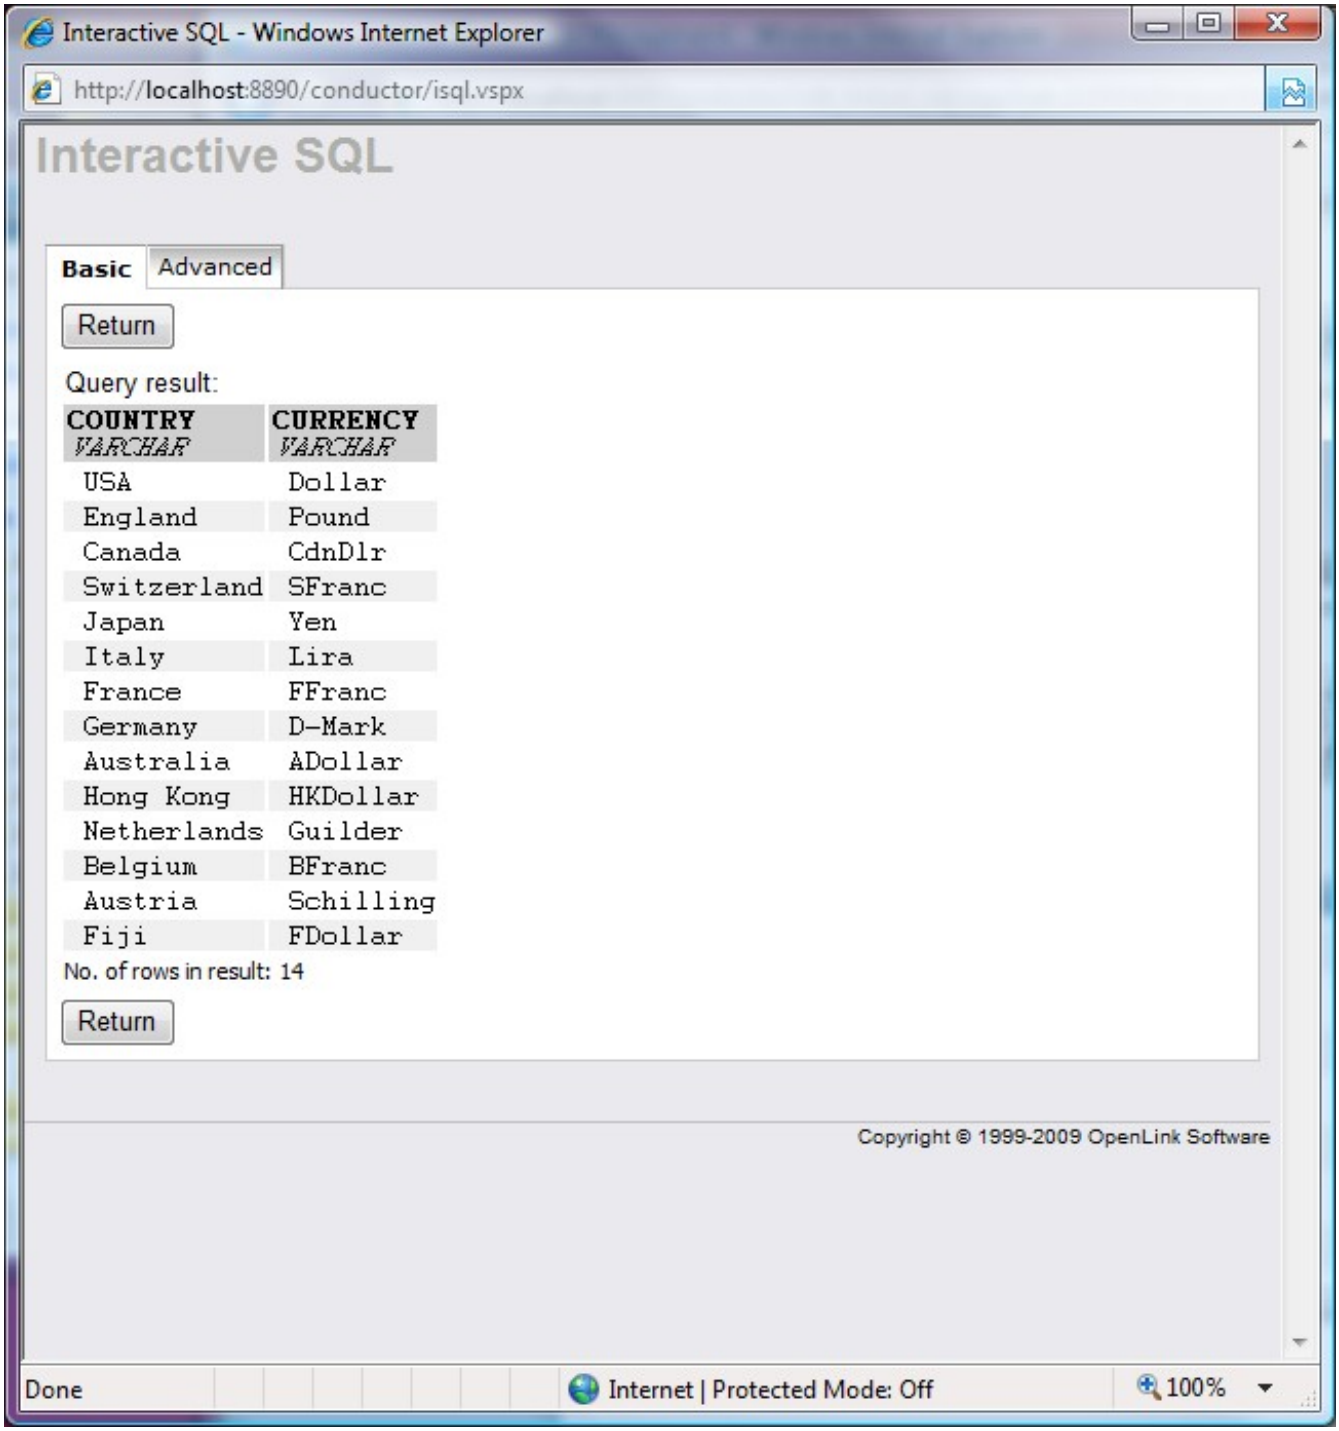
    This will display the Interactive ISQL interface which will have been already populated with a suitable SQL statement.

Figure 8.602. remotely linked tables



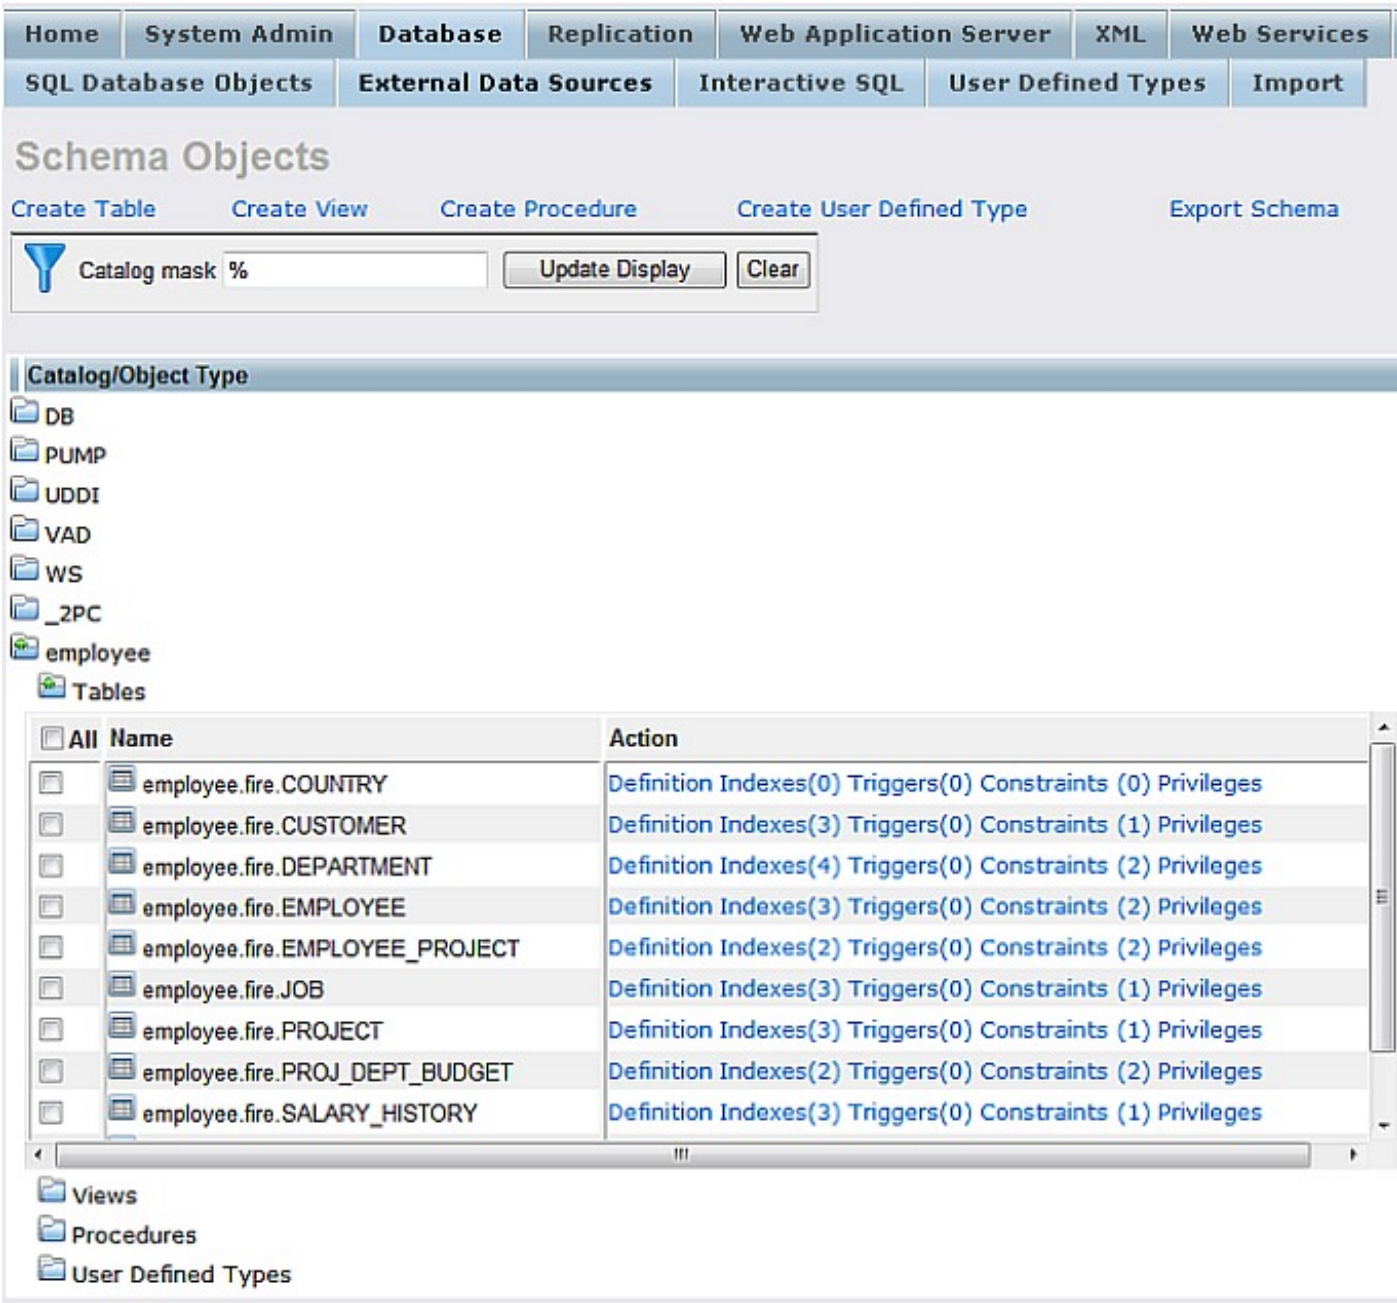
12. Select Execute to see data from the remotely linked table.

Figure 8.603. Execute



13. The tables can also be viewed as part of the Virtuoso "SQL Schema Objects" under the "employee" catalog name.

Figure 8.604. SQL Schema Objects



The Link process is now complete enabling the tables to be queried as if part of the Virtuoso Schema.

8.12.4. Creating EDM in Visual Studio 2008

The following steps can be used to create an Entity Data Model (EDM) for the Firebird employee database:

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.605. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

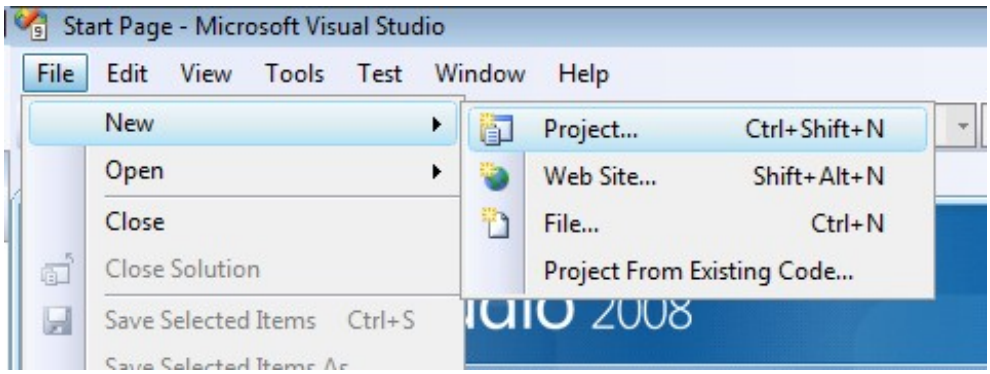
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.606. Web Application



3. When the New Project window appears, choose either

.

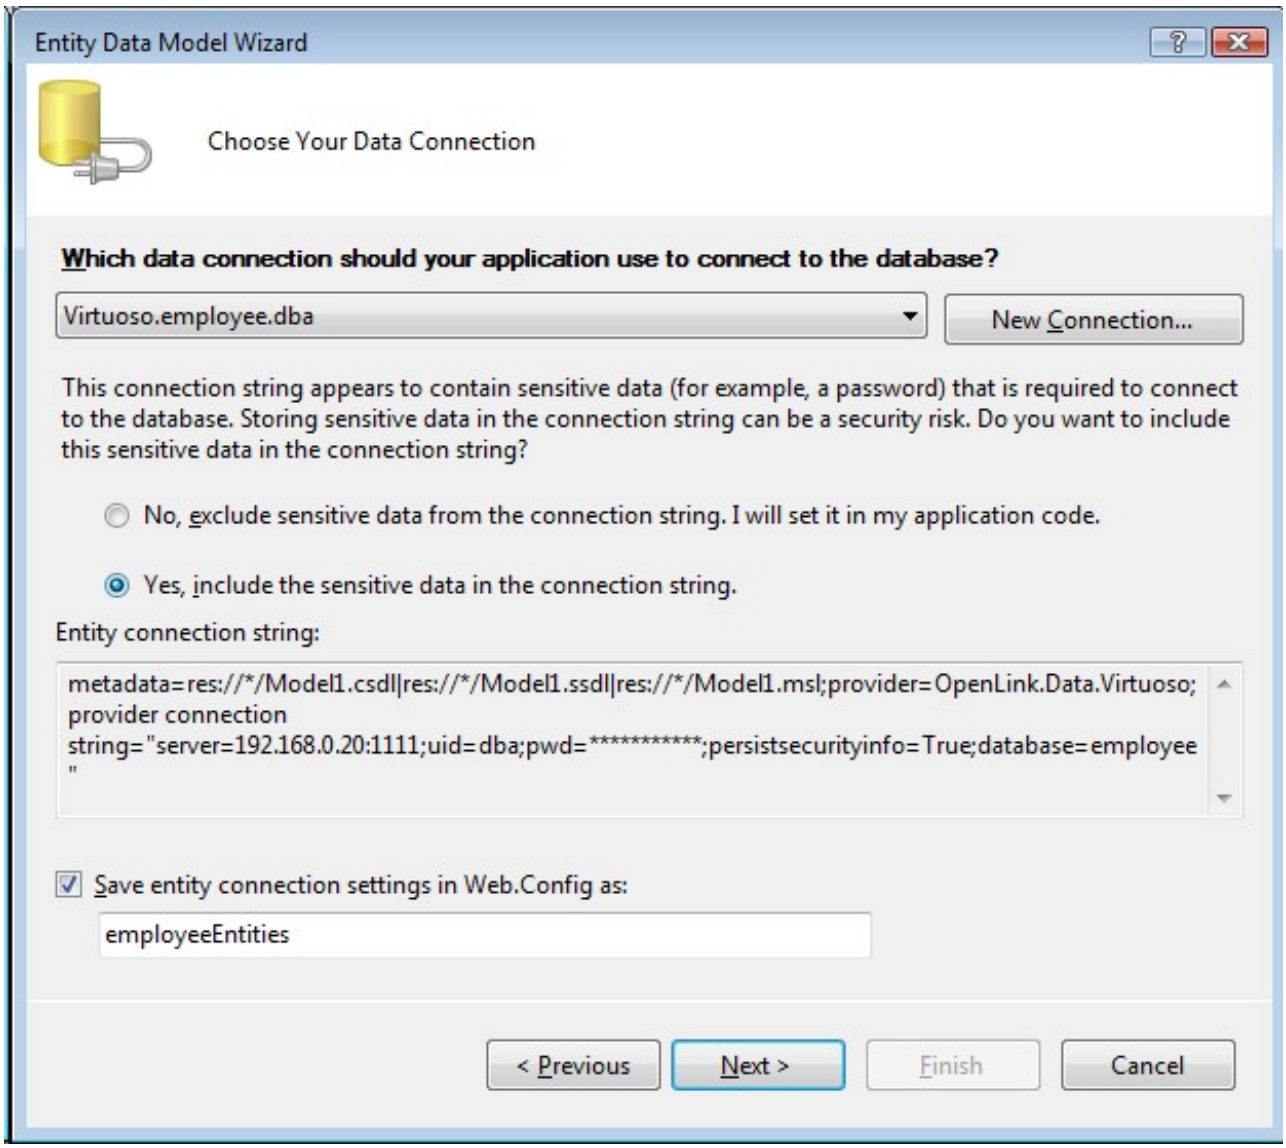
Figure 8.617. entity connect string



16. In the

Choose your Database Objects

page select the

Tables

check box to select all tables in the employee catalog for addition to the Entity Data Model. Set the

Model Namespace

to

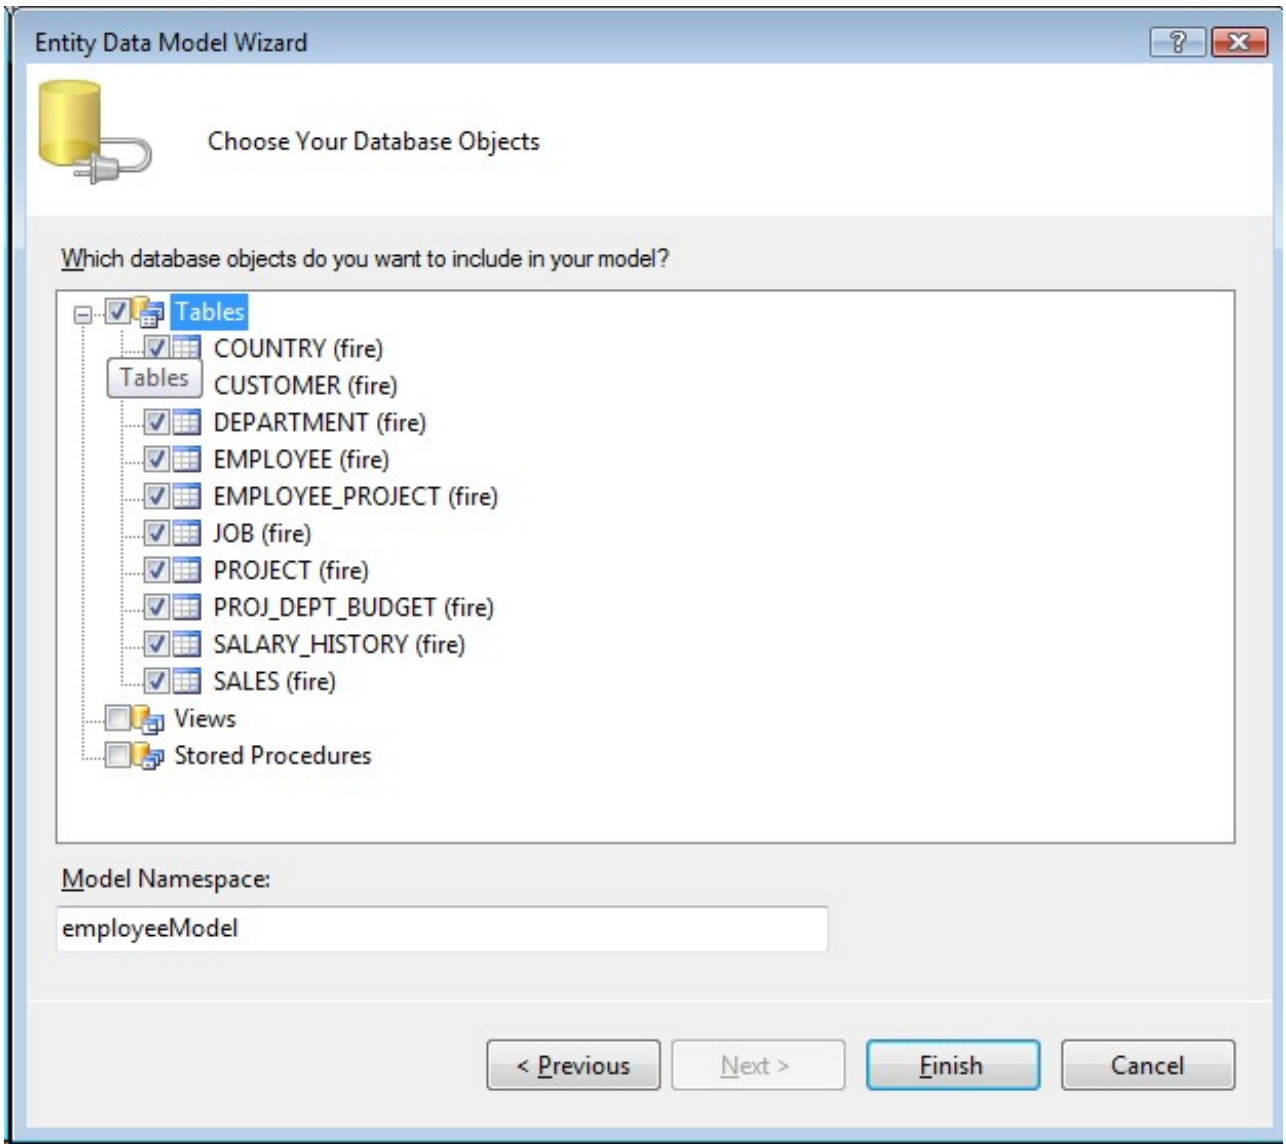
employeeModel

and click

Finish

.

Figure 8.618. Database Objects

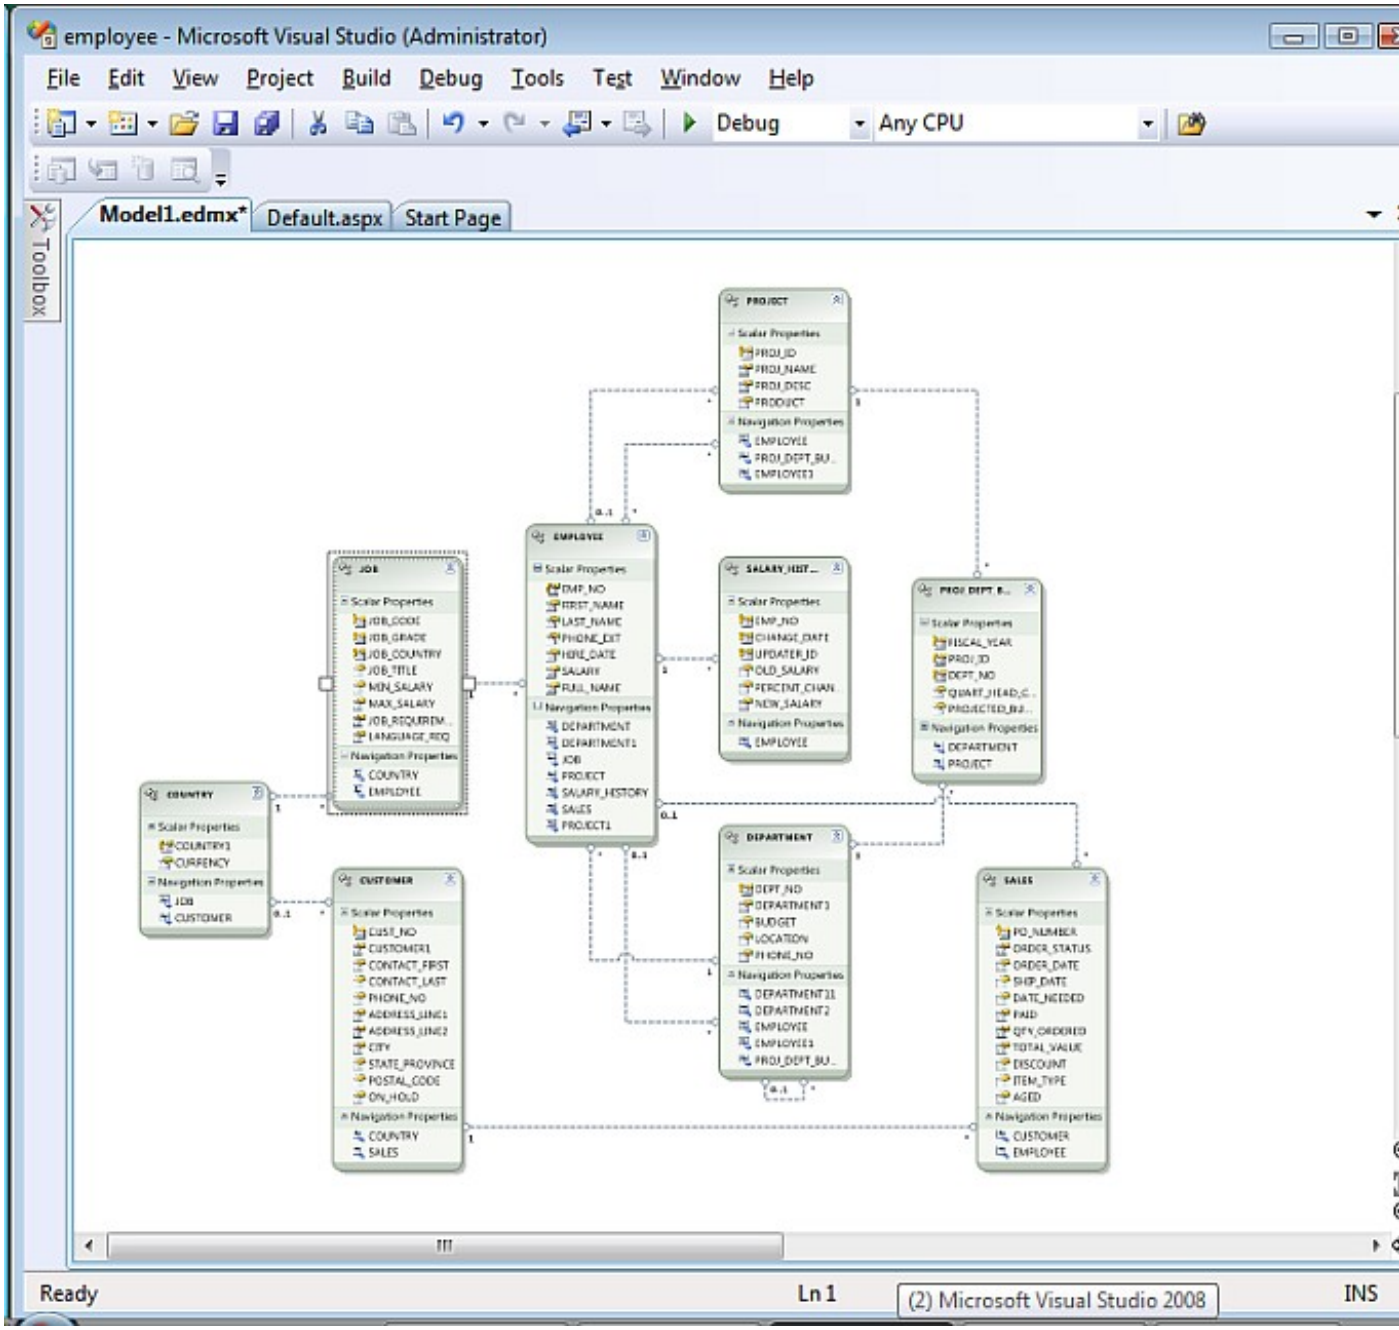


17. The

Model1.edmx

EDM will be created with the tables and relationships displayed in the Visual Studio IDE

Figure 8.619. Model1.edmx



Creation for the Entity Data Model for the Firebird employee database is now complete.

8.12.5. Using EDM to create Entity Framework based applications

Now that a Microsoft Entity Data Model has been created for the Firebird employee database, Entity Framework applications can be created to make use of it.

Entity Frameworks based ADO.NET Data Service

An ADO.Net Data Service for the Firebird tables can be created using the Entity Data Model created in the Creating EDM in Visual Studio 2008 section .

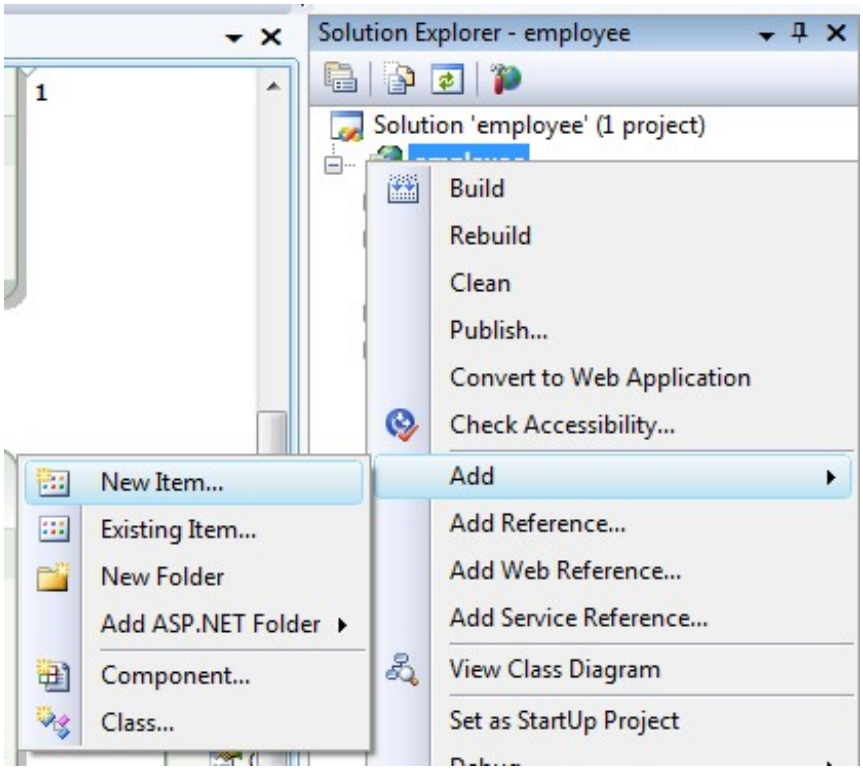
1. Open the

   employee

   project created in the Creating EDM in Visual Studio 2008 section .

2. Right click on the employee project name in the Solution Explorer pane, then select the Project -> Add New Item menu option.

Figure 8.620. employee



3. The

Add New Item

dialog will appear. Choose the

ADO.NET Data Service template

. Give it the name

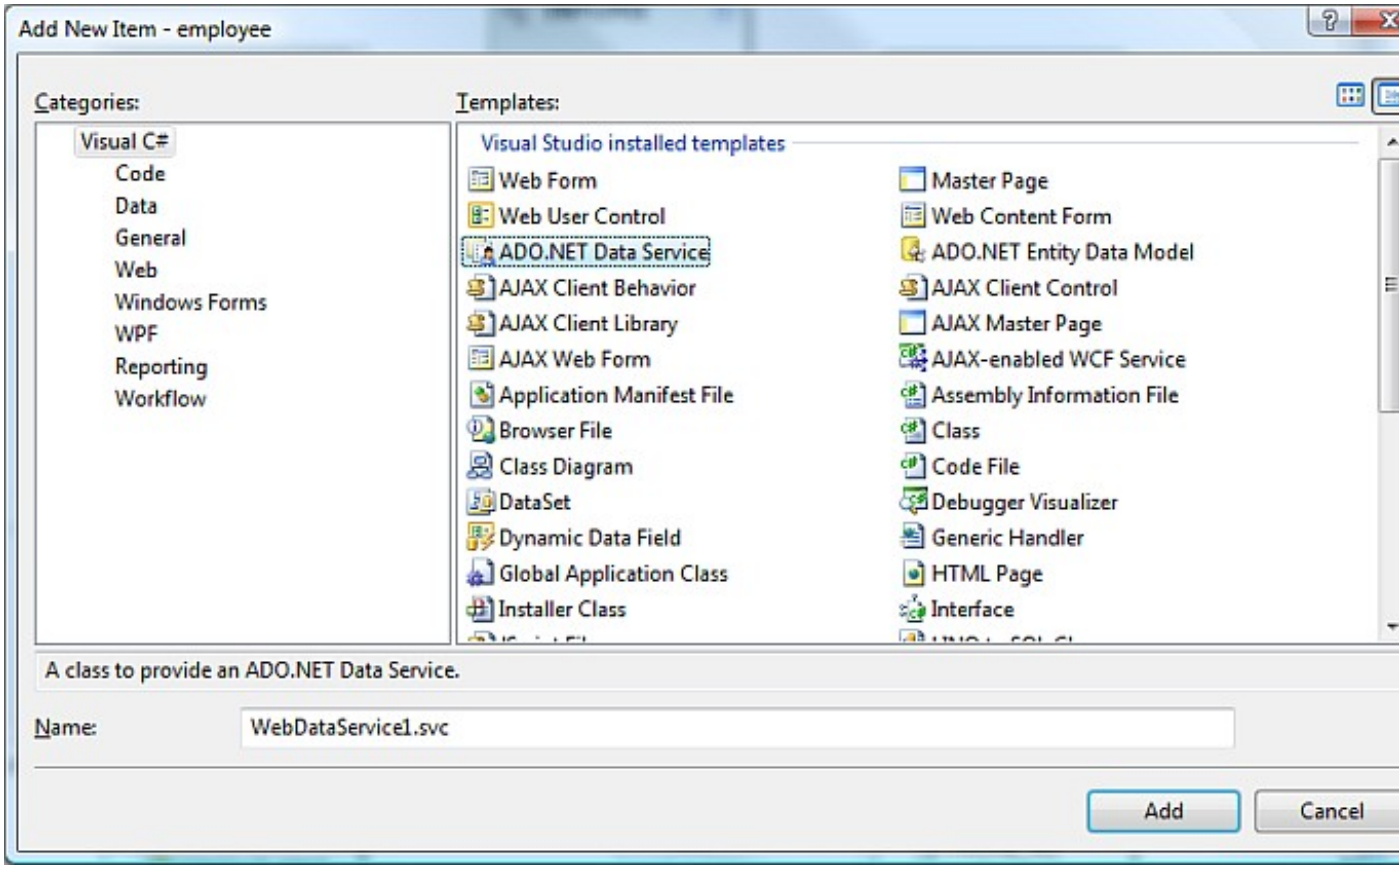
WebDataService1.svc

, and click

Add

to create the ADO.Net Data Service.

Figure 8.621. Add New Item



4. In the newly created

   WebDataService1.svc.cs

   Data Service file, add the data source class name of

   employeeEntities

   (note this is the name set in the Creating EDM in Visual Studio 2008 section) as the

   DataService

   name. Enable the access to the Data Service by adding the entry

   config.SetEntitySetAccessRule("", EntitySetRights.All);*

   in the

   InitializeService

   method.

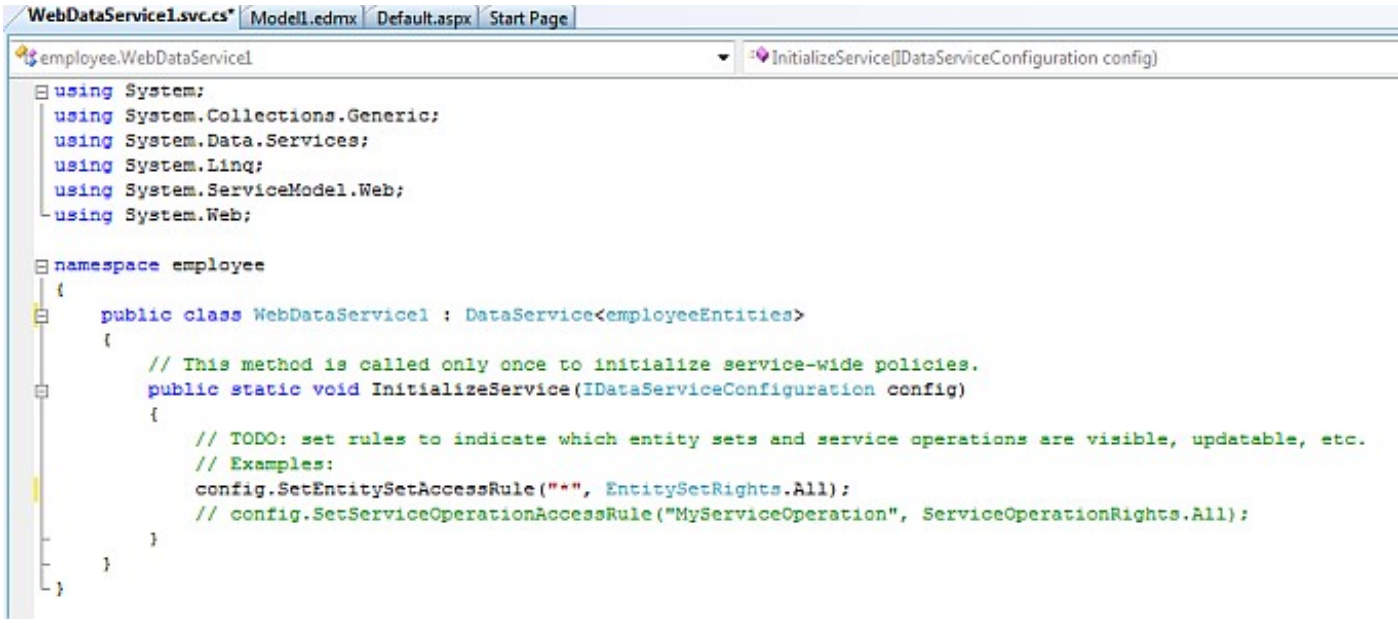
```
// C#

using System;
using System.Web;
using System.Collections.Generic;
using System.ServiceModel.Web;
using System.Linq;
using System.Data.Services;

namespace SimpleDataService
{
    public class Northwind : DataService<employeeEntities>
    {
        public static void InitializeService(IDataServiceConfiguration  config)
```

```
            {
                config.SetEntitySetAccessRule("*", EntitySetRights.All);
            }
        }
    }
```

Figure 8.622. WebDataService1.svc.cs

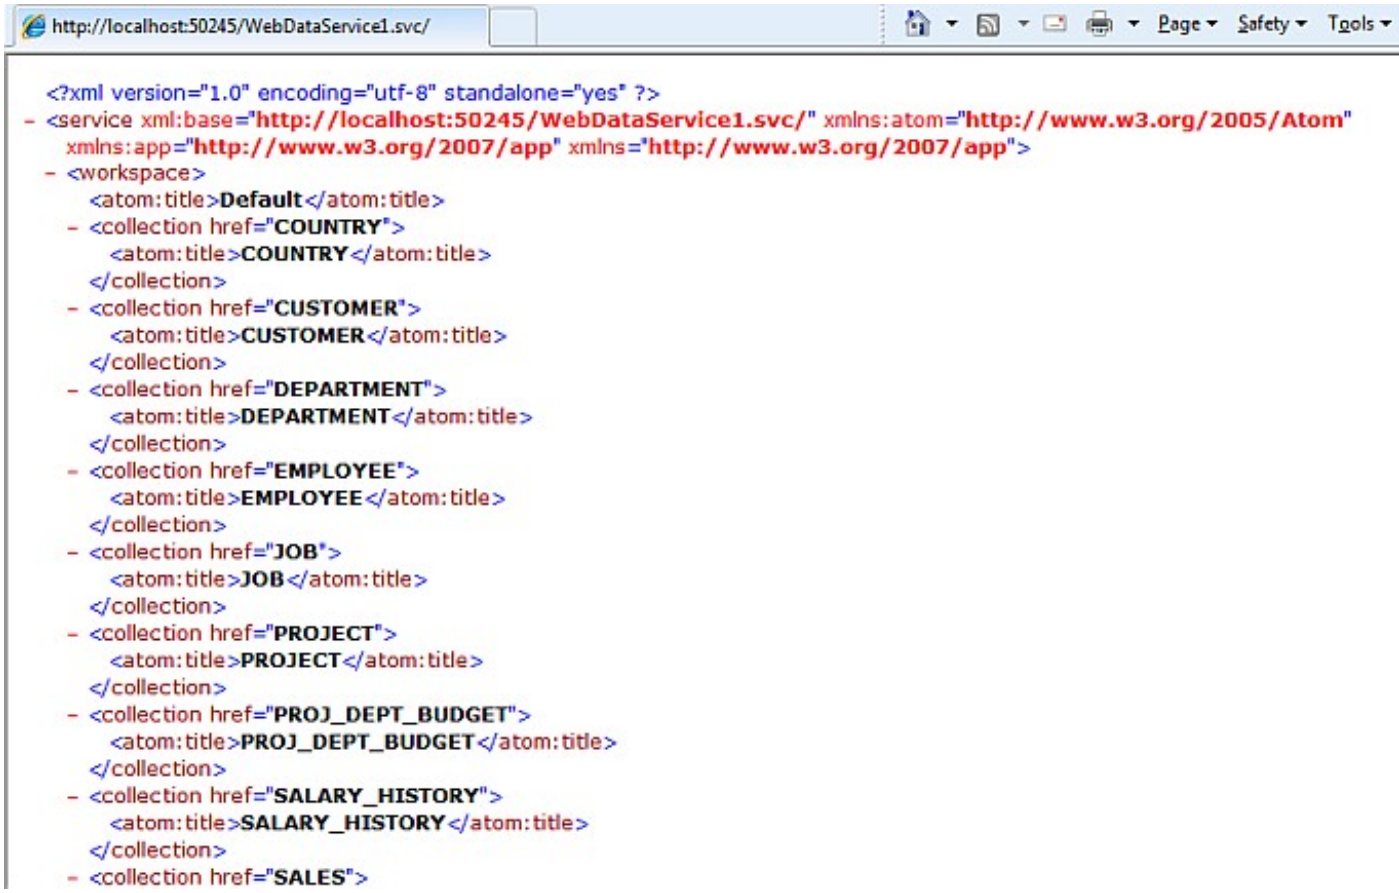


5. To test the Data Service, simply hit

   Ctrl+F5

   within Visual Studio. This will start the development web server, run the Data Services server inside and load a Web browser page displaying the list of available tables/entities for the employee database catalog.

   Figure 8.623. Data Service test



6. To access a specific entity instance like the

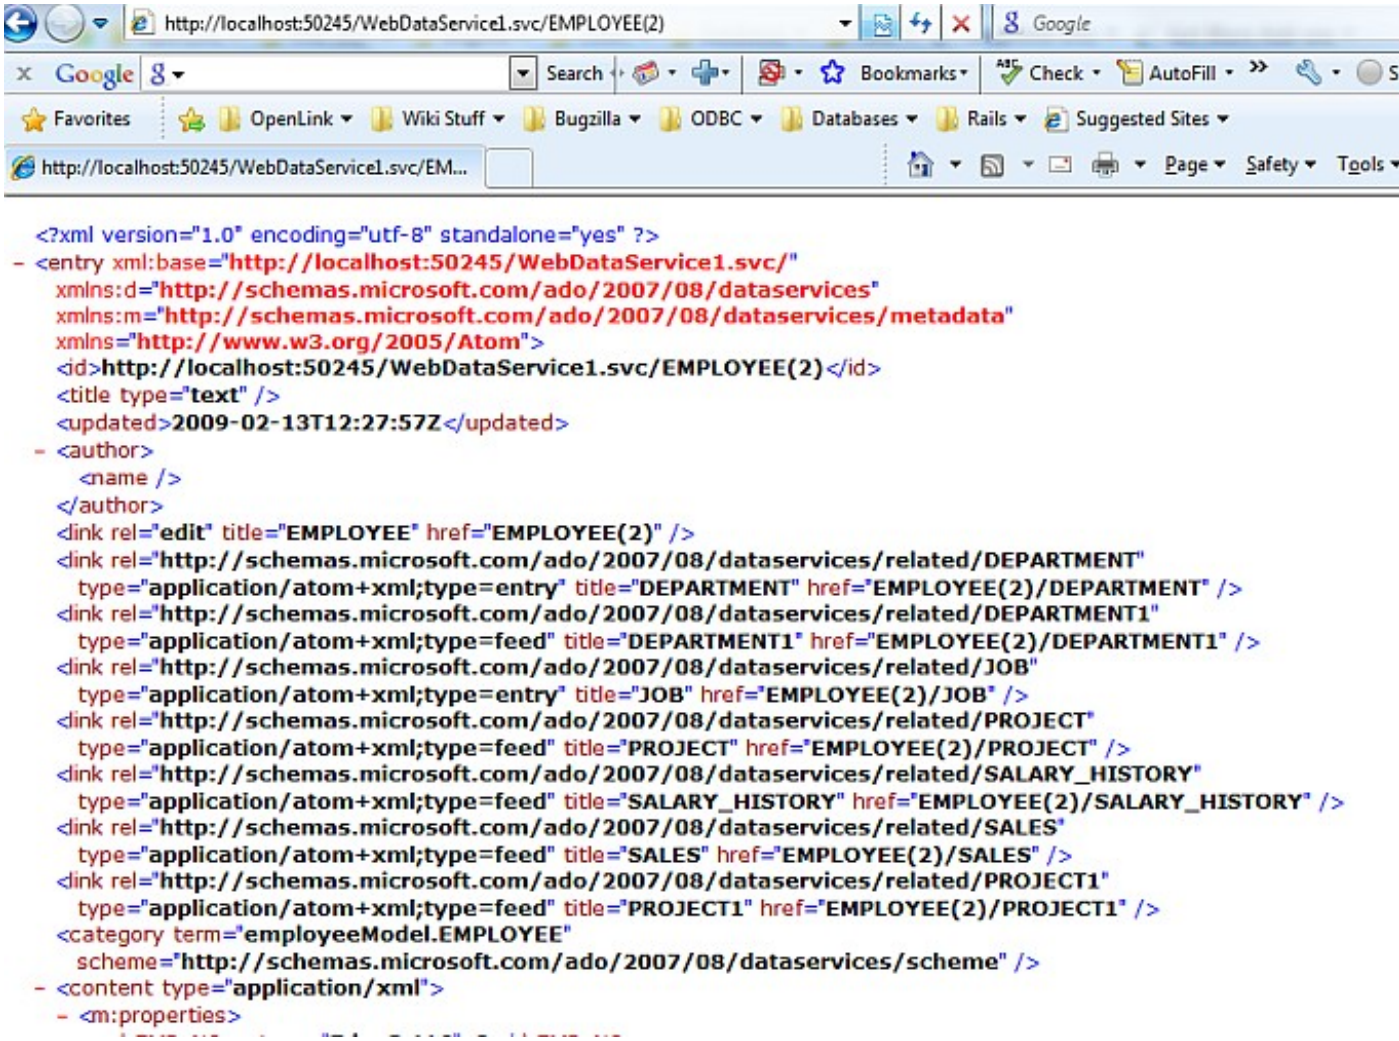
   EMPLOYEE

   table employee number

   2

   record, use this convention http://host/vdir/WebDataService1.svc/EMPLOYEE(2) .

   Figure 8.624. EMPLOYEES



Notes:

1. *Important*

   - To view

   Atom

   (the default format returned by an ADO.NET Data Service) in Internet Explorer, you must first ensure that

   Feed Reading View

   is turned

   off

   . This can be done on the

   Content tab

   of

   Tools in Internet Options

   .
2. If a Data Services entity instance URI page fails to load you can turn

Verbose

errors on by adding

config.UseVerboseErrors = true;

in the

virtuoso.svc.cs InitializeService

method to obtain more detailed information from the server as to why the page failed to load:

```
public static void InitializeService(IDataServiceConfiguration config)
{
config.UseVerboseErrors = true;
config.SetEntitySetAccessRule("*", EntitySetRights.All);
}
```

Visual Studio Windows DataGrid Form Application

This section details the steps required to create a simple Visual Studio 2008 Windows Form application, with associated DataGridView control for displaying data in selected tables from the target database.

1. Launch the Visual Studio 2008 SP1 IDE.

   Figure 8.625. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

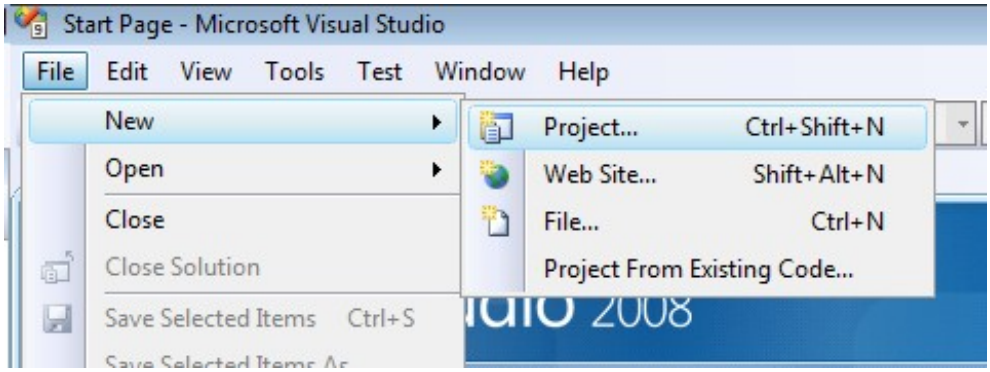
   File

   menu in Visual Studio and choosing

   New Project

   .

   Figure 8.626. Web Application



3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Windows

   and select

   Windows Form Application

   from the right-hand panel.
5. Choose a name for the project, for example

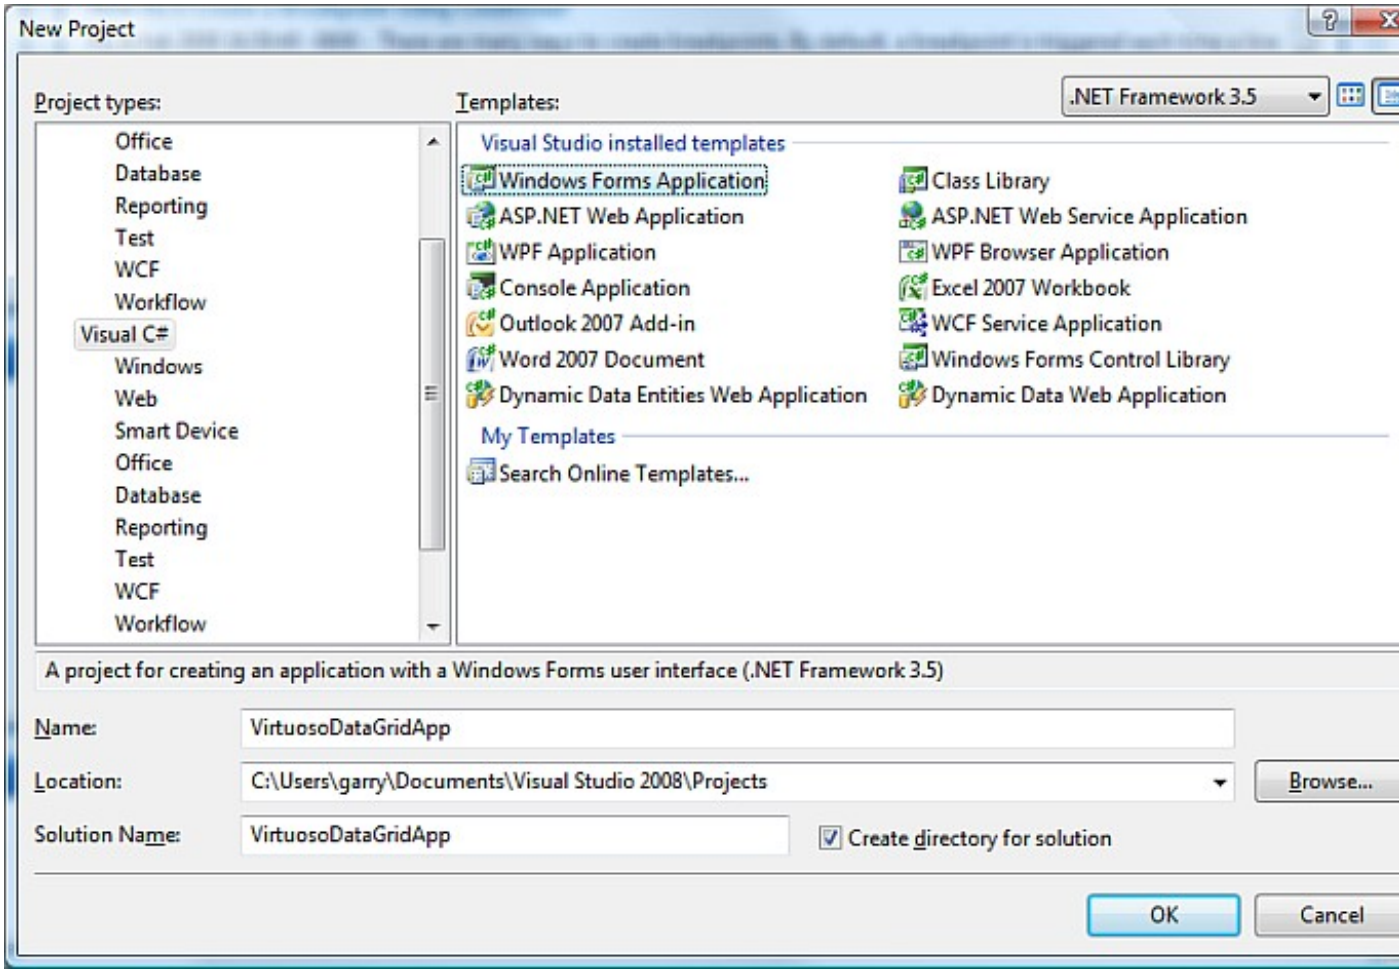
   VirtuosoDataGridApp

   , and click

   OK

   .

Figure 8.627. Web Application



6. In the

   Toolbox

   , expand

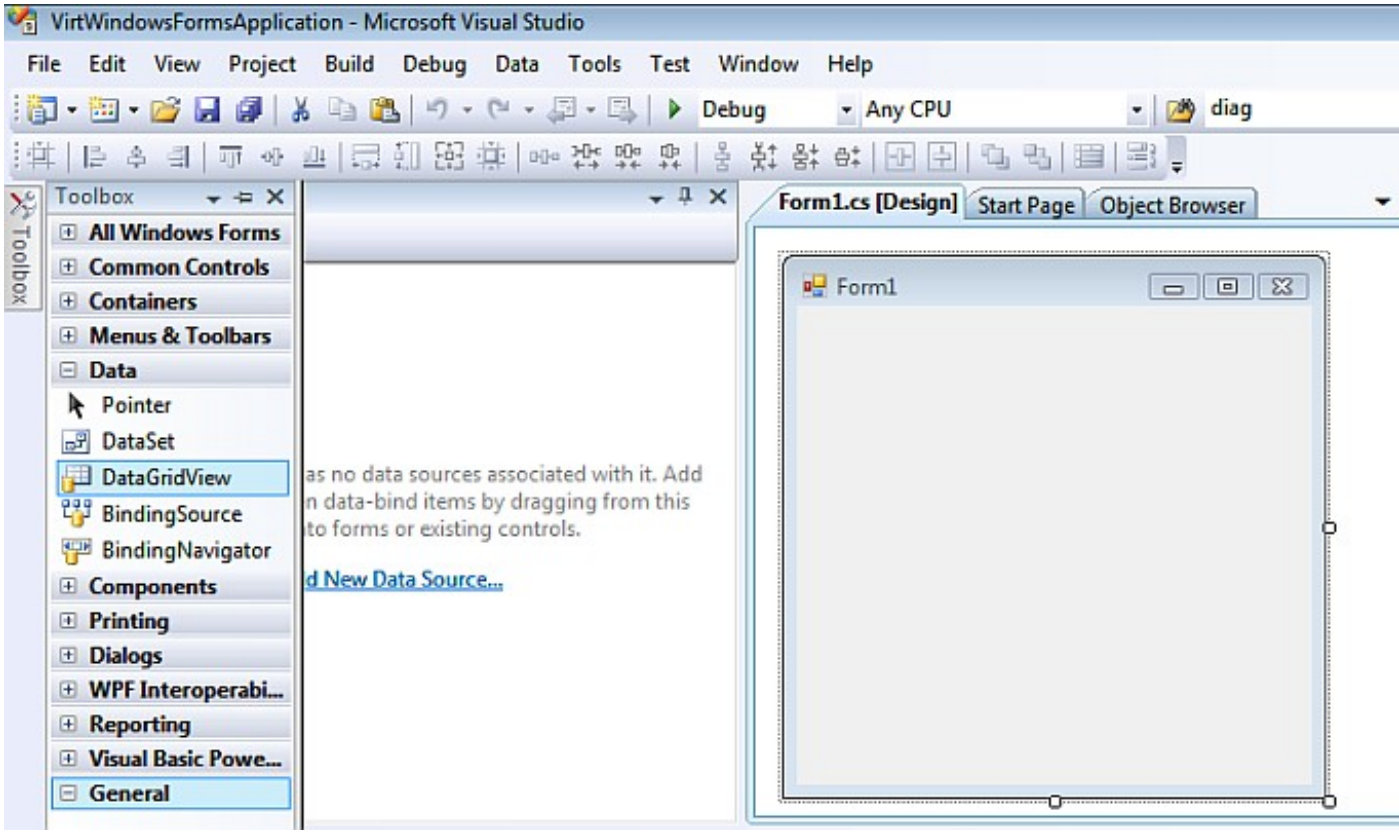
   Data Controls

   , and drag the

   DataGridView

   control onto the form.

   Figure 8.628. Toolbox



7. Click on the little

   arrow

   in the top right of the

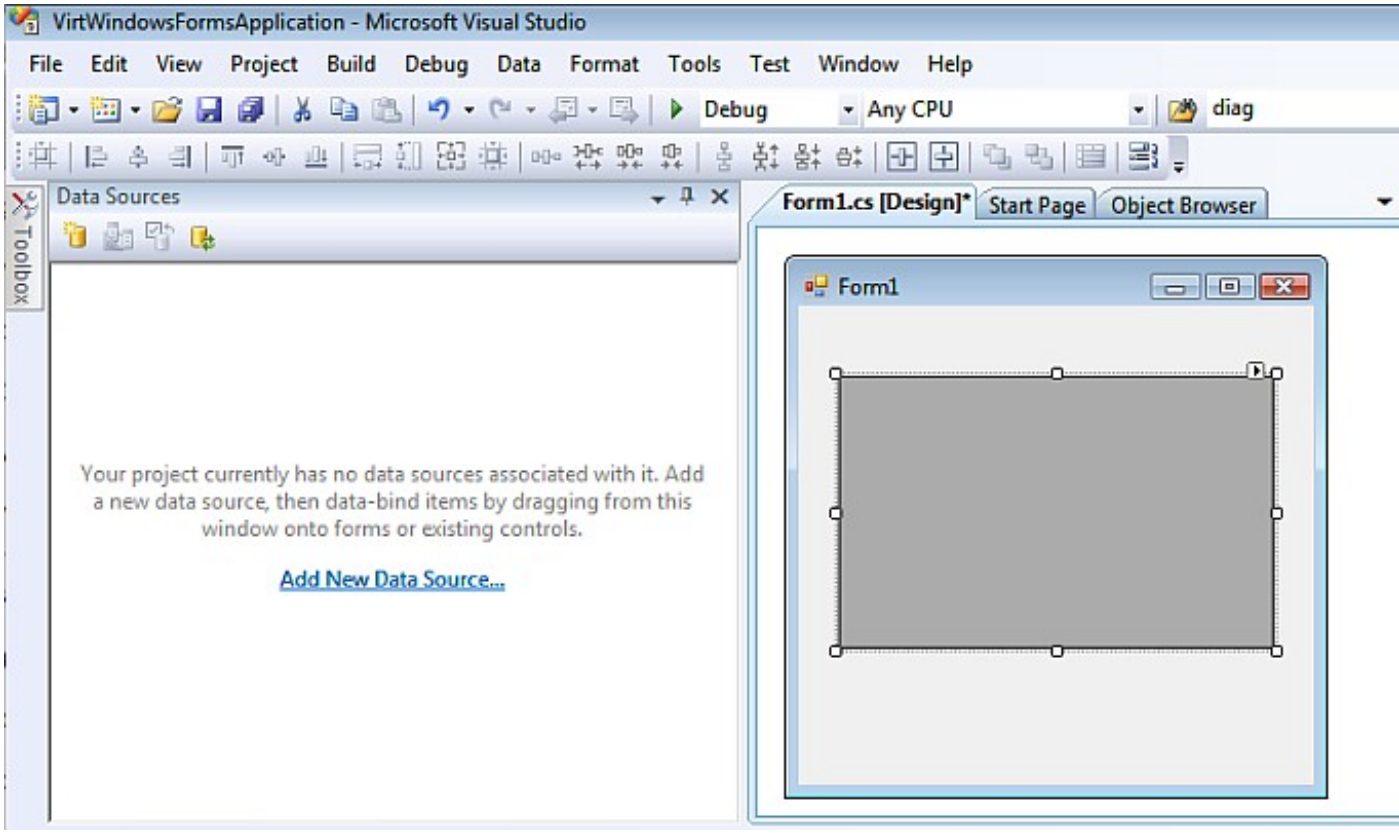
   DataGridView

   control. This loads the

   DataGridView Task

   menu.

Figure 8.629. DataGridView Task

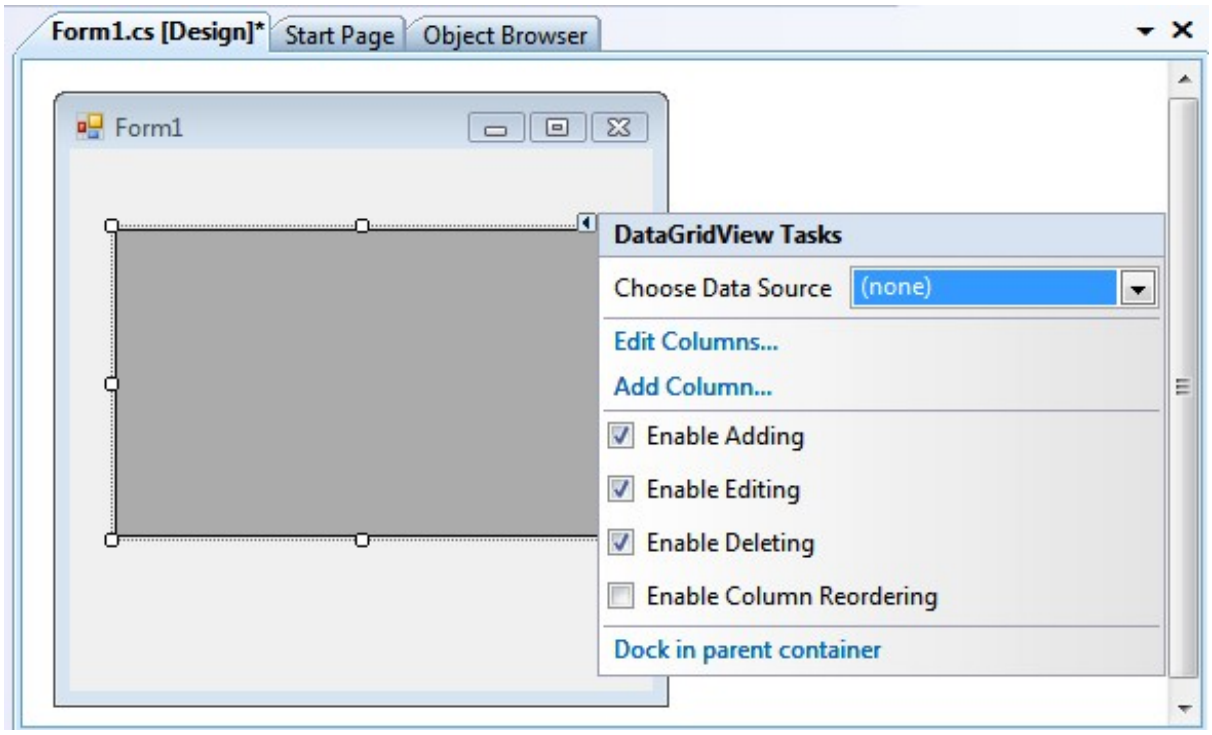


8. Click on the

   Choose Data Source

   list box.

   Figure 8.630. Choose Data Source

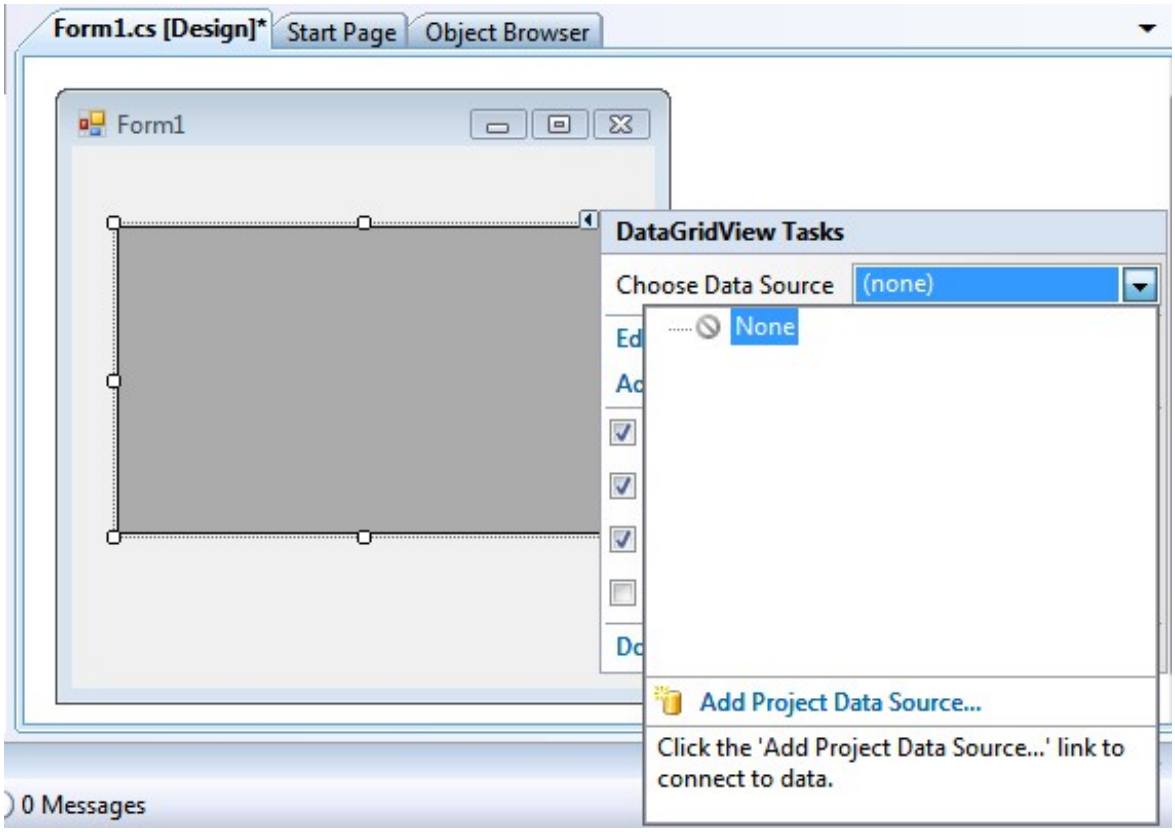


9. Click on the

   Add Project Data Source

link to connect to a data source.

Figure 8.631. Add Project Data Source



10. In the

    Data Source Configuration Wizard

    dialog

    Choose Data Source Type

    page select the

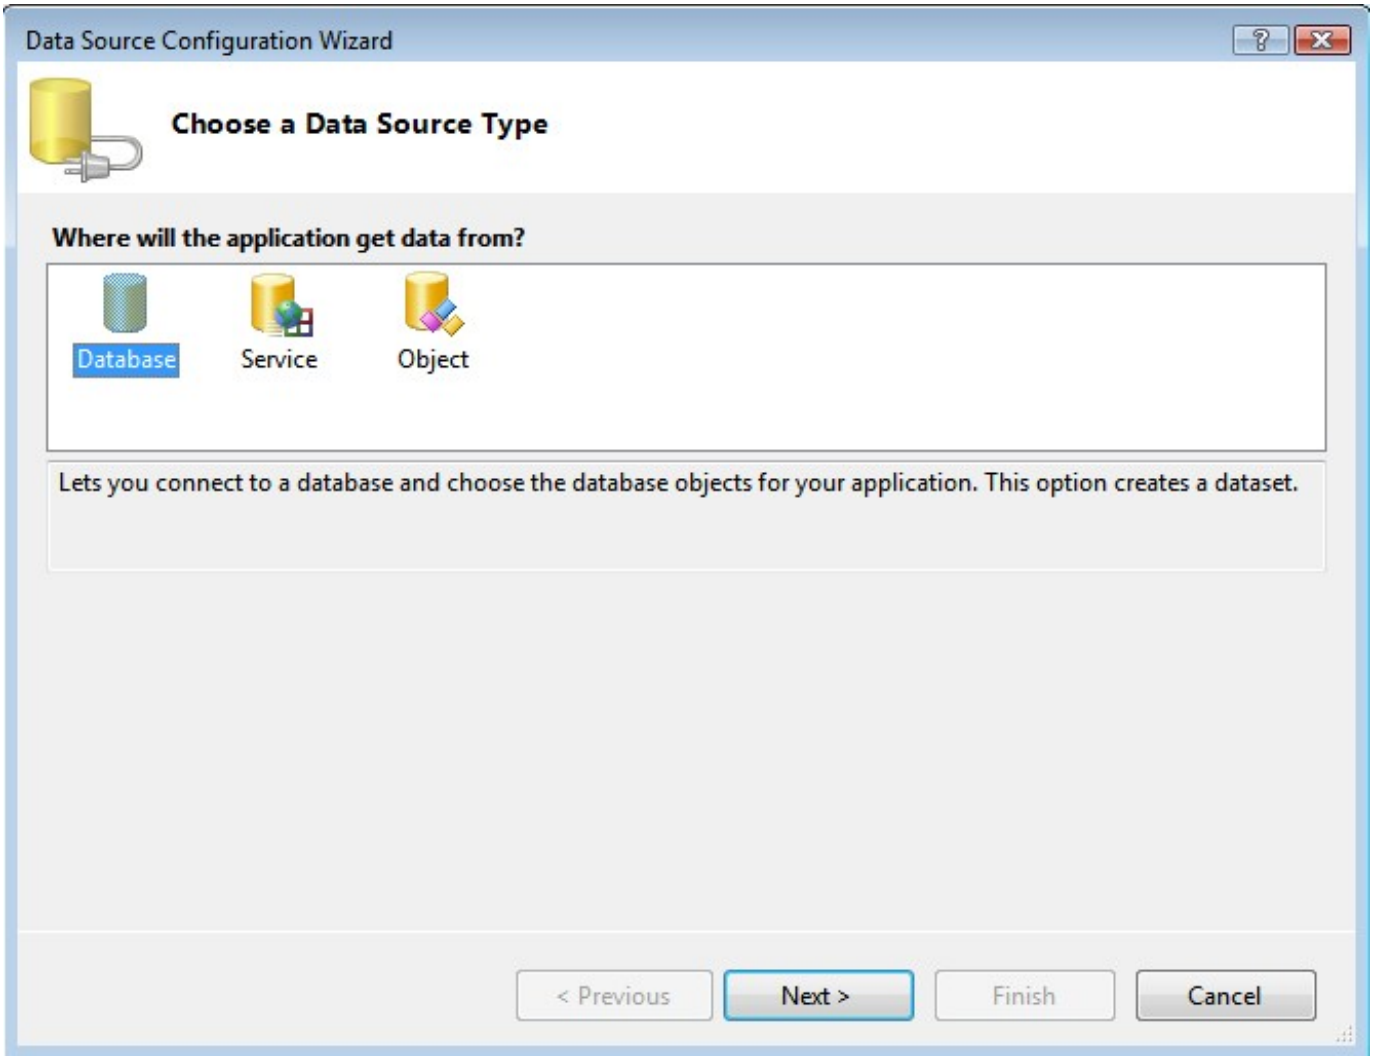
    Database

    data source type and click

    Next

    .

Figure 8.632. Data Source Type



11. In the

    Data Source Configuration Wizard

    dialog

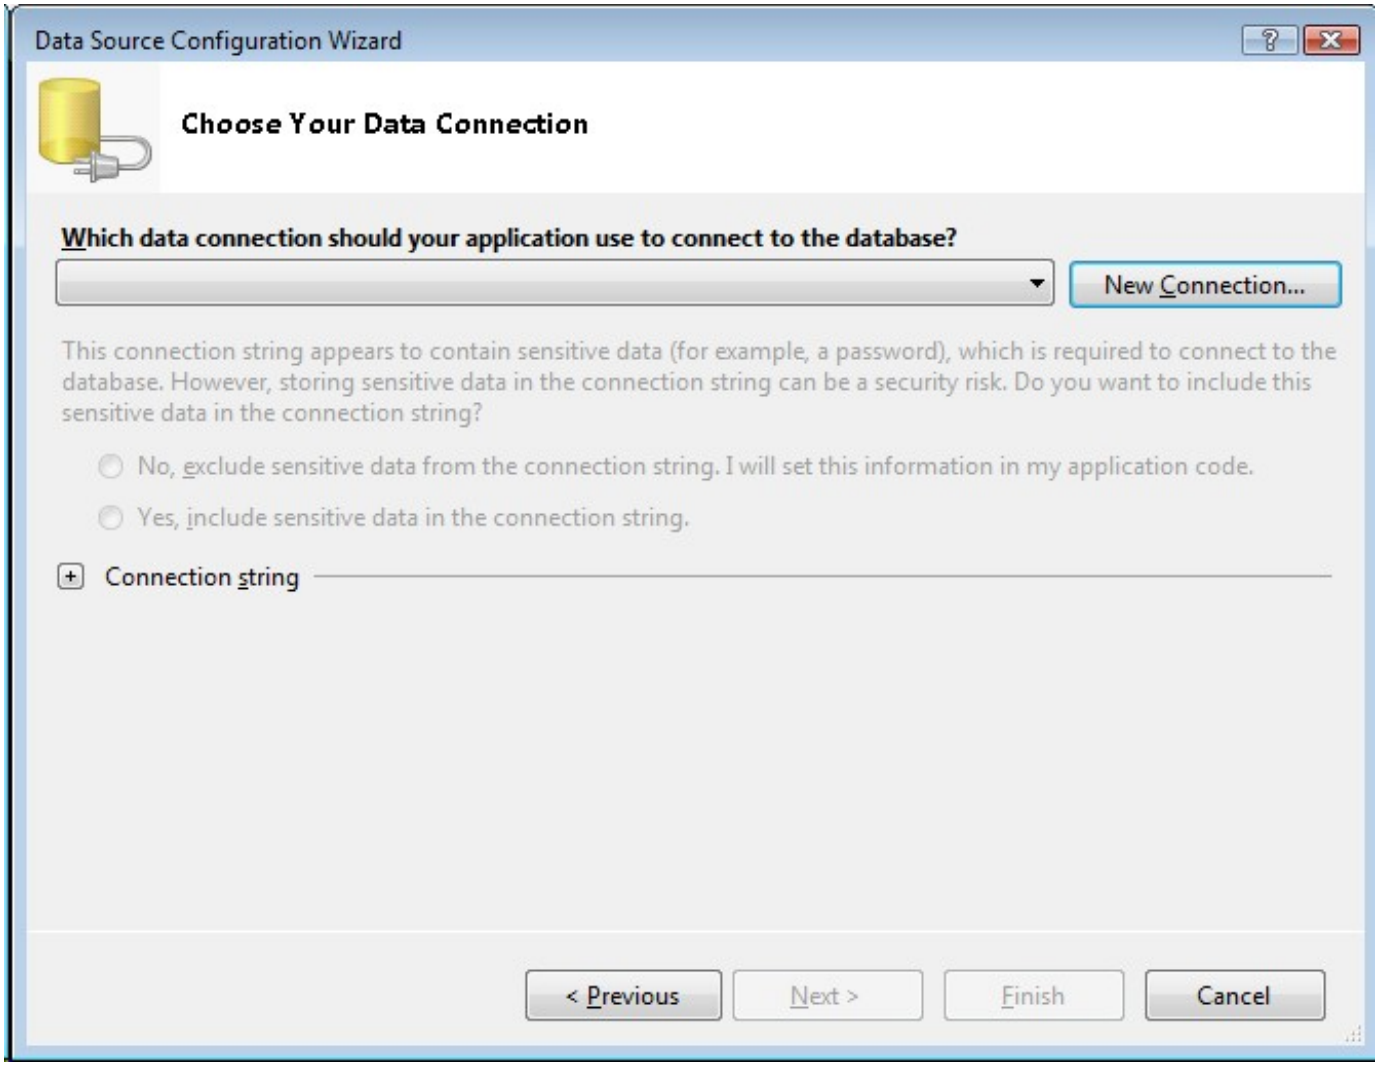
    Choose your Data Connection

    page, select the

    New Connection

    button

Figure 8.633. Data Source Configuration Wizard



12. In the

    Choose Data Source

    dialog, select the OpenLink

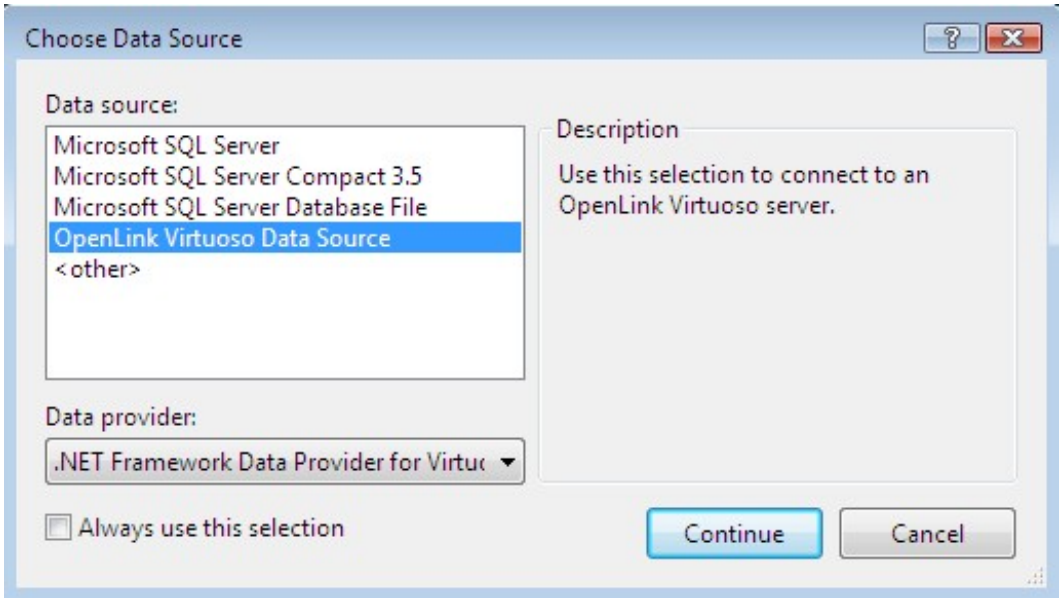
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.634. Data Source



13. In the

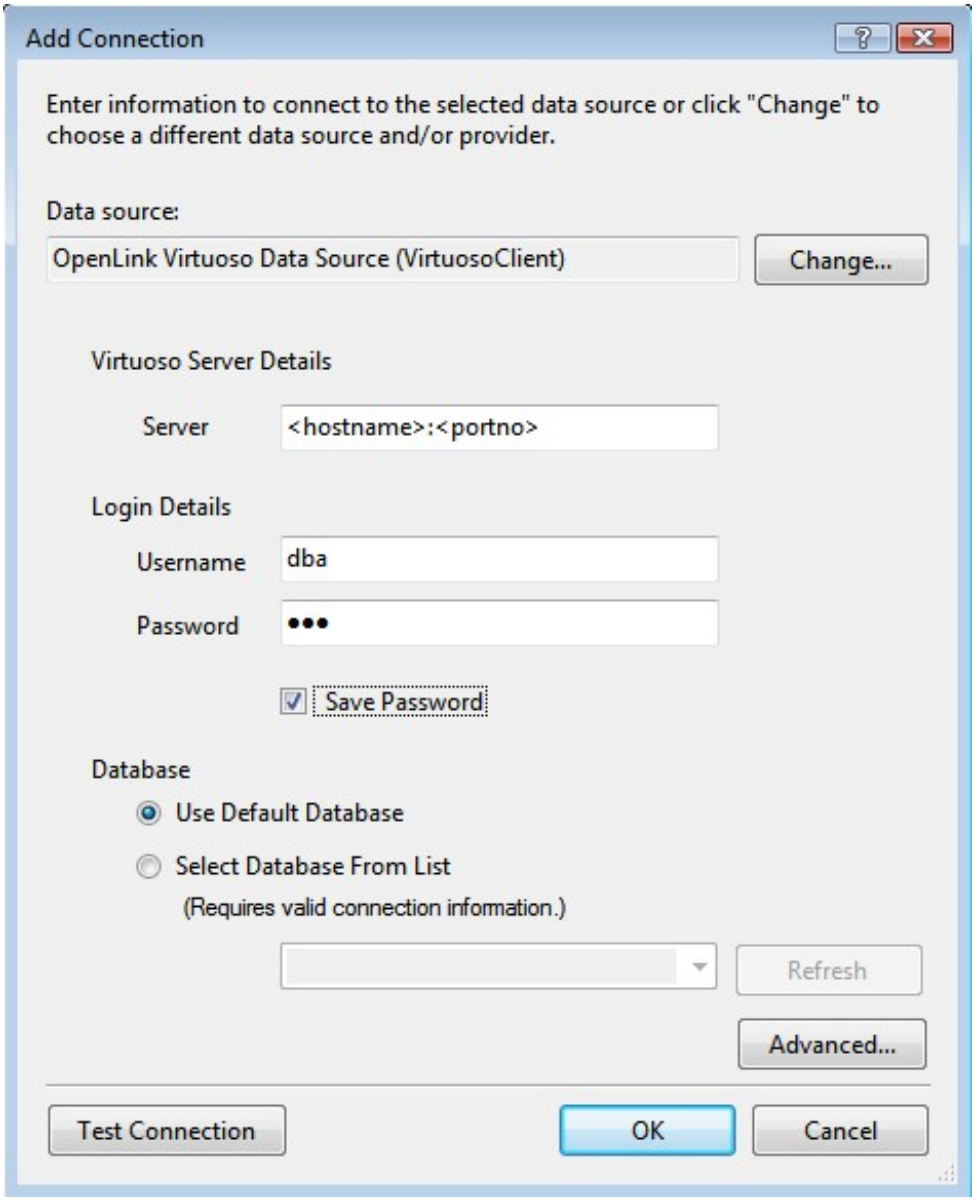
    Add Connection

    dialog, specify the

    hostname, portno, username and password

    for the target Virtuoso Server and check the Save Password check box.

    Figure 8.635. Connection Properties



14. Select the

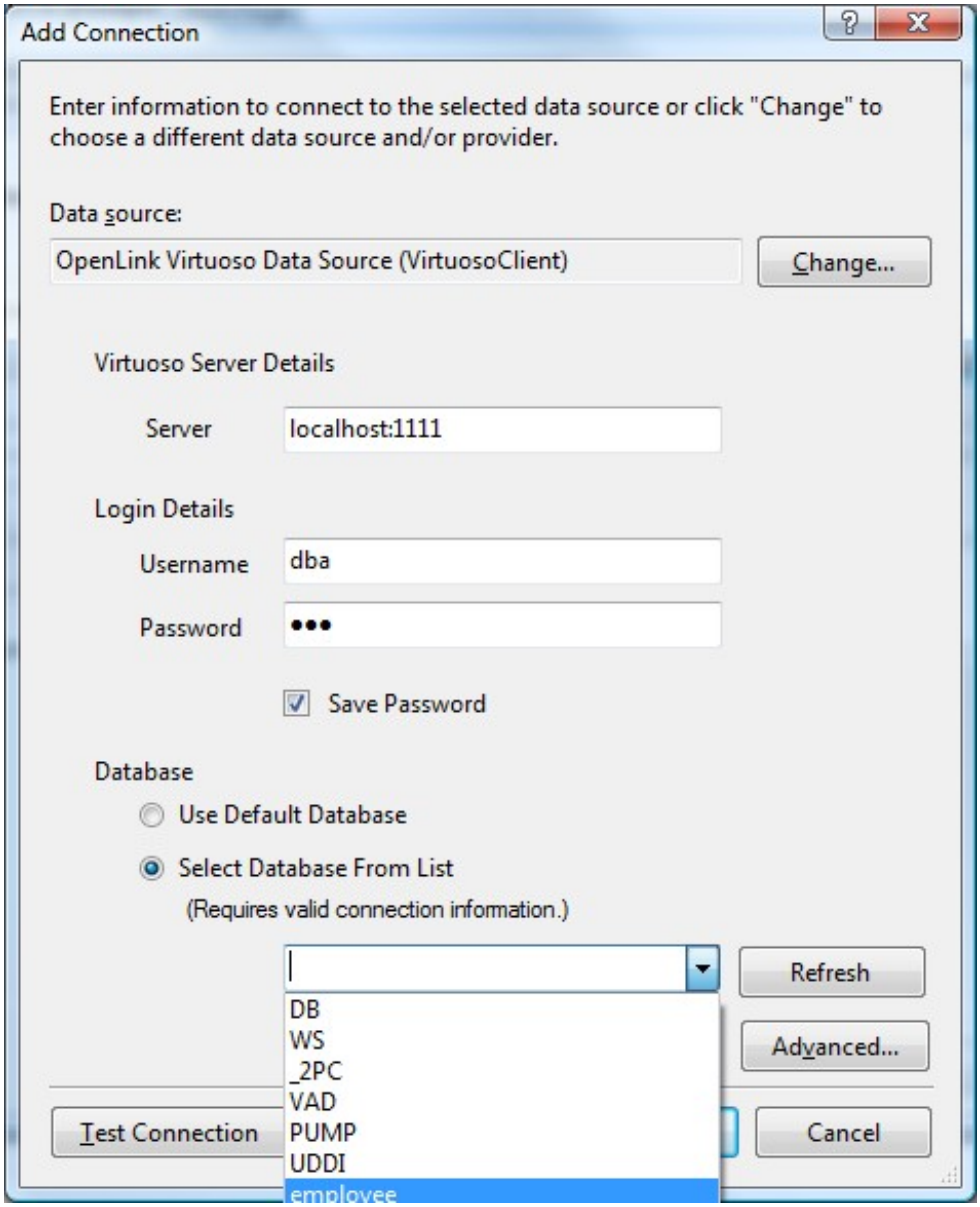
    Select Database From List

    radio button and choose the

    employee

    database from the drop down list.

    Figure 8.636. Add connection

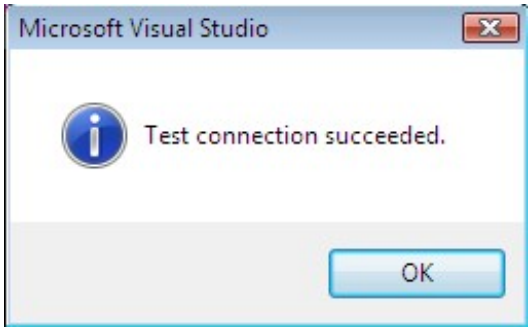


15. Click OK to add the connection.
16. Press the

    Test Connection

    dialog to verify that the database is accessible.

    Figure 8.637. Test Connection



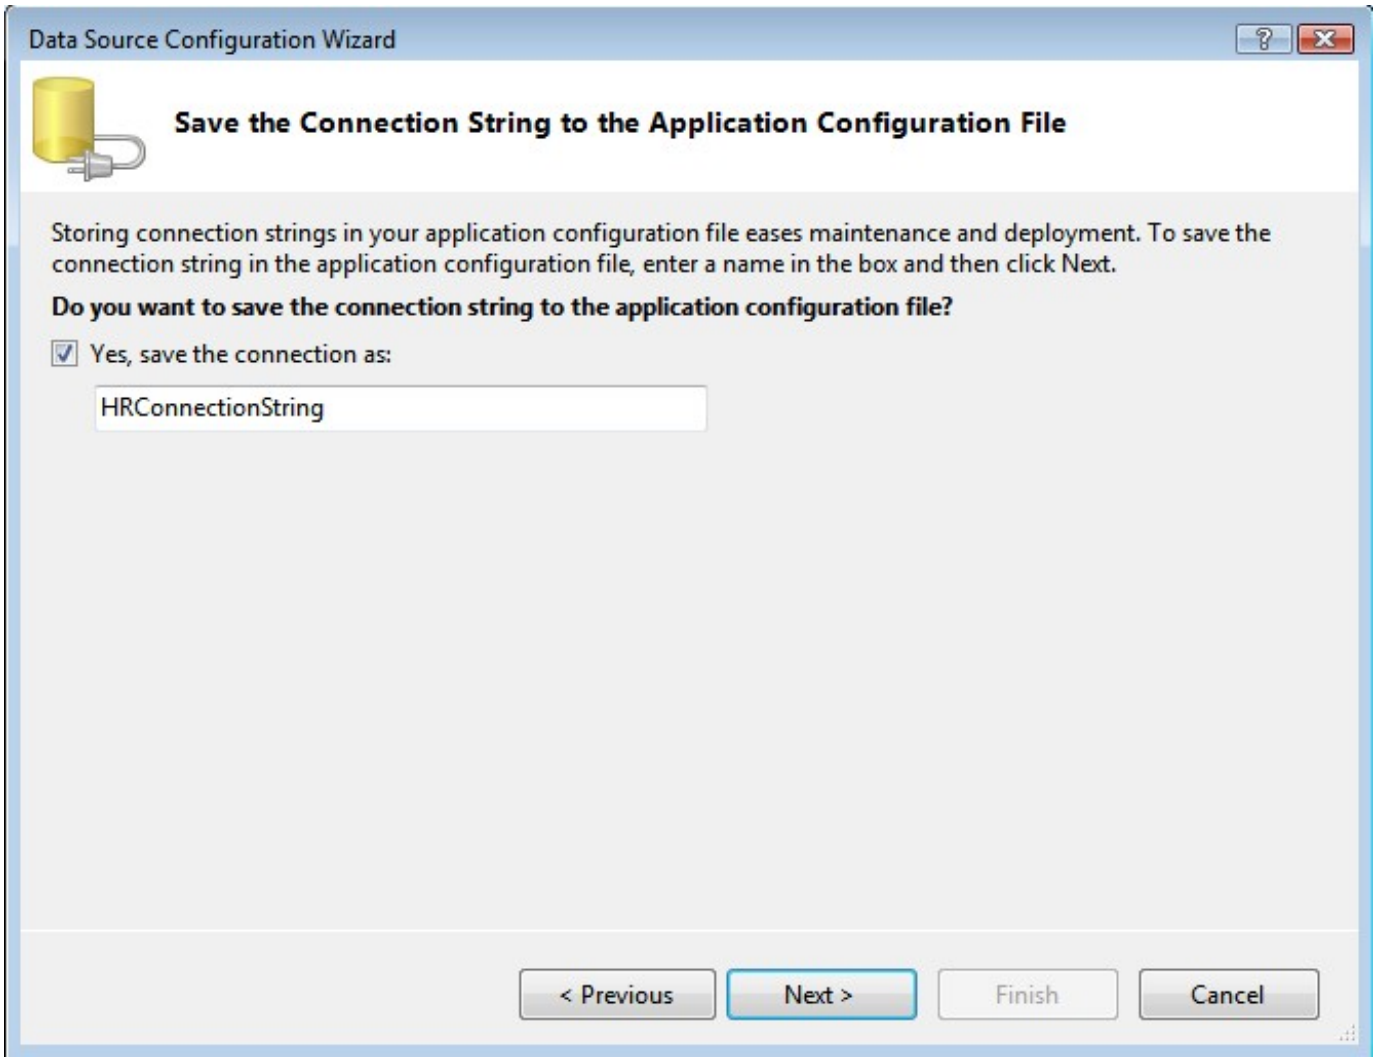
17. Leave the default connect string

    employeeConnectionString

and click

Next

Figure 8.638. employeeConnectionString



18. From the list of available tables returned for the employee database, select the

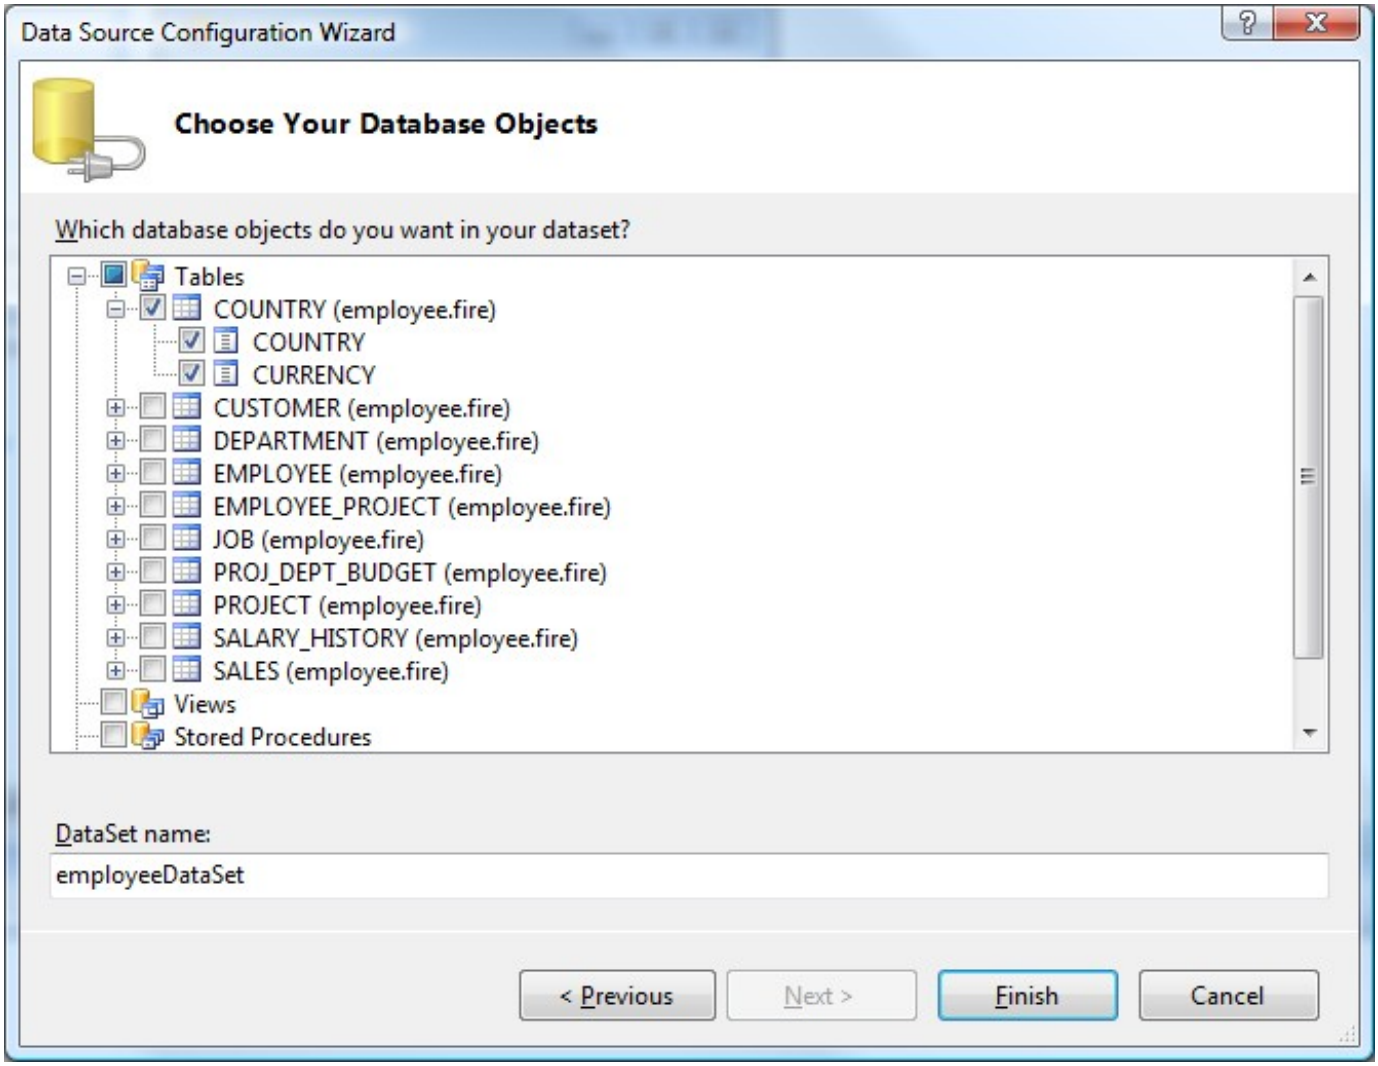
    COUNTRY

    table to be associated with the

    DataGridView

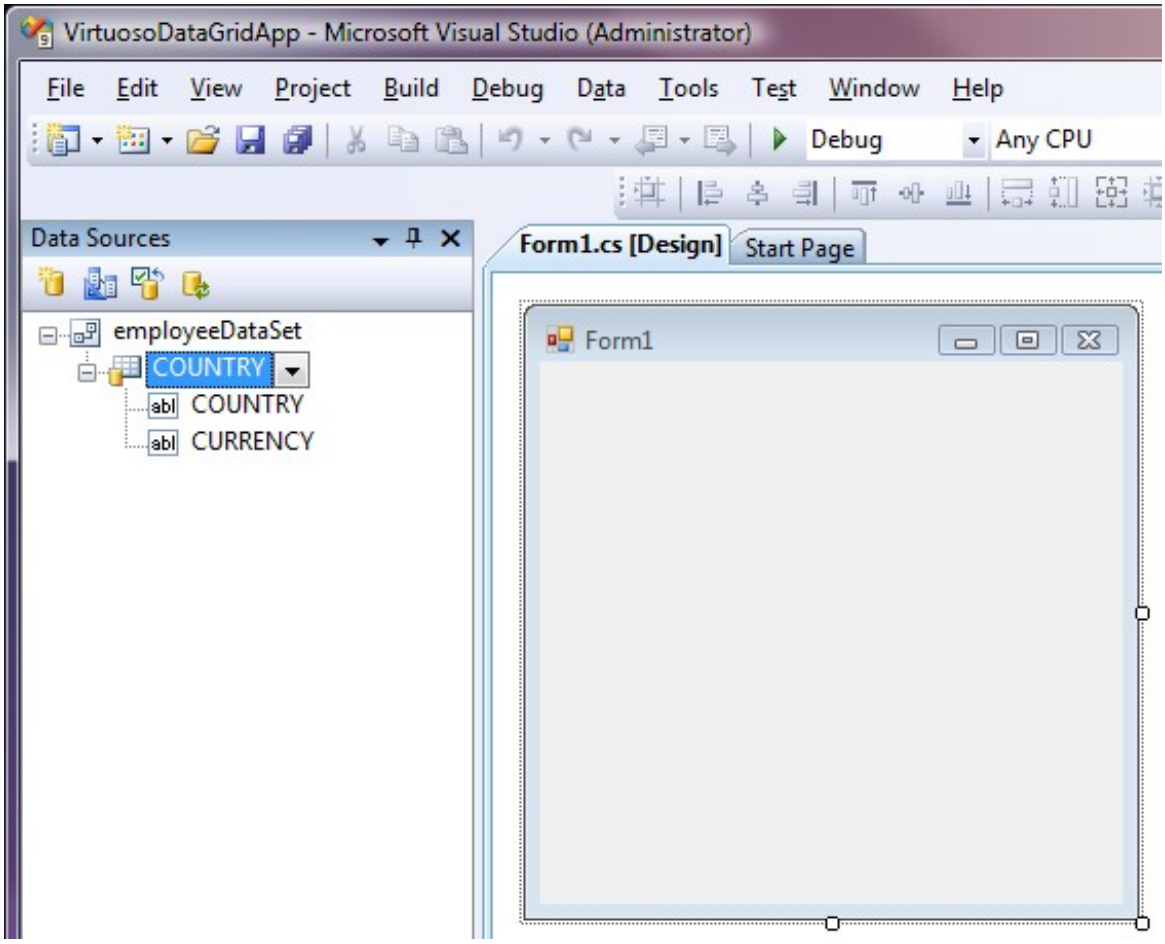
    control.

    Figure 8.639. employee database



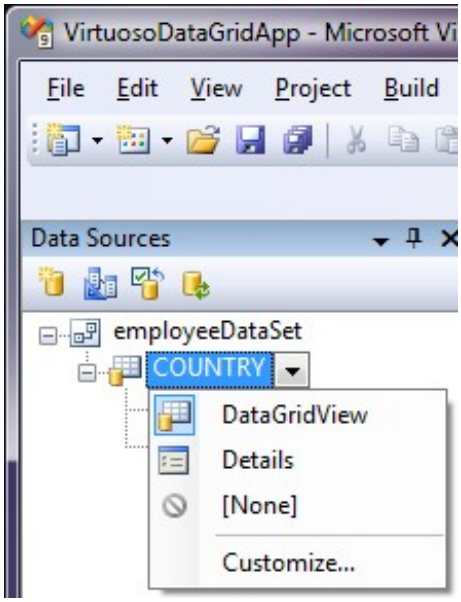
19. A DataSet for the employee database object is created

Figure 8.640. DataSet



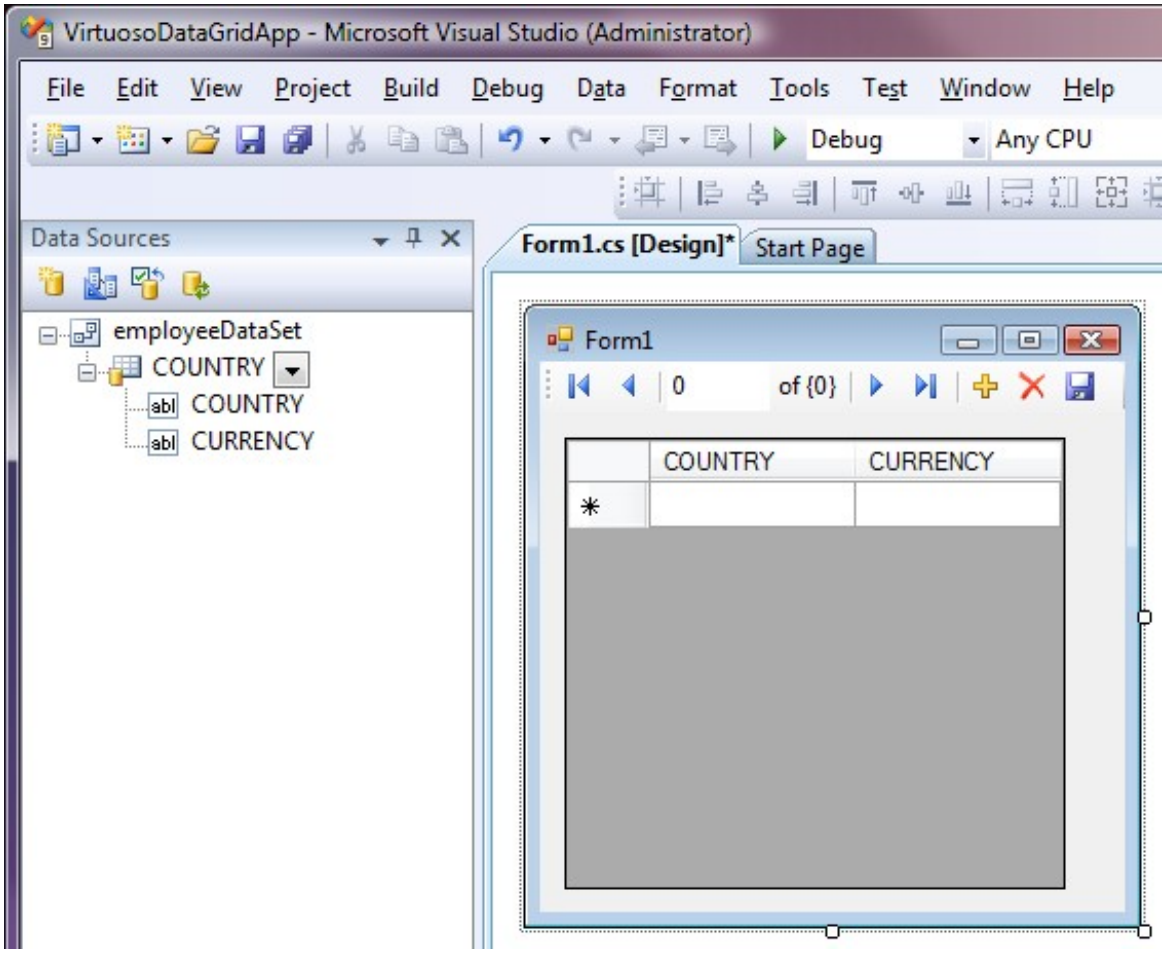
20. From the drop down list box next to the COUNTRY table ensure the DataGridView item is selected

Figure 8.641. DataGridView



21. Drag the COUNTRY DataSet item onto the Form to create a scrollable and editable association of the COUNTRY table object with the Data Grid View automatically.

Figure 8.642. association



22. To test the application, simply hit

    Ctrl+F5

    within Visual Studio or select

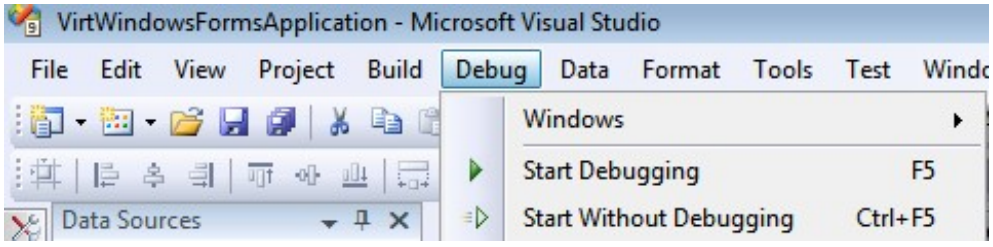
    Start Debugging

    from the

    Debug

    menu.

    Figure 8.643. Start Debugging



23. The data from the

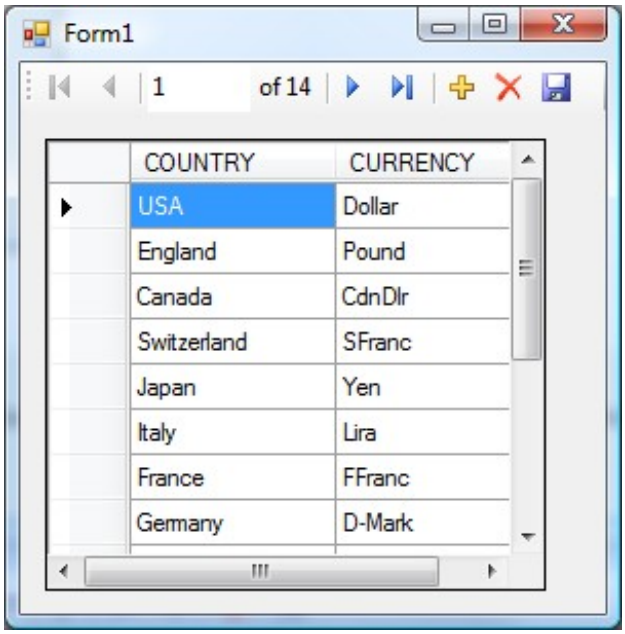
    COUNTRY

    table will be displayed in the

DataGrid

.

Figure 8.644. DataGrid

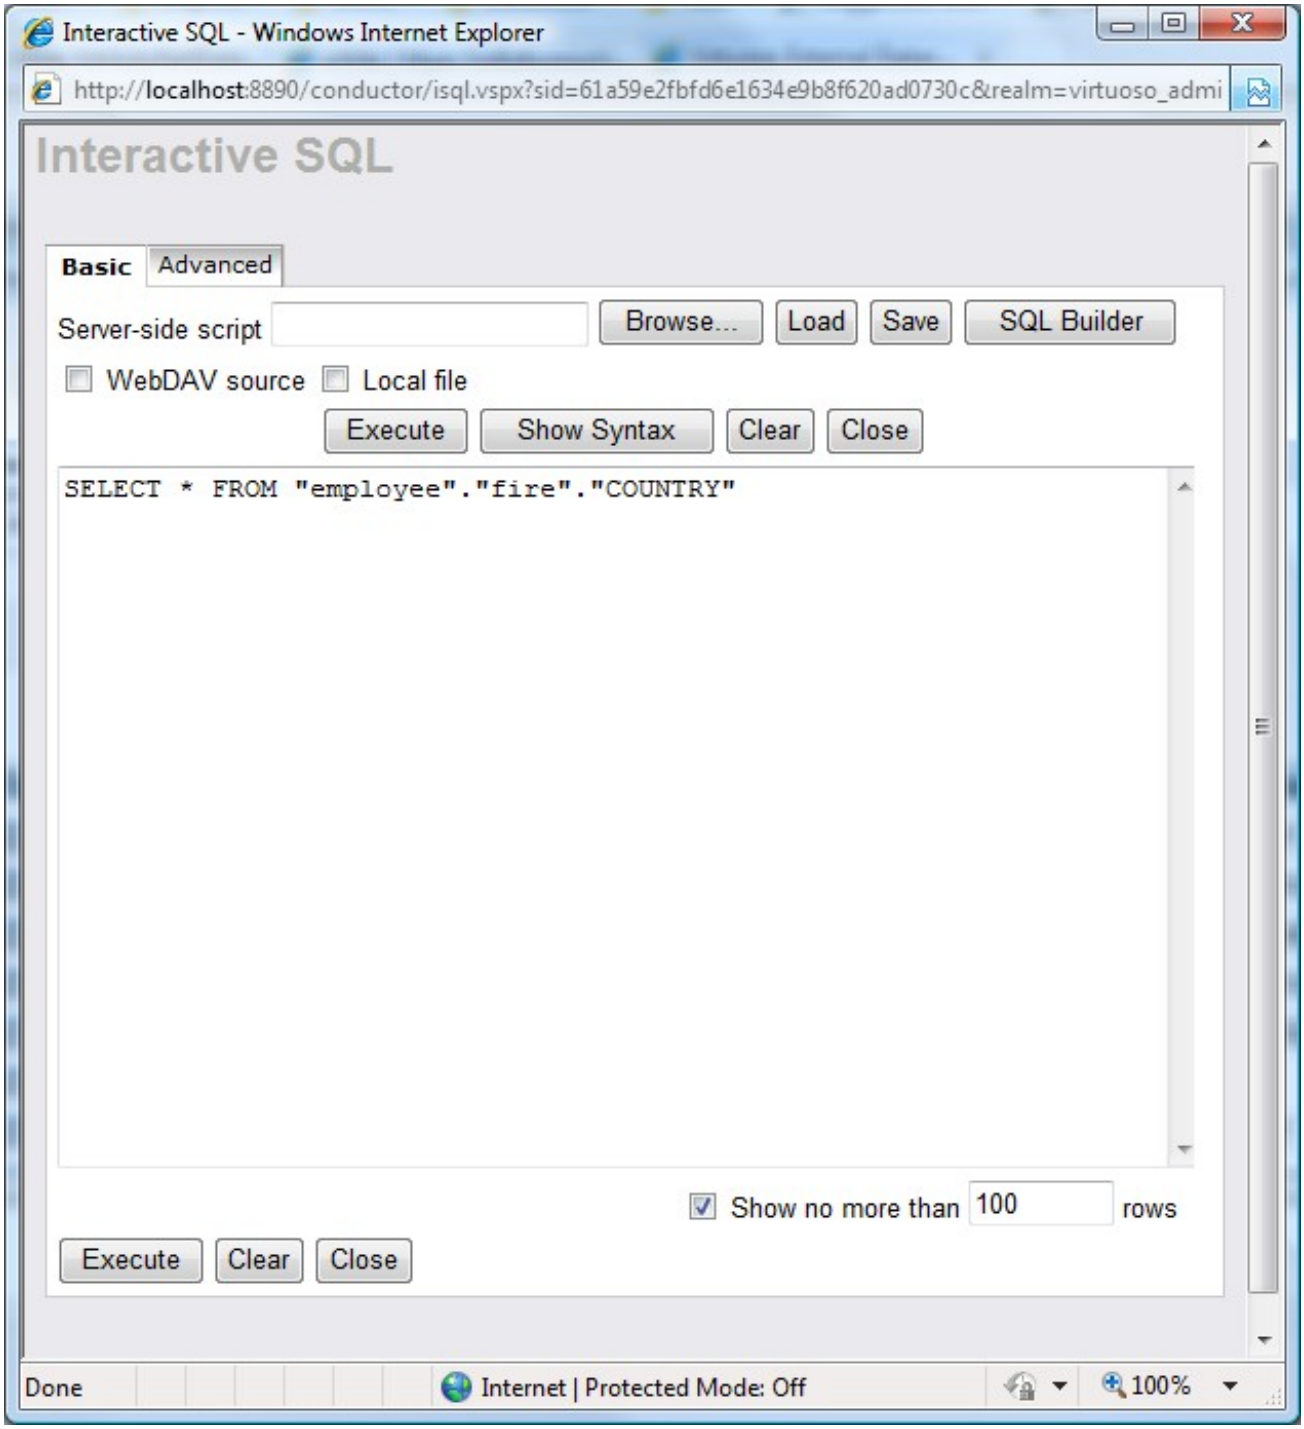


24. A new row can be inserted (updated or deleted) as indicated for the new "1111" record inserted below and the Save button clicked to save the change to the database.

Figure 8.645. new row

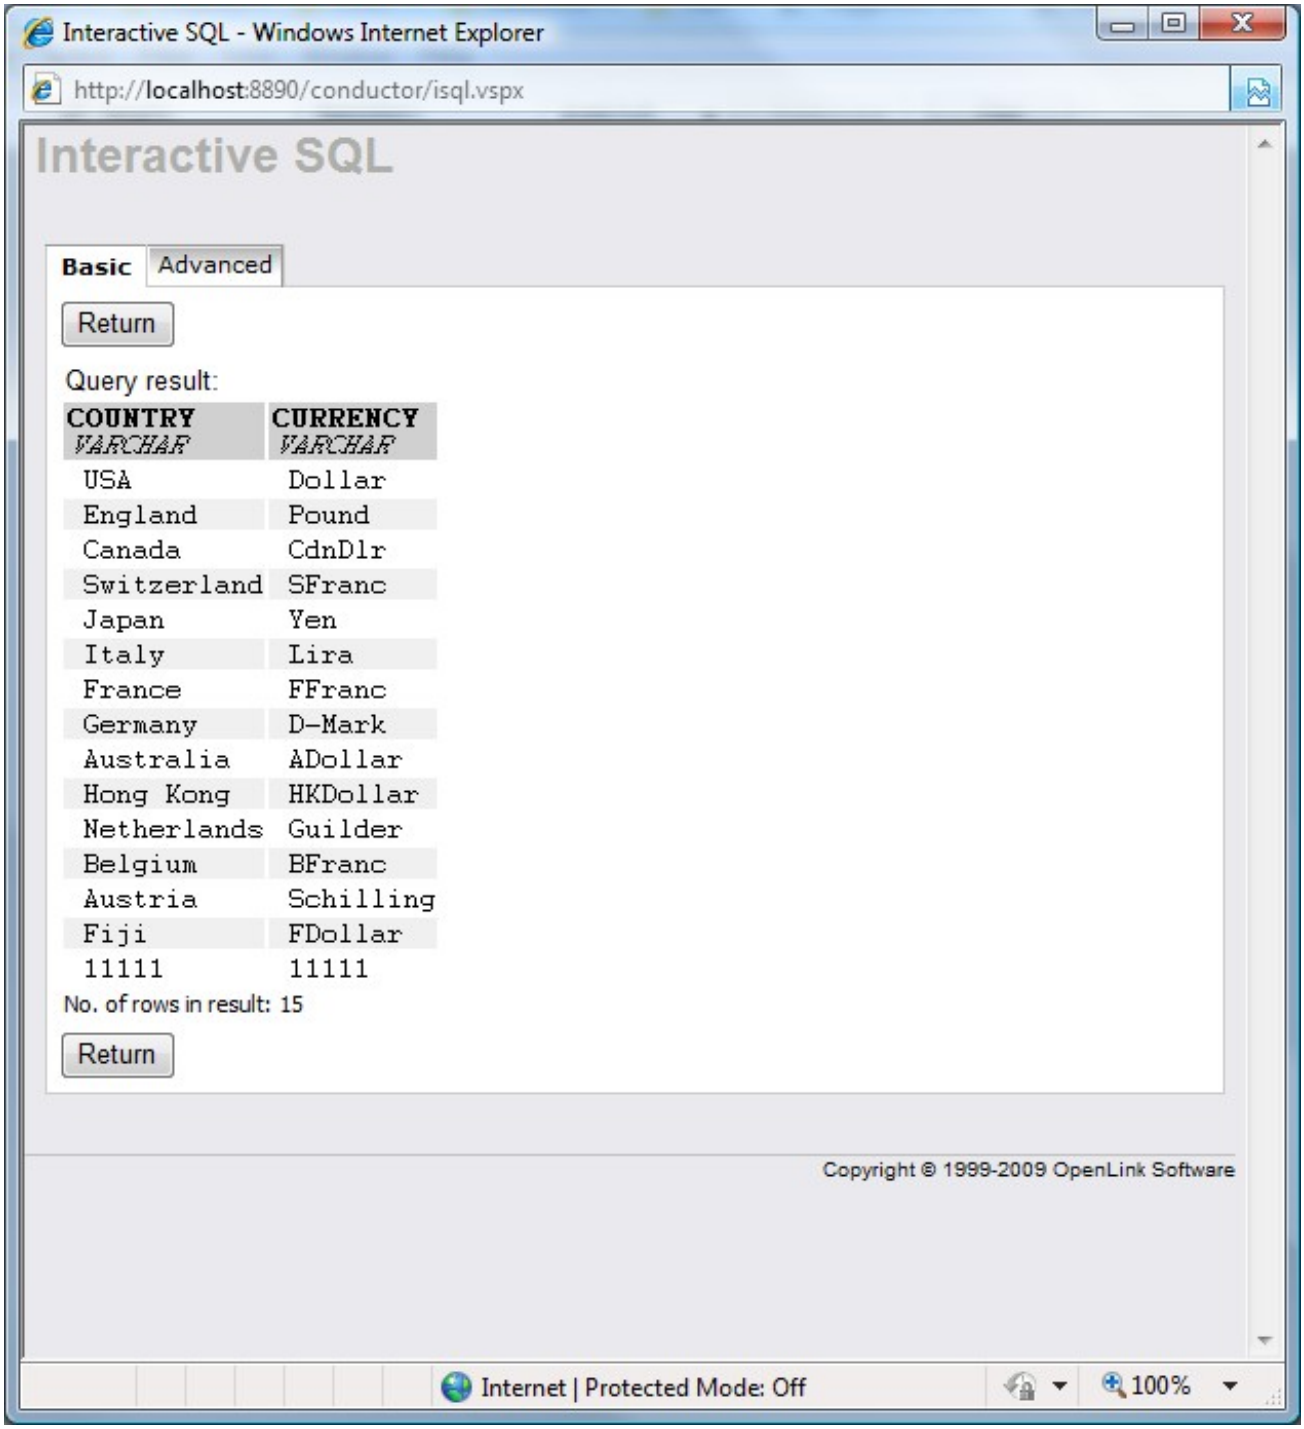
25. The Virtuoso Interactive SQL tab of the Conductor can be used to run the query select * from "employee"."fire"."COUNTRY"

Figure 8.646. Interactive SQL



26. To verify the change has been successfully made in the database.

Figure 8.647. verify



The task is now complete.

8.13. Using Microsoft Entity Frameworks to Access Microsoft SQL Server Schema Objects with Virtuoso

Abstract

This section details the steps required to provide Microsoft Entity Framework access to Microsoft SQL Server Schema Objects using the OpenLink Virtuoso Universal Server. This is achieved by linking the required Microsoft SQL Server Schema objects into Virtuoso using its built in Virtual Database engine, and then using the Virtuoso ADO.NET Entity Framework provider to query the remote Microsoft SQL Server Schema objects linked into the Virtuoso Server.

Prerequisites. The following prerequisites must be in place for this solution to be possible.

Microsoft SQL Server DBMS. A Microsoft SQL Server DBMS hosting the required Schema Objects needs to be available. In this document the *Microsoft SQL Server Northwind* sample database will be used to demonstrate the process.

A Microsoft SQL Server DBMS hosting the required Schema Objects needs to be available. In this document the *Microsoft SQL Server Northwind* sample database will be used to demonstrate the process.

ODBC Driver for Microsoft SQL Server. An Microsoft SQL Server ODBC Driver is required for Linking the Microsoft SQL Server Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for Microsoft SQL Server* will be used in this section, for which a functional ODBC Data source name of "sql2k5ma" will be assumed to exist on the machine hosting the Virtuoso Server.

An Microsoft SQL Server ODBC Driver is required for Linking the Microsoft SQL Server Schema Objects into the Virtuoso Server. The OpenLink *ODBC Driver for Microsoft SQL Server* will be used in this section, for which a functional ODBC Data source name of "sql2k5ma" will be assumed to exist on the machine hosting the Virtuoso Server.

Virtuoso Universal Server. An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

An Virtuoso installation including the Virtuoso Universal Server and ADO.NET Entity Framework Provider is required. The Virtuoso components used must be Release 5.10.x or above, this being the minimum version containing support for Microsoft Entity Frameworks

Microsoft Visual Studio 2008 SP1. Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Microsoft Visual Studio 2008 Service Pack 1 is required, this being the only version containing the necessary Entity Framework support available at the time of writing.

Tasks

Ensure Microsoft SQL Server Primary Keys (PKs) are not nullable. The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the Microsoft SQL Server database schema before attempting to generate an EDM. In the case of the Microsoft SQL Server Northwind database all tables are not nullable, thus this should not be an issue in this case.

The Visual Studio 2008 Entity Data Model (EDM) requires that all primary keys are *NOT* Nullable, and will fail to generate an EDM if any are. Thus ensure any tables to be used are defined as not nullable in the Microsoft SQL Server database schema before attempting to generate an EDM. In the case of the Microsoft SQL Server Northwind database all tables are not nullable, thus this should not be an issue in this case.

8.13.1. Install and configure OpenLink ODBC Driver for Microsoft SQL Server

The Virtuoso Virtual Database engine uses ODBC as the connectivity mechanism for linking remote database objects into its local schema. Thus a Microsoft SQL Server ODBC Driver must be available with a suitably configured DSN for connecting to the target database. The OpenLink ODBC Drivers for Microsoft SQL Server have been used in this section, although in theory any Microsoft SQL Server ODBC Driver can be used.

Installation instructions for the OpenLink ODBC Driver for Microsoft SQL Server are available from:

- Product Installation & Basic Configuration (ODBC)

8.13.2. Install and configure OpenLink Virtuoso Universal Server

- Install and configure OpenLink Virtuoso Universal Server

8.13.3. Linking Microsoft SQL Server tables into OpenLink Virtuoso

1. Start the Virtuoso Web User Interface

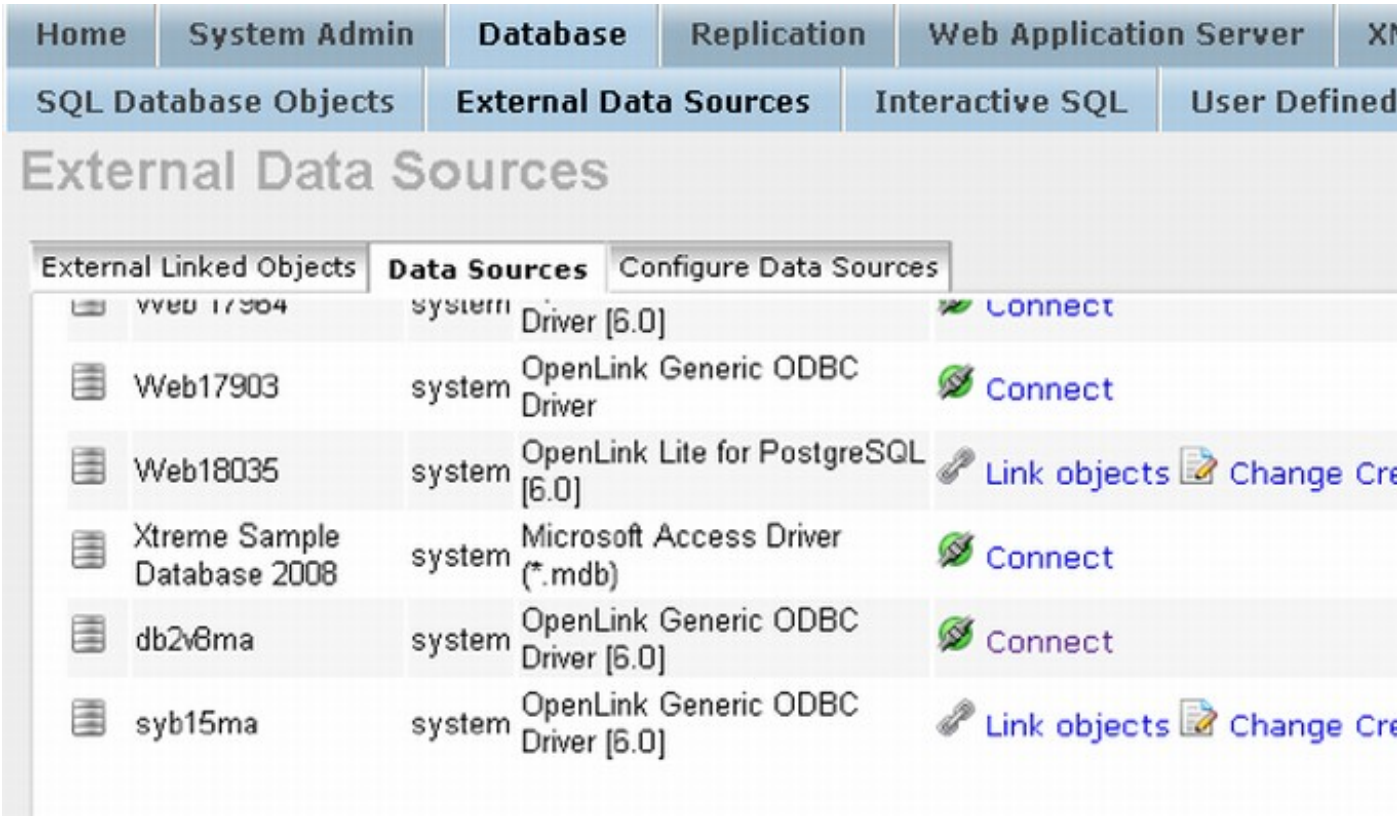
Figure 8.648. Start

2. Select the "Conductor" link in the Left Frame and Login as the "dba" user.

Figure 8.649. Conductor

3. Select the "Databases" -> "External Data Source" -> "Data Sources" tab menu items

Figure 8.650. Databases

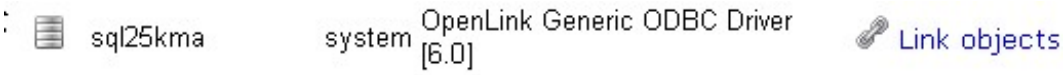


4. Select the "Connect" button for the "sql2k5ma" Microsoft SQL Server DSN.

Figure 8.651. Connect

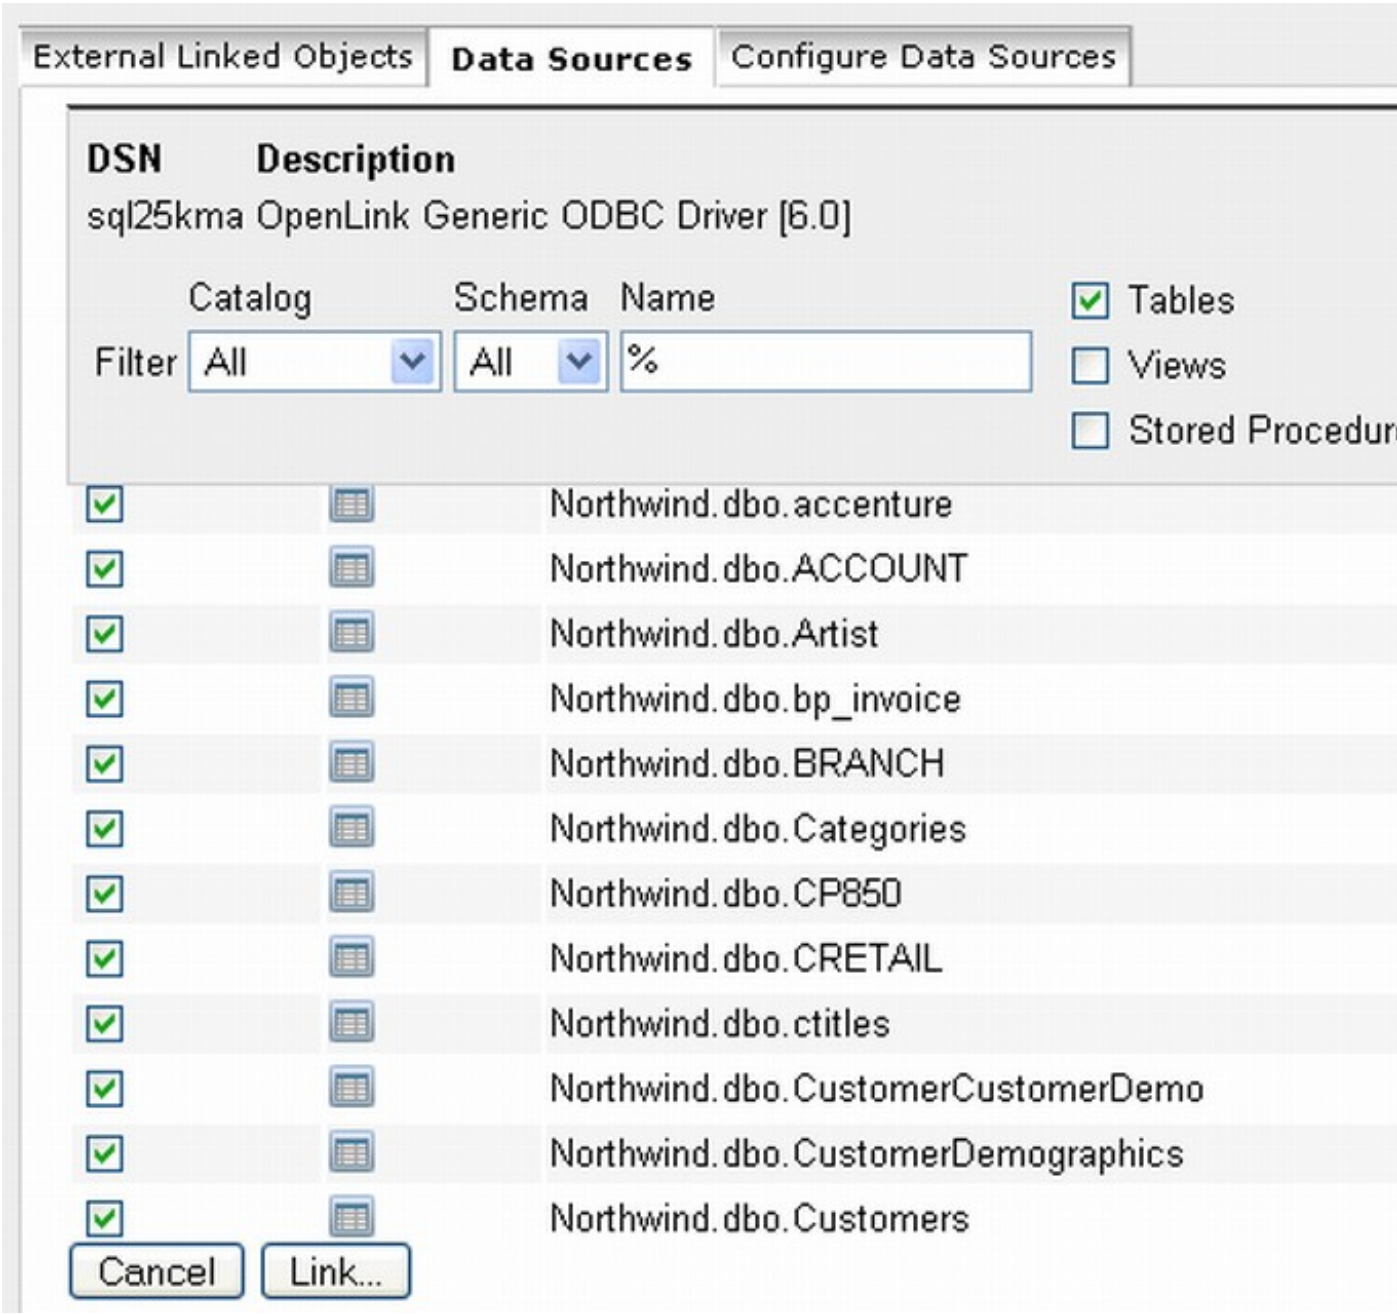
5. On successful connection Select the "Link Objects" button to obtain a list of available tables

Figure 8.652. Link Objects



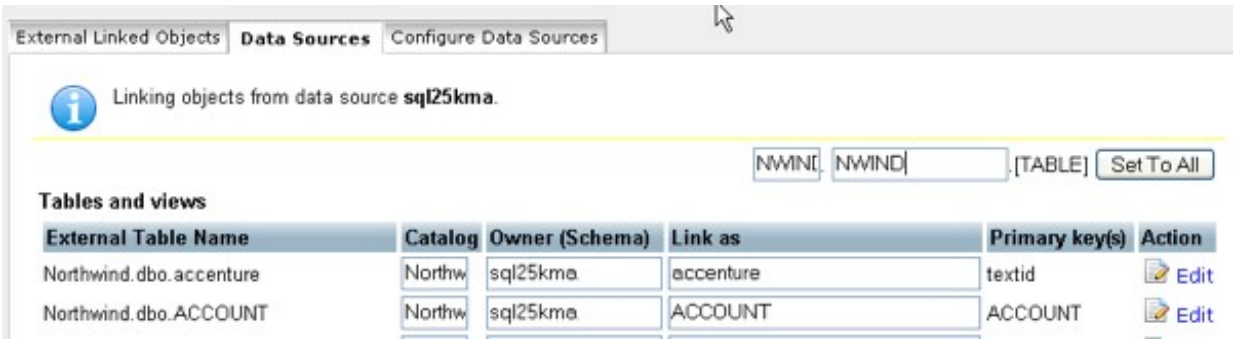
6. Select all the tables that are part of the "Northwind" catalog.

Figure 8.653. Select all tables



7. Change the Catalog for each table to be "Northwind" using the "Set All" button.

Figure 8.654. Catalog



8. All the catalog names are changed to be "NWIND"

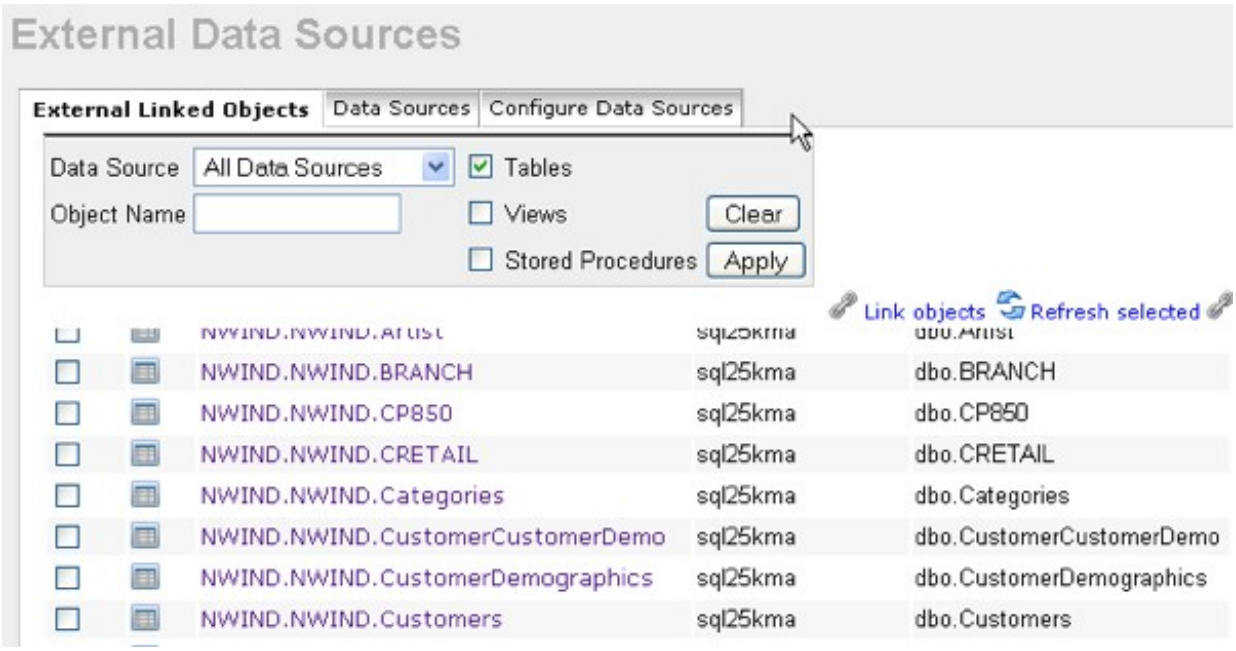
Figure 8.655. catalog names

9. Select the "Link" button to link the selected tables into Virtuoso

Figure 8.656. "Link" button

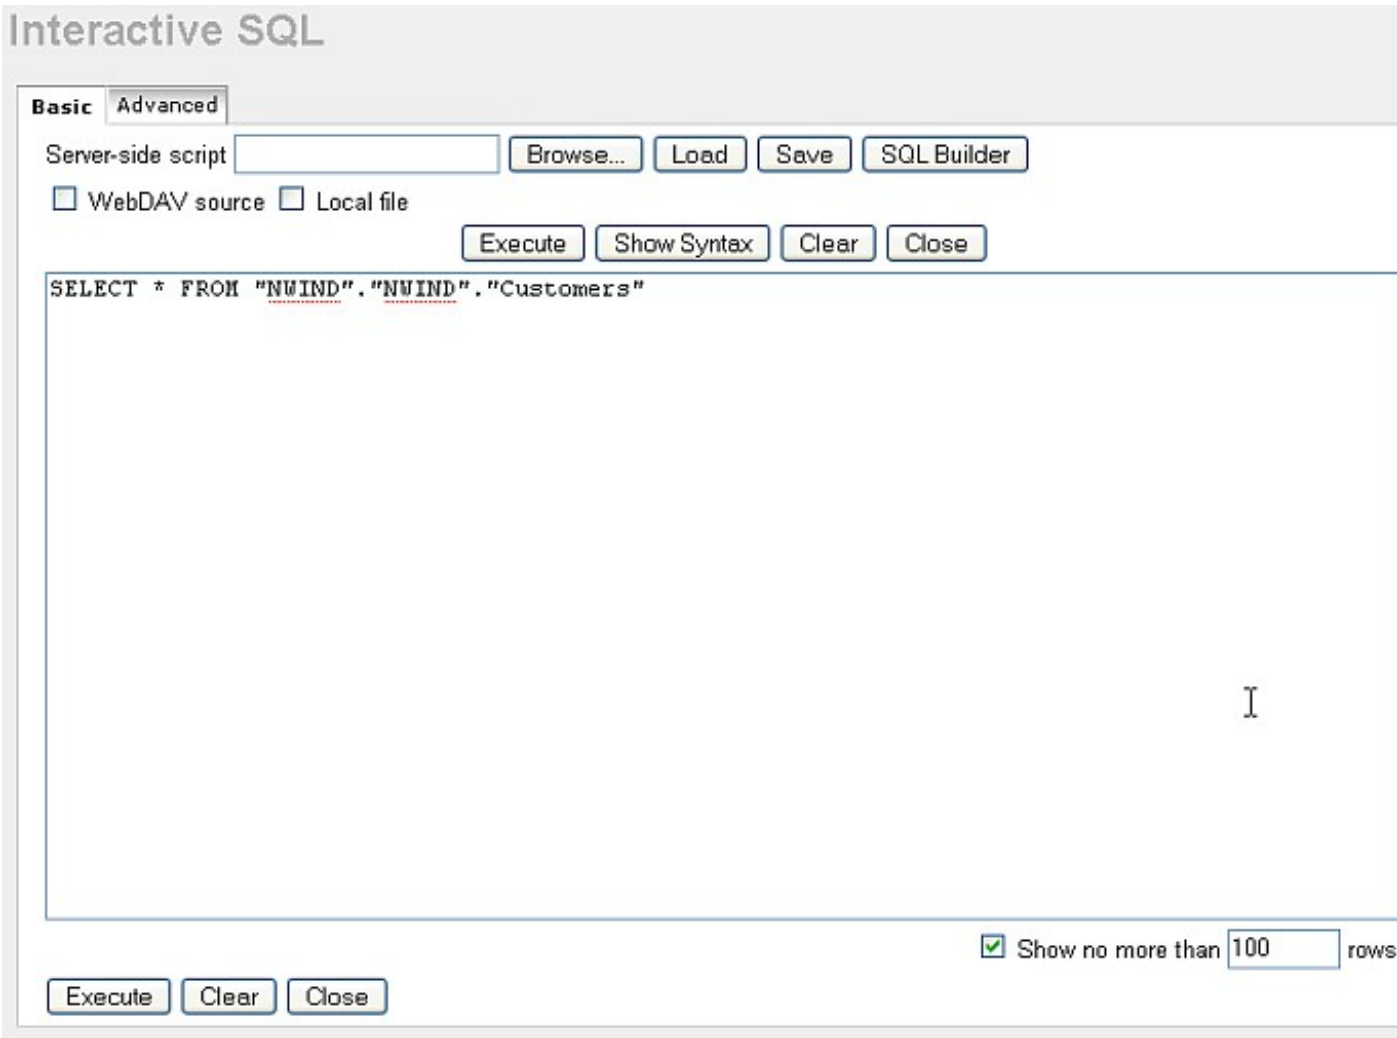
10. On completion of the Link process the tables will be displayed in the "External Linked Objects" tab.

Figure 8.657. Completion



11. At this point, you can test the remotely linked tables by clicking on the link that accompanies each table, e.g. NWIND.NWIND.Customer. This will display the Interactive ISQL interface which will have been already populated with a suitable SQL statement.

Figure 8.658. Querying

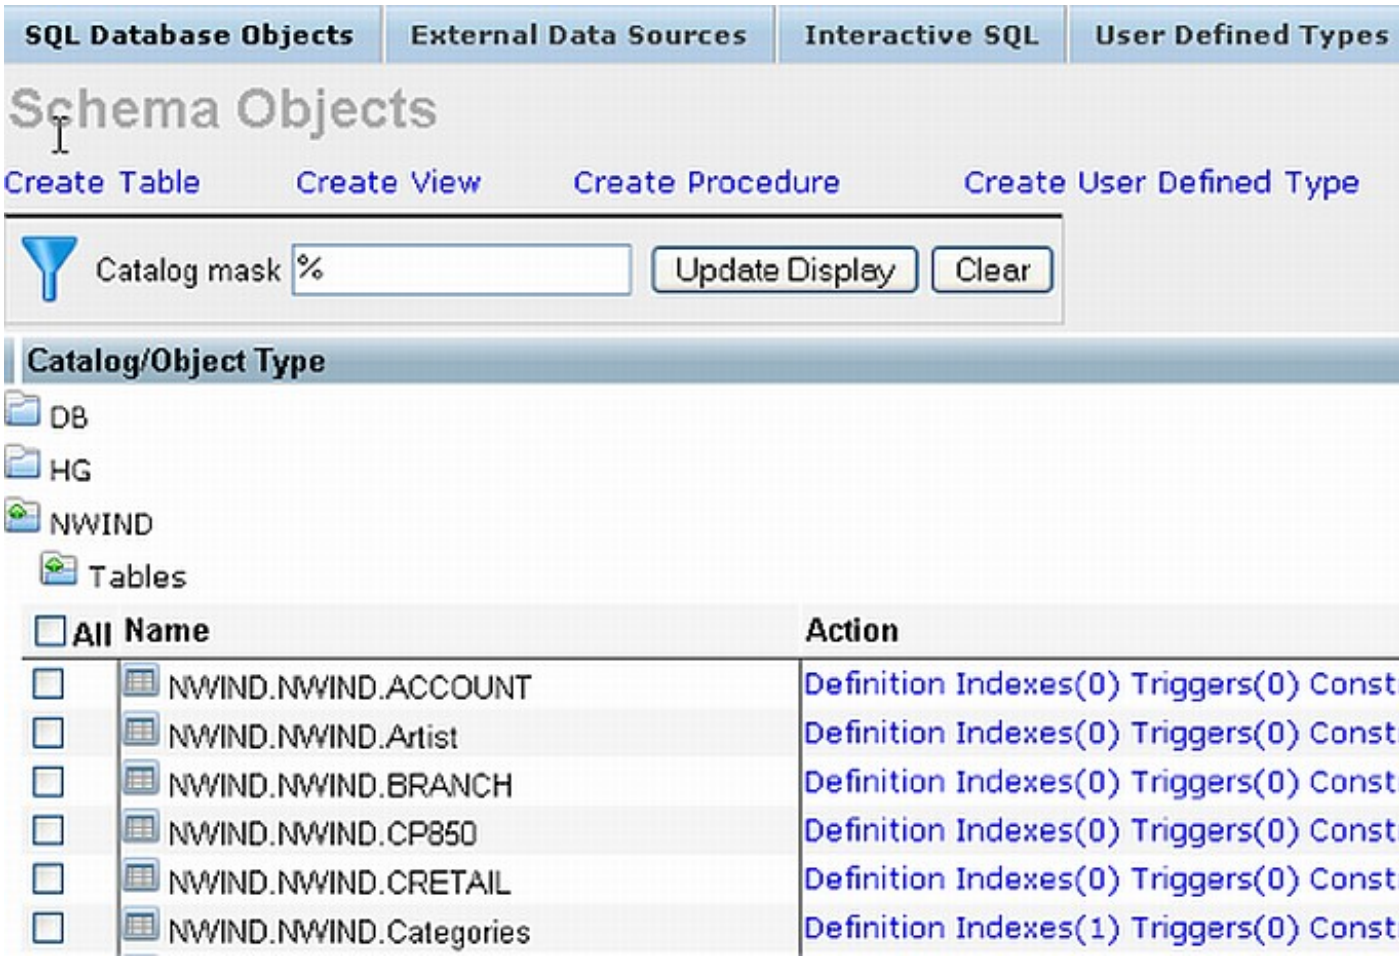


12. Select Execute to see data from the remotely linked table.

Figure 8.659. Execute

13. The tables can also be viewed as part of the Virtuoso "SQL Schema Objects" under the "Northwind" catalog name.

Figure 8.660. SQL Schema Objects



The Link process is now complete enabling the tables to be queried as if part of the Virtuoso Schema.

8.13.4. Creating EDM in Visual Studio 2008

The following steps can be used to create an Entity Data Model (EDM) for the Microsoft SQL Server Northwind database:

1. Launch the Visual Studio 2008 SP1 IDE.

Figure 8.661. Visual Studio 2008 SP1 IDE

2. Create a

   Web Application

   project by going to the

   File

   menu in Visual Studio and choosing

   New Project

   .
3. When the New Project window appears, choose either

   Visual Basic

   or

   Visual C#

   as your programming language.
4. Within the language category, click on

   Web

   and select

   ASP.NET Web Application

   from the right-hand panel.
5. Choose a name for the project, for example

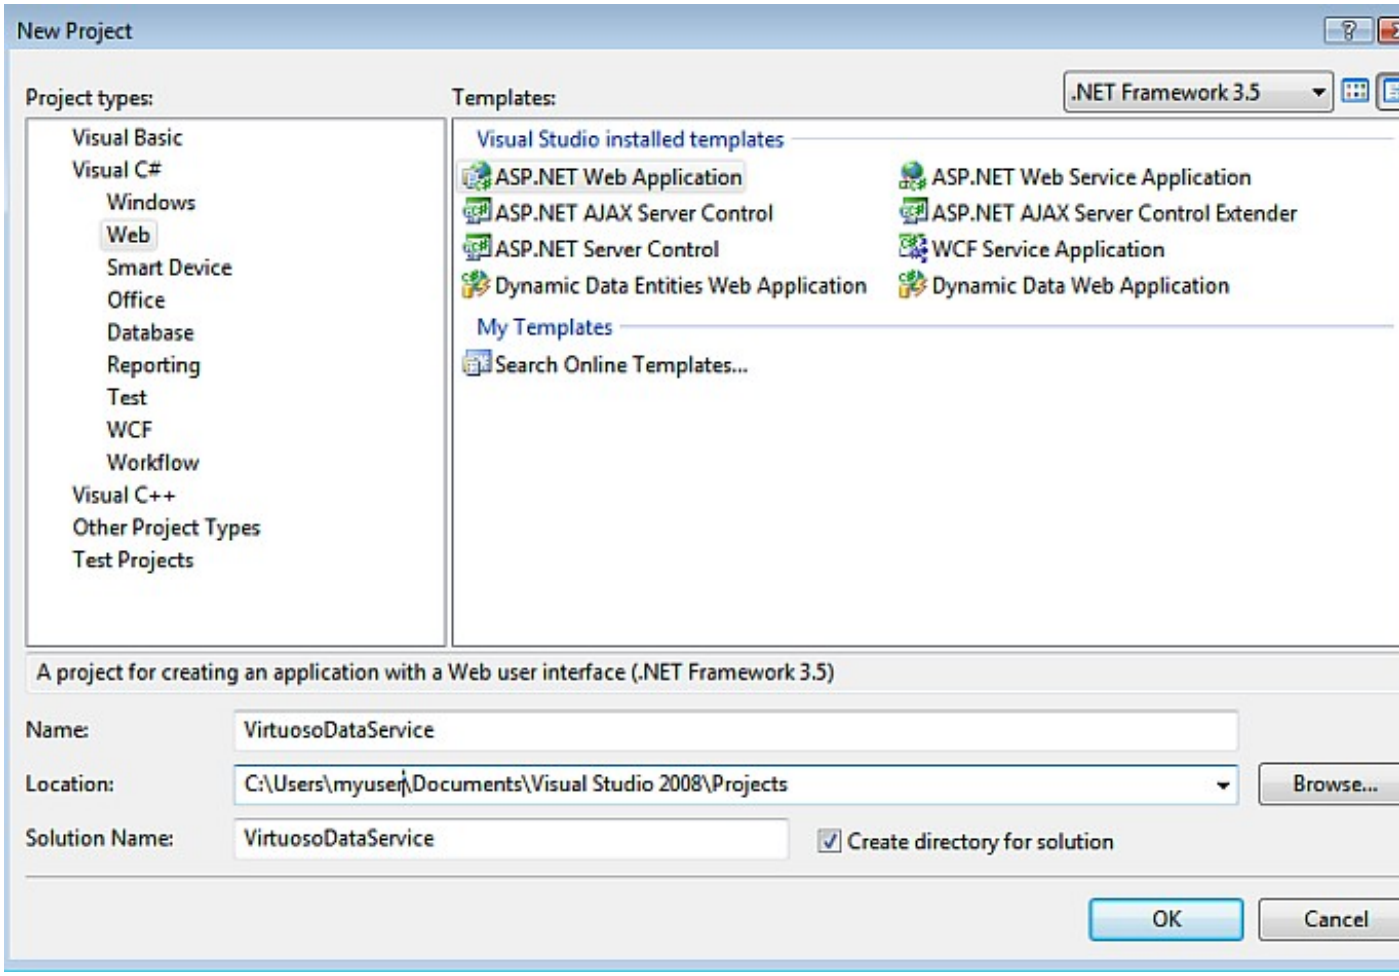
   VirtuosoDataService

   , and click

   OK

   .

Figure 8.662. name for the project

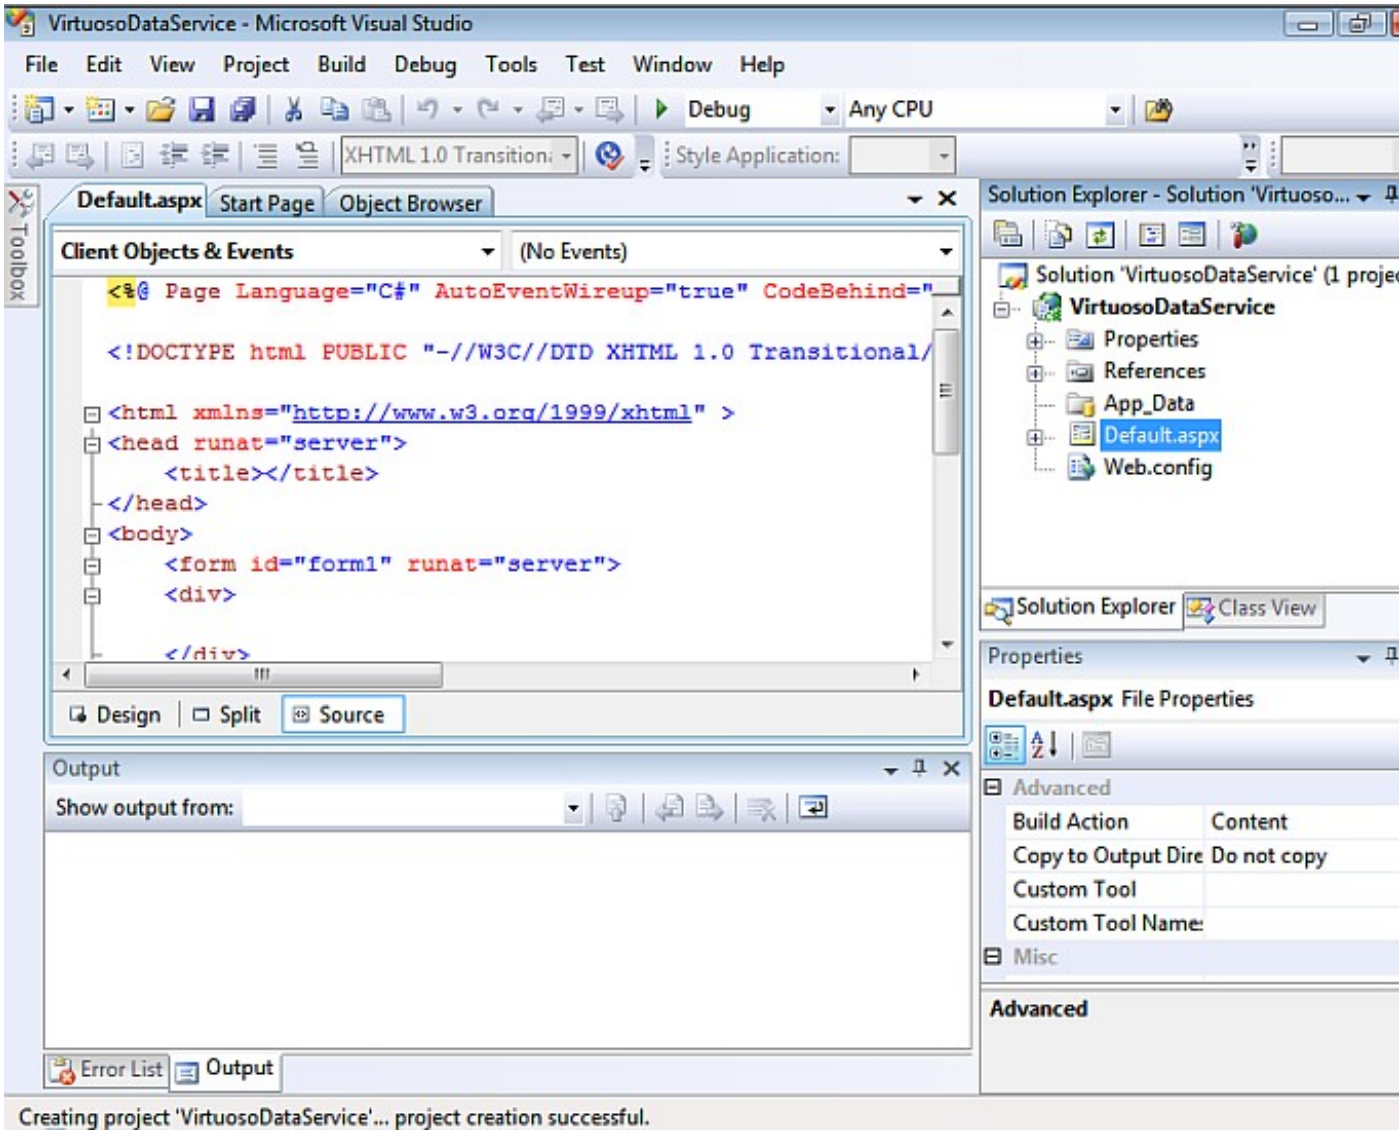


6. This will create a new project called

   VirtuosoDataService

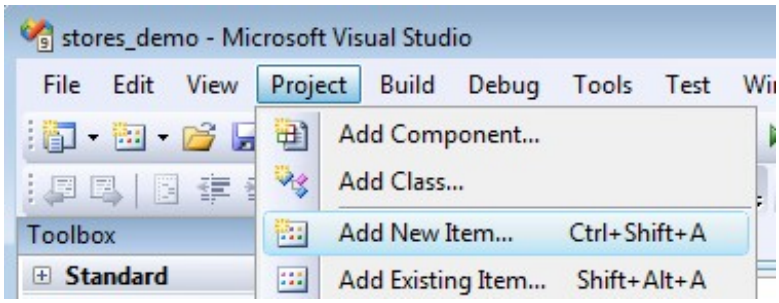
   .

Figure 8.663. create a new project



7. Right click on the VirtuosoDataService project name of the Solution Explorer pane, then select the Add -> New Item menu options.

Figure 8.664. VirtuosoDataService



8. The

Add New Item

dialog will appear. Choose the

ADO.NET Entity Data Model

template. Give it the name

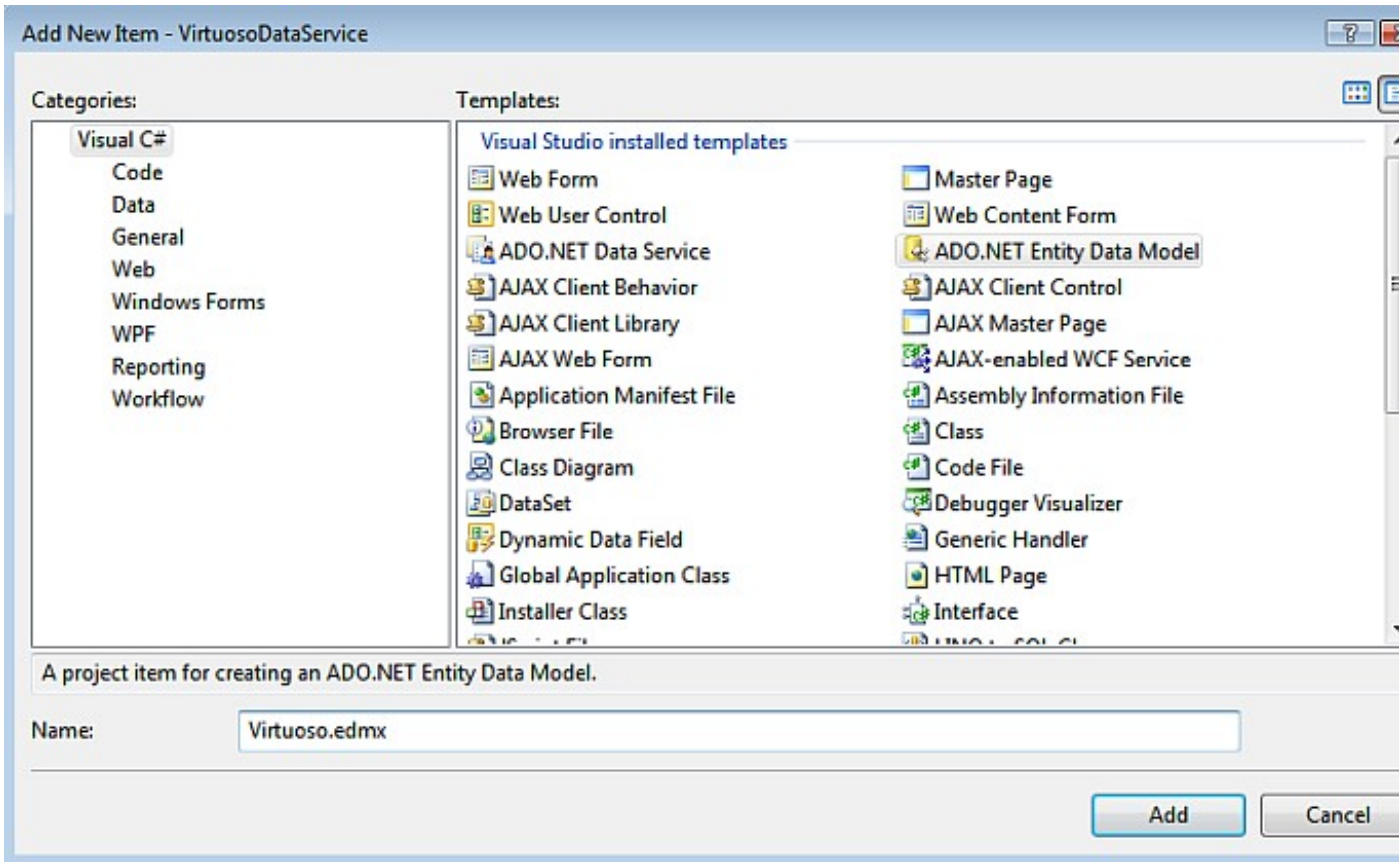
Virtuoso.edmx

and click

Add

to start the creation of the ADO.Net Entity Data Model.

Figure 8.665. Add New Item



9. In the

Entity Data Model Wizard

dialog

Choose Model Contents

page select the

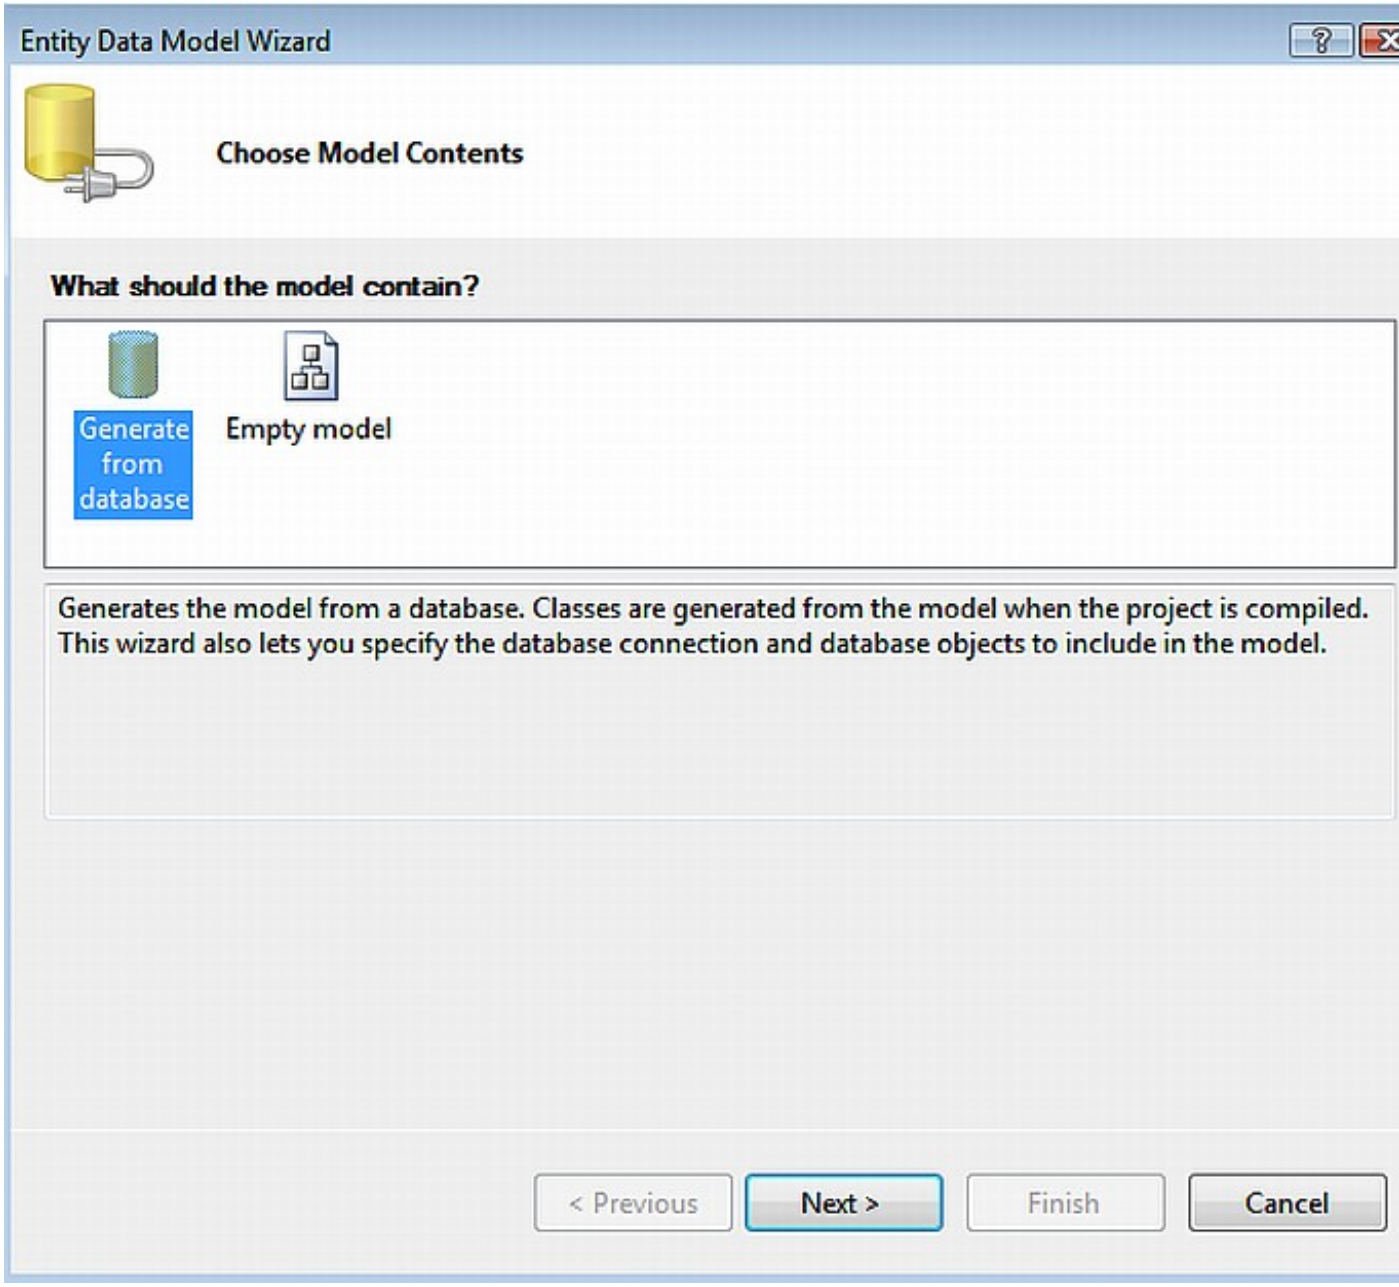
Generate from Database

model type and click

Next

.

Figure 8.666. Choose Model Contents



10. In the

    Entity Data Model Wizard

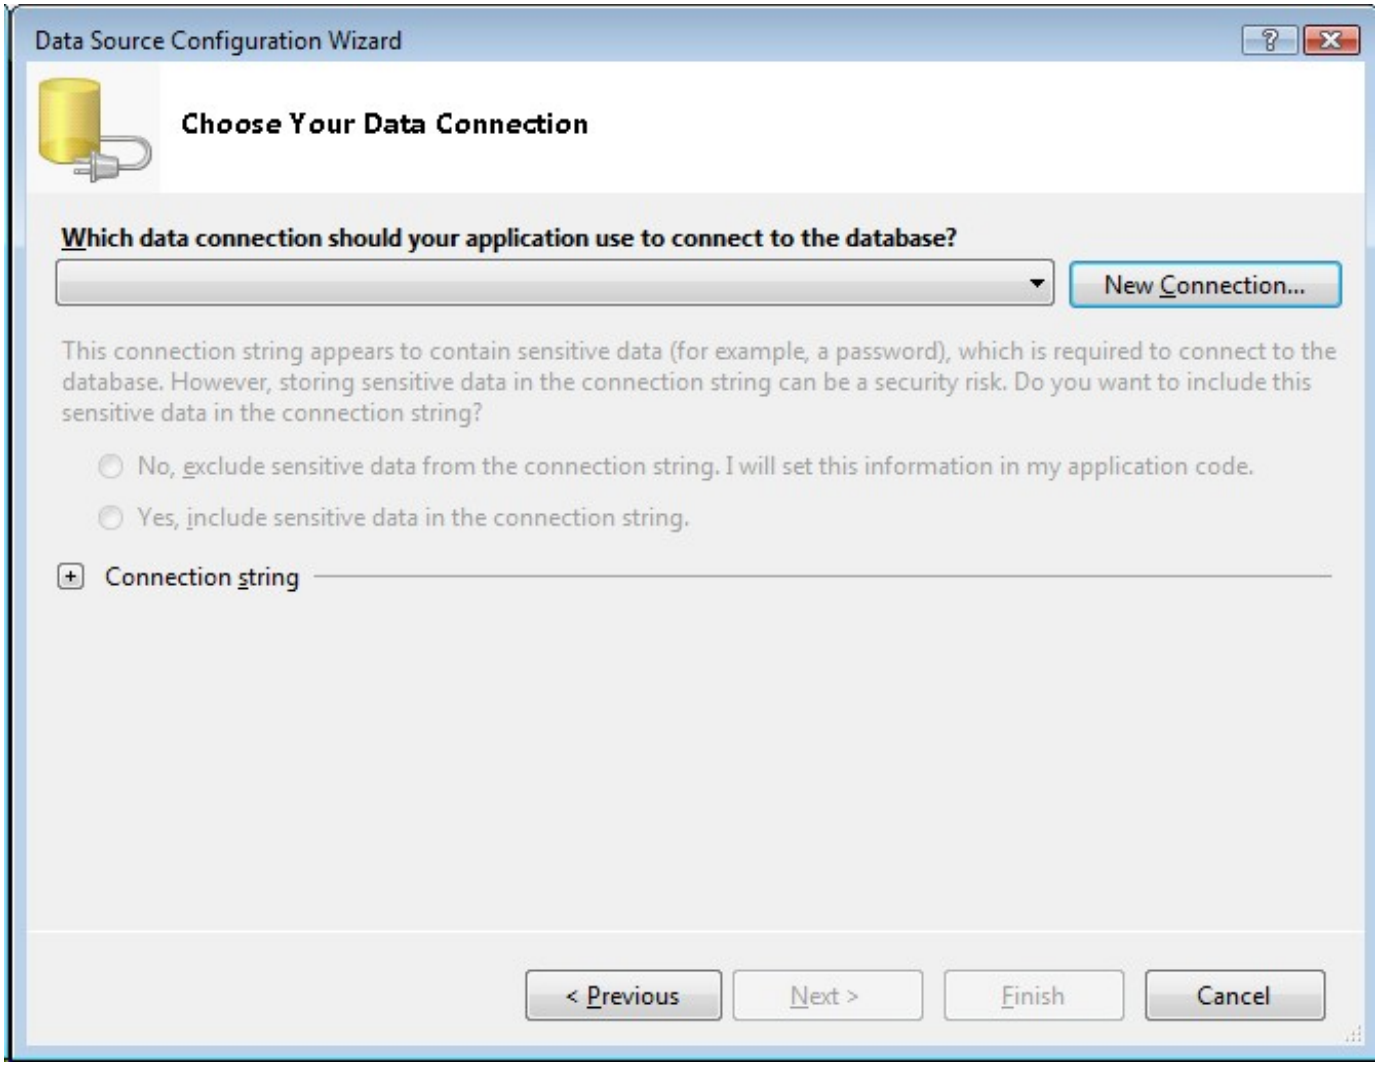
    dialog

    Choose your Data Connection

    page, select the

    New Connection button

Figure 8.667. Entity Data Model Wizard



11. In the

    Choose Data Source

    dialog, select the OpenLink

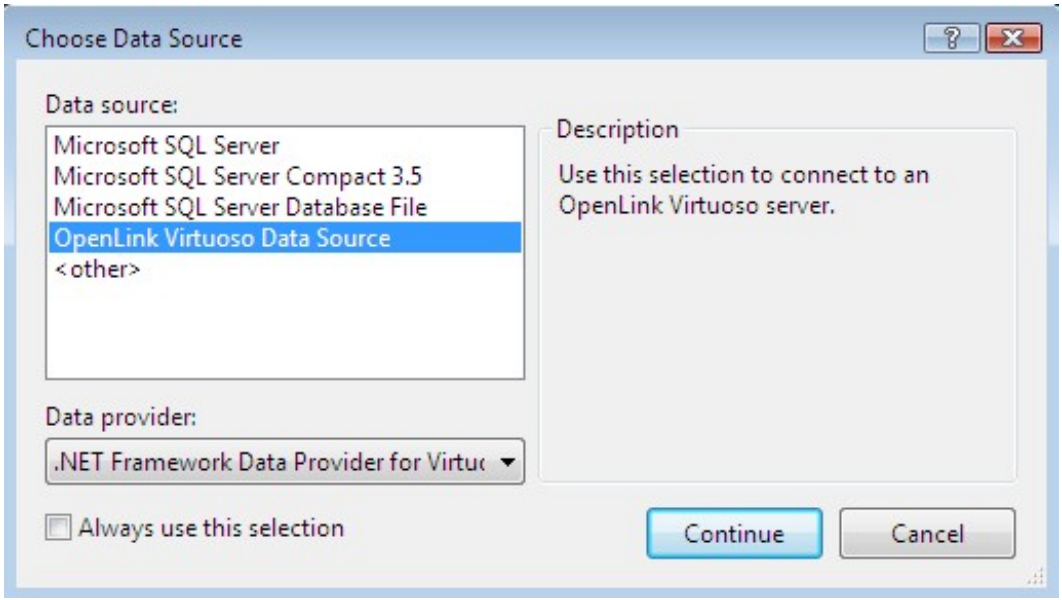
    Virtuoso Data Source

    from the list and click

    Continue

    .

Figure 8.668. Choose Data Source



12. In the

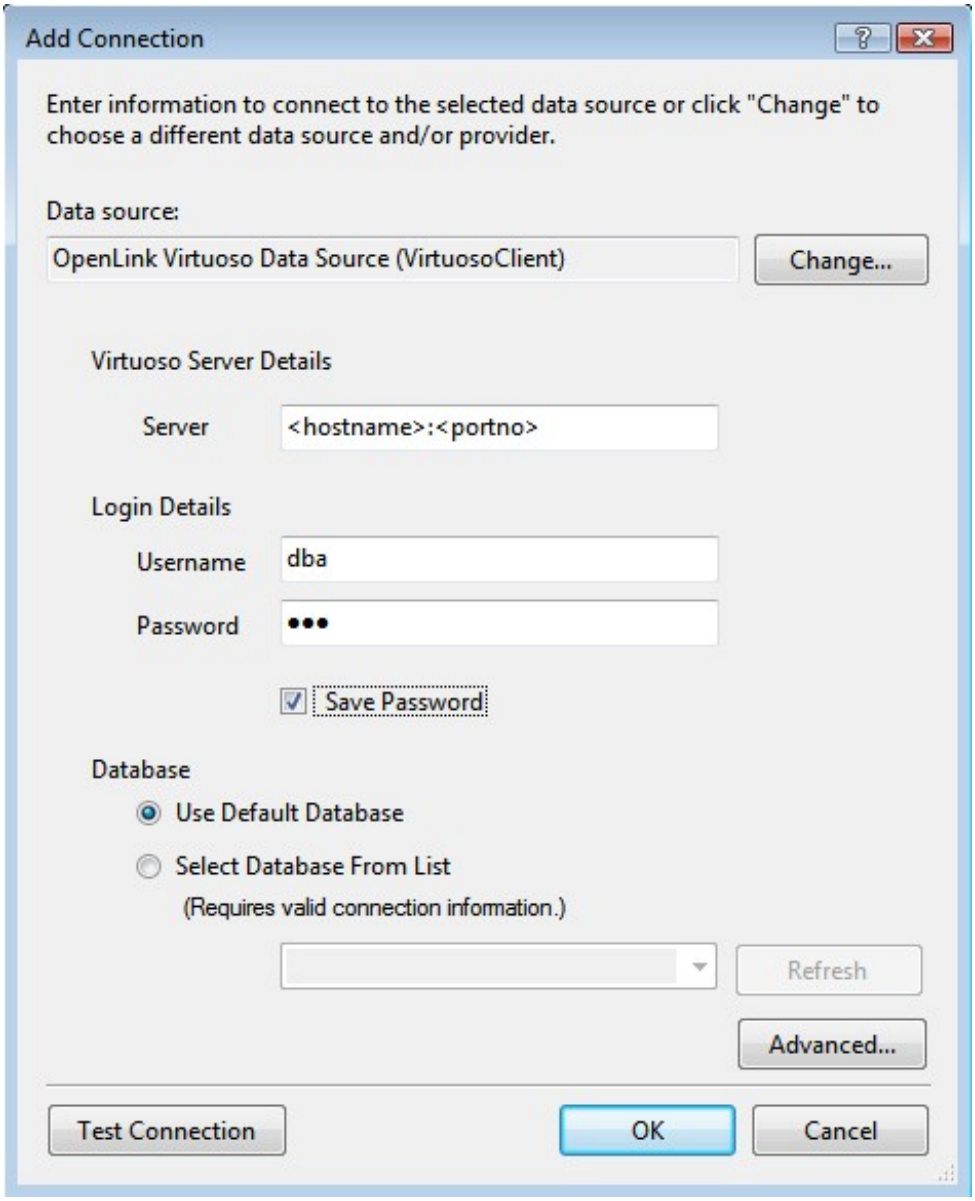
    Add Connection

    dialog, specify the

    hostname, portno, username and password

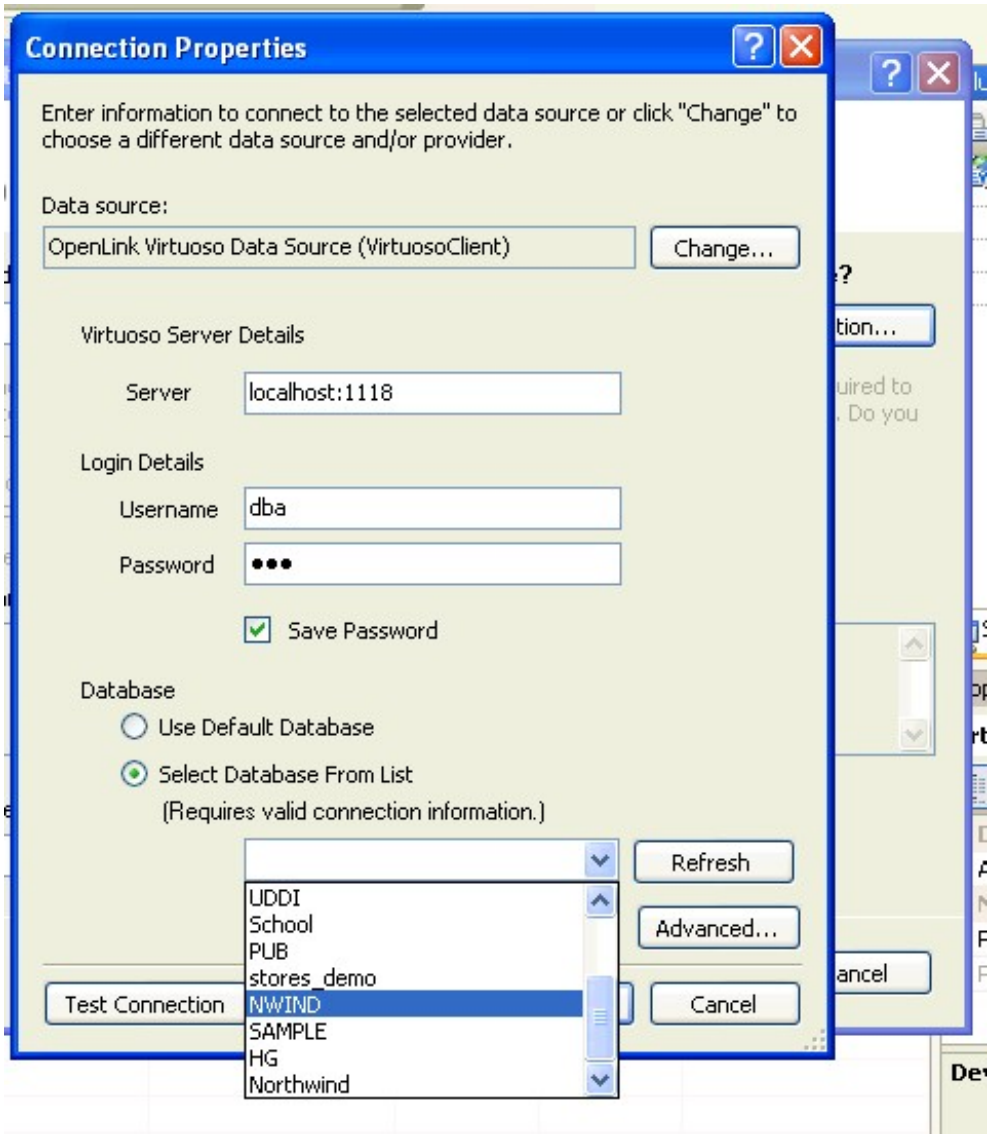
    for the target Virtuoso Server and click the Advanced button.

    Figure 8.669. Connection Properties



13. Use the Select Database From List dialog to select the NWIND catalog.

Figure 8.670. Add connection

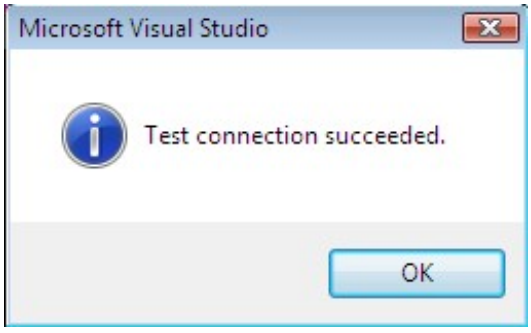


14. Press the

    Test Connection

    dialog to verify that the database is accessible. Click "OK" to persist the connection attributes, after a successful connection is verified.

    Figure 8.671. Test Connection



15. Set the

    entity connect string

    name to

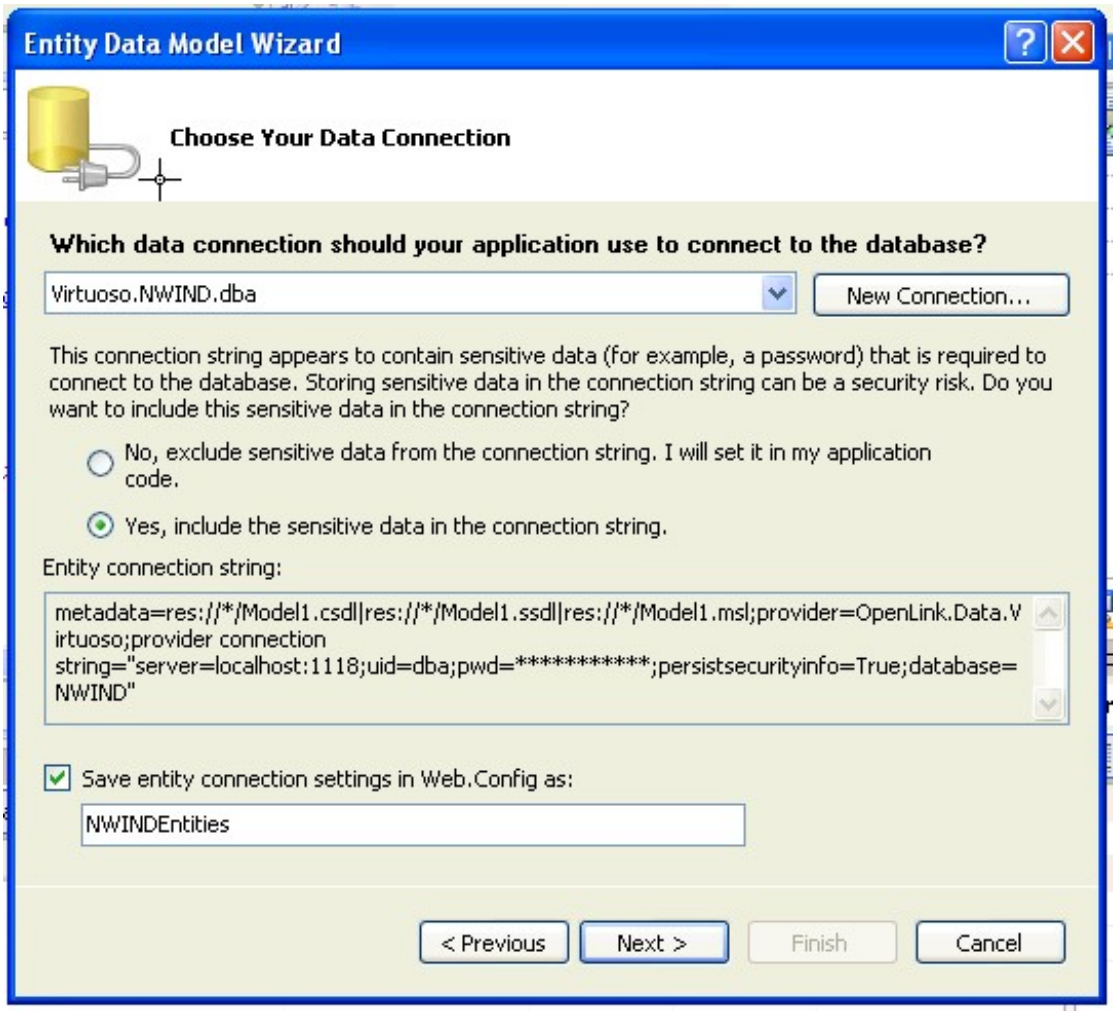
VirtuosoEntities

(note this name as it is required in the section on creating and ADO.Net Data Service) and click

Next

.

Figure 8.672. entity connect string



16. In the

    Choose your Database Objects

    page select the

    Tables

    check box to select all tables in the NWIND catalog for addition to the Entity Data Model. Set the

    Model Namespace

    to

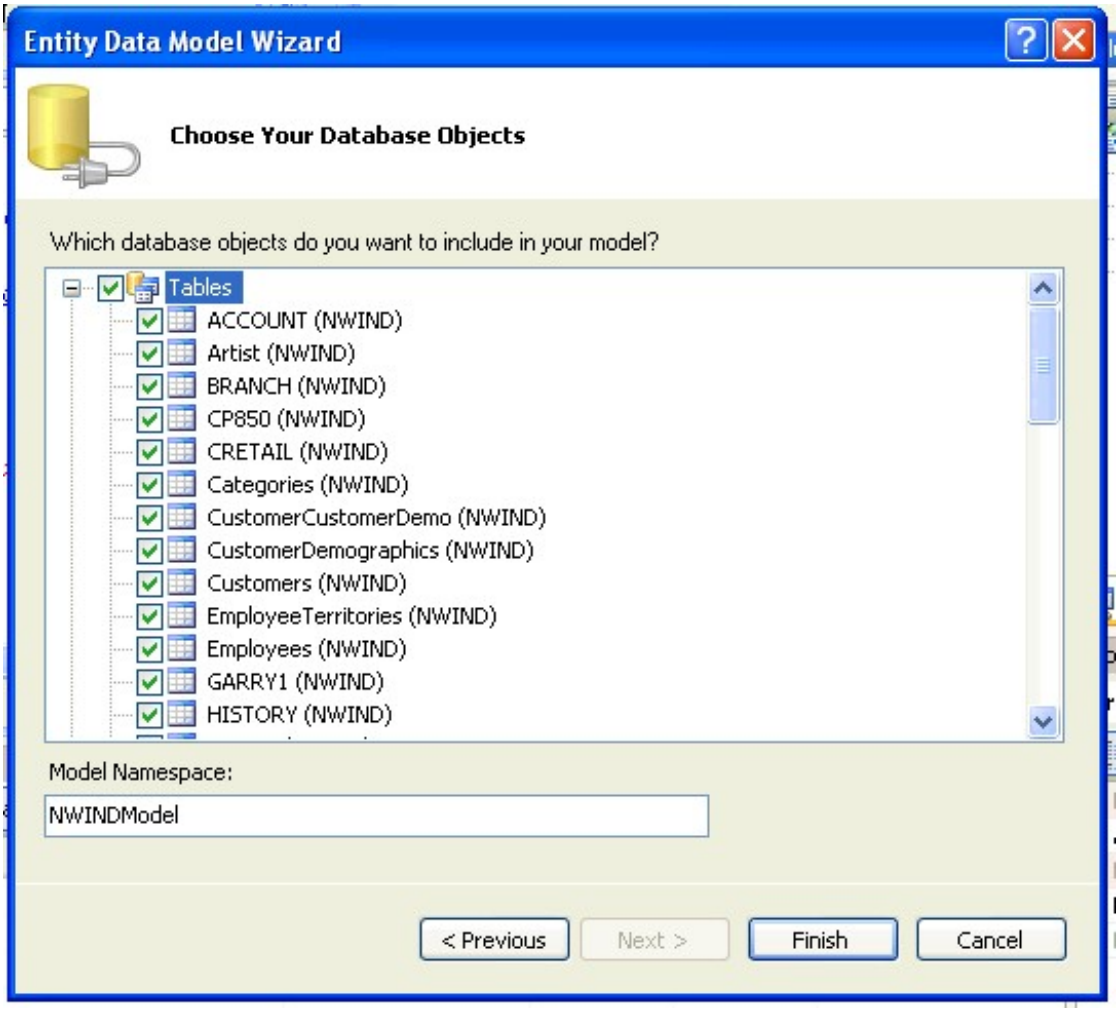
    VirtuosoModel

    and click

    Finish

.

Figure 8.673. Database Objects

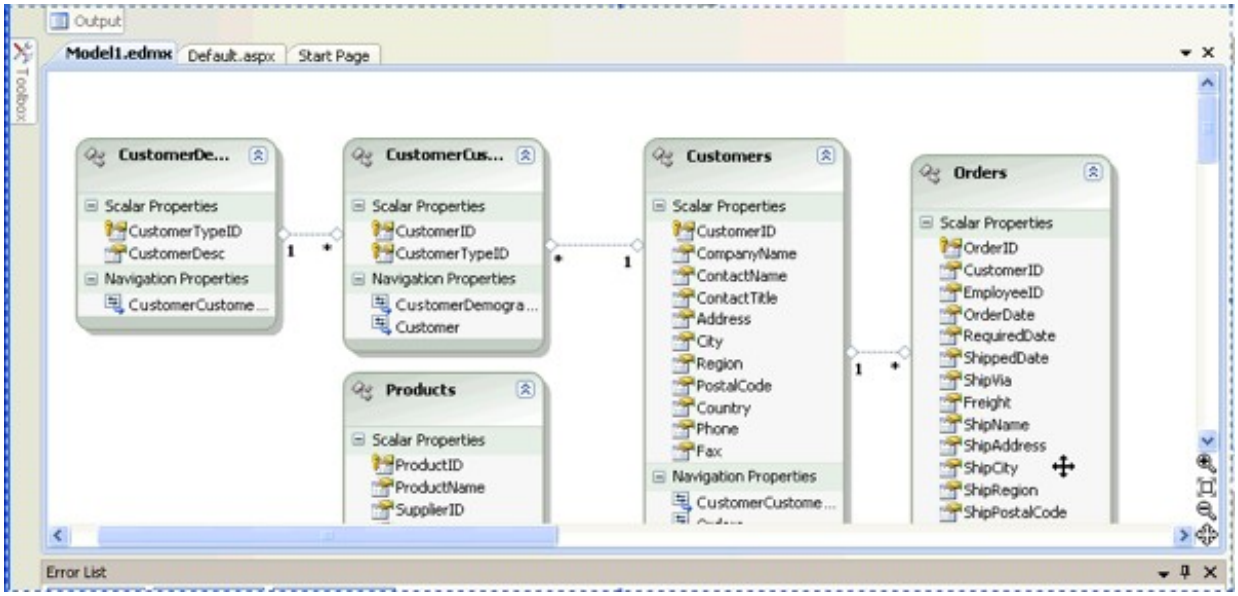


17. The

    Virtuoso.edmx

    EDM will be created with the tables and relationships displayed in the Visual Studio IDE

    Figure 8.674. Virtuoso.edmx



Creation for the Entity Data Model for the Microsoft SQL Server Northwind database is now complete.

8.13.5. Using EDM to create Entity Framework based applications

Now that a Microsoft Entity Data Model has been created for the Microsoft SQL Server Northwind database, Entity Framework applications can be created to make use of it.

Entity Frameworks based ADO.NET Data Service

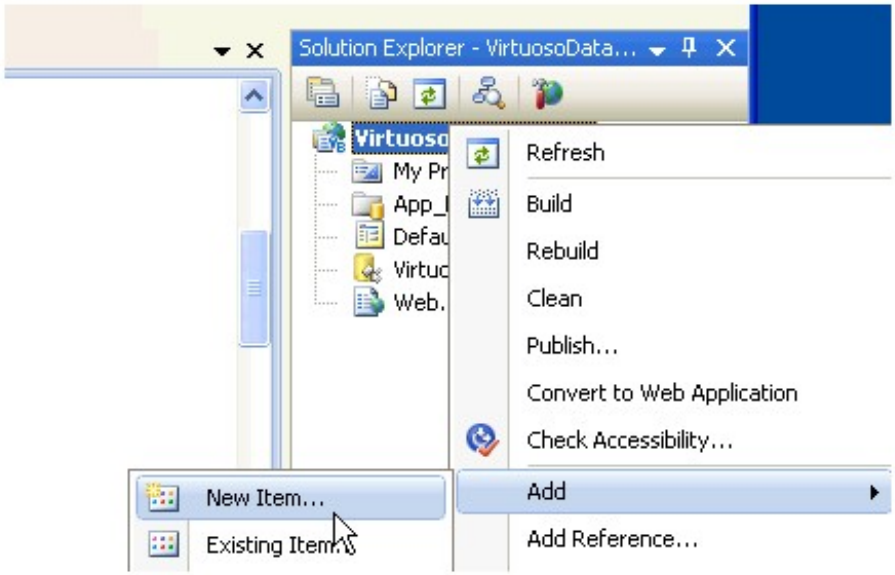
An ADO.Net Data Service for the Microsoft SQL Server tables can be created using the Entity Data Model created in the Creating EDM in Visual Studio 2008 section .

1. Open the

   VirtuosoDataService

   project created in the Creating EDM in Visual Studio 2008 section .
2. Select the Project -> Add New Item menu option.

Figure 8.675. VirtuosoDataService



3. The

   Add New Item

   dialog will appear. Choose the

   ADO.NET Data Service template

   . Give it the name

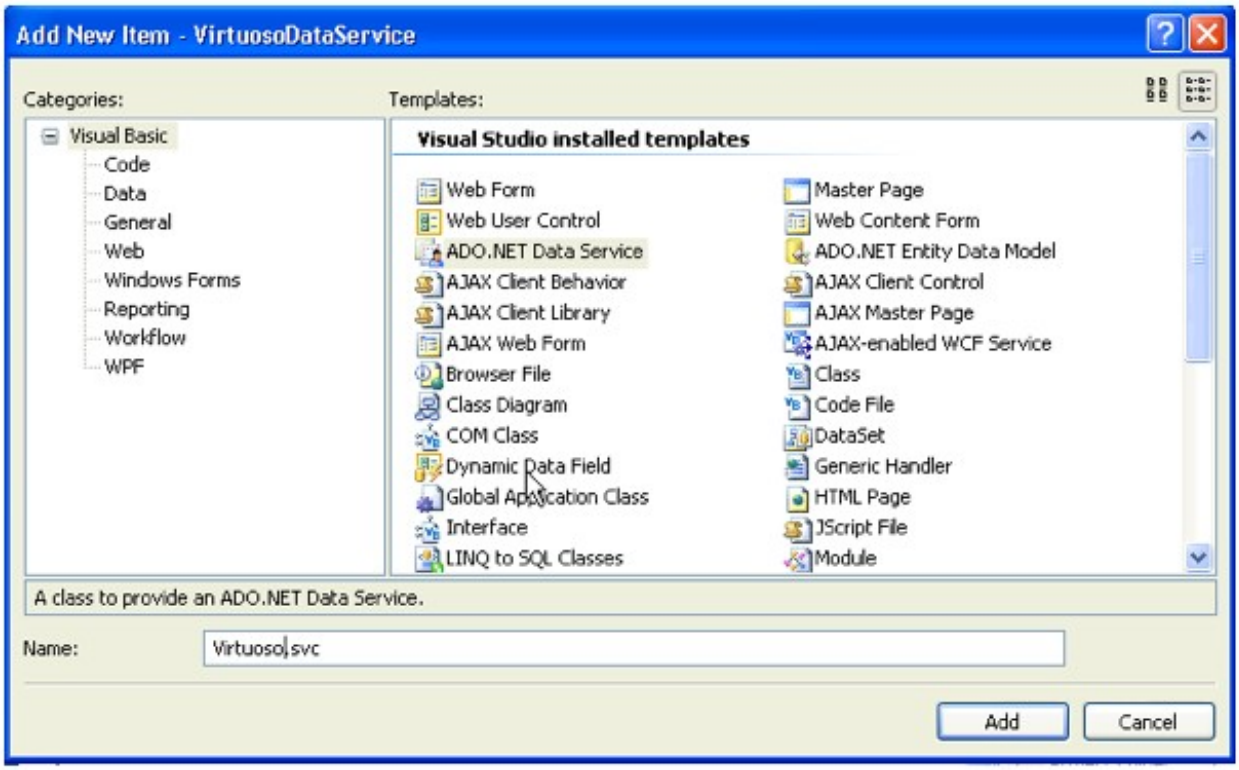
   Virtuoso.svc

   , and click

   Add

   to create the ADO.Net Data Service.

   Figure 8.676. Add New Item



4. In the newly created

   Virtuoso.svc.cs

   Data Service file, add the data source class name of

   VirtuosoEntities

   (note this is the name set in the Creating EDM in Visual Studio 2008 section) as the

   DataService

   name. Enable the access to the Data Service by adding the entry

   config.SetEntitySetAccessRule("", EntitySetRights.All);*

in the

InitializeService

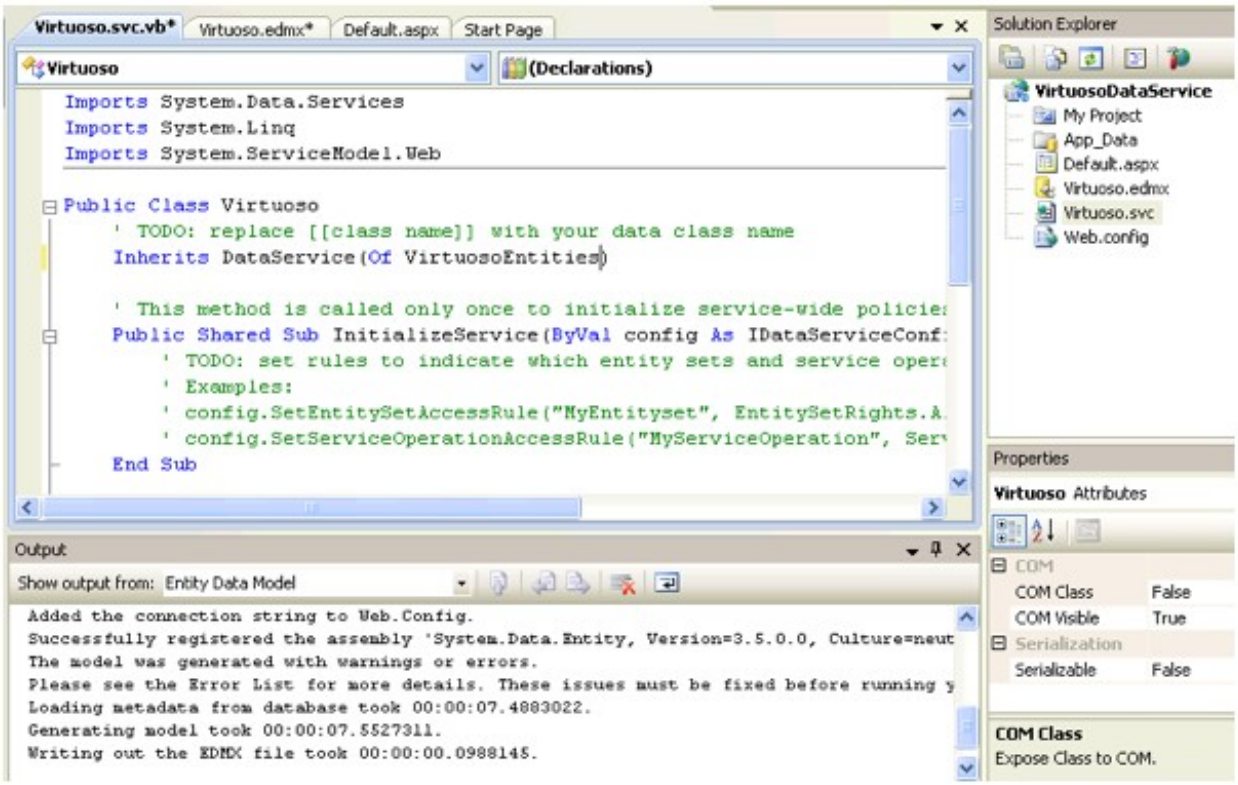
method.

```
// C#

using System;
using System.Web;
using System.Collections.Generic;
using System.ServiceModel.Web;
using System.Linq;
using System.Data.Services;

namespace SimpleDataService
{
    public class Northwind : DataService<VirtuosoDemoEntities>
    {
        public static void InitializeService(IDataServiceConfiguration  config)
        {
            config.SetEntitySetAccessRule("*", EntitySetRights.All);
        }
    }
}
```

Figure 8.677. Virtuoso.svc.cs

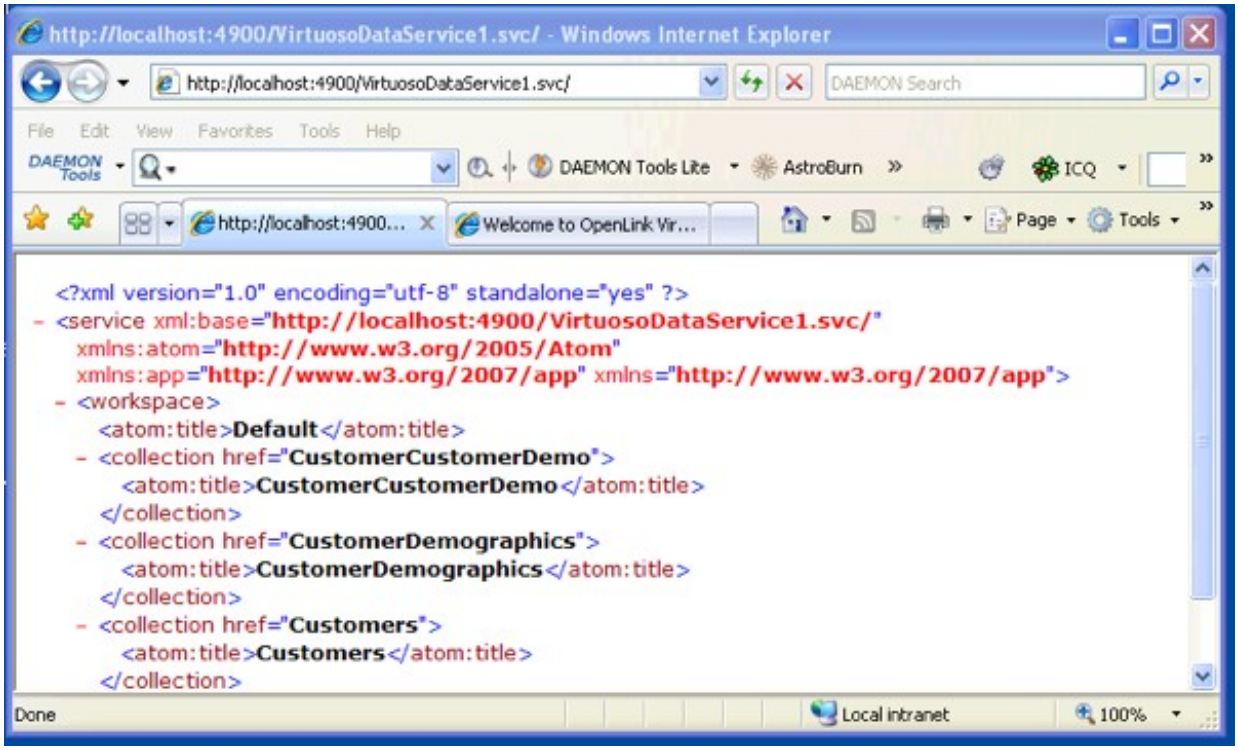


5. To test the Data Service, simply hit

   Ctrl+F5

   within Visual Studio. This will start the development web server, run the Data Services server inside and load a Web browser page displaying the list of available tables/entities for the Northwind database catalog.

Figure 8.678. Data Service test

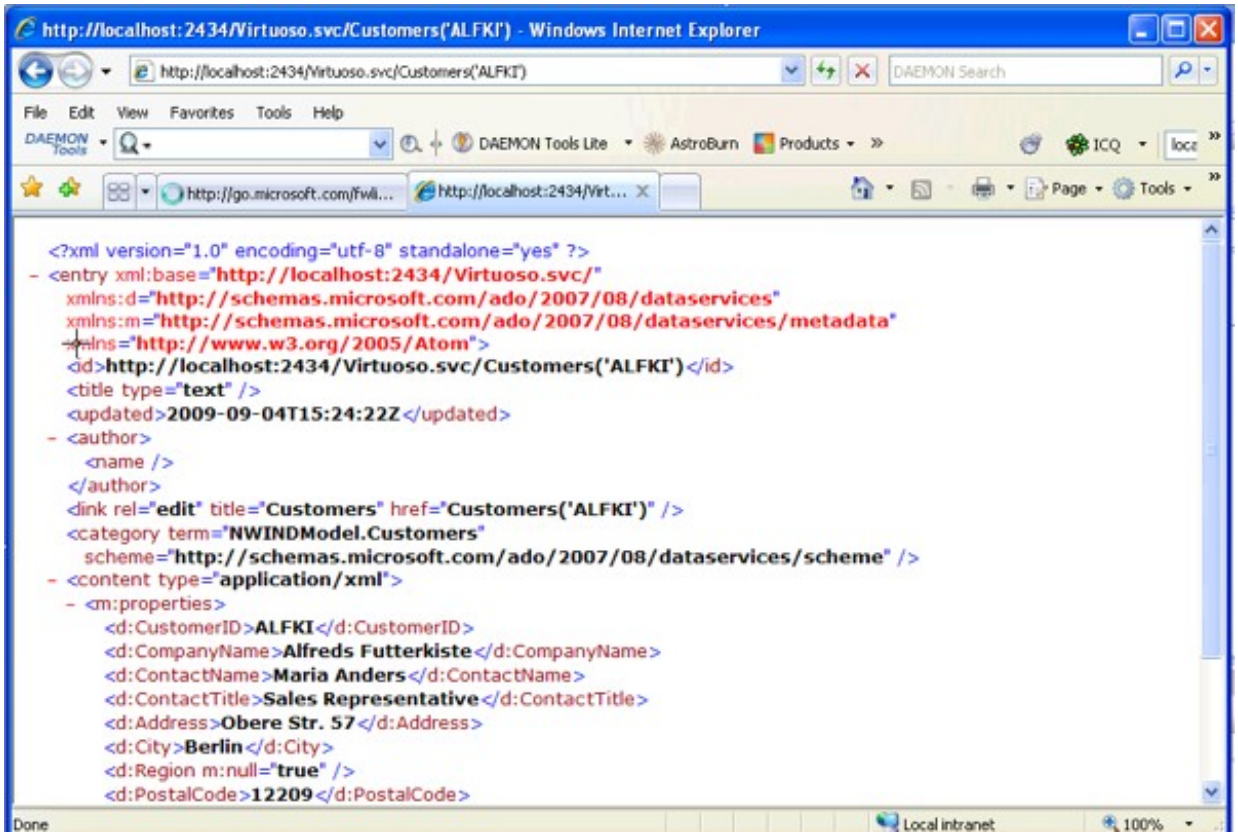


6. To access a specific entity instance like the

   Customers

   table ALFKI record, use this convention http://host/vdir/Virtuoso.svc/Customers('ALFKI').

   Figure 8.679. EMPLOYEES



Notes:

1. *Important*

   - To view

   Atom

   (the default format returned by an ADO.NET Data Service) in Internet Explorer, you must first ensure that

   Feed Reading View

   is turned

   off

   . This can be done on the

   Content tab

   of

   Tools in Internet Options

   .
2. If a Data Services entity instance URI page fails to load you can turn

   Verbose

   errors on by adding

   config.UseVerboseErrors = true;

   in the

   virtuoso.svc.cs InitializeService

   method to obtain more detailed information from the server as to why the page failed to load:

```
public static void InitializeService(IDataServiceConfiguration config)
{
config.UseVerboseErrors = true;
config.SetEntitySetAccessRule("*", EntitySetRights.All);
}
```

8.14. Parallel Operations and Bulk Data Transfer with Remote Tables

Especially when bulk copying data from a remote database into Virtuoso, parallel operation is essential for performance.

From version 7.00.3206, automatic query parallelization applies to selected remote table operations.

If read committed isolation is sufficient for remote table access, the remote table access is automatically parallelized if there is an integer key in the remote table that can be used for partitioning.

When the table is attached or when its statistics are updated with sys_stat_analyze, the remote schema is read and if there is a numeric first part of primary key, its minimum and maximum values are read. Samples of rows are read from the table at different ranges between the minimum and maximum and the values are used for filling in column value statistics in sys_col_stat.

If a remote table operation has no condition on the first part of primary key, a range condition is automatically added if the scan of the remote table is the first in a sequence of nested joins. This is the case for example when scanning the table inside a group by,

order by, hash join build side or other operation that does not immediately return rows to the client. The number of parallel ranges is given by ThreadsPerQuery in the ini file, accessed as enable_qp with sys_stat and __dbf_set. In a cluster setting, the same DSN is expected to be defined on all processes. The cluster splitting will scan a range per each slice of the elastic cluster.

The lowest range does not specify a low bound and the highest does not specify an upper bound, thus the min and max of the range column do not have to be exactly up to date.

It may be that the primary key of the remote table does not start with a numeric column. If this is the case but there still exists a column usable for splitting a scan, one can create the table in Virtuoso and declare the splitting column as first in the primary key. One can then use vd_remote_table to declare the modified table as remote and use sys_stat_analyze for getting the statistics. After this, parallel scans with the selected column used for setting ranges can be done.

Use the explain function to verify that a scan is actually parallel. One expects to see the text of the remote select followed by "split by range of <column name>" below the text of the remote statement.

In a parallel scan each range is scanned over a different connection. The transaction contexts are independent and the isolation cannot be higher than read committed. Setting a higher isolation level or selecting for update disables the parallel scan feature.

The below snippet copies a table from another Virtuoso.

```
use R1;
ATTACH TABLE lineitem
        FROM '1208'
        USER 'dba'
    PASSWORD 'dba';
```

This makes a a remote table R1.1208.LINEITEM. This is the lineitem table from the DSN "1208".

Now make a local table:

```
use DB;
CREATE TABLE LINEITEM (
    L_ORDERKEY        INTEGER NOT NULL,
    L_PARTKEY         INTEGER NOT NULL,
    L_SUPPKEY         INTEGER NOT NULL,
    L_LINENUMBER      INTEGER NOT NULL,
    L_QUANTITY        double precision NOT NULL,
    L_EXTENDEDPRICE   double precision NOT NULL,
    L_DISCOUNT        double precision NOT NULL,
    L_TAX             double precision NOT NULL,
    L_RETURNFLAG      CHAR(1) NOT NULL,
    L_LINESTATUS      CHAR(1) NOT NULL,
    L_SHIPDATE        DATE NOT NULL,
    L_COMMITDATE      DATE NOT NULL,
    L_RECEIPTDATE     DATE NOT NULL,
    L_SHIPINSTRUCT    CHAR(25) NOT NULL,
    L_SHIPMODE        CHAR(10) NOT NULL,
    L_COMMENT         VARCHAR(44) NOT NULL,
    PRIMARY KEY       (L_ORDERKEY, L_LINENUMBER) column );
```

Note the column modifier after the primary key. This ensures that the table is created in the column store mode. When copying large tables over VDB, this is nearly always done for warehousing, not for OLTP, so the column store mode is essentially always best. Insert is faster and the table takes much less space.

To transfer the data from the remote table into the local one:

```
log_enable (2);
INSERT INTO lineietm
     SELECT *
       FROM r1..llineiten;
checkpoint;
```

log_enabel (2) turns off logging an transactions and allows auto committing insert. The explicit checkpoint makes the changes durable. Killing the database server during the transfer would start without any of the effects of the transfer since there is no logging. The data reading and insertion is automatically parallelized.

Most such data transfer operations are in fact network bound since the local insert rate is well in excess of 100MB/s on a commodity server and a 1gbE connection may only transfer around 80MB/s.

The database is normally online during the transfer and the progress may be tracked by periodically counting the target table.

Chapter 9. SQL Reference

Abstract

SQL Reference.

9.1. Datatypes

CHARACTER
: CHARACTER

  VARCHAR

  VARCHAR'('INTNUM')'

  NVARCHAR

  NVARCHAR'('INTNUM')'

  CHAR'('INTNUM')'

NUMERIC
: NUMERIC

  NUMERIC'('INTNUM')'

  NUMERIC'('INTNUM','INTNUM')'

DECIMAL
: DECIMAL

  DECIMAL'('INTNUM','INTNUM')'

INTEGER
: INT

  INTEGER

  SMALLINT

FLOAT
: FLOAT

  FLOAT'('INTNUM')'

REAL
: REAL

  DOUBLE PRECISION

LONG VARCHAR
: BLOB data

VARBINARY [(precision)]
: Binary data

LONG VARBINARY
: Binary BLOB data

TIMESTAMP

TIMESTAMP

DATETIME

TIME

DATE

<UDT>
: User Defined Type with varbinary-like size properties.

LONG <UDT>
: User Defined Type with LONG varbinary-like size properties.

LONG XML
: LONG XML BLOB-like data type.

Note:
User Defined Types can be created from native or external types, composites or classes from any hosted language such as Java or .Net. Any User Defined Type can be used to define a column in a CREATE TABLE statement.

9.1.1. Date Literals

Virtuoso does not support date literals or the DATE reserved keyword. Literal dates should be enclosed in a conversion function such as `stringdate()` , as in this example:

```
select * from demo.demo.orders o
  where o.orderdate between stringdate('1994-01-01') And stringdate('1997-12-31')
```

Alternatively type casts can be used to explicitly instruct Virtuoso to assume a string as a date, see below.

9.1.2. Casting

Blob types can be cast to varchars. This will produce a string of up to 16 MB in length and an error for longer blobs.

Nothing can be cast to a blob type. Blobs only come from selecting blob columns and are created by assigning values to such columns.

Converting non-integer values to integers rounds towards 0.

Any data type can be converted to binary with the VARBINARY target data type. The result may or may not be meaningful. Specifically datetime can be converted to binary and back.

```
cast_expression :
                CAST '(' scalar_exp AS data_type [COLLATE collation_name ] ')'

collation_name :
        identifier
        | owner '.' identifier
        | qualifier '.' owner '.' identifier
```

The CAST expression converts the type of the scalar_exp into the data_type, if possible. If the conversion is not meaningful, as from a float to a date, an error is signalled.

CAST is the recommended way of converting between data types, including any conversion between strings, different number types and datetime types.

Example 9.1. Examples:

```
select cast ('2000-1-3' as date);

select cast (cast ('2000-1-3' as date) as varchar);
        = 2000-01-03 00-00-00 000000
```

9.1.3. Time & Date Manipulation

The SQL92 standard functions for time and date queries are available. These are mapped to Virtuoso internal functions as follows:

CURRENT_DATE - `curdate()`
CURRENT_TIME - `curtime()`
CURRENT_TIMESTAMP - `curdatetime()`
The results of the above functions can also be obtained using the `now()` function and casting to the appropriate target type.

Dates and times should be input or compared as literals in a standard format. The following table describes the proper methods available:

Table 9.1. Time & date syntax

Datatype	ODBC Syntax	SQL92 Casting
Date	{d 'yyyy-mm-dd'}	cast('yyyy-mm-dd' as date)
Time	{t 'hh:mm:ss'}	cast('hh:mm:ss' as time)
Datetime/timestamp	{ts 'yyyy-mm-dd hh:mm:ss[.f...]'}	cast('yyyy-mm-dd hh:mm:ss[.f...]' as datetime)

Example 9.2. Example: comparing dates

```
select datecol from table
  where datecol > cast('1900-01-01' as date)
    and datecol < cast(now() as date);
```

now() is cast for explicit compatibility although not required.

9.1.4. Declaring Collations of Expressions

A collation can be declared with CAST for string expressions. Suppose insensitive_ascii were a collation name specifying case insensitive comparison of ASCII strings, the predicate:

```
CAST 'foo' as varchar collate insensitive_ascii) = CAST 'FOO as varchar collate insensitive_ascii)
```

would be true.

This will alter the semantic of string comparison and can be used to define a collation where the collation would otherwise be default, for instance when comparing results of expressions or constants. This can also alter the default collation implied by the collation declaration in column options in CREATE TABLE.

9.2. User Defined Types

A user-defined type is a schema object, identified by a user-defined type name. The definition of a user-defined type specifies a number of components, including in particular a list of attribute definitions. The representation of a user-defined type is expressed as a list of attribute definitions.

The definition of a user-defined type may include a method specification list consisting of one or more method specifications. A method specification is either an original method specification or an overriding method specification. Each original method specification specifies the method name, the SQL parameter declaration list, the returns data type, the <language clause>, the language (if the language is not SQL), and whether it is a STATIC or CONSTRUCTOR method.

Each overriding method specification specifies the method name, the SQL parameter declaration list and the RETURNS data type. For each overriding method specification, there must be an original method specification with the same method name and SQL parameter declaration list in some proper supertype of the user-defined type. Every SQL-invoked method in a schema must correspond to exactly one original method specification or overriding method specification associated with some user-defined type existing in that schema. A method `M` that corresponds to an original method specification in the definition of a structured type `T1` is an original method of `T1` . A method `M` that corresponds to an overriding method specification in the definition of `T1` is an overriding method of `T1` . A method `M` is a method of type `T1` if one of the following holds:

M is an original method of T1

M is an overriding method of T1

There is a proper supertype T2 of T1 such that M is an original or overriding method of T2 and such that there is no method M3 such that M3 has the same method name and SQL parameter declaration list as M and M3 is an original method or overriding method of a type T3 such that T2 is a proper supertype of T3 and T3 is a supertype of T1 .

A user defined type can be a direct subtype of one (and only one) user defined type. The user defined type cannot be a subtype of itself.

A type Ta is a direct subtype of a type Tb if Ta is a proper subtype of Tb and there does not exist a type Tc such that Tc is a proper subtype of Tb and a proper supertype of Ta .

A type Ta is a subtype of type Tb if one of the following pertains:

Ta is a direct subtype of Tb ; or

Ta is a subtype of some type Tc and Tc is a direct subtype of Tb .

By the same token, Tb is a supertype of Ta and is a direct supertype of Ta in the particular case where Ta is a direct subtype of Tb . If Ta is a subtype of Tb , then Ta is proper subtype of Tb and Tb is a proper supertype of Ta . A type cannot be a proper supertype of itself. A type with no proper supertypes is a maximal supertype. A type with no proper subtypes is a leaf type.

Let Ta be a maximal supertype and let T be a subtype of Ta . The set of all subtypes of Ta (which includes Ta itself) is called a subtype family of T or (equivalently) of Ta . A subtype family is not permitted to have more than one maximal supertype. Every value in a type T is a value in every supertype of T . A value V in type T has exactly one most specific type MST such that MST is a subtype of T and V is not a value in any proper subtype of MST . The most specific type of value need not be a leaf type. For example, a type structure might consist of a type PERSON that has STUDENT and EMPLOYEE as its two subtypes, while STUDENT has two direct subtypes UG_STUDENT and PG_STUDENT . The invocation STUDENT( ) of the constructor function for STUDENT returns a value whose most specific type is STUDENT , which is not a leaf type. If Ta is a subtype of Tb , then a value in Ta can be used wherever a value in Tb is expected. In particular, a value in Ta can be stored in a column of type Tb , can be substituted as an argument for an input SQL parameter of data type Tb , and can be the value of an invocation of an SQL-invoked function whose result data type is Tb . A type T is said to be the minimal common supertype of a set of types S if T is a supertype of every type in S and a subtype of every type that is a supertype of every type in S .

Note:

Because a subtype family has exactly one maximal supertype, if two types have a common subtype, they must also have a minimal common supertype. Thus, for every set of types drawn from the same subtype family, there is some member of that family that is the minimal common supertype of all of the types in that set.

A user-defined type is declared by a user-defined type CREATE TYPE statement .

9.2.1. CREATE TYPE Statement

```
CREATE TYPE type_name
   [ UNDER type_name ]
   [ LANGUAGE language_name [ EXTERNAL NAME literal ] ]
   [ AS (type_member, ...) ]
   [ type_option [type option ] .... ]
   [ method_specification, ... ]

type_name :
  [ [ identifier  .] [ identifier ] . ] identifier

type_member :
  identifier data_type [ DEFAULT literal ] [ EXTERNAL NAME string ] [ EXTERNAL TYPE string ]
    [ __SOAP_TYPE literal ] [ __SOAP_NAME literal ]

type_option : SELF AS REF | TEMPORARY | SOAP_TYPE literal

method_specification : original_method_specification | overriding_method_specification

original_method_specification :
  [ STATIC | INSTANCE ] METHOD identifier ( [ decl_parameter, ... ] )
    RETURNS data_type [ method_characteristics ]
  |
  CONSTRUCTOR METHOD identifier ( [ decl_parameter, ... ] )  [ method_characteristics ]
```

```
overriding_method_specification :
        OVERRIDING [ INSTANCE ] METHOD identifier ( [ decl_parameter, ... ] )
    RETURNS data_type

method_characteristics :
  [ EXTERNAL TYPE literal ] [ EXTERNAL NAME string | EXTERNAL VARIABLE NAME string ]

language_name : SQL | CLR | JAVA
```

The CREATE TYPE statements declares a user defined type. Generally speaking the user defined types can be in two states: forward-referenced, declared and instantiable.

A type is in forward reference state if it's name is quoted in some other CREATE TYPE statement (as a supertype, member type or a method parameter type or return type). When a type is in forward reference state it's instances can be copied, passed as parameter values and returned by functions, but it cannot be instantiated, no type members can be accessed and no type methods can be called. Forward references are temporary objects and they disappear at server shutdown.

A type moves to the declared state when a CREATE TYPE is executed for it. In that state type methods can be called, type members can be accessed, but the type cannot be instantiated.

A type goes into instantiable state from declared state when it has no supertype or it's supertype is also in instantiable state. The server tries to move the defined types to instantiable state on every CREATE TYPE statement.

Normally the type definitions are stored into the DB.DBA.SYS_USER_TYPES system table.

This has the following layout:

```
CREATE TABLE SYS_USER_TYPES
(
 UT_NAME VARCHAR,
 UT_PARSE_TREE LONG VARCHAR,
 UT_ID integer identity,
 UT_MIGRATE_TO integer,
 primary key (UT_NAME));
```

UT_NAME - the fully qualified user defined type name.

UT_PARSE_TREE - the user defined type definition (in machine readable form).

UT_ID - the ID of the type (used in persisting type instances to/from network/storage).

UT_MIGRATE_TO - reserved for future use.

If a TEMPORARY type_option is specified, the CREATE TYPE does not write the type definition into the table - it declares the type only in server's memory. TEMPORARY types are not persistable. They disappear when the server is restarted. A TEMPORARY type cannot be a supertype or a subtype of a non-TEMPORARY type.

The `SELF AS REF` option directs the server to return a reference to the type's instance when instantiating the type, as opposed to returning the instance itself. The references are explained in more detail in the `NEW` operator.

Note:

The CREATE TYPE is an autocommitting statement.

Example 9.3. Creating User Defined Types

This example creates a SQL implemented user defined type UDT_TEST with no supertype. It has two members : A and B, two constructor methods, a static method _ADD, an ADDIT method taking either zero or two arguments and an instance method SUB_IT.

```
create type UDT_TEST
  as (A integer default 1, B integer default 2)
  CONSTRUCTOR METHOD UDT_TEST(_a integer, _b integer),
  CONSTRUCTOR METHOD UDT_TEST(),
  STATIC METHOD _ADD(_xx integer, _yy integer) returns integer specific DB.DBA.static_add,
  METHOD ADDIT() returns integer,
  METHOD ADDIT(c integer) returns integer,
  METHOD SUB_IT () returns integer;
```

This creates a subtype of UDT_TEST named UDT_TEST_SUB. UDT_TEST_SUB extends the static method _ADD of UDT_TEST so it can also take 4 arguments, overrides the method ADDIT from UDT_TEST and defines a new instance method MULTIPLY_IT.

```
create type UDT_TEST_SUB under UDT_TEST
  as (C integer default 12, _D integer default 32)
  STATIC METHOD _ADD(_xx integer, _yy integer, _zz integer, _qq integer) returns integer,
  OVERRIDING METHOD ADDIT() returns integer,
  METHOD MULTIPLY_IT () returns integer;
```

This is a SQL wrapper for a public Java type testsuite_base (see testsuite_base.java).

```
create type testsuite_base language java external name 'testsuite_base'
as (
    protected_I integer external name 'protected_I' external type 'I',
    private_I integer external name 'private_I' external type 'I',
    sZ smallint external name 'Z' external type 'Z',
    sfalseZ smallint external name 'falseZ' external type 'Z',
    sB smallint external name 'B' external type 'B',
    sC smallint external name 'C' external type 'C',
    sS smallint external name 'S' external type 'S',
    sI int external name 'I' external type 'I',
    sJ int external name 'J' external type 'J',
    sF real external name 'F' external type 'F',
    sD double precision external name 'D' external type 'D',
    sL any external name 'L' external type 'Ljava/lang/Short;',
    sAI any external name 'AI' external type '[I',
    sAL any external name 'AL' external type '[Ljava/lang/Short;',
    sstr nvarchar external name 'str' external type 'Ljava/lang/String;',
    sdat datetime external name 'dat' external type 'Ljava/util/Date;',

    tF real external name 'F',
    "F" real,

    non_existant_var integer external name 'non_existant_var' external type 'I'
   )
    static method get_static_ro_I ()
        returns integer external type 'I' external variable name 'static_ro_I',
    static method get_static_I ()
        returns integer external type 'I' external variable name 'static_I',
    static method get_protected_static_I ()
        returns integer external type 'I' external variable name 'protected_static_I',
    static method get_private_static_I ()
        returns integer external type 'I' external variable name 'private_static_I',

    static method test_bool (x integer external type 'I')
        returns smallint external type 'Z' external name 'test_bool',

    constructor method testsuite_base (),
    constructor method testsuite_base (i integer external type 'I'),

    static method echoDouble (a double precision external type 'D')
        returns any external type 'Ljava/lang/Double;' external name 'echoDouble',
    static method getObjectType (a any external type 'Ljava/lang/Object;')
        returns varchar external type 'Ljava/lang/String;' external name 'getObjectType',
    static method echoThis (a testsuite_base external type 'Ltestsuite_base;')
        returns integer external type 'I' external name 'echoThis',
    static method static_echoInt (a integer external type 'I')
        returns integer external type 'I' external name 'static_echoInt',

    static method change_it (a testsuite_base)
        returns integer external type 'I' external name 'change_it',

    method "overload_method" (i integer external type 'I')
        returns integer external type 'I',

    method echoInt (a integer external type 'I')
        returns integer external type 'I' external name 'echoInt',

    method echoInt (a double precision external type 'D')
        returns integer external type 'I' external name 'echoInt',
```

```
    method protected_echo_int (a integer external type 'I')
        returns integer external type 'I' external name 'protected_echo_int',

    method private_echo_int (a integer external type 'I')
        returns integer external type 'I' external name 'private_echo_int',

    method "echoDbl" (a double precision)
        returns double precision,

    method non_existant_method (a integer external type 'I')
        returns integer external type 'I' external name 'non_existant_method',

    static method non_existant_static_var (a integer external type 'I')
        returns integer external type 'I' external variable name 'non_existant_static_var';
```

9.2.2. ALTER TYPE Statement

```
ALTER TYPE type_name
 (  ADD ATTRIBUTE type_member
 | DROP ATTRIBUTE identifier [ CASCADE | RESTRICT ]
 | ADD method_specification
 | DROP original_method_specification [ CASCADE | RESTRICT ]

type_name :
  [ [ identifier  .] [ identifier ] . ] identifier

type_member :
  identifier data_type [ DEFAULT literal ] [ EXTERNAL NAME string ] [ EXTERNAL TYPE string ]
    [ __SOAP_TYPE literal ] [ __SOAP_NAME literal ]

type_option : SELF AS REF | TEMPORARY | SOAP_TYPE literal

method_specification : original_method_specification | overriding_method_specification

original_method_specification :
  [ STATIC | INSTANCE ] METHOD identifier ( [ decl_parameter, ... ] )
    RETURNS data_type [ method_characteristics ]
  |
  CONSTRUCTOR METHOD identifier ( [ decl_parameter, ... ] )  [ method_characteristics ]

overriding_method_specification :
        OVERRIDING [ INSTANCE ] METHOD identifier ( [ decl_parameter, ... ] )
    RETURNS data_type

method_characteristics :
  [ EXTERNAL TYPE literal ] [ EXTERNAL NAME string | EXTERNAL VARIABLE NAME string ]

language_name : SQL | CLR | JAVA
```

The ALTER TYPE statements modifies a user defined type. It can be used for adding or dropping methods and members of user defined types.

Note:
The ALTER TYPE is an autocommitting statement.

Example 9.4. Altering User Defined Types

This example uses a SQL implemented user defined type UDT_ALTER_TYPE with no supertype defined as follows:

```
create type UDT_ALTER_TYPE as (A integer default 1)
method m1 (I integer) returns integer;
create method M1 (in I integer) returns integer for UDT_ALTER_TYPE
{
 return I;
};
```

Then it adds an attribute B to it :

```
alter type UDT_ALTER_TYPE Add attribute B integer default 2;
```

Then drops the original A attribute :

```
alter type udt_ALTER_TYPE drop attribute A;
```

Now let's add a new method M2 to the type :

```
alter type UDT_ALTER_TYPE Add method M2 (ID integer) returns integer;
create method M2 (in ID integer) returns integer for UDT_ALTER_TYPE
{
  return ID + 100;
};
```

And drop the M1 method :

```
alter type UDT_ALTER_TYPE drop method M1 (ID integer) returns integer;
```

9.2.3. DROP TYPE Statement

```
DROP TYPE type_name
```

This statement reverses the effect of CREATE TYPE statement. If the type has methods defined they are deleted as well. Note that forward references cannot be dropped by a DROP TYPE.

The DROP TYPE statement can be used only for dropping types that are not referenced in another type's UNDER statement.

Example 9.5. Dropping a user-defined type

Dropping the subtype from the previous section.

```
drop type UDT_TEST_SUB;
```

9.2.4. CREATE METHOD Statement

```
CREATE [ INSTANCE | STATIC | CONSTRUCTOR ] METHOD identifier
     ( parameter, .... ) [ RETURNS data_type ] FOR type_name
     {
       .....
     }

  parameter : { IN | OUT | INOUT } identifier data_type
```

For the SQL user defined types every method should be defined in order to be callable. It is an error to call CREATE METHOD for a non-SQL type's methods (as the methods are implemented in some other non-SQL language).

There is no DROP METHOD as each CREATE METHOD will override the current method definition (if any). The method name, parameter types and the return type should match exactly the method declaration (method_specification in CREATE TYPE).

The method name for the constructors is the name of the type (without the qualifier and the owner).

For the constructor and instance methods there is a variable named `SELF` (in scope for the compound statement defining the method) representing the current type instance.

The method members and other methods are not in scope in the method's compound statement. They should be accessed through the `SELF` variable.

Example 9.6. Simple method demonstration

This example defines the two parameter constructor for the UDT_TEST type. It sets the values for the type members A and B to the values of the constructor parameters. This example uses the SQL200n syntax for method mutators (see below).

```
create constructor method UDT_TEST (in _a integer, in _b integer)
  for UDT_TEST
```

```
{
  SELF := A(SELF, _a);
  SELF := B(SELF, _b);
  return SELF;
};
```

This defines the static method _ADD for the type UDT_TEST. Note that it does not use SELF - it would be a syntax error to do so.

```
create static method _ADD (in a1 integer, in a2 integer)
  for UDT_TEST
{
  return a1 + a2;
};
```

9.2.5. Type Instances

Every user defined type can have zero or more instances. Every instance knows it's type. The instances are SQL values. They are copyable. Instances for SQL types contain placeholders for the type's members. Instances for non-SQL types contain a reference to the real instance in type's hosted environment. (Java VM for JAVA and the CLR virtual machine for CLR). So copying an instance is different for SQL and non-SQL types. When a SQL type's instance is copied a new set of members placeholders is created and all members values are copied. This way the copy does not hold any link to it's original and they can be considered as two different instances. This means that changing members' value in the copy will not affect the original.

The non-SQL types instances hold only a reference to the real instance. So copying such an instance is equivalent of making another reference to the foreign object. Thus changing the member's value in the copy WILL affect the original. Usually the foreign virtual machines have a means of explicitly copying an instance, but they are not used by the Virtuoso server when copying the SQL values.

As with the other SQL values, an instance gets destroyed when it is no longer referenced.

9.2.6. Instance References

Because the SQL types instances cannot be referenced by more than one variable/type member Virtuoso PL implements instance references. The references are created for the types marked with `SELF AS REF type_option` (see CREATE TYPE). For such types the constructor(s) make a SQL value of reference type in addition to making the instance itself. The engine places the instances in a connection specific cache of instances and returns a SQL value of type reference which points to that instance. Copying the reference value will not cause copying the instance into the cache, so a `SELF AS REF` type will behave as a hosted class with respect to changing values in the copy. A new instance in the cache will be created only when the constructor for the type is called again. The server will accept a SQL reference value in every place where an instance value is expected. When a reference is serialized, as in when storing into a column of a table, the server will serialize the instance data, not the reference itself.

The connection's instance cache is cleared after the completion of the current server operation, i.e. completion of the top level state, statement invoked by a client or the completion of processing an HTTP request. The cache will thus survive multiple transactions if these are transacted within a single client initiated operation.

9.2.7. NEW Operator

```
[ NEW ] type_name ( [ parameter_value, .... ] )
```

This returns an instance (or reference to an instance) of the user defined type type_name. It will try to match a constructor by calculating the parameter types at compile time and matching the so produced signature to the closest constructor signature (see below: finding methods). The SQL types have an implicit constructor with no parameters that assigns the DEFAULT values to the type members (if any, otherwise NULL). When a SQL constructor is called it will have the `SELF` set-up to the result of calling the implicit constructor. The NEW operator is a scalar expression and can be used wherever the SQL syntax allows scalar expressions.

9.2.8. Finding Methods - Method Signatures Generation & Comparison

A method of a user defined type is identified uniquely by the combination of the following:

the method name
number of the method's parameters
the method's parameter types
the method's return type
This combination of a method attributes is called the method's signature.

The Virtuoso Server must know the method's types of the parameter values and the return type at compile time to calculate the method signature and find exactly the method to call in the types method table. This is different from the current practice in calling stored procedures, because the compile types are not used to find the procedure.

The majority of the system functions are known at compile time to return values of a certain SQL type (e.g.: LEFT is known to return VARCHAR, ATOI returns INTEGER etc). But there are some (e.g.: AREF) that may return values of more than one type. The Virtuoso server does type arithmetic for scalar expressions at compile time already (to be able to supply columns types of a result set to ODBC clients for example), but so far the calculated type has only informative value and was not used anywhere during the compilation. All of the type checks are done at runtime. The method/constructor invocation breaks that practice by using the calculated compile time types for the scalar expressions.

Example 9.7. Method Signatures

Consider a method `m1` of type `t1` taking an INTEGER parameter and returning an integer value:

```
CREATE METHOD m1 (in x integer)
  for t1 returns integer
{ return x + 10; };
```

Now consider calling the method as follows (in a Virtuoso/PL procedure):

```
...
declare p float;
declare ret integer;
declare t1i t1;

t1i := new t1();
p := 1;

ret := t1i.m1(p);
....
```

This will yield a compilation error explaining that there is no method `m1` of user defined type `t1` . It will do that because p has a compile time type of FLOAT.

The following will also fail to compile:

```
...
declare p integer;
declare ret float;
declare t1i t1;

t1i := new t1();
p := 1;

ret := t1i.m1(p);
....
```

This time the `ret` has a declared type of FLOAT and there is no method in t1 taking 1 INTEGER parameter and returning FLOAT.

The most consistent way of specifying the compile time type of a scalar expression is to enclose it in a CAST statement, as follows:

```
...
declare p float;
declare ret integer;
declare t1i t1;

t1i := new t1();
p := 1;

ret := t1i.m1(CAST (p as integer));
....
```

This will compile and execute correctly.

9.2.9. Getting & Setting Member Values of Type Instances (member observers & mutators)

Let `T` be a user defined type that has a member `A` of type `AT` . Let `IT` be an instance of type `T` .

Member Observers (Getting Values)

There are two alternative syntaxes (both scalar expressions):

```
SQL200n :  A(<scalar_exp>)
Virtuoso extension :  <scalar_exp>.A
```

Both of the above will return a copy of the member's value of the instance in <scalar_exp> when the scalar expression <scalar_exp> has a compile time type of `T` . If the compile time type is not determined to be a user defined type `T` the first one will be compiled as a call to the SQL function `A` and the second will either generate a syntax error or the server will consider it as reference to a scope variable (depending on the type of <scalar_exp>).

These are also scalar expressions and have a compile time type `AT` .

To specify an explicit type of the scalar expression there is a third syntax:

```
(<scalar_exp> as T).A
```

This will force the server to compile a reference to the member `A` in user defined type `T` . Whether the <scalar_exp> is indeed of type `T` will be checked at runtime.

Member Mutators (Setting Values)

There are two alternative syntaxes (both scalar expressions):

```
SQL200n :  A(<scalar_exp>, <new_value_scalar_exp>)
Virtuoso extension :  <scalar_exp>.A := <new_value_scalar_exp>
```

Both of the above will set the member's value of the instance in <scalar_exp> to a copy of <new_value_scalar_exp> when the scalar expression <scalar_exp> has a compile time type of `T` . If the compile time type is not determined to be a user defined type `T` the first one will be compiled as a call to the SQL function `A` and the second will either generate a syntax error or the server will consider it as reference to a scope variable (depending on the type of <scalar_exp>).

These are also scalar expressions and have a compile time type `T` and return a copy of the <scalar_exp>. To specify an explicit type of the scalar exp there is a third syntax:

```
(<scalar_exp> as T).A := <new_value_scalar_exp>
```

This will force the server to compile a reference to the member `A` in user defined type `T` . Whether the <scalar_exp> is indeed of type `T` will be checked at runtime.

Example 9.8. Member Construction

This will make a new object of type `UDT_FR_BASE` by calling it's two int parameters constructor and will return the member `B` value of the instance stored in member `UDT_M` of `UDT_FR_BASE` .

```
select new UDT_FR_BASE (1, 2).UDT_M.B;
```

9.2.10. Calling Static Methods

Let `T` be a user defined type that has a static method `SM` .

```
T::SM ( [ parameter, .... ] )
```

This will call the static method of `SM` of `T` and will return whatever the static method returns.

Example 9.9. Calling A Static Method

```
select UDT_TEST::_ADD (1, 2);
```

9.2.11. Calling Instance Methods

Let `T` be a user defined type that has an instance method `IM` . Let `IT` be a scalar expression having a compile time type of `T` .

```
IT.IM ( [ parameter, .... ] )
```

This will call the instance method `IM` of `T` and will return whatever the `IM` returns.

Similarly to member observers/mutators the compile time type of `IT` can be specified explicitly:

```
(IT as T).IM ( [ parameter, .... ] )
```

This syntax however has an additional property in that it will call the method of the type regardless of whether it is overloaded in a subtype or not. Let `ST` be a subtype of `T` and `ST` that has the method `IM` overloaded. Let `IST` be a scalar expression that represents an instance of `ST` .

Then:

```
(IST as T).IM ( [ parameter, ... ] )
```

will call the method `IM` as defined in `T` , whereas

```
IST.IM ( [ parameter, ... ] )
```

will call the method `IM` as defined in `ST` .

Example 9.10. Calling Overloaded Instance Methods

```
CREATE TYPE UDT_BASE
  method A () returns integer;

CREATE TYPE UDT_SUB under UDT_BASE
  OVERRIDING method A () returns integer;

create method A () returns integer for UDT_BASE
{
  return 1;
}

create method A () returns integer for UDT_SUB
{
  return 2;
}

select new UDT_SUB ().A() as IMPLICIT,
  (new UDT_SUB() as UDT_BASE).A() as EXPLICIT;
```

This will return:

```
IMPLICIT                EXPLICIT
-------------------------
2                       1
```

This is done so the overloaded methods can call the base type methods.

9.2.12. Serializing & Deserializing Type Instances

Virtuoso allows serializing and deserializing of non TEMPORARY type instances. This means that the instances can be saved as a column value and can be used with the serialize/deserialize SQL functions.

Example 9.11. Storing User Defined Types

This creates a type SER_UDT, a table UDT_TABLE with a DATA column capable of storing SER_UDT instances, stores an instance of SER_UDT into the table and demonstrates some selects using the stored instance.

```
create type SER_UDT as (A integer default 12)
  method NEGATE () returns integer;

create method NEGATE () returns integer for SER_UDT
{
  return SELF.A * -1;
}

create table UDT_TABLE (ID integer primary key, DATA SER_UDT);

insert into UDT_TABLE (ID, DATA) values (1, new SER_UDT ());

select C.DATA.A from UDT_TABLE C where C.ID = 1;

select C.ID from UDT_TABLE C where C.DATA.A > 10;

select C.ID from UDT_TABLE C where C.DATA.NEGATE() < -10;
```

Note that the table alias is mandatory here.

```
select ID from UDT_TABLE where DATA.A > 10;
```

and

```
select ID from UDT_TABLE where DATA.NEGATE() < -10;
```

will both yield a syntax error.

The columns of a certain type allow storing subtype instances as well. The subtype instances will not be converted to the their supertype when stored.

If we define the type `SER_UDT_SUB` as:

```
create type SER_UDT_SUB under SER_UDT
  as (B integer default 13);
```

then we can do:

```
insert into UDT_TABLE (ID, DATA) values (2, new SER_UDT_SUB ());

select (C.DATA as SER_UDT_SUB).B from UDT_TABLE C where C.ID = 2;
```

Type instances can be stored into an ANY column:

```
create table ANY_TABLE (ID integer primary key, DATA any);

insert into ANY_TABLE (ID, DATA) values (1, new SER_UDT());
```

```
select (C.DATA as SER_UDT).A from ANY_TABLE C where C.ID = 1;
```

Example 9.12. SERIALIZE/DESERIALIZE VSEs example

```
select (DESERIALIZE (SERIALIZE (new SER_UDT ())) as SER_UDT).A;
```

The SERIALIZE VSE can be used to store larger type instances into LONG VARCHAR columns. For example:

```
create table LOB_TABLE (ID integer primary key, LOB_DATA LONG VARCHAR);

insert into LOB_TABLE (ID, LOB_DATA) values (1, SERIALIZE (new SER_UDT()));

select (DESERIALIZE (BLOB_TO_STRING (LOB_DATA)) as SER_UDT).A
  from LOB_TABLE where ID = 1;
```

The serialization/deserialization for the non-SQL type instances is done by the means of the hosted language (Java Object serialization API and CLR Binary serialization API). So to be serialized/deserialized correctly the Java classes must implement the java.io.Serializable interface and the CLR classes should have the [Serializable] attribute set. For details refer to the respective API documentation.

9.2.13. User Defined Types Utility Functions

Virtuoso implements the following user defined types utility functions:

`udt_instance_of()`
`udt_defines_field()`
`udt_implements_method()`
`udt_get()`
`udt_set()`

9.2.14. Hosted Foreign Objects in Virtuoso

Java VM Hosted Objects

A special build of Virtuoso hosts a Java VM and allows manipulation of Java classes through the SQL user defined types.

In order to access the Java class instances they have to be defined as Virtuoso types using CREATE TYPE and specifying LANGUAGE JAVA. Java classes have to be in the CLASSPATH of the hosted Java VM.

Example 9.13. Hosted Java Objects

Java (Point.java):

```
public class Point implements java.io.Serializable
{
  public double x = 0;
  public double y = 0;

  public Point (double new_x, double new_y)
  {
    x = new_x;
    y = new_y;
  }

  public double distance (Point p)
  {
    return Math.sqrt ((p.x - this.x) * (p.x - this.x) + (p.y - this.y) * (p.y - this.y));
  }
}
```

This Java class should be compiled and the corresponding Point.class should be placed in the hosted VM's classpath. Then a

Virtuoso user defined type should be created as follows:

```
create type Point language java external name 'Point'
 as (
  x double precision external name 'x',
        y double precision external name 'y'
)

constructor method Point (new_x double precision, new_y double precision),
method distance (Point p) returns double precision external name 'distance';
```

From now on the SQL Point type can be used to create instances of the Java Point class, access it's members, call it's methods and store it into tables (since the Java Point class implements the `java.io.Serializable` interface).

For the hosted Java objects a LANGUAGE JAVA should be specified. The format of EXTERNAL NAME is:

the full name of the Java class for classes (ex. 'java.lang.Class')

the name of the methods/instance members

Since Java has static members and the Virtuoso SQL types do not, Virtuoso allows read-only access to static members through static observer functions with EXTERNAL VARIABLE NAME instead of EXTERNAL NAME.

Example 9.14. Static Member Access

```
java (stat.java) :
public class stat
{
  static stat_m double;
}
```

Virtuoso SQL:

```
create type stat language java external name 'stat'
static method observe_stat_m ()
  returns double precision external variable name 'stat_m';
```

Virtuoso does automatic mapping between the Virtuoso SQL data types and the Java data types. Since Java data types are much more primitive than Virtuoso types it is safe to explicitly specify the Java type of an instance member, method parameter or method return value. This is done by using the Type Signatures format described in the Java Native Interface Specification (chapter 3 : JNI Types and Data Structures : Table 3.2). The signatures are supplied as string values to EXTERNAL TYPE clause.

To facilitate the creation of the wrapper SQL types Virtuoso uses the Java Reflection API to get the description of the class in XML form. This XML is then transformed using an XSL stylesheet to makes the CREATE TYPE statements required automatically. In the process it preserves the superclass/subclass relationships of the specified Java classes and represents them as a supertypes/subtypes in SQL. The `jvm_ref_import()` procedure is used to create the XML by calling the Java Reflection API.

The function `import_jar()` takes the same parameters as `jvm_ref_import()` but will automatically create and execute the create type statements within the Virtuoso server.

Table 9.2. Java Type to Virtuoso Type Conversions

Java Type/Class	Virtuoso Internal Type
boolean	smallint
byte	smallint
char	smallint
short	integer
int	integer

Java Type/Class	Virtuoso Internal Type
long	integer
float	real
double	double precision
byte[]	binary
java.lang.String	NVARCHAR
java.util.Date	DATETIME
[]	vector

Table 9.3. Virtuoso Type to Java Type Conversions

Virtuoso Internal Type	Java Type/Class
smallint	short
integer	integer
real	float
double precision	double
varchar	java.lang.String
nvarchar	java.lang.String
datetime	java.util.Date
timestamp	java.util.Date
binary	byte[]

For all the other types encountered in the signatures of the Java methods/members it makes a forward reference to a Virtuoso/PL user defined type based on the java class name, replacing the dot ('.') with the underscore ('_') character.

For example:

`'java.lang.System'` becomes `'java_lang_System'`

In order to correctly map a java superclass/subclass relationship between class A and class B when importing, it is necessary to include A, B and all the intermediate classes in the superclass/subclass chain in a single `import_jar()` call.

To implement serialization/deserialization for Java object the Virtuoso needs the __virt_helper Java class. This class contains utility functions implementing serialization/deserialization. This class must be in the CLASSPATH.

The Java VM hosted inside the Virtuoso binary is not started at startup, but when first needed. It's startup is marked by a message in the Virtuoso log file. An application can control the initialization of the Java VM by explicitly initializing the Java VM (preferably on server startup) by calling the VSE: `java_vm_attach()`

CLR Hosted Objects

A special virtuoso build is available to allow SQL types integration with the CLR (Common Language Runtime) on Windows. This is achieved by providing COM server in C# (virtclr.dll) that is called from the native code through COM.

The virtclr.dll library should be registered into the CLR's Global assembly cache.

The semantics of CLR hosted objects are largely the same as those described for Java hosted objects. As before, native objects need SQL Type wrappers, but with LANGUAGE CLR clause specified.

To automatically create the SQL Type wrappers based on the CLR Reflection API the Virtuoso CLR binary has a system stored procedure: `import_clr()`

There are three forms for specifying the EXTERNAL NAME of a CLR class:

- a) `<Assembly public name>/<namespace-prefixed-class-name>` Here the Virtuoso CLR host issues

Assembly.Load with `<Assembly public name>` to find the assembly. After finding it, it looks for `<namespace-prefixed-class-name>` in it.

- b) `<namespace-prefixed-class-name>` Here the Virtuoso CLR host issues Assembly.Load with `<namespace-prefixed-class-name>` . After finding it, it looks for `<namespace-prefixed-class-name>` in it.
- c) `<path-to-the-assembly-binary>/<namespace-prefixed-class-name>` Here the Virtuoso CLR host issues Assembly.LoadFrom with `<path-to-the-assembly-binary>` . After finding it, it looks for `<namespace-prefixed-class-name>` in it.

The Virtuoso CLR host does the above when creating an instance of the type, accessing static methods or properties.

However when it deserializes an serialized CLR instance it calls the CLR deserialization class BinaryFormatter. The BinaryFormatter.Deserialize calls internally Assembly.Load to find the serialized class description. So although the classes defined with EXTERNAL name as in c) above are otherwise accessible (and serializable) they will possibly not deserialize correctly (as the assembly binary may not be findable through the Assembly.Load). To avoid that CLR limitation it is advisable to use the EXTERNAL NAME forms a) and b) wherever possible.

The Assembly.Load process of finding Assemblies is very well documented on the MSDN . Note that if an assembly was loaded through Assembly.LoadFrom it is not considered as "already loaded" by the Assembly.Load. The Virtuoso CLR is a CLR runtime host. As such it can use the normal CLR configuration files. It also is able of using private assemblies.

The Create Assembly Syntax

ASPX Hosting Using the Hosted CLR

Virtuoso CLR hosting allows ASPX pages to be executed through the Virtuoso HTTP server inside the hosted CLR Virtual machine. To enable this support an additional library (virt_http.dll) needs to be registered with the Global Assembly cache. Having achieve this and copying ASPX project files under the Virtuoso HTTP server's root allows direct execution of the ASPX page. See the sample ASPX pages in the Virtuoso distribution.

If the ASPX project files reside in a WebDAV directory they are copied into a temporary file system directory under a special temporary directory (configurable by the TempASPXDir INI parameter in [HTTPServer] section of virtuoso ini file) before executed. In order to be execute correctly from WebDAV the ASPX files should have Execute WebDAV permission set them. The execution of ASPX is also controlled by the EnableDavVSP INI parameter in the [HTTPServer] as with any active content within WebDAV.

Expressing Hosted Language Supertype/Subtype Dependencies With Virtuoso/PL User-Defined-Types

It is also possible to represent the tree or in-part of Java or the CLR's superclass/subclass hierarchy with Virtuoso user defined type mappings.

Consider the following sample Java code:

```
class g1 { public int g1_value; public int mtd_g1 (int x) { return g1_value; } };
class g2 extends g1 { public int g2_value; public int mtd_g2 (int x) { return g2_value; } };
class g3 extends g2 { public int g3_value; };
class g2_sib extends g1 { public int g2_sib_value; };

class uses_types {
  public static g3 mtd (int x) { return new g3 (); }
}
```

One can create SQL user defined types for `g1` , `g2` and `g3` to represent the `g1` /`g2` / `g3` Java class hierarchy if calling `mtd_g1` and `mtd_g2` is needed:

```
create type sql_g1 language java external name 'g1' as (
    g1_value int)
method mtd_g1 (x integer) returns integer;
```

```
create type sql_g2 under sql_g1 language java external name 'g2' as (
    g2_value int)
method mtd_g2 (x integer) returns integer;

create type sql_g3 under sql_g2 language java external name 'g3' as (
    g3_value int)
method mtd_g3 (x integer) returns integer;

create type uses_types language java external name 'uses_types'
 static method mtd (x integer) returns sql_g3;
```

provided with the above, one can call `uses_types.g3 ()` method and call `mtd_g1 ()` on the returned instance in Virtuoso/PL as follows:

```
select uses_types::mtd (12).mtd_g1 (10);
```

Sometimes it is not desirable or necessary to mirror the full supertype/subtype hierarchy from Java to Virtuoso/PL.

For the above example only `sql_g2` and `sql_g3` can be defined if the goal was to call `mtd_g2()` instead of `mtd_g1()` .

When creating instances of the Virtuoso/PL user defined types to represent the data returned by the hosted code, Virtuoso tries to find the closest common ancestor of the hosted instance's class and the ones defined in Virtuoso as user defined types.

For example if in the above example a Java function returns an instance of `g3` and there is a `sql_g3` defined inside virtuoso the `g3` Java instance will be wrapped into an `sql_g3` Virtuoso/PL instance. Note that that will not depend on the presence or absence of `sql_g1` and `sql_g2` definitions - i.e. Virtuoso will favor the exact match.

If, however `sql_g3` is not defined, but `sql_g2` and `sql_g1` are, then the `g3` instance will be wrapped up in an `sql_g2` instance when returned.

Similarly, if an instance of the `g2_sib` is to be returned in Virtuoso/PL and `sql_g1` to `sql_g3` are defined, Virtuoso will wrap the `g2_sib` Java instance into an `sql_g1` SQL instance.

9.2.15. Using User Defined Types to Represent SOAP Structures

The Virtuoso SOAP server is capable of using user defined types (both native and hosted) to represent structures in SOAP requests/responses. Normally a SOAP exposed procedure would have references to defined schema types (__SOAP_TYPE for it's return type and for it's argument types). When such a schema type represents a structure (see the SOAP RPC encoding) the Virtuoso SOAP server will map the structure to an array of name/value pairs for it's members (the type of value returned by the soap_box_structure VSE). The user defined types however are better suited for representing such data. In order for a user defined type to be usable in SOAP, it must have a default constructor (no arguments). For native types that is always true (since they have the implicit constructor setting up the member's values to the respective DEFAULT values from the user defined type declaration). The Virtuoso SOAP implementation supports two ways of specifying how a SOAP value XML fragment should be materialized as a user defined type instance, as follows.

Using Schema Fragments

The `SOAP_DT_DEFINE()` function is used to map a particular schema fragment describing a composite schema type for SOAP usage. This now takes an additional optional argument to establish a link to a user defined type name:

```
create type SO_S_30
  as (
      "varString" nvarchar,
      "varInt" integer,
      "varFloat" real,
      "processingResult" nvarchar,
      "vmVersion" nvarchar)
  constructor method SO_S_30 (),
  method process_data () returns nvarchar;

soap_dt_define ('',
'<complexType name="SOAPStruct"
   xmlns:enc="http://schemas.xmlsoap.org/soap/encoding/"
   xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
```

```
    xmlns="http://www.w3.org/2001/XMLSchema"
    targetNamespace="services.wsdl"
    xmlns:tns="services.wsdl">
   <all>
     <element name="varString" type="string" nillable="true"/>
     <element name="varInt" type="int" nillable="true"/>
     <element name="varFloat" type="float" nillable="true"/>
     <element name="processingResult" type="string" nillable="true"/>
     <element name="vmVersion" type="string" nillable="true"/>
   </all>
</complexType>', 'SO_S_30');
```

The CREATE TYPE statement defines the user defined type SO_S_30 as having 5 data members, a no-parameters constructor and a processing method. The `soap_dt_define()` call maps the SO_S_30 to a schema type SOAPStruct which also has 5 data members and makes that schema type available to SOAP. Now we create a SOAP exposed stored procedure:

```
create procedure echoSOAPStructSch (
    in sst SO_S_30 __soap_type 'services.wsdl:SOAPStruct')
returns SO_S_30 __soap_type 'services.wsdl:SOAPStruct'
{
  declare processingResult nvarchar;
  processingResult := sst.process_data ();
  return sst;
};
```

When processing the SOAP request for calling that stored procedure, the SOAP server will call the default constructor for SO_S_30 (require to create the empty instance) and will fill up the values from the incoming XML fragment for the sst parameter to the members of the newly created SO_S_30 instance. Then it will pass that instance as a value for the sst parameter of the echoSOAPStructSch function. As a result echoSOAPStructSch will correctly execute the member function process_data. Then it will return the (possibly) modified SO_S_30 instance to the SOAP server. The SOAP server will make the XML fragment for the return value based on the SOAPStruct schema fragment using the values from the SO_S_30 members.

This approach allows easy migration for the existing SOAP services using structures. To upgrade a SOAP service procedure to use user defined types one should define the types and add the additional argument to `SOAP_DT_DEFINE()` .

For developing new SOAP services, however, it is redundant to create the schema fragment in addition to creating the user defined type to hold the SOAP structure.

For this reason, Virtuoso offers a second approach in using user defined types in SOAP.

Using the User Defined Type Definition

Consider the altered definition of SO_S_30 as follows:

```
create type SO_S_30
  as (
      varString nvarchar __soap_type 'string' __soap_name 'varString',
      "varInt" integer __soap_type 'int',
      "varFloat" real __soap_type 'float',
      "processingResult" nvarchar __soap_type 'string',
      "vmVersion" nvarchar)
  __soap_type 'services.wsdl:SOAPStruct'
  constructor method SO_S_30 (),
  method process_data () returns nvarchar;
```

and the procedure echoSOAPStructSch as:

```
create procedure echoSOAPStructSch (in sst SO_S_30) returns SO_S_30
{
  declare processingResult nvarchar;
  processingResult := sst.process_data ();
  return sst;
};
```

Now all we have to do is expose the echoSOAPStructSch in a SOAP service. The SOAP server will take into account the fact that the sst type and the return type are user defined types and automatically make the WSDL description (including the schema fragments) and will correctly process the incoming XML.

The SOAP names and data type names inside the user defined type definition are optional and default to the SQL member's name for names and employ a straight mapping of the PL types to the SOAP types for data types.

9.2.16. Consuming Third-Party SOAP Services via User Defined Types

Virtuoso provides function for acting as a SOAP client called `SOAP_CLIENT()` . Embedding SOAP Web Service methods in Virtuoso/PL procedures using this function, however, is not suitable in most cases, especially if the services contained a large number of parameters of different type, the procedure could become very complex, the encoding may also vary. Thus direct SOAP_CLIENT() invocation in some cases in non-trivial and may lead to errors that are hard to debug.

To aid development of Web based applications written in PL that use the SOAP protocol, Virtuoso introduces two new approaches for consuming a Web service:

generate SOAP proxy wrappers encapsulated in a PL Module

generate a User Defined Type (UDT) for SOAP proxy encapsulation.

Please note that both methods of making a SOAP proxy-wrapper requires a WSDL description. If some SOAP service does not have a corresponding WSDL, neither of these methods can be used.

The first approach can be achieved using the SOAP_WSDL_IMPORT() function. This will make a PL module utilizing the SOAP_CLIENT() function that will import the complex types and pass appropriate parameters. But it has one significant problem in that it will return the result as a parsed XML entity. The result should then be processed in the application code, which requires prior knowledge of the return parameters.

The second approach consists of creating a UDT encapsulation of the SOAP wrappers using the `WSDL_IMPORT_UDT()` .

See Also

The `SOAP_WSDL_IMPORT()` function.

The `WSDL_IMPORT_UDT()` function.

The import function `WSDL_IMPORT_UDT()` has two phases:

retrieve and expand the WSDL file (expansion will be done if import is specified)

compile the result and make SQL script with UDT definition

The following points will hold true for this method of SOAP encapsulation:

- Any XML Schema types, required for calling the target SOAP service will be imported in database.
- A UDT will be created for each service defined within the WSDL description.
- The UDT will have members: url, request, response, and debug.
    - the 'url' member designate the endpoint for SOAP invocation
    - debug is a flag to manage wrappers to return wire dumps if needed
    - request and response members will contain wire dumps if 'debug' is equal to 'true' (integer 1).
- for each method defined in the WSDL description there will be UDT's method.
- each method of UDT will contain:
    - a number IN/OUT/INOUT parameters (depending on the target method)
    - no return value, SOAP does not define explicitly return values.
    - call to the SOAP_CLIENT () function with appropriate arguments
    - XPATH over the result and transform with SOAP validation functions to ensure value of OUT and INOUT parameters.

See Also

The Virtuoso Administration Interface provides a web based interface for importing WSDL definitions and creating UDTs and procedures. This can be found in the Visual Server Administration Interface Chapter.

9.2.17. UDT Security

Security of UDTs is maintained through normal SQL GRANT and REVOKE statements via a simple extension. You can define the level of access to both native and externally hosted UDTs.

Grants for persistent user defined types are persisted into the SYS_GRANTS table. Grants on temporary user defined types are in-memory only and are lost (together with the temporary user defined type definition) when the server is restarted.

There are two GRANT/REVOKE types for UDTs as follows:

EXECUTE - all methods and members of a class are accessible to the grantee.

UNDER - the grantee can create subclasses of the class.

```
GRANT/REVOKE EXECUTE on <user_defined_type>
GRANT/REVOKE UNDER on <user_defined_type>
```

Note:

SQL modules, user defined types and SQL stored procedures are exposed to GRANT/REVOKE in the same namespace, therefore care must be taken avoid inadvertently granting to multiple objects at the same time.

9.3. XML Column Type

Virtuoso allows for native XML storage in a database table column using the `LONG XML` type. This data type is a variation of `LONG VARCHAR` that can have plain text or XML entities, persistent or non-persistent values, but will always return an XML entity when selected.

Since ODBC does not support an XML entity type this column will appear as a LONG VARCHAR when selected from ODBC based clients.

Example 9.15. Using LONG XML Columns

```
CREATE TABLE xml_col_test (
  id INTEGER,
  txt VARCHAR,
  xmltxt LONG XML
  )
  ;

  INSERT INTO xml_col_test (id, txt, xmltxt)
    VALUES (1, 'test', '<xml><test>test</test><test>test2</test></xml>');

  INSERT INTO xml_col_test (id, txt, xmltxt)
    VALUES (2, 'test', xml_tree_doc('<xml><test>test</test><test>test2</test></xml>'));

  select * from xml_col_test;
id          txt               xmltxt
INTEGER     VARCHAR           LONG VARCHAR
_______________________________________________________________________________

1           test              <xml><test>test</test><test>test2</test></xml>
2           test              <xml><test>test</test><test>test2</test></xml>
```

See Also:

The `xml_tree_doc()` also returns an XML entity and describes other functions that work with it.

9.4. Identifier Case & Quoting

Virtuoso can operate with different identifier case conventions. The CaseMode setting in the virtuoso.ini file controls this, see the virtuoso.ini configuration section of the documentation.

The default files supplied with Virtuoso specify a CaseMode of 2, which is a case insensitive mode that preserves the declaration case of identifiers.

A CaseMode of 1 specifies the upper case mode, which is most commonly used in SQL databases, e.g. Oracle. In the upper case mode, all unquoted identifiers are converted to upper case by the SQL parser. If identifiers are not quoted, the case in which they are entered is irrelevant.

The identifier quote character is the double quote ("). Quoted identifiers are processed in the case they are written in and are thus case sensitive.

SQL reserved words are case insensitive in all case modes.

If CaseMode is 0 or absent, identifiers will be treated as case sensitive in all situations, whether quoted or not.

If an identifier's name is equal to a SQL reserved word, e.g. TABLE, it must be quoted ("TABLE") in order to be used as an identifier.

If an identifier contains non-alphanumeric characters, e.g. space, '-' etc. it must be quoted regardless of CaseMode.

Although CaseMode can be changed at any time it should only be set at database creation. Changing the CaseMode may result in view or procedure code becoming invalid if it relies on specific case conventions.

9.5. Wide Character Identifiers

All Virtuoso schema columns are confined to 8-bit character fields. This will remain for backwards compatibility and performance reasons, however, there are two options available for support of non-ASCII identifier names as follows:

- Maintain an 8-bit system. Pass all 8-bit codes that enter the system and read them back according to the current database character set. This has the convenience of a 1-to-1 correspondence between the character lengths of an identifier and their representation, so it's a subject to like single character wildcards etc.

  This works well only for languages that do have single bit encodings (like western-european languages and cyrillic). But this does not work at all for the far-east languages. It also depends on the database character set and does not allow identifiers to be composed from multiple character sets.
- Store all identifiers as UTF-8 encoded unicode strings. This would allow seamless storage and retrieval of ANY character within the unicode character space. This, however, has the disadvantage of the varying character length representation which should be taken into account when comparing identifier names with LIKE.

Virtuoso supports the above cases which are switchable through the "SQL_UTF8_EXECS" = 1/0 flag in the [Client] section of the Virtuoso INI file. Setting SQL_UTF8_EXECS = 1 enables UTF-8 identifier storage and retrieval, whereas setting SQL_UTF8_EXECS = 0 disables it. The default setting is 0: disabled for backwards compatible option.

Note:

Once a non-ASCII identifier gets stored using a particular setting for the "SQL_UTF8_EXECS" flag and the flag is subsequently changed this will make the stored identifiers unreadable by normal means (but can be read by special means).

When an SQL statement comes into the driver(s) it is expanded into unicode (using either the current database character set if it is a narrow string like in SQLExecDirect, or taking it verbatim as in SQLExecDirectW). The unicode string is then encoded into UTF-8 passed to the SQL parser. The SQL parser knows that it will receive UTF-8 so it takes that into account when parsing the national character literals (N'<literal>') and the "normal" literals ('<literal>'). It will however return identifier names in UTF-8, these will then get stored into the DBMS system tables or compared against them depending on the type of statement.

All returned identifiers will be translated from UTF-8 to Unicode when returned to the client, so the client should never actually see the UTF-8 encoding of the identifiers.

Representing a string in UTF-8 will not change the identifier parsing rules or the SQL applications logic since the SQL special characters - like dot, quote, space etc - are ASCII symbols and they will get represented as a single byte sequence in UTF-8.

The upper/lower functions should be used with care when applied to identifiers: they will get narrow strings in UTF-8, so applying an upper/lower to them may cause damage to the UTF-8 encoding. That is why the identifiers should be converted explicitly to wide strings using the charset_recode function, changed to upper or lower case and then translated back to UTF-8 using the charset_recode function again.

Using single character LIKE patterns against identifiers stored as narrow strings in system tables will generally not work, as a single character may be represented with up to 6 bytes in UTF-8. An exception to that is when using single character pattern to match an ASCII character.

9.5.1. UTF-8 Implementation Notes For ODBC

All wide functions which do return an identifier, like SQLDescribeColW and friends, will return the correct wide literal. For their narrow counterparts, such as SQLDescribeCol, the UTF-8 string will first be converted to a wide string and then to a narrow string using the current database character set. However, an extension to the ODBC standard has been implemented instructing all result set returning meta-data functions, such as SQLTables and SQLTablesW, to return SQL_NVARCHAR instead of SQL_VARCHAR columns. This is not a problem for most applications since all they do is to map the result to SQL_C_CHAR on retrieval which will convert the wide string to the appropriate narrow string inside the driver using the current database character set. This will cause problems with narrow applications like MS Query, trying to get identifiers not representable in the current narrow character set, because all they will get is the "untranslatable char" mark (currently a question mark).

9.5.2. UTF-8 Implementation Notes In JDBC

Since JAVA is all unicode there are no unavoidable deviations from the JDBC standard. However when printing the Java strings to the screen or a file or getting their byte representation, the usual JAVA conversion rules apply. The types of the meta data result set columns in JDBC are somewhat debatable, but since they are usually retrieved with Resultset.getString() the Virtuoso JDBC driver will return the raw wide string instead of trying to make it VARCHAR before returning it to the application.

9.6. Qualified Names

9.6.1. Qualifiers and Owners

Virtuoso supports multiple namespaces for tables and procedures. A table or procedure is uniquely identified by a three part name consisting of qualifier, owner and name separated by dots.

Each connection has a current qualifier which is used as the default qualifier for if a name does not specify a qualifier. The owner can be omitted from a name if the qualifier and name uniquely identify the object, e.g. DB..SYS_KEYS.

Initially, all system objects have the qualifier DB and owner DBA.

The default current qualifier of all connections is DB unless otherwise specified using db.dba.user_set_qualifier.

A user can be assigned a default qualifier set as current qualifier upon login. This is done with the stored procedure db.dba.user_set_qualifier.

```
user_set_qualifier  (in user varchar, in qualifier varchar)
```

9.6.2. Default Qualifiers

The default qualifier of the user is set to be the qualifier. The names are strings and thus case sensitive.

Example:

```
db..user_set_qualifier ('U1', 'U1DATA');
```

9.6.3. USE Statement, USE identifier

This sets the default qualifier for the connection in question. The identifier cannot be an expression. The identifier is subject to whatever case conversions may be in effect.

See Also:

CaseMode Configuration parameter .

A quoted identifier will always pass in the case it is entered. An unquoted identifier will be converted to upper case if CaseMode so specifies.

9.7. Literals, Brace Escapes

9.7.1. Strings

String literals are delimited with single quotes. A double single quote is an escape notation for a single quote character inside a string literal. Additionally, standard C language escapes are supported. Support of C escapes can be turned off for compatibility with other SQL databases by using the SQL_NO_CHAR_C_ESCAPE option in the configuration file or as an ODBC connection option.

```
Literal                 meaning
''                      <empty>
''''                    '
''''''                  ''
'\t\r\n\\'              tab, carriage return, newline, backslash
'\012'                  Character 012 octal, i.e. newline
```

9.7.2. Numbers

An integer constant consist of an optional minus sign followed by decimal digits. Integer literals are of the C type long, 32 bit.

Numeric literals with a decimal point literal are internally of the DECIMAL SQL type, a variable length decimal floating point type. The Following are examples of decimal literals:

```
123.456
-16.0
```

Numeric literals which specify an exponent, e.g. 1.2e11 or 2e-3 are read as C doubles, (64 bit IEEE binary floating point). This is potentially less precise than the DECIMAL SQL type.

Integer literals outside of the 32-bit range are interpreted as DECIMAL.

9.7.3. ODBC Brace Escapes

The Virtuoso SQL parser supports the following ODBC brace escape notations:

```
{fn function (argument, ..) }           fm (arguments .)
call procedure a1, ... }

{d 'yyyy.mm.dd'}

{t 'hh:mm.ss' }

{ts 'yyyy.mm.dd hh:mm.s fraction' }

{oj  }          -- outer join
```

9.7.4. Hexadecimal Literals

Hexadecimal values can be specified literally in two ways, prefixing the plain value with '0x' or enclosed with single quotes prefixed with 'X'. The case is not important. Hex characters should always be pairs, representing a single byte, and should be at least on pair. Here are some examples:

```
X'beef'   - valid
0xbeef    - valid

X'abeef'  - not valid
X'0abeef' - valid
X''   - not valid
```

`X'<value>'` is equivalent to `0x<value>`

9.7.5. Binary Literals

Binary strings can be specified as literals prefixed with 'B' and enclosed with single quotes. The string should not be empty and should contain only 1's or 0's. Binary strings are read from the end to beginning forming bytes on each 8-th bit:

```
B'1'    = 0x01
B'1111'   = 0x0F
B'111111111'  = 0x01FF
B'100000001'  = 0x0101
B'', X'' and 0x return binary literals.
```

9.8. CREATE TABLE Statement

9.8.1. Syntax

```
    base_table_def: CREATE TABLE new_table_name '(' base_table_element_commalist ')'
                  | CREATE TABLE new_table_name as query_exp opt_with_data

column_xml_schema_def
        : '(' STRING ',' STRING ')'
        | '(' STRING ',' STRING ',' STRING ')'

opt_with_data
: /* empty */
| WITH DATA
| WITHOUT DATA
```

The CREATE TABLE statement creates a new table. The table is identified by a new_table_name, which consists of an optional qualifier, an optional owner and the name. If the qualifier is not supplied then it defaults to the current qualifier, and likewise if the table owner is not specified then this will default to the login name of the user issuing the statement.

Following the new_table_name is a list of table elements that are either column definitions or table constraints. A column must have a unique name within the table and possible super tables. The only necessary attribute of a column is a data type.

The UNDER q_table_name constraint specifies an optional supertable. The table being created will inherit all columns, indices, constraints from the supertable, specifically including the primary key. Hence the under and primary key constraints cannot be specified together. If the table being created will be owned by a non-dba user, the supertable must be owned by the same user.

The AS query_exp opt_with_data causes the table to be created based on the compile time types of columns of the SELECT expression query_exp. If WITH DATA is specified then the resultset returned by the query_exp is fed into the new table. Otherwise (if WITHOUT DATA or not specified) only the table is created.

9.8.2. NOT NULL

Optionally a column can be declared NOT NULL. Any attempts to insert NULL into column declared NOT NULL will result in an error and the insert rejected.

9.8.3. IDENTITY (Auto Increment)

The IDENTITY keyword causes the columns to be automatically incremental, meaning that each successive insert into the table will automatically assign a value greater than any previous row of the table. These columns are often referred to as "autoincrement columns". The assigned values are normally consecutive integers. There may be gaps in the sequence if some transactions that reserve a number fail to commit.

An autoincrement column may or may not be part of the primary key or of any index.

The `identity_value()` function returns the identity column value most recently assigned on the current connection. This can be used inside procedures or from clients. See also the ODBC statement option SQL_GETLASTSERIAL.

The `set_identity_column()` function allows you to change the identity column sequence value.

The IDENTITY keyword supports the SQL 3 optional clause that allows you to specify a starting value and/or step value in the table creation statement. The syntax is:

```
IDENTITY (START WITH <N>, INCREMENT BY <Y>)
```

Example 9.16. Using the IDENTITY declaration

```
CREATE TABLE DB.DBA.AI (
        AI INTEGER IDENTITY,
        XX VARCHAR,
        PRIMARY KEY (AI)
  )
;
```

Creates a table with an autoincrement primary key column AI.

```
set_identity_column("DB"."DBA"."AI", "AI", 11);
```

will cause the next row to be inserted into AI to have the AI column equal to 11.

Example 9.17. Using the IDENTITY (START WITH) declaration

```
CREATE TABLE DB.DBA.AI (
        AI INTEGER IDENTITY (START WITH 100),
        XX VARCHAR,
        PRIMARY KEY (AI)
  )
;
```

Creates a table with an autoincrement primary key column AI, whose first value will be 100 and will auto-increment from there upwards.

See Also

Sequence Objects

9.8.4. DEFAULT

This option specifies a constant default value given to the column by an INSERT that does not specify a value for the column. The constant must be compatible with the column's data type. An IDENTITY or TIMESTAMP column cannot have a default value.

9.8.5. PRIMARY KEY Constraint

This declares a column combination that will uniquely identify each row in the table. This automatically defines an index on these columns and clusters the physical rows of the table together with the index entry for this primary key index. Always specify a primary key if there is a uniquely identifying column combination on the table. This is the case for any normalized database. Hence virtually all tables should have the primary key constraint. This is substantially more efficient than defining the primary key as a unique index with CREATE INDEX. The primary key constraint exists for the purpose of guaranteeing uniqueness of a row and hence should be respected. A unique index is not a primary key and should never substitute one.

Example 9.18. Primary Key using Constraint

This example shows how to create a table with a primary key defined in full as a named primary key table constraint

```
CREATE TABLE demo_table (
  id INTEGER NOT NULL,
  txtdata VARCHAR(20),
  CONSTRAINT demo_table_pk PRIMARY KEY (id)
  )
;
```

PRIMARY KEY is a shorthand for the PRIMARY KEY (column) table constraint which is specified in the column definition. SQL-89 required that you specify NOT NULL PRIMARY KEY but SQL-92 does not because primary keys columns do not permit NULL values. This means that no members of a combination of columns that constitute a primary key can have a NULL value.

Example 9.19. Primary Key shorthand

This example shows how to create a table with a primary key defined using shorthand:

```
CREATE TABLE demo_table (
  id INTEGER NOT NULL PRIMARY KEY,
  txtdata VARCHAR(20),
  )
;
```

Or shorter still:

```
CREATE TABLE demo_table (
  id INTEGER PRIMARY KEY,
  txtdata VARCHAR(20),
  )
;
```

If a table definition has no PRIMARY KEY clause, Virtuoso will generate a default primary key column called "_IDN".

Important

Always declare a primary key using the primary key table constraint. This is always more efficient than the default primary key.

You could allow Virtuoso to generate the primary key if you simply want an IDENTITY primary key column, however this is considered lazy and, of course, not portable. If you already have a column or combination of columns that could be a candidate for a primary key, taking the default primary key from Virtuoso will reduce the overall efficiency because an extra column will be used per row that would be redundant to the data itself.

Example 9.20. Default Virtuoso Primary Key

In the absence of a PRIMARY KEY definition:

```
CREATE TABLE SAMPLE (
  THING VARCHAR
  )
;
```

will be expanded into:

```
CREATE TABLE SAMPLE (
  THING VARCHAR,
  _IDN INTEGER IDENTITY,
        PRIMARY KEY (_IDN)
  )
;
```

Tables with generated default primary keys will appear as if they have no primary key defined. The default primary key (_IDN) column will not appear in the ODBC catalog calls `SQLColumns()`, `SQLStatistics()`, `SQLPrimaryKeys()`, `SQLColumnPrivileges()`. The column can be explicitly referenced in SQL statements just as any other. The SQL "SELECT * ..." statement will omit the _IDN column. The "INSERT INTO TABLE VALUES (.)" statement does not expect a value for the _IDN column. `SQLSpecialColumns()` with the *`SQL_BEST_ROWID`* option is the only catalog call that will return the _IDN column.

The PRIMARY KEY option may not coexist with UNDER in a CREATE TABLE statement because a subtable always inherits the supertable's primary key.

See Also:

CREATE INDEX for the index options.

9.8.6. UNDER

This allows the user to create a table as a sub-table of an existing table. A sub-table will inherit all columns and constraints of its super-table, most importantly the primary key. Primary keys shall be unique in the set of rows belonging to any direct or indirect sub-table of one super-table. A select from a super-table will see all rows, including those of any sub-tables, but not vice versa. Rows inserted directly into the super-table will not be visible to sub-tables.

The primary key option may not coexist with UNDER, since a subtable always inherits the supertable's primary key.

Example 9.21. Creating sub-tables using UNDER

Here a subtable will be created for the demo_table defined earlier. Both definitions are listed for convenience. Notice that the select over the sub-table (demo_sub_table) lists all columns whereas the select from super-table does not, however rows inserted into the super-table, demo_table, will not be seen in a select from the sub-table, but rows inserted into the sub-table will be shown in a select from the super-table.

```
CREATE TABLE demo_table (
  id INTEGER PRIMARY KEY,
  txtdata VARCHAR(20),
  )
;

CREATE TABLE demo_sub_table (
  new_col VARCHAR(10),
  UNDER demo_table
  )
;

SQL> select * from demo_table;
id                txtdata
INTEGER NOT NULL  VARCHAR
_______________________________________________________________________

0 Rows. -- 20 msec.

SQL> select * from demo_sub_table;
id                txtdata               new_col
INTEGER NOT NULL  VARCHAR               VARCHAR
_______________________________________________________________________

0 Rows. -- 10 msec.
```

9.8.7. FOREIGN KEY Constraint

A FOREIGN KEY is a column of combination of columns used to retrieve a related row from a related table. These reference constraints are automatically enforced, unless explicitly disabled. This declaration can be accessed by client applications using the `SQLForeignKeys()` ODBC function. This is used by some tools to display dependencies between tables. Foreign keys are there to maintain referential integrity within the database. This constraint will ensure that rows in one table will have corresponding rows in another table, so that your orders are not made for products that do not exist, for example.

Forward references are not permitted in FOREIGN KEY. Also a table referenced in a foreign key constraint of another table cannot be dropped. It is usual to list the columns in the referenced table corresponding to the columns in the referencing table, however, this list can be omitted, in which case the set of primary key columns of the referenced table is used automatically by default. The referenced and referencing column lists must be of equal length. To declare two mutually referencing tables, ALTER TABLE must be used after both tables are defined.

Foreign key constraints are enforced by default. It is sometimes practical to disable constraint checks for performance or for convenience when importing data or making bulk updates. To disable or enable checking for foreign key constraints you can use the `fk_check_input_values()` function. This function changes the foreign key checking behavior globally across the database so it is very important to remember to enable foreign key constraint checking again afterwards.

Columns can be defined as having foreign keys and a default value, however, the default value must not violate the constraint at the time of insert or update as this will be rejected in the normal way.

Example 9.22. Creating tables with foreign key constraints

First the Primary key table must be defined before it can be referenced:

```
CREATE TABLE T1 (
  Id INTEGER NOT NULL PRIMARY KEY,
  Dt VARCHAR
  )
;
```

Now the foreign key table can be created referencing the table above:

```
CREATE TABLE T2 (
  Act INTEGER NOT NULL,  -- will refer to Id in T1
  Retr DATETIME,
  Description VARCHAR,
  CONSTRAINT FK1 FOREIGN KEY (Act) REFERENCES T1 (Id) -- the fk constraint
  )
;
```

The statement above creates the foreign key constraint in separate line of the create table statement. This can be also be written in short form with the column definition it applies to:

```
CREATE TABLE T2 (
  Act INTEGER NOT NULL REFERENCES T1 (Id),  -- refer to Id in T1
  Retr DATETIME,
  Description VARCHAR
  )
;
```

Example 9.23. Assumed Foreign Key Columns

This CREATE TABLE statement was used for creating part of Demo database. This statement does not describe the columns to be used as foreign keys on the referred tables. Since the referred tables in each case have a single Primary Key (Orders.OrderID and Products.ProductID) they need not be mentioned and will be assumed when this statement is processed.

```
CREATE TABLE Order_Details(
  OrderID INTEGER,
  ProductID INTEGER,
  UnitPrice DOUBLE PRECISION,
  Quantity SMALLINT,
  Discount REAL,
  PRIMARY KEY (OrderID, ProductID),
  FOREIGN KEY (OrderID) REFERENCES Orders,
  FOREIGN KEY (ProductID) REFERENCES Products
  )
;
```

Foreign Key Constraint Actions

Foreign key constraint actions allow the user to define what action data should take when the data they are related to by way of a foreign key is updated or deleted. The two activities that can be programmed are:

ON DELETE

ON UPDATE

The actions available for both types of activity are:

CASCADE - automatically perform the same action on the referenced data.

SET NULL - set the referenced data to NULL.

SET DEFAULT - sets the referenced data to whatever was defined as its default value.

NO ACTION - to not perform any action at all.

Example 9.24. Foreign Key Constraint Actions

Now, the foreign key table defined again, but this time with referential rules which control how data is managed when rows are updated or deleted in the primary key table:

```
CREATE TABLE T3 (
  Act INTEGER NOT NULL DEFAULT 99,  -- will refer to Id in T1
  Retr DATETIME,
  Description VARCHAR,
  CONSTRAINT Fk1 FOREIGN KEY (Act) REFERENCES T1 (Id)
    ON UPDATE CASCADE ON DELETE SET DEFAULT
  )
;
```

9.8.8. The CHECK Constraint

The CHECK constraint allows you specify and wide range of rules that will dictate whether an insert of update will be permitted. The syntax is as follows:

```
CHECK (search-condition)
```

The search condition can be simple and comparative, or quite complicated involving regular expressions.

Example 9.25. Creating a table with the CHECK constraint

Here a simple table will be created with two CHECK constraints. One the check constraints is a simple comparison ensuring participants are over 18, the other complicated constraint verifies that the email address is correct using a regular expression. Samples SQL statements follow that will demonstrate the effectiveness of the check constraints.

```
CREATE TABLE test_check (
  name VARCHAR,
  age INTEGER
    CHECK (age > 18),
  email VARCHAR
    CHECK (regexp_like(email, '^([a-zA-Z0-9_.-])+@(([a-zA-Z0-9-])+.)+([a-zA-Z0-9]{2,4})+\$'))
  )
  ;

INSERT INTO test_check (name, age, email) VALUES ('Jack', 18, 'jack@foo.bar');
  -- will cause: *** Error 22023: ... SR363: CHECK constraint violated

INSERT INTO test_check (name, age, email) VALUES ('Jill', 19, 'up@thehill.com');
  -- will be insert correctly.

INSERT INTO test_check (name, age, email) VALUES ('Jack and Jill', 37, 'ouch/!^^!!@@');
  -- will cause: *** Error 22023: ... SR363: CHECK constraint violated, also.
```

See Also:

`regexp_like()`

9.8.9. The WITH SCHEMA Constraint

The WITH SCHEMA constraint allows you force values of an XML column to match a particular schema. The syntax is as follows:

```
WITH SCHEMA (namespace-uri, top-element-name [, optional-dtd-configuration])
```

To use this feature, you should make load an XMLSchema to the server by a CREATE XML SCHEMA statement. As soon as schema is loaded, its target namespace URI can be used in WITH SCHEMA constraint to validate every new value of the column against this schema. In addition, the constraint ensures that the document is a well-formed XML document (not a well-formed generic XML entity) and checks if the name of the top level element of the document is equal to one specified in the constraint.

Depending on document size and the complexity of the schema, schema validation may be a time- and memory- consuming operation. An application can win a lot if every stored value is validated only once and avoid repeating validations on every read of the stored data, but it also may loose if the validation is actually redundant (e.g. if the data always comes from sources which produce valid content).

The parameter "optional-dtd-configuration" lets an application to specify how strict the validation should be. In real life, documents may match the schema in general, but not in minor details that are not important for a particular application. If specified, the parameter must be a string in the format described in Configuration Options of the DTD Validator . The default value is suitable for most of applications and forces the validator to check well-formedness of the document, nesting of elements, presence of all "required" attributes, syntax of values of typed elements and attributes; it also will check referential integrity of ID and IDREF attributes.

Example 9.26. Creating a table with the WITH SCHEMA constraint

Here a simple table will be created with a WITH SCHEMA constraint. Sample SQL statements follow that will demonstrate the effectiveness of the check constraints.

```
CREATE XML SCHEMA '<?xml version="1.0" encoding="utf-8" ?>
<xs:schema targetNamespace="http://www.example.com/parts"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:p="http://www.example.com/parts">
   <xs:element name="Part">
      <xs:complexType>
         <xs:choice minOccurs="0" maxOccurs="unbounded">
           <xs:element ref="p:Part"/>
         </xs:choice>
         <xs:attribute name="ID" type="xs:string" use="required" />
         <xs:attribute name="Count" type="xs:int" use="optional" />
         <xs:attribute name="Type" type="xs:string" use="optional" />
      </xs:complexType>
   </xs:element>
</xs:schema>';

create table SPARE_PARTS (
  PACK_ID integer primary key,
  CONTENT XMLType with schema ('http://www.example.com/parts', 'Part')
  );

insert into SPARE_PARTS values (1, '
<p:Part xmlns:p="http://www.example.com/parts"
xml:id="keyboard">
  <p:Part Count="101"/>
  <p:Part

```

ALTER TABLE ... MODIFY COLUMN statement does not support changes of WITH SCHEMA constraint. Double check your XMLSchema and carefully test it on real data used by an application before using this constraint. If you can't test your schema this way then calling of `xml_validate_schema()` in triggers may be safer than using the constraint: such triggers will be slower than the constraint but you can drop triggers without re-creating the table.

See Also:
CREATE XML SCHEMA Statement

`xml_validate_schema()`

9.9. DROP TABLE Statement

```
drop_table
        : DROP TABLE q_table_name
        ;
```

This statement drops a table. This requires dba privileges or ownership of the table. Any subtables are automatically dropped. Supertables are not affected.

9.10. CREATE INDEX Statement

```
index_column_commalist
        : column opt_asc_desc
        | index_column_commalist ',' column opt_asc_desc
        ;

index_option
        : CLUSTERED
        | UNIQUE
        ;

index_option_list
        : index_option
        | index_option_list index_option
        ;

opt_index_option_list
        : /* empty */
        | index_option_list
        ;

create_index_def
        : CREATE opt_index_option_list INDEX index
                ON new_table_name '(' index_column_commalist ')'
        ;
```

This creates an index on a table. Index names must be unique across a qualifier. The ascending / descending column attributes are recognized for compatibility but do not have any effect. The index is defined and populated at the execution of the statement. Pre-existing stored procedures and prepared statements will make use of the new index when appropriate.

The UNIQUE attribute enforces uniqueness of the specified columns across the table and subtables where the index is visible.

The CLUSTERED attribute is not recommended. It will cause keys to be unprefixed by key id, thus causing the key entries to be intermixed with entries of other CLUSTERED indices with adjacent values of key parts.

See:
See the Free Text section on creating free text indices.

9.11. DROP INDEX Statement

```
drop_index
        : DROP INDEX NAME opt_table
        ;

opt_table
        : /* empty */
        | q_table_name
        ;
```

This will drop an index, dba privileges or table ownership are required. A table's primary key which has the same name as the table can not be dropped.

Optionally, a table name can be given if the index name is not unique. The table name may be qualified.

9.12. ALTER TABLE Statement

```
add_column:
            ALTER TABLE q_table_name ADD opt_col_add_column add_col_column_def_list
          | ALTER TABLE q_table_name DROP opt_col_add_column add_col_column_list
          | ALTER TABLE q_table_name MODIFY opt_col_add_column column_def

add_col_column_def_list: column_def
                       | add_col_column_def_list &apos;,&apos; column_def

add_col_column_list: column
                   | add_col_column_list &apos;,&apos; column

table_rename:
            ALTER TABLE q_table_name RENAME new_table_name

alter_constraint:
            ALTER TABLE q_table_name constraint_op opt_table_constraint_def

constraint_op: ADD
             | DROP
             | MODIFY

opt_drop_behavior: /* empty */
                 | CASCADE
                 | RESTRICT

opt_table_constraint_def: CONSTRAINT identifier opt_drop_behavior
                        | table_constraint_def

view_query_spec: query_exp
               | query_no_from_spec

alter_table
        : ALTER TABLE q_table_name ADD opt_col_add_column add_col_column_def_list

        | ALTER TABLE q_table_name DROP opt_col_add_column add_col_column_list

        | ALTER TABLE q_table_name MODIFY opt_col_add_column column_def

        | ALTER TABLE q_table_name RENAME new_table_name

        | ALTER TABLE <table> ADD | DROP | MODIFY <constraint> [<constraint-name>]

<constraint> ::=
        : PRIMARY KEY '(' <column list> ')'
        | FOREIGN KEY '(' <column list> ')' <references>
        | CHECK ( search-condition )

<references> ::=
   REFERENCES <table> ['(' <column list> ')' ] <OPTIONS>

<OPTIONS>  ::=
   [ON UPDATE OPT_ACTION] [ON DELETE OPT_ACTION]
```

The ALTER TABLE statement adds or drops columns and renames tables.

Adding or dropping a column of a table will create a new version of the table's schema entry. The rows of the altered table will be changed to conform to the new definition when next updated. All newly inserted rows will be in the new row layout. This means that ALTER TABLE itself executes in fixed time without locking the table. The time to update the actual data will be spread over subsequent updates.

An added column will have a NULL value on those rows where the new column has not been set. A possible default will only apply to newly inserted rows.

When dropping a column one can execute a statement of the form UPDATE <table> SET <key> = <key> to force the physical change, causing space associated with the dropped column to be freed.

The column_def in the ADD clause may specify any column options, except PRIMARY KEY.

If the table name is not fully qualified it is completed as in any table reference. The new name in the RENAME clause is defaulted to the current qualifier and user account, as in a CREATE TABLE.

A primary key may only be modified, never dropped or added. Tables always have exactly one primary key.

The first unique index of an empty table becomes the primary key. This may thereafter not be dropped.

The primary key of an attached table may not be changed.

Foreign keys can be added. Dropping a foreign key will drop all foreign keys between the foreign key and primary key tables.

ALTER TABLE cannot be applied to an attached table.

Example 9.27. ALTER TABLE Examples

```
ALTER TABLE DISTRICT
    add D_SALES_MGR integer not null references EMPLOYEES (E_ID);

ALTER TABLE idt MODIFY PRIMARY KEY (K1, K2);

ALTER TABLE idt ADD FOREIGN KEY (d) REFERENCES idt (d);

ALTER TABLE idt ADD FOREIGN KEY (k2, k1) REFERENCES idt;

ALTER TABLE idt DROP FOREIGN KEY (d) REFERENCES idt (d);
```

9.12.1. Adding a CHECK Constraint

A CHECK constraint can be added to a table after it has been created and populated providing that none of the tables contents would violate the constraint.

Example 9.28. Adding a CHECK constraint to an existing table.

```
CREATE TABLE test_add_check (
  name VARCHAR,
  age INTEGER
  )
;

ALTER TABLE test_add_check ADD CONSTRAINT chkage CHECK (age > 18);
```

See Also:

The CHECK constraint

9.13. CREATE VIEW Statement

```
<view definition> ::=
    CREATE VIEW <table name> [ <left paren> <view column list>
                                <right paren> ]
      AS <query expression>
```

9.14. CREATE XML SCHEMA Statement

```
<xml schema definition> ::=
    CREATE XML SCHEMA <text of schema>
```

Virtuoso supports registering XML Schemas for use in WITH SCHEMA constraint for column values. The statement contains the whole text of the schema as a string constant, i.e. enclosed in single quotes. This is not the best possible syntax, because single quotes inside the text of schema should be carefully quoted, but this is de-facto standard. If the schema contains number of single quotes (e.g. attributes are in single quotes instead of typically used double quotes), try a system stored procedure

```
DB.DBA.SYS_CREATE_XML_SCHEMA (text_of_schema);
```

that will have the same effect, but is not portable.

In principle, you can register any valid XMLSchema, but some features can cause prohibitive loss of performance. It is strongly advised to compose the schema as a "standalone" document that has no references to external DTDs or external generic entities. It is also strongly advised to avoid xs:include and xs:import directives. The only sort of external references that does not affect performance is xs:include or xs:import of a registered "sibling" schema. They say that a schema X is a "sibling" of schema Y if their target namespace URIs have identical protocol names and host names and differs only in local path, and schema X imports Y using relative (not absolute!) URI that contain only relative path, (no protocol and no host).

Example 9.29. Registering Sibling Schemas

Two sibling schemas are registered here. First statement registers an XMLSchema for "http://www.example.com/parts" target namespace. Second statement registers an XMLSchema for "http://www.example.com/jobs" target namespace that imports the first schema using relative URI. The rest of statements demonstrate a single WITH SCHEMA constraint that inspect elements of these two target namespaces.

```
CREATE XML SCHEMA '<?xml version="1.0" encoding="utf-8" ?>
<xs:schema targetNamespace="http://www.example.com/parts"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:p="http://www.example.com/parts">
   <xs:element name="Part">
      <xs:complexType>
         <xs:choice minOccurs="0" maxOccurs="unbounded">
           <xs:element ref="p:Part"/>
         </xs:choice>
         <xs:attribute name="ID" type="xs:string" use="required" />
         <xs:attribute name="Count" type="xs:int" use="optional" />
         <xs:attribute name="Type" type="xs:string" use="optional" />
      </xs:complexType>
   </xs:element>
</xs:schema>'

CREATE XML SCHEMA '<?xml version="1.0" encoding="utf-8" ?>
<xs:schema targetNamespace="http://www.example.com/jobs"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:p="http://www.example.com/parts"
  xmlns:j="http://www.example.com/jobs">
   <xs:import schemaLocation="parts" />
   <xs:element name="Job">
      <xs:complexType>
         <xs:sequence>
           <xs:element ref="p:Part"/>
         </xs:sequence>
         <xs:attribute name="JobID" type="xs:string" use="required" />
      </xs:complexType>
   </xs:element>
</xs:schema>'
```

```
create table JOBS (
  PACK_ID integer primary key,
  CONTENT XMLType with schema ('http://www.example.com/jobs', 'Job')
  )

insert into JOBS values (1, '
<j:Job xmlns:j="http://www.example.com/jobs" xmlns:p="http://www.example.com/parts" JobID="asmkeyboard">
  <p:Part xmlns:p="http://www.example.com/parts"
xml:id="keyboard_03">
    <p:Part Count="101"/>
    <p:Part
xml:id="body_03"/>
  </p:Part>
</j:Job>')

*** Error 42000: [Virtuoso Driver][Virtuoso Server]XML parser detected an error:
        ERROR  : Only 0 out of 1 required attributes are defined for element <p:Part>, e.g. the element h
at line 4 column 27 of '(value to be placed in column DB.DBA.JOBS of CONTENT)'
    <p:Part Count="101"/>
-------------------------^

insert into JOBS values (2, '
<j:Job xmlns:j="http://www.example.com/jobs" xmlns:p="http://www.example.com/parts" JobID="asmkeyboard">
  <p:Part xmlns:p="http://www.example.com/parts"
xml:id="keyboard_04">
    <p:Part
xml:id="key_02" Count="101"/>
    <p:Part
xml:id="body_04"/>
  </p:Part>
</j:Job>');
```

Note:

There is no way to change a registered schema if it is used in some WITH SCHEMA constraint. Double-check any schema before using it, because it may be hard to fix the error later.

9.15. DROP XML SCHEMA Statement

```
<xml schema removal> ::=
    DROP XML SCHEMA <target URI>
```

This reverts the effect of CREATE XML SCHEMA .

The <target URI> should be a string constant that is equal to the value of "targetNamespace" attribute of "xs:schema" element of a previously declared XML schema.

The statement signals an error if the XMLSchema to be dropped is used in some WITH SCHEMA constraint.

9.16. Sequence Objects

Virtuoso supports sequence objects. These can be used to generate sequential numbers which can be used as unique identifiers. A sequence object is guaranteed never to give the same number twice. Each sequence has a name and a state. The state of a sequence is stored in the database at checkpoint time. Between checkpoints sequence states are logged so that a possible roll forward recovery will not lose information.

The SQL functions `sequence_next` () and `sequence_set` () are used to access and set the state of sequences. These take the name of the sequence as argument. This is a server/wide unique string. There are no restrictions on the length or character set of the sequence

Sequences do not have to be separately created. A sequence object will automatically be generated when first referenced by `sequence_next` () or sequence_set.

```
sequence_next (in name varchar) returns integer

sequence_set (in name varchar, in state integer, in mode integer)
```

```
                returns integer
```

Function `sequence_next` () returns the current state of the specified sequence and atomically increments it by one. The next call will thus return a number one greater than the previous. The sequence is shared between all connections and all transactions. Using a sequence never involves locking.

Function `sequence_set` () sets and returns the state of a sequence object. The next call to `sequence_next` () will return this same number. If mode equals 0, the state is set regardless of the previous state. If mode is non-zero, the state is set only if the new state is greater then the previous state. Calling sequence_set ('sequence" , 0, 1) will always return the sequence's state without changing it.

Each autoincrement column corresponds to an internal sequence object. The name of the sequence object is'DB.DBA.' plus the concatenation of the table's qualifier, owner, table name and column name, e.g. 'DB.DBA.db.dba.my_table.ai_column'. The user does not normally need to know about the sequence associated with an autoincrement column unless he or she wishes to change the sequence values using the `sequence_set()` function and the sequence objects name.

See the section on identity columns under create table and the function identity_value and the related ODBC statement option SQL_GETLASTSERIAL for more.

9.17. INSERT Statement

```
insert_statement
        : INSERT insert_mode table priv_opt_column_commalist values_or_query_spec
        ;

insert_mode
        : INTO
        | REPLACING
        | SOFT

priv_opt_column_commalist
        : /* empty */
        | '(' column_commalist ')'

        ;

values_or_query_spec
        : VALUES '(' insert_atom_commalist ')'
        | query_spec
        ;

insert_atom_commalist
        : insert_atom
        | insert_atom_commalist ',' insert_atom
        ;

insert_atom
        : scalar_exp
        ;

column_commalist
        : column
        | column_commalist ',' column
        ;

query_spec
        : SELECT opt_all_distinct selection table_exp
        ; ... See the SELECT statement next.
```

New rows (or records) are entered into a database using the INSERT statement.

If you have to enter a NULL you can simply use the keyword NULL, as you would a normal value. Since NULL is a special keyword you do not need to enclose it in single quotes.

You can specify the columns that you are inserting values into in the insert statement. One should always specify the columns that you are inserting into, in case the order of columns in the database are not as expected, or you are not inserting values into every column.

If a value is not specified for a column on insert, then the default value will be used for that column. If no default value has been specified either by a CREATE or MODIFY TABLE statement then NULL will be used.

9.17.1. INSERT SOFT

INSERT SOFT can be used in place of *INSERT INTO* if you are unsure whether the value to be inserted into a primary key column will violate that constraint. If the row with this primary key already exists, then the new row is not inserted.

```
SQL> create table insert_test(id integer primary key, txt varchar);
Done. -- 90 msec.
SQL> insert into insert_test(id, txt) values(1, 'test');
Done. -- 0 msec.
SQL> insert into insert_test(id, txt) values(1, 'test');

*** Error 23000: [Virtuoso ODBC Driver][Virtuoso Server]SR197:
  Non unique primary key on DB.DBA.insert_test. at line 4 (4) of Top-Level:
  insert into insert_test(id, txt) values(1, 'test')

SQL> insert soft insert_test(id, txt) values(1, 'testsoft');

Done. -- 0 msec.
SQL> select * from insert_test;
id                txt
INTEGER NOT NULL  VARCHAR
_______________________________________________________________________________

1                 test

1 Rows. -- 60 msec.
```

9.17.2. INSERT REPLACING

INSERT REPLACING can be used in place of *INSERT INTO* if you are unsure whether the value to be inserted into a primary key column will violate that constraint. If the row with this primary key already exists, then the new row will be inserted replacing the old values.

```
SQL> create table insert_test(id integer primary key, txt varchar);
Done. -- 90 msec.
SQL> insert into insert_test(id, txt) values(1, 'test');
Done. -- 0 msec.
SQL> insert into insert_test(id, txt) values(1, 'test');

*** Error 23000: [Virtuoso ODBC Driver][Virtuoso Server]SR197:
  Non unique primary key on DB.DBA.insert_test. at line 4 (4) of Top-Level:
  insert into insert_test(id, txt) values(1, 'test')

SQL> insert replacing insert_test(id, txt) values(1, 'testreplacing');

Done. -- 0 msec.
SQL> select * from insert_test;
id                txt
INTEGER NOT NULL  VARCHAR
_______________________________________________________________________________

1                 testreplacing

1 Rows. -- 0 msec.
```

9.18. UPDATE Statement

Existing rows (or records) are changed in the database using the UPDATE statement.

NULL values can be utilized using the `NULL` keyword without any quotes. Since NULL is a special keyword you do not need to enclose it in single quotes, doing so will cause it be read as a string-literal.

The update statement is made up by selecting the table to update, the search condition that identifies which rows you want to update, and the `column=value` of each column you wish to change.

Example 9.30. Basic Update Statement

A table can be updated using:

```
update demo.dba.employees e
  set username = 'thing'
  where email_address = 'thing@thingdom.com'
  ;
```

Example 9.31. Update from Select

It is possible to update one table based on a select from another table. Ensure that the selection is properly conditioned to update.

```
update demo.dba.employees e
        set username = (select U_NAME from DB.DBA.SYS_USERS u where u.U_EMAIL = e.email_address)
        ;
```

9.19. SELECT Statement

9.19.1. Syntax

```
< select statement: single row > ::= SELECT [ < set quantifier > ] < select list >

      INTO < select target list >

      < table expression >

< select target list > ::=
      < target specification > [ { < comma > < target specification > }... ]

< qualified join > ::=
    < table reference > [ NATURAL ] [ < join type > ] JOIN
      < table reference > [ < join specification > ]

< join type > ::=
      INNER
    | < outer join type > [ OUTER ]
    | UNION

< outer join type > ::=
      LEFT
    | RIGHT
    | FULL

< join specification > ::=

      < join condition >
    | < named columns join >

< join condition > ::= ON < search condition >

< named columns join > ::=
    USING < left parent > < join column list > < right parent >

< join column list > ::= < column name list >

< where clause > ::= WHERE < search condition >

< group by clause > ::=
    GROUP BY < grouping column reference list >

< grouping column reference list > ::=

    < grouping column reference >
```

```
        [ { < comma > < grouping column reference > }... ]

< grouping column reference > ::=

    < column reference > [ < collate clause > ]
```

9.19.2. Description

The SELECT statement is the principal means of information retrieval in SQL. A SELECT can retrieve information from one or more tables with arbitrary search criteria. SELECT's can also be nested to have the output of one serve as an input or search condition for another. Several SELECT's can be combined into one query with the UNION, INTERSECTION and EXCEPT operators.

The SELECT syntax consists of the following parts:

```
SELECT [DISTINCT] scalar_exp {, scalar_exp}
        FROM table {, table}
        WHERE < search condition >
        GROUP BY < column list >
        HAVING < search condition >
        ORDER BY < ordering spec list >
        FOR UPDATE
```

All parts are optional. If one or more of the clauses appear they must appear in the above order. All parts do not need to be specified, e.g., SELECT A FROM T FOR UPDATE is valid but SELECT A FROM T ORDER BY a WHERE < < 10 is not.

Note:
A select without a FROM clause is allowed.

This is useful for returning values of expressions to the client. Such a select always returns one row, with the values listed as columns. Typically only useful from interactive SQL.

Example:

select 1 + 2 as three;

A table reference in the FROM clause can either be a simple table name, another SELECT expression of the form described above or a join expression. A SELECT inside a FROM is called a derived table. This means that the rows selected by the derived table expression are treated as if they constituted a table. This is similar to a VIEW reference and a derived table can be thought of as an unnamed in-line VIEW declaration.

A join expression combines table references, which are either simple, derived or joined tables themselves into different joins.

A join is an operation that retrieves for each row of one table zero or more rows from another table. The join condition specifies how the rows are matched. The result of a join is a set of rows containing selected columns from both joined tables. Joins are by default so called INNER joins, which means that for a row to be in the result there must be a row matching the left table in the right table as specified by the join condition. An OUTER join is a join that will produce a result row even if there is no row in the right table for the row in the left table. The columns that would have come from the right table are then just set to NULL's.

```
table_ref ::=
        < table name > [< correlation name >]
  |     / query expression ) < correlation name >
  |     < table ref > < [NATURAL] join > < table ref > < join condition >

join ::=
        < empty >
  |     CROSS
  |     INNER
  |     LEFT [OUTER]
  |     RIGHT [OUTER]

join condition ::=
        < empty >
  |     ON < search condition >
  |     USING '(' < column > {, column} ')'
```

The < correlation name > is an identifier that is used to identify the table in a column reference if the same table appears many times in the query expression, e.g., is joined with itself.

The CROSS join has no join condition. This means that for each row in the left table all rows in the right table are included in the result.

9.19.3. Column Aliasing - AS Declaration

Virtuoso supports the AS operator in the selection list of a SELECT statement. This notation allows declaring a name and optionally a type and precision for a statement's output column.

The syntax is:

```
as_exp:
Scalar_exp AS NAME opt_data_type
```

For instance, one can write:

```
SELECT COUNT (*) AS NUMBEROFROWS FROM XX;
SELECT COUNT (*) AS NUMBEROFROWS INTEGER (2) FROM XX;
SELECT CONCATENATE (COL1, COL2) AS RESULTSTRING VARCHAR (50) FROM XX;
```

The AS expression tells the client to return specified values in the SQLDescribeCol, SQLColAttribute or equivalent calls. The semantics of statements is not otherwise affected. An AS expression can appear anywhere a scalar expression can but the only place where it has an effect is the selection list of a SELECT statement.

If a data type is given and contains a precision, that precision is returned to the client as the precision of the column in question.

9.19.4. Join examples

The following three statements produce an identical result.

```
select Orders.OrderID, ProductID
    from Orders natural join Order_Details using (OrderID)
select Orders.OrderID, ProductID
    from Orders join Order_Details on Orders.OrderID = Order_Details.OrderID
select Orders.OrderID, ProductID
    from Orders,  Order_Details where Orders.OrderID = Order_Details.OrderID
```

Note:

In all these cases if there exists no Order_Details row matching the Orders row there will no no result row corresponding to the Orders row. An outer join can can be used to also retrieve left table records for which there is no matching right table record.

```
select Orders.OrderID, ProductID
    from Orders natural left outer join Order_Details using (OrderID)
```

will produce a result identical to the above sample if for each Orders row there is at least one Order_Details row. If there is none however, the OrderID column from Orders will appear together with a NULL ProductID from the non-existent Order_Details.

A right outer join is like a left outer join with the left and right tables reversed.

9.19.5. Ordering and Grouping

The result rows of a query can be ordered based on their column values. The ORDER BY phrase allows specifying an ascending or descending sort order for a any column. The SQL interpreter will use an index if there is an index whose order reflects the order in the ORDER BY clause. If there is no appropriate index or if ascending and descending order is combined for columns of the same table the SQL interpreter will first evaluate the query and then sort the results before returning them.

See:

Optimizations below for more information.

```
select * from Employees order by BirthDate;
```

will list all employees, oldest first, in ascending order of birth date.

The GROUP BY clause allows computing functions over repeating groups. Without the GROUP by clause set functions (AVG, MIN, MAX, SUM, COUNT) may not be mixed with normal columns in a selection list. If set functions and columns are mixed, all the columns must appear in the GROUP BY section. Such a query will produce as many rows as there are distinct value combinations of the grouping columns. The set functions will be computed for each distinct column combination.

```
select OrderID, sum (UnitPrice * Quantity)
   from Order_Details group by OrderID
   having sum (UnitPrice * Quantity) > 5000  order by 2 desc;
```

Produces the OrderID and total value of the order in decreasing order of order value. The HAVING clause specifies that only orders with a value > 5000 will be counted. Note that the sum expression in having must be written identically to the same expression in the SELECT left.

The 2 in the order by refers to the second column of the select, which has no name, it being a function reference.

CUBE and ROLLUP

Virtuoso database offers a way to increase efficiency of SQL summary queries and simplify the operations. By using the options `ROLLUP` and `CUBE` in `GROUP BY` , can be executed more comprehensive summary operations. The produced result sets could be also produced without using these option but rahter with additional coding and queries.

The options `ROLLUP` and `CUBE` extend the result set of `GROUP BY` :

- `ROLLUP` : builds a consequence of subtotal aggregates on every queried level including the grand total.
- `CUBE` : this option is an extension of

  `ROLLUP` . It builds all possible subtotal aggregates combinations for given

  `GROUP BY` .

For example:

```
  SELECT j, grouping (j), k, grouping (k), t, grouping (t), SUM (i)
    FROM MyDemo
GROUP BY ROLLUP (j,k,t);

  SELECT j, grouping (j), k, grouping (k), t, grouping (t), SUM (i)
    FROM MyDemoCube
GROUP BY CUBE (j,k,t);
```

The `grouping(param)` procedure returns "1" if the column "param" is not in the dynamic GROUP BY set, and returns "0" otherwise.

The result set of:

```
  SELECT j, k, t, SUM (i)
    FROM MyDemo
GROUP BY ROLLUP (j,k,t) ;
```

is equivalent of the accumulated result sets of:

```
  SELECT j, k, t, SUM (i)
    FROM MyDemo
GROUP BY j,k,t;

  SELECT NULL, k, t, SUM (i)
    FROM MyDemo
GROUP BY k,t;

  SELECT NULL, NULL, t, SUM (i)
    FROM MyDemo
GROUP BY t;
```

```
  SELECT NULL, NULL, NULL, SUM (i)
    FROM MyDemo;
```

The result set of:

```
SELECT t,s, SUM (i) FROM MyDemo GROUP BY CUBE (t,s);
```

is equivalent of the accumulated result set of:

```
  SELECT t,s, SUM (i)
    FROM MyDemo
   GROUP BY t,s;

  SELECT t,NULL, SUM (i)
    FROM MyDemo
GROUP BY t;

  SELECT s,NULL, SUM (i)
    FROM MyDemo
GROUP BY s;

  SELECT NULL,NULL, SUM (i)
    FROM MyDemo;
```

9.19.6. Grouping Sets

The grouping sets variant of group by allows specifying exactly which combinations of groupings are needed. `CUBE` and `ROLLUP` are shorthands that expand into a grouping sets specification. This is useful for applications like faceted search where there are separate group by's on properties of interest.

The grouping function behaves identically to `CUBE` and `ROLLUP` .

The syntax is:

```
GROUP BY grouping sets (<grouping set>[,...])
```

The grouping set is a list of grouping columns in parentheses or `()` to denote an aggregate without grouping.

For example:

```
  SELECT key_table, key_is_main, COUNT (*)
    FROM SYS_KEYS
GROUP BY grouping sets ((key_table), (key_is_main), ());
```

This shows for each table the number of indices, then the number of primary key and non-primary key indices across all tables and finally the total number of indices in the schema. A `CUBE` would produce these same groupings but it would further add the `key_table` , `key_is_main` grouping.

As an extension to SQL 99 OLAP extensions, the Virtuoso grouping sets specification also supports an `ORDER BY` with optional top. In the place of a grouping set one can write:

```
ORDER BY [top k] (<column> [,...])
```

In this way a single query can produce a set of ordered result rows and different grouped aggregates on the columns in the result set.

9.19.7. Derived Tables

A SELECT expression may be used in the place of a table in a FROM clause. This provides control over where DISTINCT and ORDER BY operations are evaluated.

```
select ProductName, UnitsInStock
    from (select distinct ProductID from Order_Details) O,
        Products where Products.ProductID = O.ProductID;
```

This retrieves the name and quantity of products that have been ordered.

An equivalent phrasing would be

```
select distinct ProductName, UnitsInStock
   from Order_Details O, Products where Products.ProductID = O.ProductID;
```

The difference is that the latter retrieves a Products row for each order line whereas as the first retrieves a products row for each distinct product in the order lines. The first is therefore faster to evaluate. Also note that the rows in the DISTINCT buffer in the first example only consist of the product id whereas they are much longer in the second example.

Note that a correlation name is required for derived tables since the derived table is as such anonymous.

9.19.8. Query Expressions

```
< non-join query expression > ::=
      < non-join query term >
    | < query expression > UNION  [ ALL ]
          [ < corresponding spec > ] < query term >
    | < query expression > EXCEPT [ ALL ]
          [ < corresponding spec > ] < query term >

< corresponding spec > ::=
    CORRESPONDING [ BY < left parent >
        < corresponding column list > < right parent > ]
```

Queries can be combined by set operators `UNION`, `INTERSECTION`, and `EXCEPT` (set difference). The `ALL` keyword will allow duplicate rows in the result set. The `CORRESPONDING BY` clause allows specifying which columns will be used to determine the equality of rows from the left and right operands.

```
 select OrderID from Orders except
    corresponding by (OrderID) select OrderID from Order_Details
```

will produce the `OrderID` of orders that have no `Order_Details`. This is equivalent to:

```
select OrderID from Orders a
    where not exists (select 1 from Order_Details b
                      where a.OrderID = b.OrderID)
```

Note that the queries are executed quite differently, although to a similar effect. There may be significant difference in performance.

9.19.9. LIKE Predicate & Search Patterns

The *`LIKE`* predicate expects a pattern to be applied to a `varchar` or `nvarchar` column to qualify the results to be returned from a query.

If the pattern does not begin with an at-sign (`@`) or with two asterisks (`**`), then we test the equality of the string and pattern with ordinary wildcard matching, which behaves approximately like the filename pattern matching in the Unix shell (but not like the regular expression matching in utilities like `grep` and `sed`).

The following characters have special significance in the pattern:

`?` - Matches any single character.

`*` - Matches zero or more of any characters.

`[ ]` - (Called a group-expression here; detailed below.

The group expression `[ ]` matches any one of the enclosed characters, unless the first character following the opening `[` is `^`, then matches only if the character (in the datum string) is not any one of those specified after the `^` (i.e., the `^` negates the meaning of this expression.)

You can use character ranges like `0-9` (shorthand for `0123456789`) inside the brackets, in which case the character in the datum string must be lexically within the inclusive range of that pair. In other words, the lexical (ASCII) value of the character at

the left side of hyphen must be less than the lexical (ASCII) value of the character at the right side.

The hyphen (–) can be included in the character set by putting it as the first or last character. The right bracket (]) can be included by putting it as the first character in the expression, i.e., immediately after the opening bracket ([) or the caret (^) immediately following the opening bracket.

That is, the hyphen indicates a range between characters, unless it is the first or the last character in the group expression, in which case it matches just to itself.

Example 9.32. Examples:

```
[abc]          Matches any of the letters a, b, or c.
[^0123456789]  Matches anything, except digits. (Same as [^0-9].)
[[]            Matches [
[]]            Matches ]
[][]           Matches ] and [
[^]]           Matches anything except ]
[A-Za-z0-9]    Matches all the alphanumeric characters.
[-*+/]         Matches the four basic arithmetic operators.
[-]            Matches to single hyphen.
[]-]           Matches to ] or -
[-[] or [[-]   Matches to - or [
```

@ - Matches the character last matched to ? or group-expression. For example, ?*@ matches to all strings which begin with the same character as they end with. However, if there is neither ? nor [] expression at the left side of @ in the pattern, then @ matches just to itself (e.g., *@* should match to all e-mail addresses).

Any other characters match ONLY to themselves, that is, not even to the upper- or lower-case variants of the same letter. Use expressions like [Wo][Oo][Rr][Dd] if you want to find any mixed-case variant of the word "word", or use the substring search explained below.

However, if the pattern begins with an at-sign (@), then we compare the rest of pattern to string with the fuzzy matching, allowing differences of few characters in quality and quantity (length). If there is more than one @ at the beginning of pattern, they are all skipped, and many additional liberties are taken for the match function. The more @ signs there are at the beginning, the more fuzzy (liberal) is the search. For example, pattern "@Johnson" will match string "Jonsson", and pattern "@@Johnson" will also match "Jansson".

If the pattern begins with two asterisks (**), then we do diacritic- and case-insensitive substring search, trying to find the string given in the rest of pattern from the datum string.

Example 9.33. Example:

"**escort" will match to "Ford Escort vm. 1975".

If there are any ISO8859.1 diacritic letters (e.g., vowels with accents or umlauts, or letters like the Spanish n with ~ (tilde)) present in the datum string, then the plain unaccented (7-bit ASCII) variant of the same letter in the pattern string will match to it. However, if there is any diacritic letter specified in the pattern string, then it will match only to the upper- or lower-case variant of exactly the same diacritic letter.

The rationale behind this is that the people entering the information to the database can use the exact spelling for the word - for example, writing the word "Citroen" with the umlaut-e (e with two dots above it, ë), as it is actually written in French - and the people who search for "Citroën" can still find it without having to remember the exact orthography of the French, by just giving the word "citroen". This also allows people who have just plain 7-bit ASCII keyboards to search for words like Ra"a"kkyla" (a place in Finland, a" means umlaut-a, i.e., a with two dots above it, ä), just by entering the word raakkyla.

So the following hold for substring searches:

1) Any non-alphabetic character in the pattern matches just to itself in the datum string (e.g., ? to ? and 3 to 3).

2) Any 7-bit ASCII letter (`A-Z` and `a-z` without any diacritic signs) in the pattern matches to any diacritic variant of the same letter (as well as to the same 7-bit ASCII letter) in the datum string, either in upper- or lower-case.

3) Any diacritic letter (8-bit ISO8859.1 letter) in the pattern matches only to the same letter (in upper- or lower-case) in the datum string.

Note:

Because the internal matching functions use macros which also consider characters like `@`, `[`, `\`, `]`, and `^` to be letters, they will match against characters `` ` ``, `{`, `|`, `}`, and ~, respectively, because in some older implementations of European character sets, those characters mark the uppercase and lowercase variants of certain diacritic letters.

It is generally better to match too liberally, and so maybe sometimes give something entirely off the wall to the user, than to miss something important because of too-strict criteria.

Of course, when searching from the data which contains text in some wide-character format (like certain coding systems for Japanese and Chinese, where one character is coded with two bytes), neither fuzzy matching function nor `nc_strstr` function presented here should be used, as they would often match on entirely spurious cases.

9.19.10. The TOP SELECT Option

```
query_term :  SELECT opt_top selection ....

opt_top :  opt_all_distinct [ TOP INTNUM ]
        |  opt_all_distinct [ TOP SKIPINTNUM, INTNUM ]
        |  opt_all_distinct [ TOP (num_scalar_exp) ]
        |  opt_all_distinct [ TOP (skip_num_scalar_exp, num_scalar_exp) ]
opt_all_distinct : [ ALL | DISTINCT ]
```

The TOP n phrase can follow an optional ALL or DISTINCT keyword in a SELECT, either at top level or inside a query term of an expression or subquery. The query with the TOP option will generate at most the indicated number of result rows.

The scope of TOP is the query in question. For example

```
select top 3 row_no from t1 best union select top 3 row_no + 1 from t1;
```

Will always return 4 rows assuming there are at least 3 rows in T1.

The optional SKIPINTNUM parameter lets you offset the selection by SKIPINTNUM number of rows. If you have a ten-row table and `select top 2 from this_table` you get the first two rows, `select top 2, 2 from this_table` will return the third and fourth rows only, instead.

9.19.11. CASE, NULLIF, COALESCE, CAST Value Expressions

The CASE Expression

There are many situations where you might find it useful to alter the the data returned by a SQL query based on a few rules. For example, you may want to display Customers gender as 'Male' or 'Female' based on whether their title is 'Mr' or one of 'Miss', 'Mrs' or 'Ms'. The CASE expression can easily accommodate this.

The Syntax of CASE is:

```
CASE
  WHEN <search-condition> THEN <output>
  WHEN <search-condition> THEN <output>
  ...
  ELSE <output>
END
```

When a <search-condition> is met the corresponding <output> is returned. If no conditions are met then the <output> after is ELSE is returned as a default value.

Example 9.34. Using the CASE expression

```
SELECT Title, CustomerName,
  CASE
    WHEN Title = 'Mr' THEN 'Male'
```

```
    WHEN Title = 'Mrs' THEN 'Female'
    WHEN Title = 'Miss' THEN Female'
    WHEN Title = 'Ms' THEN 'Female'
    ELSE 'Unknown'
  END as Gender,
  Company
  FROM Customers
```

May return values such as:

```
Title   Gender  CustomerName        Company
VARCHAR VARCHAR VARCHAR             VARCHAR
_______________________________________________________

Mr      Male    Thomas Hardy        Around the Horn
Miss    Female  Christina Berglund  Berglunds shop
Mrs     Female  Hanna Moos          Blauer See Delikatessen
Mr      Male    Laurence Lebihan    Bon app
```

There is also a short hand notation for the CASE expression as follows:

```
CASE <search-parameter>
  WHEN <search-value> THEN <output>
  WHEN <search-value> THEN <output>
  ...
  ELSE <output>
END
```

This short hand is best demonstrated by the rewrite of the above example as follows:

Example 9.35. Using the CASE short-hand expression

```
SELECT Title, CustomerName,
  CASE Title
    WHEN 'Mr' THEN 'Male'
    WHEN 'Mrs' THEN 'Female'
    WHEN 'Miss' THEN Female'
    WHEN 'Ms' THEN 'Female'
    ELSE 'Unknown'
  END as Gender,
  Company
  FROM Customers
```

In both cases the ELSE keyword is optional. If ELSE is unspecified then ELSE NULL is implicit.

The NULLIF Expression

The NULLIF expression is a short hand implementation of a special case of the CASE expression for a popular demand. Consider the following CASE expression:

```
CASE col1
  WHEN 'something' THEN NULL
  ELSE col1
END
```

This is replaced by the NULLIF expression which achieves the same result using the following, much shorter expression:

```
NULLIF (col1, 'something')
```

This is often useful in situations where you have a code to denote a value as unspecified for whatever reason, but in many applications you would rather this was NULL.

The COALESCE Expression

The COALESCE expression is another application of the CASE expression to suit another frequent requirement. The syntax of COALESCE is as follows:

```
COALESCE (value-1, value-2, ..., value-n)
```

COALESCE returns the first non-NULL parameter. This is equivalent to

```
CASE
  WHEN value-1 IS NOT NULL THEN value-1
  WHEN value-2 IS NOT NULL THEN value-2
  ...
  ELSE value-n
END
```

The CAST Expression

SQL has always been considered a strongly typed language, meaning that you cannot have expressions that contain arbitrary data types. Casting is invaluable for comparing values that are obviously compatible but their data types are not, such as `1 = '1'`. This attempts compares an integer with a char which would not work unless one of the values was cast as follows:

```
cast('1' as integer) = 1
```

See Also:

The CASTING section for more information.

9.19.12. SELECT BREAKUP

Virtuoso extends the select statement with a breakup option. This option allows a single row selected by a derived table to be seen as multiple rows by the enclosing query.

This is specially useful when translating relation tables to RDF. Using breakup, one can do a single pass over a table and generate multiple triples, each presented as a separate result row.

The syntax is:

```
SELECT BREAKUP breakup_term [, ...] FROM ....
breakup_term ::=

scalar_exp [, scalar_exp...] [WHERE search_condition]
```

Each breakup term is a list of comma separated expressions with an optional search condition at the end. Each list is treated as a select list in a union, i.e., they must be of equal length and the leftmost list must provide a name for each column. This means that an AS declaration is needed if the expression is not a column.

If a breakup tern has the optional WHERE clause, the condition is evaluated in the scope of the select, i.e., all that is defined by the FROM. If the condition is true, the row represented by the breakup term is added to the result set of the breakup select, otherwise it is ignored.

A breakup select is only allowed in a derived table or a union or other set operator term inside a derived table. A top level breakup select is not allowed. To have a breakup select as the topmost select, simply write:

```
select * from (select breakup .... from ...) f;
```

Breakup cannot be mixed with distinct, top, group by or order by. Again, to combine these, use nested derived tables.

Breakup operates equally well on local and remote tables. Breakup is never passed on to a remote but the FROM of a breakup select can consist of tables from any source.

Example 9.36. Examples:

```
select * from (select breakup (a.row_no, b.fi2) (b.row_no, a.fi3 where a.fi3 is not null)
```

```
from r1..t1 a, r1..t1 b
where a.row_no < 10 and b.row_no = a.row_no)f;
```

This produces 2 rows for each result of the join, except if fi3 is null, in which case only the first term of the breakup is returned in the result set.

9.20. COMMIT WORK, ROLLBACK WORK Statement

These statements reset the current transaction. COMMIT WORK leaves all the changes made by the current transaction in effect whereas ROLLBACK work reverses them.

In both cases, the transaction will be in a fresh state, having no locks and no changes that could be rolled back. The rollback operation always succeeds, as any change is always reversible until committed. COMMIT WORK may fail if the transaction had been marked to be canceled before the COMMIT WORK operation started. A failed commit has the effect of a rollback but it will signal a SQL STATE descriptive of the error, e.g. 40001 (deadlock).

These operations are typically not needed, since the SQLTransact ODBC call and the ODBC autocommit mode are used instead for transaction control. The only use for these statements is within stored procedures, where it may be practical to break a long sequence of operations into several transactions to reduce lock contention.

These can also be used together with the WHENEVER declaration to automate retry upon deadlock inside stored procedures.

Triggers should not normally use these statements. The exception is the case where a trigger detects a state violating application consistency rules and decides to abort the transaction. This can be done by ROLLBACK WORK, typically followed by a call to the signal function for notifying the application.

Example 9.37. Examples:

```
create procedure retry (in x integer)
{
  whenever sql state '40001' goto deal;
 again:
  -- action
  return;
 deadl:
   rollback work;
   goto again;
}

create trigger sal_negative on "Employee" after update ("Salary")
{
  if ("Salary" < 0) {
    rollback work;
    signal ('A0001', 'Salary cannot be negative');
  }
}
```

txn_error , txn_killall , signal

9.21. CHECKPOINT, SHUTDOWN Statement

```
admin_statement
        : SHUTDOWN opt_log
        | CHECKPOINT opt_log
        | BACKUP opt_log
        ;
```

The checkpoint is a point in the history of a database where all the state is written on disk as a single, consistent image that contains all the state committed so far and no uncommitted state. A transaction log starts after a checkpoint and contains the information to allow the recreation of the effect of transactions committed since the checkpoint. The checkpoint state and the

transaction log together allow recovering the database up to the last committed transaction.

The CHECKPOINT statement forces a checkpoint to be made. Making the checkpoint allows starting a new transaction log. If no new log name is specified the old log is truncated to length 0 and reused for logging transactions. If the CheckpointAuditTrail option is enabled in virtuoso.ini a new log will be started even if no new log is specified in the checkpoint or shutdown statement.

The SHUTDOWN statement performs a CHECKPOINT, and terminates the server upon completion.

BACKUP is an alternate notation for backup().

Example 9.38. Examples:

```
checkpoint 'new.log';
backup 'bak.log';
shutdown 'new2.log';
```

The above sequence of commands makes a checkpoint and starts logging subsequent transactions into new.log. The backup statement makes bak.log, which represents the state prior to starting new.log. The shutdown statement makes a new checkpoint and marks new2.log as the log file to be used for logging transactions after the database restarts. The database server exits at the completion of the SHUTDOWN statement.

```
replay ('bak.log');
replay ('new.log');
```

These statements executed on an empty database will recreate the state in effect after the last transaction to commit before the SHUTDOWN statement of the previous example.

See Also

The Backup section for more backup and recovery information.

Example 9.39. Example for control the transaction logging:

```
create procedure log_test ()
{
  -- disable the transaction logging
  log_enable (0);

  -- action code, for ex.:
  delete from TAG_REL_INX;
  insert into TAG_REL_INX (TR_T1, TR_T2, TR_COUNT) select TR_T1, TR_T2, TR_COUNT from TAG_REL;

  exec('checkpoint');

  -- enable the transaction logging
  log_enable (1);
};
```

9.21.1. Checkpoint & Page Remapping

In concept, making a checkpoint consists of writing the last committed state of a page on the read-only pre-checkpoint state. This is in case the page existed before the previous checkpoint. If the page was created after the last checkpoint, making the checkpoint consists of just writing it to disk. Now if the number of pages modified between checkpoints largely exceeds the amount of RAM, the checkpoint will be a disk-to-disk copy process which takes a time proportional to the number of modified pages. This can take a long time. Virtuoso offers a mechanism called checkpoint remap. This allows making a committed state persistent, i.e. safe, without copying all the delta collected since the last checkpoint over the pre-checkpoint state.

The checkpoint remap mechanism means that a page, say number 12 get remapped to 15 when updated. Suppose now that the page were written to disk. Now we have the pre-checkpoint page on 12 and the committed post checkpoint state on 15. If a checkpoint now takes place, instead of copying 15 over 12, which may involve reading the page, we just write that 12 is actually on 15. This speeds up the checkpoint but causes one page to take the space of 2. Now suppose 12 were modified again, now we

would see that the pre checkpoint page is 15 and that the original 12 is free. The page now gets mapped to 12. The next checkpoint now will mark that 12 is 12, which was the original condition and 15 is free.

The mechanism is actually more complex but this is the basic idea. By allowing a page to occupy two pages in some situations we dramatically cut down on atomic checkpoint time and improve availability.

Now we may argue that this destroys locality since pages that were created contiguous are no longer that after an update. This is why there is also a mechanism called unremap. and there is an upper limit to checkpoint remaps. If every page were updated between checkpoints, they would alternately be in their original place or in a remote place from which the next update-checkpoint combination would return them to the original. Now this is not always the case. Also there is not always enough space to keep up to three copies of each page. Therefore there is an unremap mechanism and an upper limit to checkpoint remaps.

The *MaxCheckpointRemap* parameter in the virtuoso.ini file controls how many pages may be stored on a page other than their logical page. The *UnremapQuota* parameter in the virtuoso.ini file controls how many previously remapped pages are unremapped each time a checkpoint is made.

Having an unlimited MaxCheckpointRemap and zero UnremapQuota will cause a checkpoint to consist exclusively of a flush of dirty buffers. The downside is that a page can take the space of two for an unlimited period of time and that original locality is not maintained. Setting the maximum checkpoint remap to zero in such a situation causes the next checkpoint to unremap all checkpoint remapped pages, restoring physical sequence and freeing disk space.

See Also:
The TPC C Benchmark chapter for examples of checkpoint remapping in use on test environments.

9.22. Stored Procedures as Views & Derived Tables

Virtuoso allows using a stored procedure result set in place of a table. A view may also be defined as a stored procedure. This provides smooth integration to external procedural logic in queries.

When a procedure appears as a table, the procedure is called and its result set is inserted into a temporary space. Processing continues from that point on as if the data came from a table.

Queries involving procedure views or derived tables are subject to normal join order selection. For this purpose it is possible to associate a cost to a procedure used in a procedure view or derived table. If the option (order) clause is given at the end of the select, joins are done left to right. If a procedure is in the leftmost position in the from it will be called once for the query, if it is in the second position it will be called once for every row of the leftmost table that passes selection criteria applicable to it and so on.

Procedures used as tables can get parameters from the query. These parameters are expressed in the containing select's where clause as column = expression, where column is a parameter name of the procedure table.

A procedure derived table is of the form:

```
q_table_name '(' column_commalist ')' '(' column_def_commalist ')' alias
```

The first column commalist is the parameter list. The second column_def_list is a description of the result set, as in a CREATE TABLE statement. The correlation name alias is required if the procedure occurs as a derived table, with no view definition.

A procedure view is declared as follows:

```
CREATE procedure VIEW new_table_name
        AS q_table_name '(' column_commalist ')' '(' column_def_commalist ')'
```

The columns in the column definition list should correspond to the procedure's result set columns. The columns are explicit in the view so as to be able to interpret the view definition and to be able to compile procedures and queries using the view before the procedure itself is defined. Thus the procedure need be defined only at time of execution, not at time of definition.

The meta-data returned by ODBC catalog calls for a procedure view will show the columns as they were declared, just like a regular view. Procedure views are never updatable.

9.22.1. Procedure Table Parameters

If there is a condition that is in the top level set of AND'ed conditions in the table expression's WHERE clause and if it is an equality condition and if it references a parameter of a procedure table and if the other side of the equality does not reference the procedure table or a table to the right of it, then this condition is considered a parameter. This means that the condition is not actually evaluated but rather that the other side of the equality is evaluated before calling the procedure and that the value returned is passed to the procedure as an input parameter in the position indicated by the name in the parameter list of the view or derived table.

If the procedure table is referenced in an explicit join, as in outer or inner join syntax, only equalities in the join condition (ON clause) are eligible to specify a parameter. Equalities in the enclosing query's WHERE phrase will be considered tests on the results, not parameters.

The parameter names in the procedure view's or derived table's parameter list do not have to be names in the output columns, although this will often be the case. The number of parameters in the parameter list in the view or derived table must match that in the procedure definition but the names do not have to be the same. Only input parameters are supported.

If a parameter is specified but no applicable predicate is found, a NULL value is passed.

9.22.2. Procedure Table Result Sets

The result set is declared in the derived table or view. This should match the result_names in the procedure but the former will take precedence on the latter. If an actual result row is shorter than the declared set, the missing columns will default to NULL.

9.22.3. Procedure Tables & Security

Accessing a procedure as a table requires execute privileges on the procedure. Privileges declared on the view are not checked.

9.22.4. Procedure Table Cost and Join Order

The __cost declaration in a procedure definition can associate a cost to a procedure. This declaration is then used for assessing different join orders. Note that depending on the join order, some parameters of a procedure table may or may not be available. It is of the form __cost (n1, n2,...), where each n is a literal number. The declaration can figure anywhere in the procedure's body as a regular statement. At least one number is required. The first number is the one-time cost of calling the procedure. The second number is the number of result rows that will be produced by the call, defaulting to 1. The numbers from third onwards correspond to the parameters of the procedure from left to right. If a parameter is NOT given or is NOT known because of join order, then the cost of the single call and the result count will be multiplied by the number corresponding to the parameter.

Consider the declaration __cost (10, 3, 5);. The procedure will take 10 units of time per call and produce 3 rows if the first parameter is known. Otherwise it will take 50 units and produce 15 rows. This is a rough way to specify the selectivity of specifying a parameter versus not specifying it. One may liken this to specifying or not specifying conditions of a table's columns.

The unit of cost is an internal abstract unit. For purposes of scaling, selecting a single row from a table of 1000 on an exact match of an integer key is 3 units. The costs are shown by the explain function with a second argument of -5.

9.22.5. Limitations

There is no limitation to the number of rows in a procedure result set. The temporary storage takes place in the database similarly to a sorted ORDER BY. Number of columns is limited to the maximum number of columns in a real table. Total row size limit for tables and ORDER BY intermediate results applies. Blobs are allowed and do not count towards the row length limit.

9.22.6. Procedure Table Examples

```
create procedure n_range (in first integer, in  last integer)
{
  declare n, n2 integer;
  n := first;
  result_names (n, n2);
  while (n < last){
    result (n, 2 * n);
    n := n + 1;
```

```
  }
}

select n, n2 from n_range (first, last) (n int, n2 int) n
        where first = 2 and last = 12;
```

This returns a set of numbers from 2 to 11 and from 4 to 22.

```
select a.n, b.n from n_range (first, last) (n int, n2 int) a,
    n_range (f2, l2) (n int, n2 int) b
  where first = 2 and last = 12 and f2 = a.n - 2 and l2 = a.n + 2;
```

Here we join the second call to the procedure to the first, effectively passing the output of the left call as parameters to the right call.

```
create procedure view n_range as n_range (first, last) (n1 int, n2 decimal);
```

This defines the procedure as a view, so that it can be referenced like a table.

```
select * from n_range a, n_range b where a.first = 1 and a.last = 11
                and b.last = a.n1 + 2 and b.first = a.n1 - 2;
```

This is the previous join but now using the view.

9.23. GRANT, REVOKE Statement

```
privilege_def
        : GRANT ALL PRIVILEGES TO grantee
        | GRANT privileges ON table TO grantee_commalist opt_with_grant_option
        | GRANT grantee_commalist TO grantee_commalist opt_with_admin_option
        ;

privilege_revoke
        : REVOKE ALL PRIVILEGES FROM grantee_commalist
        | REVOKE privileges ON table FROM grantee_commalist
        | REVOKE grantee_commalist FROM grantee_commalist
        ;

opt_with_grant_option
        : /* empty */
        | WITH GRANT OPTION
        ;

opt_with_admin_option
        : /* empty */
        | WITH ADMIN OPTION
        ;

privileges
        : ALL PRIVILEGES
        | ALL
        | operation_commalist
        ;

operation_commalist
        : operation
        | operation_commalist ',' operation
        ;

operation
        : SELECT priv_opt_column_commalist
        | INSERT
        | DELETE
        | UPDATE priv_opt_column_commalist
        | REFERENCES opt_column_commalist
        | EXECUTE
        | REXECUTE
        | role_name
        ;
```

```
grantee_commalist
        : grantee
        | grantee_commalist ',' grantee

        ;

grantee
        : PUBLIC
        | user
        ;

user
        : IDENTIFIER

role_name
        : IDENTIFIER
```

The GRANT and REVOKE statements are used to define privileges on resources to users and user groups (roles). A resource is a table, view or stored procedure. A grantee can be PUBLIC, meaning any present or future user accounts or a user name. Granting a privilege to a user name means that this user AND any users which have this user as their user group have the privilege.

Only a granted privilege can be revoked. The sequence:

```
grant select on employee to public;
revoke select (e_review) from joe;
```

Is invalid because the privilege being revoked was not granted, instead it was implied by the select on all column to public.

Any role name created by the CREATE ROLE statement is a valid grantee and a valid grantable operation.

The term 'effective privilege of a user' means the set of privileges given to a user by virtue of 1. granting them to public 2. granting them to a role which is granted to the user or to a role either directly or indirectly granted to the user or 3. granting them, to the specific user. The dba user and all users whose group is 'dba' have all privileges.

The phrase

```
GRANT ALL PRIVILEGES TO user;
```

is synonymous with setting the user's group to 'dba'.

The effective privileges inside a trigger are those of the owner of the table whose trigger is executing. The privilege of executing a trigger is derived from the privilege of performing the trigger action, e.g. update of a specific column.

The effective privilege inside a stored procedure is that of the owner of the procedure. The privilege to execute a given procedure is granted with the EXECUTE clause.

Note:
The grantee names are identifiers. This means that their case can be converted to upper case unless they are quoted. The identifier case conversion depends on the global CaseMode setting.

A user may grant or revoke privileges on resources of which he/she is the owner. A user with effective dba privileges may manipulate any privileges.

Example 9.40. Examples:

```
grant update ("Salary") on "Employees" to "Manager";

grant execute on "SalesReport" to "Accounting";
```

GRANT REFERENCES is a privilege required by a user on a table so that this user can create new tables referencing such tables in foreign keys where he/she would otherwise be restricted.

Remote SQL Data Sources. To provide further consistent security to remote data, only the DBA group is permitted to use the `rexecute()` , unless explicitly granted. Caution is required here since any user granted use of `rexecute()` has full control of the remote data source set-up by the DBA, however limited to the overall abilities of the remote user on the remote data source.

Users can be granted and denied access to `rexecute()` using the following syntax:

```
GRANT REXECUTE ON '<attached_dsn_name>' TO <user_name>
REVOKE REXECUTE ON '<attached_dsn_name>' FROM <user_name>
```

UDTs. Security of UDTs is maintained through normal SQL GRANT and REVOKE statements via a simple extension. You can define the level of access to both native and externally hosted UDTs. Grants for persistent user defined types are persisted into the SYS_GRANTS table. Grants on temporary user defined types are in-memory only and are lost (together with the temporary user defined type definition) when the server is restarted.

There are two GRANT/REVOKE types for UDTs as follows:

EXECUTE - all methods and members of a class are accessible to the grantee.

UNDER - the grantee can create subclasses of the class.

```
GRANT/REVOKE EXECUTE on <user_defined_type>
GRANT/REVOKE UNDER on <user_defined_type>
```

Note:

SQL modules, user defined types and SQL stored procedures are exposed to GRANT/REVOKE in the same namespace, therefore care must be taken avoid inadvertently granting to multiple objects at the same time.

Virtual Database Procedures & Functions

9.24. SET Statement

9.24.1. ISOLATION

This allows setting a transaction isolation in a stored procedure or trigger body. The values are:

uncommitted

committed

repeatable

serializable

These are case insensitive strings.

This takes effect dynamically until replaced by another SET ISOLATION setting. The effect never persists over the return of the containing procedure or trigger. The effect does extend into procedures or triggers called from after executing the SET ISOLATION statement.

Example 9.41. Setting the isolation level

```
set isolation='serializable';
```

The initial isolation comes from the SQL_TXN_ISOLATION statement option in the ODBC API (SQLSetConnectOption). The default isolation is repeatable read.

9.24.2. LOCK_ESCALATION_PCT

This controls the escalation from row locking to page locking. A set of row locks can be converted into one page lock if: (a) All the row locks on the page belong to the same transaction, or, (b) No other transaction waits for any of these locks. The value of this parameter is the percentage of rows on a page that must be held by the transaction before the locking goes to page level. The default is 50, meaning that for a page of 120 rows the 61st row lock will escalate the lock if all the previous locks belong to the same transaction and there is no wait pending on any. A value of -1 means that locking is always at page level if there is more

than one lock on the page. A value in excess of 100 causes lock escalation to be turned off. The effect of this setting is global and persists until the server is restarted. This setting does not affect the semantic of locking.

9.24.3. transaction_timeout

This allows setting a timeout for the current transaction. The value must be an integer count of milliseconds from the beginning of the transaction. The transaction is deemed to begin when the first client statement executes inside it or, if the transaction starts from a commit work or rollback work statement in PL, from the time of this statement. If the transaction does not commit or rollback within so many milliseconds of its beginning, it is liable to get terminated, which is signalled to any code running inside the transaction as a SQL state S1T00. When this is signalled the transaction is set into an uncommittable state and must be rolled back. When the timeoutg elapses, all locks and uncommitted state belonging to the transaction are freed.

This setting remains in effect until the transaction terminates. Any timeout for a next transaction must be set separately. This feature can be used for enforcing maximum running times on operations. The timeout will take effect also if the transaction holds no locks. This setting corresponds to the Virtuoso ODBC extension SQL_TXN_TIMEOUT statement option.o

9.24.4. PARAM_BATCH

This sets the batch size used by the virtual database array parameter optimization batch size. This causes several consecutive executes of the same statement to be grouped as a single ODBC operation with array parameters. This optimizes joins of tables on different servers and searched updates, inserts and deletes on attached tables. Most ODBC drivers do not support array parameters. A value of 1 or 0 disables the optimization. This should be done if there is a driver which falsely claims to support array parameters. If a given driver returns an error when setting array parameters the VDB will detect this and will not try to use them.

The effect of this setting is global and persists until the server is restarted. The default value comes from the ArrayParameters configuration parameter.

9.25. Anytime Queries

Starting with version 6, Virtuoso offers a partial query evaluation feature that guarantees answers to arbitrary queries within a fixed time. This is intended for use in publicly available SPARQL or SQL end points on large databases. This enforces a finite duration to all queries and will strive to return meaningful partial results. Thus this provides the same security as a transaction timeout but will be more user friendly since results will generally be returned, also for aggregate queries. Outside of a public query service, this may also be handy when exploring a large data set with unknown properties.

The feature is activated with the statement

```
set result_timeout == <expression>;
```

The expression should be a count of milliseconds. The scope of the setting is the connection, thus it remains in effect past the return of the calling procedure. Setting the timeout to 0 returns to the default state of having no limit on query run time and always returning complete results. The initial value of the timeout is 0. On a web server thread, the timeout is reset to 0 at the start of processing each new request header.

After a query or cursor has exceeded the running time, it is reset. In the event of the reset occurring inside an aggregation, the part of the query that produces rows for the aggregation is terminated, the timeout is reset and the query continues by using the aggregated results that were obtained before the first timeout. If there is again a timeout, the present aggregation is reset and the query gets another lease on life for processing the results accumulated so far. Thus, a query which has a select, a group by and an order by can consume at most three timeouts. One for producing the aggregated rows, another for sorting them and finally a third for returning them to a client or iterating over them in a stored procedure.

If the timeout occurs outside an aggregation, the result set is simply truncated.

The fact of a query returning partial results is indicated by the result set ending with a S1TAT SQL state. If the result set is read to end without this state being signalled, the results are complete and the query was not interrupted. If the result set is not consumed to end, the client cannot be sure of its completeness.

The error message associated with the S1TAT state contains the human readable version of the output of db_activity () for the query. If result_timeout is non-zero, the opening of a cursor or execution of a query on a client connection or with the exec ()

function will reset the client resource consumption counters automatically. This is done so as to have the resource consumption statistics for the error message scoped to the query. To get the exact counts, the application may call db_activity (1) in the same procedure. If this is called on a client server connection with the timeout on, the counts will be reset before db_activity () is called.

The resolution of the timeout is fairly low, timeouts are checked every two seconds with default settings.

A query cannot set a timeout from inside itself. Only a stored procedure or a top level statement on a client connection can do this.

A request to SPARQL web service endpoint may specify the timeout as an additional *&timeout=<milliseconds>* parameter. The parameter value should be equal to or greater than 1000, otherwise it will be ignored. If *SPARQL* Virtuoso configuration file contains *MaxQueryExecutionTime* parameter and its value is greater than or equal to 1000 then the actual "anytime" timeout is the minimum of the requested value and the value in the configuration file.

The current standard of SPARQL protocol does not provide any support for partial results. When a SPARQL query ends with S1TAT state, the returned HTTP header contains four additional rows, *X-SQL-State:* , *X-SQL-Message:* , *X-Exec-Milliseconds:* and *X-Exec-DB-Activity:* ; the returned document is formatted according to the requested MIME type as if the result is complete.

9.26. Best Effort Union

Virtuoso offers a SQL extension for an error tolerant UNION operation. The idea is that when querying multiple remote data sources in a single union construct some of the participating data sources may be allowed to fail while still returning a result for the successfully queried data sources.

The construct is introduced by the BEST keyword before UNION or UNION ALL. If a query expression of multiple unions has a single BEST keyword the entire union chain is considered as a best effort union. It is however recommended to have the BEST keyword in FROM of all the UNION keywords.

When a run time error occurs during the evaluation of a term in a best effort union the evaluation of the term is interrupted and the union continues with the next term. The partial result set that may have been generated by the failed term is considered when making the result.

Aliasing constant columns selected in the terms of the union by the names __SQLSTATE, __MESSAGE and __SET_NO retrieve individual error messages. If these are present and a union term encounters an error an extra row is generated for the term with all NULLs and the __SQLSTATE, __MESSAGE and __SET_NO columns set to the SQL state, SQL message and the union term number respectively. If neither of these is specified and a union term fails without producing any result rows the error will not be visible.

Note

No error encountered during a best effort union will be signalled in the normal fashion.

If a term of a best effort union meets the criteria for a pass through query on a specific remote database and a transaction error occurs when evaluating it, the transaction on the VDB is not aborted as would normally happen as a result of a VDB transaction error.

Thus if a pass through term dies of deadlock on its data source the query continues normally for other data sources referenced in the best effort union. The VDB will however get the transaction error when attempting to commit the transaction where the best effort union took place since the remote transaction branch will still be deadlocked.

Example 9.42. Examples

```
select 2222, 1 / 0 from sys_users best union all select key_id, 1 / (1000 - key_id)  from sys_keys;
```

The first term will immediately hit the /0 error and will produce no rows. The second term will produce a few rows for system tables but will hit /0 when getting to key_id 1001.

To see the errors one can write:

```
select '00000' as __sqlstate, '' as __message, 2222, 1 / 0 from sys_users best union
all select '00000' as __sqlstate, '', key_id, 1 / (1001 - key_id)  from sys_keys;
```

Note

The columns are named by the first term, hence the AS declaration in the second term is optional.

The BEST keyword does not affect the ALL or CORRESPONDING BY options of UNION.

9.27. Standard and User-Defined Aggregate Functions

In addition to whole set of standard SQL aggregate functions, Virtuoso provides a method to create application-specific aggregate functions to create complex data structures inside SQL queries.

The most evident way to calculate some value that depend on number of rows of a table is to write a stored procedure that opens a cursor, then fetches row after row in a loop and repeatedly modifies some intermediate values ("accumulators") inside the loop. When the fetch operation signals that there are no more data, a final result is calculated from values of "accumulators"

E.g. to find an average of all values in a table's column COL, one may open a cursor to fetch values from the COL, then set two "accumulators" TOTAL and CNT to zero, then fetch row after row adding 1 to CNT and adding current value of COL to TOTAL. At the end of loop, an error should be signalled if CNT is zero, otherwise the result is TOTAL divided by CNT.

Obviously, a competent programmer will use built-in AVG() aggregate function inside a single SELECT statement: the code is much more readable and the use of aggregate reduces the overhead in filling in result-set and fetching from it.

More important advantage of aggregate functions is the ability to process many groups of records in parallel, performing one table scan instead of many. SQL optimizer may use sophisticated heuristics to find the fastest way of doing a complex query with aggregates but it cannot optimize the code of a stored procedure.

9.27.1. Create Aggregate Statement

```
CREATE AGGREGATE aggregate_name (parameter, parameter ...) [ RETURNS data_type ]
FROM
    init_procedure,
    acc_procedure,
    final_function
    [, merge_procedure ]

parameter : parameter_type name data_type

parameter_type : IN | INOUT
```

The create aggregate statement forces the SQL compiler to treat any call of the declared aggregate_name as special routine similar to one used for built-in aggregate functions, so the call produces a single value for resultset instead of a separate value for every row of the resultset.

Every occurrence of the aggregate_name in a select statement creates an invisible "accumulator" column in resultset. The value of "accumulator" is calculated by init_procedure, then every row of data causes a call of acc_procedure that may modify the "accumulator" then the call of final_function should get data from "accumulator" and return the total result.

The init_procedure must have one inout parameter and return nothing. It should set the parameter to the required initial value of the "accumulator". (The SQL query compiler will use the declared data type of the parameter as the data type of the "accumulator" so no casting problem may occur) equal to

The acc_procedure must have at least one inout parameter, one or more parameters of any sort and must return nothing. It should get the previously calculated value of the "accumulator" from its first parameter, calculate a new value and set the result back to the first parameter.

The final_function must have one in or inout parameter and return a value. It should get the value of the "accumulator" from its parameter and return the calculated result.

The optional merge_procedure must have two inout parameters that accept values of two "accumulators". If defined, it may be used by SQL optimizer to split the table scan into two or more scans through parts of the table. When every 'children' scan iterates some part of the table, a separate "accumulators" is used for every part. merge_procedure gets two accumulators and adds the content of the second accumulator to the content of the first. If merge_procedure is not defined, no such tricky optimization is used. This optimization is never tried if the database resides on less than four disks, if the number of CPUs is less than four and if the query contains any call of user-defined aggregate with no merge_procedure defined; thus you will probably never need to

write such a function.

The declaration of aggregate is persistent. If create aggregate statement is successful the text is stored into the SYS_PROCEDURES table. This table is read at startup so user-defined aggregates are thus always available for use and need be defined only once.

9.27.2. Drop Aggregate Statement

```
DROP AGGREGATE aggregate_name
```

The drop aggregate statement removes the declaration of aggregate_name from SYS_PROCEDURES table but does not drop or change any declarations of functions previously listed in create aggregate statement.

The syntax of the 'call' operator is the same for 'plain' and 'aggregate' functions. If an aggregate name is used in the text of stored procedure before the aggregate is actually created then it is compiled as plain function call and causes run-time errors. In order to prevent such confusion, keyword AGGREGATE may be placed right before the name of aggregate function.

9.27.3. Examples of User-Defined Aggregates

Aggregate for Composing URIs

Consider a table USER_ATTRIBUTES that contains configuration data for users of some remote web-service. Every user have a number of parameters that should be passed to that service as a part of URI when HTTP PUT is used. Every row of USER_ATTRIBUTES contain a name and a value of some parameter for some type of users.

```
create table USER_ATTRIBUTES    (
        ID              integer not null primary key,
        ATTR_NAME       varchar,
        USER_TYPE       char(4),
        ATTR_VALUE      varchar );

insert into USER_ATTRIBUTES (ID, ATTR_NAME, USER_TYPE, ATTR_VALUE) values (1, 'key1', 't1', 'val1');
insert into USER_ATTRIBUTES (ID, ATTR_NAME, USER_TYPE, ATTR_VALUE) values (2, 'key3', 't1', 'val3');
insert into USER_ATTRIBUTES (ID, ATTR_NAME, USER_TYPE, ATTR_VALUE) values (3, 'key4', 't1', 'val4');
insert into USER_ATTRIBUTES (ID, ATTR_NAME, USER_TYPE, ATTR_VALUE) values (4, 'key5', 't2', 'val5');
insert into USER_ATTRIBUTES (ID, ATTR_NAME, USER_TYPE, ATTR_VALUE) values (5, 'key6', 't2', 'val6');
insert into USER_ATTRIBUTES (ID, ATTR_NAME, USER_TYPE, ATTR_VALUE) values (6, 'key2', 't1', 'val2');
insert into USER_ATTRIBUTES (ID, ATTR_NAME, USER_TYPE, ATTR_VALUE) values (7, 'key8', 't3', 'val8');
insert into USER_ATTRIBUTES (ID, ATTR_NAME, USER_TYPE, ATTR_VALUE) values (8, 'key7', 't2', 'val7');
insert into USER_ATTRIBUTES (ID, ATTR_NAME, USER_TYPE, ATTR_VALUE) values (9, 'key9', 't4', 'val9');
```

The application contains number of places where the resulting URI for a user should be calculated. The URI is either an empty string (if no attributes are set) or a string that starts from '?' char and consists of tokens like "attribute_name=attribute_value" delimited by "&" character.

```
create function ATTR_URI_INIT (inout _env any)
{
  _env := string_output(); -- The "accumulator" is a string session. Initially it is empty.
}

create function ATTR_URI_ACC (
  inout _env any,               -- The first parameter is used for passing "accumulator" value.
  in _attrname varchar,         -- Second parameter gets the value passed by first parameter of aggregate
  in _attrvalue varchar )       -- Third parameter gets the value passed by second parameter of aggregate
{
  if (_attrname is null)        -- Attributes with NULL names should not affect the result.
    return;
  -- The non-NULL name of attribute is appended to "accumulator"
  http ('&', _env);
  http_url (_attrname, null, _env);
  http ('=', _env);
  if (_attrvalue is null)       -- NULL values of attributes are not printed.
    return;
  -- The non-null value of attribute is appended to "accumulator"
  http_url (_attrvalue, null, _env);
}
```

```
create function ATTR_URI_FINAL (inout _env any) returns varchar
{
  declare _res varchar;
-- For empty groups in the resultset,  the initialization may be bypassed
-- so the value of "accumulator" remains NULL.
-- Finalization function should always handle such case
-- by signalling an error (like built-in AVG function) or
-- by returning some default value (like this function)
  if (_env is null)
    return '';
  _res := string_output_string (_env);
  if (_res = '')
    return '';
-- In nonempty lists of URI attributes, the first '&' should be replace with '?'
  aset (_res, 0, 63);
  return _res;
}

create aggregate ATTR_URI (in _key varchar, in _val varchar) returns varchar
  from ATTR_URI_INIT, ATTR_URI_ACC, ATTR_URI_FINAL;
```

Now we are ready to run some tests. Let's try the typical case:

```
select ATTR_URI (ATTR_NAME, ATTR_VALUE) as URI from USER_ATTRIBUTES where USER_TYPE='t1';
URI
VARCHAR
_______________________________________________________________________________
?key1=val1&key2=val2&key3=val3&key4=val4
1 Rows. -- 0 msec.
```

Now let's try the case of empty set of rows to aggregate:

```
select ATTR_URI (ATTR_NAME, ATTR_VALUE) as URI from USER_ATTRIBUTES where USER_TYPE='nosuchtype';
URI
VARCHAR
_______________________________________________________________________________

1 Rows. -- 0 msec.
```

OK, we've got an empty string. Now let's try the final case:

```
select ATTR_URI (ATTR_NAME, NULL) as URI from USER_ATTRIBUTES;
URI
VARCHAR
_______________________________________________________________________________
?key1=&key2=&key3=&key4=&key5=&key6=&key7=&key8=&key9=
1 Rows. -- 0 msec.
```

The created aggregate is very fast but unusable if intermediate results should be saved in a temporary table. It may happen if the SQL statement contains clauses such as DISTINCT, ORDER BY, GROUP BY, especially if the grouping columns are not the first columns of the primary key, or if SQL optimizer thinks that it is the fastest way to calculate a join. The following version produces the same results and may work with grouping, but may be a bit slower because concatenation of long strings is slower than writing to a string session:

```
create procedure ATTR_URI2_INIT (inout _env varchar)
{
  _env := ''; -- The "accumulator" is a string. Initially it is empty.
}

create procedure ATTR_URI2_ACC (
  inout _env varchar,  in _attrname varchar,  in _attrvalue varchar ){
  if (_attrname is null)-- Attributes with NULL names should not affect the result.
    return;
  if (_attrvalue is null)-- NULL values of attributes are not printed.
    _env := concat (_env, sprintf('&amp;%U', _attrname));
  else -- The non-null value of attribute is appended to "accumulator"
    _env := concat (_env, sprintf('&amp;%U=%U', _attrname, _attrvalue));
}
```

```
create function ATTR_URI2_FINAL (inout _env any) returns varchar
{
-- For empty groups in the result set,  the initialization may be bypassed
-- so the value of "accumulator" remains NULL.
-- Finalization function should always handle such case
-- by signaling an error (like built-in AVG function) or
-- by returning some default value (like this function)
  if (_env is null)
    return '';
  if (_env = '')
    return '';
-- In nonempty lists of URI attributes, the first '&amp;' should be replace with '?'
  aset (_env, 0, 63);
  return _env;
}

create aggregate ATTR_URI2 (in _key varchar, in _val varchar) returns varchar
  from ATTR_URI2_INIT, ATTR_URI2_ACC, ATTR_URI2_FINAL;

select ATTR_URI2 (ATTR_NAME, ATTR_VALUE) as URI from USER_ATTRIBUTES where USER_TYPE='t1'
URI
VARCHAR
_______________________________________________________________________________
?key1=val1&key3=val3&key4=val4&key2=val2
1 Rows. -- 0 msec.

select USER_TYPE, ATTR_URI2 (ATTR_NAME, ATTR_VALUE) as URI from USER_ATTRIBUTES group by USER_TYPE
USER_TYPE  URI
VARCHAR  VARCHAR
_______________________________________________________________________________
t2       ?key5=val5&key6=val6&key7=val7
t1       ?key1=val1&key3=val3&key4=val4&key2=val2
t4       ?key9=val9
t3       ?key8=val8
4 Rows. -- 0 msec.
```

Aggregate for Composing XMLs

Virtuoso offers variety of ways to place relational data into XML documents, and two best of them are select statements with FOR XML clause and XML views. But in some rare cases you may prefer to compose XML as an output of plain select statement, e.g. to get a few percent faster code.

Among other things, the CREATE XML VIEW statement creates set of Virtuoso/PL functions that return various XML trees. Those functions use special 'node building' vectors to store intermediate results. NODEBLD (which stands for 'Node Building vector') stores a partially built XML tree. A xte_nodebld() function returns a new empty NODEBLD that may be converted into an element of XML tree in the future. xte_nodebld_acc() appends new children to an existing NODEBLD. xte_node_from_nodebld() converts NODEBLD into ready-to-use XML tree. xte_nodebld_final() may work either as xte_node_from_nodebld() or as a finalization function of user defined aggregate.

```
create aggregate XTE_NODEBLD (in _child any) returns any
  from xte_nodebld_init, xte_nodebld_acc, xte_nodebld_final;
```

The use of this aggregate is not as easy as creating XML views, but it avoids creating persistent objects:

```
select
  xml_tree_doc (
    xte_node_from_nodebld (
      xte_head ('UserAttributes'),
      XTE_NODEBLD (
        xte_node (xte_head ('Row', 'Id', ID, 'UserType', USER_TYPE),
          xte_node (xte_head ('Attr', 'Name', ATTR_NAME),
            ATTR_VALUE ) )
      ) ) )
  from USER_ATTRIBUTES;
callret
VARCHAR
_______________________________________________________________________________
<UserAttributes>
<Row
xml:id="1" UserType="t1"><Attr Name="key1">val1</Attr></Row>
```

```
<Row
xml:id="2" UserType="t1"><Attr Name="key2">val2</Attr></Row>
<Row

9.28. Virtuoso SQL Optimization

Virtuoso provides a cost based SQL optimizer which performs the following types of query transformation:

Join Order

Loop Invariants

Opening derived tables

Migrating enclosing predicates into derived tables or unions

Dropping unreferenced columns or results

Detection of identically false predicates

Index selection

Grouping of co-located remote tables into single remote statements

Selection of join algorithm

Virtuoso evaluates various permutations of joined tables against its cost model and determines the best fit, from which it generates a query graph. This query graph can be returned as a result set by the `explain()` SQL function. The cost model is based on table row counts, defined indices and uniqueness constraints, and column cardinalities, i.e. counts of distinct values in columns. Additionally, histograms can be made for value distribution of individual columns.

Virtuoso automatically maintains statistics about tables in the local database. When tables are attached from known types of remote DBMS's, Virtuoso also attempts to retrieve statistics information if available. The sys_stat_analyze or sys_db_stat stored procedures can be used to force an update of statistics, also recompiling all SQL statements or procedures depending on these statistics. Once this is done, this overrides the automatic statistics. The values of automatic statistics can be seen in the

SYS_COL_AUTO_STAT table.

The stored procedure:

```
DB.DBA.SYS_STAT_ANALYZE (in full_table_name varchar, in prec integer, )
```

constructs the basic table statistics and feeds it into the DB.DBA.SYS_COL_STAT system table. The DB.DBA.SYS_DB_STAT stored procedure performs this operation on the entire database.

The stored procedure:

```
DB.DBA.SYS_STAT_HISTOGRAM (in full_table_name varchar, in full_column_name varchar, in
n_buckets integer, in prec integer, )
```

constructs table column histogram and feeds it into the DB.DBA.SYS_COL_HIST system table. The default value of prec, in both cases, is 5, which implies that a five percent sample of the table will be used. A percentage of 0 means that the whole table will be read.

Example 9.43. Demonstration of the STAT_ANALYSE & STAT_HISTOGRAM Procedures

The following script is intended for use with the ISQL program as the user dba, in the DB qualifier. The foreach statement is a special feature of the ISQL utility.

```
create table "DB"."DBA"."DTTEST" ("ID" integer primary key);
foreach integer between 1 10 insert into "DB"."DBA"."DTTEST" ("ID") values (?);
sys_stat_analyze ('DB.DBA.DTTEST');
select * from DB.DBA.SYS_COL_STAT;
sys_stat_histogram ('DB.DBA.DTTEST', 'ID', 2);
select * from DB.DBA.SYS_COL_HIST;
```

That yields:

```
Resultset 1 (from DB.DBA.SYS_COL_STAT)
---------------------------------------
CS_TABLE         CS_COL           CS_N_DISTINCT CS_MIN  CS_MAX  CS_N_VALUES CS_N_ROWS
VARCHAR NOT NULL VARCHAR NOT NULL INTEGER       VARCHAR VARCHAR INTEGER     INTEGER
_______________________________________________________________________________________

DB.DBA.DTTEST    ID               10            1       10      10          10

Resultset 2 (from DB.DBA.SYS_COL_HIST)
---------------------------------------
CH_TABLE          CH_COL            CH_NTH_SAMPLE     CH_VALUE
VARCHAR NOT NULL  VARCHAR NOT NULL  INTEGER NOT NULL  VARCHAR
_______________________________________________________________________________

DB.DBA.DTTEST     id                0                 1
DB.DBA.DTTEST     id                5                 6
DB.DBA.DTTEST     id                10                0
```

9.28.1. Optimization Techniques

Join Order

The SQL compiler constructs permutations of tables in the FROM clause of a query. The qualified inner join (x inner join y on p syntax) does not dictate a join order but the outer join syntax does. Otherwise join order is subject to change by the compiler's decision. This can be disabled with the OPTION (ORDER) global query option, see sections below.

The first order tried by the optimizer is the initial left to right order of the FROM clause. The compiler remembers its best result so far attained in trying various compilations, so it will not explore branches of the table permutation tree which, while incomplete, exceed the cost of the best complete result so far. Thus a good guess of initial table order by the programmer may save compilation time.

Loop Invariants

The compiler will evaluate all expressions and predicates as early as possible.

Consider the query:

```
select count (*) from item where i_price > (select avg (i_price) from item);
```

The compiler will detect that the sub query is data-independent from the main from and thus will compute the average price before starting the select for the count. Thus the above query executes in time linear to the item table count instead of quadratic time, as it would without the removal of the invariant.

Opening Derived Tables & Views

Views are initially opened into equivalent derived tables. If a derived table in a FROM clause is sufficiently simple, i.e. has no distinct, top, group by, and is not a multiple query expression such as a union, it can be in-lined.

Example 9.44. Derived Tables & Views

```
create view i as select * from item;

select i_id from i;
```

becomes

```
select i_id from (select * from item) xx;
```

which becomes

```
select i_id from item;
```

In joins involving views representing joins, the in-lining of a derived table will add degrees of freedom to join order selection, since the tables joined in the view will not have to be laid out contiguously.

Migrating Enclosing Predicates

When there is a derived table or view expansion which cannot be in-lined, i.e. it has a group by or is a union or such, predicates of the enclosing WHERE phrase are migrated into the derived table itself. The set of predicates that may be thus migrated will be a function of the join order, thus different combinations will be tried.

Example 9.45. Example of Migrating Predicates

```
select i_id from (select * from item1 union all select * from item2) f where i_id = 11;
```

becomes

```
select i_id from (select i_id from item1
  where i_id = 11 union all select i_id from item2 where i_id = 11) f;
```

Dropping Unreferenced Columns or Results

It may happen as a result of view expansion that columns get introduced into derived table selection which are nowhere referenced in the actual query. The compiler will detect this and will not compile code accessing these. (see above for example)

Detection of Identically False Predicates

It is possible that view expansions introduce predicates that are never simultaneously true with predicates of the enclosing query. This is recognized and can result in an empty query being produced or in union terms being dropped.

The rules for combining predicates are as follows:

```
- a < b and a < c -> a < min (a, b)
```

And similarly for <=, >, and >=.

```
a in (constant1) and a in (constant2)
```

becomes identically false if the intersection of the constant lists is empty.

```
- a = b and a = c
```

becomes identically false if b and c are different constants.

This can lead to transformations such as

```
select * from (select * from item where i_type = 2 union all
  select * from item where i_type = 3) xx where i_type = 2;
```

becomes

```
select * from (select * from item where i_type = 2 ) xx where i_type = 2;
```

Index Selection

Once a join order is hypothesized, the compiler picks various indices to use for accessing tables. The predicates applicable to the table in the specific join order being considered, as well as a possible ORDER BY clause affect the index choice. If there is an ORDER BY and there is an index which can be used to directly satisfy this, the compiler tries this index as well as the index which seems best in the light of the available predicates. Thus having an applicable ORDER BY does not always imply index selection. If there is a restrictive index for row selection and an order by which could be done by following an index for which there are no predicates, the restrictive index plus sorting will be preferred.

The general rules for index selection based on predicates are:

Primary key is preferred if 2 equally good choices exist.

Equality conditions are preferred over all others.

Uniqueness of an index is a plus.

Grouping Co-Located Tables

In queries involving distributed data the principal cost factor is often the RPC latency between the participating databases. In a local area network environment with no other load we estimate one RPC to be about 5 times longer than the selection of a single row on primary key from a table of 1 million, not counting disk I/O. In wide area contexts and with effective load the difference is still more marked. Thus when considering a loop join between a local and a remote table, it becomes obvious that the remote table should be the outer loop, unless there are extremely restrictive criteria on the local table. The cost model takes such considerations into account.

The best case of remote statement compilation is when the statement can be passed through as is to the remote. This is first checked for the whole query and subsequently for each sub query or derived table. The pass-through is not possible if:

The expression involves tables from multiple remotes or local and remote ones.

The expression involves predicates or functions or SQL constructs which do not exist on the remote.

Even if a derived table or sub query can be passed through the normal SQL optimization applies, thus Virtuoso will import predicates and suggest a join order for these cases, so that the query gets rewritten with the suggested join order left to right in the text.

If one join has multiple tables from the same remote but also other tables, the optimizer will attempt to group the co-located tables together.

```
select * from r1 join t1 on r1.k = t1.k join r2 on r1.k = r2.k;
```

will preferentially be compiled as

```
select * from (select r1.k as r1_k, ... from r1, r2
```

```
where r1.k = r2.k) xx, t1 where r1_k = t1.k;
```

Note that above the join order is meant left to right and that the derived table of r1, r2 is passed through as a unit. This becomes the leading loop in the join because fewer RPC's are likely to be needed then due to row prefetch. As for placing function calls, the general rule is to place them where the arguments are, thus passed through to the remote if they are defined there. On the other hand, if these are invariant they are always computed locally. The explain function can be used to see the details of the compilation. If a function is described as being defined on the particular remote database, this information is taken into account when compiling.

Join Type Selection

Starting with Virtuoso 3.0, hash joins are used where appropriate. A hash join is about three to four times faster for a local table than with a loop join using an exact match of primary key, thus the gain is substantial.

A hash join works by scanning the shorter of two joined tables and making a hash table from the join columns. This is only possible for joins involving equality, but most joins tend to have equalities in practice.

Note:

A hash join does not need indices to be defined and the hash table constructed for one hash join may be reused by another if the table is not modified in-between.

A hash join will be preferred if there is a sufficient number of estimated accesses to the joined table in the query. If a table is expected to be accessed only once, there is less point in making the temporary hash table.

The hash join temporary structures are disk based and reside in the temporary side of the database. They do not survive a database restart but will be ad hoc reused if such are left over from earlier queries and there is no change in the base table between the construction of the hash and its reuse.

A hash join may be specially beneficial if a remote table is on the inner loop of a loop join. The n random accesses can then be replaced with a single sequential scan of the remote table.

The selected join type can be seen in the explain output. The WITH keyword can be used to explicitly specify a join type for a table, see query options below.

9.28.2. Query Options

These are effective from Virtuoso 3.0 onwards.

```
<sql_option>:
        TABLE OPTION (<table option>,...)

<table option>:
        HASH | LOOP | INDEX index_name | INDEX PRIMARY KEY | INDEX TEXT KEY

<option clause>:
        OPTION (<query_option>,...)

<query_option>:
        ORDER
```

The TABLE OPTION clause can follow a table's correlation name in a FROM clause. The OPTION clause can appear at the end of the query, after all ORDER BY and FOR specifications.

The INDEX table option is used to control which index is chosen by the optimized SQL compiler for a given table (when you want to override the one chosen automatically).

INDEX index_name - selects a named table index (unprefixed - same name as in create index).

INDEX PRIMARY KEY - selects the primary key

INDEX TEXT KEY - selects the free-text index as a driving one if there's a free-text condition over that table in the statement.

Example 9.46. Use of the OPTION & TABLE OPTION clauses

```
select count (*) from t1 a, t1 b table option  (hash) where .row_no = b.row_no option(order)
```

This forces the a, b join order and specifies that the join will be a hash join.

Example 9.47. IN Predicate and Joins

Sometimes statements of the form

```
select col from t1 where t1.key in (select key from t2)
```

get optimized into a loop over t2 and a nested lookup on t1, as in

```
select .... from (select distinct key from t2) f, t1 where t1.key = f.key.
```

This optimization is mostly done when there is an index on t1.key and the IN subquery selects fewer rows than the other conditions on t1 would select.

In some cases the developer may wish to explicitly force this optimization to be made or not to be made. This is done with the LOOP EXISTS query option, as follows:

```
select row_no from t1 where row_no in (select row_no from t1 where fi2 = 2) option (loop exists)
```

will force the IN subquery to become a joined derived table.

```
select row_no from t1 where row_no in (select row_no from t1 where fi2 = 2) option (do not loop exists)

select row_no from t1 where row_no in (select row_no from t1 where fi2 = 2 option (do not loop exists))
```

will prevent this optimization. Note that the option (do not loop exists) can be either in the subquery or in the enclosing query.

The same logic applies to IN predicates in searched update or delete statements.

9.28.3. Query Optimization Diagnostics

Queries involving a large number of possible plans may run out of memory during optimization. There are a number of settings that influence query optimization memory utilization.

These are set in the virtuoso.ini file or can be altered on a running system with `__dbf_set` function:

Table 9.4.

INI section	INI parameter name	__dbf_set function name	__dbf_set function description
Parameters	MaxMemPoolSize	*sqlo_max_mp_size*	Controlls the size limit in bytes for transient memory consumption. Increasing this may help. The given value should be over 10M, increasing this over 100M is seldom useful but can be tried.
Parameters	MaxOptimizeLayouts	*sqlo_max_layouts*	Decreasing will reduce the number of plans tried, hence save memory. Reasonable values are 0 for no limit or somewhere in excess of 500 for a limit.
Parameters	StopCompilerWhenXOverRunTime	*sqlo_compiler_exceeds_run_factor*	Setting to 1 will stop optimization once the best plan is expected to take less time and the amount of time spent optimizing so far.
Flag	enable_joins_only	*enable_joins_only*	When set, will cause the optimizer to only consider next plan candidates that are connected by a join to the existing partial plan. In other words, no cartesian products

INI section	INI parameter name	__dbf_set function name	__dbf_set function description
			will be considered. This may save some space and time.

When reporting issues with query optimization it will be useful to include statistics from the database in order to facilitate reproducing the effect. The function `stat_export()` produces a statistics summary that can be read back into another database with the `stat_import()` function.

To export statistics:

```
string_to_file('stat.dv', serialize(stat_export()), -2);
```

To load exported statistics into a database:

```
stat_import (deserialize (file_to_string ('stat.dv')));
```

When exporting statistics as part of bug reporting, make sure to first run the queries exhibiting the problem then only export the stats. The queries drive statistics gathering.

9.28.4. ANY ORDER

When applied to a select with no aggregation or order by, this causes the select to produce results in an order that may vary between consecutive executions and may not correspond to the order of any index. In a cluster situation, running a query in this manner may be up to several times more efficient. This is not the default since SQL and SPARQL require that two consecutive executions of a query return the same results in the same order even if no order by is specified. Selects that contain aggregation or order by evaluate the part which generates input to the aggregation or order in this manner automatically. This option affects the select at the end of which it occurs and all selects inside it.

example:

```
select a.row_no from t1 a, t1 b wherea.row_no = 1 + b.row_no option (any order);
```

9.28.5. VDB Statistics for the SQL Compiler Collection

In order to correctly estimate the cost of the VDB operations overhead the optimized SQL compiler should have information for the time it takes to make a "round trip" - send message and receive response from a given remote database.

Virtuoso will automatically collect such information when you first attach a table from the remote data source. The information will be cached in the `DS_CONN_STR` field of the `SYS_DATA_SOURCE` system table.

Sometimes it may be desirable to update that values manually, for example when you change the network connection etc. Virtuoso provides, for the purpose, the stored procedure:

```
vd_statistics (in _dsn varchar := '%',in vd_table_mask varchar := '%')
```

The *_dsn* parameter is a LIKE-mask for the name of the DSN as stored in DS_DSN column of SYS_DATA_SOURCE system table. Its default value is '%' having the effect to update the "round trip" times for all the remote data sources.

The *vd_table_mask* parameter is a LIKE mask for the name of the table , as stored in RT_NAME column of SYS_DATA_SOURCE system table. Its default value of '%' means update all tables.

The current round trip time can be recalculated using the function:

```
vdd_measure_rpc_time (in _dsn varchar)
```

This will return the estimated round-trip time in milliseconds. Calling this function will not alter the cached statistics for the datasource.

Before collecting statistics data by querying the (potentially very large) remote tables the Virtuoso VDB will try to collect the statistics in various less resource extensive ways.

Generally speaking some of the statistics the SQL compiler needs in order to do cost based optimization are available through one of the following channels (in order of preference):

by querying the remote DBMS statistics system tables: This will provide a varying amount of information depending on the remote and the mapping function.

through SQLStatistics() ODBC call CARDINALITY column : A platform/remote independent way. This will provide information for the row count only.

by querying the remote table to collect various aggregate functions values (like COUNT (*), AVG() etc) : most complete, but may be very slow for large remote tables.

Unfortunately the first method is DBMS dependent. Therefore some extra setup is to be done before this can return meaningful data. This is supported off the shelf for Oracle and Virtuoso.

The `SYS_STAT_ANALYZE()` Virtuoso function will do a lookup of the remote DBMS name and version (as returned by SQL_DBMS_NAME and SQL_DBMS_VER SQLGetInfo () ODBC call) in the system table DB.DBA.SYS_STAT_VDB_MAPPERS to find a Virtuoso/PL stored procedure to call for that DBMS to retrieve the statistics data from the remote DBMS'es system tables in DBMS dependent way.

The DB.DBA.SYS_STAT_VDB_MAPPERS has the following layout:

```
create table SYS_STAT_VDB_MAPPERS (
   SVDM_TYPE varchar,
   SVDM_PROC varchar not null,
   SVDM_DBMS_NAME_MASK varchar not null,
   SVDM_DBMS_VER_MASK varchar not null,
   primary key (SVDM_TYPE, SVDM_DBMS_NAME_MASK, SVDM_DBMS_VER_MASK))
```

SVDM_TYPE is the type of the statistics returned by the procedure. Currently only 'SYS_COL_STAT' is supported.

SVDM_PROC is the Fully-qualified-name of the Virtuoso/PL stored procedure to be called.

SVDM_DBMS_NAME_MASK is the LIKE kind of mask used to check the SQL_DBMS_NAME SQLGetInfo() returned string (in uppercase).

SQL_DBMS_VER_MASK is the LIKE kind of mask use to check the SQL_DBMS_VER SQLGetInfo() returned string (in uppercase)

The `SYS_STAT_ANALYZE()` will use the first matching row in the order of the primary key.

The procedure that collects the remote DBMS statistics (usually by doing rexecute() against the remote) has the following signature:

```
create procedure DB.DBA.__VIRTUOSO_SYS_COL_STAT (
    in DSN varchar,
    in RT_NAME varchar,
    in RT_REMOTE_NAME varchar
)
```

Here:

DSN is the Virtuoso dsn name.

RT_NAME is the local Virtuoso table name of the attached table (as in the RT_NAME of SYS_REMOTE_TABLE system table).

RT_REMOTE_NAME is the name of the attached table in the remote DBMS (as in RT_REMOTE_NAME of SYS_REMOTE_TABLE system table).

The procedure may return a resultset that will be written into the SYS_COL_STAT system table. The resultset has to have a row for each attached table column and the following layout:

CS_COL - this is the column name

CS_N_DISTINCT - the number of distinct non-null values in that column

CS_MIN - minimum value

CS_MAX - maximum value

CS_AVG_LEN - average data length

CS_N_VALUES - number of non-null values

CS_N_ROWS - total number of rows

Virtuoso predefines two such procedures - one for another virtuoso as a remote and the second for an Oracle DBMS. Other DBMSes can be freely added.

```
create procedure DB.DBA.__ORACLE_SYS_COL_STAT (in DSN varchar, in RT_NAME
varchar, in RT_REMOTE_NAME varchar)
returns ANY
{
  declare _meta, _res any;

  rexecute (DSN,
    'select c.COLUMN_NAME, c.NUM_DISTINCT, NULL, NULL, c.AVG_COL_LEN, t.NUM_ROWS - c.NUM_NULLS, t.NUM_ROW
    ' from ALL_TABLES t, ALL_TAB_COLUMNS c where t.TABLE_NAME = c.TABLE_NAME and t.OWNER = c.OWNER and '
    '  t.OWNER = ? and t.TABLE_NAME = ?',
    NULL, NULL, vector (name_part (RT_REMOTE_NAME, 1, NULL), name_part(RT_REMOTE_NAME, 2, NULL)), NULL, _

  if (isarray (_res) and length (_res) > 0 and isarray (_res[0]) and isarray(_meta) and isarray (_meta[0]
    {
      declare _inx, _len integer;
      _inx := 0;
      _len := length (_res);
      exec_result_names (_meta[0]);
      while (_inx < _len)
        {
          exec_result (_res[_inx]);
          _inx := _inx + 1;
        }
    }
  return NULL;
};

create procedure DB.DBA.__VIRTUOSO_SYS_COL_STAT (in DSN varchar, in RT_NAME
varchar, in RT_REMOTE_NAME varchar)
returns ANY
{
  declare _meta, _res any;

  rexecute (DSN,
    'select CS_COL, CS_N_DISTINCT, encode_base64 (serialize (CS_MIN)), encode_base64 (serialize (CS_MAX))
    ' CS_AVG_LEN, CS_N_VALUES, CS_N_ROWS from ALL_COL_STAT where CS_TABLE = complete_table_name (?, 1)',
    NULL, NULL, vector (RT_REMOTE_NAME), NULL, _meta, _res);

  if (isarray (_res) and length (_res) > 0 and isarray (_res[0]) and isarray(_meta) and isarray (_meta[0]
    {
      declare _inx, _len integer;
      _inx := 0;
      _len := length (_res);
      exec_result_names (_meta[0]);
      while (_inx < _len)
        {
          declare _res_row any;
          _res_row := _res[_inx];
          _res_row[2] := deserialize (decode_base64 (_res_row[2]));
          _res_row[3] := deserialize (decode_base64 (_res_row[3]));
          exec_result (_res_row);
          _inx := _inx + 1;
        }
    }
  return NULL;
};
```

And here are the respective registration INSERT statements for the above procedures:

```
insert soft SYS_STAT_VDB_MAPPERS (SVDM_TYPE, SVDM_PROC, SVDM_DBMS_NAME_MASK, SVDM_DBMS_VER_MASK)
 values ('SYS_COL_STAT', 'DB.DBA.__ORACLE_SYS_COL_STAT', '%ORACLE%', '%');

insert soft SYS_STAT_VDB_MAPPERS (SVDM_TYPE, SVDM_PROC, SVDM_DBMS_NAME_MASK, SVDM_DBMS_VER_MASK)
```

```
values ('SYS_COL_STAT', 'DB.DBA.__VIRTUOSO_SYS_COL_STAT', '%VIRTUOSO%', '%');
```

In order to facilitate the access to statistics in Virtuoso the following four views are created with SELECT granted to PUBLIC:

ALL_COL_STAT - subset of SYS_COL_STAT (same row layout) but only returning data for the tables the user has access to.
USER_COL_STAT - subset of SYS_COL_STAT (same row layout) but returns rows only for the user-owned tables
ALL_COL_HIST - subset of SYS_COL_HIST (same row layout) but only returning data for the tables the user has access to.
USER_COL_HIST - subset of SYS_COL_HIST (same row layout) but returns rows only for the user-owned tables

9.29. SQL Inverse Functions

Many virtual database application scenarios require performing various conversions on data in legacy tables. An example of this is currency conversions, conversions between British and metric units, replacing complex composite keys with single numeric row id's and so forth.

SQL views are the normal way of implementing such conversions. However, when making queries with selection criteria referencing the results of these conversions we often need to first convert and then test, possibly having to bring data from the source system to the virtual database. Further, we will not be able to use indices that may exist on the legacy system if we first have to convert and only then test the value of a column.

Virtuoso introduces an SQL extension for dealing with these issues. Virtuoso allows the definition of two SQL functions that are inverses of each other, for example `dollar_to_euro` and `euro_to_dollar` would be examples of inverse functions.

Thus, when we define a view like:

```
create view euro_item as Select I_id, dollar_to_euro (I_price) as I_price, I_name from item;
```

We can further declare:

```
db..sinv_create_inverse ('euro_to_dollar', 'dollar_to_euro', 1);
```

and perform the query:

```
select * from euro_item where I_price > 100;
```

Normally, this would internally perform the query:

```
select * from item where dollar_to_euro (I_price) > 100;
```

Now however it will make use of the inverse function information and we get:

```
select * from item where I_price > euro_to_dollar (100)
```

The second form is substantially more efficient since only one function call needs to be done for the whole query, not to mention the fact that if the currency conversion function were only defined on the vdb and the item table were linked from another server, all data would have to be brought over to the vdb for the conversion.

Now if the conversion function were defined only on the vdb, the amount of euros would be converted to dollars and then passed as a parameter to

```
Select * from item where I_price > ?
```

Many simple conversions can be efficiently handled by this method. For most unit and data type conversions, the conversion preserves collation order. Amount a will be greater than amount b whether a and b be expressed in euros or dollars, as long as both a and b are in the same currency. Some other conversions such as compression, encryption, hashes and mappings of arbitrary unique ids to another set of ids do not preserve collation. Whether a particular mapping preserves collation is indicated by the third argument of `sinv_create_inverse` . In the above example we see a value of 1, meaning that collation is preserved. Zero specifies that collation is not preserved.

Sometimes it will be desirable to map multi-part keys into a single key for convenience of querying or for compatibility with another database schema.

We will use the orders and customer tables from the TPC C benchmark schema to illustrate the feature. Both tables have a primary key consisting of three parts, a warehouse id, a district id and then a customer or order id. The order references the customer with a foreign key consisting of its own warehouse and district id and of a customer id.

Now we may wish to simplify the situation and make a one-column order id and a one column foreign key reference to customer for presenting the system to an outside reporting application. We will do this completely without touching the original database, all logic taking place on the virtual database.

In this case, the original keys consist of three numbers: n digits of warehouse id, 2 digits of district id and 9 digits of order or customer id. We can simply concatenate these numbers into a single decimal. To do this, we define the following functions:

```
create function num_truncate (in n numeric)
{
  return cast (cast (n as numeric) - 0.5 as numeric (40, 0));
}

create function num_mod (in x numeric, in y numeric)
{
  return (x - num_truncate (cast (x as numeric) / y) * y);
}

/* This function takes the three key parts and returns a numeric where each occupies a fixed range of dig

create function o_iid (in w_id int, in d_id int, in o_id int) returns numeric
{
  return (w_id * 100000000000 + d_id * 1000000000 + o_id);
}

/* The below three functions retrieve each of the fields encoded in the numeric produced by o_iid */

create function o_iid_w_id (in iid numeric) returns int
{
  return cast (num_truncate (iid / 100000000000) as int);
}

create function o_iid_d_id (in iid numeric) returns int
{
  return cast (num_mod (num_truncate (iid / 1000000000), 100) as int);
}

create function o_iid_o_id (in iid numeric)
{
  return cast (num_mod (iid, 1000000000) as int);
}

db..sinv_create_inverse ('O_IID', VECTOR ('O_IID_W_ID', 'O_IID_D_ID', 'O_IID_O_ID'), 0);
```

The `sinv_create_inverse` now defines an accessory for each of the arguments of o_iid. The first function in the vector retrieves the first argument of a call to o_iid, the second the second and so forth. Since we are talking about mapping a set of values into one value it does not make sense to speak of preserving a collation, thus the last argument is 0. When making this declaration we also assert that for each distinct combination of arguments of o_iid, we get a distinct value from which all the original arguments can be retrieved using the functions mentioned.

Now we define the same functions for constructing a synthetic one-part customer id. The functions are exactly the same as for the order id.

```
create function c_iid (in w_id int, in d_id int, in c_id int) returns numeric
{
  return (w_id * 100000000000 + d_id * 1000000000 + c_id);
}

create function c_iid_w_id (in iid numeric) returns int
{
  return cast (num_truncate (iid / 100000000000) as int);
}

create function c_iid_d_id (in iid numeric) returns int
{
  return cast (num_mod (num_truncate (iid / 1000000000), 100) as int);
```

```
}

create function c_iid_c_id (in iid numeric)
{
  return cast (num_mod (iid, 1000000000) as int);
}

db..sinv_create_inverse ('C_IID', VECTOR ('C_IID_W_ID', 'C_IID_D_ID', 'C_IID_C_ID'), 0);
```

Now we have defined functions for producing the synthetic keys we wish to use. Now we bind these functions to the original database using views. We assume that the original orders and customer tables are attached from a remote database under the names orders and customer.

```
create view  orders_2 as select o_iid (o_w_id, o_d_id, o_id) as o_iid numeric, c_iid (o_w_id, o_d_id, o_c

create view customer_2 as select c_iid (c_w_id, c_d_id, c_id) as c_iid numeric, * from customer;
```

As a simple test, let us get the synthetic o_c_iid from an order using the synthetic o_iid key.

```
SQL> select o_c_iid from orders_2 where o_iid = 102000000002;

returns_________

102000000935
```

The order #2 in district #2 of warehouse #1 refers to customer #935 or district #2 of warehouse #1.

```
SQL> explain ('select o_c_iid from orders_2 where o_iid = 102000000002');

returns

{

Precode:
      0: $25 "callret" := Call O_IID_O_ID (<constant (102000000002)>)
      7: $26 "callret" := Call O_IID_D_ID (<constant (102000000002)>)
      14: $27 "callret" := Call O_IID_W_ID (<constant (102000000002)>)
      21: BReturn 0
Remote  SELECT "t2"."O_C_ID", "t2"."O_D_ID", "t2"."O_W_ID" FROM "DBA"."ORDERS" "t2"  where "t2"."O_ID" =
Params ($25 "callret", $26 "callret", $27 "callret")
Output ($29 "t1.O_C_ID", $30 "t1.O_D_ID", $31 "t1.O_W_ID")

After code:
      0: $40 "O_C_IID" := Call C_IID ($31 "t1.O_W_ID", $30 "t1.O_D_ID", $29 "t1.O_C_ID")
      7: BReturn 0
Select ($40 "O_C_IID")
}
```

In this query execution plan we see that the virtual database first decomposes the synthetic o_iid into its component parts, passes these to a query run on the remote database, retrieves the components of the synthetic o_c_iid and finally assembles this and returns it to the client.

We may also use this mapping in more complex queries:

```
select count (*) from orders_2, customer_2 where o_c_iid = c_iid;
```

This uses the synthetic foreign and primary keys for joining. Normally, since the functions for making these keys are only defined on the vdb side, each order would have to be retrieved and then the corresponding customer fetched. Now however we can take advantage of the inverse declaration and decompose the comparison of the synthetic keys into comparisons of each of their arguments:

```
SQL> explain ('select count (*) from orders_2, customer_2 where o_c_iid = c_iid');

returns

{
Remote  SELECT COUNT ( *) FROM "DBA"."ORDERS" "t2" , "DBA"."CUSTOMER" "t4"  where "t4"."C_ID" = "t2"."O_C
Output ($26 "aggregate")
Select ($26 "aggregate")
```

```
}
```

We see that the SQL compiler decomposed the comparison of the c_iid's into a comparison of the original arguments of the function. This can be done because we earlier asserted that each distinct argument combination would produce a unique result of the function.

The examples covered thus far are simple in that there is a clear way of mapping the data back and forth using SQL functions. This is not always possible, for example if we wish to generate unique numeric id's from keys consisting of arbitrary strings.

To this effect, Virtuoso provides a mechanism for automatically generating mapping functions, which take a combination of n arguments of an arbitrary searchable data type and generate a unique id for each distinct combination. The ids are assigned as needed and the mapping is persisted in an automatically generated table.

We could have generated the o_iid, o_iid_w_id, o_iid_d_id and o_iid_o_id functions with the following single call:

```
db..sinv_create_key_mapping ('O_IID', vector ('W_ID', 'int', 'D_ID', 'int', 'O_ID', 'int'));
```

The first argument is the name of the mapping function to generate. The following vector lists the arguments of this function and their data types. The name of each argument is appended to the name of the mapping function, separated by an underscore for forming the inverse functions, one for each argument. Thus the functions are named exactly as in the previous example where we defined them manually.

Internally, this generates a table for keeping the w_id, d_id and o_id for each allocated o_iid. The o_iid's come from a sequence object. The functions manage this table automatically, without requiring developer intervention. The name of the sequence is the same as that of the mapping, thus sequence_set can be used for setting the sequence counter. Note that sequence names are case sensitive.

When a new combination of w_id, d_id, o_id is seen by o_iid, it inserts a row in the mapping table and assigns this a new unique number. This update of the mapping table is committed at the same time the enclosing transaction commits. The table is normally read with read committed isolation and updated with serializable isolation. This guarantees that when a single w_id, d_id, o_id combination is seen at the same time on two threads the result will be the same id being given on both threads.

Any value returned by the mapping function may at all times be used for the inverse functions. The inverse functions will return NULL if given a value that was at no time returned by the mapping function.

The table created for the mapping is named MAP_<name of the mapping function>. The system does not define an automatic cleanup function for removing established mappings because the efficient way of implementing this is quite application dependent. Such a function can however be easily written by the developer if one is needed.

Because comparison of mapping functions is reduced into pair-wise comparison of their arguments, the query

```
select count (*) from orders, customer where o_c_iid = c_iid
```

Will work even if all orders or customers have not been assigned a mapping on the vdb side. If a virtual database application wishes to retrieve rows from a remote database using a synthetic key made by functions defined with `sinv_create_key_mapping` , any value returned by the mapping function in a transaction that was successfully committed is valid and will retrieve the data intended.

9.29.1. Updating through Inverses

A view that selects calls to functions, which have inverses, is updateable. This means that the SQL compiler will use the inverse function on the value being assigned before assigning the column. This is done for both insert and update operations. No special declaration is needed. If the function with inverse has multiple arguments, all of which are columns, then assigning the function will assign all the argument columns, having called the appropriate inverse for getting each of the separate argument values.

For example:

```
SQL> insert into orders_2 (o_iid) values (1102000000003);

Done. -- 1 msec.
SQL> select * from orders_2 where o_w_id = 11;
O_IID            O_C_IID          O_ID             O_D_ID           O_W_ID           O_C_ID       O_ENT
```

```
DECIMAL          DECIMAL          INTEGER NOT NULL  INTEGER NOT NULL  INTEGER NOT NULL  INTEGER     DATE
_____________________________________________________________________________________________

1102000000003    NULL             3                 2                 11                NULL        NULL

1 Rows. -- 1 msec.
SQL> update item_euro set i_price = 120 where i_id = 1234;
```

Conclusions

The examples in this document used tables attached from remote databases because the features discussed here are most likely to be useful in such contexts. Also the query execution plans clearly show which operations take place where. The inverse function mechanism is however in no way limited to virtual database applications. All the examples will work equally well with local tables.

9.31. Bitmap Indices

A bitmap index is a special type of index that is tailored for being efficient for key columns with relatively few distinct values, i.e. low cardinality key columns. A bitmap index is created with the normal create index statement by putting the bitmap keyword in front of index, as follows:

```
create table customer (c_id int primary key, c_state char (2), c_gender char (1), .... );

create bitmap index c_gender on customer (c_gender);
create bitmap index c_state on customer (c_state);
```

Bitmap indices offer space savings of up to 1000 x in some cases and specially for large tables the savings in I/O can be very significant.

A bitmap index can only be used on tables with an integer primary key or in other situations where the last effective key part of the index is an integer. This is understandable since a bitmap index uses a bitmap for representing the values of the last key part, thus having one bitmap for each distinct combination of leading key parts. In the above example, the customer table has an integer c_id column as primary key and a character for the customer's gender and a 2 character field for the state where the customer is located. Thus, to count all the male customers in Massachusetts, one will take the males bitmap and the MA bitmap and perform a bitwise AND of the two. This will have a 1 bit corresponding to the c_id of each male customer in Massachusetts.

We also note that in order to do the count, the customer table itself does not even have to be referenced, as the bitmaps hold all the information. Even if the table did have to be referenced, for example for adding up the outstanding credit of all male customers in Massachusetts, the bitwise AND could be done first and only the relevant rows would have to be retrieved from the table itself.

Virtuoso's implementation of bitmap indices is designed to work efficiently even when the leading key parts have relatively high cardinality, i.e. many distinct values, causing there to be a large number of mostly empty bitmaps. Of course, if each bitmap has only one bit set, for example if every customer is in a different state, there is no benefit to bitmap indices. On the other hand, there is also almost no penalty, only 6 bytes more per index entry than for a regular index. Therefore, for any non-unique key where bitmap indices are applicable, even if there are only a few repeated values, bitmap indices are a safe choice. If there are at least 2 times more rows than distinct values of the keys, space savings are certain.

A bitmap index may have any number of key parts of any type, provided that the last effective part is an integer or and IRI id. The last key parts of an index are those primary key parts that do not occur elsewhere in the key. Thus, if the primary key is a single integer, bitmap indices are always applicable. However, supposing the primary key were an integer plus a string, it would be possible to make a bitmap index where the string were first, followed by the integer. This would make sense and save space if the string were not unique by itself. As another example, the RDF_QUAD system table, the default location of the Virtuoso RDF triple store, has the columns P, G, O and S, where all are IRI ID's, except for O which is ANY. Thus, The primary key is the concatenation of all columns, by default in the order GSPO. There is another key in the order PGOS which can be implemented as a bitmap index because S is an IRI ID, hence integer-like for purposes of bitmap indices.

9.31.1. Bitmap Indices and Transactions

The minimum locking unit is the row. In the case of a bitmap index, one row holds a bitmap which most often refers to many rows. Locking is therefore less granular than with regular indices. Thus, if multiple threads insert rows with bitmap indices, more waits may occur than if the index were not bitmapped. A single row of a bitmap index references maximally 8192 other rows, most often however the count is much less.

In all other respects, locking and transactional behavior are identical with other indices.

9.31.2. Performance Implications

The main advantage of a bitmap index is more compact size, reflected in less I/O. Inserting an entry takes on the average 10% longer than for another type of index, likewise for random lookups with exact key values. Sequential access is usually faster. Space savings and thereby improved working set behavior can produce dramatic gains for large tables.

9.31.3. Physical Structure and Overheads

Bitmap indices divide the range of signed 64 bit integer values into ranges holding 8192 (8K) values. Each such range where at least one bit is set is represented by a compression entry (CE). Multiple CE's can be on the same row. CE's having one bit set take 4 bytes, CE's with 512 or less bits set take 4 bytes plus 2 bytes per bit, CE's with over 512 bits set take 1K byte regardless of how many bits are set.

A bitmap index where the bitmap holds only one bit takes 6 bytes more than the corresponding non-bitmap index entry. A second value, if it falls in the same 8K range adds 2 bytes, 4 bytes if it does not fall within in the same 8K range. If more than 512 values fall within the same 8K range, the bits are represented as a 1K byte bitmap and adding subsequent values takes no extra space.

Virtuoso supports bitmap indices since version 4.5.2919.

Bitmap Indices

9.32. Transitivity in SQL

Virtuoso SQL supports tree and graph data structures represented with SQL relations through the use of transitive subqueries.

A derived table, i..e. a select inside a from clause, can be declared to be transitive. This is done by putting the TRANSITIVE modifier after the SELECT keyword, at the place where a DISTINCT or TOP modifier would go.

The syntax of this is:

```
transitive_decl ::= TRANSITIVE <trans_option>[, ...]

trans_opt :: =
        | T_MIN (INTNUM)
        | T_MAX (INTNUM)
        | T_DISTINCT
        | T_EXISTS
        | T_NO_CYCLES
        | T_CYCLES_ONLY
        | T_NO_ORDER
        | T_SHORTEST_ONLY
        | T_IN <position_list>
        | T_OUT ( <position_list )
        | T_END_FLAG  (INTNUM)
        | T_FINAL_AS NAME
        | T_STEP ( <position_or_path_spec> )
        | T_DIRECTION (INTNUM)

position_list ::=  INTNUM [,...]

position_or_path_spec ::= INTNUM | 'step_no' | 'path_id'
```

A transitive derived table has a selection that may consist of four different types of columns. These are input, output, step data and special columns. When a transitive derived table occurs in a query, the enclosing query must specify an equality condition for either all input, all output columns or both. The designation of input and output columns is for convenience only. The order of query execution will be generally decided by the optimizer, unless overridden with the T_DIRECTION option.

Consider a simplified social network application:

```
create table knows (p1 int, p2 int, primary key (p1, p2))
alter index knows on knows partition (p1 int);
create index knows2 on knows (p2, p1) partition (p2 int);

insert into knows values (1, 2);
insert into knows values (1, 3);
insert into knows values (2, 4);
```

All persons have single integer identifiers. There is a row in the knows table if person p1 claims to know person p2.

The most basic query is to find all the people that a given person knows either directly or indirectly.

```
select * from (select transitive t_in (1) t_out (2) t_distinct  p1, p2 from knows) k where k.p1 = 1;
```

The transitive derived table simply selects from the knows table. The enclosing top level query gives an initial value for the input column of the transitive select. This leaves the output column P2 unbound, so the query will iterate over the possible values of P2. Initially, the query loops over the people directly known by 1. In the next stage, it takes the binding of P2 and uses it as a new value of the input column P1 to look for people the first degree contact knows and so on, until no new values are found.

The basic meaning of the transitive modifier is that given initial values for input column(s), the subquery is evaluated to produce values for the output columns. Then these values are fed back as values of input columns and so forth, until some termination condition is reached. If there are equality conditions for columns designated as output but no conditions for columns designated as input, then the same process runs from output to input. The terms input and output do not imply execution order. If there are

bindings for both input and output columns in the enclosing query, then the transitive derived table looks for ways of connecting the input and output bindings. If no such way is found, the subquery is empty and causes the whole enclosing query to also have no result. A transitive derived table cannot be the right side of an outer join directly but can be wrapped in a derived table that is. In this way, an outer join usage is also possible, whether finding a path is optional.

The result set of a transitive subquery can be thought of as a set of paths. A path consists of one or more consecutive bindings for the input columns and is ordered. In our example, a path is p1=1, p1=2, p1=4. This is the path connecting persons 1 and 4. If there are columns in the select that are neither input or output, they too are recorded for each step of the path. The result set may include just the ends of a path, i.e. one row where the input columns have the beginning and the output columns the end of the path. This means there is one row per distinct path. The result set may also include a row for each step on each path.

In this example, we bind both ends of the transitive subquery and ask how person 1 and 4 are connected. Since the columns p1 and p2 have an equality condition, each row of the result set has these at values 1 and 4 respectively.

```
select * from (select transitive t_in (1) t_out (2) t_direction 3 t_distinct t_shortest_only  p1, p2, t_s

P1        P2        VIA                                                                    PATH

1         4         1                                                                      0
1         4         2                                                                      0
1         4         4                                                                      0
```

The three rightmost columns allow returning information in the intermediate steps of the transitive evaluation. t_step (1) means the value of the column at position 1 at the intermediate step. The t_step ('step_no) is the sequence number of the step returned. The t_step ('path_id') is a number identifying the connection path, since there may be many paths joining persons 1 and 4.

In this situation, the result set has one row per step, including a row for the initial and final steps. While the evaluation order may vary internally, the result set is presented as if the query were evaluated from input to output, i.e. looking for people known by 1, finding 2 and 3, then looking for people they know, finding that 2 knows 4, which is a solution, since p2 = 4 was specified in the outer select. If the outere query had p1 = 4 and p2 = 1, there would be an empty result set since there is no path from 4 to 1.

For example, if tables have multipart keys, there can be many input and output columns but there must be an equal number of both, since the engine internally feeds the output back into the input or vice versa. The transitive derived table may be arbitrarily complex.

We may have an application that returns extra information about a step. This could for example be a metric of distance. In such a case, a column which is neither designated as input nor output and is not a t_step () function call, will simply be returned as is.

The result set of a transitive subquery will either have one row for each state reached, or it may have one row for each step on the path to each state reached.

The first example returns only the ends of the paths, i.e. directly and indirectly known person id's. It does not return for each returned id how this person is known, through which set of connections. The second example returns a row for each step on each path. Steps will be returned if the selection has t_step () calls or columns that are neither input or output.

The forms of t_step are:

```
t_step (<column number>)
```

This returns the value that the column, one of the columns designated as input, has at this step. The input or output columns themselves, if there is a condition on them, look equal to the condition. This allows seeing intermediate values of input columns on a path.

t_step ('step_no')

This returns the ordinal number of the step on the path. Step -0 corresponds to the input variables being at the value seen in the enclosing query. Step 1 is one removed from this. Step numbering is assigned as if evaluating from input to output.

Consider this:

```
select * from (select transitive t_in (1) t_out (2) t_min (0) t_distinct   p1, p2, t_step (1) as via, t_s
P1        P2        VIA                                                                    PATH
```

```
1         1         1                                                                                                0
1         3         1                                                                                                1
1         3         3                                                                                                1
1         2         1                                                                                                2
1         2         2                                                                                                2
1         4         1                                                                                                3
1         4         2                                                                                                3
1         4         4                                                                                                3
```

This returns four paths, all starting at 1: the paths. The path from 1 to 1, the path from 1 to 2, the path from 1 to 3 and the path from 1 to 2 to 4. The path_id column has values from 0 to 3, distinguishing the four different paths returned. The p1 column is the start of the path, thus always 1 since this is given in the outer query. The p2 column is the end of the path. The via column is the value of p1 at the intermediate step. The step number where via is equal to p1 is 0. The next step number is 1. At the highest step number of each path, p2 and via are the same.

Now, let us do this in reverse:

```
select * from (select transitive t_in (1) t_out (2) t_min (0) t_distinct   p1, p2, t_step (1) as via, t_s
P1        P2        VIA                                                                                    PATH

4         4         4                                                                                      0
2         4         2                                                                                      1
2         4         4                                                                                      1
1         4         1                                                                                      2
1         4         2                                                                                      2
1         4         4                                                                                      2
```

We give an initial value to p2 and leave p1 free. Now we get three paths, the path from 4 to 4, from 2 to 4 and from 1 to 2 to 4. We enumerate the steps as if counting from input to output, albeit internally the evaluation order is the reverse. Again, step number 0 has the via column equal to p1 and the highest numbered step has via equal to p2.

Now we may look more formally at the meaning of the transitive options:

- T_MIN (INTNUM) - This means that paths shorter than the number are not returned. In the examples above, we had min at 0, so that a path of zero length was also returned, i.e. where the first output equals the outer conditions for the inputs.
- T_MAX (INTNUM) - This gives a maximum length of path. Paths longer than this many steps are not returned. A value of 1 means that the subquery is evaluated once, i.e. the outputs of the first evalyuation are not fed back into the inputs. Specifying a minimum of 0 and a maximum of one means an optional join. Specifying min and max both to 1 means an ordinary derived table.
- T_DISTINCT - This means that if a binding of input columns is produced more than once, only the first is used. Id est, the same point is not traversed twice even if many paths lead to it.
- T_EXISTS - Only one path is generated and returned.
- T_NO_CYCLES - If a path is found that loops over itself, i.e. a next step has the input values equal to the input values of a previous step on the path, the binding is ignored.
- T_CYCLES_ONLY - Only paths that have a cycle, i.e. input values of a subsequent step equal the input values of a previous step on the same path, are returned.
- T_SHORTEST_ONLY - If both ends of the path are given, the evaluation stops at the length of path where the first solution is found. If many paths of equal length are found, they are returned but longer paths are not sought.
- T_IN (column_positions) - This specifies which columns are called input.
- T_OUT (column_positions) - This specifies which columns are called output.
- T_DIRECTION INTNUM - A value of 0 (default) means that the SQL optimizer decides which way the transitive subquery is evaluated. 1 means from input to output, 2 from output to input, 3 from both ends. Supposing we are looking at how two points are related, it makes sense to start expanding the transitive closure at both ends. in the above example, this would be going from p1 to p2 on one side and from p2 to p1 on the other.

9.33. Fast Phrase Match Processor

An "annotation phrase" is a keyword or key phrase associated with some application specific data and a uniform "annotation phrase set" may map dictionary words to their descriptions or ICAO codes to airport names and co-ordinates or geographical names to maps or Wikipedia topics to links to Wikipedia pages. An application may need to scan a given text and find all occurrences of phrases from given phrase set, for various purposes, e.g., to improve the resource with additional hyperlinks, to replace technical codes with user-friendly names, or to suggest appropriate tags and keywords. Virtuoso has built-in phrase match processor that is fast enough to deal with long documents and big phrase sets in interactive applications.

9.33.1. Phrases, Phrase Sets and Phrase Classes

An annotation phrase is a pair of a key (a string that is supposed to be a word or phrase of some natural language) and a value (of any type if its serialization is shorter than 2 kilobytes or a string shorter than 10 megabytes). The key phrase will be divided into words and normalized by language-specific functions used by free text search; after normalization it should contain from one to four words. The associated value may be very long in principle, but it will add noticeable overheads related to memory allocation and copying so it is recommended to keep it short if performance is somehow important. It is usual to make the value as short as an ID in some external "detailed" table, not only for speed but to support multiple synonyms for one thing or names of a thing in different languages.

Annotation phrases are grouped in "phrase sets" and every "phrase set" belongs to some "phrase class".

Phrase classes are enumerated in a DB.DBA.SYS_ANN_PHRASE_CLASS table.

```
create table DB.DBA.SYS_ANN_PHRASE_CLASS
(
  APC_ID integer not null primary key,
  APC_NAME varchar(255) unique,         -- unique name for use in API/UI
  APC_OWNER_UID integer,                -- references SYS_USERS (U_ID), NULL if the record writable for a
  APC_READER_GID integer,               -- references SYS_USERS (U_ID), NULL if the record is readable fo
  APC_CALLBACK varchar,
  APC_APP_ENV any
  )
;
```

Phrase sets and phrase classes may contain confidential information. E.g., a phrase set may be used to check that a given outgoing document does not mention titles of confidential projects or names of persons that should act anonymously for public. So any application may specify access restrictions when a phrase class is created. The application usually sets APC_CALLBACK to name of some of its functions (but it may be any string) and APC_APP_ENV to value of any type (application may pass it to the APC_CALLBACK function as one of arguments). Phrase match processor only keeps these data in memory, unchanged, and returns to the application as a part of text processing report, so they can be used for any purpose.

Phrase class describes an access to some application-specific callback, but it does not mention any phrases at all. Individual phrases are grouped into phrase sets. Each phrase set belongs to exactly one phrase class and is restricted to one language handler. It does not necessarily mean that it should consist of phrases of one natural language, because many language handlers support mix of languages, but it may apply some restrictions.

Phrase sets are enumerated in a DB.DBA.SYS_ANN_PHRASE_SET table.

```
create table DB.DBA.SYS_ANN_PHRASE_SET
(
  APS_ID integer not null primary key,
  APS_NAME varchar(255) unique,         -- unique name for use in API/UI
  APS_OWNER_UID integer,                -- references SYS_USERS (U_ID), NULL if the record writable for a
  APS_READER_GID integer,               -- references SYS_USERS (U_ID), NULL if the record is readable fo
  APS_APC_ID integer not null,          -- references SYS_ANN_PHRASE_CLASS (APC_ID)
  APS_LANG_NAME varchar not null,       -- name of language handler that is used to split texts of phrase
  APS_APP_ENV any,
  APS_SIZE any,                         -- approximate number of phrases inserted in the set (actual or e
  APS_LOAD_AT_BOOT integer not null     -- flags whether phrases should be loaded at boot time.
  )
;
```

APS_APP_ENV can be of any type (application may pass it to the APC_CALLBACK function as one of arguments). Like APC_APP_ENV, phrase match processor only keeps it in memory and returns in a text processing report.

The APS_SIZE tweaks the amount of memory consumed by a phrase set when it's loaded. The average "price" of placing a phrase to a set is 2 bytes per phrase. Memory amounts are less than a kilobyte while APS_SIZE is below 256, less than 64 kilobytes while APS_SIZE grow up to 32 thousands of phrases and reaches its maximum of 64 megabytes when APS_SIZE reaches its practical limit of 32 million phrases. Only rough similarity to the actual number of inserts is needed, say, same order of magnitude. The exaggerated value of APS_SIZE will allocate a bit more memory and may slightly improve the speed. It is not practical to set APS_SIZE much smaller than it should be because it will cause frequent table lookups and disk buffers in use will overweight any memory savings in the phrase match processor. If there are numerous phrase sets that are used only occasionally, do not decrease APS_SIZE, instead set APS_LOAD_AT_BOOT to zero for them.

Note that if phrase set is edited intensively during server run then the number of inserted phrases is important, an effect of phrase removal is visible only after server restart. E.g. if a phrase set is frequently cleaned and refilled with new phrases then it is much better to delete an obsolete set and create a new one.

Individual annotation phrases are stored in a table DB.DBA.SYS_ANN_PHRASE, that should not be modified by applications directly by data manipulation statements. The content of the table is used to build special search structures in memory and SQL operations like INSERT and DELETE can not keep in-memory structures in sync with the content of the table. DBA may read the table but should not update; in case of occasional update all phrase sets that contain edited phrases may become unusable until server restart.

```
create table DB.DBA.SYS_ANN_PHRASE
(
  AP_APS_ID integer not null,           -- references SYS_ANN_PHRASE_SET (APS_ID),
  AP_CHKSUM integer,                    -- phrase check-sum
  AP_TEXT varchar,                      -- original text
  AP_LINK_DATA any,                     -- Associated data about links etc.
  AP_LINK_DATA_LONG long varchar,       -- Same as AP_LINK_DATA but for long content, one of two is alway
  primary key (AP_APS_ID, AP_CHKSUM, AP_TEXT)
  )
;
```

The "almost direct" way of writing to the table is via BIF `ap_add_phrases` . It gets two arguments, the integer ID of annotation phrase set and a vector of descriptions of phrases that should be edited in that phrase set. Every item of vector of descriptions is in turn vector of one or two values; first value is the text of the phrase, second value is associated application specific data, the absence of second value indicates that the phrase should be removed. If same text of phrase appears in the vector of description more than once, and associated data differ then any version of data can be stored for future use; it is the roll of dice because the vector is reordered for faster processing.

9.33.2. Phrase Set Configuration API

- `DB.DBA.ANN_PHRASE_CLASS_ADD`
- `DB.DBA.ANN_PHRASE_CLASS_DEL`
- `AP_BUILD_MATCH_LIST`: The report R is a vector of 6 elements:

    1. R[0] vector of all distinct phrase classes for phrase sets of found phrases; every pair of items represents one phrase class: first item is an integer APC_ID of a class, second item is a description of phrase class as vector of APC_NAME, APC_CALLBACK and APC_APP_ENV;
    2. R[1] vector of all distinct phrase sets of found phrases; every pair of items represents one phrase set: first item is an integer APS_ID of a class, second item is a vector of APS_NAME, APS_APC_ID, index of phrase class description in R[0] and APS_APP_ENV;
    3. R[2] vector of all distinct found phrases; every item represents a phrase as a vector of AP_APS_ID, index of phrase set description in R[1], AP_TEXT and application-specific data from AP_LINK_DATA or AP_LINK_DATA_LONG;
    4. R[3] vector of all composed arrows for the text; every item represents one place in a text, as an "arrow" described below;
    5. R[4] vector of indexes of arrows that point to words in the text; every item is an integer that is index in R[3];
    6. R[5] vector of descriptions of occurrences of annotation phrases in text; every item represents one occurrence as vector of index of first word in R[3], index of last word in R[3], index of found phrase in R[2], index of previous occurrence of same phrase in R[5].
    7. Every "arrow" A is vector of length 5 or 6, it is longer when arrow points inside occurrence of some annotation phrase.

        a. A[0] integer that indicates type of text fragment:

- 0 is for plain word (only this type occurs in reports for plain text),
- 1 is for text of opening tag,
- 2 is for text of closing tag,
- 3 is something exceptional like unrecoverable HTML syntax error

b. A[1] integer offset of the first byte of a fragment in the text
c. A[2] integer offset of the first byte after the end of a fragment
d. A[3] integer that is a bit-mask of opened but not yet closed tags
e. A[4] integer index of the arrow of the innermost tag that is opened but not yet closed where the arrow begins
f. A[5] may absent, if presents then it is a vector of indexes in R[2] of all containing phrases.

8. Bit mask of opened but not yet closed tags consists of the following bits:

```
0x00000001      PCDATA containers (such as OPTION, TEXTAREA, XBODY, XHEAD)
0x00000002      Inlined highlight tags (such as ABBR, ACRONYM, B, BDO, BIG, CITE, CODE, DFN
0x00000004      Tag A
0x00000008      Tag LABEL

0x00000010      Inlined content (such as ADDRESS, APPLET, H1-H6, LABEL, LEGEND, P, PRE, and
0x00000020      Blocks (such as BLOCKQUOTE, BUTTON, DD, DIV, DL, DT, FIELDSET, FORM, IFRAME

0x00000100      Tags of list and ordered list (MENU, OL, UL)
0x00000200      Tag LI
0x00000400      Tag DL
0x00000800      Tags DD and DT

0x00001000      Tag FORM
0x00002000      Tag SELECT
0x00004000      Tag OPTGROUP
0x00008000      Tag BUTTON

0x00010000      Tag TABLE
0x00020000      Tags inside TABLE but outside table rows (such as TBODY, TFOOT, THEAD)
0x00040000      Tag TR
0x00080000      Tags TH and TD

0x00FFFFFF      Tags XBODY and XHEAD

0x01000000      Tag HEAD
0x02000000      Tag FRAMESET
0x04000000      Tag NOFRAMES

0x10000000      Tag HTML
0x20000000      Tag BODY
0x40000000      Tags INS and DEL
0x80000000      Tag XMP
```

For long document, the report may be too long, esp. vectors R[3] and R[4]. A simple application may not need locations of every tag and every word of the document. The report_flags argument is a bitmask, and some bits control the size of the report. If bit 1 is set then closing tags are excluded from report. If bit 2 is set then only words in found phrase are placed to the report, the rest of phrases is excluded.

9.33.3. Advertisers and Advertisement Rules

Phrase sets are sufficient for many purposes but advertisement-specific applications need more built-in functionality for maximum speed. This functionality can be reused by any application that adds hyperlinks to texts depending on content of the text.

Consider advertisers that want to show links to their resources near phrases they choose as relevant, and one phrase can be chosen by many advertisers. To make the processing easier, there exists special support for phrase sets that store lists of links for phrases.

An advertiser is some very abstract "source" of annotation phrases. The exact nature of an advertiser is application-specific, but each advertiser has an identifiable account. All accounts are in one table:

```
create table DB.DBA.SYS_ANN_AD_ACCOUNT (
  AAA_ID integer not null primary key,
  AAA_NAME varchar(255) unique,         -- unique name for use in API/UI
  AAA_OWNER_UID integer,                -- references SYS_USERS (U_ID), NULL if the record writable for a
  AAA_READER_GID integer,               -- references SYS_USERS (U_ID), NULL if the record is readable fo
```

```
  AAA_DETAILS long xml,                 -- any details, e.g., in RDF
  AAA_APP_ENV any
  )
;
```

Advertisement links are stored in a separate table:

```
create table DB.DBA.SYS_ANN_LINK (
  AL_ID integer primary key,
  AL_OWNER_UID integer,                 -- references SYS_USERS (U_ID), NULL if the record writable for a
  AL_URI varchar,                       -- URI template for A HREF
  AL_TEXT varchar,                      -- text template for body of <A>
  AL_NOTE varchar,                      -- text after the link (or around it)
  AL_TAGS any,                          -- tags to add or remove
  AL_CALLBACK varchar,
  AL_APP_ENV any
  )
;
```

Advertisers, links and phrases are linked together by advertisement rules. Each rule says that if a given phrase is found in some text then a given link should be shown and a specified advertiser's account should be charged.

```
create table DB.DBA.SYS_ANN_AD_RULE (
  AAR_AAA_ID integer not null,          -- advertiser who pays for the ad
  AAR_APS_ID integer not null,          -- phrase set
  AAR_AP_CHKSUM integer not null,       -- phrase check-sum
  AAR_TEXT varchar not null,            -- original text
  AAR_AL_ID integer not null,           -- references SYS_ANN_LINK (AL_ID)
  AAR_APP_ENV any,
  primary key (AAR_AAA_ID, AAR_APS_ID, AAR_AP_CHKSUM, AAR_TEXT, AAR_AL_ID)
  )
;
```

When an annotation phrase is stored in its phrase set via advertisement API, its application-specific data is always a vector, and vector's length is divisible by three. When a new ad rule is added to the vector, it gets three new items: value of AL_ID of a link, value of advertiser's AAA_ID and AAR_APP_ENV of the ad rule.

Anyone can describe a link but can not edit other's descriptions:

```
create function DB.DBA.ANN_LINK_ADD (
  in _owner_uid integer,
  in _uri varchar,              -- value for AL_URI
  in _text varchar,             -- value for AL_TEXT
  in _note varchar,             -- value for AL_NOTE
  in _tags any,                 -- value for AL_TAGS
  in _callback varchar,
  in _app_env any) returns integer
```

So one user may create links in favor of other user even without permission, but can not edit other's links. To edit or delete, one should be an owner and pass authentication:

```
create function DB.DBA.ANN_LINK_MODIFY (
  in _id integer,
  in _owner_uid integer,
  in _uri varchar,
  in _text varchar,
  in _note varchar,
  in _tags any,
  in _callback varchar,
  in _app_env any,
  in auth_uname varchar,
  in auth_pwd varchar) returns integer

create function DB.DBA.ANN_LINK_DEL (
  in _id integer,
  in auth_uname varchar,
  in auth_pwd varchar) returns integer
```

A link can not be dropped even by its owner if it is used by some advertiser.

```
create function DB.DBA.ANN_AD_RULE_ADD (
  in aaa_name varchar,          -- Advertiser's name (or its integer AAA_ID key), to store as AAR_AAA_ID
  in aps_name varchar,          -- Name of a phrase set (or its integer APS_ID key), to store as AAR_APS_
  in _text varchar,             -- Text of the phrase, will be stored as AAR_TEXT and duplicated in an AP
  in _al_id integer,            -- ID of a link (AL_ID in DB.DBA.SYS_ANN_LINK), to store as AAR_AL_ID
  in _app_env any,              -- Application-specific data, will be stored in AAR_APP_ENV and become a
  in _lang_name varchar,        -- Language name, for verification only; an error will be signalled if th
  in auth_uname varchar,
  in auth_pwd varchar) returns integer
```

Application-specific data should be short, because for any given phrase, sum of data from all advertisers should not exceed 2 kilobytes. Fortunately, most of needed data are in DB.DBA.SYS_ANN_LINK row already so AAR_APP_ENV is frequently a NULL.

```
create function DB.DBA.ANN_AD_RULE_DEL (
  in aaa_name varchar,
  in aps_name varchar,
  in _text varchar,
  in _al_id integer,
  in _lang_name varchar,
  in auth_uname varchar,
  in auth_pwd varchar) returns integer
```

If a phrase set is edited by DB.DBA.ANN_AD_RULE_ADD / DB.DBA.ANN_AD_RULE_DEL and by ap_add_phrases() then errors are almost guaranteed (and not detected or recovered automatically in current version). The function ap_build_match_list() works fine with mix of phrase sets managed by both methods because it is not sensitive to the format of data in phrases.

9.33.4. Example

The following example demonstrates managing phrases sets and data associated with them:

```
SQL>insert replacing DB.DBA.SYS_ANN_PHRASE_CLASS (APC_ID, APC_NAME, APC_OWNER_UID, APC_READER_GID, APC_CA
values (3, 'Debug apc #3', http_dav_uid(), http_admin_gid(), 'DB.DBA.AP_DEBUG_CALLBACK', 'Debug apc #3 en
;

Done. -- 0 msec.

SQL>insert replacing DB.DBA.SYS_ANN_PHRASE_SET (APS_ID, APS_NAME, APS_OWNER_UID, APS_READER_GID, APS_APC_
values (5, 'Debug aps #5', http_dav_uid(), http_admin_gid(), 3, 'x-any', 'Debug aps #5 env', 10000, 0)
;
