__max()

__min()

__min_notnull()

__min_notnull

__min_notnull — Returns minimum value among all its arguments, ignoring NULLs entirely.

Synopsis

```
any __min_notnull ( arg1 any ,
                    arg2 any ,
                    ... ,
                    argN any ) ;
```

Description

The function returns the minimum value among all values in all its arguments by ignoring NULLs entirely.

Parameters

argI
: Values which can be with type float, integer etc.

Examples

Example 24.194.

Example 1

```
SQL> select __min_notnull (null, 1, 0);
__min_notnull
VARCHAR
_______________________________________________________________________________

0

1 Rows. -- 0 msec.
SQL> select __min (null, 1, 0);
__min
VARCHAR
_______________________________________________________________________________

NULL

1 Rows. -- 0 msec.
```

Example 2

```
SQL> SPARQL
INSERT INTO GRAPH <http://mygraph.com>
  {
    <http://mygraph2.com/pricing/#QVal1> <price1>  1 ;                    <price3> 5 .
    <http://mygraph2.com/pricing/#QVal2>                  <price2> 1 ;    <price3> 4 .
    <http://mygraph2.com/pricing/#QVal3> <price1>  6 ;    <price2> 2                 .
  };

Insert into <http://mygraph.com>, 6 (or less) triples -- done
No. of rows in result: 1

SQL> SPARQL SELECT ?s, (bif:__min_notnull (?pr1, ?pr2, ?pr3))
FROM <http://mygraph.com>
WHERE
  {
    {
      SELECT DISTINCT ?s
      WHERE
        {
```

```
          ?s ?p ?pr .
          FILTER (?p in (<price1>, <price2>, <price3>))
        }
    }
    OPTIONAL { ?s <price1> ?pr1 }
    OPTIONAL { ?s <price2> ?pr2 }
    OPTIONAL { ?s <price3> ?pr3 }
  };

Query result:
s                                     callret-1
VARCHAR                                     VARCHAR

java_call_method

java_call_method

Synopsis

java_call_method (in *class_name* varchar ,
in *instance_obj* varchar ,
in *method_name* varchar ,
in *method_ret_sig* varchar ,
arg1, ...) ;

Description

Calls a class method using the supplied parameters (if any) and returns the return value (if any). If instance_obj is supplied (not NULL) then this function searches for a non-static method otherwise for static.

Parameters

class_name
: The name of the Java class.

instance_obj
: the Java VM class instance reference value (for example returned by java_new_object VSEI). Can be NULL.

method_name
: the name of the method to call

metjod_ret_name
: the JNI type signature of the method's return value (or V for void).

arg1, ...
: method parameters (as in java_new_object).

See Also

`java_set_property()`

`java_get_property()`

`java_load_class()`

`java_new_object()`

`java_vm_detach()`

java_set_property

java_set_property — Sets a Java class property

Synopsis

```
java_set_property ( in class_name varchar ,
                    in instance_obj any ,
                    in field_name varchar ,
                    in field_ret_type_sig varchar ,
                    in field_new_value any ) ;
```

Description

Assigns a new value to either a Java class instance property referenced by instance_obj, or if instance_obj is not supplied (NULL) then sets a static Java class property.

Parameters

class_name
: the name of the java class to set property for.

instance_obj
: the Java VM class instance reference value (for example returned by java_new_object VSEI). Can be NULL.

field_name
: the name of the field in the java class.

field_ret_type_sig
: the JNI type signature of the field.

field_new_value
: the value to be set.

java_get_property

java_get_property — Gets a property value from a Java class instance.

Synopsis

java_get_property (in *class_name* varchar ,
in *instance_obj* varchar ,
in *field_name* varchar ,
in *field_ret_type_sig* varchar) ;

Description

Gets a property value from a Java class instance referenced by instance_obj. If instance_obj is not supplied, ie NULL, then it is returned as a static Java class property value.

Parameters

class_name
: the name of the java class to get the property from

instance_obj
: the Java VM class instance reference value (for example returned by java_new_object VSEI). Can be NULL.

field_name
: the name of the field in the java class

field_ret_type_sig
: the JNI type signature of the field.

Examples

Example 24.195. static value - Java's PI value returned as DOUBLE PRECISION

```
java_get_property ('java.lang.Math', NULL, 'PI', 'D');
```

Example 24.196. default time zone name in tz_name

```
tz := java_call_method ('java.util.TimeZone', NULL, 'getDefault', 'Ljava/util/TimeZone;');
tz_name := java_get_property ('java.util.TimeZone', tz, 'getDisplayName', 'Ljava/lang/String;');
```

java_load_class

java_load_class — Declares a Java class to a Java VM

Synopsis

java_load_class (in *java_class_name* varchar ,
in *java_class_bytecode* varchar) ;

Description

Defines a java class into the running Java VM. This is useful for loading .class/.jar/.zip files from a BLOB column or from the Virtuoso WebDAV repository.

Parameters

java_class_name
: the name under which the class is to be defined

java_class_bytecode
: the contents of the .class file.

Examples

Example 24.197. Loading a Java Class

Some sample Java code:

```
java_server.java:

  public class java_server {
    public static int property;
  }
```

Compiling it makes a java_server.class. Loading it in Virtuoso is as follows:

```
  java_load_class ('java_server', file_to_string ('java_server.class'));
```

See Also

`java_call_method()`

`java_set_property()`

`java_get_property()`

`java_vm_attach()`

`java_new_object()`

`java_vm_detach()`

java_new_object

java_new_object — Creates and instance of a Java class.

Synopsis

```
any java_new_object ( in class_name varchar ,
                      in arg1 any ,
                      ... ) ;
```

Description

Creates an instance of a java class, makes a global reference in the Java VM and returns it to Virtuoso as a PL object reference value.

Parameters

class_name
: the name of the java class to be instantiated. (eg: java.util.Date)

arg1, ...
: the arguments to the constructor called.

Return Types

Virtuoso object reference value.

Examples

Example 24.198. Creating new Java class instances

creates a new java.util.Date class instance and initializes it with the current time from Virtuoso.

```
cal := java_new_object ('java.util.Date', vector ('L', msec_time()));
```

creates a new java.util.Date class instance and initializes it with the current time from java VM.

```
cal := java_new_object ('java.util.Date');
```

See Also

`java_call_method()`

`java_set_property()`

`java_get_property()`

`java_load_class()`

`java_vm_attach()`

`java_vm_detach()`

java_vm_attach

java_vm_attach

Synopsis

java_vm_attach (in *classpath* varchar ,
in *vm_options* any) ;

Description

Ensures that the current working thread is attached to the Java VM. It operates as follows:

- if the Java VM is not created it creates it.
- if the java VM is running, but the current working thread is not attached as a Java VM thread it attaches it.
- if none of the above it returns.

The `java_vm_attach()` function is called implicitly in each of the other VSEs, and also when allocating, copying or deleting a Virtuoso/PL reference to a Java VM object values.

If the Java VM is already initialized and the classpath is supplied it will throw a SQL error. If the Java VM is not initialized, but it is required to execute a statement the server will implicitly call `java_vm_attach (NULL);` . The Virtuoso Java VM integration binary works with JDK 1.2 and later.

Parameters

classpath
: The classpath string to be supplied to the Java VM. If classpath is NULL the server OS environment variable CLASSPATH will be used instead.

vm_options
: A vector of name/value pairs for the Java VM initialization parameters. The format and values of the parameters is described in the JNI Enhancements Introduced in version 1.2 of the JavaTM 2 SDK document - the description of JNI_CreateJavaVM Invocation API function.

Examples

Example 24.199. Initializing the Java VM

This example initializes the Java VM by supplying a classpath of: `CLASSPATH=/usr/local/virtuoso/classes:/usr/local/jakarta-tomcat-3.3.1/lib/tomcat.jar` and sets the `tomcat.home` Java system property to `/usr/local/jakarta-tomcat-3.3.1` It is the equivalent of executing JDK/JRE 1.2 unix java tool using: `java -cp /usr/local/virtuoso/classes:/usr/local/jakarta-tomcat-3.3.1/lib/tomcat.jar -Dtomcat.home=/usr/local/jakarta-tomcat-3.3.1`

```
java_vm_attach ('/usr/local/virtuoso/classes:/usr/local/jakarta-tomcat-3.3.1/lib/tomcat.jar',
  vector ('-Dtomcat.home=/usr/local/jakarta-tomcat-3.3.1, 0);
```

See Also

`java_get_property()`

`java_load_class()`

`java_new_object()`

`java_vm_detach()`

java_vm_detach

java_vm_detach — Detaches the current Virtuoso working thread from the Java VM.

Synopsis

```
java_vm_detach (  );
```

Description

Detaches the current Virtuoso working thread from the Java VM.

See Also

`java_call_method()`

`java_set_property()`

`java_get_property()`

`java_load_class()`

`java_new_object()`

`java_vm_attach()`

jvm_ref_import

jvm_ref_import — Creates XML description of Java class

Synopsis

```
varchar jvm_ref_import ( in files any ,
                         in classes any ) ;
```

Description

This function will returns an XML description of the selected classes from the source files.

The XML produced by the JVM_REF_IMPORT can be supplied to the predefined XSL style sheet `__javavm_type` to produce the CREATE TYPE statements:

```
select xslt ('__javavm_type', xml_tree_doc (JVM_REF_IMPORT (files, classes)));
```

This can also be achieve directly using a single call to:

```
IMPORT_JAR (in files any, in classes any)
```

Parameters

files
: Null, string or vector of strings. This can contain one or many Java .class files, .zip or .jar files to pick classes from. Null means only the classes specified in the classes argument regardless of their physical location.

classes
: Wildcard string or a vector of strings specifying which classes to describe in the resulting XML.

Return Types

A varchar of XML that describes the selected Java classes.

Examples

Example 24.200. Simple Use

```
JVM_REF_IMPORT (NULL, vector ('java.lang.Object', 'java.lang.System'));
```

This will return an XML describing the Java classes java.lang.Object and java.lang.System. Because the java.lang.System class is a subclass of java.lang.Object the XML description for java.lang.System will contain a reference to java.lang.Object and only the methods/members defined in java.lang.System (because the methods/members of java.lang.Object will be inherited).

```
JVM_REF_IMPORT (NULL, 'java.lang.System');
```

As opposed to the above example this will create an XML description only for the java.lang.System class, but will also add the inherited methods/members (from java.lang.Object) as if they were methods/members of the java.lang.System class.

See Also

`import_jar()`

lcase

lcase — Converts string argument to lower case

Synopsis

lcase (*str* string);

Description

lcase returns a copy of string str with all the uppercase alphabetical characters converted to corresponding lowercase letters. This includes also the diacritic letters present in the ISO 8859/1 standard in range 192 - 222 decimal, excluding the character 223, German double-s which stays the same.

lower is an alias for lcase.

```
lcase('AbracadabrA')  -> 'abracadabra'
```

ldap_search

ldap_search — Search in an LDAP server.

Synopsis

```
any ldap_search ( in server_url varchar ,
                  in try_tls integer ,
                  in base varchar ,
                  in filter varchar ,
                  in username varchar ,
                  in password varchar ) ;
```

Description

This function performs a search in the LDAP server. It returns control to the Virtuoso/PL environment only after all of the search results have been sent by the server or if the search request is timed out by the server. The result of the search (attributes, names of the attributes, etc.) will be returned as an array result. Options to the LDAP search can be passed as an array.

Parameters

server_url
: The server URL has three parts, <protocol>://<host>:<port>. Missing parameters will be defaulted to <ldap://localhost:389> .

try_tls
: try_tls is a flag that tells the client to perform a handshake with the LDAP server using a secure connection. This is only applicable to the ldap:// protocol and not ldaps://. If a secure connection cannot be made, the connection will be insecure.

base
: base is a string representing the DN base of the search.

filter
: Filter is a string representation of the filter to apply in the search. Simple filters can be specified as attributetype=attributevalue . More complex filters are specified using a prefix notation according to the following BNF:

username
: username authorization credential

password
: password authorization credential

Return Types

This function returns an array consisting of the following elements:

```
<entry type>, (<attribute name>, (<value 1>, <value 2> ...))
```

The *entry type* can be the keyword 'entry' for search entry, 'reference' for search reference, 'extended' for extended result, or 'result' for result from search. When you specify 'result', the returned array consists of 'error' and 'error message' keywords corresponding to error codes and error descriptions.

Errors

Table 24.47. Errors signalled by ldap_search

SQLState	Error Code	Error Text	Description

SQLState	Error Code	Error Text	Description
2E000	LD020	Failed to load the wldap32.dll	
2E000	LD005	Failed to initialize LDAP connection: <reason> (<reason code>)	
2E000	LD006	Failed to set LDAP version option: <reason> (<reason code>)	
2E000	LD016	Failed to start TLS: <reason> (<reason code>)	
28000	LD007	Failed to bind synchronous LDAP connection: <reason> (<reason code>)	
42000	LD008	Failed to search	
39000	LD002	Failed to parse LDAP reference response	
39000	LD003	Failed to parse LDAP extended result	
39000	LD004	Failed to parse LDAP extended partial result	

Examples

Example 24.201. Using ldap_search

```
....
declare result any;

-- without authentication
result := ldap_search ('ldap://localhost', 0, 'c=US', '(cn=SomeBody*)', NULL);

or

-- with authentication
result := ldap_search ('ldap://localhost', 0, 'c=US', '(cn=SomeBody*)',
  'cn=root,o=opl,c=US', 'secret');

-- the result may be following array:
-- ("entry"
     ("dn" "cn="John Atanasov",mail=hellraisor@hotmail.com,c=US,o=hotmail.com"
      "mail" ("hellraisor@hotmail.com" )
      "cn" ("John Atanasov" )
      "o" ("hotmail.com" )
      "l" ("SOFIA" )
      "givenName" ("John" )
      "surname" ("Atanasov" ))
     "result"
       ("error" "0" "error message" "Success" ))

...
```

See Also

`ldap_add()`, `ldap_delete()`, `ldap_modify()`

ldap_delete

ldap_delete — Remove a leaf entry in the LDAP Directory Information Tree.

Synopsis

```
int ldap_delete ( in server_url varchar ,
                  in try_tls integer ,
                  in entrydn varchar ,
                  in username varchar ,
                  in password varchar ) ;
```

Description

This function removes a leaf entry in the LDAP Directory Information Tree.

Parameters

server_url
: The server URL has three parts, <protocol>://<host>:<port>. Missing parameters will be defaulted to <ldap://localhost:389> .

try_tls
: try_tls is a flag that tells the client to perform a handshake with the LDAP server using a secure connection. This is only applicable to the ldap:// protocol and not ldaps://. If a secure connection cannot be made, the client will fall back to using an insecure connection.

entrydn
: entrydn is a qualified string which represents the LDAP DN entry to be deleted.

username
: username authorization credential

password
: password authorization credential

Return Types

Zero for success or error code.

Errors

Table 24.48. Errors signalled by `ldap_delete`

SQLState	Error Code	Error Text	Description
2E000	LD005	Failed to initialize LDAP connection: <reason> (<reason code>)	
2E000	LD006	Failed to set LDAP version option: <reason> (<reason code>)	
2E000	LD016	Failed to start TLS: <reason> (<reason code>)	
28000	LD007	Failed to bind synchronous LDAP connection: <reason> (<reason code>)	
39000	LD012	Failed to delete the DN entry: <reason> (<reason code>)	

Examples

Example 24.202. Using ldap_delete

```
if (not ldap_delete ('ldap://localhost', 0,
  'cn=John Atanasov,mail=hellraisor@hotmail.com,c=US,o=hotmail.com', NULL))
  {
    -- the entry removed successfully, we can perform some other action
  }
```

See Also

`ldap_add()`, `ldap_modify()`, `ldap_search()`

ldap_add

ldap_add — Adds a new entry to an LDAP directory.

Synopsis

```
int ldap_add ( in server_url varchar ,
               in try_tls integer ,
               in data varchar ,
               in username varchar ,
               in password varchar ) ;
```

Description

This function adds a new entry to the LDAP directory.

Parameters

server_url
: The server URL has three parts, <protocol>://<host>:<port>. Missing parameters will be defaulted to: <ldap://localhost:389> .

try_tls
: try_tls is a flag that tells the client to perform a handshake with the LDAP server using a secure connection. This is only applicable to the ldap:// protocol and not ldaps://. If the secure connection attempt fails, the client will fall back to insecure connect.

data
: data is an array with name/value pairs representing the data to be added.

username
: username authorization credential

password
: password authorization credential

Return Types

The error status code is returned. Zero for success.

Errors

Table 24.49. Errors signalled by `ldap_add`

SQLState	Error Code	Error Text	Description
2E000	LD005	Failed to initialize LDAP connection: <reason> (<reason code>)	
2E000	LD006	Failed to set LDAP version option: <reason> (<reason code>)	
2E000	LD016	Failed to start TLS: <reason> (<reason code>)	
28000	LD007	Failed to bind synchronous LDAP connection: <reason> (<reason code>)	
2E000	LD004	The DN must be supplied	
2E000	LD004	Failed to modify err=<reason code (<reason>)	

Examples

Example 24.203. Using ldap_add

```
create procedure
sam_ldap_add (in s1 varchar, in s2 varchar)
{
  declare res, vec any;
  declare _from_add integer;

  vec := vector ('dn', concat ('cn=', s1, ' ', s2, ',o=opl,c=BG'),
         'cn', vector (concat (s1, ' ', s2)),
         'mail', vector('mail@techno-link.com'),
         'sn', vector(s2), 'telephoneNumber', vector('032-947020', '032-633710', '048 850 760'),
         'objectClass', vector('inetorgperson' ));

  _from_add := ldap_add ('ldap://buba:389', 0, vec, NULL);

  return (_from_add);
};
```

See Also

`ldap_delete()`, `ldap_modify()`, `ldap_search()`

ldap_modify

ldap_modify — Modifies an existing LDAP directory.

Synopsis

```
int ldap_modify ( in server_url varchar ,
                  in try_tls integer ,
                  in data varchar ,
                  in username varchar ,
                  in password varchar ) ;
```

Description

This function modifies an existing LDAP directory entry.

Parameters

server_url
: The server URL has three parts, <protocol>://<host>:<port>. Missing parameters will be defaulted to: <ldap://localhost:389> .

try_tls
: try_tls is a flag that tells the client to perform a handshake with the LDAP server using a secure connection. This is only applicable to the ldap:// protocol and not ldaps://.

data
: data is an array with name/value pairs representing the data of the modified entry.

username
: username authorization credential

password
: password authorization credential

Return Types

The error status code is returned.

This function will return zero on success or non-zero in case of a failure. In case of a failure the signal will be raised according to SQL error codes and Virtuoso internal error codes.

The reserved prefix for internal errors is 'LD'.

Errors

Table 24.50. Errors signalled by `ldap_modify`

SQLState	Error Code	Error Text	Description
2E000	LD005	Failed to initialize LDAP connection: <reason> (<reason code>)	
2E000	LD006	Failed to set LDAP version option: <reason> (<reason code>)	
2E000	LD016	Failed to start TLS: <reason> (<reason code>)	
28000	LD007	Failed to bind synchronous LDAP connection: <reason> (<reason code>)	
2E000	LD004	The DN must be supplied	
2E000	LD004	Failed to modify err=<reason code (<reason>)	

Examples

Example 24.204. Using ldap_modify

```
create procedure
sam_ldap_modify (in s1 varchar, in s2 varchar)
{
  declare res, vec any;
  declare _from_modify integer;

  vec := vector ('dn', concat ('cn=', s1, ' ', s2, ',o=opl,c=BG'), 'mail',
    vector('new_mail@techno-link.com'), 'telephoneNumber',
    vector('123-45-00', '032-633710', '048 850 760') );

  _from_modify := ldap_modify ('ldap://localhost:389', 0, vec, NULL);

  return (_from_modify);
};
```

`ldap_add()`, `ldap_delete()`, `ldap_search()`

left

left — returns substring taken from left of string argument

Synopsis

left (*str* string ,
count integer) ;

Description

left returns a subsequence of string str, taking count characters from the beginning of the string.

If count is zero an empty string '' is returned.

If length of str is less than count then a copy of the whole str is returned.

```
left('AbracadabrA',4) -> 'Abra'
```

length

length — Get length of argument

Synopsis

```
integer length ( in arg any );
```

Description

Returns the length of its argument.

Table 24.51. Value returned by `length` by argument datatype

Argument type	Value returned
string	number of characters
array	number of elements
NULL	zero
LOB	length if known (see below)
string_session	number of bytes written into the session
composite	sum of byte lengths of elements consisting the composite

Note

In case of a LOB that does not have a length as in the case of one supplied by a client with SQLPutData and not yet stored, a zero is returned.

Parameters

arg
: Any type that can be tested for length.

Return Values

Integer length of the argument

Errors

Table 24.52. Errors signalled by `length`

sqlstate	error code	error text	
22023	SR015	Function length is not applicable to XML tree entity	`Length` cannot calculate a length for a non-persistent XML entity.
22023	SR016	Function length does not handle arguments of type x	An invalid data type was passed as an argument to `length`

Examples

Example 24.205. Some uses of length()

```
SQL> select length('abacus'), length (NULL);
callret   callret
INTEGER   INTEGER
_____________________________________________________________________________

6         0
```

```
1 Rows. -- 11 msec.

LFS_EXP

LFS_EXP — Export retrieved web site to the local file system

Synopsis

```
WS.WS. LFS_EXP ( in host varchar ,
                 in url varchar ,
                 in root varchar ,
                 in dst varchar ) ;
```

Description

This function is used to export local content retrieved from a Web Robot Copy to the local file system.

Parameters

host
: The target host name

url
: start path on target

root
: local WebDAV collection that contains the retrieved content

dst
: absolute path to the file system directory to export content to

Return Types

The function returns a non-zero value (can be an error description) if an error occurred while exporting.

Examples

Example 24.206. Exporting to the Filesystem

```
WS.WS.LFS_EXP ('www.foo.com', '/help/', 'sites/www_foo_com', '/tmp/');
WS.WS.DAV_EXP ('www.foo.com', '/help/', 'sites/www_foo_com',
  'http://www.mydrive.com:8990/DAV/sites/');
```

See Also

WS.WS.DAV_EXP

lh_get_handler

lh_get_handler — Returns language handler

Synopsis

```
lang_handler_t * lh_get_handler ( const char * language_name );
```

Description

Returns language handler

Parameters

language_name
: Name of language handler.

Return Types

Returns language handler for given language, or universal 'x-any' handler if no matches found. Unlike elh_get_handler, it will never return NULL.

See Also

elh_get_handler

elh_load_handler

lh_load_handler

lh_load_handler

lh_load_handler — Loads given handler in global table of the server

Synopsis

```
int lh_load_handler ( lang_handler_t * new_handler );
```

Description

Loads given handler in global table of the server, using ISO 639 and RFC 1766 language IDs of the handler as keys for future table lookups. If another handler was already specified for given RFC 1766 id, table entry will be updated and will refer to new handler. If another handler was already specified for given ISO 639 id, it will be replaced only if new handler has ISO 639 language ID equal to its RFC 1766 ID.

Please do not load custom versions of 'x-any' and 'x-ftq-x-any' handlers.

Parameters

new_handler
: Pointer to the structure that lists names of the handler and its callback functions.

See Also

elh_get_handler()

elh_load_handler()

lh_get_handler()

locate

locate — returns the starting position of the first occurrence of an substring in a string

Synopsis

```
integer locate ( in string_exp1 varchar ,
                 in string_exp2 varchar ,
                 in start integer ) ;
```

Description

Returns the starting position of the first occurrence of string_exp1 within string_exp2. The search for the first occurrence of string_exp1 begins with the first character position in string_exp2 unless the optional argument, start, is specified. If start is specified, the search begins with the character position indicated by the value of start. The first character position in string_exp2 is indicated by the value 1. If string_exp1 is not found within string_exp2, the value 0 is returned.

log

log — calculate natural logarithm of an expression

Synopsis

log (in *x* double precision);

Description

log calculates the natural logarithm of its argument and returns it as a IEEE 64-bit float.

Parameters

x
: double precision

Return Values

log.

Examples

Example 24.207. Simple Examples

```
SQL> select concat ('the LOG of 0.513513 is: ', cast (log (0.513513) as varchar));
callret
VARCHAR
_______________________________________________________________________________

the LOG of 0.513513 is: -0.666480

1 Rows. -- 4 msec.
```

See Also

exp, log10, power, sqrt

log10

log10 — Calculate 10-based logarithms

Synopsis

log10 (in *x* double precision);

Description

log10 calculates the 10-based logarithm of its argument and returns it as a IEEE 64-bit float.

Parameters

x
: double precision

Return Values

Double precision.

Examples

Example 24.208. Simple Examples

```
SQL> select concat ('the LOG10 of 0.513513 is: ', cast (log10 (0.513513) as varchar));
callret
VARCHAR
_______________________________________________________________________________

the LOG10 of 0.513513 is: -0.289449

1 Rows. -- 3 msec.
```

See Also

log , exp , power , sqrt ,

log_enable

log_enable — controls transaction logging and in-statement autocommit

Synopsis

log_enable (in *bits* integer ,
in *quiet* integer) ;

Description

The `log_enable` function allows enabling or disabling regular transaction logging or autocommit after every changed row. The parameter *`bits`* is a bitmask.

Bit1
: Bit1 controls whether the transactions are written to the transaction log file (virtuoso.trx) or not.

Bit2
: Bit2 controls manual or autocommit mode.

See Also

`log_text`

log_message

log_message — print output into the system log file

Synopsis

log_message (in *str* varchar);

Description

log_message Appends a line to the system log file (typically virtuoso.log).

Parameters

str
: An informative string to append to the log file.

Return Values

None

Examples

Example 24.209. Simple example

```
SQL> log_message('1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27

dbg_printf

log_text

log_text — inserts statements into the roll forward log

Synopsis

```
log_text ( in text varchar ,
           in arg_1 any ,
           ... ) ;
```

Description

The log_text function can be used to insert a SQL statement into the roll forward log.

The log_text function causes the SQL text given as first argument to be executed at roll forward time with the following arguments as parameters, bound from left to right to the parameter markers in the statement ('?'). There can be a maximum of 8 parameters but these can be arrays.

Parameters

text
: VARCHAR SQL statement to be added in the transaction log.

arg1..arg8
: Parameters to be passed to logged statement.

Examples

Example 24.210. Log a procedure call

Log a procedure call instead of its effects.

```
create procedure xx ()
{
  log_text ('xx (?)', arg);
  log_enable (0);
  ... action code
  log_enable (1);
}
```

See Also

`log_enable`

read_log

read_log — reads Virtuoso log

Synopsis

read_log (in *file* varchar ,
in *pos* integer) ;

Description

The `read_log` function reads from the Virtuoso Transactions log file from a given position.

Parameters

file
: Virtuoso transaction log file.

pos
: A given position from which the read to start from.

Return Types

The function returns array of transaction values.

Examples

Example 24.211. Sample example

```
-- insert sample data so to change the rdf_quad index:
SQL> SPARQL INSERT INTO <g> { <s> <p> <o> };

-- create the following example procedure
SQL>
create procedure rlt (in f any, in inpos int := 0)
{
  declare h, op, g, s, p, o any;
  declare pos int;
  result_names (op, g, s, p, o);
  h := file_open (f, inpos);
  declare r, rr any;
  while ((rr := read_log (h, pos)) is not null)
    {
      declare rw, k any;
      declare i int;
      rw := null;
      k := null;
      for (i := 1; i < length (rr); i := i + 1)
        {
          r := rr[i];
          if (r[0] = 13) -- key insert
            {
              rw := r[2];
              op := 'I';
            }
          else if (r[0] in (1,8,9)) -- insert,soft,replacing
            {
              rw := r[1];
              op := 'I';
            }
          else if (r[0] in (3,14)) -- delete
            {
              rw := r[1];
              op := 'D';
```

```
            }
          if (rw is not null)
            {
              k := rw[0];
              if (k = 273) -- RDF_QUAD, should check with SYS_KEYS
                {
                  result (op, __ro2sq (rw[1]), __ro2sq (rw[2]), __ro2sq (rw[3]), __ro2sq (rw[4]));
                }
            }
        }
    }
  result (pos + inpos, '', '', '', '');
}
;

-- Call the procedure:

-- in case of no changes to the rdf_quad index are done, it will return:

lower

lower — returns a lower case version of its argument

Synopsis

lower (*str* string);

Description

lcase returns a copy of string str with all the uppercase alphabetical characters converted to corresponding lowercase letters. This includes also the diacritic letters present in the ISO 8859/1 standard in range 192 - 222 decimal, excluding the character 223, German double-s which stays the same.

lower is just an alias for lcase.

```
lcase('AbracadabrA')  -> 'abracadabra'
```

ltrim

ltrim — removes specific characters from a string

Synopsis

ltrim (*str* string ,
trimchars string) ;

Description

ltrim returns a copy of subsequence of string str with all the characters present in trimchars trimmed off from the beginning. If the second argument is omitted, it is a space ' ' by default.

rtrim is similar except that it trims from the right.

trim trims from both ends.

```
concat('*',trim('   SIMURG   '),'*') -> '*SIMURG*'
ltrim('AbracadabrA','bAr')  -> 'acadabrA'
rtrim('AbracadabrA','bAr')  -> 'Abracada'
trim('AbracadabrA','bAr')    -> 'acada'
```

__dbf_set

__dbf_set — Sets vector execution parameters.

Synopsis

__dbf_set (in *flag_name* varchar ,
out *flag_value* any) ;

Description

Sets at run time by a dba group user the vector execution parameters.

Parameters

flag_name
: Name of the flag.

flag_value
: Value of the flag.

Examples

Example 24.212. Simple Use

Set the maximum number of outstanding parallel work units to 16:

```
SQL> __dbf_set ('enable_qp', 16);
```

stat_import

stat_import — Imports database statistics

Synopsis

stat_import (in *st_name* varchar) ;

Description

This function imports produced database statistics.

Parameters

st_name
: Name of the statistics file.

Examples

Example 24.213. Simple Use

```
-- produce statistics for a given database:
SQL> string_to_file('stat.dv', serialize(stat_export()), -2);

-- import the produced statistics:
SQL> stat_import (deserialize (file_to_string ('stat.dv')));
```

See Also

`stat_export()`

stat_export

stat_export — Produces a statistics summary.

Synopsis

```
stat_export (   );
```

Description

This function produces a statistics summary that can be read back into another database with the `stat_import()` function

Parameters

Examples

Example 24.214. Simple Use

```
-- produce statistics for a given database:
SQL> string_to_file('stat.dv', serialize(stat_export()), -2);
```

See Also

`stat_import()`

make_array

make_array — returns a new array

Synopsis

```
array make_array ( in length integer ,
                   in content varchar ) ;
```

Description

This returns an array of length elements with the content element type. The initial content of the array is undefined.

Parameters

length
: Number of elements to be allocated in the resultant array.

content
: String that specifies the data type of the array to make. Valid strings are 'float', 'double', 'long' or 'any'. These correspond respectively to the C types long (32 bit signed), float (IEEE 32-bit), double (IEEE 64-bit) and untyped. The untyped array may hold a heterogeneous collection of any Virtuoso data types, including other arrays. The initial content of the array is undefined.

Return Values

An array of specified length and data type

Errors

Parameter data type checking errors

Table 24.54. Errors signalled by make_array()

sqlstate	error code	error text
22003	SR021	make_array called with an invalid count <num>
22023	SR022	Type for make_array must be float, double, long or any

make_string

make_string — make a string

Synopsis

make_string (in *count* integer) ;

Description

make_string returns a new string of length count, filled with binary zeros.

If count is zero, an empty string '' is returned.

Parameters

count
: Length of the string to be generated.

Return Values

A string with defined length is returned.

Examples

Example 24.215. Using make_string and aref

Make a string and fill it with character sequence containing the alphabet upper case characters from A to Z.

```
SQL> create procedure
alphabet_string ()
{
  declare _inx integer;
  declare _str varchar;
  _str := make_string (26);

  while (_inx < 26)
    {
      aset (_str, _inx, _inx + 65);
      _inx := _inx + 1;
    }
  return (_str);
}
;

Done. -- 6 msec.
SQL> select alphabet_string ();
callret

md5

md5 — returns the md5 checksum of its argument

Synopsis

```
checksum md5 ( in str varchar );
```

Description

`md5` calculates the MD5 checksum of its argument. The md5 message digest algorithm is defined in RFC1321 .

Parameters

str
: A string or string_output containing the data for calculating the message digest.

Return Types

A string of 32 lowercase alphanumeric characters.

Errors

Table 24.55. Errors signalled by

SQLState	Error Code	Error Text	Description

Examples

Example 24.216. Simple example

```
SQL> select md5 ('blah blah');
callret

```

See Also

RFC1321

md5_init

md5_init — returns the string serialization of a new md5 context

Synopsis

```
new md5 checksum
context md5_init (       );
```

Description

This function initializes an MD5_CTX, converts it into varchar form and returns this representation. Should be used with md5_update/md5_final.

See Also

md5_update , md5_final

md5_update

md5_update — returns the updated md5 context serialized as varchar

Synopsis

```
md5 context update md5_update ( in ctx varchar ,
                                in data varchar ) ;
```

Description

This function updates MD5_CTX with data parameter and returns the (deserialized from ctx parameter) updated context.

See Also

md5_init md5_final ,

md5_final

md5_final — returns the md5 checksum given an initialized md5 context

Synopsis

md5_final (in *ctx* varchar) ;

Description

This function finalizes the MD5_CTX and returns the final checksum.

Parameters

ctx
: A MD5_CTX

Return Types

A string md5 checksum.

See Also

`md5_init` `md5_update` ,

mime_body

mime_body — used to compose multipart/mixed MIME message body

Synopsis

```
varchar mime_body ( in mime_parts any );
```

Description

The `mime_body()` procedure is used to compose a multipart/mixed MIME body. it takes only one parameter, mime_parts, an array of `mime_part` elements such as those produced by the `mime_part()` function.

Parameters

mime_parts
: Array of mime parts such as those produced by the mime_part() function.

Return Types

The function returns a multipart mixed MIME body as text.

Examples

Example 24.217. Creating a MIME message body

This example will show the output in ISQL of producing a two part MIME message using the mime_body() and mime_part() functions.

```
SQL> select MIME_BODY (vector (MIME_PART (null,null,null,'this is a first'),
MIME_PART (null,null,'base64','this is a second')));
callret

`mime_part()`

mime_body()

mime_part

mime_part — used to compose a MIME message body part.

Synopsis

```
any mime_part ( in content_type varchar ,
                in content_disposition varchar ,
                in transfer_encoding varchar ,
                in data varchar ) ;
```

Description

This function is used to make a MIME part that can be used with the `mime_body()` function.

Parameters

content_type
: This parameter is used to specify the media type and subtype of data in the body of a message and to fully specify the native representation of such data. This header embodies much of the power of MIME. The IETF can add new official content types. Additionally, private content-type values can be defined by anyone. Such private content types have values of "x-something" or "X-something", where "something" can take on any value.

content_disposition
: This parameter provides information about how to present a body part. When a body part is to be treated as an attached file, the Content-Disposition header should include a file name parameter.

transfer_encoding
: The encoding method to use, such as base64.

data
: The content of the message.

Return Types

The function returns a MIME part for use with the `mime_body()` function.

Examples

Example 24.218. Creating a MIME message body

This example will show the output in ISQL of producing a two part MIME message using the mime_body() and mime_part() functions.

```
SQL> select MIME_BODY (vector (MIME_PART (null,null,null,'this is a first'),
MIME_PART (null,null,'base64','this is a second')));

mime_part()

mime_body()

mime_tree

mime_tree — parses MIME messages into an array structure

Synopsis

```
array mime_tree (
                 in message_text
                 string ,
                 in flag integer ) ;
```

Description

This function is intended to parse MIME (RFC2045) messages (coming from a RFC822 or HTTP sources). It parses the text and produces an array structure representing the structure of the MIME message. It copies into the structure MIME headers, but for the MIME bodies it only stores start and end offsets, thus optimizing space usage.

The parameters to mime_tree are:

message_text (string, required) - contains the text of the message to be parsed.

flag (integer, optional) - a flag describing the format of the "root" object in the text.
If flag is 1, the "root" message follows RFC822. This means mime_tree will unfold the attributes, will scan for MIME registered header fields and will take their attributes. Alternately this can be a MIME message which needs no unfolding and has attributes separated with semicolon.

If flag is 2, the "root" message follows RFC2045. This means mime_tree will scan for MIME attributes.

In either cases mime_tree will look for the Content-Type header field and will parse the "message/rfc822" and "multipart/digest" MIME bodies as nested messages.

mime_tree will return an array of 3 elements (message descriptor) with the following structure:

index 0: an array of attributes, parameters and their values, which can be passed to get_keyword or get_keyword_ucase functions.

index 1: an array of four elements: (0 - starting index of the body into the source_message text (for aref), 1 - ending index of the body, 2 - an message descriptor if the body is recognized to contain a valid RFC822 message; 0 otherwise, 3 - an array of two elements with starting and ending offset if the body is recognized as a valid RFC822 multipart message and has some things after the last MIME boundary, 0 otherwise).

index 2: an array of subpart message descriptors, if the MIME message is recognized as multipart MIME message, 0 otherwise.

Examples

consider the following message text

```
Form: Somebody <someuser@somehost>
Mime-Version: 1.0
Content-Type: "multipart/mixed";
        boundary="--the boundary"
To: self@localhost

This is a multipart MIME message
----the boundary
Content-Type: image/gif; filename="the_big_picture.gif"

GIF........
----the boundary
Content-Type: message/rfc822

From: Ford@Perfect
To: vogon
Mime-Version: 1.0
Content-Type: multipart/alternate; boundary="--sub-boundary"
```

```
This is some Message
----sub-boundary
Content-Type: text/plain

Hi
----sub-boundary
Content-Type: text/html

<P>Hi</P>
----sub-boundary--
Some garbage
----the boundary
Content-Type: text/plain

Some additional text
----the boundary--
Some additional garbage
```

MIME_TREE(the_text, 1) will produce:

```
--- the main message start
(
 ("From", "Somebody <someuser@somehost>",
      "Mime-Version", "1.0", "Content-Type",
      "multipart/mixed",
      "boundary", "--the boundary",
      "To", "self@localhost"),          --- main attributes
 (n1, n2, 0, (mg1, mg2)),               --- main message body
                                            ("This is a multipart MIME message")
 (                                      --- Sub-parts array start
  (                                     --- Sub-Part 1
   ("Content-Type", "image/gif",
        "filename",
        "the_big_picture.gif"),         --- Attributes
   (s2, e2, 0, 0),                      --- body
   0                                    --- no sub parts of the GIF
  ),
  (                                     --- Sub-Part 2

where the n1, n2, mg1, mg2, s2, e2, s3, e3, ss1, se1, g2, ge2, ss2, se2, ss3, se3, s4, e4, g1, ge1 are offsets, denoting starts and ends of the appropriate pieces within the source message, which can be used by the subseq function:

```
subseq (the_text, g1, ge1) returns the string "Some additional garbage"
```

minute

minute — get minute from a datetime

Synopsis

minute (in *dt* datetime) ;

Description

minute takes a datetime and returns an integer containing a number representing the minute of the datetime.

Parameters

dt
: A datetime .

Return Values

An INTEGER containing the minute.

Examples

Example 24.219. Simple example

Get current minute.

```
SQL> select minute (now ());
callret
INTEGER
_______________________________________________________________________________

58
```

See Also

dayname , dayofmonth , dayofweek , dayofyear , quarter , week , month , year , hour , second , timezone

mod

mod — returns the modulus of its arguments

Synopsis

mod (*dividend* integer ,
divisor integer) ;

Description

mod returns the modulus (i.e. remainder) of the division dividend/divisor. If the divisor is zero the SQL error 22012 "Division by zero" is generated.

```
mod(35,3)                       -> 2
mod(35,-3)                      -> 2
mod(-35,3)                      -> -2
mod(-35,-3)                     -> -2
mod(3,35)                       -> 3
mod(0,7)                        -> 0
mod(60,3)                       -> 0
```

month

month — get number of month from a datetime

Synopsis

month (in *dt* datetime);

Description

month takes a datetime and returns an integer containing a number representing the month of year of the datetime.

Parameters

dt
: A datetime .

Return Values

An INTEGER containing number of the month of year.

Examples

Example 24.220. Simple example

Get current month of year.

```
SQL> select month (now ());
callret
INTEGER
_______________________________________________________________________________

10
```

See Also

dayname , monthname , dayofmonth , dayofweek , dayofyear , quarter , week , year , hour , minute , second , timezone

monthname

monthname — get name of month from a datetime

Synopsis

monthname (in *dt* datetime);

Description

monthname takes a datetime and returns a string containing name of the month represented by the datetime

Parameters

dt
: A datetime .

Return Values

A VARCHAR containing name of the month.

Examples

Example 24.221. Simple example

Get name of current month.

```
SQL> select monthname(now());
callret
VARCHAR
_______________________________________________________________________________

October
```

See Also

dayname , dayofmonth , dayofmonth , dayofweek , dayofyear , quarter , week , month , year , hour , minute , second , timezone

msec_time

msec_time — Get number of milliseconds from system epoch

Synopsis

msec_time (void);

Description

msec_time returns the number of milliseconds since system epoch. It is useful for benchmarking purposes, timing operations, etc.

Parameters

No parameters
: The function does not take parameters.

Return Values

A 32-bit integer no. of milliseconds since system epoch.

Examples

Example 24.222. Simple example

Time a function

```
create procedure
fib (in n integer)
{
  if (n <= 2) return 1;
  return fib (n - 1) + fib (n - 2);
}
;

create procedure
time_fib (in n integer)
{
  declare t,i integer;
  declare msg varchar;

  result_names (msg);

  t := msec_time();
  i := fib (n);
  result (sprintf ('fib (%d) is %d, got it in %d milliseconds.',
                   n, i, msec_time() - t));
}
;

SQL> time_fib(10);
msg
VARCHAR NOT NULL
_______________________________________________________________________________

fib (10) is 55, got it in 10 milliseconds.

1 Rows. -- 21 msec.
```

now

mts_connect

mts_connect — connects Virtuoso server to MS DTC.

Synopsis

mts_connect (in *reconnect* integer) ;

Description

If reconnect flag is set to non-zero value then forces Virtuoso to connect even it have been connected already. Returns zero if succeeds. If MS DTC service is not available (W2K) or MTS is not running (NT4.0) signals error with code "MX000".

mts_get_timeout

mts_get_timeout — returns timeout of distributed transaction in milliseconds.

Synopsis

```
mts_get_timeout (   );
```

Description

If reconnect flag is set to non-zero value then forces Virtuoso to connect even it have been connected already. Returns zero if succeeds. If MS DTC service is not available (W2K) or MTS is not running (NT4.0) signals error with code "MX000".

mts_set_timeout

mts_set_timeout — sets timeout of distributed transaction.

Synopsis

mts_set_timeout (in *timeout* integer) ;

Description

sets distributed transactions timeout. 'timeout' parameter indicates amount of timeout in milliseconds. If it equals -1 then default timeout of Virtuoso transaction is used (SQL_QUERY_TIMEOUT). This function must be called directly after "SET MTS_2PC=1". The time countdown begins at moment of changing first branch.

mts_status

mts_status — checks status of current transaction or server.

Synopsis

mts_status (in *subject* varchar) ;

Description

Checks status of subject. Subject can be either 'MTS' or 'TRANSACTION'. In the first case this checks if the server is connected to MTS. In the second case, checks if 2pc control is enabled for the current transaction. This function returns status string. For 'MTS' it could be either 'connected' or 'disconnected'. For 'TRANSACTION' - either '2pc enabled' or '2pc disabled'.

sha1_digest

sha1_digest — returns string containing sha1 digest encoded in base64

Synopsis

sha1_digest (in *str* varchar);

Description

Returns string containing sha1 digest encoded in base64. This function has an alias: xenc_sha1_digest ().

Parameters

str
: A varchar value.

Return Values

`sha1_digest` returns a varchar containing sha1 digest encoded in base64.

Examples

Example 24.223. Simple Example

Base64-encode a string

```
SQL> select sha1_digest('demodemo');
callret
VARCHAR
_______________________________________________________________________________

WGPZ5MvfUi6qYuB0f86xxbJJuhM=

1 Rows. -- 25 msec.
```

See Also

`encode_base64`

`md5`

`serialize`

name_part

name_part — Returns portion of dotted name such as a fully qualified table name.

Synopsis

```
varchar name_part ( in string varchar ,
                    in idx integer ,
                    in dstring varchar ) ;
```

Description

The `name_part()` can be used to dissecting parts of a three part names (string where items are divided by dots ".") such as table names or columns names. The table name "DB"."DBA"."SYS_USERS" contains three parts which can be extracted individually using this function providing the correct index from a 0 base: 0 would return "DB", 1 would return "DBA", 2 would return "SYS_USERS".

Parameters

string
: The string to be disected.

idx
: The part index starting from 0.

dstring
: The default value if the found value is null.

Return Types

A string will be returned containing the text from the specified index.

Errors

Table 24.56. Errors signalled by

SQLState	Error Code	Error Text	Description
22023	SR014	Function name_part needs a string as argument 1, not an arg of type [type]	
22023	SR008	Function name_part needs an integer as argument 2, not an arg of type [type]	

Examples

Example 24.224. Using the name_part() function

This simple example shows the 3 parts of a table name being retrieved using the name_part() function from ISQL.

```
SQL> select name_part('"DB"."DBA"."SYS_TABLES"', 0);
callret
VARCHAR
_______________________________________________________________

"DB"

1 Rows. -- 20 msec.
SQL> select name_part('"DB"."DBA"."SYS_TABLES"', 1);
callret

_______________________________________________________________
```

```
"DBA"

1 Rows. -- 30 msec.
SQL> select name_part('"DB"."DBA"."SYS_TABLES"', 2);
callret
VARCHAR
_______________________________________________________________

SYS_TABLES"

1 Rows. -- 20 msec.
```

nntp_auth_get

nntp_auth_get — returns information about an NNTP server with authorization

Synopsis

```
array nntp_auth_get ( in server varchar ,
                      in user varchar ,
                      in password varchar ,
                      in command varchar ,
                      in group varchar ,
                      in first_message integer ,
                      in last_message integer ) ;
```

Description

The `nntp_auth_get()` is used to retrieve messages from a server requiring authorization. See nntp_get for more information.

Parameters

server
: The host to connect with. IP address or hostname:port. There is no default for port, so to connect to the standard port for NNTP, use <hostname/IP address>:119

user
: The username.

password
: The user password.

command
: Command string . Valid values are:

group
: A string containing name of the news group.

Return Types

A vector of vectors the content depends of command.

Errors

Table 24.57. Errors signalled by nntp_auth_get

SQLState	Error Code	Error Text	Description
22023	NN008	the command is not recognized	
2E000	NN002	Invalid address for News Server at [host]	
08001	NN003	Unable to Contact News Server at [host]	
08006	NN004	Lost connection with NNTP server	
08006	NN008	Misc. error in connection in nntp_auth_get	

nntp_auth_post

nntp_auth_post — Post message to NNTP server with authorization

Synopsis

```
array nntp_auth_post ( in server varchar ,
                       in user varchar ,
                       in password varchar ,
                       in body varchar ) ;
```

Description

`Nntp_auth_post` is used to post a message to the server require authorization.

Parameters

server
: The host to connect with. IP address or hostname:port. There is no default for port, so to connect to the standard port for NNTP, use <hostname/IP address>:119

user
: The username.

password
: The user password.

body
: The body string The structure of the message must comply with RFC 850 (Standard for Interchange of USENET Messages).

Return Types

1 on success or error

Errors

Table 24.58. Errors signalled by

SQLState	Error Code	Error Text	Description
2E000	NN015	Invalid address for News Server at [host]	
08001	NN016	Unable to Contact News Server at [host]	
08006	NN017	Misc. error in connection in nntp_auth_post	

nntp_get

nntp_get — Returns information about an NNTP server.

Synopsis

```
array nntp_get ( in server varchar ,
                 in command varchar ,
                 in group varchar ,
                 in first_message integer ,
                 in last_message integer ) ;
```

Description

`nntp_get()` is used to retrieve messages from a server running the Network News Transfer Protocol (NNTP) as defined in RFC977 . It returns an array whose structure depends on the *command* parameter, thus:

list : an array of vectors, each of which contain the name of the news group, the first message number, the last message number, and a single character 'y' or 'n' as a flag for posting.

group : a vector of three elements: total number of messages in the group, the number of the first message, and the number of the last message.

stat : an array of vectors, each of which contains the number of the message and the message id.

article, body, head : an array of vectors each containing the message number and the requested part of the message.

Parameters

server
: The IP address or <hostname:port> of the host with which to connect. There is no default for port , so to connect to the standard port for NNTP, use <hostname/IP address>:119.

command
: Command string . Valid values are:

group
: A string containing the name of the newsgroup.

Return Types

A vector of vectors the content of which depends on the *command* parameter.

Errors

Table 24.59. Errors signalled by

SQLState	Error Code	Error Text
22023	NN006	the command is not recognized
22023	NN001	Large ID in nntp_id_get
2E000	NN002	Invalid address for News Server at [host]
08001	NN003	Unable to Contact News Server at [host]
08006	NN004	Lost connection with NNTP server
08006	NN005	Misc. error in connection in nntp_get

Examples

Example 24.225. Get remote messages

This example retrieves messages from a remote NNTP server and stores them in a table.

```
create table my_news (m_id integer, m_group varchar, m_text long varchar,
  primary key (m_id, m_group));

create procedure get_my_news (in server varchar, in grp varchar)
{
   declare res, ent any;
   declare i, l integer;
   res := nntp_get (server, 'article', grp, 0, 1000);
   i := 0; l := length (res);
   while (i < l)
         {
     ent := res [i];
           insert replacing my_news (m_id, m_group, m_text)
       values (ent[0], grp, ent[1]);
     i := i + 1;
         }
}
```

Here is a test run. We extract the article subject with the `mail_header()` function.

```
SQL> get_my_news ('news.techno-link.com:119', 'comp.lang.java.api');

SQL> select m_id, mail_header (m_text, 'Subject') from my_news;
m_id              callret
INTEGER NOT NULL  VARCHAR

nntp_post

nntp_post — Post message to NNTP server

Synopsis

```
array nntp_post ( in server varchar ,
                  in body varchar ) ;
```

Description

`Nntp_post` is used to post a message to the server running the Network News Transfer Protocol as defined in the rfc977.

Parameters

server
: The host to connect with. IP address or hostname:port. There is no default for port, so to connect to the standard port for NNTP, use <hostname/IP address>:119

body
: The body string The structure of the message must comply with RFC 850 (Standard for Interchange of USENET Messages).

Return Types

1 on success or error

Errors

SQLState	Error Code	Error Text
2E000	NN011	Invalid address for News Server at [host]
08001	NN012	Unable to Contact News Server at [host]
08006	NN013	Misc. error in connection in nntp_post

Examples

Example 24.226. Post message to remote NNTP

This example post message to a remote NNTP server.

```
SQL> set MACRO_SUBSTITUTION off;
SQL> select nntp_post ('news.openlinksw.co.uk:119',
  'From: "Demo User" user@demo.com\r\nSubject: Test Virtuoso nntp_post function\r\nNewsgroups: openlink.p
callret
VARCHAR
_______________________________________________________________________________

1

1 Rows. -- 782 msec.
SQL>
```

now

now — returns the current transaction timestamp

Synopsis

```
now (   );
```

Description

Now returns the timestamp associated with current transaction as a DATETIME . This value is guaranteed to differ from the timestamp of any other transaction.

Examples

Example 24.227. Get a timestamp

Get a timestamp in human-readable form.

```
SQL> select datestring(now()), cast (now() as VARCHAR);
callret                  callret
VARCHAR                  VARCHAR
_______________________________________________________________________________

2001-10-08 16:31:49.000000  2001-10-08 16:31:49.000000

1 Rows. -- 99 msec.
```

Example 24.228. Table example

Store update time in a column

```
SQL> update test_table set TIME_CHANGED = now();

Done. -- 37 msec.
SQL> select cast (TIME_CHANGED as VARCHAR) from test_table;
callret
VARCHAR
_______________________________________________________________________________

2001-10-08 16:34:28.000000

1 Rows. -- 3 msec.
```

Parameters

`now` has no parameters.

Return Types

A DATETIME timestamp.

Errors

`now` does not return errors.

`datestring()` , casting , `curdate()` , `curdatetime()` , `curtime()`

DB.DBA.AMAZON_START_INSTANCE

DB.DBA.AMAZON_START_INSTANCE — Starts an existing AMI instance that user has previously stopped.

Synopsis

DB.DBA.AMAZON_START_INSTANCE (in *aws_access_key* varchar ,
in *instance_id* varchar ,
in *secret_key* varchar ,
in *http_proxy* varchar (default null)) ;

Description

Starts an existing AMI that user has previously stopped.

Parameters

aws_access_key
: Amazon Access Key ID.

instance_id
: Image instance ID (check Amazon list of instances).

secret_key
: AWS Security Token.

http_proxy
: Proxy server, can be null or empty.

Examples

Example 24.229. Simple Use

```
create procedure simple_test()
{
  declare access_key, sec_token, p_name varchar;

  access_key := 'AKIAJI7ZL427TI5EDF5A'; -- amazon manager site access key
  sec_token  := 'CGI/UMaXf2LRUctaj/HGJ57UNy/t7fNCshh8wpJg'; -- amazon manager site secret token
  p_name     := 'my_instance_of_linux';

  DB.DBA.AMAZON_START_INSTANCE (access_key, p_name, sec_token);

}
;
```

DB.DBA.AMAZON_RUN_INSTANCE

DB.DBA.AMAZON_RUN_INSTANCE — Runs new AMI instance of image.

Synopsis

DB.DBA.AMAZON_RUN_INSTANCE (
in *aws_access_key* varchar ,
in *image_id* varchar ,
in *secret_key* varchar ,
in *key_name* varchar ,
in *MinCount* integer (default 1) ,
in *MaxCount* integer (default 1) ,
in *http_proxy* varchar (default null)) ;

Description

Runs new AMI instance of image.

Parameters

aws_access_key
: Amazon Access Key ID.

image_id
: The Image ID of the AMI.

secret_key
: AWS Security Token.

key_name
: Name of public key to use (can be used for Linux images). Can be empty or null.

MinCount
: The minimum number of instances to launch. If the value is more than Amazon EC2 can launch, no instances are launched at all. Default is 1.

MaxCount
: The maximum number of instances to launch. If the value is more than Amazon EC2 can launch, the largest possible number above MinCount will be launched instead. Default is 1.

http_proxy
: Proxy server, can be null or empty.

Examples

Example 24.230. Simple Use

```
create procedure simple_test()
{
  declare access_key, sec_token, key_name, p_name varchar;

  access_key := 'AKIAJI7ZL427TI5EDF5A'; -- amazon manager site access key
  sec_token  := 'CGI/UMaXf2LRUctaj/HGJ57UNy/t7fNCshh8wpJg'; -- amazon manager site secret token
  key_name   := 'my_key';
  p_name     := 'my_instance_of_linux';

  DB.DBA.AMAZON_RUN_INSTANCE (access_key, p_name, sec_token, key_name);

}
```

```
;

DB.DBA.AMAZON_STOP_INSTANCE

DB.DBA.AMAZON_STOP_INSTANCE — Stops an existing AMI instance.

Synopsis

DB.DBA.AMAZON_STOP_INSTANCE (in *aws_access_key* varchar ,
in *instance_id* varchar ,
in *secret_key* varchar ,
in *http_proxy* varchar (default null)) ;

Description

Stops an existing AMI instance. Each time user performs transition an instance from stopped to started, OpenLink charges a full instance hour, even if transitions happen multiple times within a single hour.

Parameters

aws_access_key
: Amazon Access Key ID.

instance_id
: Image instance ID (check Amazon list of instances).

secret_key
: AWS Security Token.

http_proxy
: Proxy server, can be null or empty.

Examples

Example 24.231. Simple Use

```
create procedure simple_test()
{
  declare access_key, sec_token, p_name varchar;

DB.DBA.AMAZON_TERMINATE_INSTANCE

DB.DBA.AMAZON_TERMINATE_INSTANCE — Terminates (shuts down) an already created AMI instance.

Synopsis

DB.DBA.AMAZON_TERMINATE_INSTANCE (in *aws_access_key* varchar ,
in *instance_id* varchar ,
in *secret_key* varchar ,
in *http_proxy* varchar (default null)) ;

Description

Terminates (shuts down) an already created instance. This operation is idempotent; if you terminate an instance more than once, each call will succeed.

Parameters

aws_access_key
: Amazon Access Key ID.

instance_id
: Image instance ID (check Amazon list of instances).

secret_key
: AWS Security Token.

http_proxy
: Proxy server, can be null or empty.

Examples

Example 24.232. Simple Use

```
create procedure simple_test()
{
  declare access_key, sec_token, p_name varchar;

  access_key := 'AKIAJI7ZL427TI5EDF5A'; -- amazon manager site access key
  sec_token  := 'CGI/UMaXf2LRUctaj/HGJ57UNy/t7fNCshh8wpJg'; -- amazon manager site secret token
  p_name     := 'my_instance_of_linux';

  DB.DBA.AMAZON_TERMINATE_INSTANCE (access_key, p_name, sec_token);

}
;
```

DB.DBA.AMAZON_CREATE_VOLUME

DB.DBA.AMAZON_CREATE_VOLUME — Creates an Amazon EBS volume that can be attached to any Amazon EC2 instance in the same Availability Zone.

Synopsis

DB.DBA.AMAZON_CREATE_VOLUME (in *aws_access_key* varchar ,
in *availabilityZone* varchar ,
in *secret_key* varchar ,
in *snapshotId* varchar (default '') ,
in *volume_size* integer (default 1) ,
in *http_proxy* varchar (default null)) ;

Description

Creates an Amazon EBS volume that can be attached to any Amazon EC2 instance in the same Availability Zone. Any AWS Marketplace product codes from the snapshot are propagated to the volume.

Parameters

aws_access_key
: Amazon Access Key ID.

availabilityZone
: The Availability Zone for the new volume.

secret_key
: AWS Security Token.

snapshotId
: The snapshot from which to create the new volume.

volume_size
: The size of the volume, in GiBs.

http_proxy
: Proxy server, can be null or empty.

Examples

Example 24.233. Simple Use

```
create procedure simple_test()
{
  declare access_key, sec_token, zone varchar;

  access_key := 'AKIAJI7ZL427TI5EDF5A'; -- amazon manager site access key
  sec_token  := 'CGI/UMaXf2LRUctaj/HGJ57UNy/t7fNCshh8wpJg'; -- amazon manager site secret token
  zone       := 'us-east-1a';

  DB.DBA.AMAZON_CREATE_VOLUME (access_key, zone, sec_token);

}
;

DB.DBA.AMAZON_DEREGISTER_IMAGE

DB.DBA.AMAZON_DEREGISTER_IMAGE — Deregisters the specified AMI.

Synopsis

DB.DBA.AMAZON_DEREGISTER_IMAGE (in *aws_access_key* varchar ,
in *image_id* varchar ,
in *secret_key* varchar ,
in *http_proxy* varchar (default null)) ;

Description

Deregisters the specified AMI. Once deregistered, the AMI cannot be used to launch new instances.

Parameters

aws_access_key
: Amazon Access Key ID.

image_id
: Image ID (check Amazon list of images).

secret_key
: AWS Security Token.

http_proxy
: Proxy server, can be null or empty.

Examples

Example 24.234. Simple Use

```
create procedure simple_test()
{
  declare access_key, sec_token, image_id varchar;

  access_key := 'AKIAJI7ZL427TI5EDF5A'; -- amazon manager site access key
  sec_token  := 'CGI/UMaXf2LRUctaj/HGJ57UNy/t7fNCshh8wpJg'; -- amazon manager site secret token
  image_id   := 'my_new_image';

 DB.DBA.AMAZON_DEREGISTER_IMAGE (access_key, image_id, sec_token);

}
;
```

DB.DBA.AMAZON_CREATE_IMAGE

DB.DBA.AMAZON_CREATE_IMAGE — Creates an Amazon EBS-backed AMI from an Amazon EBS-backed instance that is either running or stopped.

Synopsis

DB.DBA.AMAZON_CREATE_IMAGE (in *aws_access_key* varchar ,
in *instance_id* varchar ,
in *image_name* varchar ,
in *secret_key* varchar ,
in *http_proxy* varchar (default null)) ;

Description

Creates an Amazon EBS-backed AMI from an Amazon EBS-backed instance that is either running or stopped.

Parameters

aws_access_key
: Amazon Access Key ID.

instance_id
: Image instance ID (check Amazon list of instances).

image_name
: New image ID (check Amazon list of images).

secret_key
: AWS Security Token.

http_proxy
: Proxy server, can be null or empty.

Examples

Example 24.235. Simple Use

```
create procedure simple_test()
{
  declare access_key, sec_token, p_name, image_id varchar;

  access_key := 'AKIAJI7ZL427TI5EDF5A'; -- amazon manager site access key
  sec_token  := 'CGI/UMaXf2LRUctaj/HGJ57UNy/t7fNCshh8wpJg'; -- amazon manager site secret token
  image_id   := 'my_new_image';
  p_name     := 'my_instance_of_linux';

  DB.DBA.AMAZON_CREATE_IMAGE (access_key, p_name, image_id, sec_token);

}
;

DB.DBA.AMAZON_CREATE_SNAPSHOT

DB.DBA.AMAZON_CREATE_SNAPSHOT — Creates a snapshot of an Amazon EBS volume and stores it in Amazon S3.

Synopsis

DB.DBA.AMAZON_CREATE_SNAPSHOT (in *aws_access_key* varchar ,
in *volumeId* varchar ,
in *secret_key* varchar ,
in *description* varchar (default 'new+snapshot') ,
in *http_proxy* varchar (default null)) ;

Description

Creates a snapshot of an Amazon EBS volume and stores it in Amazon S3. You can use snapshots for backups, to make copies of instance store volumes, and to save data before shutting down an instance.

Parameters

aws_access_key
: Amazon Access Key ID.

volumeId
: The ID of the Amazon EBS volume.

secret_key
: AWS Security Token.

description
: A description for the snapshot.

http_proxy
: Proxy server, can be null or empty.

Examples

Example 24.236. Simple Use

```
create procedure simple_test()
{
  declare access_key, sec_token, vol_id varchar;

  access_key := 'AKIAJI7ZL427TI5EDF5A'; -- amazon manager site access key
  sec_token  := 'CGI/UMaXf2LRUctaj/HGJ57UNy/t7fNCshh8wpJg'; -- amazon manager site secret token
  vol_id     := 'vol-1a2b3c4d';

  DB.DBA.AMAZON_CREATE_SNAPSHOT (access_key, vol_id, sec_token);

}
;
```

DB.DBA.AMAZON_DELETE_SNAPSHOT

DB.DBA.AMAZON_DELETE_SNAPSHOT — Deletes a snapshot of an Amazon EBS volume.

Synopsis

DB.DBA.AMAZON_DELETE_SNAPSHOT (in *aws_access_key* varchar ,
in *snapshotId* varchar ,
in *secret_key* varchar ,
in *http_proxy* varchar (default null)) ;

Description

Deletes a snapshot of an Amazon EBS volume.

Parameters

aws_access_key
: Amazon Access Key ID.

snapshotId
: The ID of the Amazon EBS snapshot.

secret_key
: AWS Security Token.

http_proxy
: Proxy server, can be null or empty.

Examples

Example 24.237. Simple Use

```
create procedure simple_test()
{
  declare access_key, sec_token, snapshotId varchar;

  access_key := 'AKIAJI7ZL427TI5EDF5A'; -- amazon manager site access key
  sec_token  := 'CGI/UMaXf2LRUctaj/HGJ57UNy/t7fNCshh8wpJg'; -- amazon manager site secret token
  snapshotId := 'snap-1a2b3c4d';

  DB.DBA.AMAZON_DELETE_SNAPSHOT (access_key, snapshotId, sec_token);

}
;

DB.DBA.AMAZON_DELETE_VOLUME

DB.DBA.AMAZON_DELETE_VOLUME — Deletes an Amazon EBS volume.

Synopsis

DB.DBA.AMAZON_DELETE_VOLUME (in *aws_access_key* varchar ,
in *volumeId* varchar ,
in *secret_key* varchar ,
in *http_proxy* varchar (default null)) ;

Description

Deletes an Amazon EBS volume. The volume must be in the available state (not attached to an instance).

Parameters

aws_access_key
: Amazon Access Key ID.

volumeId
: The ID of the Amazon EBS volume.

secret_key
: AWS Security Token.

http_proxy
: Proxy server, can be null or empty.

Examples

Example 24.238. Simple Use

```
create procedure simple_test()
{
  declare access_key, sec_token, vol_id varchar;

  access_key := 'AKIAJI7ZL427TI5EDF5A'; -- amazon manager site access key
  sec_token  := 'CGI/UMaXf2LRUctaj/HGJ57UNy/t7fNCshh8wpJg'; -- amazon manager site secret token
  vol_id     := 'vol-1a2b3c4d';

DB.DBA.AMAZON_DESCRIBE_IMAGES

DB.DBA.AMAZON_DESCRIBE_IMAGES — Describes one or more of the images (AMIs, AKIs, and ARIs) available to you.

Synopsis

DB.DBA.AMAZON_DESCRIBE_IMAGES (in *aws_access_key* varchar ,
in *secret_key* varchar ,
in *http_proxy* varchar (default null)) ;

Description

Describes one or more of the images (AMIs, AKIs, and ARIs) available to you. Images available to you include: public images, private images that you own, and private images owned by other AWS accounts but for which you have explicit launch permissions.

Parameters

aws_access_key
: Amazon Access Key ID.

secret_key
: AWS Security Token.

http_proxy
: Proxy server, can be null or empty.

Examples

Example 24.239. Simple Use

```
create procedure simple_test()
{
  declare access_key, sec_token varchar;
  declare images, image_item any;

  access_key := 'AKIAJI7ZL427TI5EDF5A'; -- amazon manager site access key
  sec_token  := 'CGI/UMaXf2LRUctaj/HGJ57UNy/t7fNCshh8wpJg'; -- amazon manager site secret token
  images     := xtree_doc (DB.DBA.AMAZON_DESCRIBE_IMAGES (access_key, sec_token));
  image_item := xpath_eval('/DescribeImagesResponse/imagesSet/item', images, 0);

}
;
```

DB.DBA.AMAZON_IMPORT_KEY_PAIR

DB.DBA.AMAZON_IMPORT_KEY_PAIR — Uploads public key to Amazon.

Synopsis

DB.DBA.AMAZON_IMPORT_KEY_PAIR (in *aws_access_key* varchar ,
in *key_name* varchar ,
in *public_key_material* varchar ,
in *secret_key* varchar ,
in *http_proxy* varchar (default null)) ;

Description

Uploads public key to Amazon

Parameters

aws_access_key
: Amazon Access Key ID.

key_name
: New name of key, which will be used on Amazon lists.

public_key_material
: base64 encoded public key.

secret_key
: AWS Security Token.

http_proxy
: Proxy server, can be null or empty.

Examples

Example 24.241. Simple Use

```
create procedure simple_test()
{
  declare access_key, sec_token, key_name varchar;
  declare pub_key, fingers, fingerPrint any ;

  access_key  := 'AKIAJI7ZL427TI5EDF5A'; -- amazon manager site access key
  ec_token    := 'CGI/UMaXf2LRUctaj/HGJ57UNy/t7fNCshh8wpJg'; -- amazon manager site secret token
  key_name    := 'my_key';
  pub_key     := encode_base64 (cast (xenc_pubkey_DER_export (key_name) as varchar));
  pub_key     := encode_base64(pub_key);
  fingers     := xtree_doc(DB.DBA.AMAZON_IMPORT_KEY_PAIR (access_key, key_name,   pub_key, sec_token));
  fingerPrint := xpath_eval('/ImportKeyPairResponse/keyFingerprint', fingers, 0);

  if (fingerPrint is not null)
    return 1;
  else
    return 0;
}
;

os_chmod

os_chmod — changes the file access mode of a file

Synopsis

os_chmod (in *path* varchar ,
in *new_mod* integer) ;

Description

`os_chmod` set the file mode bits by calling the system function chmod() with the arguments supplied.

Not all the host OSes support all the file modes. That's why the function will not throw an SQL error if the function fails.

It will return DB NULL value when the function was called successfully and the error message as a string if it failed.

In most OSes the mode is a bitmask, so one would usually use the `file_stat` to get the current mode and `bit_or` /`bit_xor` to make the new mode.

Typical bit layout (from Linux 'man 2 chmod') is :

bit 0 (mask 1) - execute/search by others
bit 1 (mask 2) - write by others
bit 2 (mask 4) - read by others
bit 3 (mask 8) - execute/search by group
bit 4 (mask 16) - write by group
bit 5 (mask 32) - read by group
bit 6 (mask 64) - execute/search by owner
bit 7 (mask 128) - write by owner
bit 8 (mask 256) - read by owner
bit 9 (mask 512) - sticky bit
bit 10 (mask 1024) - set group ID on execution
bit 12 (mask 2048) - set user ID on execution

The DirsAllowed and DirsDenied lists in Parameters section of the virtuoso configuration file (virtuoso.ini by default) are used to control disk access.

Parameters

path
: varchar relative path.

new_mod
: integer new mode for the file.

Examples

Example 24.242. Simple example

Make the virtuoso INI file readable by the others

```
SQL>select os_chmod (virtuoso_ini_path(), bit_or (cast (file_stat (virtuoso_ini_path(), 2) as integer), 4
callret
VARCHAR
_______________________________________________________________________________
```

```
NULL
```

bit_or

bit_xor

os_chown

os_chown — changes the owning group/user of a file

Synopsis

os_chown (in *path* varchar ,
in *username* varchar ,
in *groupname* varchar) ;

Description

This function requires dba privileges.

os_chown set the owning user/group of an OS file by calling the system function chown() with the arguments supplied.

Not all the host OSes support the concept of owner users and groups. That's why the function will not throw an SQL error if it fails.

It will return DB NULL value when the function was executed successfully and the error message as a string if it failed.

The function first looks up the user and group name supplied into the OS database to get the user and group IDs. it then calls the system function chown().

The DirsAllowed and DirsDenied lists in Parameters section of the virtuoso configuration file (virtuoso.ini by default) are used to control disk access.

Parameters

path
: varchar relative path.

username
: varchar the name of the OS user to own the file.

groupname
: varchar the name of the OS group to own the file.

Examples

Example 24.243. Simple example

Sets the ownership of the virtuoso INI file to virtuoso user and group

```
SQL>select os_chown (virtuoso_ini_path(), 'virtuoso', 'virtuoso');
callret
VARCHAR
_______________________________________________________________________________

NULL
```

pem_certificates_to_array

pem_certificates_to_array — converts a PEM file to an array of PEM strings

Synopsis

pem_certificates_to_array (in *pem_string* varchar) ;

Description

This gets a PEM file with (possibly) many X509 certificates among others and constructs an array containing each X509 certificate as a separate PEM string. This can serve for splitting a PEM file containing multiple certificates (for example CA file) to single certificate entries so it can be examined with get_certificate_info function. Note that the array can contain NULL elements in places where in the PEM file there are blocks other than X509 PEM certificates.

Parameters

pem_string
: text of the PEM file

Return Types

Array of PEM strings

Errors

Table 24.61. Errors signalled by pem_certificates_to_array

SQLState	Error Code	Error Text	Description
42000	CR011	Can't allocate temp space. SSL error : <error text>	
42000	CR012	Can't read certificates. SSL error : <error text>

pldbg_stats

pldbg_stats — Makes an array of line/count information based on current coverage.

Synopsis

```
any pldbg_stats ( in name varchar ,
                  in add_line_info integer ) ;
```

Description

This function is used to make an array of line/count information based on the current coverage statistics. If the procedure `name` is given (first param), then the result will contain only coverage statistic for that procedure. if the procedure name is not supplied or supplied as NULL then the result will contain coverage data for all procedures having statistic. The `add_line_info` flag is used to add code excerpt on line info.

Parameters

name
: Optional name of procedure for producing selective information.

outdir
: Optional flag to control output existence. If this flag is set to 1 then code excerpts will be contained in the output.

Return Types

An array (or vector) is returned containing the line/count information of the selected coverage data. The format is as follows:

```
(
  ("PRODECURE_NAME" "file_name" <times executed> <total lines> ) -- procedure info
  ((<line no> <no executed> "<line excerpt>" ) .... )            -- line statistics
  (("CALLER PROCEDURE" <counts> ) .... )                         -- caller statistics
  ...
)
```

`cov_load()`

`cov_store()`

`cov_report()`

`pldbg_stats_load()`

pldbg_stats_load

pldbg_stats_load — Used to load a coverage of a single procedure record as an array.

Synopsis

pldbg_stats_load (in *info* any);

Description

This function is used to load coverage information for a single procedure record. The expected format is an array. The data expected is exactly that which can be produced by `pldbg_stats()` . Only one record will can be accepted, an array of several procedure records will not be acceptable.

Parameters

info
: An array with the following format:

Return Types

None.

See Also

`cov_load()`

`cov_store()`

`cov_report()`

`pldbg_stats()`

pop3_get

pop3_get — get messages from a POP3 server

Synopsis

```
array pop3_get ( in host varchar ,
                 in user varchar ,
                 in password varchar ,
                 in buffer_size integer ,
                 in command varchar ,
                 in exclude_uidl_list vector ) ;
```

Description

`Pop3_get` is used to retrieve and delete messages from a server running the Post Office Protocol version 3 as defined in rfc1725. In its default form it returns a vector of vectors containing messages retrieved from the POP3 server. Each vector within the vector contains a pair of VARCHAR UIDL and VARCHAR Message body, i.e. to get the message body of the second message retrieved, one would use `aref (aref (msg_vec, 1), 1)` . Total length of messages retrieved will not exceed the value of *`buffer_size`* parameter in bytes.

The optional parameter *`command`* can be used to control output or delete messages. When *`command`* is passed a VARCHAR 'uidl', `pop3_get` outputs single vector containing VARCHAR UIDLs. The *`buffer_size`* constraint is effective here. Thus, the vector will only contain UIDLs of messages whose total message text length does not exceed *`buffer_size`* bytes. These message lengths are accumulated in the order returned by the POP3 server.

Command 'delete' will cause retrieved messages to be deleted from the server after retrieval.

Parameters

host
: The host to connect with. IP address or hostname:port. There is no default for port, so to connect to the standard port for POP3, use <hostname/IP address>:110

user
: string user id in remote host.

password
: string password in remote host.

buffer_size
: integer maximum total length of message text for messages/uidls to be retrieved.

command
: Command string . Valid values are empty, 'uidl' or 'delete'

exclude_uidl_list
: A vector containing UIDLs. A message whose UIDL appears in this list will not be retrieved or deleted.

Return Types

A vector of vectors containing UIDL/Message text strings or a 'flat' vector containing UIDL strings .

Errors

Table 24.62. Errors signalled by

SQLState	Error Code	Error Text	Description
2E000	PO001	Cannot resolve host in pop3_get	
08001	PO002	Cannot connect in pop3_get	
08006	PO003	No response from remote POP3 server	
08006	PO004	Not valid user in remote POP3 server	
08006	PO005	UIDL command to remote POP3 server failed	
08006	PO006	Could not get output of UIDL from remote POP3 server.	
08006	PO007	LIST command to remote POP3 server failed.	
08006	PO008	Could not get output of LIST from remote POP3 server.	
	PO009		
08006	PO010	Failed reading output of LIST command on remote POP3 server	
08006	PO011	Could not DELE messages from remote POP3 server	
08006	PO012	Could not QUIT from remote POP3 server	
08000	PO013	Argument 6 to pop3_get must be a vector	
08006	PO014	Misc. error in connection in pop3_get	

Examples

Example 24.244. Get messages from remote POP3

This example retrieves messages from a remote POP3 server and stores them in a table.

```
create table MY_MSGS (MSG_ID INTEGER IDENTITY,
                      MSG_HOST VARCHAR,
                      MSG_UIDL VARCHAR,
                      MSG_TEXT LONG VARCHAR,
                      primary key (MSG_ID, MSG_HOST, MSG_UIDL));

create procedure
get_msgs (in pop_host varchar, in pop_uid varchar, in pop_pwd varchar)
{
  declare msg_vec any;
  declare inx integer;

  msg_vec := pop3_get (concat (pop_host, ':110'),
                               pop_uid,
                               pop_pwd,
                               10000000,
                               'delete');

  inx := 0;

  while (inx < length (msg_vec))
    {
      insert into MY_MSGS (MSG_HOST, MSG_UIDL, MSG_TEXT)
             values (pop_host,
                     aref (aref (msg_vec, inx), 0),
                     aref (aref (msg_vec, inx), 1));

      inx := inx + 1;
    }
}
```

Here is a test run. Just for the fun, let's get the message subjects, too.

```
SQL> get_msgs('pop.xs4all.nl', 'ghard', '|_337h4x0R');

SQL> select MSG_UIDL, length (MSG_TEXT), get_keyword ('Subject', aref (mime_tree (MSG_TEXT), 0)) from MY_
MSG_UIDL          callret   callret

imap_get

imap_get — get messages from a IMAP4 mail server.

Synopsis

```
array imap_get ( in host varchar ,
                 in user varchar ,
                 in password varchar ,
                 in command varchar ,
                 in folder_id varchar ,
                 in list vector ,
                 in use_ssl integer ) ;
```

Description

`imap_get` is used used to work with mail server running the IMAP4 version 4rev1 as defined in rfc3501.

Parameters

host
: The host to connect with. IP address or hostname:port. There is no default for port, so to connect to the standard port for IMAP, use <hostname/IP address>:143

user
: string user id in remote host.

password
: string password in remote host.

command
: Command string . Valid values are ' list ', 'delete ', 'create ', 'select ', 'expunge ', 'rename ', 'fetch ', ' message_delete ', ' message_copy '.

folder_id
: IMAP4 mail box ID (e.g. 'INBOX', 'Draft' and etc) to work with.

list
: A list of items to work with, depends on the command.

use_ssl
: Use SSL connection, 1 - use, 0 - do not use.

Return Types

Depends on the command value:

- *list* : - list of mail boxes in selected mail box (needs folder_id, if folder_id = '' work with root of mail account). list - empty vector.

  Returns: A vector of strings containing name attributes, hierarchy delimiter, name of mailbox or empty vector.

  See more specification details .

  Example

```
SQL> select imap_get ('imap.gmail.com:993','ods.check','openlink','list','INBOX', vector (), 1);
```

```
imap_get
VARCHAR
_______________________________________________________________________________

vector(0x00491f08)

1 Rows. -- 2090 msec.

SQL> select imap_get ('imap.gmail.com:993','ods.check','openlink','list','INBOX', vector (), 1)[0]
aref
VARCHAR
_______________________________________________________________________________

(\HasNoChildren) "/" "INBOX"

1 Rows. -- 1997 msec.
```

- *delete* : deletes the selected mail box (needs folder_id). list - empty vector.

  Returns: Empty vector.

  See more specification details .

  Example

```
SQL> select imap_get ('imap.gmail.com:993','ods.check','openlink','delete','SomeBox', vector (), 1
imap_get
VARCHAR
_______________________________________________________________________________

vector()

1 Rows. -- 2090 msec.
```

- *create* : creates a new mail box in the selected mail box (needs folder_id). list - empty vector.

  Returns: Empty vector.

  See more specification details .

  Example

```
SQL> select imap_get ('imap.gmail.com:993','ods.check','openlink','create','INBOX/SomeBox', vector
imap_get
VARCHAR
_______________________________________________________________________________

vector()

1 Rows. -- 2090 msec.
```

- *select* : lists all messages in the selected mail box (needs folder_id). list - empty vector.

  This command gets the header fields of messages:

```
UID FLAGS INTERNALDATE RFC822.SIZE BODY.PEEK[HEADER.FIELDS (DATE FROM SUBJECT TO CC MESSAGE-ID REF
```

  Returns: A vector of vectors containing: UID, header fields and data separated by ' ', Data of BODY.PEEK information (the last requested parameter - BODY.PEEK[HEADER.FIELDS (DATE FROM SUBJECT TO CC MESSAGE-ID REFERENCES CONTENT-TYPE CONTENT-DESCRIPTION IN-REPLY-TO REPLY-TO LINES LIST-POST X-LABEL)]).

  Example

```
SQL> select imap_get ('imap.gmail.com:993','ods.check','openlink','select', 'INBOX', vector (), 1)
imap_get
VARCHAR
_______________________________________________________________________________

vector(0x004435a0)
```

```
1 Rows. -- 2293 msec.
SQL> select imap_get ('imap.gmail.com:993','ods.check','openlink','select', 'INBOX', vector (), 1)
aref
VARCHAR
_______________________________________________________________________________

vector(139,0x00443d50,0x00494758)

1 Rows. -- 2293 msec.
SQL> select imap_get ('imap.gmail.com:993','ods.check','openlink','select', 'INBOX', vector (), 1)
aref
VARCHAR
_______________________________________________________________________________

RFC822.SIZE 89126 INTERNALDATE "09-Nov-2011 22:47:59 +0000" FLAGS (NonJunk \Seen) BODY[HEADER.FIEL

1 Rows. -- 2230 msec.
SQL> select imap_get ('imap.gmail.com:993','ods.check','openlink','select', 'INBOX', vector (), 1)
aref
VARCHAR
_______________________________________________________________________________

Message-ID: <4EBB0319.1050200@openlinksw.com>

To: "ods.check@gmail.com" <ods.check@gmail.com>
Subject: test from OL account with attached image
Content-Type: multipart/signed; protocol="application/pkcs7-signature"; micalg=sha1; boundary="---

1 Rows. -- 2200 msec.
```

- *expunge* : expunges (deletes messages marked for deletion) the selected mail box (needs folder_id). list - empty vector.

  Returns: An empty vector.

  Example

```
SQL> select imap_get ('imap.gmail.com:993','ods.check','openlink','expunge', 'INBOX', vector (), 1
imap_get
VARCHAR
_______________________________________________________________________________

vector()

1 Rows. -- 3541 msec.
```

- *rename* : renames selected mail box. folder_id is not used, folder_id = ''. list - vector of 2 names: old and new.

  Returns: Empty vector.

  See more specification details .

  Example

```
SQL> select imap_get ('imap.gmail.com:993','ods.check','openlink','rename', '', vector ('Travel',
imap_get
VARCHAR
_______________________________________________________________________________

vector()

1 Rows. -- 2013 msec.
```

- *fetch* : fetches messages from the selected mail box (needs folder_id). folder_id is id of selected mail box, list - vector of UIDs of messages.

  Returns: A vector of vectors containing: UID and data of BODY.PEEK[] information (full message data).

  Example Get the list and UIDs of messages:

```
SQL> select imap_get ('imap.gmail.com:993','ods.check','openlink','select', 'INBOX', vector (), 1)
aref
VARCHAR
_______________________________________________________________________________

vector(139,0x00443d50,0x00494758)

1 Rows. -- 2215 msec.
```

Then get full data of message by its mail box id and UID:

```
SQL> select imap_get ('imap.gmail.com:993','ods.check','openlink','fetch', 'INBOX', vector (139),
imap_get
VARCHAR
_______________________________________________________________________________

vector(0x00442410)

1 Rows. -- 3807 msec.

SQL> select imap_get ('imap.gmail.com:993','ods.check','openlink','fetch', 'INBOX', vector (139),
aref
VARCHAR

RFC3501

position

position — returns the index of an element within an array or string

Synopsis

position (*element* any ,
array any ,
start_index integer (optional, default 1) ,
step integer (optional, default 1)) ;

Description

position returns the one-based index for the first occurrence of element within an array or string , beginning from offset start_index and iterating with step. If the second argument is a string , the first argument must be a string with a single character. If the second argument is an array of any , then depending of type of it's elements same type is expected as the first argument.

Parameters

element
: any , depends of type of elements in second argument .

array
: array , vector or string .

start_index
: integer index beginning from 1; from where to start search.

step
: integer the step between elements to be tested; default is 1 (every element)

Return Values

An integer index in array starting from 1; if not found returns zero.

Errors

Table 24.72. Errors signalled by position

SQLState	Error Code	Error Text	Description
22003	SR061	position: expects a vector whose length is divisible by [step], not of length [actual len].	
22023	SR000	position expects an array or vector, not an arg of type %d.	

Examples

Example 24.245. Simple examples

```
SQL> select position ('b', 'Abacus');
callret

vector aset aref ascii

power

power — return value of expression raised to specified power.

Synopsis

power (in *x* double precision ,
in *y* double precision) ;

Description

`power` raises x to the yth power and returns the value as a IEEE 64-bit float.

Parameters

x
: double precision

y
: double precision

Return Values

`power` returns a IEEE 64-bit float.

Examples

Example 24.246. Stored Procedure Example

Calculate squares of integers between 2 numbers.

```
SQL> create procedure
calc_pow2s (in _from integer, in _to integer)
{
  declare i integer;
  declare result double precision;

  result_names (i, result);

  i := _from;
  while (i < _to)
   {
     result (i, power (i, 2));
     i := i + 1;
   }
}
;
Done. -- 5 msec.
SQL> calc_pow2s (1, 10);
i                 result

`log`

prof_enable

prof_enable — Control virtuoso profiling

Synopsis

prof_enable (in *flag* integer) ;

Description

`prof_enable` is used to enable or disable profiling of execution times, SQL statements and web requests. Passing flag value 1, enables profiling, causing times of statement executions, which begin and end while profiling is on, to be accumulated.

When called with a flag of 0, the accumulation is stopped and results gathered so far are written into file named virtprof.out in the server's working directory. For a description of the file, see section about SQL Execution Profiling in Performance tuning part of Virtuoso documentation.

Parameters

flag
: An INTEGER . Valid values are 1 or 0.

Return Types

None.

Errors

No errors are signalled by `prof_enable`

Examples

Example 24.247. Simple example

Enable profiling.

```
SQL> prof_enable(1);
```

See Also

SQL Execution profiling.

prof_sample()

prof_sample

prof_sample — Adds a profiling sample to a profile being accumulated.

Synopsis

prof_sample (in *desc* varchar ,
in *time_spent* integer ,
in *flag* integer) ;

Description

`prof_sample` is used to adds a profiling sample to a profile being accumulated.

The first argument is the name of the sampled section, the times called and cumulative times will be totaled under this heading. The second argument is the time in milliseconds. The third argument is a flag indicating whether the section was successfully executed. 0 indicates success, 1 indicates execute of the statement, 2 indicates fetch on a statement's resultset, 4 indicates error. For more description of profiling capabilities see the section about SQL Execution Profiling in Performance tuning part of Virtuoso documentation.

Parameters

desc
: A VARCHAR . Name of the sampled section.

time_spent
: An INTEGER . Time in milliseconds.

flag
: An INTEGER . flag indicating whether the section was successfully executed. 0 - success, 1 - execute of statement, 2 - fetch on a statement's resultset, 4 - error.

Return Types

None.

Example 24.248. Example

```
create procedure do_prof_sample()
{
  declare stime integer;
  for(declare i integer;i < 5;i := i + 1){
    stime := msec_time();
    for(select * from Demo.demo.Customers) do sprintf('1');
    for(select * from Demo.demo.Employees) do sprintf('1');
    for(select * from Demo.demo.Order_Details) do sprintf('1');
    prof_sample('3 selects execute',msec_time() - stime,1);

  };

};

prof_enable(1);
select do_prof_sample();
prof_enable(0);
```

This will produce virtprof.out file of the sort:

```
Query Profile (msec)
Real 168, client wait 313, avg conc 1.863095 n_execs 6 avg exec  52
```

```
100 % under 1 s
0 % under 2 s
0 % under 5 s
0 % under 10 s
0 % under 30 s

2 stmts compiled 1 msec, 0 % prepared reused.

 %  total n-times n-errors
50 % 157      1        0     select do_prof_sample

prof_enable()

quarter

quarter — get number of quarter of year from a datetime

Synopsis

quarter (in *dt* datetime);

Description

quarter takes a datetime and returns an integer containing a number representing the quarter of year of the datetime.

Parameters

dt
: A datetime .

Return Values

An INTEGER containing number of the quarter of year.

Examples

Example 24.249. Simple example

Get current quarter of year.

```
SQL> select quarter (now ());
callret
INTEGER
_______________________________________________________________________________

4
```

See Also

dayname , monthname , dayofmonth , dayofweek , dayofyear , week , month , year , hour , minute , second , timezone

quote_dotted

quote_dotted — Returns an quoted identifier.

Synopsis

```
varchar quote_dotted ( in dsn varchar ,
                       in identifier varchar ) ;
```

Description

The `quote_dotted()` function will return the identifier (table name or column name) appropriately quoted for the remote data source. This function will obtain the appropriate quote characters from the remote data source. This function can be used in conjunction with rexecute function.

Parameters

dsn
: The remote DSN name.

identifier
: The string containing the identifier. The identifier can be a one, two or three part name, separated with the dot, '.', character.

Return Types

A string will be returned containing the quoted identifier.

Errors

Table 24.73. Errors signalled by

SQLState	Error Code	Error Text	Description
22023	VD011	Supplied DSN [name] is not valid	

Examples

Example 24.250. Using the quote_dotted() function

This simple example shows an identifier from a remote Oracle data source being correctly quoted using the quote_dotted() function from ISQL.

```
SQL> select quote_dotted ('oracle', 'DEMO.EMP');
callret
VARCHAR
_______________________________________________________________________________

"DEMO"."EMP"

1 Rows. -- 2 msec.
```

See Also

`rexecute()`

randomize

randomize — initializes the random number generator

Synopsis

randomize (in *seed* integer) ;

Description

The rnd function returns a random number between zero and n - 1, inclusive.

randomize initializes the random number generator.

The random number generator is initialized after the clock at first usage, so the produced sequences will be different each time unless specifically initialized.

rclose

rclose — Closes cursor created by rexecute()

Synopsis

rclose (in *cursor_handle* long);

Description

Closes the cursor opened to a remote DSN by the rexecute() function.

Parameters

cursor_handle
: The cursor handle used.

regexp_match

regexp_match — returns a substring matching the regular expression to the supplied string

Synopsis

```
varchar regexp_match ( in pattern any ,
                       inout str any ,
                       in change_the_str integer ) ;
```

Description

The regexp_match function returns a copy of substring of string *str* which matches the regular expression pattern.

Previous behavior of this function would cut the first characters of *str* until the end of regular expression matched substring. In this way *str* could be passed to this function again to find the next occurrence of substring that matches the regular expression. By default this behavior is not adopted by this function, but can be enabled for pre 3.2 compatibility by supplying the optional third parameter.

If either the *pattern* or *str* parameter contain wide characters this function will operate in wide mode, first converting any narrow characters to wide and returning a wide character response. Otherwise this function operates in narrow mode by default.

Parameters

pattern
: The regular expression to match.

str
: The string to be searched. In compatibility mode (change_the_str =1) this string in modified, removing the matched substring.

change_the_str
: This new parameter allows this function to operate in pre 3.2 compatibility mode which modified the original string. By default this parameter is set to "0" so that the original string is never altered.

Returns

This function returns the a substring matching the regular expression.

Examples

Example 24.251. Examples

```
CREATE PROCEDURE all_tokens(IN pattern VARCHAR, IN str VARCHAR)
{
        DECLARE wrd VARCHAR;
        DECLARE ans VARCHAR;
        DECLARE str_i VARCHAR;

        ans:='';
        str_i := str;
        wrd := regexp_match(pattern,str_i);
        WHILE (wrd IS NOT NULL)
        {
                ans := concat(ans,',',wrd);
                wrd := regexp_match(pattern, str_i, 1);
        };
        RETURN ans;
};
```

Compatibility:
The regular expressions supported here follow version 7.9 of the Perl Compatible Regular Expression (PCRE) syntax.

`regexp_parse()`

`regexp_like()`

`regexp_instr()`

`regexp_replace()`

`regexp_substr()`

regexp_parse

regexp_parse — returns substrings that match the regular expression in supplied string after an offset

Synopsis

```
index_vector regexp_parse ( in pattern string ,
                            in target_string string ,
                            in offset integer ) ;
```

Description

It applies regular expression to target_str with offset. This function returns a vector containing 2 elements for first match of the pattern and if there a sub expressions : 2 elements for each of subexpression match. The first (even numbered) element of each pair is the start index and the second (odd numbered) is the end index of the match. The regexp_parse function is more efficient than regexp_match and regexp_substr, because it doesn't allocate strings.

```
SQL> select regexp_parse('(2[34]).*(2[35])','22232225222323', 0);
callret
VARCHAR
_______________________________________________________________________________

lvector(2,14,2,4,12,14)

1 Rows. -- 10 msec.
```

Where: 2-14 is a range matched by whole expression, 2-4 is a range where '(2[34])' is matched , and 12-14 is a range where '(2[35])' subexpression matched.

Example 24.252. Examples

```
CREATE PROCEDURE all_tokens2 (IN pattern VARCHAR,IN str VARCHAR, IN offs INTEGER)
{

        DECLARE vec ANY;
        DECLARE i INTEGER;
        DECLARE out_str VARCHAR;

        vec:=regexp_parse(pattern,str,offs);
        IF ((vec IS NOT NULL) AND (length(vec)>1))
        {
                out_str:='';
                i:=0;
                WHILE ( (length(vec)/2) > i )
                {
                        out_str:=concat(out_str,'/',
                                subseq(str,aref(vec,(i)*2),
                                aref(vec,(i)*2+1)));
                        i:=i+1;
                };
                RETURN concat(out_str,test_parsing(pattern,str,aref(vec,1)+1));
        }
        return NULL;
};
```

Compatibility:
The regular expressions supported here follow version 7.9 of the Perl Compatible Regular Expression (PCRE) syntax.

1. Wikipedia
2. PCRE.org

See Also

`regexp_match()`

`regexp_like()`

`regexp_instr()`

`regexp_replace()`

`regexp_substr()`

regexp_substr

regexp_substr — returns a single captured substring from matched substring

Synopsis

```
(varchar|nvarchar) regexp_substr ( in pattern (varchar|nvarchar) ,
                                   in str (varchar|nvarchar) ,
                                   in offset integer ) ;
```

Parameters

pattern
: the regexp pattern string

str
: the data into which 1 (the first) or 0 matching substrings will be searched for

offset
: the number of regexp subexpression who's match to return : 0 for the whole matching substring, 1 for the substring matching the first regexp subexpression and so on

Description

This function will return the whole string value of the first substring in "str" that matches the regexp in "pattern" or a sub part of the first match. The regexp syntax allows subexpressions to be marked in the regular expression (using the braces syntax). An example of such type of expression will be: '(2[34]).*(2[35])' which means a regular expression having two subexpressions: '2[34]' and '2[35]'.

Examples

Example 24.253. Simple example

Let's apply the above regexp to the following source string: 22232225222323

```
SQL> select regexp_substr('(2[34]).*(2[35])','22242226222527', 0);
callret
VARCHAR
_______________________________________________________________________________

2422262225

1 Rows. -- 0 msec.
```

This returns the whole matched string from the expression.

```
SQL> select regexp_substr('(2[34]).*(2[35])','22242226222527', 1);
callret
VARCHAR
_______________________________________________________________________________

24

1 Rows. -- 0 msec.
```

This returns what has been matched for the first ('2[34]') regexp subexpression out of the whole matched substring (see above) : basically denoted as \1 in perl

```
SQL> select regexp_substr('(2[34]).*(2[35])','22242226222527', 2);
```

```
callret
VARCHAR
_______________________________________________________________________________

25

1 Rows. -- 10 msec.
```

This returns what has been matched for the second ('2[35]') regexp subexpression out of the whole matched substring. This is \2 in perl. Note that the text '22' (that corresponds to '.*' part of the regexp) is not returned by the above call because it is not contained in the second pair of braces.

Compatibility:

The regular expressions supported here follow version 7.9 of the Perl Compatible Regular Expression (PCRE) syntax.

DB.DBA.RDF_AUDIT_METADATA

DB.DBA.RDF_AUDIT_METADATA — Fix RDF metadata corruption.

Synopsis

DB.DBA.RDF_AUDIT_METADATA (in *audit_mode* integer ,
in *str_value* varchar ,
in *graph_iri* varchar) ;

Description

This function can detect and automatically fix most popular sorts of metadata corruption.

Parameters

audit_mode
: (0|1|2|3 default 0) - 0 = read-only audit operation; 1 = audit and fix; 2 = audit, fix and garbage collection for all incomplete declarations; 3 = the routine erases data it can't fix and it makes up to 10 iterations trying to erase all invalid/incomplete metadata. The bigger the number, the more errors can be fixed, at the price of more metadata changed if needed for the fix.

str_value
: Default '' is to stop if the metadata graph contains marks that some storages are being edited.

graph_iri
: Default is system metadata graph.

Examples

Example 24.254. Simple example

Automatically fix the corrupted metadata:

```
SQL> DB.DBA.RDF_AUDIT_METADATA(1, '*');
```

See Also

`DB.DBA.RDF_BACKUP_METADATA`

DB.DBA.RDF_GRAPH_SECURITY_AUDIT

DB.DBA.RDF_GRAPH_SECURITY_AUDIT — Fix graph-level security errors.

Synopsis

DB.DBA.RDF_GRAPH_SECURITY_AUDIT (in *recovery* integer) ;

Description

This function can detect and automatically fix many sorts of errors in the configuration of the graph-level security.

Parameters

recovery
: (0|1 default 0) - 0 = read-only diagnostics ; 1 = diagnostics +recovery, and makes a result-set of messages (such as found errors). The result set consists of 6 columns:

Examples

Example 24.255. Simple example

Automatically fix the corrupted metadata:

```
SQL> DB.DBA.RDF_GRAPH_SECURITY_AUDIT(1);
SEVERITY  GRAPH_IID     GRAPH_IRI  USER_ID     USER_NAME  MESSAGE
VARCHAR  VARCHAR       VARCHAR  INTEGER     VARCHAR  VARCHAR

DB.DBA.RDF_DEFAULT_USER_PERMS_SET

DB.DBA.RDF_DEFAULT_USER_PERMS_SET — Sets default permissions of user.

Synopsis

DB.DBA.RDF_DEFAULT_USER_PERMS_SET (in *uname* varchar ,
in *perms* integer ,
in *set_private* integer (default 0)) ;

Description

This function sets default permissions of user named uname to the value specified by perms.

Parameters

uname
: User name.

perms
: If perms is null, then the procedure acts as DB.DBA.RDF_DEFAULT_USER_PERMS_DEL (uname, set_private) ;

set_private
: (0|1 default 0). If set_private is true then the permission is set as default for "private" graphs otherwise it is set for "world" graphs.

Examples

Example 24.256. Example

```
-- Set 'demo' user/role to have no access to private graphs:
DB.DBA.RDF_DEFAULT_USER_PERMS_SET ('demo', 0, 1);
-- Set 'demo' user/role ability to read, update, sponge other graphs, assuming bit_or (1,2,4) = 7 :
DB.DBA.RDF_DEFAULT_USER_PERMS_SET ('demo', 7, 0);
```

DB.DBA.RDF_GRAPH_GROUP_INS

DB.DBA.RDF_DEFAULT_USER_PERMS_DEL

DB.DBA.RDF_DEFAULT_USER_PERMS_DEL — Removes the setting of default permissions of user.

Synopsis

DB.DBA.RDF_DEFAULT_USER_PERMS_DEL (in *uname* varchar ,
in *set_private* integer (default 0)) ;

Description

This function removes the setting of default permissions of user named uname. As the result, the default permission of "nobody" is used for the specified user, the future changes in permissions of "nobody" will change the access control for the user.

If set_private is true then the permission in question is the default permission for "private" graphs otherwise it is for "world" graphs.

The function works for disabled or DAV users as well as for active SQL users, so a user can be banned first and then restricted in RDF access rights or visa versa. However the function will signal an error if it is called for "nobody" or "dba" users. Default permissions for these two users can be changed but can not deleted.

Parameters

uname
: User name.

set_private
: (0|1 default 0). If set_private is true then the permission in question is the default permission for "private" graphs otherwise it is for "world" graphs.

Examples

Example 24.257. Example

DB.DBA.RDF_BACKUP_METADATA

DB.DBA.RDF_BACKUP_METADATA — Makes a backup copy of RDF metadata (i.e., descriptions of Linked Data Views and the like).

Synopsis

DB.DBA.RDF_BACKUP_METADATA (in *save_to_file* integer := 0 ,
in *backup_name* varchar := null) ;

Description

This saves all RDF metadata to file or to some graph in RDF storage, depending on first argument (nonzero for file, zero for graph). If the function gets nonzero as first argument then it creates two files, called, say, 'example.ttl', and 'example-DEBUG.ttl'. It's enough to save only the former file in order to restore metadata later, but the latter contains important additional debug information so both files should be attached to any bug report related to RDF metadata.

There are no functions to make copies of backups. File backup consists of plain TURTLE RDF files only. Backup graph is just a regular RDF graph in the default storage so it can be serialized into a file or copied into other graph. However it is important to remember that the system graph, whose name is returned by JSO_SYS_GRAPH() stored procedure, should not be edited directly. The content of the system graph is not necessarily equal to the content of a backup graph and it should be touched only by API function calls.

Parameters

save_to_file
: Value of 1 to backup to a files, 0 to backup into graph.

backup_name
: Name of destination graph or file. Graph should be empty before backup, but file with the specified name may exist before backup and will be silently overwritten. When the destination is file, the '.ttl' extension is concatenated to the backup_name. If the argument is null then the backup name will contain date and time of backup creation, like '2007-12-31T23:59.59'.

Return Types

The function returns the actual name of the created backup as a string.

DB.DBA.RDF_VOID_STORE

DB.DBA.RDF_VOID_STORE — Collects statistics for a given graph and saves it.

Synopsis

DB.DBA.RDF_VOID_STORE (in *graph* varchar ,
in *to_graph_name* varchar) ;

Description

Collects statistics for the first given graph and saves the result into the second graph. For correct results, the first graph should be loaded in the database before executing the function.

Parameters

graph
: the graph iri string to take statistics from

to_graph_name
: the graph iri string to write the void data.

Examples

Example 24.258. Simple example

```
SQL>DB.DBA.RDF_VOID_STORE('http://www.openlinksw.com/blog/~kidehen','http://example.com');
Done. -- 201 msec.

SQL>sparql
select *
from <http://example.com>

DB.DBA.TTLP

DB.DBA.TTLP_MT

DB.DBA.RDF_TRIPLES_TO_RDF_XML_TEXT

rdf_load_stop

rdf_load_stop — Stops RDF Loader threads.

Synopsis

```
rdf_load_stop (  );
```

Description

All RDF loader threads can be stopped using the command rdf_load_stop(), at which point all currently running threads will be allowed to complete and then exit.

Parameters

Examples

Example 24.259. Simple example

```
SQL> rdf_load_stop();
```

See Also

Bulk Loading RDF Source Files into one or more Graph IRIs

ld_dir()

ld_dir_all()

rdf_loader_run()

rdf_loader_run

rdf_loader_run — Performs bulk load.

Synopsis

```
rdf_loader_run ( in max_files integer := NULL ,
                 in log_enable int := 2 ) ;
```

Description

Virtuoso Bulk Loader function that performs bulk load. The function recognizes several file types, including .ttl, .nt, .xml, .rdf, .owl, .nq, .n4, and others. Internally the function uses ttlp or db..rdf_load_rdfxml, as appropriate. Please see more details for what file formats and file extensions are supported.

Note: The Virtuoso Bulk Loader functions must be present. They are pre-loaded starting with commercial version 06.02.3129 and open source version 6.1.3, but must be manually loaded into older versions.

Parameters

max_files
: Maximum files to be loaded.

log_enable
: For the default value 2 triggers are disabled, to speed the loading of data. If triggers are required (e.g., for RDF Graph replication between nodes), then the log_enable mode should be set to 3.

Examples

Example 24.260. Simple example

```
SQL> rdf_loader_run();
```

Bulk Loading RDF Source Files into one or more Graph IRIs

ld_dir()

ld_dir_all()

rdf_load_stop()

ld_dir_all

ld_dir_all — Loads from the specified directory, including any and all subdirectories.

Synopsis

ld_dir_all (in *dir_path* varchar ,
in *file_mask* varchar ,
in *target_graph* varchar) ;

Description

Adds files from the specified directory, including any and all subdirectories, to control list set up in the virtuoso.ini file.

Parameters

dir_path
: path to the folder where the files will be loaded

file_mask
: SQL like pattern to match against the files in the directory

target_graph
: target graph IRI, parsed triples will appear in that graph.

Return Types

The return value is not specified and may be changed in future versions.

Examples

Example 24.261. Simple Use

```
ld_dir_all ('/data8/', '%.gz', 'http://bsbm.org');
```

would load the RDF in all files ending in .gz from the directory (and its children) given as first parameter. The RDF would be loaded in the http://bsbm.org graph.

If NULL is given for the graph, each file may go to a different graph specified in a separate file with the name of the RDF source file plus the extension .graph.

A .graph file contains the target graph URI without any other content or whitespace.

DB.DBA.RDF_RESTORE_METADATA

DB.DBA.RDF_RESTORE_METADATA — Restores RDF metadata (descriptions of Linked Data Views and the like) from previously saved backup.

Synopsis

DB.DBA.RDF_RESTORE_METADATA (in *read_from_file* integer ,
in *backup_name* varchar) ;

Description

This restores RDF metadata from specified file or graph in RDF storage. The file or graph should be previously created by DB.DBA.RDF_BACKUP_METADATA () . It is usually safe to restore metadata from backup made by some previous version of Virtuoso server but it is good idea to call DB.DBA.RDF_AUDIT_METADATA () after such restore.

When the procedure is executed on the server that continues to serve user requests during the maintenance then SPARQL query compiler may interrupt query compilations or create queries that will return incomplete result sets. These queries may be cached till the end of metadata update procedure but the cache is flushed when the update is complete, so possible errors will be transient. If even transient errors are not appropriate then do RDF metadata update with all precautions usual for changing database schema of an application.

Parameters

read_from_file
: This flag specifies the type of the origin: it should be nonzero for file, zero for graph.

backup_name
: Name of backup file or graph as it is returned by the call of DB.DBA.RDF_BACKUP_METADATA () that created the backup.

Return Types

The return value is not specified and may be changed in future versions.

DB.DBA.RDF_AUDIT_METADATA()

DB.DBA.RDF_BACKUP_METADATA()

DB.DBA.RDF_LOAD_RDFXML_MT

DB.DBA.RDF_LOAD_RDFXML_MT — Parses the content of large RDF/XML text as a sequence of separate RDF triples.

Synopsis

DB.DBA.RDF_LOAD_RDFXML_MT (in *strg* varchar ,
in *base* varchar ,
in *graph* varchar ,
in *log_mode* integer ,
in *threads* integer ,
in *transactional* integer) ;

Description

For loading large resources when transactional integrity is not important (loading of a single resource may take more than one transaction). The function may or may not leave a transaction log, depending on `log_mode` . Hence, after successful load, one may need to execute the checkpoint statement to make sure that a server restart does not wipe out the results.

Parameters

strg
: text of the resource.

base
: base IRI to resolve relative IRIs to absolute.

graph
: target graph IRI, parsed triples will appear in that graph.

log_mode
: detail level of writing the effect of loading to the transaction log. 0 means log nothing, 1 means log only allocations of internal IDs for new IRIs and literals, 2 means log everything. If database crashes when the loading is in progress or after the loading but before checkpoint is made, 0 will means that the database become inconsistent, 1 means that the database is consistent but loaded quads may disappear so the loading should be repeated and log replay may produce wrong results if actions in it depend on the content of quad store, 2 means no danger (so the default is 2). Hence loading with mode 1 and especially mode 0 are faster than usual mode 2 but they require checkpoints after data loadings and mode 0 additionally requires a checkpoint and database backup right before the loading.

threads
: number of threads that insert quads into the database. It should not be less than 1, obviously; it is better to not set it greater than ((N-2)/k)-1 where N is the number of available CPU cores and k is the number of loadings that happen at the same time.

transactional
: controls the transaction mode which is "0" by default i.e. off and can be turned on by setting it to "1".

Return Types

The return value is not specified and may be changed in future versions.

Examples

Example 24.262. Usage Example

The following example demonstrates importing data from the rdf file resource Kingsley_Idehen.rdf which can be downloaded from here

```
SQL> DB.DBA.RDF_LOAD_RDFXML_MT (file_to_string_output ('tmp/Kingsley_Idehen.rdf'), '', 'http://example.co

DB.DBA.RDF_LOAD_RDFXML

DB.DBA.RDF_LOAD_RDFXML — Parses the content of RDF/XML text as a sequence of separate RDF triples.

Synopsis

DB.DBA.RDF_LOAD_RDFXML (in *rdfxml_text* varchar ,
in *omt_top_rdf* varchar ,
in *graph_uri* varchar) ;

Description

Parses the content of RDF/XML text as a sequence of separate RDF triples.

Parameters

rdfxml_text
: text of XML document

omt_top_rdf
: base IRI to resolve relative IRIs

graph_uri
: the IRI of destination graph

Return Types

The return value is not specified and may be changed in future versions.

Examples

Example 24.263. Simple Use

Load from local file:

```
SQL>sparql drop graph <http://www.biopax.org/prototype#sample-closure>;
Done. -- 2 msec.
SQL>DB.DBA.RDF_LOAD_RDFXML (file_to_string ('MatInf-for-Alan/Reactome_109581.owl'), '', 'http://www.biopa

DB.DBA.RDF_LOAD_RDFA — Parses the content of RDF embedded as RDFa text as a sequence of separate RDF triples.

Synopsis

DB.DBA.RDF_LOAD_RDFA (in *rdfa_text* varchar ,
in *omt_top_rdf* varchar ,
in *graph_uri* varchar) ;

Description

Parses the content of RDF embedded as RDFa text as a sequence of separate RDF triples.

Parameters

rdfa_text
: text of document containing RDFa data

omt_top_rdf
: base IRI to resolve relative IRIs

graph_uri
: the IRI of destination graph

Return Types

The return value is not specified and may be changed in future versions.

Examples

Example 24.264. Simple Use

Load from local file:

```
SQL>sparql clear graph <http://virtuoso.openlinksw.com/example>;
Done. -- 2 msec.
SQL>DB.DBA.RDF_LOAD_RDFA (file_to_string ('pricing.html'), 'http://virtuoso.openlinksw.com/pricing/#', 'h
Done. -- 106 msec.
```

Load from URI:

```
SQL>sparql clear graph <http://virtuoso.openlinksw.com/example>;
SQL> DB.DBA.RDF_LOAD_RDFA (http_get('http://virtuoso.openlinksw.com/pricing/'), 'http://virtuoso.openlink
Done. -- 109 msec.

ld_dir

ld_dir — Adds files to control list set up in the virtuoso.ini file.

Synopsis

```
ld_dir ( in dir_path varchar ,
         in file_mask varchar ,
         in target_graph varchar ) ;
```

Description

Adds files to control list set up in the virtuoso.ini file.

Parameters

dir_path
: path to the folder where the files will be loaded

file_mask
: SQL like pattern to match against the files in the directory

target_graph
: target graph IRI, parsed triples will appear in that graph.

Return Types

The return value is not specified and may be changed in future versions.

Examples

Example 24.265. Simple Use

```
ld_dir ('/data8/2848260', '%.gz', 'http://bsbm.org');
```

would load the RDF in all files ending in .gz from the directory given as first parameter. The RDF would be loaded in the http://bsbm.org graph.

If NULL is given for the graph, each file may go to a different graph specified in a separate file with the name of the RDF source file plus the extension .graph.

A .graph file contains the target graph URI without any other content or whitespace.

RDF Bulk Load Utility

DB.DBA.TTLP

DB.DBA.TTLP — parses TTL (TURTLE or N3 resource) and places its triples into DB.DBA.RDF_QUAD.

Synopsis

DB.DBA.TTLP (in *strg* any ,
in *base* varchar ,
in *graph* varchar ,
in *flags* integer) ;

Description

Parses TTL (TURTLE or N3 resource) and places its triples into DB.DBA.RDF_QUAD.

Parameters

strg
: text of the resource

base
: base IRI to resolve relative IRIs to absolute

graph
: target graph IRI, parsed triples will appear in that graph.

flags
: bitmask of parsing flags. Permits some sorts of syntax errors in resource. Default is 0, meaning no permitted deviations from the spec. Other supported bits are:

Return Types

The return value is not specified and may be changed in future versions.

Examples

Example 24.266.

For loading a file of any greater length, it is most practical to use the file_to_string_output function.

It is important the file to be accessible for the Virtuoso server. You need to have set properly the DirsAllowed parameter value in section [Parameters] of the Virtuoso database INI file. For example on Windows it could be:

```
virtuoso.ini file:
[Parameters]
...
DirsAllowed =  .\tmp
...
```

So in the example the file you want to import from, should be in the tmp folder or in its subfolder. Note that this example folder is a subfolder of the Virtuoso Server working directory.

Sample Example 1

```
SQL> ttlp (file_to_string_output ('.\tmp\data.ttl'), '', 'http://my_graph', 0);
```

Forth item in record of NQuad format is optional. If present then it is used as a graph. If missed then the default graph is used. The purpose is to make SPARQL dataset serialization possible in a "natural" way: the content of default graph is written without any

graph name specified whereas the content of named graphs is written with fouth field in place. Similarly, TriG uses default graph for triples outside graph blocks. In all these cases, base IRI is used to resolve all relative IRIs of the document, no matter what is the destination graph. Here is a simple example:

Sample Example 2 Suppose we have the simple nquad.nq file:

```
<http://www.w3.org/2002/01/tr-automation/tr.rdf> <http://purl.org/dc/elements/1.1/title> "W3C Standards a
<http://www.w3.org/People/Berners-Lee/card> <http://www.w3.org/1999/02/22-rdf-syntax-ns#type> <http://xml

DB.DBA.RDF_LOAD_RDFXML()

DB.DBA.RDF_LOAD_RDFXML_MT()

DB.DBA.TTLP_MT()

DB.DBA.TTLP_MT_LOCAL_FILE()

DB.DBA.TTLP_MT

DB.DBA.TTLP_MT — parses TTL (TURTLE), TTL(N-Triple) or NQ (N-quad) resources, and places its triples into DB.DBA.RDF_QUAD on multiple threads.

Synopsis

DB.DBA.TTLP_MT (in *strg* any ,
in *base* varchar ,
in *graph* varchar ,
in *flags* integer ,
in *log_mode* integer ,
in *threads* integer ,
in *transactional* integer) ;

Description

Loads the TTL (TURTLE or N3 resource) file on multiple threads, using parallel I/O and multiprocessing if available. The function commit partial transactions while it runs so the transaction log may contain part of loading. Moreover, the function may or may not leave a transaction log, depending on `log_mode` . Hence, after successful load, one may need to execute the checkpoint statement to make sure that a server restart does not wipe out the results.

Parameters

strg
: text of the resource

base
: base IRI to resolve relative IRIs to absolute

graph
: target graph IRI, parsed triples will appear in that graph.

flags
: bitmask of parsing flags. Permits some sorts of syntax errors in resource. Default is 0, meaning no permitted deviations from the spec. Other supported bits are:

log_mode
: detail level of writing the effect of loading to the transaction log. 0 means log nothing, 1 means log only allocations of internal IDs for new IRIs and literals, 2 means log everything. If database crashes when the loading is in progress or after the loading but before checkpoint is made, 0 will means that the database become inconsistent, 1 means that the database is consistent but loaded quads may disappear so the loading should be repeated and log replay may produce wrong results if actions in it depend on the content of quad store, 2 means no danger (so the default is 2). Hence loading with mode 1 and especially mode 0 are faster than usual mode 2 but they require checkpoints after data loadings and mode 0 additionally requires a checkpoint and database backup right before the loading.

threads
: number of threads that insert quads into the database. It should not be less than 1, obviously; it is better to not set it greater than ((N-2)/k)-1 where N is the number of available CPU cores and k is the number of loadings that happen at the same time.

transactional
: controls the transaction mode which is "0" by default i.e. off and can be turned on by setting it to "1".

Return Types

The return value is not specified and may be changed in future versions.

Examples

Example 24.267.

Example 1 Load ttl from local file:

```
SQL> DB.DBA.TTLP_MT (file_to_string_output ('tmp/users.ttl'), '', 'http://example.com');

Done. -- 381 msec.
SQL>sparql
select *
from <http://example.com>
where {?s ?p ?o}
limit 10;
s             p                   o
VARCHAR       VARCHAR             VARCHAR

Example 3 Fourth item in record of NQuad format is optional. If present then it is used as a graph. If missed then the default graph is used. The purpose is to make SPARQL dataset serialization possible in a "natural" way: the content of default graph is written without any graph name specified whereas the content of named graphs is written with fourth field in place. Similarly, TriG uses default graph for triples outside graph blocks. In all these cases, base IRI is used to resolve all relative IRIs of the document, no matter what is the destination graph. Suppose the following scenario:

There is a simple nquad.nq file:

```
<http://www.w3.org/2002/01/tr-automation/tr.rdf> <http://purl.org/dc/elements/1.1/title> "W3C Standards a

DB.DBA.TTLP()

DB.DBA.TTLP_MT_LOCAL_FILE

DB.DBA.TTLP_MT_LOCAL_FILE — parses TTL (TURTLE or N3 resource) and places its triples into DB.DBA.RDF_QUAD on multiple threads.

Synopsis

```
DB.DBA.TTLP_MT_LOCAL_FILE ( in path varchar ,
                            in base varchar ,
                            in graph varchar ,
                            in flags integer ,
                            in log_mode integer ,
                            in threads integer ) ;
```

Description

Loads the TTL (TURTLE or N3 resource) file on multiple threads, using parallel I/O and multiprocessing if available. The function commit partial transactions while it runs so the transaction log may contain part of loading. Moreover, the function may or may not leave a transaction log, depending on `log_mode` . Hence, after successful load, one may need to execute the checkpoint statement to make sure that a server restart does not wipe out the results.

Parameters

path
: path to the file in the local filesystem

base
: base IRI to resolve relative IRIs to absolute

graph
: target graph IRI, parsed triples will appear in that graph.

flags
: bitmask of parsing flags. Permits some sorts of syntax errors in resource. Default is 0, meaning no permitted deviations from the spec. Other supported bits are:

log_mode
: detail level of writing the effect of loading to the transaction log. 0 means log nothing, 1 means log only allocations of internal IDs for new IRIs and literals, 2 means log everything. If database crashes when the loading is in progress or after the loading but before checkpoint is made, 0 will means that the database become inconsistent, 1 means that the database is consistent but loaded quads may disappear so the loading should be repeated and log replay may produce wrong results if actions in it depend on the content of quad store, 2 means no danger (so the default is 2). Hence loading with mode 1 and especially mode 0 are faster than usual mode 2 but they require checkpoints after data loadings and mode 0 additionally requires a checkpoint and database backup right before the loading.

threads
: number of threads that insert quads into the database. It should not be less than 1, obviously; it is better to not set it greater than ((N-2)/k)-1 where N is the number of available CPU cores and k is the number of loadings that happen at the same time.

Return Types

The return value is not specified and may be changed in future versions.

DB.DBA.RDF_TRIPLES_TO_RDF_XML_TEXT

DB.DBA.RDF_TRIPLES_TO_RDF_XML_TEXT — Serializes vector of triples into a session, in RDF/XML syntax.

Synopsis

DB.DBA.RDF_TRIPLES_TO_RDF_XML_TEXT (inout *triples* any ,
in *print_top_level* any ,
inout *ses* any) ;

Description

Serializes vector of triples into a session, in TURTLE syntax. In current version, every triple is printed in separate top-level record (say, in rdf:Description tag), without any pretty-print or nesting optimization.

Parameters

triples
: vector of triples in 'long valmode'.

print_top_level
: zero if only rdf:Description tags should be written, non-zero if the rdf:RDF top-level element should also be written

ses
: an output stream in server default encoding

Examples

Example 24.270. Simple example

```
create procedure simple_test(in query varchar, in dflt_graph varchar)
{
  declare ses, rset, triples any;
  declare txt varchar;
  ses := string_output ();
  rset := DB.DBA.SPARQL_EVAL_TO_ARRAY (query, dflt_graph, 1);
  triples := dict_list_keys (rset[0][0], 1);
  DB.DBA.RDF_TRIPLES_TO_RDF_XML_TEXT (triples, 1, ses);
  txt := string_output_string (ses);
  dump_large_text (txt);
}
;
```

DB.DBA.RDF_64BIT_UPGRADE — Alters IRI_ID columns to get IRI_ID_8.

Synopsis

```
DB.DBA.RDF_64BIT_UPGRADE (  );
```

Description

There are two data types. IRI_ID is 4-byte and IRI_ID_8 is 8-byte. Initially, IRI_ID columns are created.
DB.DBA.RDF_64BIT_UPGRADE() alters them to get IRI_ID_8.

Note that this is to hold more that 4G of distinct IRIs, number of distinct quads is not limited by 4G even without the upgrade.

The function should be called once.

It shutdowns the server at completion upgrade so it should not be called from web-application.

Then the server should be restarted manually.

The server log should be checked for diagnostics before restart.

RDF_VIEW_SYNC_TO_PHYSICAL

RDF_VIEW_SYNC_TO_PHYSICAL — This function generates data synchronization triggers and/or actual RDF quad store data from transient Linked Data views. Basically, it enables you share physical and transient Linked Data views typically generated from 3rd party ODBC/JDBC accessible data sources.

Synopsis

```
RDF_VIEW_SYNC_TO_PHYSICAL ( in vgraph varchar ,
                            in load_data int := 0 ,
                            in pgraph varchar := null ,
                            in transaction_mode int := 1 ,
                            in atomicity int := 1 ) ;
```

Description

This function create new Transient and Materialized View pairs with option (where load = 1/0) to load data or wait for updates -- from triggers at execute time. 0 for non-transaction mode, and atomicity 0/1 determines server accessiblity where 1 indicates inaccessiblity during run. Note: applicable for Virtuoso 6.0 and higher.

Parameters

vgraph
: The transient (or virutal) named graph to which synchronization triggers are to be associated, or the actual source of data used to populate a named graph in the quad store.

load_data
: Flag that determines which operations are performed:

pgraph
: Designated quad store named graph IRI.

transaction_mode
: Integer values (0, 1, 2, or 3) which determine the transaction mode in place during synchronization. This is basically a call to log_enable () with the same values.

atomicity
: Enforces atomic mode during data synchronization. This mode of operation performs a checkpoint when completed, and is the recommended behavior for handling transient Linked Data views derived from large SQL large tables.

Return Types

any

Examples

Example 24.272.

Example 1

Using the command-line iSQL utility or its variant hosted in the HTML based Conductor, and assuming named graphs denoted by the following IRIs:

1. <http://www.openlinksw.com/schemas/odbcCustomers#> -- a named graph associated with virtual (and transient) RDF statements (triples) mapped to an ODBC accessible data source e.g., a "Customers" database.
2. <urn:rdf:materialized:view:odbc:Customers> -- a named graph to be associated with RDF statements (triples) materialized from virtual triples in the designated source named graph.

```
SQL> RDF_VIEW_SYNC_TO_PHYSICAL ('http://www.openlinksw.com/schemas/odbcCustomers#', 1, 'urn:rdf:materiali

# which is equivalent to:

SQL> RDF_VIEW_SYNC_TO_PHYSICAL ('http://www.openlinksw.com/schemas/odbcCustomers#', 1, 'urn:rdf:materiali
```

Example 2

A variant of the prior example where with ACID transaction modality enabled:

```
SQL> RDF_VIEW_SYNC_TO_PHYSICAL ('http://www.openlinksw.com/schemas/odbcCustomers#', 0, 'urn:rdf:materiali
```

Synopsis

DB.DBA.RDF_CONVERT_RDFXML_TO_TTL (in *strg* varchar ,
in *base* varchar ,
inout *ttl_ses* any) ;

Description

Converts rdf xml to ttl.

Parameters

strg
: text of the rdf resource

base
: base IRI to resolve relative IRIs to absolute

ttl_ses
: ttl resource

Return Types

The return value is not specified and may be changed in future versions.

Examples

Example 24.273. Simple example

```
create procedure DB.DBA.RDF_XML_IRI_TO_TTL (inout obj any, inout ses any)
{
  declare res varchar;
  if (isiri_id (obj))
    {
      if (obj >= min_bnode_iri_id ())
        {
          if (obj >= #ib0)

DB.DBA.RDF_GRAPH_GROUP_CREATE — Creates graph group.

Synopsis

DB.DBA.RDF_GRAPH_GROUP_CREATE (in *group_name* varchar ,
in *is_silent* integer) ;

Description

Creates graph group.

Parameters

group_name
: The name of the graph group

is_silent
: 0 (default) or 1. When set to 0, and there is already group with the given name, error will be raised. When set to 1, there will be no error message.

Return Types

The return value is not specified and may be changed in future versions.

Examples

Example 24.274. Simple example

```
SQL>DB.DBA.RDF_GRAPH_GROUP_CREATE ('TestGroup',1);
Done. -- 50 msec.
SQL> select * from DB.DBA.RDF_GRAPH_GROUP ;
RGG_IID           RGG_IRI            RGG_MEMBER_PATTERN  RGG_COMMENT
VARCHAR NOT NULL  VARCHAR NOT NULL   VARCHAR             VARCHAR
_______________________________________________________________________________

DB.DBA.RDF_GRAPH_GROUP_INS — Inserts graph into group.

Synopsis

DB.DBA.RDF_GRAPH_GROUP_INS (in *group_name* varchar ,
in *graph_uri* varchar) ;

Description

Inserts graph into a given group.

Parameters

group_name
: The name of the graph group

graph_uri
: graph uri IRI string or IRI_ID

Return Types

The return value is not specified and may be changed in future versions.

Examples

Example 24.275. Simple example

```
SQL>DB.DBA.RDF_GRAPH_GROUP_CREATE ('TestGroup',1);
Done. -- 50 msec.

DB.DBA.RDF_GRAPH_USER_PERMS_SET — Sets permissions of an the user on a graph.

Synopsis

DB.DBA.RDF_GRAPH_USER_PERMS_SET (in *graph_iri* varchar ,
in *uname* varchar ,
in *perms* integer) ;

Description

sets permissions of the user named uname on graph specified by graph_iri to the value specified by perms.

Parameters

graph_iri
: Graph IRI.

uname
: User name.

perms
: If perms is null then the function acts as DB.DBA.RDF_GRAPH_USER_PERMS_DEL (graph_iri, uname);

Examples

DB.DBA.RDF_GRAPH_USER_PERMS_GET

DB.DBA.RDF_GRAPH_USER_PERMS_GET — Gets permissions of an the user on a graph.

Synopsis

DB.DBA.RDF_GRAPH_USER_PERMS_GET (in *graph_iri* varchar ,
in *uname* varchar) ;

Description

Gets permissions of the user named uname on graph specified by graph_iri.

Parameters

graph_iri
: Graph IRI.

uname
: User name.

Return Types

Returns integer or null.

If the returned value is not null (hence an integer) then the specified user should be an active SQL user or "nobody".

Four sorts of access are returned, specified by four bits of an integer "permission bit-mask", plain old UNIX style:

- Bit 1 permits read access.
- Bit 2 permits write access via SPARUL and it's basically useless without bit 1 set.
- Bit 4 permits write access via "RDF sponge" methods and it's basically useless without bits 1 and 2 set.
- Bit 8 allows to obtain list of members of graph group; an IRI can be used as graph IRI and as graph group IRI at the same time so bit 8 can be freely combined with any of bits 1, 2 or 4.

For more details see our documentation section "Understanding Default Permissions"

Examples

Example 24.277. Example

Suppose the following Example for Blogs and Resource Sharing .

Get Ana's permissions on a given graph:

```
SQL> select DB.DBA.RDF_GRAPH_USER_PERMS_GET ('http://example.com/Anna/system', 'Anna');
Query result:
RDF_GRAPH_USER_PERMS_GET
INTEGER
 1
No. of rows in result: 1
```

DB.DBA.RDF_GRAPH_GROUP_CREATE

DB.DBA.RDF_GRAPH_GROUP_INS

DB.DBA.RDF_GRAPH_USER_PERMS_DEL

DB.DBA.RDF_GRAPH_USER_PERMS_DEL — Removes the setting of permissions of an user named uname on a given graph.

Synopsis

DB.DBA.RDF_GRAPH_USER_PERMS_DEL (in *graph_iri* varchar ,
in *uname* varchar) ;

Description

This function removes the setting of permissions of user named uname on graph specified by graph_iri. As the result, the permission of "nobody",is used for the specified user, the future changes in permissions of "nobody" will change the access control for the user on the graph in question.

The function works for disabled or DAV users as well as for active SQL users, so a user can be banned first and then restricted in RDF access right or visa versa.

Unlike DB.DBA.RDF_DEFAULT_USER_PERMS_DEL , the procedure will not signal an error if called for "nobody" or "dba" users.

Parameters

graph_iri
: Graph IRI.

uname
: User name.

Examples

Example 24.278. Example

See Example for Blogs and Resource Sharing

DB.DBA.RDF_GRAPH_GROUP_CREATE

DB.DBA.RDF_GRAPH_GROUP_INS

DB.DBA.RDF_ALL_USER_PERMS_DEL

DB.DBA.RDF_ALL_USER_PERMS_DEL — Removes all the setting of permissions of an user, both default permissions and permissions on specific graphs.

Synopsis

```
DB.DBA.RDF_ALL_USER_PERMS_DEL ( in uname varchar ,
                                in uid integer := null ) ;
```

Description

This function removes all the setting of permissions of user named uname, both default permissions and permissions on specific graphs. The only exception is that it does not remove default permissions if the specified user is "nobody" or "dba", but all graph-specific permissions are always removed.

The procedure can deal with disabled users. Moreover it can be used with entirely deleted users as soon as user id is known. It is possible to pass NULL instead of user name and an integer user ID as a second argument.

Parameters

uname
: User name

uid
: The user U_ID in the system table DB.DBA.SYS_USERS.

rdfs_rule_set

rdfs_rule_set — Adds the applicable facts of the graph into a rule set.

Synopsis

rdfs_rule_set (in *rule_name* varchar ,
in *graph_iri* varchar ,
in *remove* integer) ;

Description

This function associates a rule-name with a source named graphs identified by a named graph IRI. This named graph is contains RDF statements that constitute the desired inference rule to be created. You can use this procedure to add RDF statements from other named graphs as part as part of a rule-enhancement effort.

Parameters

rule_name
: Rule name (literal that identifies the rule).

graph_iri
: A named graph IRI that identifies the source of RDF statements to be used as inference rules,

remove
: (0|1 default 0) - where 1 indicates that the specified graph is to be removed from the rule set.

Examples

Example 24.280. Simple Usage Example

Google and Bloomberg Stock Quote Services return HTML5+Microdata based Linked Open Data using terms from Schema.org. As will be quite common, there is a case sensitive issue in regards to the HTTP URIs that identify the "Financial Quote" class. For Bloomberg we have: <http://schema.org/intangible/financialquote> and for Google: <http://schema.org/Intangible/FinancialQuote> . What follows in an *owl:equivalentProperty* relation that enables a processor of this data (e.g., SPARQL Query Processor) apply reasoning and inference based on the semantics of the *owl:equivalentProperty* relation. Using Virtuoso's SPARQL processor, you can create an inference rule declaratively via `rdfs_rule_set()` :

```
-- Suppose a ttl file inference-rule-for-stock-quotes.ttl has the following content:
<http://schema.org/intangible/financialquote>
  owl:equivalentProperty <http://schema.org/Intangible/FinancialQuote> .

-- Load the data to a Named Graph that's implicitly (in the case of Virtuoso)
-- identified by the RDF Document URL that contains the RDF statements that
-- constitute the rule being created
SQL> LOAD <http://example.com/inference-rule-for-stock-quotes.ttl> ;
Done. -- 15 msec.

-- Via SQL run the procedure:
SQL> RDFS_RULE_SET ('schema_stock_quotes', 'http://example.com/inference-rule-for-stock-quotes.ttl');
```

Example 24.281. Create Rule example

Create rule set and verify rule's existence:

```
SQL> rdfs_rule_set('myset', 'http://mygraph.com');
Done. -- 15 msec.
SQL> SELECT * FROM DB.DBA.SYS_RDF_SCHEMA ;
RS_NAME                              RS_URI                                                                RS_G
```

```
VARCHAR NOT NULL                    VARCHAR NOT NULL                                    VARCHAR
_______________________________________________________________________________

DB.DBA.RDF_GEO_FILL

DB.DBA.RDF_GEO_FILL — Converts geo:lat and geo:long properties properties into geometries.

Synopsis

DB.DBA.RDF_GEO_FILL (*n_threads* integer (optional, default 4)) ;

Description

Converts geo:lat and geo:long properties into geometries. This operation reads through all graphs and for each subject with at least one geo:lat and geo:long, a point geometry is made for each distinct lat/long pair where lat and long are in the same graph.

It should not happen in practice that a single subject has multiple lats or long within one graph. If this still happens, a geometry is made for each combination. The geometry is added to the subject with the lat and long as the value of the geo:geometry property.

This is performed in parallel on multiple threads and is optimized for cluster execution and done without transaction logging and is not transactional. To make the result persistent, the operator should do an explicit checkpoint by executing:

```
SQL>cl_exec ('checkpoint');
```

on any process of a cluster or single server. Otherwise the result may be lost if the server terminates abnormally before an automatic checkpoint is made.

Parameters

n_threads
: Number of threads to run. Default is to run 4 threads that will make geomerty objects (not counting the thread that searches for separate geo:lat and geo:long properties).

Examples

Example 24.282. Simple example

```
SQL> rdf_geo_fill ();

Done. -- 282 msec.
```

DB.DBA.RDF_GEO_ADD

DB.DBA.RDF_GEO_ADD

DB.DBA.RDF_GEO_ADD — Translates a geometry into a RDF box

Synopsis

DB.DBA.RDF_GEO_ADD (in *g* any);

Description

This function translates a geometry into a RDF box. It looks if an identical geometry already exists and if so assigns the existing id to it. If the geometry is new, it gets a new ID and is stored in the RDF literals table RDF_OBJ. At this time it is also automatically inserted into the RDF geometry index.

Note: In a cluster situation one should use the dpipe mechanism for inserting into RDF quad so as to get large numbers of inserts into a single message. This is essential for performance.

Parameters

g
: Geometry to be translated into RDF box.

Examples

Example 24.283. Simple example

```
INSERT INTO RDF_QUAD (g, s, p, o)
VALUES (
         "g",
         "s",
         iri_to_id ('http://www.w3.org/2003/01/geo/wgs84_pos#geometry'),
         DB.DBA.rdf_geo_add (rdf_box (st_point (lng, lat), 256, 257, 0, 1)));
```

DB.DBA.RDF_GEO_FILL

DB.DBA.RDF_GRAPH_COLLECT_FP_LIST

DB.DBA.RDF_GRAPH_COLLECT_FP_LIST — Gets inverse / functional properties for given graphs.

Synopsis

```
DB.DBA.RDF_GRAPH_COLLECT_FP_LIST ( in g_iid_list any ,
                                   in direct_fp integer ,
                                   inout fp_list any ) ;
```

Description

Gets inverse / functional properties for given graphs. The procedure will fetch all triples of all specified graphs during the run, so it will take some time if graphs are big and/or numerous.

Parameters

g_iid_list
: Vector of IRI_IDs of sample graphs

direct_fp
: When zero gets list of inverse functional properties; non-zero gets functional properties.

fp_list
: Variable that will be set to the vector of properties.

Return Types

any

See Also

DB.DBA.RDF_GRAPH_DIFF

DB.DBA.RDF_SUO_DIFF_TTL

DB.DBA.RDF_SUO_APPLY_PATCH

DB.DBA.RDF_GRAPH_DIFF

DB.DBA.RDF_GRAPH_DIFF — performs the core operation of preparing graph diff.

Synopsis

```
DB.DBA.RDF_GRAPH_DIFF ( in gfrom IRI_ID ,
                        in gto IRI_ID ,
                        in only_gfrom any ,
                        in only_gto any ,
                        in accuracy integer ,
                        inout fp_list any ,
                        inout invfp_list any ,
                        inout gfrom_rules any ,
                        inout gto_rules any ,
                        in equiv_map any := null ,
                        in equiv_rev any := null ) ;
```

Description

Performs the core operation of preparing graph diff - matching between nodes of two graphs.

Typically is called from wrapper that returns the diff in an extended GUO ontology (http://webr3.org/owl/guo#) as a string output in TURTLE syntax.

Parameters

gfrom
: IRI ID of the from graph

gto
: IRI ID of the destination graph

only_gfrom
: Dictionaries of triples that present only in gfrom (but have no matches in gto)

only_gto
: Dictionaries of triples that present only in gto (but have no matches in gfrom)

accuracy
: Tells the procedure what should be done if one or both graphs contain blank nodes. If zero then different bnodes are treated as distinct. Bnodes are allocated individually for each data load, so even if one and the same resource is loaded in two different graphs then these graphs will contain no blank nodes in common, accuracy=0 would result in the diff containing all triples from both graphs that have bnode subject o object. If nonzero then the procedure will try to match blank nodes, zipper style. In this case rest of arguments comes to play.

fp_list
: Vector of IRI_IDs of predicates that are supposed to be functional properties, i.e., any given subject has no more than one value of a given predicate.

invfp_list
: Vector of IRI_IDs of (supposedly) inverse functional properties, i.e., any given object could be the value of a given predicate for no more than one subject. The best source of such vectors is a good ontology suitable for both graphs. Types owl:functionalProperty and owl:inverseFunctionalProperty will provide truly "meaningful" lists of predicates that will provide really "meaningful" patch. Meaningful patches have three important advantages:

fp_list
: If NULL but accuracy is not zero then the function will call DB.DBA.RDF_GRAPH_COLLECT_FP_LIST internally, using graphs gfrom and gto as specimens.

invfp_list
: If NULL but accuracy is not zero then the function will call DB.DBA.RDF_GRAPH_COLLECT_FP_LIST internally, using graphs gfrom and gto as specimens.

gfrom_rules
: Describes how bnodes of graphs were matched, i.e., how sliders were moved along chains of predicates.

gto_rules
: Describes how bnodes of graphs were matched, i.e., how sliders were moved along chains of predicates.

equiv_map
: Dictionary that describe the match between bnodes in gfrom and gto. In equiv_map, bnodes from gfrom are keys and matching bnodes from gto are values.

equiv_rev
: Dictionary that describes the match between bnodes in gfrom and gto. In equiv_rev, same pairs are in different roles, bnodes from gfrom are values for matching bnodes from gto that are now keys. These data can be incomplete or NULL at all, but if provided then the function will trust them blindly.

Return Types

any

Fast Approximate RDF Graph Diff and Patch

DB.DBA.RDF_SUO_DIFF_TTL

DB.DBA.RDF_SUO_APPLY_PATCH

DB.DBA.RDF_GRAPH_COLLECT_FP_LIST

DB.DBA.RDF_SUO_APPLY_PATCH

DB.DBA.RDF_SUO_APPLY_PATCH — Modifies either the target graph specified in the patch via `guo:target_graph` or the graph specified by default_target_graph argument.

Synopsis

DB.DBA.RDF_SUO_APPLY_PATCH (in *patch_graph* IRI_ID ,
in *default_target_graph* IRI_ID) ;

Description

This function tries to modify either the target graph specified in the patch via `guo:target_graph` (hence, the non-NULL target_graph argument of the diff creator, DB.DBA.RDF_SUO_DIFF_TTL()) or the graph specified by default_target_graph argument. The function returns zero in case of success, non-zero value otherwise. In addition, the function produces a result set that describes the process of matching blank node in the target graph to instructions in the patch.

The TURTLE made by DB.DBA.RDF_GRAPH_DIFF can be loaded later into an empty graph and the IRI_ID of that graph can be passed as the first argument to this patch function.

Parameters

patch_graph
: IRI ID of the patch graph

default_target_graph
: IRI ID of the default target graph

Return Types

integer

DB.DBA.RDF_SUO_DIFF_TTL

DB.DBA.RDF_SUO_DIFF_TTL — performs the core operation of preparing graph diff.

Synopsis

```
DB.DBA.RDF_SUO_DIFF_TTL ( in gfrom any ,
                          in gto any ,
                          in target_graph any ,
                          in accuracy integer ,
                          inout fp_list any ,
                          inout invfp_list any ,
                          in equiv_map any := null ,
                          in equiv_rev any := null ) ;
```

Description

Performs the core operation of preparing graph diff - matching between nodes of two graphs.

Typically is called from wrapper that returns the diff in an extended GUO ontology (http://webr3.org/owl/guo#) as a string output in TURTLE syntax.

Parameters

gfrom
: varchar or UNAME or IRI_ID of the from graph

gto
: varchar or UNAME or IRI_ID of the destination graph

accuracy
: Tells the procedure what should be done if one or both graphs contain blank nodes. If zero then different bnodes are treated as distinct. Bnodes are allocated individually for each data load, so even if one and the same resource is loaded in two different graphs then these graphs will contain no blank nodes in common, accuracy=0 would result in the diff containing all triples from both graphs that have bnode subject o object. If nonzero then the procedure will try to match blank nodes, zipper style. In this case rest of arguments comes to play.

target_graph
: It is used in to the output TURTLE as value of guo:target_graph property of every guo:UpdateInstruction node, NULL value means no this property at all. If the patch procedure will not get the IRI of the graph to patch as an argument then the value of this property will be used.

fp_list
: Vector of IRI_IDs of predicates that are supposed to be functional properties, i.e. any given subject has no more than one value of a given predicate.

invfp_list
: Vector of IRI_IDs of (supposedly) inverse functional properties, i.e., any given object could be the value of a given predicate for no more than one subject. The best source of such vectors is a good ontology suitable for both graphs. Types owl:functionalProperty and owl:inverseFunctionalProperty will provide truly "meaningful" lists of predicates that will provide really "meaningful" patch. Meaningful patches have three important advantages:

fp_list
: If NULL but accuracy is not zero then the function will call DB.DBA.RDF_GRAPH_COLLECT_FP_LIST internally, using graphs gfrom and gto as specimens.

invfp_list

If NULL but accuracy is not zero then the function will call DB.DBA.RDF_GRAPH_COLLECT_FP_LIST internally, using graphs gfrom and gto as specimens.

gfrom_rules
: Describes how bnodes of graphs were matched, i.e., how sliders were moved along chains of predicates.

gto_rules
: Describes how bnodes of graphs were matched, i.e., how sliders were moved along chains of predicates.

equiv_map
: Dictionary that describe the match between bnodes in gfrom and gto. In equiv_map, bnodes from gfrom are keys and matching bnodes from gto are values.

equiv_rev
: Dictionary that describes the match between bnodes in gfrom and gto. In equiv_rev, same pairs are in different roles, bnodes from gfrom are values for mathing bnodes from gto that are now keys. These data can be incomplete or NULL at all, but if provided then the function will trust them blindly.

DB.DBA.SPARQL_RDB2RDF_CODEGEN

DB.DBA.SPARQL_RDB2RDF_CODEGEN — Creates an SQL text for a given table and an operation specified by an opcode

Synopsis

```
DB.DBA.SPARQL_RDB2RDF_CODEGEN ( in table_name varchar ,
                                in opcode integer ) ;
```

Description

The function creates an SQL text for a given table and an operation specified by an opcode.

Parameters

table_name
: The name of the table.

opcode
: Currently supported opcodes are:

Return Types

string session or vector

RDB2RDF Triggers

DB.DBA.SPARQL_RDB2RDF_LIST_TABLES

DB.DBA.SPARQL_RDB2RDF_LIST_TABLES

DB.DBA.SPARQL_RDB2RDF_LIST_TABLES — Returns a vector of names of tables that are used as sources for Linked Data Views.

Synopsis

DB.DBA.SPARQL_RDB2RDF_LIST_TABLES (in *mode* integer) ;

Description

Returns a vector of names of tables that are used as sources for Linked Data Views. Application developer should decide what to do with each of them - create triggers or do some application-specific workarounds.

Note that if some SQL views are used as sources for Linked Data Views and these views does not have INSTEAD triggers then workarounds become mandatory for them, not just a choice, because BEFORE or AFTER triggers on views are not allowed if there is no appropriate INSTEAD trigger. The mode argument should be zero in current version.

Parameters

mode

Return Types

vector

DB.DBA.RDF_SUO_APPLY_PATCH

DB.DBA.RDF_GRAPH_COLLECT_FP_LIST

rowvector_digit_sort

rowvector_digit_sort — Performs a stable "digit" sort of a given array of arrays.

Synopsis

rowvector_digit_sort (inout *data* vector ,
in *key_idx_in_row* integer ,
in *sort_ascending* integer) ;

Description

The function gets an vector that contains uniform arrays ("rows") as items, such as a result set produced by `exec` (). One element of each row is a key of sorting; it is identified by its zero-based position within the row, *`key_idx_in_row`* (if the *`data`* vector is a result set then N-th elements of all rows are from N-th column of the result set). The sorting procedure edits *`data`* and reorders rows in such a way that their keys become ordered ascending or descending, depending on *`sort_ascending`* flag.

The performed sorting is stable. It means that it will not permutate rows in vain: it will preserve the relative order of any two rows that have equal keys. Using this property, one may sort a result set by a "secondary sorting columns", starting with less significant and then by "primary sorting column". E.g., if each row contain elements for country code and province code then it is possible to make two-column sorting by sorting first by province and then by country; that will work even if province codes are not globally unique (say, if they're enumerated from 1 in each country).

This function supports only integer values of sorting keys.

Parameters

data
: A vector of rows to sort.

key_idx_in_row
: Zero-based position of key element in row, should be nonnegative and less than the length of each row.

sort_ascending
: Direction of sorting, nonzero for ascending sort, zero for descending.

Return Types

The function returns the length of the *`data`* vector.

`gvector_digit_sort()`

`gvector_sort()`

IsRef

IsRef — Returns true if non-blank IRI

Synopsis

IsRef (in *iri* any) ;

Description

Returns true if non-blank IRI

Parameters

iri
: IRI resource

Return Types

Returns 1 if the IRI is non-blank IRI. Otherwise returns 0.

Examples

Example 24.285. Simple example

```
SQL>SPARQL
SELECT COUNT(DISTINCT (?o))
WHERE
  {
    ?s ?p ?o .
    FILTER ( IsRef(?o))
  }
LIMIT 10

DB.DBA.SAMPLE

DB.DBA.SAMPLE — returns an arbitrary value from the multiset passed to it.

Synopsis

DB.DBA.SAMPLE (in *token* varchar);

Description

DB.DBA.SAMPLE is aggregate function that returns an arbitrary value from the multiset passed to it.

Note: Using the "sql:" prefix is mandatory for this aggregate.

Parameters

strg
: An item from multiset.

Return Types

any

Examples

Example 24.286.

```
SQL>SPARQL
SELECT  (sql:SAMPLE(?nick)), (sql:SAMPLE(?interest))
WHERE
  {
    ?p a foaf:Person .
    ?p foaf:nick ?nick.
    ?p foaf:interest ?interest.
  }

DB.DBA.GROUP_CONCAT

DB.DBA.GROUP_CONCAT — returns an arbitrary value from the multiset passed to it.

Synopsis

DB.DBA.GROUP_CONCAT (in *token* varchar ,
in *delim* varchar) ;

Description

DB.DBA.GROUP_CONCAT is aggregate function that performs a string concatenation across the values of an expression with a group. The order of the strings is not specified. The separator character used in the concatenation may be given with the scalar argument delimiter.

Note: the "sql:" prefix is mandatory when this aggregate is used in SPARQL queries. In SQL queries the prefix is "DB.DBA".

Parameters

token
: An item that should be added to a delimited list.

delim
: The delimeter character to be used in the concatenation.

Return Types

any

Examples

Example 24.287. Simple Use

```
SQL>SPARQL
SELECT ?name, (sql:GROUP_CONCAT(?near, ' , '))
WHERE
  {
    GRAPH ?g
      {
        [] a foaf:Person ;
        foaf:name ?name ;

DB.DBA.GROUP_CONCAT_DISTINCT

DB.DBA.GROUP_CONCAT_DISTINCT — returns a string that is concatenation of token strings delimited with delimiter

Synopsis

DB.DBA.GROUP_CONCAT_DISTINCT (in *token* varchar ,
in *delim* varchar) ;

Description

DB.DBA.GROUP_CONCAT_DISTINCT is aggregate function that performs a string concatenation across the values of an expression with a group. The order of the strings is not specified. The separator character used in the concatenation may be given with the scalar argument delimiter.

Note: the "sql:" prefix is mandatory when this aggregate is used in SPARQL queries. In SQL queries the prefix is "DB.DBA".

Parameters

token
: An item that should be added to a delimited list.

delim
: The delimeter character to be used in the concatenation.

Return Types

any

Examples

Example 24.288. Simple Use

```
SQL>SPARQL
SELECT ?name, (sql:GROUP_CONCAT_DISTINCT(?near, ' , '))
WHERE
  {
    GRAPH ?g
      {

DB.DBA.SAMPLE()

DB.DBA.GROUP_CONCAT()

DB.DBA.GROUP_DIGEST()

Differences between DB.DBA.SAMPLE, DB.DBA.GROUP_CONCAT, DB.DBA.GROUP_CONCAT_DISTINCT and DB.DBA.GROUP_DIGEST functions usage.

DB.DBA.GROUP_DIGEST

DB.DBA.GROUP_DIGEST — returns an arbitrary value from the multiset passed to it.

Synopsis

DB.DBA.GROUP_DIGEST (in *token* varchar ,
in *delim* varchar ,
in *maxlen* integer ,
in *mode* integer) ;

Description

DB.DBA.GROUP_DIGEST is aggregate function that performs a string concatenation across the values of an expression with a group. The order of the strings is not specified. The separator character used in the concatenation may be given with the scalar argument delimiter. The function is an extended version of sql:GROUP_CONCAT(), with two more arguments: maxlen and mode.

Note: the "sql:" prefix is mandatory when this aggregate is used in SPARQL queries. In SQL queries the prefix is "DB.DBA".

Parameters

token
: An item that should be added to a delimited list.

delim
: The delimeter character to be used in the concatenation.

maxlen
: The maximal allowed length of the result, in characters. Redundant values will be ignored. If the last value does not fit in the "maxlen" entirely, then it can be truncated and "..." is placed at the end of the resulting string.

mode
: Bitmask of properties. Right now only bit 1 is used and others are reserved. If the value of the argument is 1 then duplicate values are ignored; value 0 will put duplicate values like in case of sql:GROUP_CONCAT ().

Return Types

any

Examples

Example 24.289. Get all ?assets as a list with delimiters.

```
SQL>SPARQL
SELECT ?view (sql:GROUP_DIGEST (?path, ' ', 1000, 1)) as ?path_list
    (sql:GROUP_DIGEST (?asset, ' ', 1000, 1)) as ?asset_list
FROM <http://mygraph.com>
WHERE
  {
    ?view <viewPath> ?path ;
      <viewContent> ?asset ;
      <viewType>  'phyview'.
  };
```

http_nt_triple

http_nt_triple — outputs next triple to ses in NT serialization.

Synopsis

http_nt_triple (in *env* any ,
in *arg1* any ,
in *arg2* any ,
in *arg3* any ,
in *ses* any) ;

Description

Outputs next triple to ses in NT serialization.

Parameters

env
: An array of special format:

arg1
: Triple subject.

arg2
: Triple predicate.

arg3
: Triple object.

ses
: Session output.

Return Types

Any

Examples

Example 24.290. Simple Use

```
create procedure dump_rdftriples_to_nt(inout triples any, inout ses any)
{
  declare env any;
  declare tcount, tctr integer;
  tcount := length (triples);
  if (0 = tcount)
    {
      http ('# Empty NT\n', ses);
      return;
    }
  env := vector (0, 0, 0);
  for (tctr := 0; tctr < tcount; tctr := tctr + 1)
    {
      http_nt_triple (env, triples[tctr][0], triples[tctr][1], triples[tctr][2], ses);
    }
}
;

http_ttl_triple

http_ttl_triple — outputs next triple to ses in TTL serialization.

Synopsis

http_ttl_triple (in *env* any ,
in *arg1* any ,
in *arg2* any ,
in *arg3* any ,
in *ses* any) ;

Description

Outputs next triple to ses in TTL serialization. This function does not terminate the printed triple in hope that the next triple will has same "s" or pair of "s" and "p". So "intermediate" semicolon or comma can be used instead of "trailing" dot.

Parameters

env
: An array of special format:

arg1
: Triple subject.

arg2
: Triple predicate.

arg3
: Triple object.

ses
: Session output.

Return Types

Any

Examples

Example 24.291. Example 1

```
CREATE PROCEDURE dump_one_graph
  ( IN  srcgraph           VARCHAR  ,
    IN  out_file           VARCHAR  ,
    IN  file_length_limit  INTEGER  := 1000000000
  )
  {
    DECLARE  file_name  varchar;
    DECLARE  env, ses      any;
    DECLARE  ses_len,
             max_ses_len,
             file_len,
             file_idx      integer;
    SET ISOLATION = 'uncommitted';
    max_ses_len := 10000000;
    file_len := 0;
    file_idx := 1;
    file_name := sprintf ('%s%06d.ttl', out_file, file_idx);
    string_to_file ( file_name || '.graph',
```

```
                    srcgraph,
                    -2
                  );
    string_to_file ( file_name,
                    sprintf ( '# Dump of graph <%s>, as of %s\n',
                              srcgraph,
                              CAST (NOW() AS VARCHAR)
                            ),
                    -2
                  );

DB.DBA.ANN_PHRASE_CLASS_ADD

DB.DBA.ANN_PHRASE_CLASS_ADD — Returns APC_ID of a phrase class.

Synopsis

DB.DBA.ANN_PHRASE_CLASS_ADD (in *_name* varchar ,
in *_owner_uid* integer ,
in *_reader_gid* integer ,
in *_callback* varchar ,
in *_app_env* any ,
in *mode* varchar ,
in *auth_uname* varchar ,
in *auth_pwd* varchar) ;

Description

The returned value is APC_ID of a class if positive or an error code if negative. To update phrase class, no special DB.DBA.ANN_PHRASE_CLASS_UPDATE() exists, use DB.DBA.ANN_PHRASE_CLASS_ADD() with parameter "mode" equal to 'replacing'.

Parameters

_name
: a name of new phrase class

_owner_uid
: owner UID, will be stored as APC_OWNER_UID, can be NULL for public

_reader_gid
: reader GID, will be stored as APC_READER_GID, can be NULL for public

_callback
: value for APC_CALLBACK field

_app_env
: value for APC_APP_ENV field

mode
: Instructs what to do on attempt of writing over existing class: 'into' will signal, 'soft' return APC_ID of (unchanged) existing class, 'replacing' will continue with update.

auth_uname
: Authentication name

auth_pwd
: Authentication password

Examples

Example 24.292. ANN_PHRASE_CLASS_ADD

```
SQL>select ANN_PHRASE_CLASS_ADD ('My check', null, null, null, 'My check visa', '', 'dba', 'dba');
callret
INTEGER
_______________________________________________________________________________

1
```

```
1 Rows. -- 0 msec.

AP_BUILD_MATCH_LIST

DB.DBA.ANN_PHRASE_CLASS_DEL

DB.DBA.ANN_PHRASE_CLASS_DEL — Deletes phrase set.

Synopsis

DB.DBA.ANN_PHRASE_CLASS_DEL (in *_name* varchar ,
in *auth_uname* varchar ,
in *auth_pwd* varchar) ;

Description

The returned value is APS_ID of a deleted phrase set if positive or an error code if negative. A phrase set can not be deleted while used by some advertiser (as described here).

Parameters

_name
: a name of phrase set to delete

auth_uname
: Authentication name

auth_pwd
: Authentication password

Examples

Example 24.293. ANN_PHRASE_CLASS_DEL

```
SQL>select ANN_PHRASE_CLASS_ADD ('simple test', null, null, null, '123', '', 'dba', 'dba');
callret
INTEGER

AP_BUILD_MATCH_LIST

AP_BUILD_MATCH_LIST

AP_BUILD_MATCH_LIST — Returns report of all occurrences of phrases from the specified sets in the text.

Synopsis

AP_BUILD_MATCH_LIST (in *phrase_set_ids* vector of integers ,
in *source_UTF8_text* varchar not null ,
in *lang_name* varchar not null ,
in *source_text_is_html* integer ,
in *report_flags* integer) ;

Description

Forms a report that lists all occurrences of phrases from the specified sets in the text.

The report describes "phrase hits", i.e. occurrences of annotation phrases in the text, using "arrows" that point to specific fragments in the text, such as words of found phrases or HTML tags.

The structure of the report is complicated, due to contradiction in requirements. It is compact to provide reasonable performance and scalability, so common data should not be repeated, saving memory. It is complete enough to prevent application from reading omitted data from system tables, saving time.

All objects of one type are listed as items of some vector and the whole report consists of several such vectors. An item in one vector may refer to item in other vector by its index, without storing a local copy.

Detailed description of the report structure can be found here .

Parameters

phrase_set_ids
: vector of numeric identifiers of phrase sets at work, they may belong to various phrase classes, but if language of some phrase set differs from value of lang_name argument then the phrase set is silently ignored.

source_UTF8_text
: a plain text or an HTML

lang_name
: language name

source_text_is_html
: 0 for plain text, 1 for standard-compliant HTML or 2 for "dirty" HTML

report_flags
: Report flag

Examples

Example 24.294. Simple Use

Usage example can be found here .

AP_ADD_PHRASES

AP_ADD_PHRASES — Adds phrases to given set.

Synopsis

AP_ADD_PHRASES (in *phrase_id* integer ,
in *description_phrases* vector) ;

Description

The function gets two arguments, the integer ID of annotation phrase set and a vector of $ descriptions of phrases that should be edited in that phrase set.

Every item of vector of descriptions is in turn vector of one or two values; first value is the text of the phrase, second value is associated application specific data, the absence of second value indicates that the phrase should be removed. If same text of phrase appears in the vector of description more than once, and associated data differ then any version of data can be stored for future use; it is the roll of dice because the vector is reordered for faster processing.

Parameters

phrase_id
: integer ID of the annotation phrase set

description_phrases
: vector of descriptions of phrases that should be edited in that phrase set

Examples

Example 24.295. Simple Example

```
SQL>insert replacing DB.DBA.SYS_ANN_PHRASE_SET (APS_ID, APS_NAME, APS_OWNER_UID, APS_READER_GID, APS_APC_
values (5, 'Debug aps #5', http_dav_uid(), http_admin_gid(), 3, 'x-any', 'Debug aps #5 env', 10000, 0)
;
Done. -- 0 msec.

SQL>ap_add_phrases (5,
  vector (
    vector ('Debug5', 'Debug5 env'),
    vector ('Debug5 one', 'Debug5 one env'),
    vector ('Debug5 two', 'Debug5 two env'),
    vector ('Debug5 three', 'Debug5 three env'),
    vector ('Debug5 twenty one', 'Debug5 twenty one env'),
    vector ('Debug5 twenty two', 'Debug5 twenty two env'),
    vector ('Debug5 twenty three', 'Debug5 twenty three env')
    ) )
;
Done. -- 0 msec.
```

Detailed example can be found here .

iri_split

iri_split — Splits into the namespace prefix and the local part according to the TTL rules.

Synopsis

```
iri_split ( in qname varchar ,
            out local varchar ) ;
```

Description

Iri is a qualified name. It is split into the namespace prefix and the local part according to the TTL rules. The prefix is returned. If a second argument is given, it is set to the local part.

Parameters

qname
: namespace prefix

local
: local part

__xml_get_ns_prefix

__xml_get_ns_prefix — Returns prefix by given URI.

Synopsis

```
__xml_get_ns_prefix ( in str varchar ,
                      out flags int ) ;
```

Description

If str is a globally known namespace URI, its prefix is returned, else null. Flags is a bit mask where 1 means to look in the connection, 2 in the global set of known prefixes.

Parameters

str
: uri

flags
: bitmask of flags that permit some sorts of syntax errors in resource, use 0.

See Also

`xml_get_ns_uri` `xml_ns_uname` `xml_ns_iristr` `xml_nsexpand_iristr`

__xml_get_ns_uri

__xml_get_ns_uri — Returns URI by given namespace prefix.

Synopsis

```
__xml_get_ns_uri ( in str varchar ,
                   out flags int ) ;
```

Description

If str is a globally known namespace prefix, its URI is returned, else null. Flags is a bit mask where 1 means to look in the connection, 2 in the global set of known prefixes.

Parameters

str
: namespace prefix

flags
: A bit mask where 1 means to look in the connection, 2 in the global set of known prefixes.

`xml_get_ns_prefix()` `xml_ns_uname()` `xml_ns_iristr()` `xml_nsexpand_iristr()`

__xml_ns_uname

__xml_ns_uname — Returns an UNAME that is IRI --- concatenation of the expanded namespace IRI and the local part.

Synopsis

__xml_ns_uname (in *str1* varchar ,
in *str2* varchar) ;

Description

Returns an UNAME that is IRI -- concatenation of the expanded namespace IRI and the local part.

Parameters

str1
: Namespace prefix.

str2
: Local part (varchar).

Examples

Example 24.296. Simple Example

```
SQL> SELECT __xml_ns_uname ('foaf', 'knows');
__xml_ns_uname
VARCHAR
_______________________________________________________________________________

http://xmlns.com/foaf/0.1/knows

1 Rows. -- 0 msec.
```

__xml_ns_iristr

__xml_ns_iristr — Returns an varchar with box flag set to BF_IRI.

Synopsis

__xml_ns_iristr (in *str1* varchar ,
in *str2* varchar) ;

Description

This function is similar to the `xml_ns_uname` function, and it returns an varchar with box flag set to BF_IRI.

Parameters

str1
: Namespace prefix

str2
: Local part (varchar)

Examples

Example 24.297. Simple Example

Base64-encode a string

```
SQL> SELECT __xml_ns_iristr ('foaf', 'knows');
__xml_ns_iristr
VARCHAR
_______________________________________________________________________________

http://xmlns.com/foaf/0.1/knows

1 Rows. -- 1 msec.
```

See Also

`xml_ns_uname`

`xml_nsexpand_iristr`

`xml_get_ns_prefix`

`xml_get_ns_uri`

__xml_nsexpand_iristr

__xml_nsexpand_iristr — Checks if the string is QName and if it is so then replaces namespace prefix to the full namespace IRI.

Synopsis

__xml_nsexpand_iristr (in *str* varchar) ;

Description

Checks if the string is QName and if it is so then replaces namespace prefix to the full namespace IRI. Otherwise signals error if the argument is local IRI without a prefix.

Parameters

str
: QName. For ex. if QName is "prefix:local", then conveniently is replaced "prefix:" with the namespace IRI

Examples

Example 24.298. Example with FOAF namespace prefix

```
SQL> SELECT __xml_nsexpand_iristr ('foaf:knows');
__xml_nsexpand_iristr
VARCHAR
_______________________________________________________________________________

http://xmlns.com/foaf/0.1/knows

1 Rows. -- 0 msec.
```

Example 24.299. Example with no namespace prefix

```
SQL> SELECT __xml_nsexpand_iristr ('no-namespace-prefix-iri');

DB.DBA.SPARQL_EVAL

DB.DBA.SPARQL_EVAL — Local execution of SPARQL via SPARQL protocol, produces a result set of SQL values.

Synopsis

DB.DBA.SPARQL_EVAL (in *query* varchar ,
in *dflt_graph* varchar ,
in *maxrows* integer) ;

Description

Local execution of SPARQL via SPARQL protocol, produces a result set of SQL values.

Parameters

query
: text of SPARQL query to execute.

dflt_graph
: default graph IRI, if not NULL then this overrides what is specified in query

maxrows
: limit on numbers of rows that should be returned.

Return Types

any

Examples

Example 24.302. Simple Use

```
SQL>DB.DBA.SPARQL_EVAL('SELECT * WHERE {?s ?p ?o}','http://example/bookStore' ,10);
s                    p              o

: default graph IRI, if not NULL then this overrides what is specified in query

named_graphs
: vector of named graph IRIs, if not NULL then this overrides what is specified in query

req_hdr
: additional HTTP header lines that should be passed to the service; 'Host: ...' is most popular.

maxrows
: limit on numbers of rows that should be returned.

bnode_dict
: dictionary of bnode ID references.

metadata
: metadata like exec () returns.

resultset
: results as 'long valmode' value.

Return Types

any

DB.DBA.RDF_REGEX — Returns 1 if string s matches pattern p, 0 otherwise.

Synopsis

DB.DBA.RDF_REGEX (in *s* varchar ,
in *p* varchar ,
in *call* varchar := null) ;

Description

Returns 1 if string s matches pattern p, 0 otherwise

Parameters

s
: source string to check.

p
: regular expression pattern string.

coll
: unused for now (modes are not yet implemented).

Return Types

integer

Examples

Example 24.305. Simple example

```

DB.DBA.RDF_TTL2HASH — Returns a dict of triples in 'long valmode'.

Synopsis

DB.DBA.RDF_TTL2HASH (in *strg* any ,
in *base* varchar ,
in *graph* varchar) ;

Description

Returns a dict of triples in 'long valmode'.

Parameters

strg
: text of the resource

base
: base IRI to resolve relative IRIs to absolute

graph
: target graph IRI, parsed triples will appear in that graph.

Return Types

any

DB.DBA.RDF_QUAD_URI ( in g_uri varchar ,
                      in s_uri varchar ,
                      in p_uri varchar ,
                      in o_uri varchar ) ;
```

Description

Performs simple insertion of a quad where object is a node. The arguments g_uri, s_uri and p_uri should be IRI strings or IRI_IDs. All string arguments should be in UTF-8 encoding, otherwise they will be stored but are not queryable via SPARQL.

Parameters

g_uri
: graph uri IRI string or IRI_ID

s_uri
: subject IRI string or IRI_ID

p_uri
: predicate IRI string or IRI_ID

o_uri
: object IRI string or IRI_ID

DB.DBA.RDF_QUAD_URI_L_TYPED — Performs simple insertion of a quad where object is a literal value in 'SQL valmode' and can be specified datatype and language.

Synopsis

DB.DBA.RDF_QUAD_URI_L_TYPED (in *g_uri* varchar ,
in *s_uri* varchar ,
in *p_uri* varchar ,
in *o_lit* any ,
in *dt* any ,
in *lang* varchar) ;

Description

Performs simple insertion of a quad where object is a literal value in 'SQL valmode' and can be specified datatype and language. The arguments g_uri, s_uri and p_uri should be IRI strings or IRI_IDs. All string arguments should be in UTF-8 encoding, otherwise they will be stored but are not queryable via SPARQL.

Parameters

g_uri
: graph uri IRI string or IRI_ID

s_uri
: subject IRI string or IRI_ID

p_uri
: predicate IRI string or IRI_ID

o_uri
: string value of the literal

dt
: datatype as IRI string or IRI_ID, can be NULL

lang
: language as string or NULL

Return Types

any

Examples

Example 24.309. Simple example

```
SQL>DB.DBA.RDF_QUAD_URI_L_TYPED ('g_many', 's1', 'p_some', 'z016,g_many,s1,p_some', null, 'en');

regexp_replace

regexp_replace — Replaces occurrence(s) of the matching pattern in the source_string with a specified replace_string.

Synopsis

```
varchar regexp_replace ( in source_string any ,
                         in pattern any ,
                         in replace_string varchar ,
                         in position integer ,
                         in occurrence any ,
                         in match_parameter integer ) ;
```

Description

This function replaces occurrence(s) of the matching *pattern* in the *source_string* with a specified *replace_string*, allowing complex search-and-replace operations. The traditional REPLACE SQL function substitutes one string with another. Assume your data has extraneous spaces in the text and you would like to replace them with a single space. With the REPLACE function, you would need to list exactly how many spaces you want to replace. However, the number of extra spaces may not be the same everywhere in the text.

Parameters

source_string
: Source string.

pattern
: The regular expression to match.

replace_string
: By default an empty string, ''.

position
: By default this is set to 1.

occurrence
: By default this is set to 0. If you specify occurrence as DB NULL value it will replace all the occurrences of the pattern in the string.

match_parameter
: By default this is set to null.

Returns

This function returns the a substring matching the regular expression.

Examples

Example 24.310.

This example has three spaces between Joe and Smith. The REPLACE function's parameter specifies that two spaces should be replaced with one space. In this case, the result leaves an extra space where there were three spaces in the original string between Joe and Smith.

```
SELECT
  REPLACE('Joe  Smith', '  ', ' ') AS REPLACE_NORMAL,
  REGEXP_REPLACE('Joe        Smith', '( ){2,}', ' ') AS REGEXP_REPLACE;
```

```
REPLACE_NORMAL                REPLACE_REGEXP
VARCHAR                       VARCHAR
_____________________________________________

Joe Smith                     Joe Smith
```

Compatibility:

The regular expressions supported here follow version 7.9 of the Perl Compatible Regular Expression (PCRE) syntax.

`regexp_match()`

`regexp_like()`

`regexp_instr()`

`regexp_parse()`

`regexp_substr()`

regexp_instr

regexp_instr — Returns the first position of the occurrence of a regular-expression pattern in a given string.

Synopsis

```
integer regexp_instr ( in source_string varchar ,
                       in pattern varchar ,
                       in start_position integer ,
                       in occurrence integer ,
                       in return_option integer ,
                       in match_parameter integer ) ;
```

Description

This function looks for a pattern and returns the first position of the pattern. Optionally, you can indicate the *start_position* you want to begin the search. The *occurrence* parameter defaults to 1 unless you indicate that you are looking for a subsequent occurrence. The default value of the *return_option* is 0, which returns the starting position of the pattern; a value of 1 returns the starting position of the next character following the match.

This function returns the starting position of a pattern, so it works much like the familiar INSTR function. The main difference between the two functions is that REGEXP_INSTR lets you specify a pattern instead of a specific search string; thus providing greater versatility.

Parameters

source_string
: The string to search.

pattern
: The regular expression to match.

start_position
: The position to begin the search from.

occurrence
: Defaulting to 1, this parameter describes how many occurrences to look for.

return_option
: Default is 0, which returns the starting position of the pattern; a value of 1 returns the starting position of the next character following the match.

match_parameter
: Match parameter value.

Returns

This function returns the a substring matching the regular expression.

Examples

Example 24.311. Examples

This example uses `REGEXP_INSTR()` to return the starting position of the five-digit zip-code pattern within the string Joe Smith, 10045 Berry Lane, San Joseph, CA 91234. If the regular expression is written as :digit:?{5}, you will get the house number's starting position instead of the zip code's, because 10045 is the first occurrence of five consecutive digits. Therefore, you must anchor the expression to the end of the line, as indicated with the $ metacharacter, and the function will display the starting

position of the zip code regardless of the number of digits for the house number.

```
SELECT REGEXP_INSTR('Joe Smith, 10045 Berry Lane, San Joseph, CA 91234',
       '[[:digit:]]{5}\$')
       AS rx_instr;
  RX_INSTR
----------
        45
```

Compatibility:

The regular expressions supported here follow version 7.9 of the Perl Compatible Regular Expression (PCRE) syntax.

2. PCRE.org

See Also

`regexp_match()`

`regexp_like()`

`regexp_parse()`

`regexp_replace()`

`regexp_substr()`

regexp_like

regexp_like — Allows a like comparison using regular-expression.

Synopsis

```
integer regexp_like ( in source_string any ,
                      in pattern any ,
                      in match_parameter integer ) ;
```

Description

The source_string supports character datatypes (CHAR, VARCHAR2, CLOB, NCHAR, NVARCHAR2, and NCLOB but not LONG). The pattern parameter is another name for the regular expression. match_parameter allows optional parameters such as handling the newline character, retaining multiline formatting, and providing control over case-sensitivity.

Parameters

source_string
: Source string

pattern
: The regular expression to match. The following special classes are supported:

match_parameter
: This is null by default.

Examples

Example 24.312. Simple Use

The following SQL query's WHERE clause shows the REGEXP_LIKE operator, which searches the ZIP column for a pattern that satisfies the regular expression [^[:digit:]]. It will retrieve those rows in the ZIPCODE table for which the ZIP column values contain any character that is not a numeric digit.

```
SELECT postalcode FROM demo.demo.customers
 WHERE REGEXP_LIKE(postalcode, '[^[:digit:]]')

PostalCode
==========
 WA1 1DP
 S-958 22
 T2F 8M4
 EC2 5NT
 05432-043
.
.
```

Compatibility:
The regular expressions supported here follow version 7.9 of the Perl Compatible Regular Expression (PCRE) syntax.

registry_get

registry_get — Returns a current value of a registry setting

Synopsis

```
varchar registry_get ( in name varchar );
```

Description

registry_get is used to retrieve values stored within database registry.

Parameters

name
: Name of the registry setting

Return Values

A string value associated to the registry by registry_set. If the variable does not exist, a 0 (zero) is returned.

Examples

Example 24.313. Setting and Retrieving Registry Settings

```
SQL> select registry_get('var_demo');
callret
VARCHAR
_______________________________________________________________________

NULL

SQL> registry_set('var_demo', 'some arb data');

SQL> select registry_get('var_demo');
callret
VARCHAR
_______________________________________________________________________

some arb data
```

sequence_get_all

sequence_next

sequence_set

sequence_remove

registry_get_all

registry_get_all — Returns a vector of all registry settings

Synopsis

```
vector registry_get_all ( );
```

Description

The function returns a vector of even length that contains two elements for every registry setting that is now stored in the database: the name and the current value of the setting. The order of 'name-value' pairs in the resulting vector may vary from call to call. To search such a vector by a setting name, the vector can be passed as a second argument to the function `get_keyword ()`.

The returned vector is a full copy of the content of the registry. To change the actual registry, use `registry_set` .

Return Types

The function returns a vector of even length.

See Also

`registry_get`

`registry_set`

`registry_name_is_protected`

`registry_remove`

`sequence_get_all`

`sequence_next`

`sequence_set`

`sequence_remove`

registry_name_is_protected

registry_name_is_protected — The function checks if a given registry variable is read-only or protected from occasional changes.

Synopsis

registry_name_is_protected (in *name* varchar);

Description

Some registry variables are used solely by internal server routines so they should not be changed by any application. Some of these "protected" variables can be updated by DBA only (in built-in Virtuoso/PL routines) whereas some can not be updated by any Virtuoso/PL routine at all.

The function gets a variable name as a parameter and returns zero if such a variable variable can be created/modified/removed by any application, one if a variable can be modified by DBA but can not be removed and two if the variable can not be altered even by DBA.

The returned value does not indicate that the variable exists or not exists. The name of not yet existing variable can be protected anyway to prevent future misuse of an variable by an application.

The name of any protected variable starts with two underscores. It can be a good idea to not start names of application-specific registry variable with two underscores to ensure compatibility with future versions of Virtuoso Server.

Parameters

name
: The name of registry variable to check.

Return Types

The function returns an integer

Examples

Example 24.314. Two checks of variable names

One name can be used by any application, other is for internal use in the FTP server:

```
> select registry_name_is_protected ('my_example');
0

> select registry_name_is_protected ('__next_free_port');
1
```

sequence_remove

registry_set

registry_set — Associates a value to the name in the Database registry

Synopsis

```
registry_set ( in name varchar ,
               in value varchar ,
               in force integer ) ;
```

Description

This associates a value to the name in the Database registry. The name should be a string and the value must be also string.

Registry settings are kept in Database, therefore they are persistent.

Some registry variables are used solely by internal server routines so they should not be set by any application. Some of these "protected" variables can be updated by DBA only (in built-in Virtuoso/PL routines) whereas some can not be updated by any Virtuoso/PL routine at all. If the function is called by DBA then a third argument can be specified to indicate how the function should try to update such a variable, but you will probably never use this feature.

Parameters

name
: VARCHAR name to associate the value with.

value
: value to be stored. Must be of VARCHAR type. Also if needs to be stored some other datatype it needs to be serialized (see serialize and deserialize functions).

force
: Flag to indicate how the function should try to update protected variables. The value 0 is to signal an error on such an attempt, 1 is to try to update and signal an error if failed, 2 is to try to update and silently return 0 if failed.

Return Values

The function returns 1 if success, 0 if a (protected) variable value cannot be changed.

Errors

Table 24.74. Errors signalled by registry_set

SQLState	Error Code	Error Text	Description
22023	SR014	Function registry_set needs a string as argument 2, not an arg of [datatype]	
42000	SR483	Function registry_set needs nonzero third argument to modify registry variable [name].	
42000	SR484	Function registry_set can not modify protected registry variable [name].	

Examples

Example 24.315. Setting and Retrieving Registry Setting

From SQL

```
SQL> select registry_get('var_demo');
callret
VARCHAR
_______________________________________________________________________
```

```
NULL

SQL> registry_set('var_demo', 'some arb data');

SQL> select registry_get('var_demo');
callret
VARCHAR
_______________________________________________________________________

some arb data
```

registry_remove

sequence_get_all

sequence_next

sequence_set

sequence_remove

registry_remove

registry_remove — Remove a variable from registry

Synopsis

registry_remove (in *name* varchar) ;

Description

The function removes a given variable from registry, so future calls of registry_get returns zero.

Some registry variables are used solely by internal server routines so they should not be changed by any application. Nobody can remove such a "protected" variable even if some of them can be updated by DBA.

Parameters

name
: Name of variable to be removed.

Return Types

The function returns the last saved value of a variable or zero if the specified variable does not exists.

Errors

Table 24.75. Errors signalled by registry_set

SQLState	Error Code	Error Text	Description
22023	SR014	Function registry_remove needs a string as argument 1, not an arg of [datatype]	
42000	SR485	Function registry_remove can not remove protected registry variable [name].	

Examples

Example 24.316. Creation and Removal of a Registry Variable

This sequence of operations demonstrates that `registry_remove` reverts the effect of `registry_set` .

```
> select registry_get ('my_variable');
0

> select registry_set ('my_variable', 'my_value');
1

> select registry_get ('my_variable');
my_value

> select registry_remove ('my_variable');
my_value

> select registry_get ('my_variable');
0
```

sequence_remove

repeat

repeat — returns a new string consisting of its string argument repeated a given number of times

Synopsis

repeat (in *str* string ,
in *count* integer) ;

Description

repeat returns a new string, composed of the string str repeated count times. If count is zero, an empty string '' is returned.

```
repeat('bar',2) -> 'barbar'
```

replace

replace — This replaces every occurrence of the second argument in the first argument with the third argument.

Synopsis

```
string replace ( in string varchar ,
                 in what varchar ,
                 in repl_with varchar ) ;
```

Description

This replaces every occurrence of the second argument in the first argument with the third argument. The arguments can be narrow or wide strings.

Example 24.317. Example:

```
SQL> select replace ('12345512345', '23', '-----');
  =   1-----4551-----45
```

replay

replay — starts the roll forward of the given log

Synopsis

replay (in *log_file* varchar) ;

Description

This starts a roll forward of the given log. The log may have been produced by normal transaction logging, backup or crash dump. Logs may not be transferred between databases and thus cannot be rolled forward anywhere except on the database that generated them.

This function is for example useful after restoring a backup. It should be called for each archived transaction log produced since the backup, including and starting with the one that was current when the backup was made.

The operation blocks until the roll forward is complete. Other clients are not affected.

Errors

Parameter data type checking errors

Table 24.76. Errors signalled by

sqlstate	error code	error text
25000	SR074	replay must be run in a fresh transaction.
42000	FA002	Can't open file <fname>, error <OS errno> (<OS description>)

Parameters

log_file
: Full pathname of file containing the transactions to be replayed. The file must be produced by backup .

Return Values

Zero, if no error is signalled.

Examples

Example 24.318. Replaying A Log File

```
checkpoint 'new.log';
backup 'bak.log';
shutdown 'new2.log';
```

The above sequence of commands makes a checkpoint and starts logging subsequent transactions into new.log. The backup statement makes bak.log, which represents the state prior to starting new.log. The shutdown statement makes a new checkpoint and marks new2.log as the log file to be used for logging transactions after the database restarts. The database server exits at the completion of the SHUTDOWN statement.

```
replay ('bak.log');
replay ('new.log');
```

These statements executed on an empty database will recreate the state in effect after the last transaction to commit before the SHUTDOWN statement of the previous example.

repl_disconnect

repl_disconnect — terminates communication with a replication publisher

Synopsis

repl_disconnect (in *publisher* varchar) ;

Description

This terminates any communication with the publisher. Any pending synchronization communication is disconnected and all subscribed publications are marked as 'OFF'. The effect is reversed on a subscription by subscription basis by calling repl_sync for each.

Parameters

publisher
: Publisher's name.

Example

Example 24.319. Disconnecting from publisher server 'demo-srv'.

This is to disconnect from the publisher server 'demo-srv', the all subscriptions to this server will be disconnected.

```
SQL> repl_disconnect ('demo-srv');
```

REPL_GRANT

REPL_GRANT — grant privileges for subscription to a publication

Synopsis

REPL_GRANT (in *publication* varchar ,
in *grantee* varchar) ;

Description

This function is used to grant privilege for subscription to a SQL account for particular publication. The DBA accounts always have right for subscription to all available publications.

Parameters

publication
: A publication account name.

grantee
: A valid DB account name to be granted subscription rights.

Example

Example 24.320. Granting access to 'table_publication' for SQL user account 'demo'.

This is to grant permissions for table_publication publication account to subscribe with a SQL user account 'demo'.

```
SQL> DB.DBA.REPL_GRANT ('table_publication', 'demo');
```

REPL_INIT_COPY

REPL_INIT_COPY — create initial subscription state

Synopsis

REPL_INIT_COPY (in *server_name* varchar ,
in *publication* varchar ,
in *errors_mode* integer) ;

Description

This function is called on the subscriber to copy the current state of the elements of the publication from the publishing server. Copied data can include DAV collections, tables, procedures etc. Syncing the subscription using repl_sync will synchronize the subscription once it has been initialized with this function. The state copied corresponds to the state of the published data as of the last checkpoint completed on the publisher.

Parameters

server_name
: target publisher server name.

account
: publication account name.

errors_mode
: Important: this parameter is valid only for SQL replication data (tables and WebDAV). When set to 1, in case of errors as result of the replication copy, these errors are return in vector; When set to 0, in case of error, this error is return and the replication copying is stopped.

Example

Example 24.321. Loading of the initial data on subscriber

This shows setting on-line of the initial state of the subscription to 'demo_publication' from server 'demo-srv'. The data for items will be transferred thru the VDB connection. Note that on large publications this can take a lot of time.

```
SQL> DB.DBA.REPL_INIT_COPY ('demo-srv', 'demo_publication', 1);
```

repl_new_log

repl_new_log — create new publication log

Synopsis

repl_new_log (in *publication* varchar ,
in *file* varchar) ;

Description

This function switches to a new file for logging data for the publication. If the file is NULL a new file name will be generated based on the previous file name by appending or replacing a datetime field in the file name.

Parameters

publication
: publication account name.

file
: name of file to be used for publication's transactions logging, if size exceed 1Mb limit a new file suffixed with timestamp will be opened.

Example

Example 24.322. Opening a new replication log

This command can be issued on the publisher server to swith replication logging to the new file 'new_log_file_name.log'. In practice we make a publication with REPL_PUBLISH() and it opens the replication log file, so this is for maintenance only. Furthermore the replication server will switch to a new log suffixed with timestamp when current file is greater than 1,000,000 bytes.

```
SQL> repl_new_log ('demo-publication', 'new_log_file_name.log');
```

REPL_PUBLISH

REPL_PUBLISH — create publication on publisher

Synopsis

REPL_PUBLISH (in *publication* varchar ,
in *log_path* varchar ,
in *is_updateable* integer ,
in *sync_user* varchar) ;

Description

This function starts a publication and associates a file system file to it. The file will be used to log transaction records associated to the publication. The server will periodically start new files, so that replication log files do not grow indefinitely. New files will go to the same directory as the initial one and will have names suffixed with the date and time of their creation.

Parameters

publication
: Publication name. It must not contain spaces or special symbols.

log_path
: Full path and filename to the file where transactions to this account will be stored.

is_updateable
: If this parameter is specified and it is non-zero an updateable publication is created.

sync_user
: Local DB account used to replay replication feeds from subscribers (when publication is updateable).

Example

Example 24.323. Creating an updateable publication

This will create an updateable publication'demo-publication' with log 'demo-publication.log'. Replication feeds from subscribers will be replayed by used 'demo'.

```
SQL> DB.DBA.REPL_PUBLISH ('demo-publication', 'demo-publication.log', 1, 'demo');
```

REPL_PUB_ADD

REPL_PUB_ADD — add item to a publication

Synopsis

REPL_PUB_ADD (in *publication* varchar ,
in *item* varchar ,
in *type* integer ,
in *mode* integer ,
in *procedure_replication_options* integer) ;

Description

This function is used to add items to a pre-existing publication and to set replication options for the published items. Operations concerning the added item will henceforth be logged into the publication's log. Performing this operation will copy the item and optionally its definition to existing subscribers.

Parameters

publication
: publication account name.

item
: dependent on type should be:

type
: type of item, can accept following types:

mode
: mode of remote copy:

procedure_replication_options
: valid only in case of Virtuoso/PL procedure:

Example

Example 24.324. Adding a table to the publication

This is to add a table Demo.demo.Orders (available in the demo DataBase) to the an existing publication named table_publication. The default flag for removal when publication is dropped is set to off. The parameter mode is NULL as it has effect only for procedures.

```
SQL> DB.DBA.REPL_PUB_ADD ('table_publication', 'Demo.demo.Orders', 2, 0, NULL);
```

REPL_PUB_INIT_IMAGE

REPL_PUB_INIT_IMAGE — create initial image of publication on publisher

Synopsis

REPL_PUB_INIT_IMAGE (in *publication* varchar ,
in *image_file_path* varchar ,
in *bytes_per_file* integer) ;

Description

The image creation process forces checkpoint and runs in atomic mode.

If *image_file_path* does not contain path components (slashes or backslashes), image slices are stored in one of backup directories defined in virtuoso.ini using round-robin strategy.

This function is used to create image of publication to be replayed on a subscribed upon initial setup. This can be used when publication data is so large to be copied via repl_init_copy() which uses VDB operations. The image file(s) created by this function must be loaded on subscriber with replay() function in order of their creation (if image is split on to a several files).

Parameters

publication
: publication account name.

image_file_path
: full path to the image file where to store the initial image of publication.

bytes_per_file
: at which bytes count to split file into next slice.

Example

Example 24.325. Creating and loading of the initial image

This shows creating a image with inital data of the published items and store in the 'tbl_pub.log' file.

```
SQL> DB.DBA.REPL_PUB_INIT_IMAGE ('table_publication', 'tbl_pub.log', 1000000);
```

Furthermore the image can be loaded on a subscriber. Note that this command MUST be issued on the subscriber side. Note that REPL_PUB_INIT_IMAGE() will make more files when size of the initial file is greater than 1Mb, so in that case the additional files will be named tbl_pub.log.N where N is a sequence beginning from 1 and they also need to be loaded.

```
SQL> replay 'tbl_pub.log';
... if there a more than one image file load sequentially ...
SQL> replay 'tbl_pub.log.1';
...
```

REPL_PUB_REMOVE

REPL_PUB_REMOVE — remove item from publication.

Synopsis

REPL_PUB_REMOVE (in *publication* varchar ,
in *item* varchar ,
in *type* integer ,
in *flag* integer) ;

Description

This function is used to remove an item from existing publication. It's action is performed on publisher side and depending of flag it can send replication message to subscribers to remove this from subscription.

Parameters

publication
: publication account name.

item
: dependent on type should be:

type
: type of item, can accept following types:

flag
: Behavior on the subscriber side

Example

Example 24.326. Removal of an item from publication

This will remove the table Demo.demo.Products from publication. Furthermore issuing of the replication messages for this item will be stopped and subscriber will remove this entry from local description.

```
SQL> DB.DBA.REPL_PUB_REMOVE ('demo-publication', 'Demo.demo.Products', 2, 1);
```

REPL_REVOKE

REPL_REVOKE — revoke privileges for subscription

Synopsis

REPL_REVOKE (in *publication* varchar ,
in *grantee* varchar) ;

Description

Revokes Privileges for Subscription. This is called on the publisher to revoke access to the publication from the user account on the publisher. The subscriber will no longer gain access to the publication with this account.

Parameters

publication
: The publication name.

grantee
: A valid DB account name to be refused subscription rights.

Example

Example 24.327. Access to 'table_publication' removal for SQL user account 'demo'.

This is to remove permissions to subscribe from SQL user account 'demo' for table_publication publication account.

```
SQL> DB.DBA.REPL_REVOKE ('table_publication', 'demo');
```

REPL_SCHED_INIT

REPL_SCHED_INIT — adds scheduled job to synchronize subscriptions

Synopsis

```
REPL_SCHED_INIT (   );
```

Description

Adds scheduled job to synchronize all subscriptions. The server will attempt to start synchronization of all non-synchronized subscriptions at a 1 minute interval. The action can be reversed by deleting the corresponding row from the SYS_SCHEDULED_EVENTS table.

Example

Example 24.328. Enabling a synchronization for all subscriptions

This will enable scheduled task to synchronize all defined subscriptions.

```
SQL> DB.DBA.REPL_SCHED_INIT ();
```

REPL_SERVER

REPL_SERVER — defines a server that will participate in replication

Synopsis

REPL_SERVER (in *server_name* varchar ,
in *dsn* varchar ,
in *replication_address* varchar) ;

Description

This function defines a server that will participate in replication. The name is a symbolic name that should match the name specified as the ServerName configuration parameter in the replication section of the virtuoso.ini file of the server being defined. The address is the <host:port> where the server designated by the name is listening. The DSN is an ODBC data source name referring to the server, so that the subscriber can retrieve schema and other information. Note that replication communication itself does not take place through ODBC but that ODBC access to the publisher is required to initiate the subscription. In order to subscribe to publications from a server the server must first be declared with this function. If this function is called to define the local server, i.e. the given server name is the ServerName in the Replication section of the local ini file the function has no effect.

Parameters

server_name
: unique replication server name of publisher (specified in [Replication] -> [ServerName] section in ini file of publisher).

dsn
: data source name of publisher.

replication_address
: host:port pair of publishing server where this subscriber will connect to.

Example

Example 24.329. Adding a new publisher server

This is to define a new publisher server in the subscriber's Database. The DSN of publisher is named 'Virtuoso 1111', so it is started on the same machine on port 1111.

```
SQL> DB.DBA.REPL_SERVER ('demo-pub', 'Virtuoso 1111', '127.0.0.1:1111');
```

repl_unsubscribe()

repl_server_rename

repl_server_rename — rename the publishing server instance

Synopsis

repl_server_rename (
in *old_name* varchar ,
in *new_name* varchar) ;

Description

This function is useful to rename the publishing servers data (that stored in to the replication tables) after renaming the server in virtuoso.ini file. The call of the procedure will associate the all data belong to the old server name to the current server name. It will also set the appropriate transaction levels. In case of duplicate publications (publications with the same name exists in old and new server definitions) it will reject the operation.

Parameters

old_name
: The old name of the publishing server.

new_name
: The new name of the publishing server (must be the same as ServerName from Replication section of INI file).

Example

Example 24.330. Renaming of the existing publisher server

An existing publisher 'demo-pub' server is renamed to the 'working-pub'. In order to update the subscriber descriptions we MUST issue the following:

```
SQL> DB.DBA.REPL_SERVER_RENAME ('demo-pub', 'working-pub');
```

REPL_STAT

REPL_STAT — retrieve status of all subscriptions and publications

Synopsis

```
REPL_STAT (   );
```

Description

Retrieves status of all subscriptions and publications. This function is for interactive use (via ISQL tool).

Example

Example 24.331. Retrieving of the replication status

This is to show status of the subscriptions. The server shows the name of publisher, account is a name of the publication account, level is a current level of the publication and stat is a current status of the publication/subscription. Note that status for local publications are shown always as OFF, it is to show only subscription status.

```
SQL> DB.DBA.REPL_STAT ();
server                    account                   level       stat
VARCHAR                   VARCHAR                   INTEGER     INTEGER
_______________________________________________________________________________

my-rep                    my-rep                    0           OFF
demo-rep1                 demo_tb                   3           IN SYNC
```

repl_status

repl_status — returns status of a published or subscribed publication

Synopsis

repl_status (in *publisher* varchar ,
in *publication* varchar ,
out *level* integer ,
out *stat* integer) ;

Description

Given a publisher and publication name this returns the status of the publication on the local server.

Parameters

publisher
: Name of the publisher.

publication
: Name of the publication.

level
: If the publisher is the name of the local server this returns the next transaction number to be assigned to a transaction as the level output parameter.

stat
: The stat output parameter reflects the current state of the subscription. If the publisher is the local server the stat is always 0. Otherwise it has the following possible values:

Example

Example 24.332. Retrieving the subscription status

This example shows an analogue of the REPL_STAT() function.

```
create procedure MY_REPL_STAT ()
{
  declare server, account, status varchar;
  declare level, stat integer;
  status := vector ('OFF', 'SYNCING', 'IN SYNC', 'REMOTE DISCONNECTED', 'DISCONNECTED', 'TO DISCONNECT');
  result_names (server, account, level, stat);
  for select SERVER, ACCOUNT from DB.DBA.SYS_REPL_ACCOUNTS do
    {
      repl_status (SERVER, ACCOUNT, level, stat);
        result (SERVER, ACCOUNT, level, aref (status, stat));
    }
};
```

REPL_SUBSCRIBE

REPL_SUBSCRIBE — add a subscription

Synopsis

```
REPL_SUBSCRIBE ( in server_name varchar ,
                 in publication varchar ,
                 in dav_user varchar ,
                 in dav_group varchar ,
                 in replication_user varchar ,
                 in replication_password varchar ,
                 in sync_user varchar ) ;
```

Description

This function is used to subscribe to an existing publication, and to specify the local WebDAV owner for replicated WebDAV content. Before making a subscription the `repl_server()` function must be called in order to define the publishing server. After making a subscription it becomes off-line awaiting synchronization from a scheduled task or call to the `repl_sync()` function. Also the initial data of the subscription will be not loaded until `repl_init_copy()` is called or the initial image has been loaded.

Parameters

server_name
: target publisher server name.

publication
: publication account name.

dav_user
: A valid local WebDAV user account name that will own local copy. If this is null 'REPLICATION' user account will be created that will be disabled by default.

dav_group
: A valid local WebDAV group name to own the local copy.

replication_user
: Is used for authentication on the publisher. This should be a valid DB account on publisher.

replication_password
: Is used for authentication on the publisher. This should be valid password for replication_user on publisher.

sync_user
: A local DB account used to replay replication feeds.

Example

Example 24.333. Subscribing to a publication

This example shows making a subscription to the 'table_publication' published on a 'demo-srv' server. The WebDAV items will belong to the WebDAV administrator.

```
SQL> DB.DBA.REPL_SUBSCRIBE ('demo-srv','demo-publication', 'dav', 'dav', 'demo', 'demo');
```

repl_sync

repl_sync — starts the syncing process against an existing subscription

Synopsis

```
repl_sync ( in publisher varchar ,
            in publication varchar ,
            in uid varchar ,
            in password varchar ) ;
```

Description

This starts the syncing process against an existing subscription. The function returns as soon as the request has been successfully sent. The synchronization will take place in the background. If the syncing process is already underway or if the subscriber is already in sync and connected to the publisher this function has no effect. If there is no connection to the publisher at the time of calling this function and the connection fails and an error is immediately signalled. To initiate a synchronization a valid SQL account must be specified. Also the account must have rights to the publication unless publisher DBA's account is used to connect.

Parameters

publisher
: The server name of the publisher.

publication
: The name assigned to the publication.

uid
: SQL account with rights to the publication, or publishers DBA account credentials will be required.

password
: SQL account password.

Example

Example 24.334. Synchronizing a subscription

The following shows requesting a sync from publisher for an existing subscription. The account for authentication is a 'repl_user' SQL account.

```
SQL> repl_sync ('demo-srv', 'demo-publication', 'repl_user', 'repl_passwd');
```

repl_sync_all — synchronize all subscriptions

Synopsis

```
repl_sync_all (   );
```

Description

This function is used to synchronize all subscriptions. It make a synchronization requests to the all publisher and will return immediately after that. The status of subscriptions can be tested with repl_stat() function.

Example

Example 24.335. Synchronizing all subscriptions

This will start synchronization of all subscriptions.

```
SQL> repl_sync_all ();
```

repl_text

repl_text — adds a SQL statement to the log of the replication

Synopsis

repl_text (in *publication* varchar ,
in *sqltext* varchar ,
in *a-1* any ,
...) ;

Description

This SQL function adds the SQL statement to the log of the publication. The statement will typically be a procedure call but can be any SQL statement. There can be a parameters, which are bound to ?'s in the statement's text from left to right. There is no restriction on the number of parameters.

Parameters

publication
: The name of the target publication

sqltext
: sql expression with unnamed parameters if needed.

a-1 ... a-n
: parameter value, in order as in sqltext parameter.

Example

Example 24.336. Logging a SQL statement into a publication

Suppose on subscriber side we have a table 'foo' with two columns (integer and varchar). This statement will send a replication message to the subscribers to insert a row into the table 'foo'.

```
SQL> repl_text ('demo-publication', 'insert into foo values (?, ?)', 1, 'this is a test');
```

repl_this_server

repl_this_server — returns calling servers name

Synopsis

repl_this_server ( );

Description

Returns calling servers name.

Return Types

Returns the calling server's logical name, set by the ServerName entry in the Replication section of its virtuoso.ini file.

Example

Example 24.337. Local replication server name

The example statement shows name of the current replication server (defined in the INI file).

```
SQL> select repl_this_server();
callret
VARCHAR
_______________________________________________________________________________

demo-srv
```

REPL_UNPUBLISH

REPL_UNPUBLISH — drop publication on publisher

Synopsis

REPL_UNPUBLISH (in *publication* varchar) ;

Description

This function is used to remove from current replication set an existing publication. The replication messages for all existing items will be stopped, so the last replication message will instruct the subscribers that this publication is dropped. On subscriber side depending of the copy mode of items they can be removed or not, but the description entry for that publication will be removed explicitly. Any existing grants to the publication being dropped will be revoked.

Parameters

publication
: publication account name.

Example

Example 24.338. Dropping a publication

The following statement will remove the publication 'demo-publication' account from current replication set.

```
SQL> DB.DBA.REPL_UNPUBLISH ('demo-publication');
```

REPL_UNSUBSCRIBE

REPL_UNSUBSCRIBE — drop subscription

Synopsis

REPL_UNSUBSCRIBE (in *server_name* varchar ,
in *publication* varchar ,
in *item* varchar) ;

Description

This function is used to stop receiving a replication messages from a publisher server for a item or whole subscription. It will be invoked automatically when a publication is dropped. The subscriber can also invoke this function to stop receiving replication messages. The existing items can be dropped or not depending on the copy mode flag. The description entries for that subscription will be removed. There is no "undo" ability. To temporally halt the replication messages you can use repl_disconnect().

Parameters

server_name
: Name of the target publishing server.

publication
: The name of the publication.

item
: The item to removed. NULL can be supplied to remove all items.

Example

Example 24.339. Unsubscribing from a publication.

This is to stop replication on subscription 'demo-publication' from publisher server 'demo-srv'.

```
SQL> DB.DBA.REPL_UNSUBSCRIBE ('demo-srv', 'demo-publication', NULL);
```

repl_purge

repl_purge — purges transactional replication logs for specified account

Synopsis

repl_purge (in *server* varchar ,
in *account* varchar) ;

Description

This procedure purges transactional replication logs for specified account. Logs whose start replication level lags more than REPL_MAX_DELTA (1000000000) transactions behind current replication level of a specified account are removed. After `repl_purge()` is finished next `repl_purge()` run is scheduled using SYS_SCHEDULED_EVENT facility.

Account sync requests from subscribers are delayed while `repl_purge()` is running for this account.

Parameters

server
: The server name of the publisher.

account
: The name assigned to the publication.

Example

Example 24.340. Purging transactional replication logs

The following shows purging transactional replication logs for pushback account for updateable subscription 'demopub' from 'demoserver':

```
SQL> repl_purge ('demoserver', '!demopub');
```

REPL_CREATE_SNAPSHOT_PUB

REPL_CREATE_SNAPSHOT_PUB — Create bi-directional snapshot publication

Synopsis

```
None REPL_CREATE_SNAPSHOT_PUB ( in item varchar ,
                                in type integer ) ;
```

Description

This procedure should be used to create a bi-directional snapshot publication. If the *item* parameter is a table then this procedure creates an updateable snapshot log and generates an updating procedure.

Parameters

item
: Item is a DAV collection or table name.

type
: Type is used to denote the type of Item: 1 if item is a DAV collection, or 2 if item is a table name.

Return Types

None.

Examples

Example 24.341. Creating bi-directional snapshot publication

The following statement creates bi-directional snapshot publication of table 'Demo.demo.Shippers':

```
SQL> DB.DBA.REPL_CREATE_SNAPSHOT_PUB ('Demo.demo.Shippers', 2);
```

The following statement creates bi-directional snapshot publication of DAV collection '/DAV/doc':

```
SQL> DB.DBA.REPL_CREATE_SNAPSHOT_PUB ('/DAV/doc', 1);
```

REPL_UPDATE_SNAPSHOT()

REPL_SNP_SERVER()

REPL_SERVER_NAME()

REPL_CREATE_SNAPSHOT_SUB

REPL_CREATE_SNAPSHOT_SUB — Create bi-directional snapshot subscription to an existing publication.

Synopsis

```
None REPL_CREATE_SNAPSHOT_SUB ( in server varchar ,
                                in item varchar ,
                                in type integer ) ;
```

Description

This procedure should be used to create a bi-directional snapshot subscription.

Note:
This function should be run on publisher.

Parameters

server
: The name of the server defined with REPL_SNP_SERVER() . The name of the server can be obtained using REPL_SERVER_NAME() function.

item
: Item is a DAV collection or table name.

type
: Type is used to denote the type of Item: 1 if item is a DAV collection, or 2 if item is a table name.

Return Types

None.

Examples

Example 24.342. Creating bi-directional snapshot subscription

The following statement creates bi-directional snapshot subscription of server with DSN 'localhost:1121' for table 'Demo.demo.Shippers':

```
SQL> DB.DBA.REPL_CREATE_SNAPSHOT_SUB (REPL_SERVER_NAME ('localhost:1121'), 'Demo.demo.Shippers', 2);
```

The following statement creates bi-directional snapshot subscription of server with DSN 'localhost:1121' for DAV collection '/DAV/doc':

```
SQL> DB.DBA.REPL_CREATE_SNAPSHOT_SUB (REPL_SERVER_NAME ('localhost:1121'), '/DAV/doc', 1);
```

REPL_DROP_SNAPSHOT_SUB

REPL_DROP_SNAPSHOT_SUB — Drops a subscription to a bi-directional snapshot publication

Synopsis

```
None REPL_DROP_SNAPSHOT_SUB ( in server varchar ,
                              in item varchar ,
                              in type integer ) ;
```

Description

This procedure drops a subscription to a snapshot publication.

Note:
This function should be run on publisher.

Parameters

server
: The name of the server defined with REPL_SNP_SERVER() . The name of the server can be obtained using REPL_SERVER_NAME() function.

item
: Item is a DAV collection or table name.

type
: Type is used to denote the type of Item: 1 if item is a DAV collection, or 2 if item is a table name.

Return Types

None.

Examples

Example 24.343. Dropping bi-directional snapshot subscription

The following statement drops bi-directional snapshot subscription of server with DSN 'localhost:1121' for table 'Demo.demo.Shippers':

```
SQL> DB.DBA.REPL_DROP_SNAPSHOT_SUB (REPL_SERVER_NAME ('localhost:1121'), 'Demo.demo.Shippers', 2);
```

REPL_DROP_SNAPSHOT_PUB

REPL_DROP_SNAPSHOT_PUB — Drop bi-directional snapshot publication

Synopsis

```
None REPL_DROP_SNAPSHOT_PUB ( in item varchar ,
                              in type integer ) ;
```

Description

This procedure drops a snapshot publication.

Parameters

item
: Item is a DAV collection or table name.

type
: Type is used to denote the type of Item: 1 if item is a DAV collection, or 2 if item is a table name.

Return Types

None.

Examples

Example 24.344. Dropping bi-directional snapshot publication

The following statement drops bi-directional snapshot publication of table 'Demo.demo.Shippers':

```
SQL> DB.DBA.REPL_DROP_SNAPSHOT_PUB ('Demo.demo.Shippers', 2);
```

REPL_INIT_SNAPSHOT

REPL_INIT_SNAPSHOT — Initializes a bi-directional snapshot publication

Synopsis

```
None REPL_INIT_SNAPSHOT ( in server varchar ,
                          in item varchar ,
                          in type integer ,
                          in how_many integer ) ;
```

Description

This procedure should be used to initialize a bi-directional snapshot publication.

Note:
This function should be run on publisher.

Parameters

server
: The name of the server defined with REPL_SNP_SERVER() . The name of the server can be obtained using REPL_SERVER_NAME() function.

item
: Item is a DAV collection or table name.

type
: Type is used to denote the type of Item: 1 if item is a DAV collection, or 2 if item is a table name.

how_many
: This parameter specifies the number of copied rows per transaction during doing initial copy in table case (when type is 2).

Return Types

None.

Examples

Example 24.345. Initializing bi-directional snapshot subscription

The following statement does initial copy of data for bi-directional snapshot subscription of server with DSN 'localhost:1121' for table 'Demo.demo.Shippers':

```
SQL> DB.DBA.REPL_INIT_SNAPSHOT (REPL_SERVER_NAME ('localhost:1121'), 'Demo.demo.Shippers', 2);
```

REPL_DROP_SNAPSHOT_PUB()
```

REPL_UPDATE_SNAPSHOT

REPL_UPDATE_SNAPSHOT — Updates a bi-directional snapshot publication

Synopsis

```
None REPL_UPDATE_SNAPSHOT ( in item varchar ,
                            in type integer ) ;
```

Description

This procedure should be used to update a bi-directional snapshot publication. This procedure pulls all the updates from subscribers (with conflict resolution) and then pushes all the updates from publisher to all the subscribers.

Note:
This function should be run on the publisher.

Parameters

item
: Item is a DAV collection or table name.

type
: Type is used to denote the type of Item: 1 if item is a DAV collection, or 2 if item is a table name.

Return Types

None.

Examples

Example 24.346. Updating bi-directional snapshot

The following statement updates bi-directional snapshot publication of table 'Demo.demo.Shippers'.

```
SQL> REPL_UPDATE_SNAPSHOT ('Demo.demo.Shippers', 2);
```

REPL_SNP_SERVER()

REPL_SERVER_NAME()

REPL_SNP_SERVER

REPL_SNP_SERVER — Define bi-directional snapshot replication server name

Synopsis

```
varchar REPL_SNP_SERVER ( in dsn varchar ,
                          in uid varchar ,
                          in pwd varchar ) ;
```

Description

This function should be used to define a server for bi-directional snapshot replication.

Parameters

dsn
: Dsn is a data source name.

uid
: Uid is data source user name.

pwd
: Uid is data source password.

Return Types

REPL_SNP_SERVER() returns remote server name which can be used in calls to `REPL_CREATE_SNAPSHOT_SUB()`, `REPL_DROP_SNAPSHOT_SUB()` and `REPL_INIT_SNAPSHOT_SUB()` functions.

Examples

Example 24.347. Defining bi-directional snapshot replication server

The following statement defines bi-directional replication server for server with DSN 'localhost:1121':

```
SQL> REPL_SNP_SERVER ('localhost:1121', 'dba', 'dba');
```

`REPL_SERVER_NAME()`

REPL_SERVER_NAME

REPL_SERVER_NAME — Return bi-directional snapshot replication server name for specified DSN

Synopsis

```
varchar REPL_SERVER_NAME ( in dsn varchar );
```

Description

This function should be used to determine bi-directional snapshot replication server name.

Parameters

item
: Dsn is a data source name.

Return Types

REPL_SERVER_NAME() returns remote server name which can be used in calls to `REPL_CREATE_SNAPSHOT_SUB()`, `REPL_DROP_SNAPSHOT_SUB()` and `REPL_INIT_SNAPSHOT_SUB()` functions.

Examples

Example 24.348. Obtaining replication server name

The following statement demonstrates obtaining replication server name for server with DSN 'localhost:1121':

```
SQL> select REPL_SERVER_NAME ('localhost:1121');
callret
VARCHAR
_______________________________________________________________________________

demoserver2

1 Rows. -- 4 msec.
```

REPL_ADD_CR

REPL_ADD_CR — Creates conflict resolver for bi-directional transactional replication

Synopsis

```
None REPL_ADD_CR ( in tbl varchar ,
                   in name_suffix varchar ,
                   in type char ,
                   in order integer ,
                   in class varchar ,
                   in col varchar ) ;
```

Description

Simple conflict resolvers can be generated by calling this function.

Parameters

tbl
: Name of table for which conflict resolved is required.

name_suffix
: Conflict resolver name suffix.

type
: The resolved type, one of: ('I', 'U' OR 'D').

order
: Resolver order number.

class
: The kind of resolver. Class can be one of the following:

col
: This should specify the column name if class is not one of 'pub_wins', 'sub_wins' or 'custom'.

Return Types

None.

Examples

Example 24.349. Conflict Resolver

Suppose we have the following table:

```
create table items(
  item_id integer primary key,

  name varchar,
  count decimal
);
```

A 'U' conflict resolver that increments items.count in publisher table can be defined with the following statement:

```
REPL_ADD_CR('DB.DBA.items', 'count', 'U', 10, 'add', 'count');
```

REPL_ADD_DAV_CR

REPL_ADD_DAV_CR — Creates conflict resolver for bi-directional replication in DAV

Synopsis

```
None REPL_ADD_DAV_CR ( in col varchar ,
                       in name_suffix varchar ,
                       in order integer ,
                       in class varchar ) ;
```

Description

Simple conflict resolvers for DAV bi-directional replication can be generated by calling this function.

Parameters

col
: Collection for which to generate a conflict resolver for.

name_suffix
: Conflict resolver name suffix.

order
: Resolver order number.

class
: class can be one of the following:

Return Types

None.

Examples

Example 24.350. Conflict Resolver

A conflict resolver that chooses a resource with minimal creation time can be defined with the following statement:

```
REPL_ADD_DAV_CR('/DAV/regress', 'min_ctime', 100, 'min_ctime');
```

See Also

`REPL_ADD_SNAPSHOT_CR()`

REPL_ADD_SNAPSHOT_CR

REPL_ADD_SNAPSHOT_CR — Creates conflict resolver for bi-directional replication

Synopsis

```
None REPL_ADD_SNAPSHOT_CR ( in tbl varchar ,
                            in name_suffix varchar ,
                            in type char ,
                            in order integer ,
                            in class varchar ,
                            in col varchar ) ;
```

Description

Simple conflict resolvers can be generated by calling this function.

Parameters

tbl
: Name of table for which conflict resolved is required.

name_suffix
: Conflict resolver name suffix.

type
: The resolved type, one of: ('I', 'U' OR 'D').

order
: Resolver order number.

class
: The kind of resolver. Class can be one of the following:

col
: This should specify the column name if class is not one of 'pub_wins', 'sub_wins' or 'custom'.

Return Types

None.

Examples

Example 24.351. Conflict Resolver

Suppose we have the following table:

```
create table items(
  item_id integer primary key,

  name varchar,
  price decimal
);
```

A 'U' conflict resolver that averages items.price in publisher table can be defined with the following statement:

```
REPL_ADD_SNAPSHOT_CR('DB.DBA.items', 'count', 'U', 10, 'ave', 'price');
```

See Also

REPL_ADD_DAV_CR()

RDF_REPL_START

RDF_REPL_START — Enables RDF Replication.

Synopsis

```
RDF_REPL_START (   );
```

Description

This function is called to enable (start) RDF Publication.

Example

Example 24.352. Enable RDF Publication

```
SQL> DB.DBA.RDF_REPL_START();
```

RDF_REPL_STOP

RDF_REPL_STOP — Stops the RDF replication at the publishing side

Synopsis

RDF_REPL_STOP (in *quiet* integer := 0) ;

Description

This function stops the RDF replication at the publishing side. It calls `repl_unpublish` but does not make empty reates replication "publication" named '__rdf_repl' and makes a log file '__rdf_repl.log' to record changes in replicated graphs.

Parameters

quiet
: Sets silent operation mode on / off i.e. 1/ 0. Default is 0 -- errors are shown. If set to 1 -- no errors are shown.

Example

Example 24.353. Enable RDF Publication

```
SQL> DB.DBA.RDF_REPL_STOP ();
```

RDF_REPL_SYNC

RDF_REPL_SYNC — Starts the syncing process against an existing RDF subscription

Synopsis

RDF_REPL_SYNC (in *publisher* varchar ,
in *user* varchar ,
in *user_pwd* varchar) ;

Description

This function starts the syncing process against an existing RDF subscription. It will not only initial synchronisation but also wait for the end of subscription to guarantee that the total effect of INSERT and DELETE operations is correct even if these operations were made in an order that differs from the original one.

Parameters

publisher
: The server name of the publisher.

user
: SQL account with rights to the publication, or publishers DBA account credentials will be required.

user_pwd
: SQL account password.

Example

Example 24.354. Enable RDF Publication

```
SQL> DB.DBA.RDF_REPL_SYNC ('demo-rdf-srv', 'repl_user', 'repl_passwd');
```

RDF_REPL_GRAPH_INS

RDF_REPL_GRAPH_INS — Inserts graph to RDF publication.

Synopsis

RDF_REPL_GRAPH_INS (in *graph* varchar) ;

Description

This function inserts graph to enabled RDF Replication. The graphs in this replication can be more than one.

Parameters

graph
: Graph URI to be inserted.

Example

Example 24.355. Insert graph to RDF replication

```
SQL> DB.DBA.RDF_RDF_REPL_GRAPH_INS ('http://test.org');
```

Example 24.356. Replicate all graphs

To replicate all graphs (except the system graph http://www.openlinksw.com/schemas/virtrdf#), one should use http://www.openlinksw.com/schemas/virtrdf#rdf_repl_all as graph IRI:

```
SQL> DB.DBA.RDF_RDF_REPL_GRAPH_INS ('http://www.openlinksw.com/schemas/virtrdf#rdf_repl_all');
```

RDF_REPL_GRAPH_DEL

RDF_REPL_GRAPH_DEL — Deletes graph from RDF publication.

Synopsis

RDF_REPL_GRAPH_DEL (in *graph* varchar);

Description

This function deletes graph from RDF Replication.

Parameters

graph
: Graph URI to be deleted.

Example

Example 24.357. Delete graph from RDF replication

```
SQL> DB.DBA.RDF_RDF_REPL_GRAPH_DEL ('http://test.org');
```

result

result — Sends one row of results to the calling client.

Synopsis

result (in *col_1* any ,
.. ,
in *col_n* any) ;

Description

The result_names() predefines variables to be used in a result set to follow. The variables must be previously declared, from which the column data types are ascertained. This assigns the meta data but does not send any results. The result() function sends its parameters as a single row of results. These parameters should be compatible with those in the previous result_names() . The end_results() function can be used to separate multiple result sets. The result_names() can then be used to alter the structure of the next result set.

The result_names() call can be omitted if the application already knows what columns and their types are to be returned.

Parameters

col_1, ..., col_n
: The data to be sent to the client.

Examples

Example 24.358.

This example demonstrates outputting multiple result sets from a stored procedure. This procedure can be entered using ISQL but ISQL does not support multiple result sets. To view the output you can use the the sample application odbc test or another application that supports multiple result sets. The RES procedure below returns two result sets -- the first has two rows and the second has four rows. The result_names function gives each result column a type and title. This can be omitted if the application knows which columns to expect. The result function sends the actual result row. The end_result function indicates that a new result set will begin. These functions can be used inside loops or subprocedures, thus allowing with one call to yield a variable number of result sets.

```
CREATE PROCEDURE RES (IN I INTEGER)
{
  DECLARE STR, STR2 VARCHAR;

  RESULT_NAMES (I, STR);
  RESULT (I, 'FIRST');
  RESULT (I + 1, 'SECOND');
  RESULT_NAMES (I, STR, STR2);

  END_RESULT ();

  RESULT (I, 'FIRST');
  RESULT (I + 1, 'SECOND');
  RESULT (I + 2, 'THIRD', 'FF');
  RESULT (I + 3, 'FOURTH', 'FF');

  RETURN 1;
}
```

result_names

result_names

Synopsis

```
result_names ( in var_1 ,
               ... ,
               in var_n ) ;
```

Description

The `result_names()` predefines variables to be used in a result set to follow. The variables must be previously declared, from which the column data types are ascertained. This assigns the meta data but does not send any results. The `result()` function sends its parameters as a single row of results. These parameters should be compatible with those in the previous `result_names()` . The `end_results()` function can be used to separate multiple result sets. The `result_names()` can then be used to alter the structure of the next result set.

The `result_names()` call can be omitted if the application already knows what columns and their types are to be returned.

Parameters

var_1, ..., var_n
: The column variables previously declared or otherwise.

`end_result()`

rexecute

rexecute — execute a SQL statement on a remote DSN

Synopsis

```
rexecute ( in dsn varchar ,
           in sql_stmt varchar ,
           out sql_state varchar ,
           out error_message varchar ,
           in in_params vector ,
           out num_cols integer ,
           out stmt_meta vector ,
           out result_set vector ,
           out cursor_handle long ) ;
```

Description

This function can be used to execute SQL on a remote data source directly.

The *result_set* parameter is useful for obtaining a result-set quickly and easily. However, if the result-set is going to be large, this comes at a cost in terms of time and resources, particularly memory, since Virtuoso will have to obtain all results from the statement and build the result-set arrays in memory before returning back to the caller.

A more efficient way is to obtain a cursor handle and iterate through the result set one row at a time:

Use `rexecute()` to get the cursor handle.
Iterate over the results with `rnext()`
If `rmoreresults()` does not return an error or `SQL_NO_DATA_FOUND` continue the loop with `rnext()` , otherwise close the cursor with `rclose()`

To keep Virtuoso from obtaining the whole result set from the remote, pass NULL as the *result_set* parameter when calling rexecute.

`Rexecute()` supports IN parameters and can also support INOUT and OUT parameters. If INOUT and OUT parameters are to be used then cursors should not be used with this function (as the values of output parameters in ODBC are not guaranteed to be set before SQLMoreResults() returns SQL_NO_DATA_FOUND). `Rexecute` supports INOUT and OUT parameters by extending the *in_params* vector and requiring it to be a PL variable so values can be set back to it.

Unless explicitly granted, only the DBA group is permitted to use the `rexecute()` to maintain security. Caution is required here since any user granted use of `rexecute()` has full control of the remote data source set-up by the DBA, however limited to the overall abilities of the remote user on the remote data source. Users can be granted and denied access to this function using the following commands:

```
GRANT REXECUTE ON '<attached_dsn_name>' TO <user_name>
REVOKE REXECUTE ON '<attached_dsn_name>' FROM <user_name>
```

Note:
`rstmtexec()` provides a short-hand to this function.

Parameters

dsn

The data source where the SQL statement should be executed. You must make sure that you have already defined the data source using the vd_remote_data_source function or by attaching tables from it.

sql_stmt

the SQL statement to execute.

sql_state
: A varchar containing the SQL State returned from the remote data source.

error_message
: A varchar containing any error message returned from the remote.

in_params
: A vector of parameters to the statement if the executed statement has parameters. IN input parameters are specified as literals whereas OUT and INOUT parameters are specified as vectors of 3 elements for OUT and 4 elements for INOUT as follows:

num_cols
: Number of columns in the result set if the statement returned one.

stmt_meta
: A vector containing result metadata, etc.

result_set
: A vector of vectors containing each row in the result set.

cursor_handle
: The cursor handle (long).

Examples

Example 24.359. Remote execute example 1

Remote execute, retrieving the whole result from remote at once.

```
create procedure
test_rexecute_1 (in remote_dsn varchar)
{
  declare stmt varchar;
  declare mdta_out any;
  declare res_vec_out, param_vec any;
  declare sql_state, err_msg varchar;
  declare inx integer;
  declare num_cols_out integer;

  declare Company, Contact varchar;
  result_names (Company, Contact);

  stmt := 'SELECT CompanyName, ContactName FROM \
            Demo.Demo.Customers WHERE CompanyName BETWEEN ? and ?';
  sql_state := '00000';
  param_vec := vector ('A', 'B');

  rexecute (remote_dsn, stmt, sql_state, err_msg, param_vec,
            num_cols_out, mdta_out, res_vec_out, NULL);

  if (sql_state <> '00000')  -- See if we got an error
    {
      signal ('ZILCH',
              concat ('Remote execution returned ',
                      sql_state, ' ', err_msg));
    }

  -- now iterate through result set stored in res_vec_out

  inx := 0;
  while (inx < length (res_vec_out))
    {
      result (aref (aref (res_vec_out, inx), 0),
              aref (aref (res_vec_out, inx), 1));
      inx := inx + 1;
```

```
    }

  end_result ();
}

SQL> test_rexecute_1 ('Local Virtuoso Demo');
Company                   Contact
VARCHAR                   VARCHAR
_______________________________________________________________________________

4 Rows. -- 4 msec.
```

Example 24.360. Remote execute example 2

Remote execute, retrieving the result using returned cursor handle.

```
create procedure
test_rexecute_2 (in remote_dsn varchar, in max_results integer)
{
  declare stmt varchar;
  declare mdta_out any;
  declare res_vec_out, param_vec any;
  declare sql_state, err_msg varchar;
  declare inx integer;
  declare num_cols_out integer;
  declare cursor_out any;

  declare Company, Contact varchar;
  result_names (Company, Contact);

  stmt := 'SELECT CompanyName, ContactName FROM \
            Demo.Demo.Customers WHERE CompanyName BETWEEN ? and ?';
  sql_state := '00000';
  param_vec := vector ('A', 'Z');

  rexecute (remote_dsn, stmt, sql_state, err_msg, param_vec,
            num_cols_out, mdta_out, NULL, cursor_out);

  if (sql_state <> '00000')  -- See if we got an error
    {
      signal ('ZILCH',
              concat ('Remote execution returned ',
                      sql_state, ' ', err_msg));
    }

  -- now iterate through result set with cursor

  while (0 = rnext (cursor_out, res_vec_out) and inx < max_results)
    {
      result (aref (res_vec_out, 0), aref (res_vec_out, 1));
      inx := inx + 1;
    }

  rclose (cursor_out);
  end_result ();
}

SQL> test_rexecute_2 ('Local Virtuoso Demo', 10);
Company                   Contact

Example 24.361. Remote execute example 3

Remote DBMS native SQL execution

```
create procedure test_rexecute_3 (in remote_dsn varchar, in max_results integer)
{
    declare res_vec_out, param_vec, mdta_out, cursor_out any;
    declare url, stmt, sql_state, err_msg varchar;
    declare num_cols_out, inx, _id integer;

    result_names(_id,url);

    stmt := 'select id from mysql_pk';

    sql_state := '00000';
    param_vec := vector ('');

    rexecute (remote_dsn, stmt, sql_state, err_msg, param_vec, num_cols_out, mdta_out, NULL, cursor_out);

    _id := '';

    if (sql_state <> '00000')  -- See if we got an error
    {
      signal ('ZILCH',concat ('Remote execution returned ', sql_state, ' ', err_msg));
    }

    -- now iterate through result set stored in cursor_out
    inx := 0;
    while (0 = rnext (cursor_out, res_vec_out) and inx < max_results)
    {
      _id := aref (res_vec_out, 0);
      {
        whenever not found goto znext;
        select url into url from rdfstore_mysql where id = _id;
      }

       result(_id, url);

       if (0 = mod (inx, 5000))
       {
         log_message(sprintf ('%d rows copied, stay patient (id: %d)', inx, _id));
       }

        znext:;
        inx := inx + 1;
    }

  rclose (cursor_out);
  end_result ();
};
```

Example 24.362. Remote procedures with OUT params.

The following example demonstrates the use of OUT params using a sample remote procedure stored in another Virtuoso server, although this can be any database of course, and a local procedure that uses the `rexecute()` to execute it.

```
--On remote virtuoso:
create procedure FUNCRET (in data varchar) returns varchar { return concat (data, 'Out'); };

--On local virtuoso:
create procedure call_FUNCRET (in data varchar, in DSN varchar) returns integer
{
   declare params any;
   params := vector (
             vector ('out', 'varchar', 50), -- an OUT VARCHAR parameter for the result
                                            -- 50 here means receive no more than 50 bytes of
                                            -- the output value
             data                           -- the IN parameters are passed as usual
            );
   rexecute (DSN, '{?=call FUNCRET(?)}',
            null, null,
            params); -- params should be a PL variable, as it will hold the substituted
                     -- output values for the OUT and INOUT parameters upon return.
   -- retrieve the output value of the first parameter (i.e.
   -- the function return value) and return it:
   return params[0];
};
```

This should return as follows:

```
select call_FUNCRET ('abc', 'Local Virtuoso Demo');
---------------------------
abcOut
```

Example 24.363. Remote procedures with INOUT params.

As well as OUT parameters INOUT parameters can be used. Consider the following variation of the above example:

```
--On remote Virtuoso:
create procedure INOUT_PROC (inout DATA varchar)
{
   DATA := concat (DATA, 'InOut');
};

--On local Virtuoso:
create procedure call_INOUT_PROC (in DATA varchar, in DSN varchar) returns varchar
{
  declare params any;
  params := (
          vector ('inout', 'VARCHAR', 50, DATA) -- note we pass 4 element array for INOUT,
                                                -- as we need the input value for the parameter
             );
  rexecute (DSN, '{call INOUT_PROC (?)}',
                 null, null,
                 params);
  return params[0];
};
```

This, when called returns:

```
select call_INOUT_PROC ('abc', 'Local Virtuoso Demo');
----------------------
abcInOut
```

`rstmtexec()`, `rnext()`, `rmoreresults()`, `rclose()`

rstmtexec

rstmtexec — execute a SQL statement on a remote DSN, provides a result set where applicable.

Synopsis

rstmtexec (in *dsn* varchar ,
in *stmt* varchar ,
in *max_rows* integer ,
in *params_array* vector) ;

Description

This function can be used to execute SQL on a remote data source directly. It returns a result set where one is expected.

This function is wrapper for the `rexecute()` provided for convenience as a shortcut.

Unless explicitly granted, only the DBA group is permitted to use the `rstmtexec()` to maintain security. Caution is required here since any user granted use of `rstmtexec()` has full control of the remote data source set-up by the DBA, albeit limited to the overall abilities of the remote user on the remote data source. Users can be granted and denied access to this function using the following commands:

```
GRANT REXECUTE ON '<attached_dsn_name>' TO <user_name>
REVOKE REXECUTE ON '<attached_dsn_name>' FROM <user_name>
```

This command directly affects the grant to the `rexecute()` function, which is the underlying mechanism for providing this function.

Parameters

dsn
: The data source where the SQL statement should be executed. You must make sure that you have already defined the data source using the vd_remote_data_source function or by attaching tables from it.

stmt
: the SQL statement to execute on the remote data source dsn .

max_rows
: This controls the number of rows to be returned as follows:

in_params
: A vector of parameters to the statement if the executed statement has parameters. IN input parameters are specified as literals whereas OUT and INOUT parameters are specified as vectors of 3 elements for OUT and 4 elements for INOUT as follows:

Return Values

This function returns a result set.

See Also

`rexecute()` , `rnext()` , `rmoreresults()` , `rclose()`

right

right — get n rightmost characters of a string

Synopsis

right (in *str* string ,
in *count* integer) ;

Description

right returns the *count* rightmost characters of string str.

If count is zero an empty string '' is returned.

If length of str is less than count then a copy of the whole *str* is returned.

Examples

Example 24.364. Simple Example

```
right('AbracadabrA',4) -> 'abrA'
```

rmoreresults

rmoreresults — move to next result set of rexecute()

Synopsis

```
rmoreresults ( in cursor_handle long ,
               out sql_state varchar ,
               out sql_error varchar ,
               out num_cols integer ,
               out stmt_meta vector ) ;
```

Description

This function moves to the next result set when handling result sets returned by statement executed with rexecute.

Parameters

cursor_handle
: The cursor handle obtained from rexecute

sql_state
: Output parameter for returning SQL state.

sql_error
: Output parameter for returning an error message.

num_cols
: Output parameter for returning number of columns in a result row.

stmt_meta
: The metadata vector as described in documentation for rexecute .

See Also

`rexecute` , `rnext` , `rclose` .

rnd

rnd — returns a random number between 0 and n - 1 inclusive

Synopsis

```
number rnd ( in n integer );
```

Description

The rnd function returns a random number between zero and n - 1, inclusive.

Randomize initializes the random number generator.

The random number generator is initialized after the clock at first usage, so the produced sequences will be different each time unless specifically initialized.

rnext

rnext — Get next result from a remote result set

Synopsis

```
integer retcode rnext ( in cursor_handle long ,
                        out row_array vector ,
                        out sql_state varchar ,
                        out sql_error varchar ) ;
```

Description

Use `rnext` in combination with `rmoreresults` to iterate over a result set produced by a statement run in a remote data source with `rexecute` .

open a cursor with rexecute .
loop over the results with rnext
if rmoreresults does not return an error or SQL_NO_DATA_FOUND continue the loop with rnext, otherwise
close the cursor with rclose

Parameters

cursor_handle
: The long cursor handle as obtained from rexecute.

row_array
: An output vector that will contain the result columns.

sql_state
: Optional varchar output parameter for SQL state.

sql_error
: Optional varchar output parameter for any error message.

Return Values

All data is returned in output parameters.

See Also

`rexecute` , `rmoreresults` , `rclose` .

row_count

row_count — returns number of rows affected by the previous DML statement in a procedure body

Synopsis

```
integer row_count ( );
```

Description

This function returns the count of rows affected by the previous DML statement in a procedure body. The scope is local to the procedure. Calling this from ODBC will always return 0. This is the PL equivalent of the SQLRowCount ODBC function. The count is set after any in-line searched or positioned update, insert or delete. This is also set by the exec function. The count stays set until overwritten by the next DML operation. This is not set by rexecute.

Return Types

An integer representing the number of affected rows from a previous query.

rtrim

rtrim — trims given characters from right of given string

Synopsis

rtrim (*str* string ,
trimchars string) ;

Description

ltrim returns a copy of subsequence of string str with all the characters present in trimchars trimmed off from the beginning. If the second argument is omitted, it is a space ' ' by default.

rtrim is similar except that it trims from the right.

trim trims from both ends.

```
concat('*',trim('   SIMURG   '),'*') -> '*SIMURG*'
ltrim('AbracadabrA','bAr')  -> 'acadabrA'
rtrim('AbracadabrA','bAr')  -> 'Abracada'
trim('AbracadabrA','bAr')    -> 'acada'
```

search_excerpt

search_excerpt — Returns excerpts with hit words from text

Synopsis

search_excerpt (in *hit_words* any ,
in *text* varchar ,
in *within_first* int ,
in *max_excerpt* int ,
in *total* int ,
in *html_hit_tag* varchar) ;

Description

This function produces representative samples for use in displaying a query hit. There are two modes: html mode and text mode. In html mode everything looks like html tags is ignored and searching of excerpt begins from <body> tag. All found hit words highlighted by html_hit_tag.

In text mode text is treated as plain text, html tag detection is disabled and hit words is not highlighted.

Parameters

hit_words
: array of hit words to be found in text. Number of hit words can not be more than 10.

text
: original text where hit words are searched

within_first
: number of chars in text from the start to consider. Default value is 20000.

max_excerpt
: maximum length of single excerpt phrase. Default value is 90.

total
: maximum length of whole excerpt. Default value is 200.

html_hit_tag
: HTML tag which is used to highlight hit words in excerpt. Default value is "b". If it is NULL text mode is used

Return Types

varchar

Examples

Example 24.365. Creating search excerpt

creates a search excerpt from found DAV resource

```
for select RES_CONTENT from WS.WS.SYS_DAV_RES
 where contains (RES_CONTENT, 'place and knowledge')
do {
  http_value (search_excerpt (vector ('place', 'knowledge'),
                              cast (RES_CONTENT as varchar),
                              200000, 90, 200, 'b', 1),
              'P');
```

```
}
```

second

second — get second from a datetime

Synopsis

second (in *dt* datetime) ;

Description

second takes a datetime and returns an integer containing a number representing the second of the datetime.

Parameters

dt
: A datetime .

Return Values

An INTEGER containing the second.

Examples

Example 24.366. Simple example

Get current second.

```
SQL> select second (now ());
callret
INTEGER
_______________________________________________________________________________

28
```

See Also

dayname , dayofmonth , dayofweek , dayofyear , quarter , week , month , year , hour , minute , timezone

sequence_get_all

sequence_get_all — Returns a vector of states of all sequence objects

Synopsis

```
vector sequence_get_all ( );
```

Description

The function returns a vector of even length that contains two elements for every sequence object that is now stored in the database: the name and the current state. The order of 'name-state' pairs in the resulting vector may vary from call to call. To search such a vector by a setting name, the vector can be passed as a second argument to the function `get_keyword` ().

Changes in the returned vector will not alter sequence objects of the database. To change actual sequence objects, use `sequence_set` ().

Return Types

The function returns a vector of even length.

See Also

Sequence Objects

`sequence_next`

`sequence_set`

`sequence_remove`

`registry_get`

`registry_get_all`

`registry_set`

`registry_name_is_protected`

`registry_remove`

sequence_next

sequence_next — Returns the current state of the specified sequence and increments it by one.

Synopsis

```
integer sequence_next ( in name varchar ,
                        in increment_by integer ) ;
```

Description

This function returns the current state of the specified sequence and atomically increments it by one. The next call will thus return a number one greater than the previous. The sequence is shared between all connections and all transactions so an increment that is is made in one of connection will be seen in other connection immediately. Using a sequence never involves locking.

Parameters

name
: The server-wide name of a sequence.

increment_by
: This is to specify how much will be added to the sequence (must be greater than zero) If not specified defaults to 1.

Return Types

The function returns integer

See Also

Sequence Objects

`sequence_remove`

`registry_get`

`registry_get_all`

`registry_set`

`registry_name_is_protected`

`registry_remove`

sequence_remove

sequence_remove — Removes a sequence object

Synopsis

sequence_remove (in *name* varchar) ;

Description

The function removes a sequence object created before by `sequence_set` or `sequence_next` .

Parameters

name
: The name of the sequence object to be deleted.

Return Types

The function returns integer one if the sequence object is removed, zero if there was no object with the specified name.

Examples

Example 24.367. Creation and Removal of a Sequence Object

This sequence of operations demonstrates how `sequence_remove` reverts the effect of `sequence_next` .

```
> select sequence_next ('my_sequence');
0

> select sequence_next ('my_sequence');
1

> select sequence_next ('my_sequence');
2

> select sequence_remove ('my_sequence');
1

> select sequence_next ('my_sequence');
0
```

registry_remove

sequence_set

sequence_set — Sets and returns the state of a sequence object.

Synopsis

```
integer sequence_set ( in name varchar ,
                       in state integer ,
                       in mode integer ) ;
```

Description

The function sets and returns the state of a sequence object. The *mode* specifies whether a check for order of values should be made. If *mode* equals 0, the state is set regardless of the previous state. If *mode* is non-zero, the state is changed only if the new state is greater than the previous state. This gives some (weak) protection from occasional 'rewind' the sequence back to values that are already in use.

Parameters

name
: The server-wide name of a sequence.

state
: A new state of the sequence.

mode
: Flags if a new state of the sequence should be ignored if it is less than the current one.

Return Types

The function returns an integer that is equal to what the next call to `sequence_next` () will return.

Examples

Example 24.368. Different modes of sequence_set()

The sequence of calls demonstrates various calls of `sequence_set` ().

```
select sequence_set ('sample', 5, 0);
5

1 Rows. -- 0 msec.

select sequence_next ('sample');
5

1 Rows. -- 0 msec.

select sequence_next ('sample');
6

1 Rows. -- 0 msec.

-- This has no effect because current state(6) is greater than 2.
select sequence_set ('sample', 2, 1);
7

1 Rows. -- 0 msec.

select sequence_next ('sample');
7
```

```
1 Rows. -- 0 msec.

-- But this change has effect:
select sequence_set ('sample', 2, 0);
2

1 Rows. -- 0 msec.

select sequence_next ('sample');
2

1 Rows. -- 0 msec.
```

serialize

serialize , deserialize — convert any heterogeneous array or tree of arrays into a binary string and back

Synopsis

```
binary string serialize ( in tree any );

binary string deserialize ( in str varchar );
```

Description

These functions will convert any heterogeneous array or tree of arrays into a binary string and back. The format is platform independent.

```
deserialize (serialize (x))
```

is the identity function.

These functions are useful for persisting heterogeneous arrays.

Note:
The serialization can be stored as a blob, so that there is no practical length limit. The string length is however limited to 16 MB.

serialize_to_UTF8_xml

serialize_to_UTF8_xml — Converts argument to its UTF-8 string representation.

Synopsis

serialize_to_UTF8_xml (in *value* any);

Description

The function converts its argument to a narrow string in UTF-8 encoding. The way conversion is done depends on the type of the argument.

If *value* is a wide (national) string or a LONG NVARCHAR then it is directly converted to UTF-8 string.

If *value* is a string or a LONG VARCHAR then it is converted from current charset of client connection to the UTF-8.

If *value* is an XML entity then it is converted to its XML text representation in UTF-8 encoding. The resulting string is a well-formed XML document if the given entity is an element entity, otherwise it may be well-formed generic entity, i.e. it can be parsed by an XML parser only as a part of some other XML document.

If *value* is NULL, the NULL is returned.

Values of other types are first converted to VARCHAR, this intermediate VARCHAR is converted from current charset of client connection to the UTF-8 and is returned.

Parameters

value
: The value of arbitrary type to be converted into its UTF-8 string representation.

Return Types

UTF-8 string or NULL.

Examples

Example 24.369. UTF-8 encoding of non-ASCII characters

A sample document is parsed and the resulting entity is serialized to UTF-8 string.

```
select serialize_to_UTF8_xml(xtree_doc('<text>0-9 a-z A-Z &#128;-&#255; &#256;-&#511; &#1024;-&#8191;</te
callret
VARCHAR
_______________________________________________________________________________

<text>0-9 a-z A-Z fl-ÿ  -   - </text>
```

charset_recode

SERV_QUEUE_TOP

SERV_QUEUE_TOP — Retrieve target website and store within Virtuoso

Synopsis

```
WS.WS. SERV_QUEUE_TOP ( in target varchar ,
                        in WebDAV_collection varchar ,
                        in update integer ,
                        in debug integer ,
                        in function_hook varchar ,
                        in data any ) ;
```

Description

Web Robot site retrieval can be performed with the WS.WS.SERV_QUEUE_TOP PL function integrated in to the Virtuoso server.

To run multiple walking robots all you simply need to do is kick them off from separate ODBC/SQL connections and all robots will walk together without overlapping.

From a VSP interface, after calling the retrieval function you may call http_flush to keep running tasks in the server and allowing the user agent to continue with other tasks.

Parameters

target
: URI to target site.

WebDAV_collection
: Local WebDAV collection to copy the content to.

update
: Flag to set updatable, can be 1 or 0 for on or off respectably.

debug
: Debug flag, must be set to 0

function_hook.
: Fully qualified PL function hook name. If not supplied or NULL then the default function will be used.

data
: application dependent data, usually an array, is passed to the PL function hook to perform next queue entry extraction. In our example we use an array with names of non-desired sites.

Examples

Example 24.370. Retrieve External Sites

```
WS.WS.SERV_QUEUE_TOP (
  'www.foo.com', 'sites/www_foo_com', 0, 0, 'DB.DBA.my_hook',
    vector ('www.skip.me','www.bar.com')
);
```

ses_connect

ses_connect — Opens a TCP session and returns its handle.

Synopsis

```
session_handle ses_connect ( in host_and_port varchar );
```

Description

Requires dba privileges.

This function is used to establish a new TCP connection to the target host. It returns a special datatype which represents the session handle.

Parameters

host_and_port
: The host and port number of the target host in the format <host>[:<port>]. If the optional port number defaults to 80 if not supplied.

Return Types

Returns a special internal datatype that represents the session handle. This session handle can be used in other session functions. Since this is an internal type it cannot be stored.

See Also

`ses_disconnect()`

`ses_read_line()`

`ses_write()`

ses_disconnect

ses_disconnect — Disconnections a TCP session.

Synopsis

ses_disconnect (in *ses* ses_handle);

Description

This function is used to disconnect from a session and destroy the session handle. After this function is called the session handle becomes invalid and hence cannot be used for reading or writing as an error will occur.

Parameters

ses
: A valid session handle.

See Also

`ses_connect()`

`ses_write()`

`ses_read_line()`

ses_read_line

ses_read_line — Read a line of character data from a TCP session.

Synopsis

```
varchar ses_read_line ( in ses any ,
                        in throw_exception_on_eof integer ,
                        in binary_mode integer ) ;
```

Description

This function is used to read a line of character data from an open TCP session. This function will read characters until it reaches an end of line up to a maximum of 1024 characters. The session can be passed as a session_handle. If the session_handle is omitted then execution is in current session/VSP context and will read from the open HTTP session. `Ses_read_line()` will suspend execution while attempting to read from the session until the timeout period of 100 seconds expires. When the timeout expires an error will be produced to indicate that the operation was unsuccessful.

Parameters

ses
: Optional session handle. If none is supplied the current TCP client session is assumed. If this is NULL then the function will read from the string session to be sent to the client upon request completion.

throw_exception_on_eof
: Controls whether to throw an error if there is a problem reading from the session or simply return null in text mode or what ever content has has been read so far in binary mode. If this parameter is set to 1, then an error will be thrown. If this parameter is set to 0 then either null or remaining content will be returned as above.

binary_mode
: Instructs the function to be in binary or text mode.

Return Types

The characters read from the session are returned from this function.

Examples

Example 24.371. Simple demonstration of reading from the HTTP session

This example reads the first line of the session and outputs the contents. This code can be run from a vsp file.

```
<p>Some text</p>
<?vsp
    declare xx any;
    xx := ses_read_line (NULL);

    http (sprintf ('length is %d, "%s"', length (xx), xx));
?>
```

See Also

`ses_connect()`

`ses_disconnect()`

`ses_write()`

ses_write

ses_write — Write character data to an open TCP session.

Synopsis

ses_write (in *buffer* varchar ,
in *ses* session_handle) ;

Description

This function is used to write character data taken from the buffer parameter to an open TCP session. Attempts to write to a close session will result in an error being returned.

Parameters

buffer
: Character data to be sent to the session.

ses
: A valid session handle. If none is supplied the current VSP context is assumed.

See Also

`ses_connect()`

`ses_disconnect()`

`ses_read_line()`

set_row_count

set_row_count — sets the affected rows counter in the current context or in the context of the caller

Synopsis

```
integer set_row_count ( in increment integer ,
                        in what integer ) ;
```

Description

The function set_row_count () is used to set the affected rows counter in the current context or in the context of the caller. Therefore it can be used to set the affected rows counter (returned by `row_count()`) in places where an instead of trigger is used. If result of decrement of the affected rows counter is an negative integer it will be set to zero.

Parameters

increment
: An integer to be added to the affected rors counter, can be negative also

what
: The what have to be 0 or 1, 0 is the default. 0 - for update in current context the counter, 1 - to update the counter in context of the caller.

Return Types

The function returns new value of the affected rows , or -1 if action is not applicable.

Examples

Example 24.372. Setting the affected rows counter in instead of trigger

The following SQL script will make two instead of triggers on atable "hid" and inside them will are called set_row_count to set the rows inserted or updated in the second table. Also there are two procedures which are used to demonstrate the return value of row_count.

```
create table hid (id integer primary key, dt varchar);
create table sho (id1 integer primary key, dt1 varchar);

create trigger i_hid instead of insert on hid
{
  insert into sho values (id, dt);
  set_row_count (row_count(), 1);
};

create trigger u_hid instead of update on hid
{
  update sho set dt1 = dt where id1 = id;
  set_row_count (row_count(), 1);
};

create procedure test_ins ()
{
  insert into hid select * from chid;
  return row_count();
};

create procedure test_upd ()
{
  update hid set dt = '';
  return row_count ();
};
```

See Also

`row_count()`

set_user_id

set_user_id — sets the current user for execution

Synopsis

```
integer set_user_id ( in user_name varchar ,
                      in mode integer ,
                      in password varchar ) ;
```

Description

This function changes the effective user and group to that of the user defined by user_name parameter. When called by a user with DBA group privileges, the optional password may be omitted. Otherwise it has to be the valid password for user_name. The mode parameter determines persistence (context) of effects of the call: If omitted or set to integer value 1, the effective user privileges will remain in effect within current stored procedure context only - upon returning, the effective user privileges will be automatically reset to state effective before set_user_id. When mode is equal to integer value 0, the effective user privileges will remain set for duration of current ODBC session, current request in web server context, or until next call of set_user_id. This function is analogous to the UNIX 'su' command.

Parameters

user_name
: the name of SQL user account to be used as effective user and group.

mode
: optional, integer 1 (default) means change of privileges remains in effect only while within current stored procedure context.

password
: this optional parameter is needed if calling the function without DBA privileges. Password of the user user_name .

Return Types

No return value

set_identity_column

set_identity_column — sets the sequence starting value for an identity column

Synopsis

```
integer set_identity_column ( in table_name varchar ,
                              in column_name varchar ,
                              in new_value integer ) ;
```

Description

This function takes the table name, the column name and the new sequence value as parameters. It checks for the existence of the identity column, and then sets the sequence value (using the sequence_set) and returns the old sequence value. The table and column names must be properly qualified to ensure the correct resource is located. The effect of calling this function is immediate.

Parameters

table_name
: the fully qualified table name in the correct case exactly as it appears in the DB.DBA.SYS_KEYS table.

column_name
: the exact column name as it appears in the DB.DBA.SYS_COLS table.

new_value
: the new sequence value.

Return Types

the previous sequence value

sign

sign — returns -1, 0, or 1 depending on the sign of its numerical

Synopsis

sign (*num* numeric) ;

Description

sign returns either -1, 0 or 1 depending whether its numeric argument is negative, zero or positive.

```
sign(-12)                       -> -1
sign(0)                         -> 0
sign(910)                       -> 1
sign(atof('-1.23456789'))       -> -1
sign(0.0)                       -> 0
```

signal

signal — Signal an exception in the calling procedure

Synopsis

signal (in *sqlstate* varchar ,
in *message* varchar) ;

Description

This signals the given SQLSTATE with the message. The calling procedure will transfer control to the most appropriate local handler. In the absence of a local handler the procedure terminates and signals the exception in the scope where it was called from, until there either is a handler or there are no more calling procedures. If there is no handler in the entire stack of call contexts the error is signalled to the client. Handlers can be declared with whenever .. goto and the declare handler for construct. See the Virtuoso/PL documentation.

```
CREATE PROCEDURE WITHDRAW (IN C_ID VARCHAR, IN DELTA NUMERIC)
{
    DECLARE BAL NUMERIC;

    DECLARE CR CURSOR FOR SELECT C_BALANCE FROM CUSTOMER WHERE C_ID = C_ID;

    WHENEVER NOT FOUND GOTO NOCUSTOMER;

    OPEN CR (EXCLUSIVE);
    FETCH CR INTO BAL;
    IF (BAL > DELTA)
        UPDATE CUSTOMER SET C_BALANCE = BAL - DELTA WHERE CURRENT OF CR;
    ELSE
        SIGNAL ('NOMONEY', 'INSUFFICIENT BALANCE.');

    RETURN;

NOCUSTOMER:
    SIGNAL ('NOCUS', 'BAD CUSTOMER ID');
}
```

sinv_create_key_mapping

sinv_create_key_mapping — Creates a key mapping function & table.

Synopsis

sinv_create_key_mapping (in *map_name* varchar ,
in *part_defs* any ,
in *do_drops* integer := 1) ;

Description

Creates a key mapping function & table (as described in the doc section SQL Inverse Functions)

Parameters

map_name
: (string) the name of the mapping. This becomes the name of the forward function (from parts to single int value) and participates in the name of the lookup table (like MAP_ <map_name>)

part_defs
: contains an array of name/type pairs describing the parts of the mapping. The types are used in the MAP table as column types and the type names are used in naming the referenced functions (one for each part) like : <map_name>_ <part_name>

do_drops
: integer (0, 1, 2 : default value 1)

See Also

`sinv_create_inverse` , `sinv_drop_inverse`

sinv_create_inverse

sinv_create_inverse — Creates inverse mapping for the mentioned functions.

Synopsis

```
sinv_create_inverse (  in _SINVM_NAME_IN varchar ,
                       in _SINV_INVERSE any ,
                       in _SINVM_FLAGS integer ) ;
```

Description

Creates inverse mapping for the mentioned functions (as described in the doc section SQL Inverse Functions)

Parameters

_SINVM_NAME_IN
: the name of the forward function

_SINV_INVERSE
: an array of the names of the inverse functions (for each part).

_SINVM_FLAGS
: bit mask with:

See Also

`sinv_create_key_mapping` , `sinv_drop_inverse`

sinv_drop_inverse

sinv_drop_inverse — Reverses the effect of `sinv_create_inverse` procedure.

Synopsis

`sinv_drop_inverse` (in *_SINVM_NAME_IN* varchar) ;

Description

Reverses the effect of `sinv_create_inverse` procedure.

Parameters

_SINVM_NAME_IN
: the name of the forward function

See Also

`sinv_create_key_mapping`, `sinv_create_inverse`

smime_sign

smime_sign — Converts a MIME message to a signed S/MIME message

Synopsis

```
varchar smime_sign ( in msg_text varchar ,
                     in signer_cert varchar ,
                     in private_key varchar ,
                     in private_key_pass varchar ,
                     in signer_CA_certs any ,
                     in flags integer ) ;
```

Description

Converts a MIME message to a signed S/MIME message.

Parameters

msg_text
: The text of the message

signer_cert
: Signer certificate.

private_key
: Private Key

private_key_pass
: Private Key Pass

signer_CA_certs
: Array of strings of CA Certificates

flags

Return Types

This function takes a message and converts it to an S/MIME signed message based on the flags value (if supplied - default PKCS7_DETACHED).

Examples

Example 24.373. Signing a MIME Message

Example (where signed.eml contains the output from smime_sign.

```
select smime_sign ('just a test', file_to_string ('thwate_pub.pem'),
  file_to_string ('thwate_pri.pem'), 'very_secret_password',
        vector (file_to_string ('thwate_ca.pem')), 4*16 + 1);
```

smime_verify

smime_verify — Verifies signature of signed MIME message

Synopsis

```
varchar smime_verify ( in msg_text varchar ,
                       in certs any ,
                       out signer_certs any ,
                       in flags integer ) ;
```

Description

This function takes the RFC822 text of an e-mail containing an S/MIME signed message and verifies it's signature using the CA certificates in certs, which is an array of strings containing single or multiple PEM-encoded certificates.

Parameters

msg_text
: The text of the message

certs
: array of strings containing CA certificates

signer_certs
: for receipt of PEM encoded certificates

flags
: A bitmask. See table below for valid mask values. Default is 0.

Return Types

If the signer_certs is supplied, an array of PEM encoded certificates of the signers is returned.

Examples

Example 24.374. Verifying a Signed MIME Message

Example (where signed.eml contains the output from smime_sign.

```
select smime_verify (file_to_string ('signed.eml'),
  vector (file_to_string ('thwate_ca.pem')), NULL, 1)

pem_certificates_to_array

smime_encrypt

smime_encrypt — Performs encryption of a (signed) e-mail msg

Synopsis

```
varchar smime_encrypt ( in mail_message varchar ,
                        in array_of_recipient_certificates any ,
                        in cipher_name varchar ) ;
```

Description

This function performs encryption of a (signed) e-mail message.

Parameters

mail_message
: The text of the e-mail msg.

array_of_recipient_certificates
: An array of strings containing certificates (per format) of the recipient individuals. The certificates must contain RSA keys. See for reference here .

cipher_name
: Encryption algorithm 'des', 'des3', 'aes256', 'aes128' etc.

Return Types

varchar

Examples

Example 24.375. Encrypting (signed) e-mail msg

```
SQL> select smime_encrypt (file_to_string ('test.eml'),
                           pem_certificates_to_array (file_to_string ('testcerts.pem')),
                           'aes256');

smime_decrypt

smime_decrypt — Decryption of a PKCS7 encrypted smime msg

Synopsis

```
varchar smime_decrypt ( in encrypted_mail_message varchar ,
                        in recipient_certificate varchar ,
                        in recipient_key varchar ,
                        in password_for_the_key varchar ) ;
```

Description

This function performs decryption of a PKCS7 encrypted smime msg

Parameters

encrypted_mail_message
: The text of the encrypted smime message

recipient_certificate
: The certificate of the recipient (pem format)

recipient_key
: The private key of recipient matching the recipient_certificate (pem format)

password_for_the_key
: The secret to open the recipient_key (if key is encrypted)

Return Types

varchar

Examples

Example 24.376. Decryption a PKCS7 encrypted smime msg

```
select smime_decrypt (file_to_string ('test.p7m'),
                      file_to_string ('test.pem'),
                      file_to_string ('test.key.pem'),
                      'secret');
```

```
Content-Transfer-Encoding: 7bit
Content-Type: text/plain;
 charset=us-ascii

this is a test

smtp_send

smtp_send — send message to SMTP server

Synopsis

smtp_send (in *server* string ,
in *sender* string ,
in *recipient* string ,
in *body* string) ;

Description

Virtuoso can act as an SMTP client. This means that Virtuoso is able to send emails directly to a mail SMTP server. Virtuoso has a simple function to facilitate this. This can be called from stored procedures, VSP pages, triggers etc.

The sender and recipient email addresses must be enclosed with <..> and separated by commas i.e. string '<support@openlinksw.co.uk>,<sales@openlinksw.co.uk>'

The message Body contains headers such as Subject, From, To, Cc, Bcc and then continues with the actual message text itself. New lines can be added using '\r\n'

Example 24.377. Example:

```
'Subject: subject message\r\nFrom: sender\r\nTo: recipient\r\nCc:
copy\r\nBcc: copy\n\n body of message'
```

Virtuoso will pick up Subject and other headers from the body content. Note that the RFC insists there should be a NULL line between body headers and the message body text.

Example 24.378. Example:

```
smtp_send(
                'mail.example.com:25',
                '<sender@example.com>',
                '<receiver@example.com>',
                concat(
                  'X-Mailer: Virtuoso Universal Server\r\n',
                        'Date: ', soap_print_box (now (), '', 1), '\r\n',
                        'Message-ID: <', regexp_replace(cast(now() as varchar), '[- :.]', '', 1, null), '
                        'Subject: This is a test mail...\r\n',
                        'From: <sender@example.com>\r\n',
                        'To: <receiver@example.com>\r\n',
                        '\n',
                        'Hi Receiver, this is a test message from Virtuoso')
        );
```

A more involved example. It is the responsibility of the developer to ensure that the message is correctly formed, complete with all necessary headers. This example shows a complete use of the function.

soap_box_xml_entity

soap_box_xml_entity — Converts an XML entity to an SQL value given the desired SQL type.

Synopsis

```
any soap_box_xml_entity ( in entity any ,
                          in try_typed_as any ,
                          in soap_version integer ) ;
```

Description

Converts an XML entity to an SQL value based on the type of the entity and the desired SQL type. This function is called internally to convert a SOAP request parameter to a PL procedure parameter when a SOAP request is being processed by the SOAP server.

Parameters

entity
: The XML fragment as a vector (as returned from xml_tree() or a subpart of it).

try_typed_as
: A sample value, whose type is taken as a desired type for conversion.

soap_version
: Optional (default 1). The soap version (1 for SOAP 1.0, 11 for SOAP 1.1).

Return Types

The return type of `soap_box_xml_entity()` can vary according to the type of *`entity`* parameter, described by *`try_typed_as`* as follows:

If *`entity`* is NULL, the return value will be NULL.

If *`entity`* is not a vector() then its value will be cast to the *`try_typed_as`* type, if possible.

If *`entity`* is a vector() containing XML tree then it will be converted to an appropriate SQL type (vector(), varchar, integer etc.) depending on the SOAP RPC encoding rules (XMLSchema-datatypes and SOAP-RPC encoding schema) for in/out SOAP messages. i.e. it depends on the structure/content of the XML tree passed as the *`entity`* argument.

soap_dt_define

soap_dt_define — define re-define or erase the complex datatype definition for SOAP calls

Synopsis

soap_dt_define (in *name* varchar ,
in *schema_string* varchar) ;

Description

This defines a new complex SOAP datatype (usually array of structure) named 'name'.

The schema_string string represents definition as complexType element from XML Schema. The only complexContent, all and sequence elements can be used within the complexType. This means that optional elements in the defined datatype are not supported as a variant of the SOAP parameter datatype. If the schema descriptions contains an unsupported element , the SQL error will be signalled and error message will explain what element is wrong.

Parameters

name
: A varchar containing the expanded name of SOAP type to be defined/removed or an empty string (''). If an empty string is supplied this function will try to extract it from the given schema_string schema fragment (attribute @name'). Name cannot be an empty string for removing SOAP types.

schema_string
: XMLSchema excerpt as varchar or NULL (null is used for removal).

Return Types

This function returns a varchar of the name of the registered SOAP type.

Errors

This function can generate the following errors:

SODT1 22023 The element <element name> is not supported [<as child of complexContent>]

Examples

Example 24.379. Definition of an Array

```
<!-- file float_array.xsd -->

<complexType name="ArrayOffloat"
   xmlns:enc="http://schemas.xmlsoap.org/soap/encoding/"
   xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
   xmlns="http://www.w3.org/2001/XMLSchema"
   xmlns:tns="services.wsdl">
   <complexContent>
   <restriction base="enc:Array">
   <sequence>
   <element name="item" type="float" minOccurs="0" maxOccurs="unbounded" nillable="true"/>
   </sequence>
   <attributeGroup ref="enc:commonAttributes"/>
   <attribute ref="enc:offset"/>
   <attribute ref="enc:arrayType" wsdl:arrayType="float[]"/>
   </restriction>
   </complexContent>
</complexType>
```

```
<!-- eof float_array.xsd -->

can be defined from ISQL tool or in the PL procedure
SQL> DB.DBA.soap_dt_define ('ArrayOffloat', file_to_string ('float_array.xsd'));
```

Example 24.380. Definition of an Structure

```
<!-- file struct.xsd -->

<complexType name="PERSON"
   xmlns:enc="http://schemas.xmlsoap.org/soap/encoding/"
   xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
   xmlns="http://www.w3.org/2001/XMLSchema"
   xmlns:tns="services.wsdl">

   <sequence>
     <element name="firstName" type="string"/>
     <element name="lastName" type="string"/>
     <element name="ageInYears" type="int"/>
     <element name="weightInLbs" type="float"/>
     <element name="heightInInches" type="float"/>
   </sequence>
</complexType>

<!-- eof struct.xsd -->

can be defined from ISQL tool or in the PL procedure
SQL> DB.DBA.soap_dt_define ('PERSON', file_to_string ('struct.xsd'));
```

Example 24.381. Definition of composite type array of structures

```
<!-- file array_struct.xsd -->

<complexType name="ArrayOfPERSON"
   xmlns:enc="http://schemas.xmlsoap.org/soap/encoding/"
   xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
   xmlns="http://www.w3.org/2001/XMLSchema"
   xmlns:tns="services.wsdl">

   <complexContent>
   <restriction base="enc:Array">
   <sequence>
   <element name="item" type="tns:PERSON" minOccurs="0" maxOccurs="unbounded" nillable="true"/>
   </sequence>
   <attributeGroup ref="enc:commonAttributes"/>
   <attribute ref="enc:offset"/>
   <attribute ref="enc:arrayType" wsdl:arrayType="tns:PERSON[]"/>
   </restriction>
   </complexContent>

</complexType>

<!-- eof array_struct.xsd -->

can be defined from ISQL tool or in the PL procedure
SQL> DB.DBA.soap_dt_define ('ArrayOfPERSON', file_to_string ('array_struct.xsd'));
```

soap_call

soap_call — calls a function from a SOAP server and returns the result. value; deprecated, use SOAP_CLIENT () instead

Synopsis

```
any soap_call ( in host string ,
                in path string ,
                in methodURI string ,
                in methodName string ,
                in params array of (ParamName, Value) ,
                in version integer ,
                in certificate varchar ,
                in password varchar ,
                in SOAPAction varchar ) ;
```

Description

This calls a function from a SOAP server and returns the result as a return value. Params is an array of (Parameter name, Value) pairs representing the parameters passed in the SOAP call. Each of these pairs become an XML sub-entity of the procedure entity. The return value of the function is the entity inside the SOAP body of the response. In debug mode the return value is an array of 3 elements; the non-debug return value (if any) as element 0, the XML text of the request as element 1 and the XML text of the server response as element 2. This function does not use any XML types when creating the XML. It represents types as a cast to varchar would, with one exception - dates and times according to ISO8061.

The Virtuoso SOAP client can work with complex datatypes, in which case the parameters array must conform to the following convention:

```
vector ( vector ([name1], [type1]), value1, vector ([name2], [type2]), value2 ...)
```

This will cause type checking and validation of the values to be encoded for SOAP request.

Parameters

host
: DNS name or IP address of the SOAP server

path
: path into the HTTP server containing the SOAP server page

methodURI
: URI of the SOAP method being called

methodName
: Name of the SOAP method being called

params
: array of parameters to the SOAP call; array of (ParamName, Value). The Virtuoso SOAP client can work with complex datatypes. In order to support this the parameters array must conform to the following convention: vector (vector ([name1], [type1]), value1, vector ([name2], [type2]), value2 ...). This will cause type checking and validation of the values to be encoded for SOAP request.

version
: the SOAP version used in call (SOAP 1.0 = 1, SOAP 1.1 = 11). Default value = SOAP 1.0. If the value is negated : i.e. -1 or -11 then the soap_call procedure enters "debug" mode

certificate

If this parameter is specified (string or null) the HTTPS operation will be performed. Path to the HTTPS client certificate in PKCS#12 format, if this parameter is set to NULL then client will do only encrypted connection.

password
: If certificate is supplied this parameter must contain password for opening the certificate file.

SOAPAction
: SOAPAction parameter can be used to make SOAPAction header value explicit. Normally this is taken from the namespace URI and SOAP method name.

Examples

Example 24.382. Calling a SQL procedure fishselect (in str varchar)

```
declare ret any;
ret := soap_call ('example.com', '/SOAP',
         'urn:com-openlinksw-virtuoso',
         'fishselect',
         vector ('str', 'G'));
```

soap_client

soap_client — Invoke a SOAP service and returns result value.

Synopsis

```
soap_client ( in url varchar ,
              in operation varchar ,
              in target_namespace varchar default null ,
              in parameters any default null ,
              in headers any default null ,
              in soap_action varchar default '' ,
              in attachments any default null ,
              in ticket any default null ,
              in passwd varchar default null ,
              in user_name varchar default null ,
              in user_password varchar default null ,
              in auth_type varchar default 'none' ,
              in security_type varchar default null ,
              in debug integer default 0 ,
              in template varchar default null ,
              in style integer default 0 ,
              in version integer default 11 ,
              in direction integer default 0 ,
              in http_header varchar default null ,
              in security_schema any default null ,
              in time_out int default 100 ) ;
```

Description

This will invoke the specified SOAP service.

Parameters

url
: The target SOAP service endpoint URL. For SSL connections this must begin with 'https:' schema.

operation
: The name of the SOAP method to be invoked.

target_namespace
: The namespace of the SOAP request.

parameters
: parameters contained inside a vector in one of two ways:

headers
: the parameters to be printed in SOAP header element. They are contained inside a vector in following way:

soap_action
: The exact value of the SOAPAction header attribute.

attachments

DIME/MIME message attachments as array of (id, type, content)

ticket
: The key instance to perform XML signature and encryption for outgoing SOAP message. Or path to PKCS#12 file containing x509 certificate to perform secure connection over SSL with server's certificate verification. To indicate to use SSL for connection encryption only, then a number as string greater than 0 must be specified (i.e. '1').

passwd
: The password for opening the x509 certificate specified in 'ticket'.

user_name
: name for basic/digest HTTP authentication.

user_password
: The password for basic/digest HTTP authentication.

auth_type
: The type of authentication to use. Valid types are:

security_type
: This parameter governs the security method of the outgoing messages. Valid values are "encrypt" or "sign", to encrypt the message or sign it only.

debug
: If this flag is set to 1 then debug mode will be enabled. When enabled the returned message will be an array of 3 elements consisting of the request, response, and error if one occurred.

template
: The content of an XML signature template. If the default template is to be used only "[key reference for signing]" (note '[]' around name). need be specified. The server will generate a default template based on the key and default rules for making a signature.

style
: This is a bit-mask parameter that is used to specify the outgoing message format. The mask relies on the following values:

version
: the SOAP version used in call (SOAP 1.0 = 1, SOAP 1.1 = 11, SOAP 1.2 = 12). Default value = SOAP 1.1.

direction
: This flag if turned on (1) then one-way messages will be sent. In that case client doesn't expect response from SOAP server, except HTTP headers.

http_header
: This parameter is used to include custom HTTP headers in the SOAP POST request. The usual purpose of it to pass special 'X-<extension name>' header to server in order to send data that can't be included in SOAP message. For example this could be used for loop-to-self detection when replicating data collection(s) via SOAP.

security_schema
: This parameter is used to designate version of WS-Security and WS-Utility protocol to be used when secure SOAP calls will be made. The value is an array containing name/value pairs for 'wsse' (WS-Security) and 'wsu' (WS-Utility) namespace URLs. An example of the value is: vector ('wsse', WSSE_OASIS_URI, 'wsu', WSSU_OASIS_URI).

time_out
: The connection timeout. Elapsing this value and having no response from server will cause client to disconnect with an connection error.

Return Types

The function will return a XML tree of the SOAP response in simple mode. Also if one-way message is sent and no body from the SOAP server, then NULL will be returned. When advanced mode is set i.e. 'style' have second bit set, then response will be as

described earlier in 'style' parameter description.

Requirements for certificate files for HTTPS operation

When users going to do operation with an HTTPS endpoint the following are requirements to the PKCS#12 file. The file specified in parameter 'ticket' MUST contain: valid x509 certificate, certificate chain and private key. The password for opening the private key must be specified in the 'passwd' parameter. How client and server certificates and private keys are created are not subject of this document. Also see Web server documentation about how to run an HTTPS listener.

Example

Example 24.383.

References: tutorial/services WS-S-2 (triple-des), WS-S-3 (RSA), WS-S-4 (X.509 signing)

The following is an excerpt from the WS-S-2 Services tutorial to make encoded SOAP message with a shared key.

```
resp :=
        SOAP_CLIENT (
          url=>'http://example.com/SecureWebServices',
          operation=>'AddInt',
          parameters=>vector (vector ('a', 'int'), 3, vector ('b', 'int'), 4),
          auth_type=>'key',
          ticket=>xenc_key_inst_create ('WSDK Sample Symmetric Key'),
          security_type=>'encrypt',
          target_namespace=>'http://temp.uri/',
          soap_action=>'"http://temp.uri/#AddInt"',
          style=>6);
```

This will produce following SOAP message:

The encoded SOAP request

```
------------ REQUEST ------------------
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/"
          encodingType="http://schemas.xmlsoap.org/soap/encoding/" >

        eE7Dq7mt8AkKVQ==</CipherValue>
       </CipherData>
    </EncryptedData>
  </Body>
</Envelope>
---------------------------------------
```

Server approves the request and returns an unencrypted message. This shows one-way encoding only.

```
------------ RESPONSE -----------------
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/"
          encodingStyle="http://schemas.xmlsoap.org/soap/encoding/" >
  <Body xmlns="http://schemas.xmlsoap.org/soap/envelope/" >
    <AddIntResponse xmlns="http://temp.uri/" >
      <CallReturn type="http://www.w3.org/2001/XMLSchema:int" >7</CallReturn>
    </AddIntResponse>
  </Body>
</Envelope>
---------------------------------------
```

Example 24.384. Adding a SOAP:Header

This example makes call to the interop round4 test echoVoidSoapHeader (exists in the demo DB). Request and response wire dumps are listed below PL code excerpt.

```
      ...
      resp := soap_client (url=>url, operation=>'echoVoidSoapHeader',
                           parameters=>vector(),
                           headers=>vector(
                             vector('echoMeStringRequest',
                                    'http://soapinterop.org/:echoMeStringRequest',
                                    1,
                                    'http://schemas.xmlsoap.org/soap/actor/next') ,
                                    vector('String')),
                           style=>7,
                           soap_action=>'"http://soapinterop.org"',
                           target_namespace=>'http://soapinterop.org'
                           );
      ...
```

This will produce the following SOAP message:

The SOAP request

```
<SOAP:Envelope xmlns:SOAP="http://schemas.xmlsoap.org/soap/envelope/"
 xmlns:ns1="http://soapinterop.org/echoheader/"
 xmlns:ns0="http://soapinterop.org/">
   <SOAP:Header>
     <ns0:echoMeStringRequest SOAP:mustUnderstand='1' SOAP:actor='http://schemas.xmlsoap.org/soap/actor/n
       <ns1:varString>String</ns1:varString>
     </ns0:echoMeStringRequest>
   </SOAP:Header>
   <SOAP:Body>
     <echoVoidSoapHeader xmlns='http://soapinterop.org' ></echoVoidSoapHeader>
   </SOAP:Body>
</SOAP:Envelope>
```

And will receive the SOAP server response:

```
<SOAP:Envelope xmlns:SOAP="http://schemas.xmlsoap.org/soap/envelope/"
  xmlns:ns2="http://soapinterop.org/echoheader/"
  xmlns:ns1="http://soapinterop.org/"
  xmlns:ns0="http://soapinterop.org">
  <SOAP:Header>
    <ns1:echoMeStringResponse>
      <ns2:varString>String</ns2:varString>
    </ns1:echoMeStringResponse>
  </SOAP:Header>
  <SOAP:Body>
    <ns1:echoVoidSoapHeaderResponse />
  </SOAP:Body>
</SOAP:Envelope>
```

Example 24.385. Performing SOAP call over secure connection

The example code below makes a simple 'upper-case' service, exposes it under secured endpoint and invoke with x509 certificate. Note that default HTTPS listener MUST be enable in the INI file. Also the cli5.p12 certificate file MUST exists in server working directory.

```
SQL> create procedure
  WS.SOAPDEMO.SOAPTEST (in par varchar)
{
  return (upper(par));
};

SQL> grant execute on WS.SOAPDEMO.SOAPTEST to SOAPDEMO;

SQL> VHOST_DEFINE (vhost=>'*sslini*',lhost=>'*sslini*',lpath=>'/secure',
 ppath=>'/SOAP/',soap_user=>'SOAPDEMO');

-- SSL connection with server's certificate verification
SQL> select xpath_eval ('//CallReturn/text()', xml_tree_doc (
        soap_client (url=>'https://localhost:4443/secure',
        operation=>'SOAPTEST', parameters=>vector('par', 'demotext'),
        ticket=>'cli5.p12', passwd=>'secret')));
-- SSL connection only, no certificate verification
SQL> select xpath_eval ('//CallReturn/text()', xml_tree_doc (
        soap_client (url=>'https://localhost:4443/secure',
        operation=>'SOAPTEST', parameters=>vector('par', 'demotext'),
        ticket=>'1')));
-- response
callret

soap_make_error

soap_make_error — Creates a SOAP error reply XML message based on its parameters.

Synopsis

```
varchar soap_make_error ( in soap_code varchar ,
                          in sql_state varchar ,
                          in error_message varchar ,
                          in soap_version integer ,
                          in do_uddi integer ) ;
```

Description

This function creates a SOAP error reply based on the given parameters. It returns the generated XML as a varchar value.

Parameters

soap_code
: Required. The fault code according to the SOAP specification.

sql_state
: Required. The error's SQL state.

error_message
: Required. The error text.

soap_version
: Optional (default 11). The SOAP version used to encode the SOAP error reply.

do_uddi
: Optional (default 0). 1 = produce UDDI error format; 0 = SOAP error format.

Return Types

Returns generated XML as a varchar.

soap_print_box

soap_print_box — Formats an SQL value and returns it as a generated XML fragment.

Synopsis

soap_print_box (in *value* any ,
in *enclosing_tag* varchar ,
in *date_encoding_type|soap_version* integer) ;

Description

This function formats an SQL value as an XML fragment and returns it. This is used internally by the SOAP server to encode the output parameter values and return values when processing a SOAP request.

Parameters

value
: Required. Any SQL value to be represented as an XML fragment.

enclosing_tag
: Required. The XML tag to place the value into.

date_encoding_type
: Optional. Valid only if a value is a datetime. If supplied, the enclosing_tag is ignored and the date is printed out in one of the following formats:

soap_version
: Optional(Default 1). Valid only if the value type is not a datetime. The soap_version (1 for SOAP 1.0, 11 for SOAP 1.1).

Return Types

Generated XML fragment.

soap_sdl

soap_sdl — Generate SDL document for a PL module and return it as a varchar.

Synopsis

```
soap_sdl ( in module_name varchar ,
           in URL varchar ) ;
```

Description

This function generates a SDL for the procedures in a PL module the same way as /SOAP/services.xml is generated for the procedures in WS.SOAP.

Parameters

module
: Required. The name of the module to describe. This can be partial name.

URL
: Optional (default is the current VSP path if in VSP context. Otherwise error). The URL to include in the SDL file

Return Types

Returns the SDL document describing the module as an varchar value.

soap_server

soap_server — Execute SOAP request and return XML reply as a varchar.

Synopsis

```
varchar soap_server ( in req_xml any ,
                      in soap_method varchar ,
                      in lines any ,
                      in soap_version long ,
                      in procedure_mappings any ) ;
```

Description

This function executes the SOAP request in the same way as it it was directed to the `/SOAP` physical path. It returns the XML SOAP reply as a varchar value.

Parameters

req_xml
: Required. The XML entity of the SOAP request to execute.

soap_method
: Optional(default ""). The "SOAPAction" header field value

lines
: Optional(default NULL). The Request header fields (the lines parameter to the VSPs for HTTP)

soap_version
: Optional(default 11). The SOAP version (11 for SOAP 1.1 and 1 for SOAP 1.0)

procedure_mappings
: Optional(default NULL). A vector of pairs (<SOAP_method>, <PL procedure>) mapping the SOAP call request to the corresponding PL function name. If empty, then the mapping proceeds by taking the local name of the SOAP method and finding a procedure with the same name in the executing user's current qualifier and owner.

Return Types

Returns the XML SOAP reply as a varchar value.

soap_wsdl

soap_wsdl — Generate WSDL document for a PL module and return it as a varchar.

Synopsis

```
varchar soap_wsdl ( in module_name varchar ,
                    in URL varchar ) ;
```

Description

This function generates WSDL for the procedures in a PL module the same way as /SOAP/services.wsdl is generated for the procedures in WS.SOAP.

Parameters

module
: Required. The name of the module to describe. This can be partial name.

URL
: Optional(default the current VSP path if in VSP context. Otherwise error). The URL to include in the WSDL file

Return Types

Returns the WSDL document describing the module as an varchar value.

soap_wsdl_import

SOAP_WSDL_IMPORT

Synopsis

```
array DB.DBA. SOAP_WSDL_IMPORT ( in target_url varchar );
```

Description

The `soap_wsdl_import()` function is used to import operations and types definitions from an WSDL file on a remote server. The retrieved file will be parsed and PL (procedure language) wrappers will be generated for each SOAP operation that is described. The SOAP service will be represented by a PL module which will be the overall container the generated PL wrappers. Once the WSDL file has been imported the PL wrappers are automatically generated and available for use.

Parameters

target_url
: A URL to a WSDL file.

Return Types

soap_wsdl_import() returns an array that consists of the name of module, the name of PL wrapper, and a vector of parameter name/type pairs. An example of the result is: vector ([module name], [wrapper1], vector ([param1], [type1], [param2], [tyep2] ...), [wrapper2] vector (...))

Examples

Example 24.386. Importing and using a Web Services description file

```
SQL> soap_wsdl_import('http://[host:port]/chemistry.wsdl');

Done. -- 1286 msec.
SQL> select xml_tree_doc (Chemistry.getElementBySymbol('Ni'));
callret
VARCHAR
_______________________________________________________________________________

<getElementBySymbolResponse>
  <return>
    <atomicnumber>28</atomicnumber>
    <symbol>Ni</symbol>
    <name>Nickel</name>
    <mass>58.69</mass>
    <meltingPoint>1726.0</meltingPoint>
    <boilingPoint>3005.0</boilingPoint>
    <found>1751</found>
 </return>
</getElementBySymbolResponse>

Note: the namespaces from response are omitted for better reading.
```

See Also

soap_wsdl()

soap_box_structure

soap_box_structure

Synopsis

```
any soap_box_structure ( in elem1 varchar ,
                         in value1 any ,
                         in ... ,
                         in elem1 varchar ,
                         in value1 any ) ;
```

Description

This function provides a way to encapsulate a structure suitable for soap serialization. It accepts a name/value pairs which represents name and value of elements of a structure.

For example structure :

```
{
  varString 'hello',
    varInt  1234
}
```

will be represented as soap_box_structure ('varString', 'hello', 'varInt', 1234); furthermore value returned from soap_box_structure passed as an output parameter to the procedure (named structname) working as SOAP method will return :

```
    <structName>
        <varString>hello</varString>
        <varInt>1234</varInt>
</structName>
```

Please note that this is a one of possibilities to express structures for SOAP request/response in Virtuoso/PL. The other way to express structure is to use User Defined Types (see SOAP & WSDL section of the documentation).

Parameters

elem
: name which represents name of the member of a structure

value
: value which represents value of the member of a structure

Return Types

The return type of `soap_box_structure()` is an array representing a structure.

soap_current_url

soap_current_url — Returns URL used to access particular HTTP resource.

Synopsis

```
varchar soap_current_url ( );
```

Description

This function is used to get in VSP/VSPX context the URL used to access current resource (page). It check whether 'Host' header field is specified, if not will return as a host information the IP address resolved via connected socket information.

Return Types

The return type of `soap_current_url()` is an string containing the URL of the HTTP request.

space

space — returns a new string of count spaces

Synopsis

space (in *count* integer) ;

Description

`space` returns a new string, composed of count spaces. If count is zero, an empty string '' is returned.

```
space(5) -> '     '
```

split_and_decode

split_and_decode — converts escaped var=val pairs to a vector of strings

Synopsis

```
vector or string split_and_decode ( in coded_str varchar ,
                                    in case_mode integer ,
                                    in str varchar ) ;
```

Description

split_and_decode converts the escaped var=val pair inputs text to a corresponding vector of string elements. If the optional third argument is a string of less than three characters, then does only the decoding (but no splitting) and returns back a string.

Parameters

coded_str
: Input string to be converted.

case_mode
: This optional second argument, if present should be an integer either 0, 1 or 2, which tells whether "variable name"-parts (those at the left side of the fourth character given in third argument (or = if using the default URL-decoding)) are converted to UPPERCASE (1), lowercase (2) or left intact (0 or when the second argument is not given).

str
: If this argument is a string of less than three characters then this function will only decode without splitting and will return a string.

Examples

Example 24.387. Using split_and_decode

```
split_and_decode("Tulipas=Taloon+kumi=kala&Joka=haisi
            +pahalle&kuin&%E4lymystöporkkana=ilman ruuvausta",1)
produces a vector:
("TULIPAS" "Taloon kumi=kala" "JOKA" "haisi pahalle" "KUIN" NULL
"ÄLYMYSTÖPORKKANA" "ilman ruuvausta")

split_and_decode(NULL)   => NULL
split_and_decode("")     => NULL
split_and_decode("A")    => ("A" NULL)
split_and_decode("A=B")  => ("A" "B")

split_and_decode("A&B")  => ("A" NULL "B" NULL)
split_and_decode("=")    => ("" "")
split_and_decode("&")    => ("" NULL "" NULL)
split_and_decode("&=")   => ("" NULL "" "")
split_and_decode("&=&")  => ("" NULL "" "" "" NULL)
split_and_decode("%")    => ("%" NULL)
split_and_decode("%%")   => ("%" NULL)
split_and_decode("%41")  => ("A" NULL)
split_and_decode("%4")   => ("%4" NULL)
split_and_decode("%?41") => ("%?41" NULL)
```

Can also work like Perl's split function (we define the escape prefix and space escape character as NUL-characters, so that they will not be encountered at all:

```
split_and_decode('Un,dos,tres',0,'\0\0,') => ("Un" "dos" "tres")
split_and_decode("Un,dos,tres",1,'\0\0,') => ("UN" "DOS" "TRES")
split_and_decode("Un,dos,tres",2,'\0\0,') => ("un" "dos" "tres")
```

Can also be used as replace and ucase (or lcase) together, for example, here we use the comma as space-escape instead of element-separator: (not recommended, use replace and ucase instead.

```
split_and_decode("Un,dos,tres",0,'\0,')   => "Un dos tres"
split_and_decode("Un,dos,tres",1,'\0,')   => "UN DOS TRES"
```

Can be also used for decoding (some of) MIME-encoded mail-headers:

```
split_and_decode('=?ISO-8859-1?Q?Tiira_lent=E4=E4_taas?=',0,'=_')
=>  "=?ISO-8859-1?Q?Tiira lentää taas?="

split_and_decode('Message-Id: <199511141036.LAA06462@correo.unet.ar>\n
             From: "=?ISO-8859-1?Q?Jorge_Mo=F1as?=" <jorgem@unet.ar>\n
             To: "Jore Carvajal" <carvajal@wanabee.fr>\nSubject: RE: Um-pah-pah\n
             Date: Wed, 12 Nov 1997 11:28:51 +0100\n
             X-MSMail-Priority: Normal\nX-Priority: 3\n
             X-Mailer: Molosoft Internet Mail 4.70.1161\nMIME-Version: 1.0\n
             Content-Type: text/plain; charset=ISO-8859-1\n
             Content-Transfer-Encoding: 8bit\nX-Mozilla-Status: 0011',
1,'=_\n:');
=> ('MESSAGE-ID' ' <199511141036.LAA06462@correo.unet.ar>'
'FROM' ' "=?ISO-8859-1?Q?Jorge Moñas?=" <jorgem@unet.ar>'
'TO' ' "Jore Carvajal" <carvajal@wanabee.fr>'
'SUBJECT' ' RE: Um-pah-pah'
'DATE' ' Wed, 12 Nov 1997 11:28:51 +0100'
'X-MSMAIL-PRIORITY' ' Normal'
'X-PRIORITY' ' 3'
'X-MAILER' ' Molosoft Internet Mail 4.70.1161'
'MIME-VERSION' ' 1.0'
'CONTENT-TYPE' ' text/plain; charset=ISO-8859-1'
'CONTENT-TRANSFER-ENCODING' ' 8bit'
'X-MOZILLA-STATUS' ' 0011')
```

Same, but let's use space, not colon as a variable=value separator:

```
split_and_decode('Message-Id: <199511141036.LAA06462@correo.unet.ar>\n
             From: "=?ISO-8859-1?Q?Jorge_Mo=F1as?=" <jorgem@unet.ar>\n
             To: "Jore Carvajal" <carvajal@wanabee.fr>\nSubject: RE: Um-pah-pah\n
             Date: Wed, 12 Nov 1997 11:28:51 +0100\n
             X-MSMail-Priority: Normal\nX-Priority: 3\n
             X-Mailer: Molosoft Internet Mail 4.70.1161\nMIME-Version: 1.0\n
             Content-Type: text/plain; charset=ISO-8859-1\n
             Content-Transfer-Encoding: 8bit\nX-Mozilla-Status: 0011',
1,'=_\n ')
=> ('MESSAGE-ID:' '<199511141036.LAA06462@correo.unet.ar>'
'FROM:' '"=?ISO-8859-1?Q?Jorge Moñas?=" <jorgem@unet.ar>'
'TO:' '"Jore Carvajal" <carvajal@wanabee.fr>'
'SUBJECT:' 'RE: Um-pah-pah'
'DATE:' 'Wed, 12 Nov 1997 11:28:51 +0100'
'X-MSMAIL-PRIORITY:' 'Normal'
'X-PRIORITY:' '3'
'X-MAILER:' 'Molosoft Internet Mail 4.70.1161'
'MIME-VERSION:' '1.0'
'CONTENT-TYPE:' 'text/plain; charset=ISO-8859-1'
'CONTENT-TRANSFER-ENCODING:' '8bit'
'X-MOZILLA-STATUS:' '0011')
```

Of course this approach does not work with multiline headers, except somewhat kludgously. If the lines are separated by CR+LF, there is left one trailing CR at the end of each value part string.

sprintf

sprintf — returns a formatted string

Synopsis

sprintf (*format* string ,
arg_1 any ,
... ,
arg_x any) ;

Description

sprintf returns a new string formed by "printing" a variable number of arguments arg_1 - arg_x according to the format string format, that is, exactly the same way as with the sprintf function of C language. However the sprintf function enforces some additional limitations over the sprintf C function. It does not allow for single value output to take more than 2000 characters. It does support the following additional format characters:

diouxXeEfgcs - as in the C language printf

S - as 's' but escapes the single quotes by doubling them (as per SQL/92). This is suitable for constructing dynamic SQL statements with string literals inline.

```
sprintf ('insert into testit (data) values ('%S')', 'Test ''Real'' data')
    -> insert into testit (data) values ('Test ''Real'' data')
```

I - as 's' but escapes the string value to form a valid identifier name (will double the double quotes). This is suitable for constructing dynamic SQL statements with identifiers inline.

```
sprintf ('select * from "%I"', 'Big "Table" Name')
    -> select * from "Big ""Table"" Name"
```

U - as 's' but escapes the string value as an HTTP URL (same as http_url() function). Useful for making dynamic VSP content

```
sprintf ('<a href="%U">', 'day & night')
    -> <a href="day+%26+night">
```

R - use to replace leading spaces: the modifiers are one of + - # 0 and space.

```
sprintf ('%-R', ' 123')
-123
sprintf ('%-R', '  123')
--123
```

V - as 's' but escapes the string value as an HTTP Value (same as http_value). Useful for making dynamic VSP content

```
sprintf ('<INPUT name="test" value="%V">', 'day & night')
    -> <INPUT name="test" value="day &amp; night">
```

Note that the sprintf format length and precision modifiers do not apply to the extension format characters

```
sprintf('Int=%d/%o/%x, String=%s, Character=%c',
    42798,42798,42798,'la cadena',65)
 -> 'Int=42798/123456/a72e, String=la cadena, Character=A'
```

In addition, *%{varname}U* syntax extension is supported, mostly for uing connection variables in RDF IRI classes . That syntax is to print the value of client connection variable *varname* using print format *%U* . Other format characters are not supported for that feature in current version of Virtuoso but might be supported in the future.

sprintf_inverse

sprintf_inverse — returns vector on a specified pattern.

Synopsis

sprintf_inverse (*strg* string ,
format string ,
err integer) ;

Description

sprintf_inverse gets a string to parse, a format string and an integer (0,1 or 2) that indicates error recovery method. If the first argument matches the format string then it returns vector of the pattern values.

Parameters

strg
: a string to parse

format
: a format string

err
: indicates the error recovery method in case the string does not match to the format: 0 - to return NULL, 1 - to return shorter vector that consists of all values extracted before the mismatch has been detected, 2 - to return vector of expected length with NULLs instead of values that were not found due to mismatch

Examples

Example 24.388. Example 1

```
SQL> select sprintf_inverse ('qwe123asd456zxcABRACADABRA', 'qwe%dasd%dzxc%s', 2);
callret
VARCHAR
_______________________________________________________________________________

vector(123,456,0x00adfae8)

1 Rows. -- 0 msec.
SQL>
```

Example 24.389. Example 2

```
SQL> select sprintf_inverse ('---123', '%-R', 2);
callret
VARCHAR
_______________________________________________________________________________

vector(0x00b070e8)

1 Rows. -- 0 msec.
SQL>
```

sprintf_iri

sprintf_iri — returns a formatted string that is marked as an IRI string.

Synopsis

sprintf_iri (*format* string ,
arg_1 any ,
... ,
arg_x any) ;

Description

sprintf_iri is similar to sprintf and returns a new string formed by "printing" a variable number of arguments arg_1 - arg_x according to the format string format. The difference is that the returned string is marked as being IRI string so some applications and clients may distinguish between RDF reference string and RDF literal.

Note

No matter what is the default server charset or default encoding of host OS, IRI strings are supposed to be in UTF-8 encoding so string arguments to print as well as the format itself are supposed to be UTF-8. Application may use calls of `charset_recode` as arguments.

Examples

Example 24.390. Simple Use

```
create function job_history(
  in EMPLOYEE_ID integer,
  in START_DATE date) returns varchar
{
return sprintf_iri
('http://demo.openlinksw.com:8890/hr/job_history#%d_%s',
EMPLOYEE_ID, cast (START_DATE as varchar) );
};
```

sprintf_iri_or_null

sprintf_iri_or_null — returns a formatted IRI string or null if any of the arguments except the first is null.

Synopsis

sprintf_iri_or_null (
format string ,
arg_1 any ,
... ,
arg_x any
) ;

Description

sprintf_iri_or_null is similar to sprintf_iri and returns a new string formed by "printing" a variable number of arguments arg_1 - arg_x according to the format string format. The difference is that the function can return null if any of the arguments except the first one is null.

The returned string is marked as being IRI string so some applications and clients may distinguish between RDF reference string and RDF literal.

Note

No matter what is the default server charset or default encoding of host OS, IRI strings are supposed to be in UTF-8 encoding so string arguments to print as well as the format itself are supposed to be UTF-8. Application may use calls of `charset_recode` as arguments.

Examples

Example 24.391. Simple Use

```
create function job_history(
  in EMPLOYEE_ID integer,
  in START_DATE date) returns varchar
{
return sprintf_iri_or_null
('http://demo.openlinksw.com:8890/hr/job_history#%d_%s',
EMPLOYEE_ID, cast (START_DATE as varchar) );
};
```

sprintf_or_null

sprintf_or_null — returns a formatted string or null if any of the arguments except the first is null.

Synopsis

sprintf_or_null (*format* string ,
arg_1 any ,
... ,
arg_x any) ;

Description

sprintf_or_null is similar to sprintf and returns a new string formed by "printing" a variable number of arguments arg_1 - arg_x according to the format string format. The difference is that the function can return null if any of the arguments except the first one is null.

Examples

Example 24.392. Simple Use

```
create function job_history(
  in EMPLOYEE_ID integer,
  in START_DATE date) returns varchar
{
return sprintf_or_null
('http://demo.openlinksw.com:8890/hr/job_history#%d_%s',
EMPLOYEE_ID, cast (START_DATE as varchar) );
};
```

sql_columns

sql_columns — get column information from table on a remote DSN

Synopsis

```
vector sql_columns ( in dsn varchar ,
                     in qualifier varchar ,
                     in owner varchar ,
                     in table_name varchar ,
                     in column varchar ) ;
```

Description

This function corresponds to the ODBC catalog call of similar name. It and related functions are used by the virtual database to query remote data dictionaries.

The dsn argument must refer to a dsn previously defined by `vd_remote_data_source` or ATTACH TABLE.

For instance, the qualifier argument corresponds to the szTableQualifier and cbTableQualifier arguments of an ODBC catalog function. The SQL NULL value corresponds to the C NULL value. The arguments can contain % signs, which are interpreted as in LIKE.

Parameters

As defined in ODBC API for the corresponding catalog call.

Return Types

As defined in ODBC API for the corresponding catalog call.

This function returns an array, with one element for each row of the result set. Each row is represented as an array with one element for each column.

Examples

Example 24.393. Simple example

```
dbg_obj_print (sql_columns ('Local Virtuoso', 'Demo', NULL, 'Orders', NULL));
->
(
("Demo" "demo" "Orders" "OrderID" 4 "INTEGER" 10 10 <DB NULL> 2 1 <DB NULL> <DB NULL> 4 <DB NULL> 10 1 1
("Demo" "demo" "Orders" "CustomerID" 12 "VARCHAR" 5 5 <DB NULL> 2 1 <DB NULL> <DB NULL> 12 <DB NULL> 5 2
("Demo" "demo" "Orders" "EmployeeID" 4 "INTEGER" 10 10 <DB NULL> 2 1 <DB NULL> <DB NULL> 4 <DB NULL> 10 3
("Demo" "demo" "Orders" "OrderDate" 11 "DATETIME" 19 19 <DB NULL> 2 1 <DB NULL> <DB NULL> 11 3 19 4 4 )
("Demo" "demo" "Orders" "RequiredDate" 9 "DATE" 10 10 <DB NULL> 2 1 <DB NULL> <DB NULL> 9 1 10 5 5 )
("Demo" "demo" "Orders" "ShippedDate" 11 "DATETIME" 19 19 <DB NULL> 2 1 <DB NULL> <DB NULL> 11 3 19 6 6 )
("Demo" "demo" "Orders" "ShipVia" 4 "INTEGER" 10 10 <DB NULL> 2 1 <DB NULL> <DB NULL> 4 <DB NULL> 10 7 7
("Demo" "demo" "Orders" "Freight" 8 "DOUBLE PRECISION" 16 16 <DB NULL> 2 1 <DB NULL> <DB NULL> 8 <DB NULL
("Demo" "demo" "Orders" "ShipName" 12 "VARCHAR" 40 40 <DB NULL> 2 1 <DB NULL> <DB NULL> 12 <DB NULL> 40 9
("Demo" "demo" "Orders" "ShipAddress" 12 "VARCHAR" 60 60 <DB NULL> 2 1 <DB NULL> <DB NULL> 12 <DB NULL> 6
("Demo" "demo" "Orders" "ShipCity" 12 "VARCHAR" 15 15 <DB NULL> 2 1 <DB NULL> <DB NULL> 12 <DB NULL> 15 1
("Demo" "demo" "Orders" "ShipRegion" 12 "VARCHAR" 15 15 <DB NULL> 2 1 <DB NULL> <DB NULL> 12 <DB NULL> 15
("Demo" "demo" "Orders" "ShipPostalCode" 12 "VARCHAR" 10 10 <DB NULL> 2 1 <DB NULL> <DB NULL> 12 <DB NULL
("Demo" "demo" "Orders" "ShipCountry" 12 "VARCHAR" 15 15 <DB NULL> 2 1 <DB NULL> <DB NULL> 12 <DB NULL> 1
)
```

See Also

`sql_data_sources` , `sql_columns` `sql_primary_keys` , `sql_gettypeinfo` , `sql_statistics` , `sql_tables` .

sql_data_sources

sql_data_sources — get list of available DSNs

Synopsis

```
sql_data_sources (   );
```

Description

`sql_data_sources` is used to get the list of datasources available to the dsn. It returns a vector of 2 element vectors containing Data source name and type pairs.

Parameters

As defined in ODBC API for the corresponding catalog call.

Return Types

As defined in ODBC API for the corresponding catalog call.

A vector containing a 2 element vector for each defined data source with a string data source name as 1st element and a string data source type as the 2nd element.

Examples

Example 24.394. Simple Use

```
SQL> select aref (aref (sql_data_sources(), 0), 0);
callret
VARCHAR
_______________________________________________________________________________

Local Virtuoso

1 Rows. -- 4 msec.
```

See Also

`sql_columns` `sql_primary_keys` , `sql_gettypeinfo` , `sql_statistics` , `sql_tables` .

sql_gettypeinfo

sql_gettypeinfo — return type information from a remote DSN

Synopsis

```
vector sql_gettypeinfo ( in dsn varchar ,
                         in type integer ) ;
```

Description

You can use the functions described here to find out information about the remote datasources that you are using. These could be especially useful in Virtuoso PL later on if you are not able to know everything about the remote tables ahead of time for the ATTACH TABLE statement. statement

These SQL functions correspond to the ODBC catalog calls of similar name.

The dsn argument must refer to a dsn previously defined by vd_remote_data_source or ATTACH TABLE.

By default information for all the data types supported by the remote is returned. The optional type argument (defaults to SQL_ALL_TYPES) limits the information returned to cover only the ODBC type number supplied.

These functions return an array, with one element for each row of the result set. Each row is represented as an array with one element for each column.

```
dbg_obj_print (sql_gettypeinfo ('Local Virtuoso'));
->
(
 ("character" 1 2000 "'" "'" "length" 1 1 3 0 0 0 "varchar" <DB NULL> <DB NULL> )

sql_primary_keys

sql_primary_keys — get primary key information about a table on a remote DSN

Synopsis

```
vector sql_primary_keys ( in dsn varchar ,
                          in qualifier varchar ,
                          in owner varchar ,
                          in table_name varchar ) ;
```

Description

You can use the functions described here to find out information about the remote datasources that you are using. These could be especially useful in Virtuoso PL later on if you are not able to know everything about the remote tables ahead of time for the ATTACH TABLE statement. statement

These SQL functions correspond to the ODBC catalog calls of similar name. These are used to access the data dictionary of remote data sources inside the ATTACH TABLE process.

The dsn argument must refer to a dsn previously defined by vd_remote_data_source or ATTACH TABLE.

For instance, the qualifier argument corresponds to the szTableQualifier and cbTableQualifier arguments of an ODBC catalog function. A SQL NULL value corresponds to the C NULL value. The arguments can contain % signs, which are interpreted as in LIKE.

These functions return an array, with one element for each row of the result set. Each row is represented as an array with one element for each column.

Parameters

dsn
: The data source name string

qualifier
: Qualifier string . May contain wildcards as in 'De%'.

owner
: Table owner string . May contain wildcard characters in 'Dem%'.

table_name
: Table name string . May contain wildcard characters in 'Cust%'.

Return Types

As defined in ODBC API for the corresponding catalog call.

An array, with one element for each row of the result set. Each row is represented as an array with one element for each column.

Examples

Example 24.395. Simple Example

```
dbg_obj_print (sql_primary_keys ('Local Virtuoso', 'Demo', NULL, 'Orders'));
->
(
 ("Demo" "demo" "Orders" "OrderID" 1 "Orders" "Demo" "demo" "Orders" )
)
```

See Also

sql_statistics

sql_statistics — retrieve statistics information on remote DSN

Synopsis

```
vector sql_statistics ( in dsn varchar ,
                        in qualifier varchar ,
                        in owner varchar ,
                        in table_name varchar ,
                        in is_unique integer ,
                        in detail integer ) ;
```

Description

This SQL function corresponds to the ODBC catalog call of similar name. It is used to access the data dictionary of remote data sources inside the ATTACH TABLE process.

The dsn argument must refer to a dsn previously defined by vd_remote_data_source or ATTACH TABLE.

The qualifier argument corresponds to the szTableQualifier and cbTableQualifier arguments of an ODBC catalog function. A SQL NULL value corresponds to the C NULL value. The arguments can contain % signs, which are interpreted as in LIKE.

These functions return an array, with one element for each row of the result set. Each row is represented as an array with one element for each column.

Parameters

As defined in ODBC API for the corresponding catalog call.

Return Types

As defined in ODBC API for the corresponding catalog call.

An array with one element for each row of the result set. Each row is represented as an array with one element for each column.

Examples

Example 24.396. Simple Example

```
dbg_obj_print (sql_statistics ('Local Virtuoso', 'Demo', NULL, 'Orders', 0, 1));
->
(
 ("Demo" "demo" "Orders" 0 "Demo" "Orders" 3 1 "OrderID" <DB NULL> <DB NULL> <DB NULL> <DB NULL> )
)
```

See Also

`sql_data_sources` , `sql_columns` `sql_primary_keys` , `sql_gettypeinfo` , `sql_tables` .

sql_tables

sql_tables — get list of tables from remote DSN

Synopsis

```
vector sql_tables ( in dsn varchar ,
                    in qualifier varchar ,
                    in owner varchar ,
                    in table_name varchar ,
                    in tabletype varchar ) ;
```

Description

This function corresponds to the ODBC catalog call of similar name. It and related functions are used by the virtual database to query remote data dictionaries.

The dsn argument must refer to a dsn previously defined by vd_remote_data_source or ATTACH TABLE.

The qualifier argument corresponds to the szTableQualifier and cbTableQualifier arguments of an ODBC catalog function. A SQL NULL value corresponds to the C NULL value. The arguments can contain % signs, which are interpreted as in LIKE.

Parameters

As defined in ODBC API for the corresponding catalog call.

Return Types

As defined in ODBC API for the corresponding catalog call.

This function returns an array, with one element for each row of the result set. Each row is represented as an array with one element for each column.

Examples

Example 24.397. Simple example

```
dbg_obj_print (sql_tables ('Local Virtuoso', 'Demo', NULL, NULL, NULL));
->
(
 ("Demo" "demo" "Categories" "TABLE" <DB NULL> )
 ("Demo" "demo" "Customers" "TABLE" <DB NULL> )
 ("Demo" "demo" "Employees" "TABLE" <DB NULL> )
 ("Demo" "demo" "Order_Details" "TABLE" <DB NULL> )
 ("Demo" "demo" "Orders" "TABLE" <DB NULL> )
 ("Demo" "demo" "Products" "TABLE" <DB NULL> )
 ("Demo" "demo" "Shippers" "TABLE" <DB NULL> )
 ("Demo" "demo" "Suppliers" "TABLE" <DB NULL> )
)
```

See Also

sql_data_sources , sql_columns sql_primary_keys , sql_gettypeinfo , sql_statistics .

sql_special_columns

sql_special_columns — get special column information from table on a remote DSN

Synopsis

```
vector sql_special_columns ( in dsn varchar ,
                             in qualifier varchar ,
                             in owner varchar ,
                             in table_name varchar ,
                             in scope integer ,
                             in nullable integer ) ;
```

Description

This function corresponds to the ODBC catalog call of similar name. It and related functions are used by the virtual database to query remote data dictionaries.

First argument of the ODBC SQLSpecialColumns is always SQL_BEST_ROWID.

The dsn argument must refer to a dsn previously defined by `vd_remote_data_source()` or ATTACH TABLE.

For instance, the qualifier argument corresponds to the szTableQualifier and cbTableQualifier arguments of an ODBC catalog function. The SQL NULL value corresponds to the C NULL value. The arguments can contain % signs, which are interpreted as in LIKE.

Parameters

As defined in ODBC API for the corresponding catalog call.

Return Types

As defined in ODBC API for the corresponding catalog call.

This function returns an array, with one element for each row of the result set. Each row is represented as an array with one element for each column.

Examples

Example 24.398. Simple example

```
dbg_obj_print (sql_special_columns ('Local Virtuoso', 'Demo', 'demo', 'Orders', 0, 0));
->
(
 (0ld "OrderID" 4 "INTEGER" 10 10 <DB NULL> 1 )
)
```

See Also

`sql_data_sources` , `sql_columns` `sql_primary_keys` , `sql_gettypeinfo` , `sql_statistics` , `sql_tables` .

sql_procedures

sql_procedures — get procedures information for a remote DSN

Synopsis

```
vector sql_procedures ( in dsn varchar ,
                        in qualifier varchar ,
                        in owner varchar ,
                        in name varchar ) ;
```

Description

This function corresponds to the ODBC catalog call of similar name. It and related functions are used by the virtual database to query remote data dictionaries.

The dsn argument must refer to a dsn previously defined by `vd_remote_data_source()` or ATTACH TABLE.

For instance, the qualifier argument corresponds to the szTableQualifier and cbTableQualifier arguments of an ODBC catalog function. The SQL NULL value corresponds to the C NULL value. The arguments can contain % signs, which are interpreted as in LIKE.

Parameters

As defined in ODBC API for the corresponding catalog call.

Return Types

As defined in ODBC API for the corresponding catalog call.

This function returns an array, with one element for each row of the result set. Each row is represented as an array with one element for each column.

Examples

Example 24.399. Simple example

```
dbg_obj_print (sql_procedures ('Local Virtuoso', 'DB', 'DBA', 'VT_INC_INDEX_DB_DBA_MAIL_MESSAGE'));
->
(
 ("DB" "DBA" "VT_INC_INDEX_DB_DBA_MAIL_MESSAGE" <DB NULL> <DB NULL> <DB NULL> <DB NULL> 0ld )
)
```

See Also

`sql_data_sources` , `sql_columns` `sql_primary_keys` , `sql_gettypeinfo` , `sql_statistics` , `sql_tables` .

sql_write_private_profile_string

sql_write_private_profile_string — Sets a DSN's attribute value

Synopsis

```
integer sql_write_private_profile_string ( in dsn varchar ,
                                           in type varchar ,
                                           in name varchar ,
                                           in value varchar ) ;
```

Description

This function corresponds to the ODBC catalog call of similar name. It and related functions are used by the virtual database to query remote data dictionaries.

The type argument must be either 'system' or 'user'.

Sets a data source attribute by calling SQLWritePrivateProfileString from the ODBC Installer API.

Parameters

type denotes the DSN type.

others are passed to the SQLWritePrivateProfileString

Return Types

Returns the SQL state.

See Also

sql_data_sources , sql_columns sql_primary_keys , sql_gettypeinfo , sql_statistics , sql_tables .

sql_get_private_profile_string

sql_get_private_profile_string — Gets the DSN's attributes list

Synopsis

```
vector sql_get_private_profile_string ( in dsn varchar ,
                                        in type varchar ) ;
```

Description

This function corresponds to the ODBC catalog call of similar name. It and related functions are used by the virtual database to query remote data dictionaries.

The type argument must be either 'system' or 'user'.

Gets the data source attributes by calling SQLGetPrivateProfileString from the ODBC Installer API.

Parameters

dsn
: is the first argument passed to SQLGetPrivateProfileString.

type
: denotes the DSN type.

Return Types

Returns an array of 2-element arrays representing the name/value pairs.

See Also

`sql_data_sources` , `sql_columns` `sql_primary_keys` , `sql_gettypeinfo` , `sql_statistics` , `sql_tables` .

sql_config_data_sources

sql_config_data_sources — Configures a remote DSN as in the DSN attribute string

Synopsis

```
vector sql_config_data_sources ( in driver varchar ,
                                 in type varchar ,
                                 in attrib varchar ) ;
```

Description

This function creates or modifies a user or system data source based on the semicolon separated list of DSN attributes.

The type argument must be either 'system' or 'user'.

Configures the data source by calling SQLWriteDSNToIni/SQLWritePrivateProfileString/SQLSetConfigMode from the ODBC Installer API.

Parameters

driver is the Driver name passed to SQLWriteDSNToIni.

Return Types

Returns the ODBC status code.

See Also

sql_data_sources , sql_columns sql_primary_keys , sql_gettypeinfo , sql_statistics , sql_tables .

sql_get_installed_drivers

sql_get_installed_drivers — get column information from table on a remote DSN

Synopsis

```
vector sql_get_installed_drivers ( );
```

Description

This function corresponds to the ODBC Installer call of similar name. It and related functions are used by the virtual database to query remote data sources.

Parameters

None

Return Types

As defined in ODBC API for the corresponding catalog call.

This function returns an array of varchars.

Examples

Example 24.400. Simple example

```
dbg_obj_print (sql_get_installed_drivers ());
->
(
 "OpenLink Generic 32 Bit Driver v4.0"
)
```

See Also

`sql_data_sources` , `sql_columns` `sql_primary_keys` , `sql_gettypeinfo` , `sql_statistics` , `sql_tables` .

sql_remove_dsn_from_ini

sql_remove_dsn_from_ini — removes a DSN from the ODBC registry

Synopsis

```
vector sql_remove_dsn_from_ini ( in dsn varchar ,
                                 in dsn_type varchar ) ;
```

Description

This function corresponds to the ODBC installer call of similar name. It and related functions are used by the virtual database to handle remote data sources.

Parameters

As defined in ODBC Installer API for the corresponding catalog call.

Return Types

None.

See Also

`sql_data_sources` , `sql_columns` `sql_primary_keys` , `sql_gettypeinfo` , `sql_statistics` , `sql_tables` .

sql_transact

sql_transact — get list of available DSNs

Synopsis

sql_transact (in *dsn_name* varchar ,
in *rollback* integer) ;

Description

This procedure can be used to control the commit/rollback behavior of a particular remote data source during a Virtuoso transaction such as in a stored procedure.

Under normal circumstances Virtuoso will correctly commit or rollback all associated work as expected, however it may be desirable intervene. When issued without the second parameter a commit will be forced upon the current transactions of the dsn_name above the call to `sql_transact` regardless of overall outcome. When rollback = 1 is set then a rollback will be forced likewise, hence this will not rollback work on the remote dsn_name prior to `sql_transact` .

Parameters

dsn_name
: The name of the data source being used on the remote.

rollback
: Activate the desired behavior. Set to 1 for rollback, ignore to commit.

Return Types

None.

Examples

Example 24.401. Control remote rollback/commit behavior

This code fragment can be used to demonstrate the effects of directly controlling the rollback/commit behavior of remote data sources connected to Virtuoso.

```
create procedure TEST_ROLLBACK ()
{
  commit work;
  insert into mydsn..rb_test values (1);
  sql_transact('mydsn');
  insert into mydsn..rb_test values (2);
  rollback work;
};

create procedure TEST_ROLLBACK ()
{
  commit work;
  insert into mydsn..rb_test values (1);
  sql_transact('mydsn', 1);
  insert into mydsn..rb_test values (2);
  commit work;
};

delete from mydsn..rb_test;

commit work;
TEST_COMMIT();
select MIN (ID) from mydsn..rb_test;
```

```
-- returns 1

delete from mydsn..rb_test;

commit work;
TEST_ROLLBACK();
select MIN (ID) from mydsn..rb_test;

-- returns 2
```

See Also

sql_columns sql_primary_keys , sql_gettypeinfo , sql_statistics , sql_tables .

sql_write_file_dsn

sql_write_file_dsn — Creates a new file DSN

Synopsis

```
integer sql_write_file_dsn ( in dsn varchar ,
                             in string varchar ,
                             in value varchar ) ;
```

Description

This function calls the SQLWriteFileDSN as follows :

SQLWriteFileDSN (dsn, 'ODBC', string, value)

Parameters

As described in the SQLWriteFileDSN

Return Types

Returns the SQL state.

See Also

`sql_data_sources` , `sql_columns` `sql_primary_keys` , `sql_gettypeinfo` , `sql_statistics` , `sql_tables` .

sql_driver_connect

sql_driver_connect — Tries connecting using supplied connection string

Synopsis

```
integer sql_driver_connect ( in conn_str varchar );
```

Description

This function calls SQLDriverConnect with the supplied connection string and immediately disconnects after the call.

Parameters

As described in the SQLDriverConnect in connection string

Return Types

Returns the SQL return code (or exception on an ODBC error).

See Also

`sql_data_sources` , `sql_columns` `sql_primary_keys` , `sql_gettypeinfo` , `sql_statistics` , `sql_tables` .

sqrt

sqrt — calculate square root

Synopsis

sqrt (in *x* double precision);

Description

`sqrt` calculates the square root of its argument and returns it as a IEEE 64-bit float.

Parameters

x
: double precision

Return Values

`sqrt` returns a IEEE 64-bit float.

Examples

Example 24.402. Stored Procedure Example

Calculate square roots of integers between 2 numbers.

```
SQL> create procedure
calc_sqrts (in _from integer, in _to integer)
{
  declare i integer;
  declare result double precision;

  result_names (i, result);

  i := _from;
  while (i < _to)
   {
     result (i, sqrt (i));
     i := i + 1;
   }
}
;
(0) (0) (1) (1) (1) (1) (1) (1) (1) (1) (2) (2) (2) (1)
Done. -- 7 msec.
SQL> calc_sqrts(1, 10);
i                 result
INTEGER NOT NULL  DOUBLE PRECISION NOT NULL
_____________________________________________________________________________

`exp` , `sqrt` , `log10` , `power`

status

status — Returns statistics for a running server as a result set

Synopsis

status (in *option* varchar);

Description

Depending of input parameter displays a statistics for running server.

Note that counters reported by status will be reset after server startup.

Parameters

option
: This option controls the level of detail of the output returned from this procedure. Possible options are:

Return Types

Status returns a result set with one varchar column, one row per line of text in the status report.

Example

Example 24.403. Retrieving Server Status

```
SQL> status('rhck');

key_estimate

key_estimate — Get an estimate of row count for a given set of leading index key parts

Synopsis

key_estimate (in *table_name* varchar ,
in *index_name* varchar ,
in *k1* any ,
...) ;

Description

Given a table and an index, this function takes a random sample of the index, with the first key part equal to the third argument, the second equal to the fourth argument and so on. If only the table and index are given, the returned value is the approximate count of the entire index.

Normal cast rules are applied to convert the arguments to the types of the corresponding key parts. If the cast fails, -1 is returned.

The estimates are typically within 10% of the real count. If there have been random deletions or inserts leading to uneven page filling or if index entries are of greatly varying $ length, the estimates may be less precise.

Parameters

table_name
: The name of the table as appears in SYS_KEYS, case sensitive.

index_name
: The name of the index as appears in sys_keys, case sensitive.

k1
: The value of the first key part. Any number of arguments, up to the number of key parts in the index in question may follow.

Return

Key_estimate returns the approximate count of entries in the index with the specified values in the leading key parts. -1 if cannot be determined.

Example

Example 24.404. Returns the approximate count of entries in index STR1 where the first key part is the string '123'.

```
select key_estimate ('DB.DBA.T1', 'STR1', '123');
```

strcasestr

strcasestr — case-insensitive substring search

Synopsis

strcasestr (in *str* string ,
in *sub* string) ;

Description

`strcasestr` performs a case-insensitive substring search, returning a zero-based index pointing to beginning of first occurrence of *`sub`* or NULL if not found.

Parameters

str
: String to search from.

sub
: Substring to search for.

Return Types

An integer zero-based index to first occurrence of *`sub`* .

Examples

Example 24.405. Sample example

```
strstr('AbracadabrA','abrA')
    -> 7 (Found from the eighth character onwards)
strcasestr('AbracadabrA','abrA')
    -> 0 (Found from the beginning of string)
```

See Also

`strstr` .

strchr

strchr — strchr returns a zero-based index to the first occurrence of the character.

Synopsis

strchr (*str* string ,
char string or integer) ;

Description

strchr returns a zero-based index to the first occurrence of char. If char is not found NULL is returned. char can be given either as an integer ASCII value or a string, in which case the first character of that string is searched fo.

```
strchr('AbracadabrA','A')
                -> 0 (Found as the first character).
strrchr('AbracadabrA',65)
                -> 10 (Found as the eleventh character)
```

stringdate

stringdate — Convert a string to a datetime

Synopsis

stringdate (in *str* varchar) ;

Description

stringdate converts dates and timestamps from text to the internal DATETIME type.

The external format is: YYYY.MM.DD hh:mm.ss uuuuuu where uuuuuu represents number of microseconds.

If trailing parts are omitted from the string given to stringdate, they are assumed to be zero. The three first parts are mandatory. Note that use of

```
cast (x as datetime)
```

is preferred over this function.

Parameters

str
: A varchar date in human-readable (external) format.

Errors

Table 24.81. Errors signalled by `datestring` and `stringdate`

SQLState	Error Code	Error Text	Description
22007	DT006	Cannot convert <offending string> to datetime	
22002	DT007	Nulls not allowed as parameters to stringdate	

Examples

Example 24.406. Stringdate example with datestring_GMT

We are at central european time zone CET(GMT+1).

```
SQL> use Demo;

 Done. -- 3 msec.
 SQL> select (datestring_GMT (stringdate ('2000-01-01 22:00')));
 callret

```

See Also

`datestring`

The discussion of TIMESTAMP datatype in section Database Concepts of the documentation.

stringtime

stringtime — converts string to a time

Synopsis

```
time stringtime ( in str varchar );
```

Description

Converts the argument to a time. Same as

```
cast (x as time)
```

string_output

string_output — make a string output stream

Synopsis

string_output (in *threshold* integer) ;

Description

A string output stream is a special object that may be used to buffer arbitrarily long streams of data. They are useful for handling data that would not otherwise fit within normal varchar size limitations. The HTTP output functions optionally take a string output stream handle as a parameter and then output to said stream instead of the HTTP client. A string output stream can be assigned to a database column in insert or update, causing the characters written to the stream to be assigned to the column as a narrow string.

The function `string_output_string` can be used to produce a varchar out of a string output stream. It may be called repeatedly to obtain several copies of the data. `http_rewrite` can be used to flush a string output stream.

If a string output stream is passed to the function `result` the data stored in it is sent to the client.

The string output object cannot be copied. It cannot therefore be assigned between two variables or passed by value (as an IN parameter.) It can be passed by reference (OUT, INOUT parameter.)

Parameters

threshold
: Optional size threshold, exceeding this the object will be stored in a temp directory specified by 'TempSesDir' INI parameter.

Examples

Example 24.407. Handling string output streams

This example takes a string as an argument, creates a new string output stream, writes the string into the stream and inserts stream contents to a DB table.

```
create table
foo_table (
a integer identity,
b long varchar,
primary key (a));

create procedure
foo_out (in x varchar)
{
  declare str_out any;
  declare str varchar;

-- Pass correct result metadata to client
  result_names (str);

-- Get a new string output stream
  str_out := string_output();

  http (x, str_out);

-- These produce the same result
  result (string_output_string (str_out));
  result (str_out);

-- insert string output contents
  insert into foo_table (b) values (str_out);
```

```
-- Write it again to the string output
  http (concat (' ', x), str_out);

  result (str_out);
}
;

SQL> foo_out ('Ceterum censeo, Carthaginem esse delendum!');
str
VARCHAR NOT NULL
_____________________________________________________________________________

Ceterum censeo, Carthaginem esse delendum!
Ceterum censeo, Carthaginem esse delendum!
Ceterum censeo, Carthaginem esse delendum! Ceterum censeo, Carthaginem esse delendum!

2 Rows. -- 2 msec.

SQL> select * from foo_table;
a                 b
INTEGER NOT NULL  LONG VARCHAR
_____________________________________________________________________________

1                 Ceterum censeo, Carthaginem esse delendum!

1 Rows. -- 2 msec.
```

See Also

string_output_stream, http, http_value

string_output_flush

string_output_flush — resets the state of the string_output object

Synopsis

string_output_flush (inout *stream* any) ;

Description

This function resets the state of the string output object. The string associated with the string output is dropped and is of 0 characters after this call.

Parameters

stream
: stream to clear, must have been created by the string_output function.

Examples

Example 24.408. Flush the String Output Stream

```
<?vsp
  declare ses nay;
  ses := string_output ();
  http ('this text never be displayed' , ses);
  string_output_flush (ses);
  http ('stream test' , ses);
  http (string_output_string (ses));
?>
```

string_output_gz_compress

string_output_gz_compress — compress a string_output with gzip algorithm

Synopsis

string_output_gz_compress (in *str_out_in* string_session ,
out *str_out_out* string_session) ;

Description

The string_output_gz_compress compresses its string_output argument using the gzip algorithm and writes the result to another string_output given as an argument. When successful, the number of bytes written to *str_out_out* is returned.

Parameters

str_out_in
: A string session as returned by string_output function.

str_out_out
: A string session as returned by string_output function.

Return Types

INTEGER number of bytes written to *str_out_out*

Examples

Example 24.409. GZIP test

Test if the gzip implementation works.

```
create procedure
gz_test_1 (in fname varchar)
{
  declare dta, dta_2, res any;
  declare len integer;

  res := string_output ();
  dta_2 := string_output ();
  dta := file_to_string_output (fname);

  result_names (len);

  -- send length of input to client

  result (length (dta));

  -- compress and return compressed size.

  result (string_output_gz_compress (dta, res));
  gz_uncompress (string_output_string (res), dta_2);

  if (md5 (dta) <> md5 (dta_2))
    signal ('SNAFU', 'GZIP algorithm implementation is faulty.');

  result (length (dta));
  end_result();
}
;

SQL> gz_test_1 ('tmp/test.dat');
len
```

```
INTEGER
_______________________________________________________________________________

11689
2477
11689

3 Rows. -- 11 msec.
```

See Also

string_output

string_output_string

string_output_string — produce a string out of a string output stream

Synopsis

string_output_string (in *string_out* any) ;

Description

This function is used to produce a string from contents of a string output stream. See `string_output` for more information about string output streams.

Parameters

string_out
: The string output stream

Return Values

A varchar with the contents of the string output stream.

Examples

Example 24.410. Convert string output stream into a string

Create a string output, write 'foo' and ' bar' into it, convert to string and produce a result.

```
SQL> create procedure
ex_string_output_string ()
{
  declare s_out any; s_out := string_output();
  declare s varchar;

  result_names (s);
  http('foo', s_out);
  http(' bar', s_out);
  s := string_output_string (s_out);
  result (s);
}
;

SQL> ex_string_output_string ();
s
VARCHAR NOT NULL
_____________________________________________________________________________

foo bar

1 Rows. -- 5 msec.
```

See Also

`string_output` , `http` , `http_value` , `http_rewrite` .

string_to_file

string_to_file — writes a varchar to a file

Synopsis

string_to_file (in *path* varchar ,
in *string* varchar ,
in *mode* integer) ;

Description

This function requires dba privileges.

`string_to_file` writes a varchar value or string session to a file. The path is relative to the server's working directory. The mode is an integer value interpreted as a position. A mode of 0 writes the content starting at offset 0. A mode of -1 appends to the end of the file. The append option is probably the most useful for producing application level logs, etc.

The string argument can also be a string output object. In this case the content is used as the string.

If the mode is -2, the new content supersedes the old. This is different from 0 in that the file will be truncated if the new content is shorter than the old.

The DirsAllowed and DirsDenied lists in Parameters section of the virtuoso configuration file (virtuoso.ini by default) are used to control disk access. An error 42000/FA024 is signalled if an attempt is made to write to a file in a directory to which disk access is not explicitly allowed.

Parameters

path
: varchar relative path.

string
: varchar or string session to write to the file.

mode
: integer mode.

Examples

Example 24.411. Simple example

Write an entry to an application log

```
SQL>string_to_file ('logs/applog.txt',
  concat (datestring(now()),'\t','Application started.\n'), -1);

Done. -- 4 msec.
SQL> quit;
bash$ cat logs/applog.txt
2001-03-19 15:15:12.000000      Application started.
bash$
```

See Also

`file_to_string`

strrchr

strrchr — returns a zero-based index to the last occurrence of the char in str.

Synopsis

strrchr (*str* string ,
char string or integer) ;

Description

strchr returns a zero-based index to the last occurrence of char in string. If char is not found NULL is returned. char can be given either as an integer ASCII value or a string, in which case the first character of that string is searched for in str.

```
strchr('AbracadabrA','A')
                -> 0 (Found as the first character).
strrchr('AbracadabrA',65)
                -> 10 (Found as the eleventh character)
```

strstr

strstr — substring search

Synopsis

strstr (in *str* string ,
in *sub* string) ;

Description

`strstr` performs a substring search, returning a zero-based index pointing to beginning of first occurrence of *`sub`* or NULL if not found.

Parameters

str
: String to search from.

sub
: Substring to search for.

Return Types

An integer zero-based index to first occurrence of *`sub`* .

Examples

Example 24.412. Sample example

```
strstr('AbracadabrA','abrA')
    -> 7 (Found from the eighth character onwards)
strcasestr('AbracadabrA','abrA')
    -> 0 (Found from the beginning of string)
```

See Also

`strcasestr` .

subseq

subseq — returns substring of a string or sub-vector of a vector

Synopsis

subseq (*str* string or vector ,
from integer ,
to integer or NULL) ;

Description

subseq returns a copy of subsequence of string or vector str using zero-based indices from (inclusive) and to (exclusive) to delimit the substring or the vector extracted.

If to is omitted or is NULL, then it equals by default to the length of str, i.e. everything from from to the end of str is returned.

If to and from are equal, an empty string "(empty vector) is returned.

If from is greater than to or length of str an error is signalled.

If str is NULL then NULL is returned.

```
subseq('AbracadabrA',0,4) -> 'Abra'
subseq('AbracadabrA',4,8) -> 'cada'
subseq('AbracadabrA',7)    -> 'abrA'
subseq(string,0,strchr(string,'/'))
subseq(vector (1, 2, 3), 2) -> vector (3)
subseq(vector (1, 2, 3), 0, 2) -> vector (1, 2)
```

The last one with string argument returns a copy of the string cut from the first slash, leaving it and everything following out, and in the case where there are no slashes present, returns a copy of the whole string.

substring

substring — returns a substring of a string

Synopsis

substring (*str* string ,
from integer ,
sublen integer) ;

Description

Returns a substring of string str. The start index is 1 based. The substring is sublen characters long.

This function follows SQL 92.

```
substring('AbracadabrA',1,4) -> 'Abra'
substring('AbracadabrA',5,4) -> 'cada'
substring('AbracadabrA',8,4) -> 'abrA'
```

sub_schedule

sub_schedule — add scheduled job for periodic synchronization of a subscription

Synopsis

sub_schedule (in *server_name* varchar ,
in *publication* varchar ,
in *interval* integer) ;

Description

Add scheduled job for periodically synchronizing a subscription.

Parameters

server_name
: target publisher server name.

publication
: publication name.

interval
: interval between synchronization attempts (in minutes).

system

system — runs a shell command from SQL

Synopsis

system (in *command* varchar) ;

Description

The system function will run a shell command from SQL. The shell command is executed in the server's current directory as the user that owns the database server process.

This function is available to dba users only. Since this is a security risk this feature is normally disabled. It can be enabled by setting the AllowOSCalls setting in virtuoso.ini to 1.

uptime

uptime — returns a string result set with how much time server have been up.

Synopsis

```
uptime (   );
```

Description

The uptime function will run a string result set with how much time server have been up.

Examples

Example 24.413. Simple Use

```
SQL> uptime();
VARCHAR
_______________________________________________________________________________

13 hour(s), 12 minute(s)

1 Rows. -- 59 msec.
```

See Also

`system()`

SYS_DB_STAT

SYS_DB_STAT — gathers common statistical information about the database.

Synopsis

```
SYS_DB_STAT ( in pcnt integer ,
              in ignore_vdb integer ) ;
```

Description

The SYS_DB_STAT procedure gathers common information about the whole Virtuoso database, including attached remote tables. It traverses each table and populates the SYS_COL_STAT table with data collected. SYS_DB_STAT can be used in random mode when not all rows of the tables are used to gather statistics of the database.

SYS_DB_STAT gathers the following information for each column, COL, traversed in the database:

SYS_COL_STAT - SQL command
CS_N_DISTINCT - count (distinct XXX)
CS_MIN - min (XXX)
CS_MAX - max (XXX)
CS_AVG_LEN - avg (raw_length (XXX))
CS_N_VALUES - count (XXX)
CS_N_ROWS - count (XXX)

Parameters

pcnt
: Rate that affects percentage of database coverage. Zero means that the whole database is read. The default is 5, for a random sample of approximately 5 percent of each table.

ignore_vdb
: By default SYS_DB_STAT does not analyze the remote tables. To allow statistics gathering over linked tables, set this parameter to zero. Remote tables can be very large or access to them can be very slow or both. If this parameter is set to zero and pcnt is zero, SYS_DB_STAT will read the remote tables from start to end which may take very long. If pcnt is non-zero, this function will use its knowledge of the remote DBMS to get statistics in a DBMS specific manner if the DBMS is supported. See sys_stat_vdb_mappers table.

Return Types

None.

See Also

sys_stat_histogram

sys_stat_analyze

sys_lockdown

sys_lockdown — Set virtuoso in lockdown state and back.

Synopsis

```
sys_lockdown ( in lock_action integer ,
               in listeners_mode integer ) ;
```

Description

You must have DBA privileges to run that function.

Calling this with lock_mode = 1 causes the server not to accept any new client connections, except ones coming from localhost (127.0.0.1). This will also shut down any other listeners and terminate any possibly pending processing, rolling back all open transactions and disconnecting all clients, except ones from localhost. Calling thi with lock_mode 0 reverses the effect.

Parameters

lock_action
: (0|1) - 0 = unlock the server; 1 = lock the server

listeners
: (0|1 default 0) - 0 = don't serve the listener sockets; 1 = close the listener sockets

Return Types

Lock mode (lock_action = 1) if already in that mode returns 0 otherwise returns 1

Unlock mode (lock_action = 0) if already in that mode returns 0 otherwise returns 2

sys_stat

sys_stat — Return statistical information about the Virtuoso server.

Synopsis

any **sys_stat** (in *stat_name* varchar);

Description

This function returns the statistic related to the requested statistic name give as a parameter to the function.

Parameters

stat_name
: The name of the statistic to look-up and return. This can be one of:

Return Types

Statistic to be returned. Can be a value such as the server version, or a string such as the database name.

Examples

Example 24.414. Returning simple statistics.

```
SQL> select concat(sys_stat('st_dbms_name'), ' - ', sys_stat('st_dbms_ver'));
callret
VARCHAR
_______________________________________________________________________________

OpenLink Virtuoso PHP4 Server - 03.00.2402
```

sys_stat_analyze

sys_stat_analyze — Collects statistics on a table and its columns for use in SQL optimization

Synopsis

```
sys_stat_analyze ( in table_name varchar ,
                   in pcnt integer ,
                   in ignore_vdb integer ) ;
```

Description

Collects (or updates) column statistics for the table columns. It collects minimum, maximum average and distinct values for a column and a row count for the table and inserts the data into the DB.DBA.SYS_COL_STAT table. It does not make histograms for the columns.

The statistics are then used by the Optimized SQL compiler. All the cached compilations are discarded, because some of them may compile differently in the light of the new data.

This function will normally consider the entire database with the exception of remote tables. Since you may be concerned about time or remote tables this operation is configurable using the optional parameters, `pcnt` and `ignore_vdb`.

Parameters

table_name
: The full name of the table exactly as in the KEY_TABLE column of SYS_KEYS.

pcnt
: Determines the sample size for statistics gathering. A value of 0 will read the whole table. The default is 5, for an approximately five percentsample of the table.

ignore_vdb
: Determines whether remote tables are considered. By default remote tables (ignore_vdb = 1) are ignored. Setting this value to 0 will cause this function to gather statistical information for remote tables also. A percentage of 0 will read the remote table from beginning to end. A non-zero percentage will access the statistics tables of the remote DBMS if it is of a supported type, see the sys_stat_vdb_mappers table.

See Also

sys_stat_histogram

SYS_DB_STAT()

sys_stat_histogram

sys_stat_histogram — Collects a column value histogram for use in SQL optimization

Synopsis

```
sys_stat_histogram (
    in table_name varchar ,
    in column_name varchar ,
    in n_buckets integer ,
    in prec integer ) ;
```

Description

This function collects (or updates) values distribution data for a given column.

It splits the sorted column values in n_buckets intervals and collects the last value of each interval. The values are then inserted into the SYS_COL_HIST table.

If the table in question has not been analyzed, then it calls SYS_STAT_ANALYZE for the table.

The histograms are then used by the Optimized SQL compiler. All the cached compilations are discarded, because some of them may compile differently in the light of the new data.

Parameters

table_name
: The full name of the table exactly as in the KEY_TABLE column of SYS_KEYS.

column_name
: The full name of the column exactly as in the COLUMN column in SYS_COLS.

n_buckets
: How much intervals to form. If more intervals are available, the estimation of column predicates costs is more precise.

prec
: The density of the rows examined. Defaults to 1 (all the rows)

See Also

`SYS_DB_STAT()`

sys_stat_analyze

table_set_policy

table_set_policy — Sets policy function to table.

Synopsis

table_set_policy (in *tablename* varchar ,
in *policypl* varchar ,
in *policy_scope* varchar) ;

Description

Sets policy function to table.

Parameters

tablename
: is the table to which the policy applies

policypl
: is the actual Virtuoso Stored Procedure based policy

policy_scope
: defines the scope of the policy in relation to SQL statement processing using one of more of the following values; I (for Inserts), D (for Deletions), U (for Updates), S (for Selects).

Return Types

varchar

Note:

Note that the policy_pl procedure should have the following signature (this is how it's called by the Virtuoso SQL compiler to get the policy) :

```
<procedure_name> (in table varchar, in op varchar) returns varchar
```

See Also

`table_drop_policy()`

table_drop_policy

table_drop_policy — Drops policy function from table.

Synopsis

```
table_drop_policy ( in _tb varchar ,
                    in _type varchar ) ;
```

Description

Drops policy function from table.

Parameters

_tb
: is the table to which the policy applies

_type
: defines the scope of the policy in relation to SQL statement processing using one of more of the following values; I (for Inserts), D (for Deletions), U (for Updates), S (for Selects).

Return Types

None.

Note:
Note that if either the table or the procedure gets dropped the policy is also autodropped.

See Also

`table_set_policy()`

strcontains

strcontains — Performs substring search

Synopsis

strcontains (in *str* string ,
in *sub* string) ;

Description

`strcontains` performs a substring search, returning 1 or 0.

Parameters

str
: String to search from.

sub
: Substring to search for.

Return Types

1 if found, 0 if not found.

Examples

Example 24.415. Simple example

```
SQL> select strcontains('AbracadabrA','abrA');
strcontains
INTEGER
_______________________________________________________________________________

1

1 Rows. -- 0 msec.

SQL> select strcontains('AbracadabrA','XZ');
strcontains
INTEGER
_______________________________________________________________________________

0

1 Rows. -- 0 msec.
```

`starts_with`.

`end_with`.

starts_with

starts_with — Checks whether string X begins with Y

Synopsis

starts_with (in *str* string ,
in *sub* string) ;

Description

`starts_with` checks whether string X begins with Y, ignoring occurencies of Y in other places. Returns 1 or 0.

Parameters

str
: String to search from.

sub
: Substring to search for.

Return Types

1 if found, 0 if not found.

Examples

Example 24.416. Simple example

```
SQL> select starts_with('AbracadabrA','Abr');
starts_with
INTEGER
_______________________________________________________________________________

1

1 Rows. -- 0 msec.
```

See Also

`strcasestr`.

`strcontains`.

ends_with

ends_with — Checks whether string X ends with Y

Synopsis

ends_with (in *str* string ,
in *sub* string) ;

Description

`ends_with` checks whether string X ends with Y, ignoring occurencies of Y in other places. Returns 1 or 0.

Parameters

str
: String to search from.

sub
: Substring to search for.

Return Types

1 if found, 0 if not found.

Examples

Example 24.417. Simple example

```
SQL> select ends_with('AbracadabrA','rA');
ends_with
INTEGER
_______________________________________________________________________________

1

1 Rows. -- 0 msec.
```

See Also

`strcasestr`.

`strcontains`.

`starts_with`.

tcpip_gethostbyname

tcpip_gethostbyname — Returns IP address by host domain name

Synopsis

```
varchar tcpip_gethostbyname ( in name varchar );
```

Description

This calls the system function gethostbyname() and returns h_addr from the hostent structure or empty string if no hostent structure returned (host not exists).

Parameters

name
: DNS name of the host

Return Types

A string containing IP address of the host or empty string if not exists

tcpip_gethostbyaddr

tcpip_gethostbyaddr — Returns fully qualified DNS name of the host associated with given IP address

Synopsis

```
varchar tcpip_gethostbyaddr ( in address varchar );
```

Description

This calls the system function gethostbyaddr() and returns h_name from the hostent structure returned by it. If no hostent structure returned, then it returns it's argument.

Parameters

address
: A string containing an IP address

Return Types

Returns fully qualified DNS name of the host associated with 'address'. If no such address the return will contain same value as 'address' parameter.

tmp_file_name

tmp_file_name — returns the unique file name within temporary directory of the operating system

Synopsis

```
varchar tmp_file_name ( in prefix varchar ,
                        in suffix varchar ) ;
```

Description

The following function is used to obtain unique name of a file, which is located in temporary directory on file system. The two optional parameters can be supplied: prefix of the file and extension for it. These will be prepended and appended (dot MUST be omitted) to the unique string. The directory where this file is located depends of $TMPDIR or %TMP% environment settings for UNIX's and Windows platforms respectively. If these environment settings are not available or empty, the defaults will be used for the operation system. (in practice for most UNIX's it's /tmp or /var/tmp directory). Note that this function do NOT open the file, it only give us a name.

Parameters

prefix
: prefix to the file name to be added. MUST be at most five characters.

suffix
: extension to the file to be added, the leading dot MUST be omitted.

Errors

Parameter data type checking errors

Examples

Example 24.418. Getting a unique file name

```
SQL> select tmp_file_name('FOO', 'EXT');
callret
VARCHAR
_______________________________________

/tmp/FOOFoCnq5.EXT

1 Rows. -- 7 msec.
```

tidy_html

tidy_html — Invoke built-in version of HTML Tidy utility to fix typical errors in HTML text

Synopsis

tidy_html (in *raw_html* varchar ,
in *tidy_config* varchar) ;

Description

This function improves the given source HTML text, by invoking a custom version of HTML Tidy utility. To learn more about Tidy see http://www.w3.org/People/Raggett/tidy/ . Some particular combinations of errors in source HTML may cause Tidy to misinterpret the source so the output may be incomplete or corrupted. This is an unavoidable problem, due to heuristic nature of the procedure. On the other hand, Tidy will process almost any HTML suitable for some "popular" browser, e.g. Internet Explorer or Netscape Navigator.

Parameters

raw_html
: Source HTML text to process. Note that the encoding of this text must be specified in tidy_config string, and default encoding of session will not be mentioned by Tidy.

tidy_config
: Configuration string is a list of options, delimited by newlines, with exactly the same syntax as original Tidy's configuration file. Not all options of original Tidy will work, due to obvious reasons, unsupported options will be silently ignored, so you may read your favorite Tidy's configuration file by file_to_string function and pass it to tidy_html.

Return Types

Errors

Table 24.82. Errors signalled by tidy_html

SQLState	Error Code	Error Text	Description
XTID2		HTML Tidy failed	The given HTML text contains serious errors. To get detailed list of them, call tidy_list_errors with same parameters as tidy_html.

Examples

Example 24.419.

```
fine_html := tidy_html (ugly_html, '
indent: auto
indent-spaces: 2
wrap: 72
markup: yes
output-xml: no
input-xml: no
show-warnings: yes
numeric-entities: yes
quote-marks: yes
quote-nbsp: yes
quote-ampersand: no
break-before-br: no
uppercase-tags: no
uppercase-attributes: no
char-encoding: latin1
new-inline-tags: cfif, cfelse, math, mroot,
```

```
    mrow, mi, mn, mo, msqrt, mfrac, msubsup, munderover,
    munder, mover, mmultiscripts, msup, msub, mtext,
    mprescripts, mtable, mtr, mtd, mth
  new-blocklevel-tags: cfoutput, cfquery
  new-empty-tags: cfelse');
```

tidy_list_errors

tidy_list_errors — Invoke built-in version of HTML Tidy utility to get list of errors in given input HTML text

Synopsis

tidy_list_errors (in *raw_html* varchar ,
in *tidy_config* varchar) ;

Description

This function lists errors in given source HTML text, by invoking some custom version of HTML Tidy utility. To learn more about Tidy see http://www.w3.org/People/Raggett/tidy/ .

Parameters

raw_html
: Source HTML text to validate. Note that the encoding of this text must be specified in tidy_config string, and default encoding of session will not be mentioned by Tidy.

tidy_config
: Configuration string, space-delimited list of options, exactly as in original Tidy's command-line or in Tidy's configuration file. Not all options of original Tidy will work, due to obvious reasons, unsupported options will be silently ignored, so you may read your favorite Tidy's configuration file by file_to_string function and pass it to tidy_list_errors. For more details, see tidy_html .

Return Types

Text with the list of found errors and warnings, as string of type varchar.

Errors

This function should not signal errors. Unlike `tidy_html` , it will log errors into the resulting string without signalling them.

See Also

timezone

timezone — get timezone difference from a datetime

Synopsis

timezone (in *dt* datetime ,
in *ignore_timezone* integer) ;

Description

The function returns timezone offset of its first argument, as an integer value in minutes. If the first argument is timezoneless and second argument is missing or zero then the returned value is NULL. If the first argument is timezoneless and second argument is nonzero then the returned value is 0.

Parameters

dt
: A datetime .

ignore_timezone
: Flag

Examples

Example 24.420. Simple example

Get current timezone.

```
SQL> select timezone (now ());
callret
INTEGER
_______________________________________________________________________________

120
```

trace_off

trace_off — Disable extra logging for Virtuoso server

Synopsis

```
integer trace_off ( in parameter varchar );
```

Description

You must have DBA privileges to run that function.

This function is used to disable logging of various information enabled by default with the TraceOn ini file option or with the trace_on() function.

Return Types

Upon success zero will be returned, otherwise an error is.

Errors

Table 24.83. Errors signalled by `trace_off`

SQLState	Error Code	Error Text
22005	SR323	"option" is not valid trace_off option

Examples

Example 24.421. Simple example

To show users logs to the server and failed user logs

```
SQL> trace_off ('user_log', 'failed_log');

Done. -- 0 msec.
SQL>
```

See Also

`trace_on()`

`trace_status()`

trace_on

trace_on — Enable extra debug logging

Synopsis

```
integer trace_on ( in parameter varchar );
```

Description

This function requires dba privileges.

This function enables logging specified server operations for debugging purposes. The log entries will be shown at the server console (if started with foreground option) and will be written into the server message log file. The traceable events are divided into several groups: user activity, transactions, compilation of the SQL statements, DDL statements, statements execution and VDB actions.

Parameters

The following options are available for logging:

user_names - include the full user name, otherwise user ID will be logged.

user_log - log the connects/disconnects for users.

failed_log - log incorrect logins.

compile - log the names of procedures / triggers name compiled.

ddl_log - log the DDL statements execution.

client_sql - log the compilation of the client's SQL statements (first 500 chars).

errors - log all server errors.

dsn - log the connection/disconnection to DSNs, registration and removal of the DSNs, compilation of the SQL statements executed thru the VDB.

sql_send - log the compilation of SQL statements executed thru the VDB.

transact - log the transactions.

remote_transact - log the remote transactions.

exec - log SQL statement execution.

soap - log SOAP server requests and responses.

thread - log THRD_1 %ld OS threads freed. This is when OS threads are freed due to inactivity (being idle for more than ThreadCleanupInterval time).

cursor - log CURS_[0-9] - various VDB statements actions.

Return Types

Upon success zero will be returned, otherwise an error is signalled.

The message log file and/or server debug screen will list details for activated log options. The formats are as follows:

```
USER_0 (user) (IP) (peer) logout
USER_1 (user) (IP) (peer) login

FAIL_0 (user) (IP) (peer)

COMP_0 (user) (IP) (peer) trigger (name)
COMP_1 (user) (IP) (peer) procedure (name)

DDLC_0 (user) (IP) (peer) Create table (name)
DDLC_1 (user) (IP) (peer) Drop table (name)
DDLC_2 (user) (IP) (peer) Create procedure (name)
DDLC_3 (user) Drop procedure (name)
```

```
DDLC_4 (user) Create view (name)
DDLC_5 (user) Create index (name) or (table name)
DDLC_6 (user) Drop index (name) or (table name)
DDLC_7 (user) Rename table (new name) or (old name)
DDLC_8 (user) Create trigger (name) or (table name)
DDLC_9 (user) drop trigger (name) or (table name)

CSLQ_0 (user) (IP) (peer) (sql)

ERRS_0 (code) (server code) (error text)

DSNL_0 (dsn) (sql)
DSNL_1 Disconnecting DSN (name)
DSNL_2 (user) (IP) Registration remote data source (name)
DSNL_3 (user) Disconnect remote data source (name)

DSNS_0 (dsn) (sql) (prepare)
DSNS_1 (dsn) (sql) (execute)

LTRS_0 (user) (from) (peer) Begin transact tnx
LTRS_1 (user) (from) (peer) (Commit / Rollback) transact txn
LTRS_2 (user) (from) (peer) Restart transact txn

RTRS_0 (user) (from) (peer) (dsn) Begin transact tnx autocommit: (on/off)
RTRS_1 (user) (from) (peer) (dsn) (Commit / Rollback) transact tnx autocommit: (on/off)

EXEC_0 (user) (from) (peer) Exec cursor (stmt)
EXEC_1 (user) (from) (peer) (stmt) Exec (n) time(s)

SOAP_0 (request)
SOAP_1 (response)
```

Errors

Table 24.84. Errors signalled by `trace_on`

SQLState	Error Code	Error Text
22005	SR322	"option" is not valid trace_on option

Examples

Example 24.422. Simple example

To show users logging in to the server and failed user logins

```
SQL> trace_on ('user_log', 'failed_log');

Done. -- 0 msec.
SQL>

The server console  and log file may thus contain lines such as:
...
17:17:24 Server online at 1111 (pid 2173)
17:17:36 USER_0 0 xxx.xx.xx.xxx 1111:2 logout
17:17:40 USER_1 0 xxx.xx.xx.xxx 1111:3 login
17:17:45 USER_0 0 xxx.xx.xx.xxx 1111:3 logout
17:18:04 FAIL_0 dba xxx.xx.xx.xxx
...
```

See Also

`trace_off()`

`trace_status()`

trace_status

trace_status — show current trace settings

Synopsis

```
void trace_status ( );
```

Description

You must have DBA privileges to run that function.

This function returns an array of all available trace options and current status of the traces.

Examples

Example 24.423. Example

This is to show the current state of all trace log options.

```
SQl> create procedure trace_status_show ()
   {
     declare i, l integer;
     declare opt, status varchar;
     declare arr any;
     arr := trace_status();
     i := 0; l := length (arr);
     result_names (opt, status);
     while (i < l)
       {
         result (arr[i], arr[i+1]);
         i := i + 2;
       }
   };

SQL> trace_status_show();
opt                       status
VARCHAR                   VARCHAR
_______________________________________________________________________________

user_log                  off
failed_log                off
compile                   on
ddl_log                   off
client_sql                off
errors                    off
dsn                       off
sql_send                  off
transact                  on
remote_transact           off
exec                      off
soap                      off
```

See Also

`trace_on()`

`trace_off()`

tree_md5

tree_md5 — returns MD5 checksum of array argument

Synopsis

```
string tree_md5 ( in tree any );
```

Description

Returns a string of 16 characters representing the binary MD5 checksum of the argument. The argument can be any array or scalar.

Parameters

tree
: String or string_session to be processed with MD5 algorithm.

Return Values

A string of 32 lower case hex digits that are the result of the MD5 algorithm used on the data argument.

Errors

Parameter data type checking errors

HS_Resolve

HS_Resolve — Returns URL that represents the given DOI

Synopsis

```
string HS_Resolve (     in doi_val
                        string );
```

Description

Returns URL that represents the given DOI. The function is installed from the hslookup plugin which uses http://www.handle.net/.

Note that you need to have in your Virtuoso database ini file in section Plugins added the hslookup.dll file, which location should be in the plugins folder under your Virtuoso server installation. For ex:

```
[Plugins]
LoadPath = ./plugin
...
Load6    = plain,hslookup
```

Parameters

doi_val
: DOI value

Return Values

A string of URL that represents the given DOI.

Examples

Example 24.424. Simple example

```
SQL> select HS_Resolve('10.1038/35057062');
callret
VARCHAR
_______________________________________________________________________________

http://www.nature.com/doifinder/10.1038/35057062

1 Rows. -- 22 msec.
```

trigonometric

acos , asin , atan , cos , sin , tan , cot , degrees , radians , atan2 , pi — trigonometric functions

Synopsis

acos (in *x* double precision) ;

asin (in *x* double precision) ;

atan (in *x* double precision) ;

cos (in *x* double precision) ;

sin (in *x* double precision) ;

tan (in *x* double precision) ;

cot (in *x* double precision) ;

degrees (in *x* double precision) ;

radians (in *x* double precision) ;

atan2 (in *x* double precision ,
in *y* double precision) ;

pi ( ) ;

Description

All these functions work with double precision floating point numbers. They convert their argument to an IEEE 64-bit float and return a result of that type.

```
:  acos arc cosine
:  asin arc sine
:  atan arc tangent
:  cos  cosine
:  sin  sine
:  tan  tangent
:  cot  cotangent
:  degrees  convert an angle in radians to degrees.
:  radians  convert an angle in radians to degrees.
:  atan2  arc tangent with x and y coordinates, can return an angle in any quadrant.
:  pi   return pi.
```

trim

trim — removes characters from both ends of string argument

Synopsis

trim (*str* string ,
trimchars string) ;

Description

`trim` returns a copy of subsequence of string str with all the characters present in trimchars trimmed off from the beginning. If the second argument is omitted, it is a space ' ' by default.

`rtrim` is similar except that it trims from the right.

trim trims from both ends.

```
concat('*',trim('   SIMURG   '),'*') -> '*SIMURG*'
ltrim('AbracadabrA','bAr')  -> 'acadabrA'
rtrim('AbracadabrA','bAr')  -> 'Abracada'
trim('AbracadabrA','bAr')    -> 'acada'
```

txn_error

txn_error — poison current transaction forcing rollback

Synopsis

txn_error (in *code* integer) ;

Description

Calling this function will poison the current transaction. This means that it is forced to roll back at when committed. The code can be in integer that selects the error message generated when trying to commit. This is useful before signalling application errors from SQL code that runs in manual commit mode. This can ensure that even if the client attempts a commit after getting the error signalled by the application the transaction will not commit.

In most cases the code should be the constant 6, resulting the in the 'transaction rolled back due to previous SQL Error'.

Table 24.85. Transaction error codes

code	SQL state	Error ID	SQL message	Description
1	S1T00	SR171	Transaction timed out	
2	40001	SR172	Transaction deadlocked	
3	40003	SR173	Transaction out of disk	
4	40004	SR174	Log out of disk	
5	23000	SR175	Uniqueness violation. Transaction killed	
6	4000X	SR176	Transaction rolled back due to previous SQL error	The safest way of poisoning a transaction
7	4000X	SR177		Reserved for system use
8	08U01	SR324	Remote server has disconnected making the transaction uncommittable. Transaction has been rolled back	
9	40001	SR325	Transaction aborted due to a database checkpoint or database-wide atomic operation. Please retry transaction	
10	40005	SR325	Transaction aborted because its log after image size went above the limit	
11	40006	SR337	Transaction aborted because the server is out of memory	
12	4000X	SR177		Reserved for system use
13	08C02	SR337	Transaction aborted due to cluster connection failure	
14	40001	SR337	Transaction aborted due to async rollback in cluster	
15	40007	CLTSY	Transaction not committable because async update branch not synced before commit. Commit has overtaken the branch message or the branch message was lost by the network	
16	40007	CLPNC	Transaction prepared but not committed. Probably dropped commit message. The branch will automatically query coordinator for the final status. The situation will reset itself in a few seconds	
17	4000X	SR177		Reserved for system use
18	42000	RPERM	No permission to delete from given graph	
anything else	4000X	SR177	Misc Transaction Error	

txn_killall

txn_killall — kill all pending transactions

Synopsis

txn_killall (in *code* integer) ;

Description

This function will terminate all pending transactions. This can be used for resetting infinite loops in stored procedures etc.

The code determines the error reported to the client. Number 6 is preferable, corresponding to the 'transaction rolled back due to previous SQL error'. See `txn_error` for all supported codes.

Once any SQL statement or procedure notices that its transaction is dead, e.g. deadlocked, it signals the error and takes appropriate action, which is typically to signal the error to the caller and ultimately to the client.

Examples

```
txn_killall (1);
```

-- kills all transactions with the S1T00 'timed out' error.

ucase

ucase — returns upper case version of string argument

Synopsis

ucase (*str* string) ;

Description

`ucase` returns a copy of string str with all the lowercase alphabetical characters converted to corresponding uppercase letters. This includes also the diacritic letters present in the ISO 8859/1 standard in range 224 - 254 decimal, excluding the character 255, y diaeresis, which is not converted to a German double-s.

upper is just an alias for ucase.

```
ucase('AbracadabrA')  -> 'ABRACADABRA'
```

Parameters

str
: String to convert to upper case.

uddi_delete_binding

uddi_delete_binding — Causes one or more *bindingTemplate* structures to be deleted.

Syntax

```
<uddi_delete_binding
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <authInfo/>
        <bindingKey/>
        [ <bindingKey/> ...]
</uddi_delete_binding>
```

Attributes & Children

authInfo
: This required argument is an element that contains an authentication token obtained using the get_authToken call.

bindingKey
: One or more uuid_key values that represent specific instances of known bindingTemplate data.

Return Types

Upon successful completion, a *dispositionReport* is returned with a single success indicator.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.86. Errors signalled by uddi_delete_binding

Error Code	Description
E_invalidKeyPassed	signifies that one of the *uuid_key* values passed did not match with any known *bindingKey* values. No partial results will be returned; if any *bindingKey* values passed are not valid, this error will be returned.
E_authTokenExpired	signifies that the authentication token value passed in the authInfo argument is no longer valid because the token has expired.
E_authTokenRequired	signifies that the authentication token value passed in the authInfo argument is either missing or is not valid.
E_userMismatch	signifies that one or more of the *bindingKey* values passed refers to data not controlled by the entity the authentication token represents.
E_operatorMismatch	signifies that one or more of the *bindingKey* values passed refers to data not controlled by the server that received the request for processing.

uddi_delete_business

uddi_delete_business — Remove one or more *businessEntity* structures.

Syntax

```
<uddi_delete_business
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <authInfo/>
        <businessKey/>
        [ <businessKey/> ...]
</uddi_delete_business>
```

Attributes & Children

authInfo
: This required argument is an element that contains an authentication token obtained using the get_authToken call.

businessKey
: One or more uuid_key values that represent specific instances of known businessEntity data.

Return Types

Upon successful completion, a *dispositionReport* structure is returned with a single success indicator.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.87. Errors signalled by uddi_delete_business

Error Code	Description
E_invalidKeyPassed	signifies that one of the *uuid_key* values passed did not match with any known *businessKey* values. No partial results will be returned; if any *businessKey* values passed are not valid, this error will be returned.
E_authTokenExpired	signifies that the authentication token value passed in the authInfo argument is no longer valid because the token has expired.
E_authTokenRequired	signifies that the authentication token value passed in the authInfo argument is either missing or is not valid.
E_userMismatch	signifies that one or more of the *businessKey* values passed refers to data not controlled by the entity the authentication token represents.
E_operatorMismatch	signifies that one or more of the *businessKey* values passed refers to data that is not controlled by the server that received the request for processing.

uddi_delete_service

uddi_delete_service — Remove one or more *businessService* structures.

Syntax

```
<uddi_delete_service
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <authInfo/>
        <serviceKey/>
        [ <serviceKey/> ...]
</uddi_delete_service>
```

Attributes & Children

authInfo
: This required argument is an element that contains an authentication token obtained using the get_authToken call.

serviceKey
: One or more uuid_key values that represent specific instances of known businessService data.

Return Types

Upon successful completion, a *dispositionReport* message is returned with a single success indicator.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.88. Errors signalled by uddi_delete_service

Error Code	Description
E_invalidKeyPassed	signifies that one of the *uuid_key* values passed did not match with any known *serviceKey* values. No partial results will be returned; if any *serviceKey* values passed are not valid, this error will be returned.
E_authTokenExpired	signifies that the authentication token value passed in the *authInfo* argument is no longer valid because the token has expired.
E_authTokenRequired	signifies that the authentication token value passed in the *authInfo* argument is either missing or is not valid.
E_userMismatch	signifies that one or more of the *serviceKey* values passed refers to data not controlled by the entity the authentication token represents.
E_operatorMismatch	signifies that one or more of the *serviceKey* values passed refers to data not controlled by the server that received the request for processing.

uddi_delete_tModel

uddi_delete_tModel — Remove or retire one or more *tModel* structures.

Syntax

```
<uddi_delete_tModel
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <authInfo/>
        <tModelKey/>
        [ <tModelKey/> ...]
</uddi_delete_tModel>
```

Attributes & Children

authInfo
: This required argument is an element that contains an authentication token obtained using the get_authToken call.

tModelKey
: One or more URN-qualified uuid_key values that represent specific instances of known tModel data. All tModelKey values begin with a uuid URN qualifier (e.g. "uuid:" followed by a known tModel UUID value.)

Return Types

Upon successful completion, a *dispositionReport* structure is returned with a single success indicator.

Behavior
: If a tModel is deleted and any other managed data references that tModel by uuid_key (e.g. within a categoryBag , identifierBag or within a tModelInstanceInfo structure) then the tModel will not be physically deleted as a result of this call. Instead it will be marked as hidden. tModels hidden in this way are still accessible to their owner, via the get_registeredInfo call; however, they will be omitted from any results returned by calls to find_tModel .

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.89. Errors signalled by uddi_delete_tModel

Error Code	Description
E_invalidKeyPassed	signifies that one of the URN-qualified *uuid_key* values passed did not match with any known *tModelKey* values. No partial results will be returned; if any *tModelKey* values passed are not valid, this error will be returned. Any *tModelKey* values passed without a uuid URN qualifier will be considered invalid.
E_authTokenExpired	signifies that the authentication token value passed in the *authInfo* argument is no longer valid because the token has expired.
E_authTokenRequired	signifies that the authentication token value passed in the *authInfo* argument is either missing or is not valid.
E_userMismatch	signifies that one or more of the *tModelKey* values passed refers to data not controlled by the entity the authentication token represents.
E_operatorMismatch	signifies that one or more of the *tModelKey* values passed refers to data that is not controlled by the server that received the request for processing.

uddi_discard_authToken

uddi_discard_authToken — Inform a UDDI server that the authentication token can be discarded.

Syntax

```
<uddi_discard_authToken
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <authInfo/>
</uddi_discard_authToken>
```

Description

The *uddi_discard_authToken* message is used to tell a UDDI-enabled server that the authentication token can be discarded. Subsequent calls that use the same *authToken* may be rejected. This message is optional for UDDI-enabled servers that do not manage session state or that do not support the *get_authToken* message.

Attributes & Children

authInfo
: This required argument is an element that contains an authentication token. Authentication tokens are obtained using the get_authToken message.

Return Types

Upon successful completion, the server returns a *dispositionReport* is returned with a single success indicator. Discarding an expired *authToken* will be reported as a success condition.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.90. Errors signalled by get_authToken

Error Code	Description
E_authTokenRequired	signifies that the authentication token value passed in the *authInfo* argument is either missing or is not valid.

uddi_find_binding

uddi_find_binding — Retrieves matching bindings

Syntax

```
<uddi_find_binding
  serviceKey="uuid_key"
  generic="1.0"
  [ maxRows="nn" ]
  xmlns="urn:uddi-org:api" >
        [<findQualifiers/>]
        <tModelBag/>
</uddi_find_binding>
```

Description

The *uddi_find_binding* message returns a *bindingDetail* message that contains a *bindingTemplates* structure with zero or more *bindingTemplate* structures matching the criteria specified in the argument list.

Attributes & Children

maxRows
: This optional integer value allows the requesting program to limit the number of results returned.

serviceKey
: This uuid_key is used to specify a particular instance of a businessService element in the registered data. Only bindings in the specific businessService data identified by the serviceKey passed will be searched.

findQualifiers
: This collection of findQualifier elements can be used to alter the default behavior of search functionality.

tModelBag
: This is a list of tModel uuid_key values that represent the technical fingerprint the server should locate in a bindingTemplate structure contained within the businessService instance specified by the serviceKey value. If more than one tModel key is specified in this structure, only bindingTemplate information that exactly matches all of the tModel keys specified will be returned (logical AND). The order of the keys in the tModel bag is not relevant. All tModelKey values begin with a uuid URN qualifier (e.g. "uuid:" followed by a known tModel uuid value.

Return Types

This function returns a *bindingDetail* message on success. In the event that no matches were located for the specified criteria, the *bindingDetail* structure returned in the response will be empty; that is, it will contain no *bindingTemplate* data.

In the event of a large number of matches, a UDDI-enabled server may truncate the result set. If this occurs, the response message will contain the *truncated* attribute with the value of this attribute set to true.

Searching using *tModelBag* will also return any *bindingTemplate* information that matches due to *hostingRedirector* references. The resolved *bindingTemplate* structure will be returned, even if that *bindingTemplate* is owned by a different *businessService* structure.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.91. Errors signalled by uddi_find_binding

Error Code	Description
E_invalidKeyPassed	signifies that the *uuid* _key value passed did not match with any known *serviceKey* or *tModel* key values. The error structure will signal which condition occurred first.
E_tooManyOptions	signifies that more than one mutually exclusive argument was passed.
E_unsupported	signifies that one of the *findQualifier* values passed was invalid.

uddi_find_business

uddi_find_business — Retrieves a *businessList* message matching supplied criteria.

Syntax

```
<uddi_find_business
  generic="1.0"
  [ maxRows ="nn" ]
  xmlns="urn:uddi-org:api" >
        [<findQualifiers/>]
        <name/> | <identifierBag/> | <categoryBag/> | <tModelBag/> | <discoveryURLs>
</uddi_find_business>
```

Attributes & Children

All arguments listed here are mutually exclusive except *findQualifiers* .

maxRows
: This optional integer value allows the requesting program to limit the number of results returned.

findQualifiers
: This collection of findQualifier elements can be used to alter the default behavior of search functionality.

name
: This string value is a partial name. The businessList return message contains businessInfo structures for businesses whose name matches the value passed (leftmost match).

identifierBag
: This is a list of business identifier references. The returned businessList contains businessInfo structures matching any of the identifiers passed (logical OR).

categoryBag
: This is a list of category references. The returned businessList contains businessInfo structures matching all of the categories passed (logical AND).

tModelBag
: The registered businessEntity data contains bindingTemplates that in turn contain specific tModel references. The tModelBag argument lets you search for businesses that have bindings that are compatible with a specific tModel pattern. The returned businessList contains businessInfo structures that match all of the tModel keys passed (logical AND). tModelKey values must be formatted as URN qualified uuid values (e.g. prefixed with "uuid:")

discoveryURLs
: This is a list of URLs to be matched against the data associated with the discoveryURLs contents of registered businessEntity information. To search for a URL without regard to useType attribute values, pass the useType component of the discoveryURL elements as empty attributes. If useType values are included, then the match will be made only on registered information that matches both the useType and URL value. The returned businessList contains businessInfo structures matching any of the URLs passed (logical OR).

Return Types

This function returns a *businessList* on success. In the event that no matches were located for the specified criteria, a *businessList* structure with zero *businessInfo* structures is returned.

In the event of a large number of matches, a UDDI-enabled server may truncate the result set. If this occurs, the *businessList* will contain the *truncated* attribute with the value set to true.

Searching using *tModelBag* will also return any *businessEntity* that contains *bindingTemplate* information that matches due to *hostingRedirector* references. In other words, the *businessEntity* that contains a

bindingTemplate with a *hostingRedirector* value referencing a *bindingTemplate* that matches the *tModel* search requirements will be returned.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.92. Errors signalled by get_authToken

Error Code	Description
E_nameTooLong	signifies that the partial name value passed exceeds the maximum name length designated by the UDDI-enabled server.
E_tooManyOptions	signifies that more than one search argument was passed.
E_unsupported	signifies that one of the *findQualifier* values passed was invalid.

uddi_find_service

uddi_find_service — Retrieves *serviceList* message matching search criteria

Syntax

```
<uddi_find_service
  businessKey="uuid_key"
  generic="1.0"
  [ maxRows ="nn" ]
  xmlns="urn:uddi-org:api" >
        [<findQualifiers/>]
        <name/> | <categoryBag/> | <tModelBag/>
</uddi_find_service>
```

Attributes & Children

The *name* , *categoryBag* , and *tModelBag* arguments are mutually exclusive.

maxRows
: This optional integer value allows the requesting program to limit the number of results returned.

businessKey
: This uuid_key is used to specify a particular BusinessEntity instance.

findQualifiers
: This collection of findQualifier elements can be used to alter the default behavior of search functionality.

name
: This string value represents a partial name. Any businessService data contained in the specified businessEntity with a matching partial name value gets returned.

categoryBag
: This is a list of category references. The returned serviceList contains businessInfo structures matching all of the categories passed (logical AND).

tModelBag
: This is a list of tModel uuid_key values that represent the technical fingerprint the server should locate within a bindingTemplate structure contained within any businessService contained by the businessEntity specified. If more than one tModel key is specified in this structure, only businessServices that contain bindingTemplate information that matches all of the tModel keys specified will be returned (logical AND).

Return Types

This function returns a *serviceList* on success. In the event that no matches were located for the specified criteria, the *serviceList* structure returned will contain an empty *businessServices* structure. This signifies zero matches.

In the event of a large number of matches, a UDDI-enabled server may truncate the result set. If this occurs, the *serviceList* will contain the *truncated* attribute with the value of this attribute set to true.

Searching using *tModelBag* will return serviceInfo structures for all qualifying *businessService* data, including matches due to *hostingRedirector* references. In other words, if the *businessEntity* whose *businessKey* is passed as an argument contains a *bindingTemplate* with a *hostingRedirector* value, and that value references a *bindingTemplate* that matches the *tModel* search requirements, then the *serviceInfo* for the *businessService* containing the *hostingRedirector* will be returned.

Errors

Table 24.93. Errors signalled by uddi_find_service

Error Code	Description
E_invalidKeyPassed	signifies that the *uuid_key* value passed did not match with any known *businessKey* or *tModel* key values. The error structure will signal which condition occurred first.
E_nameTooLong	signifies that the partial name value passed exceeds the maximum name length designated by the server.
E_tooManyOptions	signifies that more than one mutually exclusive argument was passed.
E_unsupported	signifies that one of the *findQualifier* values passed was invalid.

uddi_find_tModel

uddi_find_tModel — locate list of tModel entries matching supplied criteria

Syntax

```
<uddi_find_tModel
  generic="1.0"
  [ maxRows ="nn" ]
  xmlns="urn:uddi-org:api" >
        [<findQualifiers/>]
        <name/> | <identifierBag/> | <categoryBag/>
</uddi_find_tModel>
```

Description

This uddi_find_tModel message is for locating a list of tModel entries that match a set of specific criteria. The response will be a list of abbreviated information about tModels that match the criteria (tModelList).

Attributes & Children

The arguments to this call are mutually exclusive except findQualifiers

maxRows
: This optional integer value allows the requesting program to limit the number of results returned.

findQualifiers
: This collection of findQualifier elements can be used to alter the default behavior of search functionality.

name
: This string value represents a partial name. The returned tModelList contains tModelInfo structures for businesses whose name matches the value passed (leftmost match).

IdentifierBag
: This is a list of business identifier references. The returned tModelList contains tModelInfo structures matching any of the identifiers passed (logical OR).

categoryBag
: This is a list of category references. The returned tModelList contains tModelInfo structures matching all of the categories passed (logical AND).

Return Types

This function returns a tModelList on success. In the event that no matches were located for the specified criteria, an empty tModelList structure will be returned (e.g. will contain zero tModelInfo structures). This signifies zero matches.

In the event of a large number of matches, a UDDI-enabled server may truncate the result set. If this occurs, the tModelList will contain the *truncated* attribute with the value of this attribute set to true.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.94. Errors signalled by uddi_find_tModel

Error Code	Description
E_nameTooLong	

Error Code	Description
	signifies that the partial name value passed exceeds the maximum name length designated by the UDDI-enabled server.
E_tooManyOptions	signifies that more than one mutually exclusive argument was passed.
E_unsupported	signifies that one of the findQualifier values passed was invalid.

uddi_get_authToken

uddi_get_authToken — Obtain authentication token.

Syntax

```
<uddi_get_authToken
  generic="1.0"
  xmlns="urn:uddi-org:api"
  userID="someLoginName"
  cred="someCredential">
</uddi_get_authToken>
```

Description

The *uddi_get_authToken* message is used to obtain an authentication token. Authentication tokens are opaque values that are required for all other publisher API calls. This message is not required for UDDI-enabled servers that have an external mechanism defined for users to get an authentication token. This API is provided for implementations that do not have some other method of obtaining an authentication token or certificate, or that choose to use password-based authentication.

Attributes & Children

userID
: This required attribute argument is the identifier that an authorized entity was assigned by a UDDI-enabled server. Each UDDI-enabled server provides a way for entities to obtain userids and passwords that are valid only at that server.

cred
: This required attribute argument is the password or credential that is associated with the entity.

Return Types

uddi_get_authToken returns an *authToken* message containing a valid *authInfo* element usable in subsequent calls requiring an *authInfo* value.

Errors

If an error occurs in processing this message, the server returns a *dispositionReport* structure in a SOAP Fault. The following error information will be relevant:

Table 24.95. Errors signalled by uddi_get_authToken

Error Code	Description
E_unknownUser	signifies that the UDDI-enabled server that received the request does not recognize the userID and/or password argument values passed as credentials

uddi_get_bindingDetail

uddi_get_bindingDetail — Request run-time *bindingTemplate* location information.

Syntax

```
<uddi_get_bindingDetail
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <bindingKey/>
        [ <bindingKey/> ...]
</uddi_get_bindingDetail>
```

Description

The *uddi_get_bindingDetail* message requests the run-time *bindingTemplate* information for the purpose of invoking a registered business API.

Attributes & Children

bindingKey
: One or more uuid _key values that represent specific instances of known bindingTemplate data.

Behavior
: In general, it is recommended that bindingTemplate information be cached locally by applications so that repeated calls to a service described by a bindingTemplate can be made without having to make repeated round trips to a registry. In the event that a call made with cached data fails, the uddi _get_bindingDetail message can be used to get fresh bindingTemplate data. This is useful in cases such as when a service you are using relocates to another server or is restored at a disaster recovery site.

Return Types

This function returns a *bindingDetail* message on successful match of one or more *bindingKey* values. If multiple *bindingKey* values were passed, the results will be returned in the same order as the keys passed.

In the event of a large number of matches, a server may truncate the result set. If this occurs, the *bindingDetail* result will contain the *truncated* attribute with the value of this attribute set to true.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.96. Errors signalled by uddi_get_bindingDetail

Error Code	Description
E_invalidKeyPassed	signifies that one of the *uuid_key* values passed did not match with any known *bindingKey* key values. No partial results will be returned; if any *bindingKey* values passed are not valid *bindingKey* values, this error will be returned.

uddi_get_businessDetail

uddi_get_businessDetail — returns complete *businessEntity* information for one or more specified *businessEntities*

Syntax

```
<uddi_get_businessDetail
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <businessKey/>
        [ <businessKey/> ...]
</uddi_get_businessDetail>
```

Attributes & Children

businessKey
: one or more uuid_key values that represent specific instances of known businessEntity data.

Return Types

This function returns a *businessDetail* message on successful match of one or more *businessKey* values. If multiple *businessKey* values were passed, the results will be returned in the same order as the keys passed.

In the event of a large number of matches, a server may truncate the result set. If this occurs, the *businessDetail* response message will contain the *truncated* attribute with the value of this attribute set to true.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.97. Errors signalled by uddi_get_businessDetail

Error Code	Description
E_invalidKeyPassed	signifies that one of the *uuid_key* values passed did not match with any known *businessKey* values. No partial results will be returned; if any *businessKey* values passed are not valid, this error will be returned.

uddi_get_businessDetailExt

uddi_get_businessDetailExt — Returns extended *businessEntity* information for one or more specified *businessEntities*.

Syntax

```
<uddi_get_businessDetailExt
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <businessKey/>
        [ <businessKey/> ...]
</uddi_get_businessDetailExt>
```

Description

The *uddi_get_businessDetailExt* message returns extended *businessEntity* information for one or more specified *businessEntities*. This message returns exactly the same information as the *get_businessDetail* message, but may contain additional attributes if the source is an external registry that is compatible with this API specification, rather than a UDDI-enabled server.

Attributes & Children

businessKey
: One or more uuid_key values that represent specific instances of known businessEntity data.

Return Types

This message returns a *businessDetailExt* message on successful match of one or more *businessKey* values. If multiple *businessKey* values were passed, the results will be returned in the same order as the keys passed.

In the event of a large number of matches, a server may truncate the result set. If this occurs, the *businessDetailExt* response message will contain the *truncated* attribute with the value of this attribute set to true.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.98. Errors signalled by uddi_get_businessDetailExt

Error Code	Description
E_invalidKeyPassed	signifies that one of the *uuid_key* values passed did not match with any known *businessKey* values. No partial results will be returned; if any *businessKey* values passed are not valid, this error will be returned.
E_unsupported	signifies that the implementation queried does not support the extended detail function. If this occurs, *businessDetail* information should be queried via the *get_businessDetail* message. UDDI-enabled servers will not return this code, but will instead return a *businessDetailExt* result with full *businessDetail* information embedded.

uddi_get_registeredInfo

uddi_get_registeredInfo — Retrieve an abbreviated list of all *businessEntity* keys.

Syntax

```
<uddi_get_registeredInfo
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <authInfo/>
</uddi_get_registeredInfo>
```

Description

The *uddi_get_registeredInfo* message is used to get an abbreviated list of all *businessEntity* keys and *tModel* keys controlled by the entity associated with the credentials passed.

Attributes & Children

authInfo
: This required argument is an element that contains an authentication token. Authentication tokens are obtained using the get_authToken API call.

Return Types

Upon successful completion, the server returns a *registeredInfo* structure listing abbreviated business information in one or more *businessInfo* structures, and *tModel* information in one or more *tModelInfo* structures. This message is useful for determining the extent of registered information controlled by a single entity.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.99. Errors signalled by uddi_get_registeredInfo

Error Code	Description
E_authTokenExpired	signifies that the authentication token value passed in the *authInfo* argument is no longer valid because the token has expired.
E_authTokenRequired	signifies that the authentication token value passed in the *authInfo* argument is either missing or is not valid.

uddi_get_serviceDetail

uddi_get_serviceDetail — request full information about a known *businessService* structure

Syntax

```
<uddi_get_serviceDetail
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <serviceKey/>
        [ <serviceKey/> ...]
</uddi_get_serviceDetail>
```

Attributes & Children

serviceKey
: one or more uuid_key values that represent specific instances of known businessService data.

Return Types

This message returns a *serviceDetail* message on successful match of one or more *serviceKey* values. If multiple *serviceKey* values were passed, the results will be returned in the same order as the keys passed.

In the event of a large number of matches, a server may truncate the result set. If this occurs, the response will contain a *truncated* attribute with the value of this attribute set to true.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.100. Errors signalled by uddi_get_serviceDetail

Error Code	Description
E_invalidKeyPassed	signifies that one of the *uuid_key* values passed did not match with any known *serviceKey* values. No partial results will be returned; if any *serviceKey* values passed are not valid, this error will be returned.

uddi_get_tModelDetail

uddi_get_tModelDetail — Request full information about a known *tModel* structure.

Syntax

```
<uddi_get_tModelDetail
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <tModelKey/>
        [ <tModelKey/> ...]
</uddi_get_tModelDetail>
```

Attributes & Children

tModelKey
: one or more URN qualified uuid_key values that represent specific instances of known tModel data. All tModelKey values begin with a uuid URN qualifier such as "uuid:" followed by a known tModel uuid value.

Return Types

This message returns a *tModelDetail* message on successful match of one or more *tModelKey* values. If multiple *tModelKey* values were passed, the results will be returned in the same order as the keys passed.

In the event of a large number of matches, a server may truncate the result set. If this occurs, the response will contain a *truncated* attribute with the value of this attribute set to true.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.101. Errors signalled by uddi_get_tModelDetail

Error Code	Description
E_invalidKeyPassed	signifies that one of the URN-qualified *uuid_key* values passed did not match with any known *tModelKey* values. No partial results will be returned; if any *tModelKey* values passed are not valid, this error will be returned. Any *tModelKey* values passed without a uuid URN qualifier will be considered invalid.
E_keyRetired	signifies that the request cannot be satisfied because the owner has retired the *tModel* information. The *tModel* reference may still be valid and used as intended, but the information defining the *tModel* behind the key is unavailable.

uddi_save_binding

uddi_save_binding — save or update a complete *bindingTemplate* structure

Syntax

```
<uddi_save_binding
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <authInfo/>
        <bindingTemplate/>
        [<bindingTemplate/>...]
</uddi_save_binding>
```

Description

The *uddi_save_binding* message is used to save or update a complete *bindingTemplate* structure. This message can be used to add or update one or more *bindingTemplate* structures to one or more existing *businessService* structures.

Attributes & Children

authInfo
: This required argument is an element that contains an authentication token, obtained using the get_authToken call.

bindingTemplate
: One or more complete bindingTemplate structures. The order in which these are processed is not defined. To save a new bindingTemplate , pass a bindingTemplate structure with an empty bindingKey attribute value.

Behavior
: Each bindingTemplate structure passed must contain a serviceKey value that corresponds to a registered businessService controlled by the same identity saving the bindingTemplate data. The effect of this call is to establish the parent businessService relationship for each bindingTemplate affected by this call. If the same bindingTemplate (determined by matching bindingKey value) is listed more than once, any relationship to the containing businessService will be determined by processing order, which is determined by the position of the bindingTemplate data in first-to-last order.

Return Types

This message returns a *bindingDetail* message that reflects the newly registered information for the affected *bindingTemplate* structures.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.102. Errors signalled by uddi_save_binding

Error Code	Description
E_invalidKeyPassed	signifies that the request cannot be satisfied because one or more *uuid_key* values specified is not a valid key value, or that a *hostingRedirector* value references a *bindingTemplate* that itself contains a *hostingRedirector* value.
E_authTokenExpired	signifies that the authentication token value passed in the *authInfo* argument is no longer valid because the token has expired.
E_authTokenRequired	signifies that the authentication token value passed in the *authInfo* argument is either missing or is not valid.
E_userMismatch	signifies that one or more of the *uuid_key* values passed refers to data that is not controlled by the entity represented by the authentication token.

Error Code	Description
E_operatorMismatch	signifies that one or more of the *uuid_key* values passed refers to data that is not controlled by the server that received the request for processing.
E_keyRetired	signifies that the request cannot be satisfied because one or more *uuid_key* values specified has previously been hidden or removed by the requester. This specifically applies to the *tModelKey* values passed.
E_invalidURLPassed	an error occurred with one of the *uploadRegister* URL values.
E_accountLimitExceeded	signifies that user account limits have been exceeded.

uddi_save_business

uddi_save_business — Save or update information about a complete *businessEntity* structure.

Syntax

```
<uddi_save_business
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <authInfo/>
        <businessEntity/>
        [<businessEntity/>...] | <uploadRegister/> [<uploadRegister/>...]
</uddi_save_business>
```

Description

The *uddi_save_business* message is used to save or update information about a complete *businessEntity* structure. This message has the broadest scope of all of the save calls in the publisher's API, and can be used to make sweeping changes to the published information for one or more *businessEntity* structures controlled by an identity.

Attributes & Children

Either *businessEntity* arguments or *uploadRegister* arguments may be passed in a given *uddi_save_business* message, but not both. Any number of *businessEntity* or *uploadRegister* values can be passed in a single save (up to a server-imposed limit), but the two types of parameters may not be mixed.

authInfo
: This required argument is an element that contains an authentication token obtained using the get_authToken call.

businessEntity
: One or more complete businessEntity structures can be passed. These structures can be obtained in advance by using the get_businessDetail call or by any other means.

uploadRegister
: one or more resolvable HTTP URL addresses that each point to a single and valid businessEntity or businessEntityExt structure. This variant argument allows a registry to be updated to reflect the contents of an XML document that is URL-addressable. The URL must return a pure XML document that only contains a businessEntity structure as its top-level element, and be accessible using the standard HTTP-GET protocol.

Behavior
: If any of the uuid_key values within in a businessEntity structure (e.g. any data with a key value regulated by a businessKey , serviceKey , bindingKey , or tModelKey) is passed with a blank value, this is a signal that the data that is so keyed is being inserted. This does not apply to structures that reference other keyed data, such as tModelKey references within bindingTemplate or keyedReference structures, since these are references.

Return Types

This message returns a *businessDetail* message that reflects the new registered information for the *businessEntity* information provided.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.103. Errors signalled by uddi_save_business

Error Code	Description

Error Code	Description
E_invalidKeyPassed	signifies that one of the *uuid_key* values passed did not match with any known *serviceKey* values. No partial results will be returned; if any *serviceKey* values passed are not valid, this error will be returned.
E_authTokenExpired	signifies that the authentication token value passed in the authInfo argument is no longer valid because the token has expired.
E_authTokenRequired	signifies that the authentication token value passed in the authInfo argument is either missing or is not valid.
E_userMismatch	signifies that one or more of the *uuid_key* values passed refers to data that is not controlled by the individual who is represented by the authentication token.
E_operatorMismatch	signifies that one or more of the *businessKey* values passed refers to data that is not controlled by the UDDI-enabled server that received the request for processing.
E_keyRetired	signifies that the request cannot be satisfied because one or more *uuid_key* values specified has previously been hidden or removed by the requester. This specifically applies to the *tModelKey* values passed.
E_invalidURLPassed	an error occurred with one of the *uploadRegister* URL values.
E_accountLimitExceeded	signifies that user account limits have been exceeded.

uddi_save_service

uddi_save_service — Adds or updates one or more *businessService* structures.

Syntax

```
<uddi_save_service
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <authInfo/>
        <businessService/> [<businessService/>...]
</uddi_save_service>
```

Attributes & Children

authInfo
: This required argument is an element that contains an authentication token obtained using the get_authToken call.

businessService
: One or more complete businessService structures can be passed. These structures can be obtained in advance by using the get_serviceDetail call or by any other means.

Return Types

This message returns a *serviceDetail* message that reflects the newly registered information for the affected *businessService* structures.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.104. Errors signalled by uddi_save_service

Error Code	Description
E_invalidKeyPassed	signifies that the request cannot be satisfied because one or more *uuid_key* values specified is not a valid key value. This includes any *tModelKey* references that are unknown.
E_authTokenExpired	signifies that the authentication token value passed in the *authInfo* argument is no longer valid because the token has expired.
E_authTokenRequired	signifies that the authentication token value passed in the *authInfo* argument is either missing or is not valid.
E_userMismatch	signifies that one or more of the *uuid_key* values passed refers to data not controlled by the entity that the authentication token represents.
E_operatorMismatch	signifies that one or more of the *uuid_key* values passed refers to data not controlled by the server that received the request for processing.
E_keyRetired	signifies that the request cannot be satisfied because one or more *uuid_key* values specified has previously been hidden or removed by the requester. This specifically applies to the *tModelKey* values passed.

uddi_save_tModel

uddi_save_tModel — Adds or updates one or more *tModel* structures.

Syntax

```
<uddi_save_tModel
  generic="1.0"
  xmlns="urn:uddi-org:api" >
        <authInfo/>
        <tModel/> [<tModel/>...] | <uploadRegister/> [<uploadRegister/>...]
</uddi_save_tModel>
```

Attributes & Children

authInfo
: This required argument is an element that contains an authentication token obtained using the get_authToken call.

tModel
: One or more complete tModel structures can be passed. If adding a new tModel , the tModelKey value should be passed as an empty element.

uploadRegister
: One or more resolvable HTTP URL addresses that each point to a single and valid tModel structure. This variant argument allows a registry to be updated to reflect the contents of an XML document that is URL-addressable. The URL must return a pure XML document that only contains a tModel structure as its top-level element, and must be accessible using the standard HTTP-GET protocol.

Return Types

This message returns a *tModelDetail* message containing the new registered information for the effected *tModel* structures.

Errors

If an error occurs in processing this message, a *dispositionReport* structure will be returned to the caller in a SOAP Fault. The following error information will be relevant:

Table 24.105. Errors signalled by uddi_save_tModel

Error Code	Description
E_invalidKeyPassed	signifies that the request cannot be satisfied because one or more *uuid_key* values specified is not a valid key value. This will occur if a *uuid_key* value is passed in a *tModel* that does not match with any known *tModel* key.
E_authTokenExpired	signifies that the authentication token value passed in the *authInfo* argument is no longer valid because the token has expired.
E_authTokenRequired	signifies that the authentication token value passed in the *authInfo* argument is either missing or is not valid.
E_userMismatch	signifies that one or more of the *uuid_key* values passed refers to data not controlled by the entity represented by the authentication token.
E_operatorMismatch	signifies that one or more of the *uuid_key* values passed refers to data not controlled by the server that received the request for processing.
E_keyRetired	signifies that the request cannot be satisfied because one or more *uuid_key* values specified has previously been hidden or removed by the requester. This specifically applies to the *tModelKey* values passed.
E_invalidURLPassed	an error occurred with one of the *uploadRegister* URL values.
E_accountLimitExceeded	signifies that user account limits have been exceeded.

udt_defines_field

udt_defines_field — Determines whether a user defined type contains a specified member.

Synopsis

```
integer udt_defines_field ( in udt any ,
                            in member_name varchar ) ;
```

Description

This function is used to determine whether the supplied member_name is a member contained by the supplied udt.

Parameters

udt
: A user defined type name as varchar or type instance.

member_name
: The requested member name.

Return Types

This function returns either 1 (true) or 0 (false). 1 (true) is returned if the udt contains a member whose name is equal to the value of member_name, or 0 otherwise.

Examples

Example 24.425. Simple Use

```
select udt_defines_field (new SER_UDT(), 'A');
```

returns 1

```
select udt_defines_field (new SER_UDT_SUB(), 'A');
```

returns 1

```
select udt_defines_field (new SER_UDT(), 'B');
```

returns 0;

See Also

`udt_get()`

`udt_implements_method()`

`udt_set()`

udt_get

udt_get — Retrieves a copy of the requested member from a user defined type instance

Synopsis

```
any udt_get ( in udt_inst any ,
              in member_name varchar ) ;
```

Description

This function returns a copy of the member named member_name, if any, for type instance udt_inst. It is the functional equivalent of member observer.

Parameters

udt_inst
: a user defined type instance.

member_name
: the name of the requested member.

Return Types

This function returns a copy of the requested member, if any.

Examples

Example 24.426. Observing members

This example simply fetches a member from a user defined type.

```
....
declare inst SER_UDT;

inst := new SER_UDT ();
return udt_get (inst, 'A');
....
```

See Also

`udt_defines_field()`

`udt_implements_method()`

`udt_instance_of()`

`udt_set()`

udt_implements_method

udt_implements_method — provides a handle to the first method with specific name in a user defined type.

Synopsis

```
any udt_implements_method ( in udt any ,
                            in method_name varchar ) ;
```

Description

This returns a non-zero value (true) if the udt has an instance method with a name equal to the value of method_name. For methods with the same name, but with different signatures this function will return the handle of the first method in order of definition. If a method is not found, 0 will be returned. The return value can be used to call the method using the indirect call statement. In which case an instance should be passed as a first argument to the indirect call statement.

Parameters

udt
: Type name as varchar or a type instance.

method_name
: The requested method name as a varchar.

Return Types

An integer will be returned. If the named method is not contained within the user defined type 0 (false) will be returned. Otherwise an integer representing the handle to first definition of a contained method with that name will be returned.

Examples

Example 24.427. Finding methods within a UDT

This example demonstrates how one might go about utilizing the handle of a method if found within a user defined type.

```
....
declare mtd any;
declare inst SER_UDT;

inst := new SER_UDT ();
mtd := udt_implements_method (inst, 'NEGATE');

if (mtd <> 0)
  return call (mtd) (inst);
else
  signal ('42000', 'No method NEGATE');
....
```

See Also

`udt_get()`

`udt_defines_field()`

`udt_instance_of()`

`udt_set()`

udt_instance_of

udt_instance_of — returns the type name of supplied type or compares two input types.

Synopsis

```
varchar udt_instance_of ( in udt any );

integer udt_instance_of ( in udt1 any ,
                          in udt2 any );
```

Description

This function returns information about the supplied type(s). There are two versions of this function, one returns the name of the type of the supplied argument, and the other than compares two supplied arguments for matching types. An error will be signalled if either of the types is not defined.

Parameters

udt, udt1, udt2
: Varchar or type instance.

Return Types

`udt_instance_of(udt)` returns the fully qualified name of the type represented by the udt argument.

`udt_instance_of(udt1, udt2)` returns 1 (true) if udt1 is of the same type or a subtype of udt2. Otherwise it returns o (false).

Examples

Example 24.428. Using udt_instance_of()

```
select udt_instance_of ('SER_UDT')
```

returns `DB.DBA.SER_UDT` (if the `SER_UDT` type was created by DBA in the DB database).

```
select udt_instance_of (new SER_UDT())
```

returns `DB.DBA.SER_UDT` (if the `SER_UDT` type was created by DBA in the DB database).

```
select udt_instance_of ('SER_UDT_SUB', 'SER_UDT');
```

Returns 1

```
select udt_instance_of (new SER_UDT(), 'SER_UDT_SUB');
```

Returns 0;

udt_set()

udt_set

udt_set

Synopsis

udt_set (in *udt_inst* any ,
in *member_name* varchar ,
in *new_value* any) ;

Description

This copies the instance udt_inst, sets new_value to the member with a name equal to the value of member_name (if any) and returns the modified instance copy. This is a functional equivalent of a member mutator.

Parameters

udt_inst
: A user defined type instance

member_name
: The name of the requested member

new_value
: The new value to be set

Return Types

A modified copy of udt_inst with the_value set for member_name.

Examples

Example 24.429. Setting user defined type member values

This sample code block shows a user defined type member's value being set.

```
....
declare inst SER_UDT;

inst := new SER_UDT ();
inst := udt_set (inst, 'A', 30);
return inst.A;
....
```

unimport_clr

unimport_clr — This function automatically drops the SQL Type wrappers based on the CLR Reflection API.

Synopsis

```
any unimport_clr ( in assemblies_vector any ,
                   in classes_vector any ) ;
```

Description

This function automatically drops the SQL Type wrappers based on the CLR Reflection API. If there is compiled Virtuoso/PL code that references the type it will fail to execute (with a compilation error) when executed or compiled.

Parameters

assemblies_vector
: a vector of assembly names (as VARCHAR) to look into (or null).

classes_vector
: a vector of type names to create SQL type wrappers for (or null to mark all the types in the assemblies specified by assemblies_vector. In that case the assemblies_vector cannot be NULL).

Examples

Example 24.430. Dropping an imported Class

Now this library must be introduced to the Virtuoso Server. In ISQL use the following commands to test the CLR:

```
SQL> DB..unimport_clr (vector ('sanity'), vector ('sanity'));

Done. -- 300 msec.
SQL> select sanity::test('Rob');

*** Error 37000: [Virtuoso Driver][Virtuoso Server]UD041: No user defined type DB.DBA.sanity
at line 2 of Top-Level:
select sanity::test('Rob')
```

The Runtime Hosting Chapter

unimport_jar

unimport_jar — Drops SQL wrapper types of selected Java classes

Synopsis

```
void unimport_jar (     in files any ,
                        in classes
                        any );
```

Description

This function calls the `jvm_ref_import()` function to produce the XML, then transforms it to a set of DROP TYPE statements and executes them.

Parameters

files
: Null, string or vector of strings. This can contain one or many Java .class files, .zip or .jar files to pick classes from. Null means only the classes specified in the classes argument regardless of their physical location.

classes
: Wildcard string or a vector of strings specifying which classes to describe in the resulting XML.

Examples

Example 24.431. Simple Use

```
SQL> import_jar (null, vector ('java.lang.System'));

Done. -- 126 msec.
SQL> select java_lang_System::getProperty('java.vm.name');
callret
NVARCHAR
_______________________________________________________________________________

Java HotSpot(TM) Client VM
SQL> unimport_jar (null, vector ('java.lang.System'));

Done. -- 54 msec.
SQL> select java_lang_System::getProperty('java.vm.name');

*** Error 37000: [Virtuoso Driver][Virtuoso Server]UD041: No user defined type DB.DBA.java_lang_System
at line 8 of Top-Level:
select java_lang_System::getProperty('java.vm.name')
```

`jvm_ref_import()`

updateXML

updateXML — Create a changed copy of given document by replacing some nodes.

Synopsis

```
any updateXML ( in source any ,
                in path1 varchar ,
                in replacement1 any ,
                in path2 varchar ,
                in replacement2 any ,
                ... ,
                in pathN varchar ,
                in replacementN any ) ;
```

Description

This is a synonym name for XMLUpdate() function. This name is added for compatibility with Oracle 9i.

upper

upper — returns upper case version of string argument

Synopsis

upper (*str* string);

Description

`ucase` returns a copy of string str with all the lowercase alphabetical characters converted to corresponding uppercase letters. This includes also the diacritic letters present in the ISO 8859/1 standard in range 224 - 254 decimal, excluding the character 255, y diaeresis, which is not converted to a German double-s.

upper is just an alias for ucase.

```
ucase('AbracadabrA')  -> 'ABRACADABRA'
```

USER_CHANGE_PASSWORD

USER_CHANGE_PASSWORD — Change the password of an existing user account.

Synopsis

```
USER_CHANGE_PASSWORD ( in name varchar ,
                       in old_pwd varchar ,
                       in new_pwd varchar ) ;
```

Description

This function is used to change the password of an existing user account.

Parameters

name
: A string containing the name of the user whose password is to be changed.

old_pwd
: A string containing the old password of the user.

new_pwd
: A string containing the new password to be used.

Return Types

None

USER_CREATE

USER_CREATE — create a new user account

Synopsis

```
USER_CREATE ( in name varchar ,
              in password varchar ,
              in options vector ) ;
```

Description

This function creates a new user account. The account is valid for SQL and/or DAV, depending n options.

Parameters

name
: The name of the user account as a string.

password
: The clear text password for the user account.

options
: A vector of name-value pairs for user options, even elements for option names, odd ones for values. Arbitrary options can be supplied. The Virtuoso reserved options can be found in the User Options sub-section of the User Administration Section.

Return Types

None

USER_DROP

USER_DROP — This deletes a user ccount, optionally including schema objects, DAV resources and other possible resources owned by the user.

Synopsis

USER_DROP (in *name* varchar ,
in *cascade* integer) ;

Description

This is used to remove an existing user account from local security schema.

Parameters

name
: A string containing the name of the user account to be deleted.

cascade
: This flag (0/1) specifies whether to delete the stored procedures/functions, PL modules, tables and user defined types owned by the user. It cannot drop assembly definitions (created with CREATE ASSEMBLY), because CREATE ASSEMBLY is a database wide operation (done by the DBA group) so the assembly has no owner (since you can not drop DBA). The default value is zero. Sometimes it is not possible to drop the resources, for example if a table owned by the user is referenced by foreign key in a table that would not be dropped. The drop user will detect that and will print the appropriate error message (giving up the operation).

Return Types

None

USER_GET_OPTION

USER_GET_OPTION — Retrieve a user option for a given user account.

Synopsis

USER_GET_OPTION (in *name* varchar ,
in *opt* varchar) ;

Description

This function is used to retrieve an existing user option.

Parameters

name
: The name of the user account.

opt
: Option name.

Return Types

any, depending on option

USER_GRANT_ROLE

USER_GRANT_ROLE — Assign an existing role to an existing security object.

Synopsis

```
USER_GRANT_ROLE ( in name varchar ,
                  in role varchar ,
                  in grant_opt int ) ;
```

Description

This function is used to assign an existing role to an existing security object. This is the same as the `GRANT <role>` statement.

All roles assigned to the role object will be inherited.

Parameters

name
: The name of the security object to affect.

role
: The name of the role (group) to be assigned to the security object.

grant_option
: A flag (0 or 1) indicating whether this object can grant this role to other security objects.

Return Types

None

USER_REVOKE_ROLE — Removes a role from an existing security object.

Synopsis

```
USER_REVOKE_ROLE ( in name varchar ,
                   in role varchar ) ;
```

Description

This function is used to remove a role from the specified security object. This is equivalent to using the `REVOKE <role>` statement.

Parameters

name
: The name of the security object to affect.

role
: The name of the role (group) to be removed from the security object.

Return Types

Synopsis

```
USER_SET_QUALIFIER ( in name varchar ,
                     in qual varchar ) ;
```

Description

This function is used to change the default catalog (qualifier/database) of a given user account.

Parameters

name
: A string containing the name of the user account.

qual
: A string containing the initial default qualifier of the session after a SQL client login.

Return Types

None

Synopsis

```
USER_SET_OPTION ( in name varchar ,
                  in opt varchar ,
                  in value any ) ;
```

Description

This function is used to set a User Option. The options can be any one of those described in User Options section or any other option. Note that existing option will be replaced.

Parameters

name
: The name of the user account to affect.

opt
: Option name.

value
: The new value of the named option.

Return Types

None

user_set_password

user_set_password — Allows dba to change a user's password.

Synopsis

```
user_set_password ( in user_name string ,
                    in new_password string ) ;
```

Description

Explicitly sets a new password for the SQL account *user_name* to *new_password*. Only users in the dba group may execute this function. It allows the database administrator to reset lost passwords of SQL accounts. The new password will be set without further confirmation, so the DBA must be sure of the new password.

Parameters

user_name
: SQL user account name to change.

new_password
: New password for the user as plain text.

Errors

Parameter data type checking errors

Table 24.106. Errors signalled by `user_set_password()`

SQL Code	Error Message	Virtuoso Code
42000	Function user_set_password restricted to dba group	SR285
42000	The user <user_name> does not exist	SR286
42000	The new password for <user_name> cannot be empty	SR287

username

username — returns the login name of the current user

Synopsis

```
username (   );
```

Description

Returns the login name of the user of the connection. Selecting `user` is equivalent.

Parameters

None

Return Values

A string containing the login name of current user

Examples

Example 24.432. Get current DB user

```
SQL> select username();
callret
VARCHAR
_______________________________________________________________________________

dba

1 Rows. -- 5 msec.
SQL> select user;
callret
VARCHAR
_______________________________________________________________________________

dba

1 Rows. -- 4 msec.
```

uudecode

uudecode — Decodes a string previously encoded by uuencode

Synopsis

uudecode (in *input* string ,
in *mode* integer) ;

Description

Uudecode transforms uuencoded data into original form. Uuencode may return a number of sections as a vector of them, each of these sections should be decoded by separate call and results should be concatenated in order to compose original text. The mode of decoding should match to the mode used for encoding, of course.

RFC 2045, (N. Borenstein, N. Freed. MIME (Multipurpose Internet Mail Extensions) Part One: The Format of Internet Message Bodies), contains detailed description of most important encodings used by mail systems. Older RFC 1521 is now obsoleted.

Currently, eight conventions are used for mail attachments. In Virtuoso, they are enumerated by integer IDs.

Table 24.107. Unicode-like standards, supported by Virtuoso

ID	Standard	Description
1	"Native" UUencode	Optional header is one line started by "begin " or "<pre>begin " keyword, with some system-specific data after it. Optional footer is one line started by "end" keyword.
2	Base-64, UNIX version	There are no agreements about headers or footers.
3	Base-64, MIME version	This standard is very similar to "Base-64, UNIX version". Virtuoso, like all modern mail clients, feel no difference between them when decode sections, because the only difference is in the number of data bytes per line.
4	XXencode	This standard is an obsolete standard, similar to Unicode, but not compatible. There are no agreements about headers or footers.
5	BinHex	There are no header or footer lines, but first line of every section should be prefixed by colon (':') character.
6-9	reserved	More standards may be used in the future. It is unsafe to assume that all existing standards are listed here. Real application will often receive messages with unknown or misspelled encodings' names, syntax errors in data etc.
10	MIME Plain-Text	This "encoding" is suitable only for texts. They are stored "as is", but line ends will not be preserved.
11	MIME Quoted-Printable (for texts)	This encoding is suitable for any sort of textual data, because ASCII printable characters are stored "as is" and only nonprintable characters are encoded. UNIX linefeeds (LF chars) will be encoded as "hard breaks", so decoding side may convert them into its own system-specific "line end" chars, e.g. in CRLF sequence.
12	MIME Quoted-Printable (for binaries)	This encoding is suitable for any sort of data but it is especially useful for textual data, because ASCII printable characters are stored "as is" and only nonprintable characters are encoded. No "hard breaks" will be used for UNIX linefeeds (LF chars) of source file, so the file will be decoded exactly as it was encoded, no matter which character sequence is used for "line end" in the decoder's OS. When in trouble, whether the data encoded are text or binary, use this variant ("for binaries"): text may be easily recovered by recipient if linefeeds are wrong whereas binary data will become unusable if encoded as text.

If there's no information about the encoding used in the message, zero may be passed to the uudecode() function instead of proper ID. uudecode() will try to guess the proper algorithm. In any case, decoder feels no difference between modes 2 and 3 (two slightly different "Base64" encodings) and between modes 11 and 12 (two "Quoted-Printable" methods which are different only encoding side). Application may try all methods in turn if automatic guess will fail.

Parameters

input
: String or string-output session with data to be encoded.

mode
: Integer ID of encoding to be used.

Return Types

Vector of strings, where every string contains all data lines of a section.

Errors

Table 24.108. Errors signalled by

SQLState	Error Code	Error Text	Description
22003	UUD01	Unsupported type of UU-encoding (...)	
22003	UUD02	Data string contains errors [...]	
22003	UUD03	Encoded data ended prematurely	
22003	UUD04	No data found to be decoded	

Examples

Example 24.433. Encoding with auto-detection of the encoding type

The function gets a string 'Hello' in BinHex encoding and zero to let it guess that the encoding is BinHex. The call returns 'Hello'.

```
-- note doubled single quotes inside string literal
select uudecode (':5''9XE''m:', 0);
Hello
```

See Also

uuencode , uuvalidate

uuencode

uuencode — Encodes string or string session into sequence of printable characters, suitable for transfer via "ASCII-only" data channels

Synopsis

uuencode (in *input* string or string session ,
in *mode* integer ,
in *maxlines* integer) ;

Description

There are many protocols, like classic UNIX uuencode, which are used to transmit binary files over transmission mediums that do not support other than simple ASCII data. The epoch of physical lines of such sort is in past but file attachments in most popular mail systems still follow old regulations.

Encoded data are transmitted as a sequence of one or more "sections". They may be stored or sent as independent documents. Every section contains some range of original document's data. They may be decoded one after another, and original document may be composed by concatenation of decoded fragments. If the document is small (or if there's no limit on the size of message), it may be sent as single section.

Every section has some header and footer and a set of lines with data between them. Headers and especially footers are usually optional and may vary from system to system whereas data lines are described by standards. Data lines of any two consequent sections may be concatenated together, if needed, to create longer section.

`uuencode` creates a vector of strings, where every string contains some number of data lines, without headers or footers. A Virtuoso/PL stored procedure may be used to create some output stream(s) and put there sections of appropriate format with data lines from vector. Every item of the created vector will contain up to *`maxlines`* lines of data, usually 60 to 80 bytes per line; *`maxlines`* may vary from 10 to 120000 so section may be 0.8Kb to 10Mb long depending on your choice. Last section may be shorter than other, if only partially filled. 10Mb limit may be bypassed by sending of sections one after another without intermediate footers or headers, but please keep in mind that you cannot concatenate two strings in memory if the sum of their lengths exceeds system-wide 10Mb.

RFC 2045, (N. Borenstein, N. Freed. MIME (Multipurpose Internet Mail Extensions) Part One: The Format of Internet Message Bodies), contains detailed description of most important encodings used by mail systems. Older RFC 1521 is now obsoleted.

Currently, eight conventions are used for mail attachments. In Virtuoso, they are enumerated by integer IDs.

Table 24.109. Unicode-like standards, supported by Virtuoso

ID	Standard	Description
1	"Native" UUencode	Optional header is one line started by "begin " or "<pre>begin " keyword, with some system-specific data after it. Optional footer is one line started by "end" keyword.
2	Base-64, UNIX version	There are no agreements about headers or footers.
3	Base-64, MIME version	This standard is very similar to "Base-64, UNIX version". Virtuoso, like all modern mail clients, feel no difference between them when decode sections, because the only difference is in the number of data bytes per line.
4	XXencode	This standard is an obsolete standard, similar to Unicode, but not compatible. There are no agreements about headers or footers.
5	BinHex	There are no header or footer lines, but first line of every section should be prefixed by colon (':') character. Application should place colon before data lines of every section. (this function will prepare only data lines without this prefix).
6-9	reserved	More standards may be used in the future. It is unsafe to assume that all existing standards are listed here. Real application will often receive messages with unknown or misspelled encodings' names,

ID	Standard	Description
		syntax errors in data etc.
10	MIME Plain-Text	This "encoding" is suitable only for texts. They are stored "as is", but line ends will not be preserved.
11	MIME Quoted-Printable (for texts)	This encoding is suitable for any sort of textual data, because ASCII printable characters are stored "as is" and only nonprintable characters are encoded. UNIX linefeeds (LF chars) will be encoded as "hard breaks", so decoding side may convert them into its own system-specific "line end" chars, e.g. in CRLF sequence.
12	MIME Quoted-Printable (for binaries)	This encoding is suitable for any sort of data but it is especially useful for textual data, because ASCII printable characters are stored "as is" and only nonprintable characters are encoded. No "hard breaks" will be used for UNIX linefeeds (LF chars) of source file, so the file will be decoded exactly as it was encoded, no matter which character sequence is used for "line end" in the decoder's OS. When in trouble, whether the data encoded are text or binary, use this variant ("for binaries"): text may be easily recovered by recipient if linefeeds are wrong whereas binary data will become unusable if encoded as text.

Parameters

input
: String or string-output session with data to be encoded.

mode
: Integer ID of encoding to be used.

maxlines
: Number of data lines per section. Should be in range 10 to 120000, otherwise nearest suitable value will be used without reporting any error.

Return Types

Vector of strings, where every string contains all data lines of a section.

Errors

Table 24.110. Errors signalled by

SQLState	Error Code	Error Text	Description
22023	UUE01	Function uuencode needs a string output or a string as argument 1, not an arg of type ... (...)

uudecode , uuvalidate

uuvalidate

uuvalidate — Encodes string or string session into sequence of printable characters, suitable for transfer via "ASCII-only" data channels

Synopsis

uuvalidate (in *input* string or string session ,
in *mode* integer) ;

Description

This function tries to ensure what applied data have a pointed encoding mode. If mode parameter is 0 (ie unknown) or if the validation fails, it will try to determine which mode was used in fact.

RFC 1521, (N. Borenstein, N. Freed. MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies), contains detailed description of most important encodings used by mail systems. RFC 2045, (N. Borenstein, N. Freed. MIME (Multipurpose Internet Mail Extensions) Part One: The Format of Internet Message Bodies).

Currently, eight conventions are used for mail attachments. In Virtuoso, they are enumerated by integer IDs.

Table 24.111. Unicode-like standards, supported by Virtuoso

ID	Standard	Description
1	"Native" UUencode	Optional header is one line started by "begin " or "<pre>begin " keyword, with some system-specific data after it. Optional footer is one line started by "end" keyword.
2	Base-64, UNIX version	There are no agreements about headers or footers.
3	Base-64, MIME version	This standard is very similar to "Base-64, UNIX version". Virtuoso, like all modern mail clients, feel no difference between them when decode sections, because the only difference is in the number of data bytes per line.
4	XXencode	This standard is an obsolete standard, similar to Unicode, but not compatible. There are no agreements about headers or footers.
5	BinHex	There are no header or footer lines, but first line of every section should be prefixed by colon (':') character. Application should place colon before data lines of every section. (this function will prepare only data lines without this prefix).
6-9	reserved	More standards may be used in the future. It is unsafe to assume that all existing standards are listed here. Real application will often receive messages with unknown or misspelled encodings' names, syntax errors in data etc.
10	MIME Plain-Text	This "encoding" is suitable only for texts. They are stored "as is", but line ends will not be preserved.
11	MIME Quoted-Printable (for texts)	This encoding is suitable for any sort of textual data, because ASCII printable characters are stored "as is" and only nonprintable characters are encoded. UNIX linefeeds (LF chars) will be encoded as "hard breaks", so decoding side may convert them into its own system-specific "line end" chars, e.g. in CRLF sequence.
12	MIME Quoted-Printable (for binaries)	This encoding is suitable for any sort of data but it is especially useful for textual data, because ASCII printable characters are stored "as is" and only nonprintable characters are encoded. No "hard breaks" will be used for UNIX linefeeds (LF chars) of source file, so the file will be decoded exactly as it was encoded, no matter which character sequence is used for "line end" in the decoder's OS. When in trouble, whether the data encoded are text or binary, use this variant ("for binaries"): text may be easily recovered by recipient if linefeeds are wrong whereas binary data will become unusable if encoded as text.

Parameters

input
: String or string-output session with data to be encoded.

mode
: Integer ID of encoding to be used.

Return Types

Vector of strings, where every string contains all data lines of a section.

Errors

Table 24.112. Errors signalled by

SQLState	Error Code	Error Text	Description
22003	UUV01	Unsupported type of UU-encoding (..)	

Examples

Example 24.435. Detection of encoding type

The function gets a string 'Hello' in BinHex encoding and returns 5 indicating that the string is probably in BinHex encoding.

```
-- note doubled single quotes inside string literal
select uuvalidate (':5''9XE''m:', 0);
5
```

USER_KEY_STORE

USER_KEY_STORE — Saves a key in the database and in case the database is restarted, the key will be loaded again.

Synopsis

```
USER_KEY_STORE (  in username varchar ,
                  in key_name varchar ,
                  in key_type varchar ,
                  in key_format varchar ,
                  in key_pwd varchar ,
                  in key_value varchar := NULL ) ;
```

Description

This function saves a key in the database and in case the database is restarted, the key will be loaded again.

Parameters

username
: User name

key_name
: Key name

key_type
: Key type

key_format
: Key format

key_pwd
: Key password

key_value
: Key value

Examples

Example 24.436. Persisting a key & certificate

The example below persists a key named 'id_rsa' and certificate created for it into user's key space. Thus after server restart the key will be available again.

```
SQL> USER_KEY_STORE (user, 'id_rsa', 'X.509', 2, '', xenc_pkcs12_export ('id_rsa', 'CA Certificate', ''))
```

See Also

`xenc_pkcs12_export()`

VAD_CHECK

VAD_CHECK — Checks the package has not been altered since installation

Synopsis

```
array DB.DBA. VAD_CHECK ( in package_name varchar );
```

Description

This checks to see if the elements of the package are as they are defined in the original distribution. A list of differing elements is returned. This does not always indicate a corruption since a later version or another package may add columns to tables, and some resources may be customized after installation.

Parameters

package_name
: name of package '/' version e.g: 'virtodp/1.0'

Return Types

A list of differing elements is returned as an array of 3-item structures: key, initial value, final value.

VAD_CHECK_INSTALLABILITY

VAD_CHECK_INSTALLABILITY — Checks the presence and correct versions of required packages and of the Virtuoso platform

Synopsis

```
varchar DB.DBA. VAD_CHECK_INSTALLABILITY ( in package_uri varchar );
```

Description

Checks the presence and correct versions of required packages and of the Virtuoso platform. It does not execute any pre-install Virtuoso/PL code from the package, so there is no guarantee that installation will be successful if the check found no error.

Parameters

package_uri
: URI of VAD file

See Also

`vad_check_uninstallability()`

`vad_fail_check()`

VAD_CHECK_UNINSTALLABILITY

VAD_CHECK_UNINSTALLABILITY — Checks if the package can be uninstalled.

Synopsis

```
varchar DB.DBA. VAD_CHECK_UNINSTALLABILITY ( in package_name varchar );
```

Description

Checks if the package can be uninstalled. It does not executes any pre-uninstall Virtuoso/PL code from the package, so there is no guarantee that uninstallation will be successful if the check found no error.

Parameters

package_name
: name of package '/' version e.g: 'virtodp/1.0'

VAD_FAIL_CHECK

VAD_FAIL_CHECK — Signals package check failure

Synopsis

```
DB.DBA. VAD_FAIL_CHECK ( in msg varchar );
```

Description

makes "rollback work", exits from atomic mode and fails server with raw_exit(-1)

Parameters

msg
: text of message

See Also

`vad_check_uninstallability()`

`vad_check_installability()`

`vad_install()`

`vad_pack()`

`vad_safe_exec()`

`vad_uninstall()`

VAD_INSTALL

VAD_INSTALL — Invoke VAD installation process

Synopsis

```
varchar DB.DBA. VAD_INSTALL ( in package_uri varchar ,
                              in source_type integer ) ;
```

Description

Invoke the install operation from interactive SQL or from the web user interface. This will:

- enter into atomic mode
- Check for version and prerequisite package compatibility
- Run the pre-install SQL script
- Load all SQL code and other resources in the order given by the developer
- Run any post install SQL code
- If DB.DBA.VAD_INSTALL() succeeded the server comes back on-line.

If there was a failure in mid-install, such as running out of disk or some other serious unrecoverable database error, the server exits. The installation can be undone manually by halting the server, deleting the transaction log file and restarting. The server will start from the checkpoint as if the installation was never attempted.

Parameters

package_uri
: URI of VAD file

source_type
: The second parameter to VAD_INSTALL controls whether the given path to the package is taken as a filesystem path or a DAV path. Value of 1 means the path is interpreted as a DAV path. The default value is 0 which means the VAD package is read from filesystem path.

VAD_LOAD_FILE

VAD_LOAD_FILE — executes statements of a SQL file

Synopsis

```
DB.DBA. VAD_LOAD_FILE (     in fname varchar
);
```

Description

This splits a plain sql file into single statements and executes them one by one. The root directory for this procedure is the 'code' root of VAD's repository.

Parameters

fname
: path to file to exec

See Also

`vad_load_sql_file()`

VAD_LOAD_SQL_FILE

VAD_LOAD_SQL_FILE — Loads SQL file and executes its content's statements.

Synopsis

```
DB.DBA. VAD_LOAD_SQL_FILE ( in sql_file_name varchar ,
                            in grouping integer ,
                            in report_errors varchar ,
                            in is_dav integer ) ;
```

Description

Loads SQL file (can be regular file or DAV resource) and then splits its content into single statements and executes them one by one. Along the process, the function makes needed reports and changes 'VAD_errcount' registry variable.

Parameters

sql_file_name
: For files, this parameter is either absolute or relative to server's working directory. The directory should be readable according to the virtuoso.ini settings. For DAV resources, the sql_file_name is always absolute: ('/DAV/<folder-name>...').

grouping
: Always set this parameter to 1.

report_errors
: The supported values for this parameter are:

is_dav
: This parameter is 0 for plain file and 1 for resource loaded in DAV.

Examples

Example 24.437. Simple Use

```
DB.DBA.VAD_LOAD_SQL_FILE ('./conductor/vdir_helper.sql', 1, 'report', 0);
```

VAD_PACK

VAD_PACK — get VAD resource

Synopsis

```
varchar DB.DBA. VAD_PACK ( in sticker_uri varchar ,
                           in base_uri_of_resources varchar ,
                           in package_uri varchar ) ;
```

Description

This function gets the resource identified by the sticker_uri, which contains the vad:package root element. The URIs present there are interpreted in the context of the base_uri_of_resources and the individual resources are fetched. These are parsed to make sure that they are syntactically correct and the resources are appended to the generated package resource, which is stored into the result_uri. vad_pack() returns a human-readable log of error and warning messages, vad_pack() will signal errors if some resources or database objects will be unavailable. By convention, VAD package files have the extension '.vad'.

Parameters

sticker_url
: stickers file URI

base_uri_of_resources
: inlined resources root

package_uri
: path of output VAD file

Return Types

vad_pack() returns a human-readable log of error and warning messages, vad_pack() will signal errors if some resources or database objects will be unavailable.

VAD_SAFE_EXEC

VAD_SAFE_EXEC — execute without signalling errors

Synopsis

```
DB.DBA. VAD_SAFE_EXEC (
    in expr varchar
);
```

Description

Safe way to do something without generating an exception, e.g.: when it is necessary to drop a table without insurance of it's existence.

Parameters

expr
: text of expression

VAD_UNINSTALL

VAD_UNINSTALL — Vad package uninstallation

Synopsis

```
varchar DB.DBA. VAD_UNINSTALL ( in package_name varchar );
```

Description

Invokes the uninstall operation from interactive SQL or from the web user interface. This will:

- enter into atomic mode
- Check if no other package is using the subject of uninstall
- Run the pre-uninstall SQL script
- Run any post-uninstall SQL code
- Remove all VSP and XSLT and other web resources from their designated place in DAV or the Virtuoso Web root where permitted.
- If DB.DBA.VAD_UNINSTALL() succeeded the server comes back on-line. If there was a failure in mid-uninstall, such as running out of disk or some other serious unrecoverable database error, the server exits. The failed uninstallation can be undone manually. As usual, halting the server, deleting the transaction log file and restarting will force the server to start from the checkpoint as if the uninstallation was never attempted.

Parameters

package_name
: name of package '/' version e.g: 'virtodp/1.0'

vd_remote_data_source

vd_remote_data_source — prepares a remote DSN for use

Synopsis

```
vd_remote_data_source ( in dsn varchar ,
                        in connstr varchar ,
                        in user varchar ,
                        in password varchar ) ;
```

Description

A remote data source is uniquely identified by its DSN, the dsn argument to this function. The connstr argument is presently ignored. The user and password are the login name and password to use when communicating with the remote data source. All Virtuoso users dealing with the remote data source will appear as this user to the remote data source. Virtuoso will make as many connections as there are concurrent users of the data source. Connections are cached by Virtuoso.

The default qualifier of the user of the remote data source is usually not relevant. This function connects to the DSN in order to retrieve various meta data, which it stores locally. The DSN should be defined in the server's environment and the DSN's database should be on line.

Parameters

dsn
: The name of the remote datasource to prepare.

connstr
: Currently ignored parameter.

user
: username for the connection.

password
: password for the user.

Return Types

Status of the connection attempt.

Errors

Manually Setting Up A Remote Data Source

vd_remote_proc_wrapper

vd_remote_proc_wrapper — Creating a PL wrapper for remote procedure execution

Synopsis

```
varchar vd_remote_proc_wrapper ( in dsn varchar ,
                                 in remote_name varchar ,
                                 in local_name varchar ,
                                 in metadata any ,
                                 out status_code varchar ,
                                 out error_message varchar ,
                                 in make_resultset integer ,
                                 in description varchar ) ;
```

Description

This is to create a PL stored procedure to execute a Remote Stored Procedures. It returns results as a SQL result set as well as an array(vector) depending of the 'make_resultset' flag.

Parameters

dsn
: the remote datasource name

remote_name
: name of the remote procedure

local_name
: name of the PL wrapper to be created locally

metadata
: A vector of vectors containing a parameters information each of vectors need to have following structure:

status_code
: returns SQL status code of the PL wrapper generation

error_message
: returns the error message if status code is different than 00000

make_resultset
: A flag 0/1 default 0. If is true (1) the wrapper will be generated to return result set. Otherwise will be generated to return an array.

description
: The text of a comment to added to the wrapper. It then will be shown as a method description if the PL wrapper is published as a SOAP method.

Examples

Example 24.438. Creating a PL wrapper which returns resultset

The following example will create a PL wrapper to invoke the MS SqlServer Stored Procedure 'Northwind.dbo.CustOrderHist'

```
-- the wrapper creation (fragment of Virtuoso/PL)
declare state, msg varchar;
vd_remote_proc_wrapper ('Northwind.dbo.CustOrderHist', 'MS.SQL.CustOrderHist',
```

```
'sql_lite', vector (vector ('IN', '_CustomerID', 'VARCHAR', '')), state, msg , 1, 'This is a test');
if (state <> '00000')
  signal (state, msg);

-- PL wrapper source that will be created
create procedure "MS"."SQL"."CustOrderHist" (IN "_CustomerID" VARCHAR) returns any array array
{
--PL Wrapper for remote procedure
--##This is a test
--"DSN:sql_lite PROCEDURE:Northwind.dbo.CustOrderHist"
declare dta, mdta any;
declare params any;
params := vector ("_CustomerID");
set_user_id ('dba');
rexecute ('sql_lite', '{call "Northwind"."dbo"."CustOrderHist" (?)}', NULL, NULL, params, 0, mdta, dta);
exec_result_names(mdta[0]);
declare i, l integer;
i := 0; l := length (dta);
 while(i<l) {
   exec_result(dta[i]);
   i:=i+1;
 }
}

-- result from execution
SQL> "MS"."SQL"."CustOrderHist" ('ALFKI');

rexecute vd_remote_data_source

vd_remote_table

vd_remote_table — declares an existing table as resident on a DSN previously declared with vd_remote_data_source

Synopsis

```
vd_remote_table ( in dsn varchar ,
                  in local_name varchar ,
                  in remote_name varchar ) ;
```

Description

Declares an existing table as resident on a data source previously declared with vd_remote_data_source().

This function declares the table local_name as table remote_name on the dsn. The tables names should be full, names with qualifier and owner. The names are case sensitive and must be in the exact case where they appear in the local and remote schemas.

If remote_name is NULL, the effect of a possible previous vd_remote_table is reversed. The table is thereafter treated as a local table, except in procedures and statements compiled when the remote declaration was in effect.

Parameters

dsn
: The name of the remote datasource previously connected using vd_remote_data_source()

local_name
: Fully qualified name of a local table.

remote_name
: Fully qualified name of the remote table.

vd_statistics

VD_STATISTICS — Update VDB RPC cost statistics for given DSN

Synopsis

```
DB.DBA. VD_STATISTICS ( in _dsn varchar ,
                        in vd_table_mask varchar ) ;
```

Description

This procedure will update the RPC round-trip statistics for selected data sources.

Parameters

_dsn
: This parameter is a LIKE mask for the name of the data source, as stored in DS_DSN column of SYS_DATA_SOURCE system table. Its default value of '%' means update the "round-trip" times for all remote data sources.

vd_table_mask
: This parameter is a LIKE mask for the name of the table , as stored in RT_NAME column of SYS_DATA_SOURCE system table. Its default value of '%' means update all tables.

`vdd_measure_rpc_time()`

vdd_disconnect_data_source

vdd_disconnect_data_source — Disconnects a data source if no active transactions are using resources from it.

Synopsis

vdd_disconnect_data_source (in *dsn* varchar) ;

Description

You must have DBA privileges to run that function.

This function disconnects all the idle opened connections to a VDB datasource. If there are active transactions server-side, using connections to that datasource, they are not closed. After they finish, this function can be called again to disconnect the new idle connections.

The datasource continues to be valid and any subsequent transactions using this datasource will open a new connection to it.

Parameters

dsn
: The name of the remote datasource to disconnect.

Manually Setting Up A Remote Data Source

vdd_measure_rpc_time

vdd_measure_rpc_time — Estimate VDB RPC round-trip for a given DSN in milliseconds

Synopsis

```
float vdd_measure_rpc_time ( in _dsn varchar );
```

Description

This function will return the estimated number of milliseconds to perform an RPC round trip on the DSN supplied.

Parameters

_dsn
: The name of the data source to estimate round-trip time for.

Return Types

The length of time taken in milliseconds as a float type.

See Also

`vd_statistics()`

vector

vector — make a vector

Synopsis

vector (*elem1* any ,
elem2 any ,
... ,
elem-n any) ;

Description

`vector` returns a new vector (one-dimensional array) constructed from the given arguments.

Parameters

elem1..n
: Values of any types (not necessarily of one and the same type).

Return Values

A vector (heterogeneous array) of as many elements as there were arguments containing copies of the arguments.

Examples

Example 24.439. Inspecting a vector with dbg_obj_print

SQL clients can not process vectors directly so the simplest way to look at the content of a vector is to print it no server's console.

```
dbg_obj_print (vector (1, 2.34, 'A string', atof('3.14')))
```

Example 24.440. Pretty-print function for vectors

The following function gets a heterogeneous vector of strings, nubers and other vectors and returns a string that is an SQL expression that will return a copy of a given vector.

```
create procedure DUMP_VEC_IMPL (inout _vec any, inout _ses any)
{
  declare _len, _ctr integer;
  if (193 <> __tag (_vec))
    {
      if (isstring (_vec))
        http (WS.WS.STR_SQL_APOS (_vec), _ses);
      else
        http (cast (_vec as varchar), _ses);
      return;
    }
  _len := length (_vec);
  _ctr := 0;
  http ('\nvector (', _ses);
  while (_ctr < _len)
    {
      if (_ctr > 0)
        http (', ', _ses);
      DUMP_VEC_IMPL (_vec[_ctr], _ses);
      _ctr := _ctr+1;
    }
  http (')', _ses);
```

```
}

create function DUMP_VEC (in _vec any)
{
  declare _ses any;
  _ses := string_output();
  DUMP_VEC_IMPL (_vec, _ses);
  return string_output_string (_ses);
}

select DUMP_VEC (vector ('abc', 1, vector (3.1415), vector ()));
callret
VARCHAR
_______________________________________________________________________________

vector ('abc', 1,
vector (3.1415),
vector ())

1 Rows.
```

See Also

aset aref vector_concat

vector_concat

vector_concat — concatenate vectors

Synopsis

```
vector vector_concat ( vec1 vector ,
                       vec2 vector ,
                       ... ,
                       vec-n vector ) ;
```

Description

`vector_concat` takes a variable number of vectors (heterogeneous arrays) and constructs a new vector containing copies of each (top level) element in the arguments.

Parameters

vec1..n
: vector .

Return Values

A vector made of copies of elements contained in vec1..n.

Examples

Example 24.441. Simple Use

```
dbg_obj_print (vector_concat (vector (now(), 'black', 'crow'),
                              vector ('said', 'nevermore')));

dbg_obj_print (vector_concat (vector ('a','b'),
                              vector (vector ('c', 'd'), 'e')));
```

Would output something like this on the Virtuoso console:

```
({ts 2001-08-07 16:57:12.000000}  "black" "crow" "said" "nevermore" )
("a" "b" ("c" "d" ) "e" )
```

VHOST_DEFINE

VHOST_DEFINE — define a virtual host or virtual directory

Synopsis

```
Void DB.DBA. VHOST_DEFINE ( in vhost varchar ,
                            in lhost varchar ,
                            in lpath varchar ,
                            in ppath varchar ,
                            in is_dav boolean ,
                            in is_brws boolean ,
                            in def_page varchar ,
                            in auth_fn varchar ,
                            in realm varchar ,
                            in ppr_fn varchar ,
                            in vsp_user varchar ,
                            in soap_user varchar ,
                            in sec varchar ,
                            in ses_vars boolean ,
                            in soap_opts any ,
                            in auth_opts any ,
                            in opts any ,
                            in is_default_host integer ) ;
```

Description

VHOST_DEFINE is used to define virtual hosts and virtual paths on the Virtuoso HTTP server. Effectively this procedure inserts a row in table DB.DBA.HTTP_PATH Virtuoso supports both flavours of virtual hosting: IP-based and name-based.

Parameters

vhost
: A string containing the virtual host name that the browser presents as Host: entry in the request headers. i.e. Name-based virtual hosting. The default value is taken from the Virtuoso INI file.

lhost
: A string containing the address of the network interface the Virtuoso HTTP server uses to listen and accept connections. The default value is taken from the Virtuoso INI file.

lpath
: A string containing the path component of the URI for the logical path.

ppath
: A string containing the physical path that the logical path points to. i.e. a directory or a path to dav collection on server.

is_dav
: An integer . If non-zero, it indicates that the physical_path points to a collection in DAV repository. Default value is 0.

is_brws
: An integer . If non-zero, it indicates that the server will generate a directory listing in case a default page is absent. Default value is 0.

def_page

A string containing the file name of the default page. Default value is NULL.

auth_fn
: A string that contains the fully qualified Virtuoso/PL procedure name of authentication hook function that will check and perform authentication for this virtual host or directory. If NULL, Virtuoso will not attempt authentication. The default value is NULL.

realm
: A string with the realm to be passed to the authentication function auth_func . The default value is NULL.

ppr_fn
: A string containing the fully qualified name of the Virtuoso/PL stored procedure used for post-processing of the page. The default values is NULL.

vsp_user
: A string containing a valid DB user name. The VSP pages contained in the virtual directory shall be run with the grants effective for this user at time of execution. The default values is NULL.

soap_user
: A string containing a valid SOAP user for SOAP calls. The default values is NULL.

sec
: Security restrictions (SSL, Digest). The default values is NULL.

ses_vars
: An integer . If non-zero, indicates that session variables are persistent. The default values is 0.

soap_opts
: Options for SOAP service. The default values is NULL. The SOAP options are name-value pairs contained in a vector: i.e. vector ('name1', 'value1', ...). The SOAP server accepts the optional parameters as described in Optional parameters to the SOAP endpoint .

auth_opts
: Options for the authentication hook and HTTPS listen hosts. The default values is NULL. If the sec_method (security method) defined as 'SSL' the following auth_options must be supplied: https_cert - HTTPS server certificate file path, https_key - HTTPS server private key file path. In addition to check X509 certificate of clients, the https_cv option with path to the file containing trusted certificate authorities must be supplied and https_cv_depth - integer to set depth of client certificate checking.

opts
: Extension options to the virtual directory itself. The default is NULL. When it's used the value MUST be a vector of name and value pairs. The supported extension options are: "noinherit" - denotes that all paths requested and matched this directory will be treated only as physical location (no expansion, no inheritance). It may used with a single page to the directory mapping. "xml_templates" - This denotes that .xml files under that directory and indirect children will be treated as a XML Template files (i.e. they will be executed). "executable" - this flag is used to override the execution permissions of the active pages stored within WebDAV repository (i.e. if it's set the active pages will be executed no matter what are their execution permission flag)

is_default_host

Return Types

The Return is VOID.

Examples

Example 24.442. Define Virtual Hosts

The following command will:

listen on port 8889 of the interface corresponding with host.foo.com
maps /appsimple -> /samples/appsimple/
can get a directory listing
SQL user which will perform VSP execution is WS
the persistent session variables flag is on, so can be used in VSPs

```
SQL> VHOST_DEFINE (vhost=>'www.foo.com:8889',
  lhost=>'host.foo.com:8889',
  lpath=>'/appsimple',
  ppath=>'/samples/appsimple/',
  is_brws=>1,
  vsp_user=>'WS',
  ses_vars=>1);
```

listen on standard HTTP port (80)
maps /appurl -> /samples/appurl/
can get a directory listing
SQL user which will perform VSP execution is WS
the persistent session variables flag is on , can be used in VSPs

```
SQL> VHOST_DEFINE (vhost=>'www.foo.com',
  lhost=>'host.foo.com',
  lpath=>'/appurl',
  ppath=>'/samples/appurl/',
  is_brws=>1,
  vsp_user=>'WS',
  ses_vars=>1);
```

HTTPS server listen on 443 port (will accept HTTP connections via SSL)
maps /secure -> /samples/appurl/
SQL user which will perform VSP execution is DBA
The server certificate is in the ./server.cert file
and server private key is in the ./server.key file

```
SQL> VHOST_DEFINE (vhost=>'www.foo.com:443',
  lhost=>'host.foo.com:443',
  lpath=>'/secure',
  ppath=>'/samples/appurl/',
  sec=>'SSL',
  vsp_user=>'dba',
  auth_opts=>vector ('https_key','./server.key','https_cert','./server.cert'));
```

If a browser points to the URL http://www.foo.com/ it will get a directory listing of /samples/appurl/, or if a browser points to http://www.foo.com:8889/ it will will get a directory listing of /samples/appsimple/.

The following example demonstrates the use of SOAP options used in Interop testing.

```
  VHOST_DEFINE (lpath=>'/Interop',
                ppath=>'/SOAP/',
                soap_user=>'INTEROP',
                soap_opts=> vector(
                              'SchemaNS','http://soapinterop.org/xsd',
                              'Namespace','http://soapinterop.org/',
                              'MethodInSoapAction','no',
                              'ServiceName', 'InteropTests',
                              'HeaderNS', 'http://soapinterop.org/echoheader/',
                              'CR-escape', 'yes'));
```

Example that covers TLS mutual authentication and custom re-write rules handlers for 403 and 401 HTTP Status responses:

```
DB.DBA.VHOST_DEFINE (
      lhost=>':443',
```

```
      vhost=>'example.com',
      lpath=>'/DAV',
      ppath=>'/DAV/',
      is_dav=>1,
      vsp_user=>'dba',
      ses_vars=>0,
      opts=>vector ('url_rewrite', 'rdf_sink_rule_list', '401_page',
'demo/authenticate.vsp', '403_page', 'demo/authenticate.vsp'),
      sec=>'SSL',
      auth_opts=>vector ('https_cert', 'db:john_smith_CA2', 'https_key',
'db:john_smith_CA2', 'https_verify', 3, 'https_cv_depth', 10),
      is_default_host=>0
```

VHOST_REMOVE

VHOST_REMOVE — remove a virtual host or virtual directory

Synopsis

```
Void DB.DBA. VHOST_REMOVE ( in vhost varchar ,
                            in lhost varchar ,
                            in lpath varchar ,
                            in del_vsps integer ) ;
```

Description

`vhost_remove` is used to remove virtual hosts and virtual paths on the Virtuoso HTTP server. Effectively this procedure deletes a row in the table `DB.DBA.HTTP_PATH` . Virtuoso supports both flavours of virtual hosting: IP-based and name-based.

Parameters

vhost
: A string containing the virtual host name that the browser presents as Host: entry in the request headers. i.e. Name-based virtual hosting. Default value as defined in the Virtuoso INI file.

lhost
: A string containing the address of the network interface the Virtuoso HTTP server uses to listen and accept connections. Default value as defined in the Virtuoso INI file.

lpath
: A string containing the path component of the URI for the logical path.

del_vsps
: if a positive number will indicate to the server to drop all compilations of VSP files in this domain. Default value is 0.

Return Types

The return is VOID.

Examples

Example 24.443. Removing Virtual Host Definitions

```
SQL> VHOST_REMOVE (vhost=>'www.foo.com:8889',
  lhost=>'host.foo.com:8889',
  lpath=>'/appsimple');
```

Now, attempts to retrieve http://www.foo.com:8889/ will be rejected.

The Virtuoso Web Server Chapter in the Virtuoso Manual for discussion on this topic.

vhost_remove .

virtuoso_ini_path

virtuoso_ini_path — Return full name of configuration INI file

Synopsis

```
virtuoso_ini_path (   );
```

Description

This function returns the complete path to the configuration INI file. It is typically used by the cfg_ functions that modify or read the contents of the INI file.

Examples

Example 24.444. Simple examples

```
SQL> select virtuoso_ini_path();
callret
VARCHAR
_______________________________________________

D:\Program Files\OpenLink\Virtuoso 2.5\demo\demo.ini

1 Rows. -- 60 msec.
```

See Also

`cfg_section_count cfg_section_name cfg_item_count cfg_item_name cfg_item_value cfg_write`

server_root

server_root — Returns server working directory.

Synopsis

```
server_root (   );
```

Description

This function returns the complete physical path to server working directory.

Examples

Example 24.445. Simple examples

Show in the result the server working directory and INI file name:

```
SQL> select server_root(), virtuoso_ini_path ();
callret                                  callret
VARCHAR                                  VARCHAR
_________________________________________

C:\Program Files\OpenLink\Virtuoso 5.0\   C:\Program Files\OpenLink\Virtuoso 5.0\demo\demo.ini

1 Rows. -- 20 msec.
```

vsp_calculate_digest

vsp_calculate_digest — calculate on server-side a digest to perform a HTTP digest authentication

Synopsis

vsp_calculate_digest (in *username* varchar ,
in *password* varchar ,
in *credentials* any) ;

Description

The vsp_calculate_digest() function is used to calculate on server-side a digest to perform a HTTP digest authentication. When the authentication type is 'digest' the function will return a md5 checksum based on credentials, user name and password. The checksum calculation will be made as required for HTTP Digest authentication to compare against 'response' element of credentials. If the authentication is basic a NULL will be returned.

Parameters

username
: A string with name of the user account name

password
: A string with a plain text password from the users table (can be from external LDAP server etc.)

credentials
: A vector of name/value pairs (the keyword and value are strings) of:

Return Types

A string containing md5 digest, if 'authtype' option is 'digest'. Otherwise returns null.

Examples

Example 24.446. A VSP page performing digest authentication

The following page check for digest authentication and returns OK if authentication succeeds, otherwise it asks for authentication again.

```
<?vsp
    declare auth any;
    declare cs varchar;
    auth := app_auth_vec (lines);
    if (not isarray (auth))
      app_get_auth ();
    cs := vsp_calculate_digest ('u1', 'secret', auth);
    if (cs is not null and cs = get_keyword ('response',auth))
       http ('OK');
    else
      app_get_auth ();
?>

-- making the HTTP Digest authentication header
create procedure app_get_auth ()
 {
   http_request_status ('HTTP/1.1 401 Unauthorized');
   http_header (sprintf ('WWW-Authenticate: Digest realm="%s", domain="%s", nonce="%s", opaque="%s"
 };

-- returns an array suitable for vsp_calculate_digest
create procedure app_auth_vec (in lines any)
 {
```

```
  declare ahdr, arr, authvec any;
  ahdr := http_request_header (lines, 'Authorization');
  if (isstring (ahdr) and ahdr like 'Digest%')
    {
      ahdr := subseq (ahdr, 6, length (ahdr));
      arr := split_and_decode (ahdr, 0, '\0\0,=');
      authvec := vector ('authtype', 'Digest', 'method', http_request_get ('REQUEST_METHOD'));
      foreach (varchar elm in arr) do
        {
          declare elm1 varchar;
          elm1 := trim (elm, '" ');
          authvec := vector_concat (authvec, vector (elm1));
        }
     }
   return authvec;
}
```

vhost_define

vt_batch

vt_batch — Returns a vt batch object.

Synopsis

```
batch object vt_batch ( );
```

Description

This object can be used to update a free text index by feeding document information into it using vt_batch_d_id to set the free text document ID and vt_batch_feed to feed actual words.

This object may not be assigned to other variables and may only be passed as an inout parameter.

The batch is applied to the index by calling the VT_BATCH_PROCESS_<table>_<column> function generated by CREATE TEXT INDEX .

`vt_batch_update()`

`vt_create_text_index()`

vt_batch_d_id

vt_batch_d_id — Specify a document to update in a vt batch.

Synopsis

vt_batch_d_id (in *d_id* any);

Description

Multiple documents may be indexed or unindexed with a single batch. In this case this function will be called for each document id, in ascending order of ID.

Parameters

d_id
: the free text document ID of the row whose index entry is to be updated.

Errors

Table 24.115. Errors signalled by

SQLState	Error Code	Error Text	Description

See Also

vt_drop_ftt()

vt_batch()

vt_batch_update()

vt_create_text_index()

vt_batch_feed

vt_batch_feed — Add words to a free text update batch.

Synopsis

vt_batch_feed (in *vt_batch* any ,
in *text_or_xml* any ,
in *is_del* integer ,
in *is_xml* integer) ;

Description

This function allows you to add words to a free text update batch. It can be called in sequence to feed group of documents that share a common document ID and the result is similar to the single call whose *text_or_xml* parameter is concatenation of documents of that group. It is even allowed to mix XML and non-XML documents by feeding an XML document and some text documents: the first document to feed may be an XML document, other documents should be only texts.

If one wishes to mix XML and non-XML documents, knowledge of details of the indexing method is needed. vt_batch_feed assigns a sequence number to every word of the provided document using an internal counter. The call of vt_batch_d_id not only sets document id but also resets this counter to 0. The first element of an XML document should have number 0 so it is impossible to feed an XML document if there were other calls of vt_batch_feed after the last vt_batch_d_id . Moreover, xcontains will ignore words from text documents that were fed after the first XML document, only contains will use all data.

Parameters

vt_batch
: must be an object returned by vt_batch on which vt_batch_d_id has been called; e.g. it can be called inside the index hook function

text_or_xml
: must be a blob, wide blob, varchar, nvarchar or XML entity object.

is_del
: if 0 means that the data is to be added, 1 means the data is to be deleted.

is_xml
: if 1, means that the text_or_xml must be a well formed XML fragment and that it will be indexed for use with xcontains . The default is 0 that means "plain text".

Return Types

None.

Examples

Please refer to examples for function vt_batch_feed_offband() .

See Also

vt_drop_ftt()

vt_batch()

vt_batch_feed_offband()

vt_batch_update()

vt_create_text_index

vt_batch_feed_offband

vt_batch_feed_offband — Add offband information to a free text update batch.

Synopsis

vt_batch_feed_offband (in *vt_batch* any ,
in *clustered_values* string ,
in *is_del* integer) ;

Description

This function allows you to add offband information to a free text update batch. This should be done by index and unindex hook functions of the free text index if and only if the index is created with both "CLUSTERED WITH (...)" and "USING FUNCTION" options and the hook function returns non-zero value, i.e. disables standard indexing of the document.

This function is needed only for very unusual free text indexes.

Parameters

vt_batch
: must be an object returned by vt_batch on which vt_batch_d_id has been called.

clustered_values
: must be a string that is made by serialization of a vector of offband values: the length of vector is equal to number of columns listed in "CLUSTERED WITH (...)" option of "CREATE TEXT INDEX" statement and elements of the vector should be values of the listed fields for the current document.

is_del
: if 0 means that the data is to be added, 1 means the data is to be deleted.

Return Types

The returned value may vary from version to version and should not be user by application code

Examples

Example 24.447. Free text indexing of composed text clustered with offband columns

Table LEADS contains descriptions of articles of some set of newspapers. Hook functions compose text that contains not only subject of article, but also title and first name of the author. The hook function should return non-zero value to disable default processing of text of SUBJECT field but it also disables the default processing of offband values. If the call of `vt_batch_feed_offband` is missing then free text search of documents is still OK but the call like SELECT ORG_ID FROM LEADS_TEST WHERE CONTAINS (SUBJECT, 'sample lead', OFFBAND, ORG_ID) will return NULLs instead of correct values from ORG_ID column because they will not be retrieved from free text index by "OFFBAND, ORG_ID".

```
create table LEADS (
  ORG_ID      integer not null,     -- ID of a newspaper.
  LEAD_ID     integer not null,     -- Internal ID of an article in a newspaper.
  FREETEXT_ID integer not null,     -- Global document ID of an article.
  SUBJECT     varchar (255),        -- Brief content of an article or a lead.
  NAME_FIRST  varchar (30),         -- First name of the author.
  NAME_LAST   varchar (30),         -- Last name of the author.
  TITLE       varchar (255),        -- Title of an article.
  primary key (ORG_ID, LEAD_ID));

create procedure LEADS_SUBJECT_INDEX_HOOK (inout vtb any, inout pkeyid integer)
{
  declare text_to_index varchar;
  declare oid any;
```

```
  text_to_index := coalesce (
    (select concat (
      coalesce (SUBJECT, ''), ' ',
      coalesce (TITLE, ''), ' ',
      coalesce (NAME_FIRST, '') ) from LEADS
    where FREETEXT_ID = pkeyid), null);
  if (text_to_index is null)
    return 0;
  oid := coalesce ((select ORG_ID from LEADS where FREETEXT_ID = pkeyid), null);

vt_create_text_index

VT_BATCH_UPDATE

VT_BATCH_UPDATE — Set batch mode update of free text indexing.

Synopsis

```
integer DB.DBA. VT_BATCH_UPDATE ( in table varchar ,
                                  in flag varchar ,
                                  in interval_minutes integer ) ;
```

Description

This function controls the time of update of a text index. If flag is ON, changes are accumulated into a change tracking table and applied as a batch. If flag is OFF, the text index is updated in the same transaction as the indexed data itself. The change tracking table is automatically created and is named VTLOG_<q>_<o>_<table>, in the qualifier and owner of the indexed table, where q, o and table are the qualifier, owner and name of the table. The changes accumulated into that table can be explicitly applied to the index using the VT_INC_INDEX_<q>_<o>_<table> function.

Parameters

table
: the name of the table to perform batch updating of.

flag
: If ON, updates are in batch mode, if OFF, they are synchronous.

interval_minutes
: the update interval. NULL means that updates are not scheduled.

                       in encoding_name integer ,
                       in silent integer ) ;
```

Description

The vt_create_text_index procedure adds a text index to an existing table. There can at most be one text index per table, including super tables and subtables.

The table argument is a string naming the table. The column is the name of the column to index. The id_col should be the name of a unique integer row identifier column. If null, the system will either add such a column or use an existing integer primary key if one is available. The is_xml argument, if non-0, specifies that the values of the indexed column should be checked for XML well formedness and that the XML structure should be taken into account in indexing the values.

Use the CREATE TEXT INDEX statement as an alternative to the vt_create_text_index function.

In order for a table to be referenced in a text index it must have a uniquely identifying integer key. If the table in question has such a key this can be used as the id column. If there is no such column this procedure makes one. Using a previously existing identifier column saves space and if that is the primary key of the table this also saves in retrieval time.

If the table being indexed has a single part integer primary key vt_create_text_index will automatically use this as the identifier. Note that the zero and negative numbers may not be used as identifier values.

Creating the index will read through the table's contents and generate the index. When the table is changed the index can either be updated after each change or periodically, depending on the application needs. The rationale for background maintenance of the text index is that it is up to several times more efficient to maintain a text index in batches of several changed documents than after each single document change. The default maintenance mode is synchronous, meaning that each insert, delete or update of the indexed column will be immediately reflected in the index. This mode can be set using the `vt_batch_update()` procedure. The mode should be set to batch if there are any massive operations on the table.

It will create two additional tables:

```
<datatable>_<datacolumn>_WORDS
```

and

```
VTLOG_<datatable_qualifieri>_<data_table_owner>_<data_table_name>
```

and two procedures:

```
vt_index_<datatable_qualifier>_<data_table_owner>_<data_table_name>
                (in to_delete integer)
```

and

```
vt_inc_index<datatable_qualifieri>_<data_table_owner>_<data_table_name> ().
```

The table <datatable>_<datafield>_WORDS contains the full text index data.

The table VTLOG_<datatable>_<datafield> is an update tracking table, similar to the snapshot log table but using the key column instead of the primary key.

Note:
in the transaction semantics section that there is the sync mode for the purpose of creating a text index.

Parameters

table
: the table containing the data to index.

col
: the column in the data table containing the data to index (a long varchar column).

id_col
: an integer unique indexed column used by the free text index as a key. If Virtuoso tries to choose such a column among the existing in the table and if it doesn't find a suitable column it adds such a column with the name <datacolumn>_ID, fills that up and makes an unique index on it.

is_xml
: if greater than 0 installs two additional triggers before insert and before update on the data table to ensure the data being inserted into it are valid XML documents.

defer_generation
: if nonzero then the free-text index will not be filled by actual data immediately after the creation. It will remain empty until explicit request for "incremental indexing".

clustered_columns
: a vector of names of "clustered columns" or NULL to not store such data in the index.

use_hook_function
: if nonzero, two user-defined Virtuoso/PL functions will be called when free-text data are updated, not the default system routine. These functions are recognized by their special names: <datatable>_<datafield>_INDEX_HOOK will be called to index new documents and <datatable>_<datafield>_UNINDEX_HOOK will be called to remove obsolete index information about deleted documents.

language_name
: the name of the language that is used for building the index. If the parameter is omitted or is equal to '*ini*' string, indexing routines will use the language specified in server's configuration.

encoding_name
: the name of the encoding that is used by default to index source texts. If the parameter is omitted or is equal to '*ini*' string, indexing routines will use the encoding specified by charset of the RDBMS connection that is in use when the index is created.

silent
: Flag with values 1/0. Default is 0. When set to 0, the function signals error if the text index exists. If set to 1, the function signals no error if the text index exists.

Examples

Example 24.448. Creating A Text Index Using FT functions

```
create table xml_text (xt_id integer, xt_file varchar,
                       xt_text long varchar, primary key (xt_id));
```

```
create index xt_file on xml_text (xt_file);

vt_create_text_index ('xml_text',
                        'xt_text', null, 1);
```

-- create a text index on xt_text with XML well formedness checking on

```
VT_INDEX_DB_DBA_XML_TEXT (0);
```

-- populate the text index based in the data in the table.

```
VT_inc_INDEX_DB_DBA_XML_TEXT ();
```

-- refresh the index to reflect changes to the data since the last call

-- to this function or the initial call to VT_INDEX_DB_DBA_XML_TEXT.

```
vt_batch_update ('DB.DBA.XML_TEXT', 'on', 10);
```

-- sets the index maintenance to be asynchronous, refreshed at maximum intervals of 10 minutes or at every scheduler cycle if the latter is longer than 10 minutes.

```
vt_batch_update ('DB.DBA.XML_TEXT', 'off', null);
```

-- sets the index maintenance to be synchronous, within the same transaction

-- as the operation changing the indexed data.

VT_DROP_FTT

VT_DROP_FTT — drop free text trigger

Synopsis

```
DB.DBA. VT_DROP_FTT ( in target_table_name varchar ,
                      in opt_data_column or NULL varchar ) ;
```

Description

Drops free text trigger.

Parameters

DATA_COLUMN
: column where content is stored

target_table_name
: the table containing the trigger

vt_is_noise

vt_is_noise — determines whether input is a noise word

Synopsis

vt_is_noise (in *word* varchar ,
in *encoding* varchar ,
in *language* varchar) ;

Description

Determines whether input is a noise word.

Parameters

word
: Narrow string of the word to be checked

encoding
: valid encoding string

language
: valid language string

Return Values

1 or 0. This function will return 1 if the encoded word in the specified language is considered a noise word, or 0 if not.

Examples

Example 24.449. Determining if a word is a Noise Word

```
select vt_is_noise ('a', 'UTF-8', 'X-ANY');
```

will return 1

```
select vt_is_noise ('effective', 'UTF-8', 'X-ANY');
```

will return 0

week

week — get number of week from a datetime

Synopsis

week (in *dt* datetime) ;

Description

week takes a datetime and returns an integer containing a number representing the week of year of the datetime.

Parameters

dt
: A datetime .

Return Values

An INTEGER containing number of the week of year.

Examples

Example 24.450. Simple example

Get current week of year.

```
SQL> select week (now ());
callret
INTEGER
_______________________________________________________________________________

42
```

dayname , monthname , dayofmonth , dayofweek , dayofyear , quarter , month , year , hour , minute , second , timezone

wsdl_import_udt

WSDL_IMPORT_UDT — Returns a string containing a UDT definition

Synopsis

```
varchar WSDL_IMPORT_UDT ( in url varchar ,
                          in f varchar ,
                          in exec any ) ;
```

Description

This function is used to create a user defined type (UDT) definition automatically based on a WSDL file. The source WSDL is supplied via a URL.

The returned definition can be saved to a file and/or executed automatically to provide instant access to the new UDT.

Note:
To save the file you must have an appropriate ACL defined.

Parameters

url
: The URI of the target WSDL file to build a UDT definition of.

f
: The name of the file if the definition is to be saved. This will produce a file on the file system under the server root directory.

exec
: This flag indicates whether the definition should be immediately executed upon import. This takes the form of 0 or 1. The default value of 0 will not execute the definition.

Return Types

This function returns the text of the UDT definition as a varchar.

Examples

Example 24.451. Simple example of a WSDL driven UDT

Web Service proxy wrapper for Redcoal SMS SOAP interface:

```
SQL> WSDL_IMPORT_UDT ('http://xml.redcoal.com/soapserver.dll/wsdl/ISoapServer', 'redcoal.sql');
```

This will create the following file on file system called `redcoal.sql` :

```
-- Automatically generated code
-- imported from WSDL URI: "http://xml.redcoal.com/soapserver.dll/wsdl/ISoapServer"
-- UDT class
drop type "ISOAPServerservice"
;

create type "ISOAPServerservice"
  as
    (
      debug int default 0,
      url varchar default 'http://xml.redcoal.com/soapserver.dll/soap/ISoapServer',
      request varchar,
      response varchar
    )
```

```
-- Binding: "http://tempuri.org/:ISOAPServerbinding"

method "SendTextSMS"
       (
        "strInSerialNo" any,
        "strInSMSKey" any,
        "strInRecipients" any,
        "strInMessageText" any,
        "strInReplyEmail" any,
        "strInOriginator" any,
        "iInType" any,
        "strOutMessageIDs" any,
        "return" any
       ) returns any,

.... more methods follows ; do not supplied for brevity

method "RedWebServiceVersion"
       (
        "return" any
       ) returns any,

method style () returns any
;

-- Methods

create method "SendTextSMS"
       (

  "strOutMessageIDs" := soap_box_xml_entity_validating ("strOutMessageIDs",
    'http://www.w3.org/2001/XMLSchema:string', 0);
  "return" := xml_cut (xpath_eval ('//return', xe, 1));
  "return" := soap_box_xml_entity_validating ("return", 'http://www.w3.org/2001/XMLSchema:int', 0);

  return _result;
}
;

.... more method definitions follows ; not supplied for brevity

create method "RedWebServiceVersion"
       (
        out "return" any
       ) for "ISOAPServerservice"
{
  declare action, namespace, enc varchar;
  declare style int;
  declare _result, _body, xe any;
  action := 'urn:SOAPServerImpl-ISOAPServer#RedWebServiceVersion';

  namespace := 'urn:SOAPServerImpl-ISOAPServer';

  style := 0;

  if (self.debug)
    style := style + 2;
  _result := SOAP_CLIENT (
               url=>self.url,
               operation=>'RedWebServiceVersion',
               soap_action=>action,
               target_namespace=>namespace,
               parameters=>vector
                       (

                       ),
               style=>style
              );
  if (self.debug)
    {
      _body := _result[0];
      self.request := _result[1];
      self.response := _result[2];
    }
  else
    _body := _result;
  xe := xml_cut (xml_tree_doc (_body));
  "return" := xml_cut (xpath_eval ('//return', xe, 1));
  "return" := soap_box_xml_entity_validating ("return",
    'http://www.w3.org/2001/XMLSchema:string', 0);

  return _result;
}
;
```

This script, executed via the ISQL tool, or automatically if the 'exec' flag is set to 'true', will define the desired UDT in database. Developing a simple application for checking the Redcoal SMS SOAP interface could be done as follows using a stored procedure:

```
create procedure
redcoaltest ()
{
  declare svc "ISOAPServerservice";
  declare res nvarchar;
  svc := new "ISOAPServerservice" ();
```

```
  svc."RedWebServiceVersion" (res);
  result_names (res);
  result (res);
}
;
```

Which could have the following output:

```
SQL> redcoaltest();
res
NVARCHAR
_______________________________________________

5.0

1 Rows. -- 1974 msec.
```

wst_cli

wst_cli — Request a security token from WST endpoint

Synopsis

```
token wst_cli ( in req soap_client_req ,
                in policy any ) ;
```

Description

This function is for use with a SOAP client contacting a WS-Trust endpoint for a security token.

Parameters

req
: A UDT containing soap_client parameters as described in WS-RM.

policy
: contains policy to be applied, an example:

Return Types

A security token.

See Also

WS Reliable Messaging

USER_KEY_LOAD

USER_KEY_LOAD — Register and existing key.

Synopsis

```
USER_KEY_LOAD (   in key_name varchar ,
                  in key_value any ,
                  in key_type varchar ,
                  in key_format varchar ,
                  in key_passwd varchar ,
                  in key_pkey any );
```

Description

This function is used to register and persist an existing key in the Virtuoso server. This is needs to be made once per key/certificate, and does not need to be repeated after server restart, unless the key is erased and has to be redefined.

Parameters

key_name
: The key reference, as a 'Sample Key' or 'file:keys/srv.pem'

key_value
: When the key is an internal reference i.e. non 'file:', the content of a key. The default value is NULL.

key_type
: The key algorithm, possible values are "3DES", "RSA", "DSA", "X.509", "AES".

key_format
: The format of the key content storage, possible values are "DER", "PEM", "PKCS12".

key_passwd
: The password for opening the key if required, this can be NULL to indicate no password required.

key_pkey
: When an X.509 certificate is imported, this can be supplied to load the corresponding private key also. This is optional. Note that when the PKCS#12 format is used to import an X.509 certificate, the private key is in the 'key_value', hence this parameter in such case must be omitted.

Return Types

None.

Example

Example 24.452. Simple Use

To load and persist an X.509 certificate contained in the file wss.pfx in the server working directory one can use:

```
USER_KEY_LOAD ('file:wss.pfx', NULL, 'X.509', 'PKCS12', 'virt');
```

To load and persist a shared secret:

```
USER_KEY_LOAD ('WSDK Sample Symmetric Key', 'EE/uaFF5N3ZNJWUTR8DYe+OEbwaKQnso', '3DES', 'DER', null);
```

To load a DSA key contained in a file dsa.der:

```
USER_KEY_LOAD ('file:dsa.der', NULL, 'DSA', 'DER', null);
```

dsig_template_ext

dsig_template_ext — Generates a Digital signature template based on a XML document.

Synopsis

```
varchar dsig_template_ext ( in xdoc any ,
                            in tmpl varchar ,
                            in wss_ver any ,
                            in ns-n varchar ,
                            in elm-n varchar ,
                            in ... varchar ) ;
```

Description

The function is used to generate dynamically a digital signature template containing references to be signed.

Parameters

xdoc
: input XML document

tmpl
: a string containing base XML template

wss_ver
: vector containing WS-Security and WS-Utility version URIs

ns-n
: namespace to match

elm-n
: element name to match

Return Types

On success the function will return a string containing a XML template suitable to pass to the `xenc_encrypt` . The elements matching listed in *`elm-n`* from namespace URIs in *`ns-n`* and having Id attribute will be included in the XML signature reference list.

Examples

Example 24.453. Making a XML signature template

```
create procedure XENC_TEMPLATE (in body varchar, in key_name varchar)
{
  declare tmpl, algo varchar;
  declare ns any;

  -- OASIS WS-Security extensions
  ns := vector (
        'wsse', 'http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd',
        'wsu', 'http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd'
        );

  algo := xenc_get_key_algo (key_name);
  if (algo is null)
    return NULL;

  -- base XML template
```

```
  tmpl := sprintf ('<?xml version="1.0" encoding="UTF-8"?>
<Signature xmlns="http://www.w3.org/2000/09/xmldsig#" >
  <SignedInfo>
    <CanonicalizationMethod Algorithm="http://www.w3.org/2001/10/xml-exc-c14n#" />
    <SignatureMethod Algorithm="%s" />
  </SignedInfo>
  <SignatureValue></SignatureValue>
  <KeyInfo>
    <KeyName>%s</KeyName>
  </KeyInfo>
</Signature>', algo, key_name);

  return dsig_template_ext (xtree_doc (body), tmpl, ns,
      'http://schemas.xmlsoap.org/soap/envelope/', 'Body',
       -- WS-Addressing
      'http://schemas.xmlsoap.org/ws/2004/03/addressing', 'Action',
      'http://schemas.xmlsoap.org/ws/2004/03/addressing', 'From',
      'http://schemas.xmlsoap.org/ws/2004/03/addressing', 'To',
      'http://schemas.xmlsoap.org/ws/2004/03/addressing', 'MessageID',
      'http://schemas.xmlsoap.org/ws/2004/03/addressing', 'ReplyTo',
      'http://schemas.xmlsoap.org/ws/2004/03/addressing', 'FaultTo',
      'http://schemas.xmlsoap.org/ws/2004/03/addressing', 'RelatesTo'
      );

}
;
```

x509_certificate_verify

x509_certificate_verify — Verifies X.509 certificate

Synopsis

```
varchar x509_certificate_verify ( in cert varchar ,
                                  in cacerts any ,
                                  in flags varchar ) ;
```

Description

This function takes a X.509 certificate and verifies it against list of CA certificates. It checks for various certificate attributes such as self signed, expiration date etc. If an error is detected it will be signalled.

The certificates are passed as a strings containing X.509 certificate binary data in DER (raw) format.

Parameters

cert
: The X.509 certificate to be verified

cacerts
: array of strings containing CA certificates

flags
: A string containing comma separated list of verification options. See table below for valid values.

Return Types

None

Errors

Table 24.118. Errors signalled by `x509_certificate_verify`

SQLState	Error Code	Error Text	Description
22023	CR014	Invalid certificate	The input can't be decoded as a X.509 certificate
22023	CR016	Can not allocate a X509 store	
22023	CR019	Invalid CA certificate	Some of CA certificates can not be loaded due to bad format
22023	CR017	Can not allocate X509 verification context	
22023	CR018	Can not initialize X509 verification context	
22023	CR015	X509 error: [the verification error text]	

Examples

Example 24.454. Verification of a X.509 certificate

```
SQL> x509_certificate_verify (file_to_string ('keys/srv/cert.cer'), vector (file_to_string ('keys/srv

Done. -- 29 msec.
```

xenc_X509_certificate_serialize

xenc_X509_certificate_serialize — Exports a X.509 certificate from user's repository

Synopsis

```
varchar xenc_X509_certificate_serialize ( in name varchar );
```

Description

This function is used to export X.509 from user's space.

Parameters

name
: The name of the key associated with X.509 certificate.

Return Types

The function returns base64 encoded string containing X.509 certificate in DER (raw) format. Also the certificate will contain the key associated with it.

Examples

Example 24.455. Exporting a X.509 certificate

The example exports a X.509 certificate associated with 'dsa-test' key from user's space.

```
...
declare x509 varchar;
x509 := xenc_X509_certificate_serialize ('dsa-test');
...
```

xenc_decrypt_soap

xenc_decrypt_soap — Decrypt and verify a SOAP message

Synopsis

```
varchar xenc_decrypt_soap ( in xml_text varchar ,
                            in soap_version int ,
                            in validate_flag int ,
                            in encoding varchar ,
                            in lang varchar ,
                            in opts any ,
                            out keys any ) ;
```

Description

The function is used to decrypt and optionally verify signature (depends of a `validate_flag` parameter) of a SOAP message.

Parameters

xml_text
: A string containing SOAP message

soap_version
: An integer indication SOAP version (11 for v1.1, 10 for 1.0 etc)

validate_flag
: Bit mask flag. See below for details.

encoding
: The message (xml_text) character encoding

lang
: The message (xml_text) language

opts
: A vector containing options for User Name token profile. For example : vector ('UsernameToken', vector ('label', 'lab1', 'keyAlgorithm' , '[3des algo uri]'))

keys
: if supplied the parameter will be set with keys names used for decryption and signature verification. The structure is as follows : vector (vector ([enc-key1],[enc-key2],...), vector ('[signing token name]', '[matching token]')). Where enc-key is a key used to decrypt the message fragment; '[signing token name]' is the temporary key used to validate the signature and '[matching token]' is the token (key) from user's space that matches the signing token.

Return Types

On success the function returns decrypted SOAP message.

Examples

Example 24.456. Decrypting SOAP message

```
declare ekeys, opts, decoded any;
opts := vector ('UsernameToken',
                vector ('label',
                        'Application-Label',
                             'keyAlgorithm',
```

```
                                    'http://www.w3.org/2001/04/xmlenc#tripledes-cbc'));
      decoded := xenc_decrypt_soap (body_str, 11, 6, 'UTF-8', 'x-any', opts, ekeys);
```

See Also

`xenc_encrypt()`

xenc_delete_temp_keys

xenc_delete_temp_keys — Remove the temporary keys from user's space

Synopsis

```
int xenc_delete_temp_keys ( );
```

Description

When signing an XML document or doing the reverse work like verification etc. number of temporary keys are created in user's space. These keys at some point may not needed anymore, so they can be removed from memory.

Return Types

The function returns number of temp keys removed.

Examples

Example 24.457. Delete temporary keys

```
SQL> select xenc_delete_temp_keys ();
callret
VARCHAR
_______________________________________________________________________________

1
```

xenc_encrypt

xenc_encrypt — Encrypt and optionally sign a SOAP message

Synopsis

```
varchar xenc_encrypt ( in message varchar ,
                       in soap_ver int ,
                       in template varchar ,
                       in ns any ,
                       in xp-n varchar ,
                       in ki-n any ,
                       in what-n varchar ,
                       ... ) ;
```

Description

Encrypt SOAP message and optionally attach an XML signature. The keys are retrieved from the key store of the calling user account.

Parameters

message
: A string containing SOAP message

soap_ver
: SOAP version (11 = 1.1, 10 = 1.0 etc.)

template
: a string containing Digital signature template.

ns
: an array of strings containing WS-Security extension and WS-Utility version information.

xp-n
: XPath expression to locate n-th part of the message to be encrypted

ki-n
: Key instance to encrypt the part

what-n
: 'Content' - the content under located element will be encrypted; 'Element' the located element and content will be encrypted.

Return Types

On success the function will return a string containing encrypted and optionally signed SOAP message.

Examples

Example 24.458. Encrypting and signing SOAP message

```
...
ns := vector ();
template := dsig_template_ext (...);
keyi := xenc_key_inst_create ('myAES', xenc_key_inst_create ('rsa-test'));
resp := xenc_encrypt (request, 11, template, ns, '/Envelope/Body', keyi, 'Content');
```

```
...
```

encrypt

encrypt — Encrypt content in base64 encoding

Synopsis

```
varchar encrypt ( in string_session any ,
                  in key_name varchar ) ;
```

Description

Returns encrypted content in base64 encoding. The algorithm to encrypt depends of the key, so if the key is AES the AES will be used, if it is 3DES it is 3DES etc. The AES key can be created with xenc_key_AES_rand_create (key_name, 256). Alternatively 3DES key can be generated with xenc_key_3DES_rand_create ().

Parameters

string_session
: A content to be encrypted.

key_name
: The key name keeping secret.

Return Types

On success the function will return encrypted content in base64 encoding.

Examples

Example 24.459. Simple Use

```
-- The 'ses' is a function which print the string into a string session:
xenc_key_AES_rand_create ('kaes', 256).
decrypt (encrypt (ses ('data to encrypt'), 'kaes'), 'kaes');
```

decrypt

decrypt — Encrypt content in base64 encoding

Synopsis

```
varchar decrypt ( in base64_string_session any ,
                  in key_name varchar ) ;
```

Description

Returns decrypted content as a string_session. The algorithm to encrypt depends of the key, so if the key is AES the AES will be used, if it is 3DES it is 3DES etc. The AES key can be created with xenc_key_AES_rand_create (key_name, 256). Alternatively 3DES key can be generated with xenc_key_3DES_rand_create ().

Parameters

base64_string_session
: A base64 string content to be decrypted.

key_name
: The key name keeping secret.

Return Types

On success the function will return decrypted content as a string_session.

Examples

Example 24.460. Simple Use

```
-- The 'ses' is a function which print the string into a string session:
xenc_key_AES_rand_create ('kaes', 256).
decrypt (encrypt (ses ('data to encrypt'), 'kaes'), 'kaes');
```

TOTP_generate

TOTP_generate — Returns TOTP string Time-based One-time Password Generator (rfc6238)

Synopsis

```
varchar TOTP_generate ( in start_date datetime ,
                        in date datetime ,
                        in step integer ,
                        in return_digits integer ,
                        in key_name varchar ,
                        in digest_algo varchar ) ;
```

Description

Returns TOTP string Time-based One-time Password Generator (rfc6238).

Parameters

start_date
: T0 (zero time, usually 1970-1-1) .

date
: The current time ex. now () .

step
: Time step in secconds, usually 30.

return_digits
: How much digits to return, from 1 to 8.

key_name
: The key name keeping secret. Note: when setting up the key, should use 20 bytes for hmac-sha1, 32 bytes for hmac-sha256. Also the systems that are used for TOTP should have time synchronized.

digest_algo
: string, one of hmac-sha1 or hmac-sha256 .

Return Types

On success the function will return TOTP string Time-based One-time Password Generator (rfc6238).

Examples

Example 24.461.

```
xenc_key_RAW_read ('k2', encode_base64 (cast (hex2bin ('313233343536373839303132333435363738393031323334
select TOTP_generate (stringdate ('1970-01-01Z'), stringdate ('2603-10-11 11:33:20Z'), 30, 8, 'k2', 'hma
```

xenc_key_inst_create()

xenc_get_key_algo

xenc_get_key_algo — Determine XML signature algorithm of a key

Synopsis

varchar **xenc_get_key_algo** (in *key_name* varchar);

Description

The function is used to determine signing algorithm supported by given key.

Parameters

key_name
: Name of a key from user's space.

Return Types

The function returns string containing algorithm identifier value as described in http://www.w3.org/TR/xmldsig-core .

Examples

Example 24.462. Determine signing algorithm of a key

```
SQL> select xenc_get_key_algo ('myKey');
callret
VARCHAR
_______________________________________________________________________________

http://www.w3.org/2000/09/xmldsig#dsa-sha1
```

xenc_get_key_identifier

xenc_get_key_identifier — Determine a key identifier

Synopsis

```
varchar xenc_get_key_identifier ( in key_name varchar );
```

Description

The function returns key identifier.

Parameters

key_name
: Name of the key

Return Types

The function returns a base64 encoded string containing the key identifier. If key identifier is not available (the key have no identifier or key does not exists a NULL will be returned).

Examples

Example 24.463. Determine the key identifier

```
SQL> select xenc_get_key_identifier ('myKey');
callret
VARCHAR
_______________________________________________________________________________

LtVJHvVXJFFvzRnfrCaKmdxQaGQ=
```

xenc_key_3DES_read

xenc_key_3DES_read — Importing a triple-des key into user's repository

Synopsis

xenc_key_3DES_read (in *name* varchar ,
in *key_data* varchar) ;

Description

This function is used to import a triple-des serialized key into user's repository and register it with a name supplied.

Note that key will not be persisted. It is loaded in the memory only.

Parameters

name
: Name of the key to register

key_data
: The base64 encoded binary data with key material

Return Types

No return value.

Examples

Example 24.464. Loading a shared secret

```
xenc_key_3DES_read ('Sample Symmetric Key', 'EE/uaFF5N3ZNJWUTR8DYe+OEbwaKQnso');

xenc_key_DSA_read

xenc_key_DSA_read — Importing a DSA key into user's repository

Synopsis

xenc_key_DSA_read (in *name* varchar ,
in *key_data* varchar) ;

Description

This function is used to import a DSA serialized key into user's repository and register it with a name supplied.

Note that key will not be persisted. It is loaded in the memory only.

Parameters

name
: Name of the key to register

key_data
: The base64 encoded binary data with DSA key material

Return Types

No return value.

Examples

Example 24.467. Loading a shared secret

```
xenc_key_DSA_read ('myDSAkey', 'MII..skipped..Klmu+tlaA==');
```

`xenc_key_RSA_create()`

xenc_key_AES_create

xenc_key_AES_create — Used to make a symmetric key.

Synopsis

xenc_key_AES_create (in *name* varchar ,
in *bits* int ,
in *secret* varchar) ;

Description

Used to make a symmetric session key for AES encryption algorithm.

Parameters

name
: The name of the key.

bits
: Number of bits in generated key. The values supported are 128, 192 and 256 bits.

secret
: The shared secret for key generation.

Return Types

None.

Example

Example 24.469. Simple Use

```
xenc_key_AES_create ('ses_key', 128, 'mysecret');

xenc_key_create_cert

xenc_key_create_cert — Import a key from a certificate

Synopsis

xenc_key_create_cert (in *name* varchar ,
in *cert* varchar ,
in *type* varchar ,
in *fmt* int ,
in *pkey* varchar ,
in *pass* varchar) ;

Description

The function is used to import a key (usually an asymmetric key like RSA or DSA) into user's space from a certificate.

Parameters

name
: The name of the key to be registered

cert
: String containing the certificate

type
: 'X.509' is only supported value

fmt
: The input format of the certificate: 3 - "DER", 1 - "PEM" or 2 - "PKCS#12".

pkey
: When an X.509 certificate is imported, this can be supplied to load the corresponding private key also. This is optional. Note that when the PKCS#12 format is used to import an X.509 certificate, the private key is in the 'cert', hence this parameter in such case must be omitted.

pass
: The password to unlock the private key. If not required this can be NULL to indicate no password is needed.

Examples

Example 24.471. Importing a key from X.509 certificate

```
...
xenc_key_create_cert ('myRSA', file_to_string ('keys/mycert.pfx'), 'X.509', 2, NULL, 'secret');
xenc_set_primary_key ('myRSA');
...
```

xenc_key_DSA_create

xenc_key_DSA_create — Used to make asymmetric DSA key.

Synopsis

xenc_key_DSA_create (in *name* varchar);

Description

Used to make asymmetric DSA key for digital signatures. The generated key will contain private and public keys.

Parameters

name
: The name of the key.

Return Types

None.

Example

Example 24.472. Simple Use

```
xenc_key_DSA_create ('myDSAkey');
```

xenc_key_exists

xenc_key_exists — Check if named encryption key is in the user's repository

Synopsis

```
int xenc_key_exists ( in name varchar );
```

Description

The function checks if key with given name exists in the user's keys.

Parameters

name
: The name of the key

Return Types

The function returns integer 1 - true or 0 - false (zero) if key exists or not

Examples

Example 24.473. Simple Use

```
SQL> select xenc_key_exists ('MyKey');
VARCHAR
_______________________________________________________________________________

0

1 Rows. -- 1 msec.
```

See Also

`xenc_key_remove()`

xenc_key_inst_create

xenc_key_inst_create — Key instance generation

Synopsis

```
any xenc_key_inst_create ( in name varchar ,
                           in super any ) ;
```

Description

The function is used to make a key reference used in encryption functions.

Parameters

name
: Name of the key to be instantiated.

super
: Optional parameter, is specified must contains a key reference to the super key. In other words the key used to encrypt key specified by name .

Return Types

On success the function returns a non-null value containing key reference data.

Examples

Example 24.474. Key instance creation

The example specifies to use an AES key to be used as a session key, also AES will be encrypted with a RSA one.

```
...
keyi := xenc_key_inst_create ('myAES', xenc_key_inst_create ('rsa-test'))
...
```

See Also

`xenc_key_exists()`

xenc_key_remove

xenc_key_remove — This will delete a key from current user's space.

Synopsis

xenc_key_remove (in *key_name* varchar) ;

Description

This will delete a key from current user's space.

Parameters

key_name
: The name of the key.

Example

Example 24.475. Simple Use

```
xenc_key_remove ('file:dsa.der');
```

See Also

`xenc_key_exists()`

xenc_key_serialize

xenc_key_serialize — Extracts a key from user's repository

Synopsis

```
varchar xenc_key_serialize (
                                in name
                                varchar ,
                                in public int
                                );
```

Description

The function returns a string containing base64 encoded binary key data. It is used to extract symmetric or asymmetric keys. So if key is asymmetric (RSA or DSA) the second parameter designate which part to extract private or public.

Parameters

name
: The key name.

public
: 1 - export public part, 0 - export private key if exists.

Return Types

The function returns serialized key material.

Examples

Example 24.476. Exporting a RSA public key.

The 'ServerPrivate.pfx' is a own RSA key so we exporting public part to supply to some party to encrypt data for us.

```
SQL> select xenc_key_serialize ('ServerPrivate.pfx', 1);
callret
VARCHAR
_______________________________________________________________________________

MIGJAoGBAMuSqCUCsie6RGUPBdtyM3fPF+yN5ot34i9/IPmjfmlSOlOQ/A9eYClJyvxRVDEHkkNFJWUzPWVRDoIEsUsYgBA6ls8qfai6X

1 Rows. -- 1 msec.
```

xenc_set_primary_key

xenc_set_primary_key — Associate a X.509 certificate with a key

Synopsis

xenc_set_primary_key (in *name* varchar) ;

Description

This function is used to associate a key (to be used as primary) with a X.509 certificate. Usually this function is called after key import from a X.509 certificate.

Parameters

name
: Name of the key to be processed.

Return Types

No return value.

Examples

Example 24.477. Importing a key from X.509 certificate

```
...
xenc_key_create_cert (key_name, key_value, key_type, fmt, NULL, key_passwd);
xenc_set_primary_key (key_name);
...
```

See Also

`xenc_key_create_cert()`

xenc_x509_ss_generate

xenc_x509_ss_generate — Creates a self-signed X.509v3 certificate

Synopsis

xenc_x509_ss_generate (in *key_name* varchar ,
in *serial* integer ,
in *validity* integer ,
in *subject* vector ,
in *extensions* vector) ;

Description

This function is used to create a self-signed X.509 certificate by given private key

Parameters

key_name
: The name of the key used to create and sign the certificate

serial
: The serial number

validity
: Certificate's validity in days

subject
: An array of name/value pairs representing the subject aka name enties

extensions
: An array of name/value pairs to add as X.509v3 extensions to certificate

Examples

Example 24.478. Self-signed certificate generation

The example below shows how could be created RSA private key, then self-signed certificate and finally to be stored in the user's key store.

```
...
xenc_key_RSA_create ('id_rsa', atoi (get_keyword ('num', params, '1024')));
xenc_x509_ss_generate ('id_rsa', sequence_next ('ca_id_rsa'), 365,
         vector ('C', get_keyword ('c', params),

xenc_x509_generate

xenc_x509_generate — Generates a X.509v3 certificate using client's public key

Synopsis

xenc_x509_generate (in *ca_key_name* varchar ,
in *public_key_name* varchar ,
in *serial* integer ,
in *validity* integer ,
in *subject* vector ,
in *extensions* vector ,
in *hours* integer) ;

Description

This function creates a X.509v3 certificate from a public key and sign the certificate with CA private key

Parameters

ca_key_name
: The name of CA key, the key must have corresponding certificate.

public_key_name
: The name of the public key used to create certificate, it is given by certificate owner to CA. Note that public key must be imported already in CA'a key space.

serial
: The serial number

validity
: Certificate's validity in days

subject
: An array of name/value pairs representing the subject aka name enties

extensions
: An array of name/value pairs to add as X.509v3 extensions to certificate

hours
: If specified it is added to the days which allows a more fine-grained control over the expiration date.

Examples

Example 24.479. Issuing a certificate

The example below decodes a public key sent from client and then issue a certificate and sign it with CA's key 'id_rsa'. The client's key is create as temp key.

```
declare kname, cvalue varchar;
kname := xenc_SPKI_read (null, replace (get_keyword ('key', params), '\r\n', ''));
xenc_x509_generate ('id_rsa', kname, sequence_next ('ca_id_rsa'), 365,
                vector (
                        'CN', get_keyword ('name', params, name),
                        'C',  get_keyword ('c', params, name),
                        'O',  get_keyword ('o', params, name),
                        'OU', get_keyword ('ou', params, name),
                        'emailAddress', get_keyword ('email', params)
                        ),
```

```
                    vector (
                      'subjectAltName',
                      'URI:'||webid,
                      'nsComment',
                      'Virtuoso Generated Certificate',
                            'authorityKeyIdentifier',
                            'keyid,issuer:always'));
```

xenc_pkcs12_export

xenc_pkcs12_export — Generates a secure Public-Key Cryptography Standards (PKCS#12) file from a PEM (base64 encoded DER) file comprised of an X.509 certificate and an associated Private Key.

Synopsis

```
xenc_pkcs12_export ( in key_name varchar ,
                     in name varchar ,
                     in pass varchar ,
                     in export_chain integer := 0 ,
                     in additional_certs varchar ) ;
```

Description

Generates a secure Public-Key Cryptography Standards (PKCS#12) file from a PEM (base64 encoded DER) file comprised of an X.509 certificate and an associated Private Key.

Parameters

key_name
: Name that identifies private key associated with X.509 certificate.

name
: Name to used to identify each pkcs#12 object bundle.

pass
: A password or pass phrase used to encrypt the pkcs#12 file

export_chain
: 1/0 - to export the certificate chain if there is a such

additional_certs
: Certificates in PEM format to be added to the bundle even if they are not in the certificate chain stored in the memory object of the certificate

Examples

Example 24.480. Persisting a key & certificate

The example below persists a key named 'id_rsa' and certificate created for it into user's key space. Thus after server restart the key will be available again.

```
USER_KEY_STORE (user, 'id_rsa', 'X.509', 2, '', xenc_pkcs12_export ('id_rsa', 'CA Certificate', ''));
```

xenc_pem_export

xenc_pem_export — Export of a certificate and optionally private key in PEM format

Synopsis

xenc_pem_export (in *key_name* varchar ,
in *pk_flag* integer) ;

Description

The function is used to export certificate in PEM format, optionally it can export also private key (if present)

Parameters

key_name
: The key name which keeps the certificate

pk_flag
: A flag : 1 or 0, by default 0. It denotes to export or to skip exporting private key.

Examples

Example 24.481. Creating a certificate and exporting it in PEM format

The example below imports a client public key, then it creates a certificate and sign it with CA's private key and finally it exports the generated certificate in PEM format.

```
kname := xenc_SPKI_read (null, replace (get_keyword ('key', params), '\r\n', ''));
xenc_x509_generate (
    'id_rsa',
    kname,
    sequence_next ('ca_id_rsa'),
    365,
                vector (
                        'CN', get_keyword ('name', params, name),
                        'C',  get_keyword ('c', params, name),
                        'O',  get_keyword ('o', params, name),
                        'OU', get_keyword ('ou', params, name),
                        'emailAddress', get_keyword ('email', params)
                        ),
                vector (
                  'subjectAltName',
                  'URI:'||webid,
                  'nsComment',
                  'Virtuoso Generated Certificate',
                        'authorityKeyIdentifier',
                        'keyid,issuer:always'));
cvalue := xenc_pem_export (kname);
```

Example 24.482. Export Web Server certificate for Virtuoso HTTPS endpoints

This example exports Web Server certificate generated for Virtuoso HTTPS Endpoint:

1. Configure an HTTPS Listener for handling HTTPS requests from HTTP user agents (clients).
2. Suppose the generate certificate from the previous step has name "https_key_localhost"
3. To export the certificate, execute from iSQL:

```
SQL> SELECT xenc_pem_export ('https_key_localhost');
```

xenc_SPKI_read

xenc_SPKI_read — Imports a public key from simple public key infrastructure (SPKI)

Synopsis

xenc_SPKI_read (in *key_name* varchar ,
in *key_data* varchar) ;

Description

This function is used to read an RSA public key from SPKI content.

Parameters

key_name
: The name of the key to be created, if null is given a temp key will be created

key_data
: The SPKI content

Examples

Example 24.483. SPKI reading

The example below creates a temp key.

```
kname := xenc_SPKI_read (null, replace (get_keyword ('key', params), '\r\n', ''));
```

xenc_bn2dec

xenc_bn2dec — Prints as a string a big number serialized as binary using base64 encoding.

Synopsis

xenc_bn2dec (in *num* varchar) ;

Description

Prints as a string a big number serialized as binary using base64 encoding

Parameters

num
: The bas64 encoded string containing a binary representation of a big number

xenc_key_RSA_create

xenc_key_RSA_create — Used to make RSA key.

Synopsis

xenc_key_RSA_create (in *name* varchar ,
in *bits* int) ;

Description

Used to make RSA key.

Parameters

name
: The name of the key.

bits
: Number of bits in generated key. The values supported are from 512 to 2048.

Return Types

None.

Example

Example 24.484. Simple Use

```
xenc_key_RSA_create ('myRSAkey', 1024);
```

xenc_x509_csr_generate

xenc_x509_csr_generate — Generate Certificate Signing Request (CSR)

Synopsis

```
varchar xenc_x509_csr_generate ( in cli_pk_name varchar ,
                                 in subject array ,
                                 in extensions array ) ;
```

Description

This function generates Certificate Signing Request (CSR)

Parameters

cli_pk_name
: The user's private key name.

subject
: An array of name/value pairs representing the subject aka name enties, for ex:

extensions
: An array of name/value pairs to add as X.509v3 extensions to certificate.

Return Types

String

xenc_x509_from_csr()

xenc_x509_generate()

xenc_x509_from_csr

xenc_x509_from_csr — Generate x509 certificate from CSR.

Synopsis

```
varchar xenc_x509_from_csr ( in ca_key_name varchar ,
                             in cli_key_name varchar ,
                             in csr_str varchar ,
                             in serial_no varchar ,
                             in days_validity varchar ,
                             in hours_validity varchar ) ;
```

Description

This function generates Certificate Signing Request (CSR). The function return 1 upon success, sql error on failure. The new certificate can be exported in PEM format with `xenc_pem_export(cli_key_name)` .

Parameters

ca_key_name
: The name of CA private key which will be used to sign certificate.

cli_key_name
: The name of a key which will be created and will contains the client certificate.

csr_str
: pem encoded CSR.

serial_no
: Serial number.

days_validity
: How many days will be valid the certificate.

hours_validity
: How many hours will be valid the certificate.

Return Types

the function returns 1 upon success, sql error on failure.

Errors

Table 24.120. Errors signalled by `xenc_x509_from_csr`

SQLState	Error Code	Error Text	Description
22023	XECXX	The key [name of the key] already exists	
22023	XECXX	Missing or invalid signer certificate	
22023	XECXX	Invalid certificate request	
22023	XECXX	Invalid certificate request public key	
22023	XECXX	Signature did not match the certificate request	
22023	XECXX	Invalid certificate request subject name	
42000	XECXX	Can not create x.509 structure	
42000	XECXX	Can not sign certificate	

SQLState	Error Code	Error Text	Description
42000	XECXX	The type of public key is not supported mus tbe RSA or DSA	
42000	XECXX	Can not create a key	
42000	XECXX	Can not sign certificate : [the sign error text]	

Example

Example 24.486. Generating a Certificate Signing Request (CSR)

The following example demonstrates how to generate Certificate Signing Request (CSR).

- Using Conductor, for user dba import a certificate with primary key and with name id_rsa.
- Execute:

```
SQL>create procedure csr_demo()
{
declare kname, cvalue varchar;
declare _key any;
declare _output int;

       xenc_key_RSA_create ('RSAKey1', 1024);

    _key := xenc_x509_csr_generate ('RSAKey1',
                vector (
                        'CN', 'Demo user',
                        'C',  'US',
                        'O',  'OpenLink',
                        'OU', 'Accounts',
                        'emailAddress', 'demo@openlinksw.com'),
                vector ('subjectAltName', 'URI: http://www.openlinksw.com/dataspace/person/demo#this', 'n
                        'authorityKeyIdentifier', 'keyid,issuer:always'));

   xenc_x509_from_csr ('id_rsa', 'MyKey1', _key , sequence_next ('ca_id_rsa'), 365, 100);
   return xenc_pem_export ('MyKey1');

}
;

xte_head

xte_head — Returns the vector corresponding to a head of a XML element

Synopsis

xte_head (in *tagname* varchar ,
in *attr1name* varchar ,
in *attr1val* varchar ,
... ,
in *attrNname* varchar ,
in *attrNval* varchar) ;

Description

This function takes odd number of parameters and creates vector which corresponds to a head of a XML element. The first parameter is a tag name of the head. The remaining parameters are optional. Each even parameter is a name of an attribute, each next odd parameter is a value of this attribute. If two or more attributes have the same name, the head would have only the last pair.

Parameters

tagname
: The tag name of the head

attrIname
: The name of the I-th attribute

attrIval
: The value of the I-th attribute

Errors

Table 24.121. Errors signalled by `xte_head`

SQLState	Error Code	Error Text	Description
42000	XTE01	Function xte_head should have an odd number of parameters	

Examples

Example 24.487. Simple Use

The xte_head() call below takes three strings

```
xte_head ('supplier', 'CompanyName', 'Seller' )
```

and produces the result vector which corresponds the following head of a XML element:

<supplier CompanyName="Seller">

xte_node

xte_node — Returns the vector corresponding to a XML element

Synopsis

xte_node (in *head* any ,
in *arg1* any ,
... ,
in *argN* any) ;

Description

This function returns the vector which corresponds to a XML element. The first parameter is a head of the element. The remaining parameters are optional. Each optional parameter either is a XML element or a string. Two or more successive strings are concatenated.

Parameters

argI
: A XML element or a string

Errors

Table 24.122. Errors signalled by xte_node

SQLState	Error Code	Error Text	Description
42000	XTE02	Function xte_node should have at least one parameter	

Examples

Example 24.488. Simple Use

The xte_node() call

```
xte_node(xte_head ('supplier', 'CompanyName', 'Seller'), 'this string will be ', 'concatenated with it')
```

produces a vector corresponding the following XML element:

<supplier CompanyName="Seller">this string will be concatenated with it </supplier>

xte_nodebld_acc()

xte_nodebld_final()

xte_nodebld_init()

xte_nodebld_acc

xte_nodebld_acc — Adds to the first arguments all remaining arguments

Synopsis

```
xte_nodebld_acc ( in acc any ,
                  in arg1 any ,
                  ... ,
                  in argN any ) ;
```

Description

The xte_nodebld_acc() function successively adds the remaining arguments to the first one. If the last items of the first argument and some following arguments are strings, they are concatenated. All successive strings are concatenated. The value of the first item is the number of the non-empty items in the returned vector. The length of the returned vector is the sum of the length of the first argument and number of the remaining arguments.

Parameters

acc
: A vector initiated by xte_nodebld_init() function and filled by xte_nodebld_acc() functions

argI
: A string or a vector returned by xte_node_from_nodebld or xte_node functions

Errors

Table 24.124. Errors signalled by `xte_nodebld_acc`

SQLState	Error Code	Error Text	Description
22003	SR345	Too few arguments for xte_nodebld_acc	
22003	SR346	The first argument of xte_nodebld_acc is not made by xte_nodebld_init() function	

Examples

Example 24.490. Simple Use

```
create procedure test_nodebld()
              {
                declare acc any;
                xte_nodebld_init (acc);
                xte_nodebld_acc (acc,'string1', string2');
                xte_nodebld_acc(acc, 'string3',xte_node(xte_head ('supplier', 'CompanyName','Seller')));
                . . .
              }
```

The length of the vector acc as the result of the two xte_nodebld_acc() calls below is equal to 4, but only three items are not empty:

'3' (number of not empty elements of the vector including this item)

'string1string2string3' (the result of concatenation)

vector corresponding the following XML element: <supplier CompanyName="Seller"> </supplier>

xte_nodebld_final()

xte_nodebld_init()

xte_nodebld_final

xte_nodebld_final — Corrects input vector

Synopsis

xte_nodebld_final (inout *arg* any ,
in *head* any) ;

Description

By default this function reduces all last empty items from the first argument and returns it, but supplied a second argument it also replaces the first item of the first argument by the second argument, but does not commit the return.

Parameters

arg
: The vector created by the xte_nodebld_init() and filled by xte_nodebld_acc() function

head
: A vector returned by xte_head() function

Errors

Table 24.125. Errors signalled by `xte_nodebld_final`

SQLState	Error Code	Error Text	Description
22003	SR347	Too few arguments for xte_nodebld_final	
22003	SR348	The first argument of xte_node_nodebld_final is not made by xte_nodebld_init() function	

Examples

Example 24.491. xte_nodebld_final() with a single argument

Before the xte_nodebld_final() call the length of the vector acc is equal to 16, after the call the length is 3. The vector acc does not correspond to a xml document - there is no a root tag. The result of the xte_nodebld_final() may be used as argument for xte_node_from_nodebld() to get a vector corresponding to complete xml document.

```
create procedure test1_nodebld()
              {
                declare acc any;
                xte_nodebld_init (acc);
                xte_nodebld_acc (acc,'string1', string2');
                xte_nodebld_acc(acc, 'string3',xte_node(xte_head ('supplier', 'CompanyName','Seller')));
                acc:=xte_nodebld_final(acc);
                            . . .
              }
```

Example 24.492. xte_nodebld_final() with two arguments.

The vector acc below is corresponding to the following XML element:

<product>string1string2string3

<supplier CompanyName="Seller"></supplier>

</product>

```
create procedure test2_nodebld()
              {
                declare acc any;
                declare "Res" any;
                declare "ResLen" integer;
                result_names ("ResLen", "Res");
                xte_nodebld_init (acc);
                xte_nodebld_acc (acc,'string1', 'string2');
                xte_nodebld_acc(acc, 'string3',xte_node(xte_head ('supplier', 'CompanyName','Seller')));
                xte_nodebld_final(acc, xte_head('product'));
                result (length(acc), xml_tree_doc (acc));
              }
test_nodebld()
ResLen      Res
INTEGER     VARCHAR
_______________________________________________________________________________

3           <product>string1string2string3<supplier CompanyName="Seller" /></product>
```

XMLAGG

XMLAGG — Produces a forest of elements from a collection of XML values

Synopsis

`vector` **`XMLAGG`** `(` *value_expression* any `);`

Description

`XMLAGG` is aggregate function that produces a forest of XML elements from the given list of xml elements. It concatenates the values returned from one column of multiple rows, unlike `XMLCONCAT` , which concatenates the values returned from multiple columns in the same row.

The order of element in the result of `XMLAGG` is defined by the order of retrieval of the source data rows. It is important to remember that the order of rows in an SQL resultset defined only if there's an explicit ORDER BY clause. Hence if the order of elements in the resulting forest is important then XMLAGG should be applied to data that comes from inner SELECT statement that has an ORDER BY clause, not e.g. from a table reference.

Note that `XMLAGG` is actually declared as `DB.DBA.XMLAGG` but it is not important for plain use: for compatibility with other systems, any call of `XMLAGG` in any SQl statement is always replaced with the call of `DB.DBA.XMLAGG` , no matter which qualifier and user name are in use.

Parameters

value_expression
: the result of one of the following functions XMLAGG , XMLCONCAT , XMLELEMENT , or XMLFOREST .

Return Types

The aggregate returns a vector that is a suitable input for functions `XMLELEMENT` , `XMLCONCAT` and `xml_tree_doc` .

Examples

Example 24.494. XMLAGG() enclosed in XMLELEMENT()

The following example produces an 'Emp' element with attribute 'Title' and a list of all employees having the title 'Sales Representative' as element content.

```
select XMLELEMENT ('Emp', XMLATTRIBUTES ('Sales Representative' as "Title"),
       XMLAGG (XMLELEMENT ('Name', "FirstName", ' ', "LastName")))
  from "Demo"."demo"."Employees"
 where "Title" = 'Sales Representative';

callret
VARCHAR
_______________________________________________________________________________

<Emp Title="Sales Representative">
  <Name>Nancy Davolio</Name>
  <Name>Janet Leverling</Name>
  <Name>Margaret Peacock</Name>
  <Name>Michael Suyama</Name>
  <Name>Robert King</Name>
  <Name>Anne Dodsworth</Name>
</Emp>

1 Rows.
```

Example 24.495. XMLAGG() that produces a sorted document

The result of the previous example contains an unsorted list of names. This is because data rows were retrieved from "Demo"."demo"."Employees" in primary key order, and this order has nothing common with fields "FirstName" and "LastName". To produce the sorted result, the query should contain ORDER BY in a subquery. These two variants will work identically if "FirstName" never contains whitespaces or nonprintable control characters, but the last one is formally more correct.

```
select XMLELEMENT ('Emp', XMLATTRIBUTES ('Sales Representative' as "Title"),
       XMLAGG (XMLELEMENT ('Name', "FirstName", ' ', "LastName")))
 from
    (select "FirstName", "LastName"
     from "Demo"."demo"."Employees"
     where "Title"= 'Sales Representative'
     order by 1, 2) as subq;

callret
VARCHAR
_______________________________________________________________________________

<Emp Title="Sales Representative">
  <Name>Anne Dodsworth</Name>
  <Name>Janet Leverling</Name>
  <Name>Margaret Peacock</Name>
  <Name>Michael Suyama</Name>
  <Name>Nancy Davolio</Name>
  <Name>Robert King</Name>
</Emp>

1 Rows.

select XMLELEMENT ('Emp', XMLATTRIBUTES ('Sales Representative' as "Title"),
       XMLAGG (XMLELEMENT ('Name', full_name)))
  from
    (select concat ("FirstName", ' ', "LastName") as full_name
     from "Demo"."demo"."Employees"
     where "Title"= 'Sales Representative'
     order by 1) as subq;

callret
VARCHAR
_______________________________________________________________________________

XMLELEMENT()

XMLATTRIBUTES()

XMLFOREST()

XMLCONCAT()

XMLATTRIBUTES

XMLATTRIBUTES — Creates a list of attributes and their values

Synopsis

XMLATTRIBUTES (*string_expr1 [AS alias1]* varchar ,
string_expr2 [AS alias2] varchar ,
... ,
string_exprN [AS aliasN] varchar) ;

Description

This function creates a vector that may be used only as argument of XMLELEMENT function. The vector has an even number of elements, each odd element is a name of an attribute, an even element is its value. If the attribute value is NULL, then no attribute and no value is created. If none of the attribute is created, then the function returns NULL. If string_expr is a column name, then you can omit the AS clause, and Virtuoso uses the partially escaped form of the column name as the attribute name.

Parameters

String_exprI [AS aliasI]
: string value; AS clause is mandatory if it is not a column name but an expression of some other sort.

Examples

Example 24.496. XMLATTRIBUTES() with two parameters

The following example produces an 'EmpName' elements with two attributes (if value of the column 'Region' is not NULL) or with one attribute (if value of the column 'Region' is NULL)

```
select XMLELEMENT ("EmpName",
                   XMLATTRIBUTES ("FirstName" || ' ' || "LastName" as "Name", "Region" ))
  from "Demo"."demo"."Employees";
callret
VARCHAR
_______________________________________________________________________________
<EmpName Name="Nancy Davolio" Region="WA" />
<EmpName Name="Andrew Fuller" Region="WA" />
<EmpName Name="Janet Leverling" Region="WA" />
<EmpName Name="Margaret Peacock" Region="WA" />
<EmpName Name="Steven Buchanan" />
<EmpName Name="Michael Suyama" />

XMLFOREST()

XMLAGG()

XMLCONCAT()

XMLAddAttribute

XMLAddAttribute — Add an attribute to the given node of an XML tree document

Synopsis

```
integer XMLAddAttribute ( inout source any ,
                          in mode integer ,
                          in attr_name any ,
                          in attr_value any ) ;
```

Description

The function modifies the `source` document by adding an attribute to the current node of `source` entity. The `source` should be an XML tree entity, not "persistent XML" one, should be an element entity (not attribute, text etc.) and should not be a root entity. Parameters `attr_name` and `attr_value` can be of any types that can be casted to string. `attr_name` can be an attribute entity, in this case both the name and the value of `attr_name` attribute is used and `attr_value` code must be omitted.

The `mode` specifies how to resolve duplicate attribute names, if an `source` entity already has an attribute whose name is equal to `attr_name` . Mode 0 is similar to "insert into": the function signals an error if an attribute already exists. Mode 1 is similar to "insert soft": the function do nothing if an attribute already exists and not signalling an error. Mode 2 is similar to "insert replacing": the function either adds a new attribute or replacing the value of existing attribute.

Parameters

source
: The XML tree entity to change.

mode
: The mode of resolving duplicate attribute names.

attr_name
: The name of a new attribute (or an attribute XML entity that specifies both name and value of an attribute.

attr_value
: The value of a new attribute

Return Types

The function returns integer that indicate the actual operation performed. The zero value means that there was no change ("insert soft" when an attribute already exists). The value one means that a new attribute was added, the value two means that an existing attribute was replaced.

Examples

Example 24.497. Different modes of calling XMLAddAttribute

The sample procedure contains three calls of `XMLAddAttribute` with different values of `mode` , for "insert into", "insert soft" and "insert replacing" behaviour.

```
create procedure XMLAddAttribute_demo ()
{
  declare DESCRIPTION varchar (33);
  declare XMLENTITY, ent any;
  result_names (DESCRIPTION, XMLENTITY);
  result ('EXAMPLE 1', 'Adding a new attribute');
  ent := xpath_eval ('//b', xtree_doc('<a><b attrX="x" attrY="y"/></a>'));
  result ('The document to modify:', xpath_eval('/', ent));
```

```
  result ('An element node to change:', ent);
  XMLAddAttribute (ent, 0, 'attrZ', 'z');
  result ('The document after modification:', xpath_eval('/', ent));
  result ('EXAMPLE 2', 'Failed adding of an (existing) attribute');
  ent := xpath_eval ('//b', xtree_doc('<a><b attrX="x" attrY="y"/></a>'));
  result ('The document to modify:', xpath_eval('/', ent));
  result ('An element node to change:', ent);
  XMLAddAttribute (ent, 1, 'attrX', 'xNEW');
  result ('The document after modification:', xpath_eval('/', ent));
  result ('EXAMPLE 3', 'Successful replacing of an existing attribute');
  ent := xpath_eval ('//b', xtree_doc('<a><b attrX="x" attrY="y"/></a>'));
  result ('The document to modify:', xpath_eval('/', ent));
  result ('An element node to change:', ent);
  XMLAddAttribute (ent, 2, 'attrX', 'xNEW');
  result ('The document after modification:', xpath_eval('/', ent));
}
Done. -- 00000 msec.

XMLReplace()

XMLAppendChildren()

XMLInsertBefore()

XMLInsertAfter()

XMLAppendChildren

XMLAppendChildren — Modify an XML document by adding new children to the given entity.

Synopsis

XMLAppendChildren (inout *source* any ,
in *insertion1* any ,
in *insertion2* any ,
... ,
in *insertionN* any) ;

Description

The function modifies the XML document of the given *source* XML tree entity by adding new children to the node specified by the entity. The *source* entity should be XML tree entity, not "persistent XML" entity. The value of *source* can be either an element entity or a root entity; *source* can not be an attribute entity or a leaf entity like text or processing instruction.

The values passed in parameters *insertion1* ... *insertionN* will be converted into XML nodes according to rules described in section Composing Document Fragments From DOM Function Arguments.

After calling the function, parameter *source* is still a valid XML entity that points to the modified node. The value passed as *source* can be used in the rest of caller procedure.

Parameters

source
: The XML tree entity whose document should be modified. This document should not be locked (see Changing XML Entities in DOM Style for details).

parameterI
: The value to be added as as child node of source .

Return Types

The function returns NULL.

Examples

Example 24.498. XMLAppendChildren in a Virtuoso/PL procedure

The sample procedure contains two calls of `XMLAppendChildren` . First call append three children to a node; second call demonstrates how text nodes can be merged.

```
create procedure XMLAppendChildren_demo()
{
  declare DESCRIPTION varchar (40);
  declare ENTITY, ent any;
  result_names (DESCRIPTION, ENTITY);
  result ('EXAMPLE1', 'Plain appending of some children');
  ent := xpath_eval ('//b', xtree_doc ('<a><b>Hello</b></a>'));
  result ('The document to modify', xpath_eval ('/', ent));
  result ('The node to be extended', ent);
  XMLAppendChildren (ent, xtree_doc ('<comma/>'), ' world', xtree_doc ('<excl/>'));
  result ('The changed document', xpath_eval ('/', ent));
  result ('The original entity is updated', ent);
  result ('EXAMPLE2', 'Appending that cause concatenation of text nodes');
  result_names (DESCRIPTION, ENTITY);
  ent := xpath_eval ('//b', xtree_doc ('<a><b>Hello</b></a>'));
  result ('The document to modify', xpath_eval ('/', ent));
```

```
  result ('The node to be extended', ent);
  XMLAppendChildren (ent, ', ', ' world', '!');
  result ('The changed document', xpath_eval ('/', ent));
  result ('The original entity is updated', ent);
}

Done. -- 00000 msec.

XMLCONCAT

XMLCONCAT — Creates a forest of elements by concatenating a list of XML values

Synopsis

XMLCONCAT (*value_expr1* varchar ,
value_expr2 varchar ,
... ,
value_exprN varchar) ;

Description

XMLCONCAT accepts a list of XML value expressions as its arguments, and produces a forest of elements by concatenating the XML values that are returned from the same row to make one value. XMLCONCAT works like XMLFOREST , except that XMLCONCAT parameters is a list of XML elements. Null expressions are dropped from the result. If all the value expressions are null, then the function returns NULL.

Parameters

value_expr1
: a vector returned by XMLELEMENT , XMLFOREST , or XMLCONCAT functions, or an entity object returned by corresponding functions (e.g. xtree_doc , xquery_eval or path_eval). In the latter case the entity object must not be an attribute.

Errors

Table 24.127. Errors signalled by XMLCONCAT

SQLState	Error Code	Error Text	Description
22003	SR355	Too few arguments for XMLCONCAT	There must be at least one argument
22003	SR359	Invalid argument type NVARCHAR (225) for arg N to XMLCONCAT	The entity object returned by xpath_eval must not be an attribute
22003	SR360	XMLCONCAT doesn't concatenate attributes	The entity object returned by xquery_eval must not be an attribute

Examples

Example 24.499. XMLCONCAT() with two parameters

The following example produces an XML elements for the 'FName', 'LName', 'country' and 'nationality', concatenates the result, and creates a one-column result set:

```
select XMLCONCAT (
        XMLELEMENT ('FName', "FirstName"),
        XMLELEMENT ('LName', "LastName"),
        xquery_eval('//country', xtree_doc('<a><country>USA</country></a>')),
        xpath_eval('//nationality', xtree_doc('<a><nationality>RUSSIAN</nationality></a>')))
from "Demo"."demo"."Employees";

callret
VARCHAR
_____________________________________________________________________________
<FName>Nancy</FName><LName>Davolio</LName><country>USA</country><nationality>RUSSIAN</nationality>
<FName>Andrew</FName><LName>Fuller</LName><country>USA</country><nationality>RUSSIAN</nationality>

. . .
```

```

XMLAGG()

XMLATTRIBUTES()

XMLELEMENT()

XMLFOREST()

XMLELEMENT

XMLELEMENT — Creates XML element

Synopsis

XMLELEMENT (*tag_name* varchar ,
list_of_attributes sequence ,
child_or_attribute1 any ,
child_or_attribute2 any ,
... ,
child_or_attributeN any) ;

Description

XMLELEMENT takes an element name for identifier, an optional collection of attributes for the element, and arguments that make up the element's content. It returns a XML element. The second parameter may be omitted and at that time the rest parameters may be present. If one of the arguments is a call of the xpath_eval returning an attribute value, then this value would be added to element's content (not to element's attributes).

Parameters

tag_name
: name of the element, it must be valid XML element name

list_of_attributes
: a vector returned by XMLATTRIBUTES function. If the vector is NULL, then no attribute is created.

child_or_attributeI
: a string, or name of a column, or concatenation of the names and/or strings, or a vector returned by XMLELEMENT , XMLFOREST , XMLCONCAT , or XMLAGG functions, or an entity object returned by corresponding functions (e.g. xtree_doc or xquery_eval). If the entity object is an attribute entity, then it is joined to the list of the element's attributes. If a parameter is NULL, then no child element or attribute is created for that parameter.

Errors

Table 24.128. Errors signalled by XMLELEMENT

SQLState	Error Code	Error Text	Description
22003	SR354	Too few arguments for XMLELEMENT	There must be at least one argument

Examples

Example 24.500. XMLELEMENT() with a single argument

XMLELEMENT creates an 'Title' element without content.

```
SQL> select XMLELEMENT ('Title') from "Demo"."demo"."Employees";
callret
VARCHAR
_______________________________________________________________________________

<Title />
<Title />
. . .
9 Rows. -- 2 msec.
```

Example 24.501. XMLELEMENT() with content

The following example produces an 'Emp' element with three attributes (the 'region' attribute is calculated by `xquery_eval`) and five nested subelements

```
select XMLELEMENT ('Emp',
                    XMLATTRIBUTES ( "EmployeeID" AS "EmpID", "Title"),
                    XMLELEMENT ('Name', "FirstName" || ' ' || "LastName" ),
                    xquery_eval('//@region', xtree_doc ('<a region="WA"></a>')),
                    XMLFOREST ("PostalCode", "City" as "city"),
                    XMLCONCAT (XMLELEMENT ('HomePhone', "HomePhone"),
                               XMLELEMENT ('BirthDate', "BirthDate")))
  from "Demo"."demo"."Employees"
  where "EmployeeID"=1;

callret
VARCHAR
_______________________________________________________________________________

<Emp EmpID="1" Title="Sales Representative" region="WA">
  <Name>Nancy Davolio</Name>
  <city>Seattle</city>
  <PostalCode>98122</PostalCode>
  <HomePhone>(206) 555-9857</HomePhone>
  <BirthDate>1948-12-08</BirthDate>
</Emp>
```

Example 24.502. XMLELEMENT() with the aggregate function XMLAGG()

This example produces 'Emp' elements, with the list of the 'Name' of all employees.

```
select XMLELEMENT ('Emp',
                    XMLAGG (XMLELEMENT('Name', "FirstName", ' ', "LastName")))
  from "Demo"."demo"."Employees";
callret
VARCHAR

XMLFOREST()

XMLFOREST

XMLFOREST — Produces a forest of XML elements

Synopsis

XMLFOREST (*string_expr1 [AS alias1]* varchar , *string_expr2 [AS alias2]* varchar , *...* , *string_exprN [AS aliasN]* varchar) ;

Description

XMLFOREST produces a forest of XML elements from the given list of arguments. The arguments may be string expressions with optional aliases. If string expression is a column name, then you can omit the AS clause, and Virtuoso uses the partially escaped form of the column name as the name of the enclosing tag. If the expression evaluates to NULL, then no element is created for that expression. If none of the element is created, then the function returns NULL.

Parameters

string_exprI [AS aliasI]
: string value; AS clause is mandatory if the argument is not a column name but an expression of some other sort.

Errors

Table 24.129. Errors signalled by XMLFOREST

SQLState	Error Code	Error Text	Description
37000	SQ074	The special SQL function has invalid argument	An argument is neither a column name nor an expression with an alias.

Examples

Example 24.503. XMLFOREST() with five parameters.

The following example produces five (or four) elements ('FName', 'LName', 'str', 'Title', and 'Region' - if there is a value) from the string expressions 'FirstName', 'LastName', 'string', 'Title', and 'Region', concatenates the elements produced for each employee, and produces one row for each employee in the result set.

```
select XMLFOREST (
  "FirstName" as "FName", "LastName" as "LName",
  'string' as "str", "Title", "Region" )
from "Demo"."demo"."Employees";
callret
VARCHAR
_____________________________________________________________________________

<FName>Nancy</FName>
<LName>Davolio</LName>
<str>string</str>
<Title>Sales Representative</Title>
<Region>WA</Region>

. . .
```

```
<FName>Anne</FName>
<LName>Dodsworth</LName>
<str>string</str>
<Title>Sales Representative</Title>

9 Rows.
```

The following example always produces five elements: empty 'Region' element is created for NULL values. Note the difference in the last rows of this and the previous query results:

```
select XMLFOREST (
  "FirstName" as "FName", "LastName" as "LName",
  'string' as "str", "Title", coalesce ("Region", '') as "Region")
from "Demo"."demo"."Employees";
callret
VARCHAR
_______________________________________________________________________________

<FName>Nancy</FName>
<LName>Davolio</LName>
<str>string</str>
<Title>Sales Representative</Title>
<Region>WA</Region>

. . .

<FName>Anne</FName>
<LName>Dodsworth</LName>
<str>string</str>
<Title>Sales Representative</Title>
<Region></Region>

9 Rows.
```

XMLInsertAfter

XMLInsertAfter — Modify an XML document by inserting new children after the node specified by given entity.

Synopsis

XMLInsertAfter (inout *source* any ,
in *insertion1* any ,
in *insertion2* any ,
... ,
in *insertionN* any) ;

Description

The function modifies the XML document of the given `source` XML tree entity by adding new siblings to the node specified by the entity. Siblings will be added right after the node. The `source` entity should be XML tree entity, not "persistent XML" entity. The value of `source` should be a node entity; `source` can not be an attribute entity or a root entity.

The values passed in parameters `insertion1` ... `insertionN` will be converted into XML nodes according to rules described in section Composing Document Fragments From DOM Function Arguments.

After calling the function, parameter `source` is still a valid XML entity that points to the same node. The value passed as `source` can be used in the rest of caller procedure.

Parameters

source
: The XML tree entity whose document should be modified. This document should not be locked (see Changing XML Entities in DOM Style for details).

parameterI
: The value to be added as as child node of source .

Examples

Example 24.504. XMLInsertBefore in a Virtuoso/PL procedure

The sample procedure contains two calls of `XMLInsertAfter` . First call insert two new element nodes just after the given node; second call demonstrates how text nodes can be merged.

```
create procedure XMLInsertAfter_demo()
{
  declare DESCRIPTION varchar (40);
  declare ENTITY, ent any;
  result_names (DESCRIPTION, ENTITY);
  result ('EXAMPLE1', 'Plain inserting of some children');
  ent := xpath_eval ('//child0', xtree_doc ('<a><child0></child0></a>'));
  result ('The document to modify', xpath_eval ('/', ent));
  result ('The place of insertion', ent);
  XMLInsertAfter (ent, xtree_doc ('<child1/>'), xtree_doc ('<child2/>'));
  result ('The changed document', xpath_eval ('/', ent));
  result ('The original node is updated', ent);
  result ('EXAMPLE2', 'Appending that cause concatenation of text nodes');
  ent := xpath_eval ('//b/text()', xtree_doc ('<a><b>Hello</b></a>'));
  result ('The document to modify', xpath_eval ('/', ent));
  result ('The place of insertion', ent);
  XMLInsertAfter (ent, ', world!');
  result ('The changed document', xpath_eval ('/', ent));
  result ('The original node is updated', ent);
}
```

XMLInsertBefore

XMLInsertBefore

XMLInsertBefore — Modify an XML document by inserting new children before the node specified by given entity.

Synopsis

XMLInsertBefore (inout *source* any ,
in *insertion1* any ,
in *insertion2* any ,
... ,
in *insertionN* any) ;

Description

The function modifies the XML document of the given *source* XML tree entity by adding new siblings to the node specified by the entity. Siblings will be added right before the node. The *source* entity should be XML tree entity, not "persistent XML" entity. The value of *source* should be a node entity; *source* can not be an attribute entity or a root entity.

The values passed in parameters *insertion1* ... *insertionN* will be converted into XML nodes according to rules described in section Composing Document Fragments From DOM Function Arguments.

After calling the function, parameter *source* is still a valid XML entity that points to the same node. The value passed as *source* can be used in the rest of caller procedure.

Parameters

source
: The XML tree entity whose document should be modified. This document should not be locked (see Changing XML Entities in DOM Style for details).

parameterI
: The value to be added as as child node of source .

Return Types

The function returns NULL.

Examples

Example 24.505. XMLInsertBefore in a Virtuoso/PL procedure

The sample procedure contains two calls of `XMLInsertBefore` . First call insert two new element nodes just before the given node; second call demonstrates how text nodes can be merged.

XMLReplace

XMLAddAttribute

XMLAppendChildren

XMLInsertAfter

XMLReplace

XMLReplace — Modify a given XML document by replacing some nodes.

Synopsis

```
any XMLReplace ( inout source any ,
                 in location1 any ,
                 in replacement1 any ,
                 in location2 any ,
                 in replacement2 any ,
                 in ... ,
                 in locationN any ,
                 in replacementN any ) ;
```

Description

The function takes of the XML document referenced by `source` XML tree entity and modifies it by replacing nodes specified by `location1` , `location2` , ..., `locationN` with values specified by `replacement1` , `replacement2` , ...,`replacementN` . At the end of function call, the `source` points to the root of a modified entity.

The `source` parameter should be an XML tree entity whose document is not locked (see Changing XML Entities in DOM Style for details).

Every `replacementI` may be an XML tree entity, a NULL or a value of some other type that will be converted to varchar before use.

For simplicity, consider the case when there is only one `location1` XML entity and only one `replacement1` . If the `location1` is an XML entity that is not in the source document then no modifications is made in `source` . If `replacement1` is an entity that is in the source document then a temporary "cut" of `replacement1` is created, like `xml_cut` is called).

If the `location1` is an attribute entity then the value of the attribute is changed. If `replacement1` is NULL then the attribute is removed at all, otherwise its value is set to the string value of the `replacement1` .

If the `location1` is not an attribute entity but a entity then `location1` is replaced with the value of `replacement1` . The method of replacement depends on the type of the replacement value. If `replacement1` is NULL then the `location1` node is simply removed from the result; if the node is the root or a single child of the root then function immediately returns NULL (because XML document can not be totally empty), otherwise the parent of the `location1` will simply have one child less. If `replacement1` is an non-empty string then `location1` is replaced with a new text node whose string value is equal to `replacement1` . If `replacement1` is an empty string then the effect is exactly the same as in case of NULL because the string value of a text node can not be empty. If `replacement1` is an XML entity that is a root entity of some document then the highlighted node is replaced with a sequence of copies of all children of that root. If `replacement1` is an XML entity of some other sort (XML element, text, comment etc.) then the that is not a root entity of some document then the highlighted node is replaced with a sequence of copies of all children of that root.

After changing the `source` , some normalization may happen. The modified document may contain adjacent text nodes; every sequence of such nodes is replaced with one text node whose string value is a concatenation of string values of that nodes. E.g. if the `location1` is an element <a/> that resides between two text nodes "text1" and "text2" and it is removed (by replacing with NULL) then these text nodes become neighbors; normalization will replace them with a single text node "text1text2"

Now consider the case of more than one replacement made in one function call. If more than one pair of location and replacement is given then the function first finds all locations, then it performs all replacements, then it performs an normalization. It is very important to understand that the order of making replacements has nothing to do with the order of pairs of parameters in the function call. If some location node is an ancestor of some other location node then the effect of the replacement of the descendant location node is void: the descendant is replaced first; then the ancestor is replaced as a whole, no matter if some of its descendants are modified. The order of parameters in the function call is used to resolve ambiguity If two locations are equal: the

last pair of parameters will have a higher priority.

If the *source* is an instance of XMLType then its inner XML document is changed and "is validated" flag is reset to 0 indicating that there is no warranty that the modified version of document matches the declared schema even if the original document matched.

Parameters

source
: A source XML tree entity. It is an error to pass persistent XML entity as an argument.

locationI
: An XML entity that points to the node to replace. For compatibility with other implementations, it can be NULL, a pair of arguments is silently ignored in this case.

replacementI
: A replacement value for XML node pointed by locationI ; it may be NULL or XML tree entity or a string or anything else but not an persistent XML entity.

Return Types

The function returns NULL.

Examples

Example 24.506. XMLReplace in a Virtuoso/PL procedure

The sample procedure contains two calls of `XMLReplace` . First call replaces element 'c' with a copy of element 'replacement'. Second call demonstrates two replacements in parallel: elements titled 'c1' and 'c3' are replaced with text nodes.

```
create procedure XMLReplace_demo ()
{
  declare DESCRIPTION varchar(42);
  declare XMLENTITY, ent, ent2, ent_to_corrupt any;
  result_names (DESCRIPTION, XMLENTITY);
  ent := xtree_doc('<a><b><q/>-<c>Hello</c>-</b></a>');
  result ('EXAMPLE 1', 'A simple replacement of one element with other');
  result ('The document to modify:', ent);
  ent_to_corrupt := xquery_eval ('//c', ent);
  result ('Node to be replaced:', ent_to_corrupt);
  XMLReplace (ent, ent_to_corrupt, xtree_doc('<replacement/>'));
  result ('The document after modification:', ent);
  result ('Node to be replaced is outdated:', ent_to_corrupt);
  result ('...e.g. it'' not a descendant of its root:', xpath_eval('/', ent_to_corrupt));
  result ('EXAMPLE 2', 'Two replacements in parallel');
  ent2 := xtree_doc('<a><b><c1>Hello1</c1><c2>Hello2</c2><c3>Hello3</c3></b></a>');
  result ('The document to modify:', ent2);
  XMLReplace (ent2, xquery_eval('//c1', ent2), 'world1', xquery_eval('//c3', ent2), 'world3');
  result ('The document after modification:', ent2);
}

Done. -- 00000 msec.

xml_auto

xml_auto — prepares and executes given SQL for XML string output

Synopsis

xml_auto (in *sql_text* varchar ,
in *params* any ,
in *string_output* any) ;

Description

This function prepares and executes the given SQL string, which should be a query expression with the FOR XML clause at the end of the last term. The query is passed the parameters from the params vector, which should have one element for each ? in the query text, values assigned from left to right. Consider the query: select a, b from table where a = ? and b = ?; then the params vector could reasonably be:

```
vector(1, 'myfilter')
```

.

The result set is converted to XML and appended to the *string* _output. If the *string* _output is omitted and the function executes in the context of a VSP page, the output is sent to the stream going to the user agent.

Parameters

sql_text
: Valid SQL query using the FOR XML clause. Parameterized queries can be constructed using the question mark (?) to specify a parameter place-holder that will be replaced at run time with the appropriate value from the params vector.

params
: Vector of parameters, one element per ? used in the query.

string_output
: String variable or stream for receiving the result.

Return Types

If you omit the third parameter, this function will output to the context of the calling VSP page.

Errors

Table 24.130. Errors signalled by xml_auto

SQLState	Error Code	Error Text	Description
42000		http output function outside of http context and no stream specified	From an attempt to send the output directly to a non HTTP target such as ISQL.
42000		Column 1 of the result set of the select statement should be of INTEGER type when FOR XML EXPLICIT clause is used	
42000		Column 2 of the result set of the select statement should be of INTEGER type when FOR XML EXPLICIT clause is used	

Examples

Example 24.507. Producing XML from SQL

The procedure below takes an SQL string, evaluates it - converting to XML - and produces a result set where the XML text is returned as a varchar column. Parameters are not passed in this example for the sake of simplicity.

```
create procedure xmla (in q varchar)
{
  declare st any;
  st := string_output ();
  xml_auto (q, vector (), st);
  result_names (q);
  result (string_output_string (st));
}
```

`xml_auto_schema()`, `xml_auto_dtd()`

xml_auto_dtd

xml_auto_dtd — returns an XML DTD for the result of a SQL query with a FOR XML clause

Synopsis

```
varchar xml_auto_dtd ( in query varchar ,
                       in root_element varchar ) ;
```

Description

This function returns an XML DTD for the results of a SQL query with a FOR XML clause. The returned DTD will apply to the output generated by xml_auto with the query in question after wrapping it into the specified root element.

Parameters

query
: valid SQL query

root_element
: name of root element to wrap result into

Return Types

varchar of the resultant DTD

Errors

If the *query* argument is not a valid SQL statement, i.e. SQL compiler signals an error message, the function resignals the error.

Examples

Example 24.508. Simple Use

```
SQL> select xml_auto_dtd ('  select "category"."CategoryID", "CategoryName",
    "ProductName", "ProductID"
    from "Demo".."Categories" "category", "Demo".."Products" as "product"
    where "product"."CategoryID" = "category"."CategoryID" for xml auto element', 'root');
callret

xml_auto()

xml_auto_schema()

xml_auto_schema

xml_auto_schema — returns an XML schema for the result of an SQL query with a FOR XML clause

Synopsis

```
varchar xml_auto_schema ( in query varchar ,
                          in root_element varchar ) ;
```

Description

This function returns an XML schema for the results of an SQL query with a FOR XML clause. The returned schema will apply to the output generated by `xml_auto()` with the query in question after wrapping it in the specified root element.

Parameters

query
: SQL query

root_element
: name of root element container

Return Types

varchar result containing the schema of the XML document.

Errors

If the *query* argument is not a valid SQL statement, i.e. SQL compiler signals an error message, the function resignals the error.

Examples

Example 24.509. Simple Schema Generation

```
SQL> select xml_auto_schema ('  select "category"."CategoryID", "CategoryName",
                  "ProductName", "ProductID"
          from "Demo".."Categories" "category", "Demo".."Products" as "product"
          where "product"."CategoryID" = "category"."CategoryID"
          for xml auto element', 'root');
 callret

xml_auto_dtd()

xml_create_tables_from_mapping_schema_decl

xml_create_tables_from_mapping_schema_decl — returns a vector containing strings. Each string is a command to drop a table or a foreign key or to create table.

Synopsis

xml_create_tables_from_mapping_schema_decl (in *base_uri* varchar ,
in *mapping_schema_file* varchar ,
in *content_encoding* varchar ,
in *content_language* varchar) ;

Description

`xml_create_tables_from_mapping_schema_decl` takes a file containing mapping schema and returns a vector containing strings. Each string is a command to drop a table or a foreign key or to create table. All tables and fields are mentioned in the mapping schema. If a field type is not defined in the mapping schema, the VARCHAR type is used.

Parameters

base_uri
: in HTML parser mode change all absolute references to relative from given base_uri (http://<host>:<port>/<path>)

mapping_schema_file
: well formed XML document containing a mapping schema

content_encoding
: string with content encoding type of <document>; valid are 'ASCII', 'ISO', 'UTF8', 'ISO8859-1', 'LATIN-1' etc., defaults are 'UTF-8' for XML mode and 'LATIN-1' for HTML mode

content_language
: string with language tag of content of <document>; valid names are listed in IETF RFC 1766, default is 'x-any' (it means 'mix of words from various human languages)

Return Types

A vector containing strings

Example 24.510. Extracting tables from mapping schema

Let we have the following mapping schema in the catmp.xsd file

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
            xmlns:sql="urn:schemas-microsoft-com:mapping-schema">
<xsd:annotation>
  <xsd:appinfo>
    <sql:relationship name="CategoryProduct"
          parent="Demo.demo.Categories"
          parent-key="CategoryID"
          child="Demo.demo.Products"
          child-key="CategoryID" />
  </xsd:appinfo>
</xsd:annotation>

  <xsd:element name="category" sql:relation="Demo.demo.Categories" type="CategoryType" />
   <xsd:complexType name="CategoryType" >
     <xsd:sequence>
        <xsd:element name="product"
                    sql:relation="Demo.demo.Products"
                    sql:relationship="CategoryProduct" >
```

```
            <xsd:complexType>
               <xsd:attribute name="ProductName" type="xsd:string" />
            </xsd:complexType>
         </xsd:element>
      </xsd:sequence>
         <xsd:attribute name="CategoryID"  type="xsd:integer" />
         <xsd:attribute name="description"  sql:field="Description"  type="xsd:string" />
    </xsd:complexType>
</xsd:schema>
```

the _result vector after the call

```
_result := xml_create_tables_from_mapping_schema_decl (
  'http://localhost.localdomain/xmlrepository',
  'catmp.xsd', 'UTF-8', 'x-any');
```

will contain the following six strings

```
drop table "Demo"."demo"."Categories",

ALTER TABLE "Demo"."demo"."Products" DROP CONSTRAINT "Demo.demo.Products_Demo.demo.Categories_FK",

drop table "Demo"."demo"."Products",

create table "Demo"."demo"."Categories"
("Description"  VARCHAR, "CategoryID" INTEGER, PRIMARY KEY ("CategoryID")),

create table "Demo"."demo"."Products" ("CategoryID"  INTEGER, "ProductName"  VARCHAR),

ALTER TABLE "Demo"."demo"."Products" ADD CONSTRAINT "Demo.demo.Products_Demo.demo.Categories_FK"
FOREIGN KEY ("CategoryID") REFERENCES "Demo"."demo"."Categories" ("CategoryID")
```

xml_cut

xml_cut — creates a new XML document which contains a copy of data pointed by given XML tree- or XPER- entity

Synopsis

xml_cut (in *source_entity* any (XML entity)) ;

Description

In some special cases, some part of XML document, being pointed by a XML entity, should be copied into a new separate document with new entity pointing to the top-level element or the root of this document. One reason for doing this is optimization of XPER processing (see xper_cut). Another way to use this functionality is passing of some XML entity to a function, when function uses XPath operations with references to the "document's root".

Example 24.511. A sample of hidden bug

```
create procedure get_C (inout b any)
{
  return cast (xpath_eval('//C', b) as varchar);
}

create procedure hidden_bug_1()
{
  declare abc any;      -- some XML document
  declare b_list any;   -- a vector of all B elements of the doc
  declare c1 varchar;   -- a name of first variable
  declare c2 varchar;   -- a title of second variable
  abc := xtree_doc ('<A><B
xml:id="1_01"><C>One</C></B><B
xml:id="2_01"><C>Two</C></B></A>');
  b_list := xpath_eval ('//B', abc, 0);
  -- now b_list is a vector of two items, '<B
xml:id="1_02"><C>One</C></B>' and '<B
xml:id="2_02"><C>Two</C></B>'.
  c1 := get_C ( aref (b_list, 0));
  -- looks fine, c1 is '<C>One</C>'
  c2 := get_C ( aref (b_list, 1));
  -- looks strange fine, c2 is '<C>One</C>',
  -- while the expected value is '<C>Two</C>'.
}
```

The origin of the bug is '//C' path in get_C(), which returns not the "C element inside given b element", but "C element inside the document where given b element is located", thus get_C returns the first C element in the whole document with any of two B elements given.

There are two ways to fix this bug. It is better to correct get_C():

```
create procedure get_C (inout b any)
{
  return cast (xpath_eval('./C', b) as varchar);
}
```

If you cannot patch get_C() for some reason, xml_cut will help, but it will waste both memory and CPU time for copying a branch of XML tree:

```
create procedure hidden_bug_1()
{
...
  c1 := get_C ( xml_cut (aref (b_list, 0)));
...
}
```

The current node of the resulting entity is the node that is a copy of the current node of the source entity. In common, the top-level node of the copied subtree becomes the current node of the result. There are two special cases, however. If the source entity is an attribute entity, then the result is also an attribute entity and the attribute name remains the same. If the source entity points to the root of the document, the resulting entity also points to the root of the copied document, not to its top-level node.

With XPER entity given, xml_cut() works exactly as xper_cut().

Parameters

source_xper
: XML Entity to be converted into new document

See Also

`xper_cut()`

xml_doc_output_option

xml_doc_output_option

Synopsis

```
varchar xml_doc_output_option ( in xml_entity any ,
                                in option_name varchar ,
                                in option_value varchar ) ;
```

Description

This function reads or updates the specified XSLT output option value of the given `xml_entity` .

The function updates the option if parameter `option_value` is provided, otherwise it returns the current value of the option without any side effects.

Supported options are "method", "version", "encoding", "omit-xml-declaration", "standalone", "doctype-public", "doctype-system", "indent" and "media-type", but do not support"cdata-section-elements". When the entity is serialized, the effect is very similar to the effect of the same option specified in xsl:output element of an XSLT that created the entity.

Note that output options are properties of the whole document, not properties of some particular node in the document, so the effect of the update is document-wide. Please also note that the effect of 'preamble' options "omit-xml-declaration", "standalone", "doctype-public" and "doctype-system" is visible only when the root entity of the document is serialized, not any descendant entity. Even the serialization of top-level element of the document is not affected by these settings. The XML preamble is serialized only if the document is composed by an XSLT processor or "doctype-system" is set or at least one of two boolean properties "omit-xml-declaration" and "standalone" is set to "yes".

According to the DTD rules, "doctype-public" has no effect on serialization if "doctype-system" is not set.

Parameters

xml_entity
: An XML entity such as that returned by the xslt() function.

option_name
: A name of output option to in question.

option_value
: A new value of output option. This is a string or NULL (that reset option to default). Allowed values of boolean properties "omit-xml-declaration" and "standalone" are "yes" and "no", as it is in XSLT 1.0.

Return Types

The function returns a string that is a value of the option or NULL if the option is not set.

Errors

This function can generate the following errors:

22023 SR003 Function xml_doc_output_option needs an XML entity as argument 1, not an arg of type <type_name> (<type>)

Examples

Example 24.512. Assessing the SYSTEM DTD location

```
create function test_output_option (
  in cnt any, in opt_name any, in opt_value any)
```

```
{
  declare xt, ses any;
  declare oldval, newval varchar;
  xt := xtree_doc (cnt, 2, '', 'UTF-8');
  oldval := xml_doc_output_option (xt, opt_name);
  xml_doc_output_option (xt, opt_name, opt_value);
  newval := xml_doc_output_option (xt, opt_name);
  return concat (
    sprintf ('Old value of "%s" is "%s"\nNew value is "%s"\nThe result:\n',
       opt_name,
       cast (oldval as varchar),
       cast (newval as varchar) ),
    serialize_to_UTF8_xml (xt) );
}

select test_output_option (
  '<div xmlns="http://www.w3.org/1999/xhtml">Hello</div>',
  'doctype-system', 'http://www.example.com/xhtml.dtd')
callret
VARCHAR
_______________________________________________________________________________

Old value of "doctype-system" is "(NULL)"
New value is "http://www.example.com/xhtml.dtd"
The result:
<?xml version="1.0" encoding="UTF-8" ?>
<!DOCTYPE http://www.w3.org/1999/xhtml:div
  SYSTEM "http://www.example.com/xhtml.dtd">
<n0:div xmlns:n0="http://www.w3.org/1999/xhtml">Hello</n0:div>

1 Rows. -- 1 msec.
```

`xtree_doc()`

xml_load_schema_decl

xml_load_schema_decl — returns a string with list of errors detected by XML Schema processor on reading given XML Schema definition document.

Synopsis

xml_load_schema_decl (in *base_uri* varchar ,
in *document_uri* varchar ,
in *content_encoding* varchar ,
in *content_language* varchar) ;

Description

Loads given file using base_uri. Try to parse file of XML Schema definition and check it for correctness to XML Schema specification.

Parameters

base_uri
: in HTML parser mode change all absolute references to relative from given base_uri (http://<host>:<port>/<path>)

content_encoding
: string with content encoding type of <document>; valid are 'ASCII', 'ISO', 'UTF8', 'ISO8859-1', 'LATIN-1' etc., defaults are 'UTF-8' for XML mode and 'LATIN-1' for HTML mode

content_language
: string with language tag of content of <document>; valid names are listed in IETF RFC 1766, default is 'x-any' (it means 'mix of words from various human languages)

dtd_validator_config
: configuration string of the validator, default is empty string meaning that DTD validator should be fully disabled and only critical errors should be reported

Return Types

Human readable list of errors if applicable as a varchar.

Validating XML Against a XML Schema

Example 24.513. Simple Use

```
declare _result varchar;
_result := xml_load_schema_decl (
  'http://localhost.localdomain/xmlrepository',
  'persons.xsd', 'UTF-8', 'x-any');

if (_result = '') _result := 'NO ERRORS DETECTED';
```

`xml_validate_schema()`

`xml_auto_schema()`

`xml_view_schema()`

xml_validate_dtd()

xml_load_mapping_schema_decl

xml_load_mapping_schema_decl — creates a xml view from mapping schema.

Synopsis

xml_load_mapping_schema_decl (in *base_uri* varchar ,
in *mapping_schema_file* varchar ,
in *content_encoding* varchar ,
in *content_language* varchar) ;

Description

`xml_load_mapping_schema_decl` takes a file containing mapping schema and creates a xml view.

Parameters

base_uri
: in HTML parser mode change all absolute references to relative from given base_uri (http://<host>:<port>/<path>)

mapping_schema_file
: well formed XML document containing a mapping schema

content_encoding
: string with content encoding type of <document>; valid are 'ASCII', 'ISO', 'UTF8', 'ISO8859-1', 'LATIN-1' etc., defaults are 'UTF-8' for XML mode and 'LATIN-1' for HTML mode

content_language
: string with language tag of content of <document>; valid names are listed in IETF RFC 1766, default is 'x-any' (it means 'mix of words from various human languages)

Example 24.514. Creating a xml view from a mapping schema

The xml view created by

```
xml_load_mapping_schema_decl (
   'http://localhost.localdomain/xmlrepository',
   'catmp.xsd', 'UTF-8', 'x-any');
```

from the file catmp.xsd containing the following mapping schema

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
            xmlns:sql="urn:schemas-microsoft-com:mapping-schema">
<xsd:annotation>
  <xsd:appinfo>
    <sql:relationship name="CategoryProduct"
          parent="Demo.demo.Categories"
          parent-key="CategoryID"
          child="Demo.demo.Products"
          child-key="CategoryID" />
  </xsd:appinfo>
</xsd:annotation>

  <xsd:element name="category" sql:relation="Demo.demo.Categories" type="CategoryType" />
   <xsd:complexType name="CategoryType" >
     <xsd:sequence>
        <xsd:element name="product"
                    sql:relation="Demo.demo.Products"
                    sql:relationship="CategoryProduct" >
           <xsd:complexType>
              <xsd:attribute name="ProductName" type="xsd:string" />
```

```
            </xsd:complexType>
          </xsd:element>
       </xsd:sequence>
          <xsd:attribute name="CategoryID"  type="xsd:integer" />
          <xsd:attribute name="description"  sql:field="Description"  type="xsd:string" />
      </xsd:complexType>
</xsd:schema>
```

is identical to xml view created by

```
create xml view "cat" as
{
  "Demo"."demo"."Categories" "C" as "category"
        ("CategoryID", "Description" as "description")
    {
      "Demo"."demo"."Products" "P" as "product"  ("ProductName")
        on ("P"."CategoryID" = "C"."CategoryID")
    }
}
```

`xml_load_schema_decl()`

`xml_load_schema_decl()`

`xml_view_schema()`

xml_namespace_scope

xml_namespace_scope — Returns a vector of all namespace declarations in all ancestors of the given XML entity.

Synopsis

```
vector xml_namespace_scope ( in ent XML Entity ,
                             in use_default_ns integer ) ;
```

Description

The function returns a vector of even length that consists of all declared namespace prefixes and namespace URIs from the `ent` and all its ancestors. This information is needed for processing XML documents that contains a mix of data and XPath expressions, such as BPEL documents.

Parameters

ent
: The entity to process.

use_default_ns
: Flags if the resulting array should contain declarations of default namespace. If it is zero then only declarations of namespace prefixes are listed; if non-zero then all declarations are listed.

Return Types

The function returns a vector of even length that contains narrow strings in UTF-8 encoding.

Examples

Example 24.515. Adding namespace declarations to the XPath expression

The function gets an entity whose string-value is an XPATH expression and returns the text of expression with all namespace declarations that are in scope. The resulting expression is context-independent. This is useful for BPEL-like applications and for extracting XPATH expressions from XML Schema documents.

```
create procedure xpath_add_namespace_scope (in ent any, in use_default_ns integer)
{
  declare _expn varchar;
  declare _ses any;
  declare _scope any;
  declare _ctr any;
  _expn := charset_recode (xpath_eval ('string(.)', ent), '_WIDE_', 'UTF-8');
  _scope := xml_namespace_scope (ent, use_default_ns);
  _ctr := length (_scope);
  if (_ctr = 0)
    return _expn;
  _ses := string_output ();
  http ('[', _ses);
  while (_ctr > 0)
    {
      if (_scope[_ctr-2] = '')
        http (sprintf (' xmlns="%s"', _scope[_ctr-1]), _ses);
      else
        http (sprintf (' xmlns:%s="%s"', _scope[_ctr-2], _scope[_ctr-1]), _ses);
      _ctr := _ctr - 2;
    }
  http (' ] ', _ses);
  http (_expn, _ses);
  return string_output_string (_ses);
}

select xpath_add_namespace_scope (
```

```
  xquery_eval (
'declare namespace xsd="http://www.w3.org/2001/XMLSchema";
//xsd:keyref[@name="ISBNnumber"]/xsd:field/@xpath',
    xtree_doc (
'<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
        targetNamespace="http://www.publishing.org"
        xmlns="http://www.publishing.org">
  <xsd:element name="Book"  minOccurs="1" maxOccurs="unbounded">
    <xsd:keyref name="ISBNnumber" refer="BookDB_ISBN">
      <xsd:selector xpath="."/>
      <xsd:field xpath="ISBN"/>
    </xsd:keyref>
  </xsd:element>
  <!-- The rest of the XML Schema file is skipped -->

</xsd:schema>')),
  1 );

callret
VARCHAR
_______________________________________________________________________________

[ xmlns="http://www.publishing.org" xmlns:xsd="http://www.w3.org/2001/XMLSchema" ] ISBN
```

See Also

xpath_eval

xml_add_system_path

xml_add_system_path — Adds path to the internal list of system paths.

Synopsis

xml_add_system_path (in *path* varchar) ;

Description

When validating XML parser tries to resolve system entities it searches in http_root directory. If it fails parser iterates internal list of system paths and tries to find required files there. The function adds new path in this list. List of system paths contains one directory item by default - "file://system/".

NOTE: List of system paths is not persistent. It means that you must add desired path each time when server starts. An ideal place for this operation in "autoexec.isql" file.

xml_get_system_paths

xml_get_system_paths — Returns vector of all system paths.

Synopsis

```
xml_get_system_paths (  );
```

xml_persistent

xml_persistent — returns an entity object ('XPER entity') created from given XML document

Synopsis

xml_persistent (in *document* varchar ,
in *parser_mode* integer ,
in *base_uri* varchar ,
in *content_encoding* varchar ,
in *content_language* varchar ,
in *dtd_validator_config* varchar) ;

Description

This parses the argument, which is expected to be a well formed XML fragment and returns a parse tree as a special object with underlying disk structure, named "persistent XML" or "XPER" While the result of `xml_tree()` is a memory-resident array of vectors, the XPER object consumes only a little amount of memory, and almost all data is disk-resident.

This function is equivalent to `xper_doc()` , and the only difference is in the order of arguments; xper_doc() has the same order of arguments as `xml_tree()` .

Parameters

document
: well formed XML or HTML documen

parser_mode
: 0, 1 or 2; 0 - XML parser mode, 1 - HTML parser mode, 2 - 'dirty HTML' mode (with quiet recovery after any syntax error)

base_uri
: in HTML parser mode change all absolute references to relative from given base_uri (http://<host>:<port>/<path>)

content_encoding
: string with content encoding type of <document>; valid are 'ASCII', 'ISO', 'UTF8', 'ISO8859-1', 'LATIN-1' etc., defaults are 'UTF-8' for XML mode and 'LATIN-1' for HTML mode

content_language
: string with language tag of content of <document>; valid names are listed in IETF RFC 1766, default is 'x-any' (it means 'mix of words from various human languages)

dtd_validator_config
: configuration string for the DTD validator, default is empty string meaning that DTD validator should be fully disabled. See Configuration Options of the DTD Validator for details.

Return Types

Parse tree as a structure of nested heterogeneous vectors.

Examples

Example 24.516. XML_Persistent

```
declare tree any;

tree := xml_persistent (file_to_string ('doc.html'), 1,
                'http://localhost.localdomain/', 'ISO');
```

```
...
tree := xml_persistent (file_to_string ('doc.xml'));
```

See Also

xml_tree , xper_doc , xml_view_dtd , xml_validate_dtd

xml_template

xml_template — Execute XML template from Virtuoso PL

Synopsis

xml_template (in *xml_document_entity* any ,
in *parameters* vector ,
inout *session* string_session) ;

Description

The `xml_template()` function was introduced to enable PL programming to make use of XML templates. This function expects an XML entity for the first argument, that will be the XML template file contents. Usually this entity is composed making use of the `xtree_doc()` function from the XML template file.

The second argument should be a vector of name-value pairs of the parameters for XML template.

The last argument is an output string stream for the result. If the output stream is not specified the HTTP internal stream will be used if it is available, otherwise an error will be signalled.

Parameters

xml_document_entity
: XML entity such as that returned by xtree_doc()

parameters
: Vector or name-value pairs: vector('name1', 'value1', 'name2', 'value2', ...).

session
: Output stream for handling the results of XML template. If this parameter is unspecified then the HTTP internal stream will be assumed, which if not applicable will signal an error.

Return Types

A URL of the XSLT stylesheet for further transformation will be returned. If xsl attribute was not specified in the XML template then the return value will be NULL.

xml_tree

xml_tree — Parses an XML fragment and returns the parse tree as nested vectors.

Synopsis

xml_tree (in *document* varchar ,
in *parser_mode* integer ,
in *base_uri* varchar ,
in *content_encoding* varchar ,
in *content_language* varchar ,
in *dtd_validator_config* varchar) ;

Description

This parses the argument, which is expected to be a well formed XML fragment and returns a parse tree as a structure of nested heterogeneous vectors.

Parameters

document
: (mandatory) A well formed XML or HTML document

parser_mode
: 0, 1 or 2; 0 - XML parser mode, 1 - HTML parser mode, 2 - 'dirty HTML' mode (with quiet recovery after any syntax error)

base_uri
: (optional) in HTML parser mode change all absolute references to relative from given base_uri (http://<host>:<port>/<path>)

content_encoding
: (optional) string with content encoding type of <document> valid is 'ASCII', 'ISO', 'UTF8', 'ISO8859-1', 'LATIN-1'.

content_language
: (optional) - string with language tag of content of <document>; valid names are listed in IETF RFC 1766, default is 'x-any' (it means 'mix of words from various human languages).

dtd_validator_config
: configuration string for DTD validator, default is empty string meaning that DTD validator should be fully disabled. See Configuration Options of the DTD Validator for details.

Return Types

vector of vectors representing the parsed tree of XML.

Examples

Example 24.517. Making an XML tree

```
declare tree any;

tree := xml_tree (file_to_string ('doc.html'), 1,
                'http://localhost.localdomain/', 'ISO');
...
tree := xml_tree (file_to_string ('doc.xml'));
```

See Also

`xslt`, `xml_uri_get`, `xml_validate_dtd`.

xml_tree_doc

xml_tree_doc — returns an entity object given a tree from xml_tree

Synopsis

xml_tree_doc (in *tree* any ,
in *base_uri* varchar) ;

Description

This returns an entity object given a tree of the form returned by xml_tree.

If it is given a string as an argument, it will automatically generate the parse tree and use it to make the entity instead requiring you to run the string through xml_tree first. Note that it is better to use `xtree_doc` or `xper_doc` for converting source XML text directly to an XML entity.

If the argument is an XML tree entity, the function will return it as is, so e.g. redundant calls of `xml_tree_doc` will have no effect. The only thing xml_tree_doc can alter in the returned value is base URI of the document entity: if *`base_uri`* is provided and is not NULL, and argument entity has no base URI set then the provided URI is assigned to the returned entity.

Any other type of argument is illegal, including XML persistent entity.

Parameters

tree
: either an XML tree such as that returned by xml_tree(), or a string of XML data. If a string is provided then it will automatically generate the parse tree and form an entity instead of requiring you to run the string through xml_tree() first.

base_uri
: Base URI of the original document, if known. It will be useful if the document is not "standalone" and some entity references are relative references to resources located "somewhere near" the "top-level" document passes as "tree" parameter.

Return Types

XML entity object

Errors

Table 24.131. Errors signalled by

SQL State	Error Code	Error Text	Description

Examples

Example 24.518. Transforming an XML Document

```
declare doc_base varchar;
declare doc_tree any;

doc_base := 'virt://WS.WS.SYS_DAV_RES.RES_FULL_PATH.RES_CONTENT:/DAV/docsrc/';
doc_tree := xml_tree_doc(xml_tree(
    xml_uri_get(doc_base, 'virtdocs.xml')
      ), doc_base);

http_value(
  xslt('virt://WS.WS.SYS_DAV_RES.RES_FULL_PATH.RES_CONTENT:/DAV/stylesheets/html_chapter.xsl',
```

```
            doc_tree
          )
        );
```

xml_tree

xslt

xml_uri_get

xml_tree_doc_media_type

xml_tree_doc_media_type

Synopsis

varchar **xml_tree_doc_media_type** (in *xml_entity* any);

Description

This function returns the media type in effect for the result of the xslt() (XSL-T) transformation , based on xsl:output "media-type" and "method" attributes of the XSL-T style-sheet applied. It accepts an entity (potentially resulting from using xslt()) as a argument and will return a string containing the media-type.

Parameters

xml_entity
: An XML entity such as that returned by the xslt() function.

Return Types

If xsl:output "media-type" specified in XSL-T sheet it's value will be returned. If no "media-type" is specified, the valid results dependent on the <xsl:output "method" attribute are:

if unknown : non-string value

if 'html' : 'text/html'

if 'xhtml' : 'text/html'

if 'xml' : 'text/xml'

if 'text' : 'text/plain'.

Errors

This function can generate the following errors:

22023 SR003 Function xml_tree_doc_media_type needs an XML entity as argument 1, not an arg of type <type_name> (<type>)

Examples

Example 24.519. Assessing the media type

```
-- x.xsl --

`xml_tree_doc()`

xml_uri_get

xml_uri_get — Retrieve a resource based on a URI

Synopsis

```
varchar DB.DBA. xml_uri_get ( in base varchar ,
                              in ref varchar ) ;
```

Description

This function combines a base URI and a relative URI and returns the referenced resource.

The supported protocol identifiers are http: file: and virt:. The virt: allows referencing data stored in local Virtuoso tables without passing through HTTP. See 'Entity References in Stored XML' for details.

The effective URI will be the reference if the URI of the reference is absolute. Otherwise it will be the base URI modified by the relative reference.

Authorization is derived from the SQL or DAV identification of the caller. The DAV identification is used if processing DAV content in response to a DAV request. The SQL user account is used otherwise.

xml_uri_get returns the text of the requested resource. If specific encodings or special authentication schemes are desired one may use http_get directly.

Parameters

base
: A string containing the name of the location (URI) of the resource to be referenced.

ref
: The name of the resource as a relative reference from the base URI.

Return Types

The referenced resource.

Errors

Table 24.132. Errors signalled by

SQL State	Error Code	Error Text	Description

Examples

Example 24.520. Basic Application of xml_uri_get()

```
declare doc_base varchar;
declare doc_tree any;

doc_base := 'virt://WS.WS.SYS_DAV_RES.RES_FULL_PATH.RES_CONTENT:/DAV/docsrc/';
doc_tree := xml_tree_doc(xml_tree(
    xml_uri_get(doc_base, 'virtdocs.xml')
      ), doc_base);

http_value(
  xslt('virt://WS.WS.SYS_DAV_RES.RES_FULL_PATH.RES_CONTENT:/DAV/stylesheets/html_chapter.xsl',
    doc_tree
```

```
        )
    );
```

xml_validate_dtd

xml_validate_dtd — returns a string with list of errors detected by DTD validator on reading given XML document

Synopsis

xml_validate_dtd (in *document* varchar ,
in *parser_mode* integer ,
in *base_uri* varchar ,
in *content_encoding* varchar ,
in *content_language* varchar ,
in *dtd_validator_config* varchar) ;

Description

This parses the argument, which is expected to be an XML fragment (possibly with syntax errors, violations of validity conditions etc.) and returns a human-readable list of errors as a string. DTD validation may be performed during any reading of XML source in functions `xml_tree()` , `xml_persistent()` or `xper_doc()` , so that an application may check XML source on the fly; severe constraint violations in source XML will be signalled as SQL runtime errors.

Parameters

document
: XML or HTML document to check

parser_mode
: 0 or 1; 0 - XML parser mode 1 - HTML parser mode

base_uri
: in HTML parser mode change all absolute references to relative from given base_uri (http://<host>:<port>/<path>)

content_encoding
: string with content encoding type of <document>; valid are 'ASCII', 'ISO', 'UTF8', 'ISO8859-1', 'LATIN-1' etc., defaults are 'UTF-8' for XML mode and 'LATIN-1' for HTML mode

content_language
: string with language tag of content of <document>; valid names are listed in IETF RFC 1766, default is 'x-any' (it means 'mix of words from various human languages)

dtd_validator_config
: configuration string of the validator, default is empty string meaning that only critical errors should be reported. See Configuration Options of the DTD Validator for details.

Return Types

Human readable list of errors if applicable as a varchar.

Validating XML Against a DTD

Example 24.521. Simple Use

```
declare _result varchar;
_result := xml_validate_dtd (
  _text, 0, 'http://localhost.localdomain/xmlrepository', 'UTF-8', 'x-any',
  'Validation=SGML FsaBadWs=IGNORE BuildStandalone=ENABLE MaxErrors=100');

if (_res = '') _res := 'NO ERRORS DETECTED';
```

See Also

`xml_validate_schema()`

`xml_view_dtd()`

`xml_view_schema()`

xml_validate_schema

xml_validate_schema — returns a string with list of errors detected by DTD and XML Schema validator on reading given XML document.

Synopsis

```
xml_validate_schema ( in document varchar ,
                      in parser_mode integer ,
                      in base_uri varchar ,
                      in content_encoding varchar ,
                      in content_language varchar ,
                      in dtd_validator_config varchar ) ;
```

Description

This parses the argument, which is expected to be an XML fragment (possibly with syntax errors, violations of validity conditions etc.) and returns a human-readable list of errors as a string. If there is a "schemaLocation" attribute in root element, XML Schema declaration will be loaded and partial schema validation will be performed. If this attribute does not exist and the Validation option below is not set to DISABLED, then an error will be returned: ('FATAL : Schema declaration is not loaded').

The XML Schema validation routines are tightly coupled with DTD validator. If the document contains both Schema and DTD information then both validations are made in the same time in order to provide as accurate diagnostics as possible. However, it is impossible to check whether the declared DTD matches or contradicts to the declared Schema, so the parser performs two independent validations to every item of source data. E.g. if DTD contradicts to the schema in description of some particular element and data in the document does not contain this element then no errors is reported; but if sun an element occurs in the document then either DTD validator or Schema validator will log an error.

Parameters

document
: XML or HTML document to check

parser_mode
: 0 or 1; 0 - XML parser mode 1 - HTML parser mode

base_uri
: in HTML parser mode change all absolute references to relative from given base_uri (http://<host>:<port>/<path>)

content_encoding
: string with content encoding type of <document>; valid are 'ASCII', 'ISO', 'UTF8', 'ISO8859-1', 'LATIN-1' etc., defaults are 'UTF-8' for XML mode and 'LATIN-1' for HTML mode

content_language
: string with language tag of content of <document>; valid names are listed in IETF RFC 1766, default is 'x-any' (it means 'mix of words from various human languages)

dtd_validator_config
: configuration string of the validator, default is empty string meaning that DTD validator should be fully disabled and only critical errors should be reported. It is very probable that this is not the best choice for your application, so please refer Configuration Options of the DTD Validator to find out how to let validator to do better job.

Return Types

Human readable list of errors if applicable as a varchar.

Validating XML Against a DTD

Example 24.522. Simple Use

```
declare _result varchar;
_result := xml_validate_schema (
  _text, 0, 'http://localhost.localdomain/xmlrepository', 'UTF-8', 'x-any',
  'Validation=SGML FsaBadWs=IGNORE BuildStandalone=ENABLE MaxErrors=100');

if (_res = '') _res := 'NO ERRORS DETECTED';
```

xml_view_dtd

xml_view_dtd — returns an XML DTD for the output of given XML VIEW

Synopsis

```
varchar xml_view_dtd ( in view_name varchar ,
                       in root_element varchar ) ;
```

Description

This function will return an XML DTD for the output of a given XML VIEW. The returned DTD will be valid if the HTTP_... output of the view is wrapped into the specified root element.

Parameters

view_name
: Name of an XML View.

root_element
: Name of the root element.

Return Types

XML DTD for the given XML VIEW

See Also

`xml_view_schema()`

`xml_validate_dtd()`

`xml_persistent()`

xml_set_ns_decl

xml_set_ns_decl — Registers the XML NS prefix as persistent or keeps it in properties of client connection depending on the persistance bits input value.

Synopsis

xml_set_ns_decl (in *prefix* varchar ,
in *iri* varchar ,
in *bits* integer) ;

Description

Registers the XML NS prefix as persistent or keeps it in properties of client connection depending on the persistance bits input value.

Parameters

prefix
: namespace prefix

iri
: namespace IRI

bits
: persistance bits: bit 1 - keeps NS decl in properties of client connection i.e stores the assignment in connection parameters so only the current connection will see the namespace prefix declaration; bit 2 - makes NS decl persistent, i.e. stores the declaration in global in-memory hashtable as well as in a system table, loaded at server startup time, visible from all connections

Examples

Example 24.523. Northwind

```
DB.DBA.XML_SET_NS_DECL ('northwind', 'http://demo.openlinksw.com/schemas/northwind#', 2);
```

xml_remove_ns_by_prefix xml_remove_ns_by_prefix;

xml_view_schema

xml_view_schema — returns an XML schema for the output of given XML VIEW

Synopsis

```
varchar xml_view_schema ( in query varchar ,
                          in root_element varchar ) ;
```

Description

This function return an XML schema for the output of given XML VIEW. The returned schema will be valid if the HTTP_... output of view wrapped into the specified root element.

Parameters

query
: a string which contains a name of XML view

root_element
: a string containing the element name in which the XML schema would be wrapped

Return Types

XML Schema

Errors

xmlsql_update

xmlsql_update — Performs insert/update/delete operations based on an XML updategram.

Synopsis

xmlsql_update (in *xml_grams* XML_Entity ,
in *input_parameters* vector ,
in *debug* integer) ;

Description

`xmlsql_update()` supports XML-based insert, update, and delete operations performed on an existing table in the database. See Updategrams basics in the "Web and XML section" for a detailed explanation.

Parameters

xml_grams
: Mandatory parameter containing the XML document with gram(s). This can be produced with sequential calls to the xml_tree() and xml_tree_doc() functions.

input_parameters
: Optional array or vector of parameter pairs (parameter_name, parameter_value).

debug
: The debug parameter takes values 1/0 to enable(1) or disable(0) printing of the SQL statements it generates from the updategrams on the server's standard output. If not specified the default is disabled (0).

Return Values

Zero, if no error is signalled.

Errors

Table 24.134. Errors signalled by xmlsql_update

Error Code	Error Text
XP370	xmlsql_update needs an entity as argument
42000	xmlsql_update expects a vector of even length as second argument
SX999	Empty parameters list
SX998	Too many values for query
SX998	No columns specified in updategram

XMLUpdate

XMLUpdate — Create a changed copy of given document by replacing some nodes.

Synopsis

```
any XMLUpdate ( inout source any ,
                in path1 varchar ,
                in replacement1 any ,
                in path2 varchar ,
                in replacement2 any ,
                ... ,
                in pathN varchar ,
                in replacementN any ) ;
```

Description

The function takes of the XML document referenced by `source` XML tree entity, makes a copy of that document; then it modifies the copy by finding fragments that are values of `path1` , `path2` , ..., `pathN` XPATH expressions and replacing them with values specified by `replacement1` , `replacement2` , ...,`replacementN` ; the modified copy is returned as the result of the function call.

Every `pathI` should be a string that is a correct XPATH expression. Every such expression is evaluated according to the rules for XPATH expressions in XSLT (attribute entities are not cast to their string values). The context node is `source` , context size and position are both equal to 1.

Every `replacementI` may be an XML tree entity, a NULL or a value of some other type that will be converted to varchar before use.

For simplicity, consider the case when there is only one `path1` XPATH expression parameter and only one `replacement1` . First of all, a copy of the document of the `source` XML tree entity is created. Then `path1` is evaluated.

If the result of evaluation is not an XML entity then no replacement is made and the copy of the source document is returned unchanged. If the result is an XML entity that is not in the source document (e.g. an entity returned by the call of document(...) function.) then no replacement is made either.

If the result of evaluation is an XML entity in the source document then the function finds a node in the copied document that is a copy of the node in the source that is returned by XPATH evaluation. This node in the copied document will be referred to as a "highlighted" node.

If the result of evaluation is an attribute entity then the value of the attribute in the highlighted node is changed. If `replacement1` is NULL then the attribute is removed at all, otherwise its value is set to the string value of the `replacement1` .

If the result of evaluation is not an attribute entity but a entity then the highlighted node is replaced with the value of `replacement1` . The method of replacement depends on the type of the replacement value. If `replacement1` is NULL then the highlighted node is simply removed from the result; if the node is the root or a single child of the root then function immediately returns NULL instead of an XML entity (because XML document can not be totally empty), otherwise the parent of the highlighted node will simply have one child less. If `replacement1` is an non-empty string then the highlighted node is replaced with a new text node whose string value is equal to `replacement1` . If `replacement1` is an empty string then the effect is exactly the same as in case of NULL because the string value of a text node can not be empty. If `replacement1` is an XML entity that is a root entity of some document then the highlighted node is replaced with a sequence of copies of all children of that root. If `replacement1` is an XML entity of some other sort (XML element, text, comment etc.) then the that is not a root entity of some document then the highlighted node is replaced with a sequence of copies of all children of that root.

After editing the copied document, some normalization may happen. The modified document may contain adjacent text nodes; every sequence of such nodes is replaced with one text node whose string value is a concatenation of string values of that nodes.

E.g. if the highlighted node is an element <a/> that resides between two text nodes "text1" and "text2" and the highlighted node is removed, then these text nodes become neighbors; normalization will replace them with a single text node "text1text2"

Now consider the case of more than one replacement made in one function call. If more than one pair of XPATH expression and replacement is given then the function first finds all highlighted nodes, all together, then it performs all replacements, then it performs an normalization. It is very important to understand that the order of making replacements has nothing to do with the order of pairs of parameters in the function call. If some highlighted node is an ancestor of some other highlighted node then the effect of the replacement of the descendant highlighted node is void: the descendant is replaced first; then the ancestor is replaced as a whole, no matter if some of its descendants are modified. If a node is the result of two different XPATH expressions ("highlighted more than once"), the order of parameters in the function call is used to resolve ambiguity: the last pair of parameters will have a higher priority.

Parameters

source
: A source XML tree entity. It is an error to pass persistent XML entity as an argument.

pathI
: A text of XPATH expression to be used in order to find nodes to replace.

replacementI
: A replacement value for XML nodes found by pathI ; it may be NULL or XML tree entity or a string r anything else but not an persistent XML entity.

Return Types

If the *source* parameter is an XML tree entity then the function returns an XML tree entity that points to the root of the modified copy of the source document or a NULL. If the *source* is an instance of XMLType then a non-schema based instance of XMLType is created from the resulting XML tree entity.

Examples

Example 24.525. A simple replacement of one element with other

The call of function XMLUpdate replaces element 'c' with a copy of element 'replacement'.

```
select XMLUpdate (xtree_doc('<a><b><q/>-<c>Hello</c>-</b></a>'), '//c', xtree_doc('<replacement/>'))
callret
VARCHAR
_______________________________________________________________________________

<a>
<b>
<q />-
<replacement />-
</b>
</a>
```

Example 24.526. Two replacements in parallel

Elements titled 'c1' and 'c3' are replaced with text nodes.

```
select XMLUpdate (xtree_doc('
<a>
<b>
<c1>Hello1
</c1>
<c2>Hello2
</c2>
<c3>Hello3
</c3>
</b>
```

```
</a>'), '//c1', 'world1', '//c3', 'world3')
callret
VARCHAR
_______________________________________________________________________________

<a>
<b>world1
<c2>Hello2
</c2>world3
</b>
</a>
```

xslt

xpath_eval

xpath_eval — Applies an XPATH expression to a context node and returns result(s).

Synopsis

xpath_eval (in *xpath_expression* varchar ,
in *xml_tree* XML Entity ,
in *index* integer ,
in *named_params* vector) ;

Description

This function returns the result of applying the XPath expression to the context node. By default only the first result is returned, but supplying a third argument allows you to specify an index for the value; the default assumes a value of 1 here. A value of 0 returns an array of 0 or more elements, one for each value selected by the XPath expression.

When this function returns an entity in a result set, the client will see an nvarchar value containing the serialization of the entity, complete with markup. When the entity is passed as an SQL value it remains an entity referencing the node of a parsed XML tree, permitting navigation inside the tree.

The expression can be passed parameters by specifying a fourth argument to `xpath_eval()` . This will be a vector of name/value pairs. The values can be referenced from inside XPath expression by using their names with '$' prefix. You may use any Virtuoso data type. The names in the parameter vector should appear without the '$' sign. If any of the parameter values is NULL the parameter will be ignored because NULL has no XPath counterpart. If the same name appears more than once in the vector, the last name/value pair is used and all preceding pairs with this name are silently ignored. Obviously, names should be strings that are valid XPath variable names.

Parameters

xpath_expression
: A valid XPATH expression. In almost all application this is a string. There is a tricky extension that is used by BPEL-like applications: xpath_expression can be an XML entity whost string-value is a valid XPATH expression. An example of such an entity is "select" or "test" attribute in XSLT stylesheet. This trick lets XPATH processor to resolve namespace prefixes by looking at namespace declarations at the header of the stylesheet.

xml_tree
: An XML entity such as that returned from the xtree_doc() function.

index
: Result index. This parameter is optional. If omitted a value of 1 is assumed, meaning only the first result is returned. If a value of 0 is supplied then an array of 0 or more elements is returned containing one element per result.

named_params
: A vector of keyword/value parameters to be passed to the XPath processor.

Return Types

This function will return the first or *`index`* selected result of applying the XPath expression to the *`xml_tree`* input. If an *`index`* value of 0 is supplied then the output is an array.

Errors

Table 24.135. Errors signalled by xpath_eval

SQL State	Error Code	Error Text	Description
XP370	XI009		

SQL State	Error Code	Error Text	Description
		Argument 2 of xpath_eval must be an entity, not a value of type [type name] ([type code])	The *xml_tree* parameter should always be an entity. In some cases the XPath expression does not use context entity, but it should be provided anyway (e.g. some fake document).

Examples

Example 24.527. Finding the Authors of Document Titles

```
select xt_file, xpath_eval ('//author', t) from xml_text
        where xpath_contains (xt_text, '//chapter/title[. = 'Introduction']', t);
```

This will select all titles that are descendants of chapter and have a string value of 'Introduction'. This will next evaluate *//author* in the context of each, retrieving the author entities in the document of the title.

Example 24.528. xpath_eval and Repeating Nodes.

This example shows how the xpath_eval can be used to retrieve multiple node answers to queries. First to set the scene consider the following statements that create a table with XML inside.

```
CREATE TABLE t_articles (
        article_id int NOT NULL,
        article_title varchar(255) NOT NULL,
        article_xml long varchar
        );

insert into t_articles (article_id, article_title) values (1, 'a');
insert into t_articles (article_id, article_title) values (2, 'b');

UPDATE t_articles SET article_xml = '
<beatles id = "b1">
<beatle instrument = "guitar" alive = "no">john lennon</beatle>
<beatle instrument = "guitar" alive = "no">george harrison</beatle>
</beatles>'
WHERE article_id = 1;

UPDATE t_articles SET article_xml = '
<beatles id = "b2">
<beatle instrument = "bass" alive = "yes">paul mccartney</beatle>
<beatle instrument = "drums" alive = "yes">ringo starr</beatle>
</beatles>'
WHERE article_id = 2;
```

Now we make a query that will return a vector of results, each vector element corresponding to a node-set of the result.

```
SELECT xpath_eval('//beatle/@instrument', xml_tree_doc (article_xml), 0)
        AS beatle_instrument FROM t_articles WHERE article_id = 2;
```

The repeating nodes are returned as part of a vector, the third argument to xpath_eval is set to 0, which means that it is to return all nodes.

Otherwise, we can select the first node-set by supplying 1 as the third parameter to xpath_eval:

```
SELECT xpath_eval('//beatle/@instrument', xml_tree_doc (article_xml), 1)
        AS beatle_instrument FROM t_articles WHERE article_id = 2;
```

Example 24.529. Passing a named parameter to the XPath

```
SQL> select xpath_eval(
  '//phone[../name like $$n]',
  xtree_doc ('<phonebook>
```

```
      <dept><name>Installation Service</name><phone>555-1111</phone></dept>
      <dept><name>Tech Support</name><phone>555-1112</phone></dept>
    </phonebook>'),
  1,
  vector('n', 'Tech%') );
callret
VARCHAR
_______________________________________________________________________________

<phone>555-1112</phone>
```

Like in SQL queries, XPath parameters are used to avoid printing literal values into the text of the query. The listing above demonstrates how to find the phone of the first department whose name is like the specified pattern.

Note that if the text of the XPath expression is entered as a string in ISQL, dollar signs in front of parameter names should be doubled, as in this sample. ISQL uses the same syntax ($name) for macro expansion, and double dollar sign is replaced by ISQL with single dollar sign character.

xcontains SQL Predicate

xper_cut

xper_cut — creates a new "persistent XML"document which contains a copy of data pointed by given XPER entity

Synopsis

xper_cut (in *source_xper* XML_Entity) ;

Description

As noted in the Storage in Database section, a subtree may be extracted from a document during writing of "persistent XML" entity into field of type LONG VARCHAR. The procedure of converting a subtree into complete document is known as "cutting". Cutting is performed only for "persistent XML" documents, it has nothing common with serialization of XML entities in form of plain XML text.

Usually it is the job of the Server itself who decides whether a cutting operation should be performed or not, without any specific activity at application level. The CPU time occupied due to cutting is up to 10 times greater than the CPU time of plain copying of LONG VARCHAR, but the amount of disk I/O is about the same, so the optimization rules discussed below are important only for time-critical, memory-located database applications.

The Virtuoso Server tries to reduce the number of cuttings to an absolute minimum. First of all, cutting is not performed when a given XML entity refers to the root of the document, or to the only child of the root, because the result of such cutting will be identical to original document. In addition, every document remembers the result of last cutting performed on data from this document, so if data of some XML entity are saved in many places without saving of other XML entities between them, cutting will be done only once and plain copying will be done for every subsequent saving.

The only situation when cutting may be seriously optimized by the application developer is in code like the following:

```
declare _blank_forms, _plain, _isdn any;
_blank_forms := xml_persistent ('file://blank_forms.xml');
_plain = xpath_eval ('/forms/form[@name = ''Phone Installation'']', _blank_forms);
_isdn = xpath_eval ('/forms/form[@name = ''ISDN Installation'']', _blank_forms);
for select ID as _id, SERVICE as _service, ADDRESS as _address from CLIENTS do
{
  if (is_isdn(_service))
    {
      insert into JOB_DETAILS (ID, QUERY_XML) values (_id, _isdn);
    }
  else
    {
      insert into JOB_DETAILS (ID, QUERY_XML) values (_id, _plain);
    }
}
```

Calls of xpath_eval are outside the loop, so it is faster than retrieval of suitable form for every selected record. But values of both _plain and _isdn shares the same underlying XML document and they will be assigned many times by the 'insert' operation. The XML document has no place to cache two results of cuttings, so new cutting will be done every time when _isdn entity is saved after _plain or _plain saved after _isdn. To optimize, it is better to cut them once outside the loop:

```
declare _blank_forms, _plain, _isdn any;
_blank_forms := xml_persistent ('file://blank_forms.xml');
_plain = xper_cut (xpath_eval ('/forms/form[@name = ''Phone Installation'']', _blank_forms));
_isdn = xper_cut (xpath_eval ('/forms/form[@name = ''ISDN Installation'']', _blank_forms));
for select ID as _id, SERVICE as _service from CLIENTS do
{
  if (is_isdn(_service))
    {
-- _isdn entity points to the root of its own document, cutting is not needed for root.
      insert into JOB_DETAILS (ID, QUERY_XML) values (_id, _isdn);
    }
  else
    {
-- similarly, _plain entity points to the root of its own document.
      insert into JOB_DETAILS (ID, QUERY_XML) values (_id, _plain);
```

```
    }
}
-- If no records found by the 'select' and no inserts done,
-- then we've made two cuts for nothing...
```

The current node of the resulting entity is the node that is a copy of the current node of the source entity. In common, the top-level node of the copied subtree becomes the current node of the result. There are two special cases, however. If the source entity is an attribute entity, then the result is also an attribute entity and the attribute name remains the same. If the source entity points to the root of the document, the resulting entity also points to the root, not to its top-level node.

Parameters

source_xper
: XML Entity

xml_doc()

xper_doc()

xper_right_sibling(), xper_left_sibling(), xper_parent(), xper_root_entity(), xper_tell(), xper_length()

xper_doc

xper_doc — returns an entity object ('XPER entity') created from an XML document

Synopsis

```
xper_doc ( in document varchar ,
           in parser_mode integer ,
           in base_uri varchar ,
           in content_encoding varchar ,
           in content_language varchar ,
           in dtd_validator_config varchar ,
           in index_attrs integer ) ;
```

Description

This parses the argument, which is expected to be a well formed XML fragment and returns a parse tree as a special object with underlying disk structure, named "persistent XML" or "XPER" While the result of xml_tree is a memory-resident array of vectors, the XPER object consumes only a little amount of memory, and almost all data are disk-resident. XPERs are better then "XML trees" for large documents and for "write once -- read many" stores such as a table with one XML document per row used as a "library" of documents. To be saved in a LONG VARCHAR column, "XML tree" entity will be converted back to plain text of XML syntax; but "XPER" entity will be saved as a ready-to-use disk structure.

Parameters

document
: well formed XML or HTML document

parser_mode
: 0, 1 or 2; 0 - XML parser mode, 1 - HTML parser mode, 2 - 'dirty HTML' mode (with quiet recovery after any syntax error)

base_uri
: in HTML parser mode change all absolute references to relative from given base_uri (http://<host>:<port>/<path>)

content_encoding
: string with content encoding type of <document>; valid are 'ASCII', 'ISO', 'UTF8', 'ISO8859-1', 'LATIN-1' etc., defaults are 'UTF-8' for XML mode and 'LATIN-1' for HTML mode.

content_language
: string with language tag of content of <document>; valid names are listed in IETF RFC 1766, default is 'x-any' (it means 'mix of words from various human languages)

dtd_validator_config
: configuration string for DTD validator, default is empty string meaning that DTD validator should be fully disabled. See Configuration Options of the DTD Validator for details.

index_attrs
: 1 or 0, indicating if additional free-text indexing information must be stored for all attributes of the document. It is 1 by default. If set to '0', it will produce a disk structure compatible with old versions of Virtuoso and will give a small benefit in disk usage but it will disable some important optimizations in free-text search operations.

Return Types

XML entity with underlying parse tree of source document; the tree will be a special sort of BLOB.

Examples

Example 24.530. Xper_Doc

```
declare tree any;

tree := xper_doc (file_to_string ('doc.html'), 1,
                'http://localhost.localdomain/', 'ISO');
...
tree := xper_doc (file_to_string ('doc.xml'));
...
-- String cannot be longer than 10 megabytes. String session can.
tree := xper_doc (file_to_string_output ('huge_doc.xml'));
...
-- A special way to read local files.
-- Strings started from characters 'file://'
-- are treated as local filesystem URIs.
tree := xper_doc ('file://doc.xml');
```

xper_cut

xper_right_sibling, xper_left_sibling, xper_parent, xper_root_entity, xper_tell, xper_length

xper_locate_words

xper_locate_words — returns a smallest fragment of persistent XML entity object ('XPER entity') such that it contains some range of words in its text

Synopsis

xper_locate_words (in *entity* any ,
in *starting_word* integer ,
in *ending_word* integer) ;

Description

This receives the XML entity and returns its fragment or signals an error.

Parameters

entity
: A 'persistent XML' entity to be searched

starting_word
: The number of the leftmost word which should be in the selected fragment

ending_word
: The number of the rightmost word which should be in the selected fragment

XPER navigation

xper_right_sibling , xper_left_sibling , xper_parent , xper_root_entity , xper_tell , xper_length — low-level navigation functions for persistent XMLs, useful for import of huge amounts of XML data

Synopsis

xper_right_sibling (in *xper_entity* XML_entity);

xper_left_sibling (in *xper_entity* XML_entity);

xper_parent (in *xper_entity* XML_entity);

xper_root_entity (in *xper_entity* XML_entity);

xper_tell (in *xper_entity* XML_entity);

xper_length (in *xper_entity* XML_entity);

Description

All these functions work with "persistent XML" (XPER) entities only, signalling errors if given entity points to "XML tree". They are useful when applications need to read a huge XML document, especially something like a datasheet dump or event log with a large number of uniform records, and is required to process all records of the document, e.g. import them into the database.

Consider a real sample of import all data from ODP's content.xml dump which contains more than 2,000,000 descriptions of various Web-sites, and the length of the file is more than 600Mb. The file has root element named 'RDF' and all descriptions are their children named either 'Topic' or 'ExternalPage'. This code looks suitable for importing these children:

```
create procedure
  import_content_xml ()
  {
    for select _frag, xpath_eval('local_name()', _frag) as _tag from SOURCE_XML
      where NAME='content.xml' and xpath_contains(XPER,'/RDF/*',_frag)
    do
    {
      if (_tag='Topic') import_topic (_frag);
      else
      {
        if (_tag='ExternalPage') import_external (_frag);
        else log_import_error (_frag, "Unknown type of record");
      }
    }
  };
  -- This should load files like content.xml, and place XPERs into SOURCE_XML table

read_source_xmls();
  -- Now SOURCE_XML is filled and data should be imported.

import_content_xml();
import_structure_xml();
import_profiles_xml();
 ...
```

It looks fine and it passes small tests but it will not work on real data!

First problem is regular checkpoints (every 1 hour by default), so import_content_xml has no chance to be completed if it takes 1.5 hours of CPU time; the function checkpoint_interval should be used to temporarily disable these checkpoints. Then, the length of transaction log become extremely large after switching checkpoints off, and it is better to insert explicit checkpoints between calls of these functions. Finally, import_content_xml will change more than 4 gigabytes of data in one transaction. This would be impossible on any 32-bit platform, because both memory available and address space become insufficient. Adding intermediate

'commit work' statements inside the loop's body will not help because both 'commit work' and 'rollback work' statements will close all opened cursors. Loop 'for select ... from ... do' uses an implicit cursor to iterate the resultset, but the 'commit work' operator will close this cursor and abort the loop.

Function xper_right_sibling is designed specially to solve the last problem. It allows you to iterate children of some element without using any cursor at all. It returns the right child of the entity passed as its argument. If the given entity is the last child of its parent, the function will return NULL. Similarly, xper_left_sibling will return the previous child or NULL for the first child, xper_parent will return parent of entity or NULL for the document's root and xper_root_entity will return the root for any entity. Using these functions, it is possible to scan the document forward (from left to right), backward and to "climb up" toward the root of the elements' tree. These functions are called *XML Navigation Functions* because they are like the statements "next record", "prev record" etc., used in cursor like navigation of databases.

There are no special functions to "go down", e.g. to find first children of given element, because xpath_eval can do any such movement very quickly.

Sometimes data import is controlled from some client application. If one operation takes hours, some sort of "progress bar" becomes very useful, at least to see whether application works or hangs. xper_length takes an XPER entity and returns whole length of XPER disk image in bytes. xper_tell takes an XPER entity and returns something like entity's offset inside the document. Their results may be used by the client application to monitor the progress and estimate the time until completion. They may be especially useful for debugging purposes, e.g. to report position of error. Unfortunately "xper_seek" is not possible for XPERs, unlike typical random access to files.

Ultimately, the working version of the procedure described above will look like this:

```
create procedure
  import_content_xml ()
  {
    declare _frag any;
    declare _tag any;
    declare _nodeid any;
    declare _r_id varchar;
    declare _about, _title, _description varchar;
    declare CurTime varchar;
    declare Frags, Inserts, Pos, Length integer;

    select _frag1 into _frag from SOURCE_XML
      where NAME = 'content.xml' and xpath_contains (XPER, '/RDF/*', _frag1);

    if (not isentity(_frag)) signal('42ODP', 'XML source "Content" is empty');

    Frags := 0;
    Inserts := 0;
    Length := xper_length(_frag);
    result_names (CurTime, Frags, Pos, Length);
    -- It's not the best way to process deadlocks, but it may be better than nothing.

    whenever sqlstate '40001' goto next_frag;

    next_frag:

    -- Server will inform client application about progress after every 10000 records.
    if (mod(Frags,10000) = 0)
    {
      -- Note that if it needs to estimate the time to completion, time should be measured
      -- on server side, because results may be returned on batches to reduce network
      -- traffic, and it may be a significant delay between call of result function on
      -- server and fetch on client side.
      CurTime := cast(now() as varchar);
      Pos := xper_tell(_frag);
      result (CurTime, Frags, Inserts, Pos, Length);
    }
    _tag := xpath_eval('local-name()', _frag);
    if (_tag = 'Topic')
    {
      import_topic(_frag);
      goto advance;
    }
    if (_tag = 'ExternalPage')
    {
```

```
    import_external(_frag);
    goto advance;
  }
  log_import_error (_frag, "Unknown type of record");
  goto nocommit_advance;

  advance:
  Inserts := Inserts + 1;
  -- Note that it may be faster to have 1 commit per 100 or 1000 records in some cases.

  commit work;

  nocommit_advance:
  Frags := Frags + 1;

  _frag := xper_right_sibling(_frag);
  if (isentity(_frag)) goto next_frag; -- If _frag is NULL, we've completed the import.

  CurTime := cast(now() as varchar);
  result (CurTime, Frags, Inserts, Length, Length);
};

checkpoint_interval(0);
checkpoint;

read_source_xmls();
checkpoint;

import_content_xml();
checkpoint;

import_structure_xml();
checkpoint;

import_profiles_xml();
checkpoint;
...

checkpoint_interval(60);
```

Parameters

xper_entity
: Persistent XML entity to operate on.

xper_doc()

xper_cut()

xpf_extension

xpf_extension — declare an XPath extension function

Synopsis

```
void xpf_extension ( in fname varchar ,
                     in procedure_name varchar ) ;
```

Description

This function is used to declare a new XPath extension function or redefine an existing function. It can be used in XPath queries and XSLT stylesheets. You should use QNames for extension functions. Note that the standard XPath functions cannot be redefined.

`xpf_extension()` stores the functions into the SYS_XPF_EXTENSIONS system table.

```
CREATE TABLE
  DB.DBA.SYS_XPF_EXTENSIONS (
      XPE_NAME VARCHAR PRIMARY KEY,
      XPE_PNAME VARCHAR
      )
```

The input parameters will be retrieved as a strings and then will be converted to the datatype of the corresponding argument of the stored procedure.

Parameters

fname
: The name of the extension function, which must be the expanded QName of the extension function

procedure_name
: The fully qualified name of the PL procedure which acts as the extension function. The procedure in question must be granted to PUBLIC, otherwise it will not be registered and error will be signalled.

Return Types

None (void).

Errors

Table 24.136. Errors signalled by

SQLState	Error Code	Error Text	Description
42001	XPE01	The function <procedure_name> does not exists	if procedure to define as a XPATH extension function is not existing one.
42001	XPE02	The <built-in XPATH|XQUERY> function " <func name>" cannot be re-defined	if XPATH or XQUERY function to be registered is a core function.

Examples

Example 24.531. Declaring a New XSLT Function

First define a PL procedure, then declare an XPath extension function and to represent it.

```
SQL> create procedure DB.DBA.str_concat (in a varchar, in b varchar)
```

```
      {
        return concat (a, ':', b);
      };

SQL> xpf_extension ('http://example.com/virtuoso/xslt:concat_strings', 'DB.DBA.str_concat');
```

The source of the ([http_root]/ext.xsl) XSLT stylesheet

```
<?xml version='1.0'?>

<xsl:stylesheet
    xmlns:xsl="http://www.w3.org/TR/WD-xsl"
  xmlns:virt="http://example.com/virtuoso/xslt">

  <xsl:template match="/doc">
    <HTML>
     <BODY>
     <xsl:if test="function-available('virt:concat_strings')">
      <xsl:value-of select="virt:concat_strings ('foo', 'bar')"/>
     </xsl:if>
     </BODY>
    </HTML>
  </xsl:template>
</xsl:stylesheet>
```

The source of the

```
([http_root]/ext.vsp)
```

VSP page:

```
<?vsp
  http_xslt ('file:/ext.xsl');
?>
<doc>
<a/>
</doc>
```

This will produce the following HTML page:

```
<HTML><BODY>foo:bar</BODY></HTML>
```

Using the definition of the XPath extension function, we can include it in XPath expressions.

```
SQL> select p from ws..sys_dav_res
where xpath_contains (RES_CONTENT,
'[xmlns:virt=''http://example.com/virtuoso/xslt'']
virt:concat_strings (''Title '', string(/chapter/title))', p);
```

This will return the contents of any '/chapter/title' nodes, prefixed with constant string 'Title'.

`xpf_extension_remove`

xpf_extension_remove

xpf_extension_remove — discards an XPath extension function

Synopsis

```
void xpf_extension_remove ( in fname varchar ,
                            in procedure_name varchar ) ;
```

Description

Removes a user-defined XPath function.

Parameters

fname
: The expanded QName of the extension function to be removed

procedure_name
: The fully qualified name of the PL procedure which acts as the extension function.

Return Types

None (void).

Errors

Table 24.137. Errors signalled by

SQLState	Error Code	Error Text	Description
42001	XPE03	The <built-in XPATH|XQUERY> function " <func name>" cannot be removed	if XPATH or XQUERY function to be un-registered is a core function.

`xpf_extension()`

xquery_eval

xquery_eval — Applies an XQUERY expression to a context node and returns result(s).

Synopsis

xquery_eval (in *xquery_expression* varchar ,
in *xml_tree* XML Entity ,
in *index* integer ,
in *named_params* vector) ;

Description

The xquery_eval function returns the result of applying the xquery expression to the context node. By default only the first result is returned, but supplying a third argument allows you to specify an index for the value, the default assumes a value of 1 here. A value of 0 returns an array of 0 or more elements, one for each value calculated by the xquery expression.

When an entity is returned in a result set to a client the client will see an nvarchar value containing the serialization of the entity, complete with markup. When the entity is passed as a SQL value it remains an entity referencing the node of a parsed XML tree, permitting navigation inside the tree.

The expression can be passed parameters by specifying a fourth argument to `xquery_eval()` . This will be a vector of name/value pairs. The values can be referenced from inside XPath expression by using their names with '$' prefix. You may use any Virtuoso data type. The names in the parameter vector should appear without the '$' sign. If any of the parameter values is NULL the parameter will be ignored because NULL has no XPath counterpart. If the same name appears more than once in the vector, the last name/value pair is used and all preceding pairs with this name are silently ignored. Obviously, names should be strings that are valid XQuery variable names.

Parameters

xquery_expression
: A valid XQuery expression. In almost all applications this is a string. There is a tricky extension that is used by BPEL-like applications: xpath_expression can be an XML entity whost string-value is a valid XQuery expression. An example of such an entity is "select" or "test" attribute in XSLT stylesheet. This trick lets XQuery processor to resolve namespace prefixes by looking at namespace declarations at the header of the stylesheet.

xml_tree
: An XML entity such as that returned from the xtree_doc() function.

index
: Result index. This parameter is optional. If omitted a value of 1 is assumed, meaning only the first result is returned. If a value of 0 is supplied then an array of 0 or more results is returned containing one element per result. (Note that results can be in turn sequences of atomic values).

named_params
: A vector of keyword/value parameters to be passed to the XQuery processor.

Return Types

This function will return the first or index selected result of applying the xpath expression to the *`xml_tree`* input. If an index value of 0 is supplied then the output is an array.

Examples

Example 24.532. Finding the Authors of Document Titles

```
select xt_file, xquery_eval ('<authors>//author</authors>', t) from xml_text
        where xpath_contains (xt_text, '//chapter/title[. = 'Introduction']', t);
```

This will select all titles that are descendants of chapter and have a string value of 'Introduction'. This will next evaluate //author in the context of each, retrieving the author entities in the document of the title and construct an element whose name is "authors" and list of children contains all retrieved entities.

`xpath_eval()`

xpath_contains SQL predicate

xcontains SQL predicate

`processXQuery()`

xslt

xslt — returns an XML document transformed by an XSLT stylesheet

Synopsis

```
xml_entity xslt ( in sheet_uri varchar ,
                  in entity any ,
                  in sheet_params vector ) ;
```

Description

This function takes the URI of a stylesheet and an XML entity and produces an XML entity representing the transformation result of the given entity with the given stylesheet. The result tree is separate from the argument tree and the only reference to it is the returned entity. Errors occurring in the transformation will be signalled as SQL states, with XML or XSLT specific conditions beginning with XS or XP.

The stylesheet can be passed parameters by specifying a third argument to `xslt()` . This will be a vector of name/value pairs. The values can be referenced from inside XPath expressions in the stylesheet. You may use any Virtuoso data type. The names in the parameter vector should appear without the '$' sign. If any of the parameter values is NULL the parameter will be ignored because NULL has no XPath counterpart. If the same name appears more than once in the vector, the last name/value pair is used and all preceding pairs with this name are silently ignored. Obviously, names should be strings that are valid XPath variable names.

`xslt()` applies the transformation in the sheet to the specified entity. The result is the root element of the result tree, an XML entity. This entity can be used as input to another transformation, can be serialized and sent to an HTTP client or stored, etc.

The URI of the sheet is used to locate the stylesheet. The protocol can be http, file or virt. Once the stylesheet has been retrieved it is cached and not refetched until the cache is invalidated with `xslt_stale()` . Included or imported style sheets will be fetched automatically, using the initial URI as base for any relative references. The *`sheet_uri`* is the URI of a stylesheet. This should be an absolute URI resolvable with `xml_uri_get()` . If the URI has previously been used as a stylesheet and has not been marked stale with `xslt_stale()` , Virtuoso will use the cached data instead of fetching and parsing the stylesheet resource.

When a resource with a .xsl extension is stored into the WebDAV, Virtuoso marks as stale any related cached resource. The URI for such stylesheets will be

```
virt://WS.WS.SYS_DAV_RES.RES_FULL_PATH.RES_CONTENT:<path>
```

. See the section about entity references in stored text for more on this type of URI. If the URI uses the file protocol, Virtuoso will compare the date of the file against the date of the cached stylesheet, automatically reloading the sheet if the file changes. This protocol is subject to the limitations on file system access imposed by the host operating system and the virtuoso.ini file system access control settings.

Parameters

sheet_uri
: URI pointing to the location of an XSL stylesheet.

entity
: parsed XML entity such as that returned by the xtree_doc() function

sheet_params
: A vector of keyword/value parameters to be passed to the XSLT engine for use in the transformation.

Return Types

An XML entity resulting from transforming the given XML entity input with the given style sheet.

Examples

Example 24.533. Basic Use

```
declare sheet, xml varchar;
declare xml_entity, myparams any;

sheet := 'virt://WS.WS.SYS_DAV_RES.RES_FULL_PATH.RES_CONTENT:/DAV/stylesheets/mysheet.xsl';
xml := 'virt://WS.WS.SYS_DAV_RES.RES_FULL_PATH.RES_CONTENT:/DAV/xmlsource/myxml.xml';
xml_entity := xtree_doc(xml);

myparams := vector('chapter', 'overview', 'imgroot', '/DAV/images/');

http_value(xslt(sheet, xml_entity, myparams));
```

This code will send the resultant transformation to the http stream. Note that the *xml_entity* must be a parsed XML entity such as that produced by *xtree_doc*.

```
<?xml version='1.0'?>

<xsl:stylesheet
    xmlns:xsl="http://www.w3.org/TR/WD-xsl">

  <xsl:param name="chapter">default</xsl:param>
  <xsl:param name="imgroot"></xsl:param>

  <xsl:template match="/">
    <xsl:text>Value of chapter: </xsl:text><xsl:value-of select="$chapter" />
    <xsl:text>Value of imgroot: </xsl:text><xsl:value-of select="$imgroot" />
  </xsl:template>

</xsl:stylesheet>
```

This style sheet illustrates using parameters. Note how default values can be provided in the style sheet when the parameters are declared using the *xsl:param* tag.

xslt_format_number

xslt_format_number — returns formatted string representation of a numeric value

Synopsis

xslt_format_number (*number* any ,
format_string varchar) ;

Description

xslt_format_number is an function wrapper for the format-number() XSLT function.

It always uses the default formatting parameters described in the XSLT standard.

Parameters

number
: integer , numeric or string .

format_string
: string

Return Values

An string representation of the numeric value of *number* converted according to the format *format_string* .

Examples

Example 24.534. Simple examples

```
xslt_format_number (5351, '#,###'),        5,351
xslt_format_number ('5351', '#.00'),       5351.00
xslt_format_number (53.51, '#.0000'),      53.5100
xslt_format_number (53.51, '0000.0000'),   0053.5100
xslt_format_number (53.51, '0000.####'),   0053.51
xslt_format_number (53.56, '0.0');            53.6
```

casting

xslt_sheet

xslt_sheet — declares an XSL stylesheet for use

Synopsis

xslt_sheet (in *uri* varchar ,
in *entity* any) ;

Description

This function takes a name and the root element of a parsed XML document and defines these as a stylesheet. The unique element child of the entity object's document should be an xsl:stylesheet element. Included or imported stylesheets will be located relative to the base URI of the entity passed to `xslt_sheet()` . Once a stylesheet thus defined it can be used as the stylesheet argument of xslt.

Parameters

uri
: The location of the XSLT style sheet

entity
: A valid XSL style sheet, XML entity parsed using the xml_tree_doc() function

Examples

Example 24.535. Preparing a Style Sheet from the File System

The `xslt_view()` function first defines the style sheet from a file. The `xslt_sheet()` function is called with the name and the root element of the parsed file. `xslt_view()` next gets the string to process, parses the string as XML and converts the parse tree into an entity object. This is then passed to the `xslt()` function. The result is another entity object. This is finally serialized as XML text and written into the file *`xslt.out`* .

```
create procedure xslt_view (in v varchar, in xst varchar)
{
  declare str, r varchar;
  xslt_sheet (xst, xml_tree_doc (xml_tree  (file_to_string (xst))));
  str := xml_view_string (v);
  r := xslt (xst, xml_tree_doc (xml_tree (str)));
  declare str any;
  str := string_output ();
  http_value (r, 0, str);
  string_to_file ('xslt.out', string_output_string (str), 0);
}
```

See Also

`xml_tree_doc()`

xslt_stale

xslt_stale — force reload of XSL stylesheet

Synopsis

xslt_stale (in *uri* varchar);

Description

This function can be used to force Virtuoso to reload a cached stylesheet from the URI when next used with `xslt()` or `http_xslt()` . Using this function before every application of the stylesheet is extremely inefficient. If stylesheets are stored in the database, you can use this function in an update trigger on the table storing the stylesheets but you don't have to use it before every application of the sheet.

This function never needs to be applied to a stylesheet URI with the file:// protocol since `xslt()` and `http_xslt()` will automatically detect a stale cache entry. However if the stylesheet is stored on a remote web server, or if the stylesheet contains subdocuments (e.g. external XML entities, xsl:include or xsl:import statements) this function is needed to force a reload.

Parameters

uri
: The location of the style sheet to force a reload.

Errors

The function never signals any errors. E.g. it is not an error if the specified stylesheet does not exist or if the specified stylesheet is used by other transaction when the `xslt_stale()` is called.

Examples

Example 24.536. Simple Use

```
sheet := 'virt://WS.WS.SYS_DAV_RES.RES_FULL_PATH.RES_CONTENT:/DAV/stylesheets/document.xsl';
xslt_stale (sheet);
xslt(sheet, xml_doc_tree);
```

`xslt()`

`http_xslt()`

xtree_doc

xtree_doc — returns an entity object created from an XML document

Synopsis

xtree_doc (in *document* varchar ,
in *parser_mode* integer ,
in *base_uri* varchar ,
in *content_encoding* varchar ,
in *content_language* varchar ,
in *dtd_validator_config* varchar) ;

Description

This parses the argument, which is expected to be a well formed XML fragment and returns a parse tree as a special memory-resident object. While xper_doc creates some disk-resident data structure, xtree_doc() will work faster but it may require more memory. You may wish to use xtree_doc for small documents (e.g. less than 5 megabytes and xper_doc for larger documents.

Parameters

document
: well formed XML or HTML document

parser_mode
: 0, 1 or 2; 0 - XML parser mode, 1 - HTML parser mode, 2 - 'dirty HTML' mode (with quiet recovery after any syntax error)

base_uri
: in HTML parser mode change all absolute references to relative from given base_uri (http://<host>:<port>/<path>)

content_encoding
: string with content encoding type of <document>; valid are 'ASCII', 'ISO', 'UTF8', 'ISO8859-1', 'LATIN-1' etc., defaults are 'UTF-8' for XML mode and 'LATIN-1' for HTML mode.

content_language
: string with language tag of content of <document>; valid names are listed in IETF RFC 1766, default is 'x-any' (it means 'mix of words from various human languages')

dtd_validator_config
: configuration string for DTD validator, default is empty string meaning that DTD validator should be fully disabled. See Configuration Options of the DTD Validator for details.

Return Types

XML entity with underlying parse tree of source document; the tree will be a memory-resident structure of nested heterogeneous vectors.

Examples

Example 24.537. xtree_doc

```
declare tree any;

tree := xtree_doc (file_to_string ('doc.html'), 1,
                'http://localhost.localdomain/', 'ISO');
...
```

```
tree := xtree_doc (file_to_string ('doc.xml'));
```

xmlStorageSystem.registerUser

xmlStorageSystem.registerUser — Register a user with the XML Storage System

Synopsis

```
structure xmlStorageSystem.registerUser ( in email string ,
                                          in name string ,
                                          in password string ,
                                          in clientPort integer ,
                                          in userAgent string ,
                                          in serialNumber string ) ;
```

Description

This method allows users to register within XML Storage System. The actions performed on the server are:

make a new Web account named <email> with the password specified.
make a home-folder in WebDAV repository as /DAV/<email>.
make a sub-folder called "blog".

Parameters

email
: For user identification, this should be a valid email account.

name
: A human readable name for the user account.

password
: The password for authentication. Note that this is the only call that sends the password in clear-text. All other functions send the password as a MD5 hash.

clientPort
: Currently ignored and reserved for future use.

userAgent
: Currently ignored and reserved for future use.

serialNumber
: Currently ignored and reserved for future use.

Return Types

This method returns a structure as follows:

```
'usernum' string    account id
'flError' boolean   0 success, 1 fault
'message' string    fault message (can be used to handle error cases)
```

Examples

Example 24.538. Registering a new user

```
SQL> SOAP_CLIENT (url=>'http://example.com/xmlStorageSystem',
                  operation=>'registerUser', parameters=>vector
                 ('email','user@example.domain', 'name', 'Somebody Name',
                  'password', 'xxx', 'clientPort', 0, 'userAgent', '' , 'serialNumber', ''));
```

```
- SOAP response
<registerUserResponse>
  <Result>
    <usernum>user@example.domain</usernum>
    <flError>0</flError>
    <message>Welcome, Somebody Name</message>
  </Result>
</registerUserResponse>
```

See Also

`xmlStorageSystem.getServerCapabilities()`

`xmlStorageSystem.deleteMultipleFiles()`

`xmlStorageSystem.saveMultipleFiles()`

xmlStorageSystem.mailPasswordToUser

xmlStorageSystem.mailPasswordToUser — Mail password to user.

Synopsis

```
structure xmlStorageSystem.mailPasswordToUser ( in email string );
```

Description

This method is used to send the password for user identified by email. To work properly the default SMTP server Virtuoso INI file setting must be set properly.

Parameters

email
: For user identification, this should be a valid email account.

Return Types

This method returns a structure as follows:

```
'flError' boolean                   0 success, 1 fault
'message' string                    fault message (can be used to handle error cases)
```

Examples

Example 24.539. Mailing the XML Storage System Users Password to the User

Simple example of mailing the users password.

```
SQL> SOAP_CLIENT (url=>'http://example.com/xmlStorageSystem',
operation=>'mailPasswordToUser', parameters=>vector ('email','user@example.domain'));

SOAP response:

<mailPasswordToUserResponse>
  <Result>
    <flError>1</flError>
    <message>Mail service is not available on that server.</message>
  </Result>
</mailPasswordToUserResponse>
```

Note : in this case emailing was failed

`xmlStorageSystem.registerUser()`

`xmlStorageSystem.getServerCapabilities()`

`xmlStorageSystem.deleteMultipleFiles()`

`xmlStorageSystem.saveMultipleFiles()`

xmlStorageSystem.getServerCapabilities

xmlStorageSystem.getServerCapabilities — Retrieve server specific information.

Synopsis

```
structure xmlStorageSystem.getServerCapabilities ( in email string ,
                                                   in password string ) ;
```

Description

This method is used to obtain information about the capabilities of the server, such as files size limitations, supported types, etc...

Parameters

email
: For user identification, this should be a valid email account.

password
: The MD5 hash of the password.

Return Types

This method returns a structure as follows:

```
'flError' boolean                  0 success, 1 fault
'message' string                   fault message (can be used to handle error cases)
 ctBytesInUse integer              how many bytes are used on repository
 legalFileExtensions string array  which extensions are recognized
 maxBytesPerUser integer           total bytes available for this user
 maxFileSize integer               largest file size for upload (bytes)
 yourUpstreamFolderUrl string      base URL for user's blog on repository
```

Examples

Example 24.540. Retrieving the XML Storage System Capabilities

Simple example of fetching the server capabilities.

```
SQL> SOAP_CLIENT (url=>'http://example.com/xmlStorageSystem',
    operation=>'getServerCapabilities', parameters=>vector
    ('email','user@example.domain', 'password', md5('xxx'));

SOAP response:

<getServerCapabilitiesResponse>
   <Result>
     <ctBytesInUse>14</ctBytesInUse>
     <flError>0</flError>
       <legalFileExtensions>
         <item>ai</item>
         <item>aif</item>
         <item>aifc</item>
       </legalFileExtensions>
     <maxBytesPerUser>41943040</maxBytesPerUser>
     <maxFileSize>1048576</maxFileSize>
     <message />
     <yourUpstreamFolderUrl>http://example.com/DAV/user@example.domain/blog/</yourUpstreamFolderUrl>
   </Result>
</getServerCapabilitiesResponse>
```

`xmlStorageSystem.registerUser()`

`xmlStorageSystem.mailPasswordToUser()`

`xmlStorageSystem.deleteMultipleFiles()`

`xmlStorageSystem.saveMultipleFiles()`

xmlStorageSystem.deleteMultipleFiles

xmlStorageSystem.deleteMultipleFiles — Remove files from XML Storage System Directory

Synopsis

```
structure xmlStorageSystem.deleteMultipleFiles ( in email string ,
                                                 in password string ,
                                                 in relativepathList array ) ;
```

Description

This method is used for removing files from the repository.

Parameters

email
: For user identification, this should be a valid email account.

password
: The MD5 hash of the password.

relativepathList
: Array of strings of paths relative to the <user home>/blog folder in WebDAV to be deleted.

Return Types

This method returns a structure as follows:

```
'flError' boolean                  0 success, 1 fault
'message' string                   fault message (can be used to handle error cases)
'errorList' array of string        contains a list of errors corresponding to files
                  which cannot be removed.  Successfully deleted files have an empty string.
```

Examples

Example 24.541. Using the XML Storage System to Delete Multiple Files

Simple example of removing a file.

```
SQL> SOAP_CLIENT (url=>'http://example.com/xmlStorageSystem', operation=>'deleteMultipleFiles',
     parameters=>vector ('email','user@example.domain', 'password', md5('xxx'),
       'relativepathList', vector ('test.txt'));

- SOAP Response

<deleteMultipleFilesResponse>
  <Result>
   <flError>0</flError>
   <message />
   <errorList>
     <item />
   </errorList>
  </Result>
</deleteMultipleFilesResponse>
```

`xmlStorageSystem.mailPasswordToUser()`

`xmlStorageSystem.getServerCapabilities()`

`xmlStorageSystem.saveMultipleFiles()`

xmlStorageSystem.saveMultipleFiles

xmlStorageSystem.saveMultipleFiles — Upload a set of files to XML Storage System directory.

Synopsis

```
structure xmlStorageSystem.saveMultipleFiles ( in email string ,
                                               in password string ,
                                               in relativepathList array ,
                                               in fileTextList array ) ;
```

Description

This method allows users to upload a set of files. The files will be stored in WebDAV repository and will be accessible via HTTP.

Parameters

email
: For user identification, this should be a valid email account.

password
: The MD5 hash of the password.

relativepathList
: Array of strings of target paths relative to the <user home>/blog folder in WebDAV.

fileTextList
: An array of strings containing the contents of the files to be uploaded. These must be in the same sequence as the relativepathList. i.e. relativepathList[i] is name for fileTextList[i].

Return Types

This method returns a structure as follows:

```
'flError' boolean                  0 success, 1 fault
'message' string                   fault message (can be used to handle error cases)
'urllist' array of string   contains list of URLs corresponding to uploaded files
'yourUpstreamFolderUrl' string      base URL for upload
```

Examples

Example 24.542. Using the XML Storage System to Save Multiple Files

Simple example of saving a file.

```
- Invocation:

SQL> SOAP_CLIENT (url=>'http://example.com/xmlStorageSystem', operation=>'saveMultipleFiles',
    parameters=>vector ('email','user@example.domain', 'password', md5('xxx'),
      'relativepathList', vector ('test.txt'), 'fileTextList', vector ('this is a test'));

- SOAP Response

<saveMultipleFilesResponse>
  <Result>
    <flError>0</flError>
    <message />
    <urllist>
      <item>http://example.com/DAV/user@example.domain/blog/test.txt</item>
    </urllist>
    <yourUpstreamFolderUrl>http://example.com/DAV/user@example.domain/blog/</yourUpstreamFolderUrl>
```

```
    </Result>
  </saveMultipleFilesResponse>
```

`xmlStorageSystem.registerUser()`

`xmlStorageSystem.mailPasswordToUser()`

`xmlStorageSystem.getServerCapabilities()`

`xmlStorageSystem.deleteMultipleFiles()`

XMLType.XMLType

XMLType.XMLType

Synopsis

```
constructor method XMLType.XMLType ( in src any ,
                                     in schema_uri any ,
                                     in validated any ,
                                     in wellformed any ) ;
```

Description

The method creates an XMLType instance from *src* XML entity. If parameter *src* is not an XML entity then it is converted to it via internal call of `xtree_doc()` or `xml_tree_doc()` . A schema may be associated with an XML entity by passing its URI as *schema_uri* ; this schema can be used later to validate the structure of the document.

Parameters

src
: An XML entity or a value that can be converted to an XML entity.

schema_uri
: An URI of the schema of the document. The default is NULL to make result non-schema based.

validated
: An integer flag that indicates if the document is already validated against the schema of the document (this is to avoid redundant validations). The default is 0.

wellformed
: This parameter is unused and is listed solely for compatibility.

Return Types

The method returns a new instance of XMLType.

Examples

Example 24.543. Simple Use

```
create table XMLTYPE_TEST (I integer primary key, XMLVAL long xml)

Done. -- 00000 msec.

insert into XMLTYPE_TEST values (1, XMLType('<emp><empno>221</empno><ename>John</ename></emp>'))

Done. -- 00000 msec.

insert into XMLTYPE_TEST values (2, XMLType('<po><pono>331</pono><poname>PO_1</poname></po>'))

Done. -- 00000 msec.

select e.XMLVAL.extract ('//empno/text()').getNumVal() as EMPNO
  from XMLTYPE_TEST as e
  where e.XMLVAL.existsNode('/emp/empno') = 1
EMPNO

XMLType.createNonSchemaBasedXML

XMLType.createNonSchemaBasedXML — Returns a copy of the given instance with the schema reference removed.

Synopsis

XMLType.createNonSchemaBasedXML ( );

Description

The function returns a copy of the given instance with the schema reference removed.

Return Types

The function returns a new instance of XMLType.

Examples

Example 24.544. Converting a schema-based instance to non schema-based

The procedure creates a non schema-based copy of a sample schema-based instance.

```
create procedure schema_removal_test ()
{
  declare orig_instance XMLType;
  declare non_schema_copy XMLType;
  declare PROBE varchar;
  result_names (PROBE);
  orig_instance := XMLType ('<sample-xml/>', 'http://www.example.com/test.xsd');
  result (concat (
    '"orig_instance" is declared as schema-based, URI=',
    orig_instance.getSchemaURL() ) );
  non_schema_copy := orig_instance.createNonSchemaBasedXML();
  result (concat (
    '"non_schema_copy" is non schema-based, URI=',
    cast (non_schema_copy.getSchemaURL() as varchar) ) );
}

See Also

XMLType.createSchemaBasedXML()

XMLType.createSchemaBasedXML

XMLType.createSchemaBasedXML — Returns a copy of the given instance with new schema reference.

Synopsis

XMLType.createSchemaBasedXML (in *schema_url* varchar) ;

Description

The function creates a new instance of XMLType by copying the given one and assigning a new schema URL to it. Parameter `schema_url` specifies a new URL; if it is omitted then a non-schema based instance is created like the `XMLType.createNonSchemaBasedXML()` function.

The returned copy has an internal "validated" flag set to 0, even if the new URL is equal to the URL of the original instance.

Parameters

schema_url
: The location of a schema of a new instance.

Return Types

The member function returns a new instance of XMLType.

Examples

Example 24.545. Converting a non schema-based instance to schema-based one

The procedure creates a schema-based copy of a sample non schema-based instance.

```
create procedure schema_assignment_test ()
{
  declare orig_instance XMLType;
  declare schema_based_copy XMLType;
  declare PROBE varchar;
  result_names (PROBE);
  orig_instance := XMLType ('<sample-xml/>');
  result (concat (
    '"orig_instance" is declared as non schema-based, URI=',
    cast (orig_instance.getSchemaURL() as varchar) ) );
  schema_based_copy := orig_instance.createSchemaBasedXML (
    'http://www.example.com/test.xsd' );
  result (concat (
    '"schema_based_copy" is schema-based, URI=',
    schema_based_copy.getSchemaURL() ) );
}

"schema_based_copy" is schema-based, URI=http://www.example.com/test.xsd

2 Rows. -- 00000 msec.
```

See Also

`XMLType.createNonSchemaBasedXML()`

XMLType.createXML

XMLType.createXML — Creates an XML Type instance.

Synopsis

```
static method XMLType.createXML ( in src any ,
                                  in schema_uri varchar ,
                                  in validated integer ,
                                  in wellformed any ) ;
```

Description

The static method creates an XMLType instance from the *src* XML entity. If the parameter *src* is not an XML entity then it is converted to it via an internal call of `xtree_doc()` or `xml_tree_doc()` . A schema may be associated with an XML entity by passing its URI as *schema_uri* ; this schema can be used later to validate the structure of the document.

Parameters

src
: An XML entity or a value that can be converted to an XML entity.

schema_uri
: A URI of the schema of the document. The default is NULL to make result non-schema based.

validated
: An integer flag that indicates if the document is already validated against the schema of the document (this is to avoid redundant validations). The default is 0.

wellformed
: This parameter is unused and is listed solely for compatibility.

Return Types

The method returns a new instance of XMLType.

Examples

Example 24.546. Creating instances of XMLType

The procedure creates two instances (a schema-based and a non schema-based) and demonstrates that these instances are filled with proper data.

```
create procedure createxml_test ()
{
  declare test1 XMLType;
  declare test2 XMLType;
  declare PROBE varchar;
  result_names (PROBE);
  test1 := createXML ('<test attr="value1"/>');
  test2 := createXML ('<test attr="value2"/>', 'http://www.example.com/test.xsd');
  result (concat (
    '"test1" is created as non schema-based, URI=',
    cast (test1.getSchemaURL() as varchar) ) );
  result (concat (
    'Sample data from "test1": value of test/@attr is ',
    test1.extract ('test/@attr') ) );
  result (concat (
    '"test2" is created as schema-based, URI=',
    test2.getSchemaURL() ) );
  result (concat (
```

```
    'Sample data from "test2": value of test/@attr is ',
    test2.extract ('test/@attr') ) );
}

createxml_test ()
PROBE

`xtree_doc()`

`xper_doc()`

XMLType.existsNode

XMLType.existsNode — Tests node existence having evaluated given XPATH expression.

Synopsis

XMLType.existsNode (in *xpath_expn* varchar ,
in *namespace_map* varchar) ;

Description

The member function calculates the given XPATH expression *xpath_expn* using the XML entity of the instance as a context node. If a *namespace_map* parameter is given then the function adds namespace declarations from this parameter into the beginning of *xpath_expn* before the evaluation. The function returns 1 if the first result of XPATH evaluation is a node or 0 if there are no results or if the first result is not a node.

Parameters

xpath_expn
: A text of XPATH expression to evaluate.

namespace_map
: A string that is a list of namespace prefix declarations delimited by whitespace characters. If the xpath_expn expression also contains a list of declarations then these two lists are concatenated.

Return Types

The function returns integer 1 or 0

Examples

Example 24.547. A table with an XMLType column

This populates a table with XML data and then reports which rows contain 'empno' element inside 'emp'.

```
create table TEST_XMLS  (I integer primary key, XMLVAL XMLType);
insert into TEST_XMLS  values (1, XMLType('<emp><empno>221</empno><ename>John</ename></emp>'));
insert into TEST_XMLS  values (2, XMLType('<po><pono>331</pono><poname>PO_1</poname></po>'));
insert into TEST_XMLS  values (3, XMLType('<oil-rig
xml:id="14a" water="0.413"/><oil-rig
xml:id="14b" water="0.402"/>'));
select e.I, e.XMLVAL.existsNode('/emp/empno')
  from TEST_XMLS  as e
I                 callret
INTEGER NOT NULL  INTEGER
_______________________________________________________________________________

1                 1
2                 0
3                 0

3 Rows. -- 00000 msec.
```

See Also

`XMLType.extract()`

XMLType.extract

XMLType.extract — Evaluates given XPATH expression.

Synopsis

XMLType.extract (in *xpath_expn* varchar ,
in *namespace_map* varchar) ;

Description

The member function calculates the given XPATH expression *xpath_expn* using the XML entity of the instance as a context node. If a *namespace_map* parameter is given then the function adds namespace declarations from this parameter into the beginning of *xpath_expn* before the evaluation. The function returns the first result of the XPATH evaluation or NULL if there are no results. If the result is an XML entity then it is converted into a non-schema based instance of XMLType.

Parameters

xpath_expn
: A text of XPATH expression to evaluate.

namespace_map
: A string that is a list of namespace prefix declarations delimited by whitespace characters. If the xpath_expn expression also contains a list of declarations then these two lists are concatenated.

Return Types

The function returns a non-schema based XMLType instance, NULL or a value of any other type

Examples

Example 24.548. A table with an XMLType column

This populates a table with XML data and then selects 'ename' element from the appropriate record.

```
create table TEST_XMLS  (I integer primary key, XMLVAL XMLType);
insert into TEST_XMLS  values (1, XMLType('<emp><empno>221</empno><ename>John</ename></emp>'));
insert into TEST_XMLS  values (2, XMLType('<po><pono>331</pono><poname>PO_1</poname></po>'));
insert into TEST_XMLS  values (3, XMLType('<oil-rig
xml:id="14a_01" water="0.413"/><oil-rig
xml:id="14b_01" water="0.402"/>'));
select e.XMLVAL.extract ('//ename').getCLobVal() as ENAME
  from TEST_XMLS  as e
  where e.XMLVAL.existsNode('/emp/empno')
ENAME
NVARCHAR
_______________________________________________________________________________

<ename>John</ename>

`XMLType.existsNode()`

XMLType.getClobVal

XMLType.getClobVal — This function returns the serialization of the current node like XPATH function 'serialize()', i.e. a text in XML syntax.

Synopsis

XMLType.getClobVal ( );

Description

This function returns the serialization of the current node. This is similar to the XPATH function 'serialize()', i.e. a text in XML syntax.

Return Types

The function returns wide string.

Examples

Example 24.549. A table with an XMLType column

This populates a table with XML data and then selects string representation of 'ename' element from the appropriate record.

```
create table TEST_XMLS  (I integer primary key, XMLVAL XMLType);
insert into TEST_XMLS  values (1, XMLType('<emp><empno>221</empno><ename>John</ename></emp>'));
insert into TEST_XMLS  values (2, XMLType('<po><pono>331</pono><poname>PO_1</poname></po>'));
insert into TEST_XMLS  values (3, XMLType('<oil-rig
xml:id="14a_02" water="0.413"/><oil-rig
xml:id="14b_02" water="0.402"/>'));
select e.XMLVAL.extract ('//ename').getCLobVal() as ENAME
  from TEST_XMLS  as e
 where e.XMLVAL.existsNode('/emp/empno')
ENAME
NVARCHAR
_______________________________________________________________________________

<ename>John</ename>

1 Rows. -- 00000 msec.
```

See Also

`XMLType.getStringVal()`

`XMLType.getNumVal()`

XMLType.getNamespace

XMLType.getNamespace — Returns the namespace of the top level element providing the instance is schema-based rather than a fragment.

Synopsis

```
XMLType.getNamespace (   );
```

Description

The member function returns the namespace URI of the top level element providing that the given instance is schema-based and is well-formed. This function returns NULL if the instance is a fragment. If there are many top level elements then they may have different namespace URIs and if there is no top level element then there is nothing to return. It also returns NULL if the instance is non-schema based for compatibility.

Return Types

This function returns a wide string or NULL.

Examples

Example 24.550. Factors that affect the result of getNamespace()

The following statements demonstrate how various circumstances may force getNamespace() to return NULL.

```
-- First of all, top level element may have a name with no namespace.
select XMLType('<local />').getNamespace()
_____________________________________________________________________________
NULL

-- Compatibility: the instance should be schema-based.
select XMLType('<z:qname xmlns:z="http://www.example.com/"/>').getNamespace()
_____________________________________________________________________________
NULL

-- This is schema-based, but top level element has no namespace.
select XMLType('<local />', 'http://www.example2.com/test.xsd').getNamespace()
_____________________________________________________________________________
NULL

-- Note that for XPATH processor return an empty string, not a NULL,
-- as a namespace uri of a name with no URI.
select xpath_eval('namespace-uri(.)', XMLType('<local />', 'http://www.example2.com/test.xsd'))
_____________________________________________________________________________

1 Rows. -- 00000 msec.

-- Schema-based instance with nonempty namespace URI.
select XMLType('<z:qname xmlns:z="http://www.example.com/"/>', 'http://www.example2.com/test.xsd').getNam
_____________________________________________________________________________

`XMLType.isFragment()`

XMLType.getNumVal

XMLType.getNumVal — This function returns the integer-value of the current node like XPATH function 'number()'.

Synopsis

```
XMLType.getNumVal (   );
```

Description

This function returns the integer-value of the current node. This is similar to the XPATH function 'number()'.

Return Types

The member function returns integer.

Examples

Example 24.551. A table with an XMLType column

This populates a table with XML data and then selects the numeric value of an 'empno' element from the appropriate record.

```
create table TEST_XMLS  (I integer primary key, XMLVAL XMLType);
insert into TEST_XMLS  values (1, XMLType('<emp><empno>221</empno><ename>John</ename></emp>'));
insert into TEST_XMLS  values (2, XMLType('<po><pono>331</pono><poname>PO_1</poname></po>'));
insert into TEST_XMLS  values (3, XMLType('<oil-rig
xml:id="14a_03" water="0.413"/><oil-rig
xml:id="14b_03" water="0.402"/>'));
select e.XMLVAL.extract ('//empno').getNumVal() as EMPNO
  from TEST_XMLS  as e
  where e.XMLVAL.existsNode('/emp/empno')
EMPNO
DECIMAL

`XMLType.getStringVal()`

`XMLType.getClobVal()`

XMLType.getRootElement

XMLType.getRootElement — Returns top-level element of the given instance (NULL for fragment)

Synopsis

```
XMLType.getRootElement (   );
```

Description

If the given instance is well-formed then this function will return the top-level element of the document that is stored within the instance. If the given instance is a fragment then NULL will be returned because there may be no top-level elements or too many of them.

Note that in spite of this functions name this function actually returns the a top-level node rather than not a root node. According to the W3C XPATH standards, the root element is an implicit node whose children are top-level elements, comments, processing instructions and maybe text nodes. E.g. if a correct HTML document is started by tag <HTML> and ended by corresponding </HTML> tag then the only top-level node is the "HTML " element node and this node is a single child of the root node.

If the given instance is well-formed then the function returns a top-level element of the document that is stored in the instance. If the given instance is fragment then NULL is returned, because there may be no top-level elements or too many of them.

If the given instance is schema-based then the returned instance is based on the same schema.

Return Types

The function returns an XMLType instance.

Examples

Example 24.552. A table with an XMLType column

First select statement lists well-formed documents; second one lists the only fragment in the table.

```
create table TEST_XMLS  (I integer primary key, XMLVAL XMLType);
insert into TEST_XMLS  values (1, XMLType('<emp><empno>221</empno><ename>John</ename></emp>'));
insert into TEST_XMLS  values (2, XMLType('<po><pono>331</pono><poname>PO_1</poname></po>'));
insert into TEST_XMLS  values (3, XMLType('<oil-rig
xml:id="14a_04" water="0.413"/><oil-rig
xml:id="14b_04" water="0.402"/>'));

select e.I, e.XMLVAL.getRootElement().getClobVal()
  from TEST_XMLS as e
  where e.XMLVAL.getRootElement() is not null
I                 callret
INTEGER NOT NULL  NVARCHAR
_______________________________________________________________________________

1                 <emp><empno>221</empno><ename>John</ename></emp>
2                 <po><pono>331</pono><poname>PO_1</poname></po>

`XMLType.isFragment()`

XMLType.getSchemaURL

XMLType.getSchemaURL — Returns the URL of the XML schema definition for schema based instances, NULL for non-schema based.

Synopsis

```
XMLType.getSchemaURL (  );
```

Description

The function returns the URL of the XML Types associate XML schema. This applies only to schema based instances. It will return NULL for non-schema based types.

Return Types

The function returns string.

Examples

Example 24.553. Simple test

The call of XMLType constructor creates an schema-based instance and `getSchemaURL()` returns the specified URL

```
select XMLType('<sample />', 'file://xmlschema/test0001/clean.xsd').getSchemaURL()
callret
VARCHAR
_______________________________________________________________________________

file://xmlschema/test0001/clean.xsd

1 Rows. -- 00000 msec.
```

See Also

`XMLType.isSchemaBased()`

XMLType.getStringVal

XMLType.getStringVal — The function returns the string-value of the current node like XPATH function 'string()'.

Synopsis

```
XMLType.getStringVal (   );
```

Description

The function returns the string-value of the current node. This is similar to the XPATH function 'string()'.

Return Types

The member function returns wide string.

Examples

Example 24.554. A table with an XMLType column

This populates a table with XML data and then selects the string-value of an 'ename' element from the appropriate record.

```
create table TEST_XMLS  (I integer primary key, XMLVAL XMLType);
insert into TEST_XMLS  values (1, XMLType('<emp><empno>221</empno><ename>John</ename></emp>'));
insert into TEST_XMLS  values (2, XMLType('<po><pono>331</pono><poname>PO_1</poname></po>'));
insert into TEST_XMLS  values (3, XMLType('<oil-rig
xml:id="14a_06" water="0.413"/><oil-rig
xml:id="14b_06" water="0.402"/>'));
select e.XMLVAL.extract ('//ename').getStringVal() as ENAME
  from TEST_XMLS  as e
  where e.XMLVAL.existsNode('/emp/empno')
ENAME

`XMLType.getNumVal()`

`XMLType.getClobVal()`

XMLType.isFragment

XMLType.isFragment — The function returns 1 if the instance is an XML generic entity or 0 if it is a plain document.

Synopsis

```
XMLType.isFragment (   );
```

Description

The function checks the number of children elements of the root of the document root of the given instance. If there are no such documents or there are many of them then the document is not well-formed, for example it can not be fully validated against an XML schema. However it can be used as a fragment of a larger document: it can be declared as an external generic entity and then referenced in a top-level document or in one of its subdocuments. For example a book can be stored in XML as a root document that includes subdocuments, one or more chapter per subdocument.

The function returns 1 if the given XMLType instance is a fragment and returns 0 if it is a well-formed XML document.

Return Types

Integer value 1 or 0.

Examples

Example 24.555. Basic test

The table DB.DBA.SYS_USERS always contains more than one user record so the call of XMLAGG that returns one element per record creates an valid generic entity but not a valid document.

```
select XMLAGG (XMLELEMENT ("User",U_NAME)) from DB.DBA.SYS_USERS;
callret
VARCHAR
_______________________________________________________________________________

<User>BACKUP</User><User>SOAP</User><User>dba</User><User>demo</User>

`XMLType.getRootElement()`

XMLType.isSchemaBased

XMLType.isSchemaBased — Returns 1 if the given XMLType instance is schema-based, otherwise returns 0.

Synopsis

```
XMLType.isSchemaBased (   );
```

Description

Returns 1 if the given XMLType instance is schema-based, i.e. if it has a URI of an XML schema that can be used for schema validation via `XMLType.schemaValidate()` .

Return Types

The function returns 1 or 0.

Examples

Example 24.556. Simple tests

The following three calls display the behaviour of the `isSchemaBased()` . Note that it does no actual checks whether the document is valid against the declared schema or even the validity of schema URI itself.

```
select XMLType('<clean />').isSchemaBased()
callret
INTEGER
_______________________________________________________________________________

0

1 Rows. -- 00000 msec.

select XMLType('<clean />', 'http://no.such.schema.exists').isSchemaBased()
callret
INTEGER
_______________________________________________________________________________

1

1 Rows. -- 00000 msec.
```

See Also

`XMLType.getSchemaURL()`

XMLType.isSchemaValid

XMLType.isSchemaValid — Validates the given XMLType instance against an arbitrary XML schema, returns 1 if successful, 0 if errors are detected.

Synopsis

XMLType.isSchemaValid (in *schema_url* varchar ,
in *top_element_name* varchar) ;

Description

The function validates the given XMLType instance against the XML schema located at *schema_url* . The name of the current node of the XML entity should match *top_element_name* if it is specified.

The *schema_url* is optional for schema based instances: the default value is the URI of the associated schema of the instance. For non-schema based instances the *schema_url* is required, an error is signalled otherwise.

The function does not use or modify internal "validated" flag that is e.g. used by XMLType.schemaValidate() . It is true even if the given *schema_url* is equal to the URI of own schema of the instance.

Parameters

schema_url
: The URI of the schema to apply.

top_element_name
: The allowed name of top level element of the instance.

Return Types

The function returns 1 if the validation is passed, 0 if it is failed.

Examples

Example 24.557. Failed schema validation

The example creates an XMLType instance that is a document with a single element node"bad" and tries to validate it against XMLschema "file://xmlschema/test0001/clean.xsd" that does not match actual content of the document. The call of isSchemaValid() returns zero indicating failed validation.

```
select XMLType('<bad />', 'file://xmlschema/test0001/clean.xsd').isSchemaValid()
callret
INTEGER
_______________________________________________________________________________

0

1 Rows. -- 00000 msec.
```

See Also

XMLType.isSchemaValidated()

XMLType.setSchemaValidated()

XMLType.schemaValidate()

XMLType.isSchemaValidated

XMLType.isSchemaValidated — Returns 1 or 0 indicating if the XML entity has been validated against the associated schema.

Synopsis

```
XMLType.isSchemaValidated (   );
```

Description

The function returns the value of a special internal "is validated" flag of the given XMLType instance.

Return Types

An integer value 1 or 0.

Examples

Example 24.558. Sample use

These two calls demonstrate how the "is validated" flag can be set without making an actual validation in the call of XMLType constructor:

```
-- Line 75: select XMLType('<bad />', 'file://xmlschema/test0001/clean.xsd').isSchemaValidated()
callret
INTEGER
_______________________________________________________________________________

0

1 Rows. -- 00000 msec.

-- Line 77: select XMLType('<bad />', 'file://xmlschema/test0001/clean.xsd'), 1).isSchemaValidated()
callret
INTEGER
_______________________________________________________________________________

1

1 Rows. -- 00000 msec.
```

See Also

`XMLType.setSchemaValidated`

`XMLType.schemaValidate`

XMLType.schemaValidate

XMLType.schemaValidate — Validates the schema based XMLType instance against its schema and signals an error in case of failed validation.

Synopsis

```
XMLType.schemaValidate (   );
```

Description

The member function signals an error if called for a non-schema based instance. If an instance is schema-based but the validation has already been done, the call has no effect. Otherwise, a schema-based instance is validated against its schema. If the validation fails, an error is signalled. If the validation is successful then a special internal "validated"flag is set.

Return Types

The function returns a string that contains a validation log if an instance has not been validated before, otherwise it returns null or signals an error.

Examples

Example 24.559. Failed schema validation

The example creates an XMLType instance that is a document with a single element node"bad" and declared schema "file://xmlschema/test0001/clean.xsd" that does not match actual content of the document. The call of `schemaValidate()` signals an error.

```
select XMLType('<bad />', 'file://xmlschema/test0001/clean.xsd').schemaValidate();

*** Error 42000: [Virtuoso Driver][Virtuoso Server]Top-level element name <q> is unknown
at line 76 of load 'XmlType.sql':
select XMLType('<bad />', 'file://xmlschema/test0001/clean.xsd').schemaValidate()
```

See Also

`XMLType.isSchemaValidated()`

`XMLType.setSchemaValidated()`

`XMLType.isSchemaValid()`

XMLType.setSchemaValidated

XMLType.setSchemaValidated — Changes the internal "is validated" flag of the given XMLType instance.

Synopsis

`XMLType.setSchemaValidated` (in *flag* integer default 1);

Description

Every XMLType instance has a special internal "is validated" flag; The first successful call of the member function `XMLType.schemaValidate()` will set this flag to 1 indicating that next such calls are redundant and should do nothing. If a given XMLType instance is made by a procedure that guarantees the match of the result to an expected schema then one can set this flag without running actual validation. It is also possible to reset this flag to 0 in order to force the next call of `XMLType.schemaValidate()` to perform a validation.

Parameters

flag
: An integer that becomes a new value of the flag.

Return Types

The function returns a new value of the flag.

Examples

Example 24.560. Default use

This call prevents the value of myXMLinstance from being validated in the future.

```
myXMLinstance.setSchemaValidated();
```

See Also

`XMLType.isSchemaValidated`

`XMLType.schemaValidate`

XMLType.toObject

XMLType.toObject

Synopsis

```
XMLType.toObject ( in schema varchar ,
                   in element varchar ) ;
```

Description

This member function is not yet implemented.

XMLType.transform

XMLType.transform

Synopsis

XMLType.transform (*stylesheet* XMLType ,
params_map vector) ;

Description

This member function is not implemented and signals an error if called.

Use `xslt()` built-in function instead.

See Also

`xslt()`

sql:column

sql:column — Returns the value of a column from SQL result-set.

Synopsis

```
any sql:column ( constant column_name varchar ) ;
```

Description

This is actually not a function but a special macro that is converted to a reference to a global parameter.

Parameters

column_name
: A string constant (literal, not an expression) that is a column name in plain SQL syntax. It can be a column name (and it can be qualified to specify a table name or an alias name). It can be a name of a Virtuoso/PL variable.

Return Types

The value of the sql:column() invocation is the value of some SQL column or variable. If the type of the value is not supported by XQuery interpreter then it will be converted according to generic rules for XQuery parameters.

Examples

Example 24.561. Various invocations of sql:column

These two statements will produce identical results:

See Also

Pre-compilation of XPath and XQuery Expressions

and

and — Returns false if a value of some argument is false, otherwise returns true.

Synopsis

```
boolean and ( val1 boolean ,
              val2 boolean ,
              ... ,
              valN boolean ) ;
```

Description

This function calculates the values of its arguments from left to right. If the value of the calculated parameter is false, the function returns false immediately, without calculating the remaining parameters. If the list of arguments ends without any false value calculated, the function returns true (thus it will return true if called without arguments).

The name of this function is the same as the name of "and" XPATH and XQUERY operator. Thus it must be surrounded by double quotes when used in XPATH or XQUERY expressions. Moreover, this function is not a part of XPATH standard, so it cannot be used if portability is important.

Parameters

vali
: Value of boolean expression argument

Return Types

boolean

Examples

Example 24.562. Control over sequence of search operations

If two conditions must be checked, where one is simple and another is hard to calculate, then "and" may be used to calculate second condition only if first is true, to reduce average time of processing

```
"and" ( authors,
  document(concat('http://www.lib20.org/findxml.cgi?isbn=',@isbn))/status[@outofprint='NO'] )
```

See Also

not or every

append

append — Creates an sequence of all items from given sequences.

Synopsis

```
sequence append ( seq1 sequence ,
                  seq2 sequence ,
                  ... ,
                  seqN sequence ) ;
```

Description

This function calculates all given arguments from left to right, and creates a sequence which contains all items of the first calculated sequence, then all items of the second calculated sequence and so on, preserving the order of items from every sequence. The result is identical to the result of XQUERY "comma operator".

This function is not a part of XPATH 1.0 or XQUERY 1.0 libraries of standard functions.

Parameters

SeqI
: The sequence of items to be placed into the resulting sequence

Return Types

Sequence

Examples

Example 24.563.

```
append(/abstract, /chapter, /appendix/section)
```

See Also

tuple

assign

assign — Creates a local variable and assign a value to it.

Synopsis

```
null assign ( var_name string ,
              var_value any ) ;
```

Description

This function calculates the first argument, *var_name* , and converts it to the string, if needed. Then it checks if there is a local variable or parameter with such name. If not found, it checks if there is a global variable or parameter with such name. If nothing found in both cases, a new local variable is created with this name. The the value of found or created variable is changed to the value of the second argument, *var_value* .

The value of the variable may be accessed like the value of any variable created by <xsl:variable> XSL element or FLWR operator of XQUERY. The same $name should be used to get the value.

In XSLT, common rules for local variables are used for variables created by assign() function.

This function is not a part of XPATH 1.0 or XQUERY 1.0 libraries of standard functions. It may produce strange results if used in XQUERY expressions in order to change the value of local variable created by FLWR expression. It may cause infinite loop if used in XSLT expressions in order to change the value of a variable used in currently executed <xsl:apply-templates> instruction. For both safety and portability, it is much better to use <xsl:variable> and <xsl:param> XSL elements in stylesheets or LET operator in XQUERY expressions. In addition, let() function is not portable, but it may be used in XPATH or XSLT without the risk of undesired effects.

Parameters

var_name
: The name of variable which must be found or created.

var_value
: The value which should be assigned to the variable.

Return Types

Null

Examples

Example 24.564.

Increment local variable $counter by 1.

```
assign('counter', $counter+1);
```

See Also

let()

avg

avg — Returns average value of all its arguments.

Synopsis

```
number avg ( arg1 any ,
             arg2 any ,
             ... ,
             argN any ) ;
```

Description

The function returns the average of all values in all its arguments, For each node in every argument node-set, it converts the string-value of the node to a number and adds the result to the sum. If some arguments are not node-sets, they are converted to numbers first and added to the sum. Then sum is divided by number of values added and the result is returned.

This function is not a part of XPATH 1.0 standard library.

Parameters

argI
: A node-set of nodes whose string values must be converted to numbers and added to the result, or single value.

Return Types

Table 24.138. Errors signalled by

SQLState	Error Code	Error Text	Description
XP001	XPF06	Nonempty sequence of values expected as argument(s) of XPATH function avg(); avg() of nothing is senseless	This happens if the function is called without arguments, or with all arguments set to empty node-sets.

Examples

Example 24.565.

```
avg(/report[@type="daily-sales"]/total)
```

See Also

sum max min

boolean

boolean — Converts its argument to boolean

Synopsis

```
boolean boolean ( obj any );
```

Description

The function converts its argument to a boolean as follows:

- A number is true if and only if it is neither zero nor NaN.
- A node-set is true if and only if it is non-empty.
- A string is true if and only if its length is non-zero.
- An object of a type other than the four basic types is converted to a boolean in a way that is dependent on that type.

Parameters

obj
: The object to be converted into boolean.

Return Types

Boolean

Examples

Example 24.566.

The following expressions are true:

```
boolean('aaa') = true()
boolean('false') = true()
boolean(false()) = false()
boolean(.) = true()
boolean('0') = true()
boolean(0) = false()
```

See Also

string() number()

ceiling

ceiling — Returns the smallest integer that is not less than the argument.

Synopsis

```
integer ceiling ( num number );
```

Description

This function returns the smallest (closest to negative infinity) number that is not less than the argument and that is an integer. In other words, it "rounds up" the given value.

Parameters

num
: The value to be "rounded up"

Return Types

Examples

Example 24.567.

The following expressions are true:

```
ceiling(2.5) = 3
ceiling(2) = 2
ceiling(-2.5) = -2
ceiling(-2) = -2
```

See Also

floor() round()

fn:collection

fn:collection — Returns parsed documents contained in given collections.

Synopsis

```
node()* fn:collection ( uri anyURI ,
                        base_uri string ,
                        recursive_mode int ,
                        parser_mode int ,
                        encoding string ,
                        language string ,
                        dtd_config string ) ;
```

Description

This function takes one or more collection URI's and returns the parsed documents contained in these collections as a sequence.

If no uri is specified, the function returns the sequence of the nodes in the default collection in the dynamic context. The default collection is a home DAV collection. If user does not have default DAV collection, an error is signalled.

Local DAV collections
: Local DAV collections can be accessed either by providing "http://local.virt/DAV/" or "http://localhost:PORT/" URI. The "http://local.virt/DAV/" can be used even if the local http server is not enabled. The "http://localhost:PORT" URI is less efficient and takes the data over HTTP, so "http://local.virt/DAV/" is preferred.

Table Collections
: fn:collection specially recognizes URI's which beginning with "virt://". Such a URI relates to a local table, the content of a specified column is returned as the collection (table collection). The URI contains three parts: table name, id column name, xml content column name. For instance, if the table definition is:

Home path in local DAV collections
: fn:collection also supports UNIX style home paths. If URI begins with ~ the next term will treated as user name and is will be substituted by path to home DAV collection. For instance, ~john/test/test2/ can be parsed as http://local.virt/DAV/home/john/test/test2 URI.

Remote DAV collections, WEB collections
: Any other URI which begins with "http://" refers to remote DAV collections. The function uses the PROPFIND DAV method to get the list of documents contained in the collection. If the remote server does not support this method the function tries to do a HTML GET with the uri and returns all documents referenced from the result (WEB collection). In this case the function makes two http requests.
When a web page is scanned for document reference by fn:collection it searches <a href=...> tags and returns downloaded and parsed documents referenced in href. If href contains relative reference it is resolved using web page address as base uri.
In this release fn:collection does not support any collections except DAV collections, WEB collections, table collections.

Authentication
: Remote DAV and WEB collections may need authentication information. fn:collection supports two ways of providing authentication information. First one is to provide user name and password by setting appropriate connection variables:

Parameters

uri
: collection URI. If the uri is a relative xs:anyURI, it is resolved against the value of the base-URI property from the static context or from base_uri .

base_uri

If uri is an relative URI string, not an absolute one then base_uri is used to make it absolute.

parser_mode
: Sets the mode for parsing documents in collection (0 - XML parser mode, 1 - HTML parser mode, 2 - 'dirty HTML' mode (with quiet recovery after any syntax error).

encoding
: string with content encoding type of <document>; valid are 'ASCII', 'ISO', 'UTF8', 'ISO8859-1', 'LATIN-1' etc., defaults are 'UTF-8' for XML mode and 'LATIN-1' for HTML mode.

language
: string with language tag of content of <document>; valid names are listed in IETF RFC 1766, default is 'x-any' (it means 'mix of words from various human languages')

dtd_config
: configuration string for DTD validator, default is empty string meaning that DTD validator should be fully disabled. See Configuration Options of the DTD Validator for details.

Return Types

node*

Examples

Example 24.568. Example of using remote DAV collection:

```
<result>
  { for $a in fn:collection ( "http://www.somdavservice.com:8081/DAV/test1/" )
        return
                <res>{ $a/value/text() }</res>
  }
</result>
```

Example 24.569. Example of using relative URI:

```
xquery_eval('
 <pre>
    { for \044n in fn:collection("/docs", ., 2)
          return (document-get-uri(\044n), " - ", name (\044n/*[1]), "\n")
    }
 </pre> ', xtree_doc ('<stub/>', 0, 'http://www.somdavservice.com:8081/') );
```

Example 24.570. Example of using default collection:

```
xquery_eval('
 <div>
    { for \044anchor in fn:collection()//a
          return <b> { \044anchor } </b>
    }
 </div> ', xtree_doc ('<stub/>') );
```

See Also

document()

doc()

xtree_doc()

xml_uri_get()

concat

concat — Returns the concatenation of its arguments.

Synopsis

```
string concat ( strg1 string ,
                strg2 string ,
                ... ,
                strgN string ) ;
```

Description

The function converts all its arguments into strings using the same rules as XPATH function string(), then it performs concatenation and returns the resulting string.

XPATH 1.0 standard states that concat() function must have at least 2 arguments, but in Virtuoso XPATH this restriction is eliminated. concat() may be called without arguments (it will return an empty string) or with one argument (it will work like string() function). This may be useful if the text of XPATH expression must be generated by an application.

Parameters

strgI
: String or a value of any type which may be converted into a string.

Return Types

Examples

Example 24.571.

```
concat('Order ', @orderno, ' dated ', @issuedate)
```

See Also

string()

contains

contains — Returns true if the first argument string contains the second argument string, and otherwise returns false.

Synopsis

```
boolean contains ( haystack string ,
                   needle string ) ;
```

Description

For two given strings, this function checks if the first string contains the second string. If any argument is not a string, it is converted to string using rules from string() XPATH function. Thus if the second argument has no string value, the function returns true, because it will be converted to an empty string first.

Parameters

haystack
: String where the search is performed

needle
: String to search

Return Types

Boolean

Examples

Example 24.572.

```
contains ('OpenLink Virtuoso', 'Link')
```

See Also

string() starts-with() ends-with()

count

count — Returns the number of values in the sequence.

Synopsis

```
integer count ( seq any );
```

Description

Returns 1 if the argument is a single value or a count of elements in the given sequence of values.

This function must be called with an argument, it do nothing with context. To count nodes in context node-set, use last().

Parameters

seq
: Sequence of values to be counted.

Return Types

Integer

Errors

This function never returns any errors

Examples

Example 24.573.

```
count(//*)
```

See Also

empty() last()

create-attribute

create-attribute — Creates a special "attribute descriptor" object.

Synopsis

```
attribute create-attribute ( attrname string ,
                             attrvalue string ) ;
```

Description

This is an internal XQUERY function and you will probably never need to call it explicitly. It is not a part of library of standard XQUERY 1.0 functions.

This function creates an special object, called "attribute descriptor", which may be used only as argument of create-element() XQUERY function. Every attribute descriptor will force create-element() function to add an attribute with specified name and value into opening tag of the created element. If attribute with such name already exists, its value will be replaced.

Parameters

attrname
: Name of attribute which should be created or changed

attrvalue
: Value of of attribute

Return Types

Attribute descriptor

See Also

create-comment()

create-element()

create-pi()

create-comment

create-comment — Creates a "comment" XML tree entity.

Synopsis

```
entity create-comment ( comment-text string );
```

Description

This is an internal XQUERY function and you will probably never need to call it explicitly. It is not a part of library of standard XQUERY 1.0 functions.

This function creates an XML entity of sort "comment" that contains given text.

Parameters

comment-text
: The text content of the comment

Return Types

XML tree entity

See Also

create-attribute()

create-element()

create-pi()

create-element

create-element — Creates an element with specified name, attributes and children

Synopsis

```
node create-element ( head sequence ,
                      child1 any ,
                      child2 any ,
                      ... ,
                      childN any ) ;
```

Description

This is an internal XQUERY function and you will probably never need to call it explicitly. It is not a part of library of standard XQUERY 1.0 functions.

This function creates a new "XML Tree" element whose name is a string-value of the first item of *head* sequence, with attributes and children specified by the rest of *head* sequence and by the list of arguments *child1* , *child2* , ... *childN* .

First of all, a new element will be created, without attributes or children. The name of element will be taken from the first item of the *head* sequence. Then attributes will be created from the second and third items of *head* , from fourth and fifth and so on. In every pair of items will specify name and value of some attribute. Non-string items will be converted to strings first. It is an error to specify the same attribute name twice in *head* sequence.

When the "opening tag" of the element is prepared, children are added, in the same order as they are specified by arguments *child1* , *child2* , ... *childN* . If the value of some argument is a sequences (e.g. a node-set), items of the sequence are added as separate children in the same order as they are in the sequence. Nodes are added "as-is", numbers, strings and other "scalar" values are converted to strings first and these strings are converted into PCDATA (text) children.

"Attribute descriptor" objects are not converted to children elements; if descriptor item is found, one attribute in the opening tag of the created element is added or changed and the descriptor is removed from the list of children.

When all children are prepared, some normalization is performed. If there are two or more adjacent PCDATA (text) children, they are replaced with one PCDATA children whose text is a concatenation of texts of all that children.

Parameters

head
: Name of the element or a sequence of name and attributes of the element.

childI
: Children node or sequence of children node.

Return Types

Node

Errors

Table 24.139. Errors signalled by

SQLState	Error Code	Error Text	Description
XP001	XPFC0	At least one argument (name of element to be created) must be passed to create-element XPATH function.	create-element is called without arguments.

SQLState	Error Code	Error Text	Description
XP001	XPFC1	No name of element in the first argument of create-element XPATH function.	The *head* sequence is empty.
XP001	XPFC2	Last attribute has no value specified in the first argument of create-element XPATH function.	The *head* sequence is of even length.
XP001	XPFC3	Unsupported type of element of the first argument of create-element XPATH function.	Current version may create name and attributes of elements only from strings, entities and numbers.
XP001	XPFC4	Duplicate attribute names in first argument of create-element XPATH function.	Duplicate attribute names may appear in attribute descriptors but not in the *head* argument.
XP001	XPFC5	First argument of create-element XPATH function must be string, symbol or sequence of them.	The function was unable to prepare name of element.
XP001	XPFC6	Error in XPATH user extension function or internal error: sequence argument is not flat in create-element XPATH function.	A value of XQUERY "sequence" type should not contain other sequences as its items, i.e. it must be "flat".
XP001	XPFC7	Invalid special entity found in argument of create-element XPATH function.	An invalid object (probably built by XPATH extension function) is specified as child entity.
XP001	XPFCA	Persistent XML entities are not fully supported by create-element XPATH function.	The function creates "XML Tree" element, "Persistent XML" entity can not become a children of "XML Tree".
XP001	XPFCB	Unsupported type of argument in create-element XPATH function.	Some argument or some item of an argument may not be converted to a string or a node, so a children may not be created.

Examples

Example 24.574.

Two following XQUERY expressions are equivalent:

```
<H1>{'Hello, '}<B>{'world'}</B></H1>
create-element('H1', 'Hello, ', create-element('B', 'world'))
```

See Also

create-attribute()

create-comment()

create-pi()

create-pi

create-pi — Creates a "processing instruction" XML tree entity.

Synopsis

```
entity create-pi ( piname string ,
                   pivalue string ) ;
```

Description

This is an internal XQUERY function and you will probably never need to call it explicitly. It is not a part of library of standard XQUERY 1.0 functions.

This function creates an XML entity of sort "processing instruction". If *pivalue* is an empty string, the resulting processing instruction will have no value at all, exactly as if the *pivalue* is not passed at all.

Parameters

piname
: Name of processing instruction that should be created

pivalue
: String data stored in processing instruction

Return Types

XML tree entity of type "processing instruction"

See Also

create-attribute()

create-comment()

create-element()

current

current — Returns a node-set that has the current node as its only member.

Synopsis

```
node-set current ( void);
```

Description

The function returns a node-set that has the current node as its only member. For an outermost expression (an expression not occurring within another expression), the current node is always the same as the context node. For an expression occurring within another expression, e.g. within predicate in some path, the current node is the same as the context node of the first step in the path.

Please refer XSL standard before the first use of this function, to understand exact difference between "current" and "context" node.

XSLT 1.0 states that it is an error to use the current() function in a XSL "pattern", e.g. in "match" attribute of <xsl:key> element, because patterns have no value assigned for current node assigned processing. Instead of reporting the error, Virtuoso's XSLT processor uses context node if current node is not set.

Return Types

Node-set that has exactly one member.

Examples

Example 24.575. Function current() in top-level expression.

These two elements produce the same result:

```
<xsl:value-of select="current()"/>
<xsl:value-of select="."/>
```

Example 24.576. Function current() inside the path.

For current node, which is equal to context node of whole <xsl:apply-templates> key, try to find such item of glossary in the document, that the name of item is equal to "ref" attribute of current node.

```
<xsl:apply-templates select="//glossary/item[@name=current()/@ref]"/>
```

distinct

distinct — Removes double entities from the input sequence

Synopsis

```
sequence distinct ( input sequence );
```

Description

The function takes a single parameter which is sequence of XML entities (nodes or values) and returns the sequence that results from removing from input sequence all but one of a set of elements that are identical each other. If input sequence is the empty, the empty sequence is returned.

Note that the `distinct` is not a part of XPATH 1.0 or XQuery 1.0 standard library, it is rather a generalization of standard `distinct-nodes` and `distinct-values` functions.

Parameters

input
: The sequence of XML entities

Return Types

Sequence

Examples

Example 24.577. Removing double entities

In the following example the file example.xml is

```
<a>
<b/>
<b/>
</a>
```

The result of the query

```
<result>
   {
   distinct(for $r in document("example.xml")//b return $r)
   }
</result>
```

is only one 'b' element:

```
<result>
<b/>
</result>
```

doc

doc — Returns data from XML doc other than the main source document.

Synopsis

```
node-set doc ( document_uri varchar );
```

Description

The function tries to access an XML text at location specified by *document_uri* .

If the *document_uri* argument is node-set, not a string, then a node-set is returned as if document() function is applied to string-value of the first node of the node-set.

The result of call doc($uri) is similar to the call of function document() with default parameters:

```
document($uri, document-uri(.), 0, 'UTF-8', 'x-any', 'Include=ERROR IdCache=ENABLE')
```

I.e. the retrieved document should be XML or XHTML (but not an old-style HTML) in 'UTF-8' encoding, content language is 'x-any' (it means 'mix of words from various human languages'), DTD should be read but validation should be disabled; errors on including subdocuments should be reported as errors and thus should abort the processing; a dictionary of element's IDs should be created in order to support XQuery 'pointer operator'.

Parameters

document_uri
: An absolute or relative URI that points to a well formed XML or HTML document. If the URI is relative, then the base URI of context node is used to convert the given URI into absolute one.

Return Types

Node-set

Errors

The function may signal variety of errors when it reads the requested document(s) from network or from local resources. It may even cause deadlocks e.g. if documents are retrieved from the Virtuoso's own webserver and these documents must be created on the fly from data that are locked by Virtuoso/PL procedure that invokes the XPATH processor.

Examples

Example 24.578. Simple reading of a standalone XML document

Read a standalone document from http://www.example.com/sales/prices.xml

```
doc("http://www.example.com/sales/prices.xml")
```

See Also

document()

document-literal()

xtree_doc()

xper_doc()

document

document — Returns data from XML documents other than the main source document.

Synopsis

```
node-set document ( document_uri varchar ,
                    base_uri varchar ,
                    parser_mode integer ,
                    content_encoding varchar ,
                    content_language varchar ,
                    dtd_validator_config varchar ) ;
```

Description

The function tries to access an XML text at location specified by *document_uri* and optionally *base_uri* . On success, it parses the text and returns the root entity of the "XML Tree" document; the result is identical to the entity created by xtree_doc() Virtuoso/PL function.

If the *document_uri* argument is node-set, not a string, then a node-set is returned as if document() function is applied to string-value of every node of the node-set.

Note that the list of attributes of the function differs from specified in XSLT 1.0 standard. In XPATH 1.0, there is no such function at all.

Parameters

document_uri
: An absolute or relative URI that points to a well formed XML or HTML document. If the URI is relative, then the base_uri must be specified.

base_uri
: The URI that is used to resolve all relative URIs (i.e. to convert them into absolute in order to locate and load subdocuments) and to change 'local' absolute references to relative when in HTML mode.

parser_mode
: 0, 1 or 2; 0 - XML parser mode, 1 - HTML parser mode, 2 - 'dirty HTML' mode (with quiet recovery after any syntax error)

content_encoding
: string with content encoding type of document; valid are 'ASCII', 'ISO', 'UTF8', 'ISO8859-1', 'LATIN-1' etc., defaults are 'UTF-8' for XML mode and 'LATIN-1' for HTML mode.

content_language
: string with language tag of content of document; valid names are listed in IETF RFC 1766, default is 'x-any' (it means 'mix of words from various human languages')

dtd_validator_config
: configuration string for DTD validator, default is "Include=ERROR IdCache=ENABLE" meaning that DTD should be read but validation should be disabled; errors on including subdocuments should be reported as errors and thus should abort the processing; a dictionary of element's IDs should be created in order to support XQuery 'pointer operator'. See Configuration Options of the DTD Validator for details.

Return Types

Node-set

Errors

Table 24.140. Errors signalled by document()

SQLState	Error Code	Error Text	Description
XP001	XPF09	Too many arguments passed to XPATH function document()	The number of parameters may vary only from 1 to 6.
XP001	XPF10	XML entity or a string expected as \"base_uri\" argument of XPATH function document()	If presents, the second argument of the function must be either a string or an XML entity whose XML document has a suitable base URI.

The function may signal variety of errors when it reads the requested document(s) from network or from local resources. It may even cause deadlocks e.g. if documents are retrieved from the Virtuoso's own webserver and these documents must be created on the fly from data that are locked by Virtuoso/PL procedure that invokes the XPATH processor.

Examples

Example 24.579. Simple reading of a standalone XML document

Read a standalone document from http://www.example.com/sales/prices.xml

```
document("http://www.example.com/sales/prices.xml")
```

Example 24.580. Simple reading of a non-standalone document

Read a non-standalone document from local mirror but access its subdocuments as if it is retrieved directly from 'http://www.example.com/sales/prices.xml', so e.g. the subdocument that is referenced as 'termsandconditions.xml' is retrieved from http://www.example.com/sales/termsandconditions.xml but not from http://webcache.localdomain/examplesales/termsandconditions.xml .

```
document("http://webcache.localdomain/examplesales/prices.xml", "http://www.example.com/sales/prices.xml"
```

See Also

doc()

document-literal()

xtree_doc()

xper_doc()

document-literal

document-literal — Parses given XML text and returns the resulting XML data.

Synopsis

```
node-set document-literal ( document_text varchar ,
                            cache_uri varchar ,
                            parser_mode integer ,
                            content_encoding varchar ,
                            content_language varchar ,
                            dtd_validator_config varchar ) ;
```

Description

The function tries to parse an XML text as if it is obtained from a location specified by *cache_uri* . On success, it returns the root entity of the "XML Tree" document; the result is identical to the entity created by xtree_doc() Virtuoso/PL function.

When XPath processor parses a document, it saves it in a temporary cache. If a cached document is accessed again then no actual retrieval or parsing is made and a cached value is returned. The cache persists till the end of execution of a XPath query or till the end of the XSLT transformation if the XPath expression is a part of XSLT stylesheet. The *cache_uri* specifies the URI used as a key if the parsed document is cached. If *cache_uri* is not specified or the specified value is equal to an empty string, then no caching is performed. If the specified *cache_uri* is not equal to an empty string then it should distinct from URIs of other XML resources that are sources of the XPath query, to prevent confusion.

The *cache_uri* is also used by XML parser as a base URI to resolve relative URIs of external entities, so it is a good idea to specify some absolute URI if the parsed text is not a "standalone" document.

The *document_text* argument may be a sequence, not a single string. In this case a node-set is returned as if `document-literal` is applied to string-value of every element of the sequence. It is obvious that caching should not be used if there's a chance that the sequence may have more than one distinct element.

Note that the `document-literal` is not a part of XPATH 1.0 or XQuery 1.0 standard library.

Parameters

document_text
: well formed XML or HTML text

cache_uri
: The URI that is used to resolve all relative URIs (i.e. to convert them into absolute in order to locate and load subdocuments) and to change 'local' absolute references to relative when in HTML mode.

parser_mode
: 0, 1 or 2; 0 - XML parser mode, 1 - HTML parser mode, 2 - 'dirty HTML' mode (with quiet recovery after any syntax error)

content_encoding
: string with content encoding type of document_text ; valid are 'ASCII', 'ISO', 'UTF8', 'ISO8859-1', 'LATIN-1' etc., defaults are 'UTF-8' for XML mode and 'LATIN-1' for HTML mode.

content_language
: string with language tag of content of document_text ; valid names are listed in IETF RFC 1766, default is 'x-any' (it means 'mix of words from various human languages')

dtd_validator_config

configuration string for DTD validator, default is "Include=ERROR IdCache=ENABLE" meaning that DTD should be read but validation should be disabled; errors on including subdocuments should be reported as errors and thus should abort the processing; a dictionary of element's IDs should be created in order to support XQuery 'pointer operator'. See Configuration Options of the DTD Validator for details.

Return Types

Node-set

Errors

Table 24.141. Errors signalled by document-literal()

SQLState	Error Code	Error Text	Description
XP001	XPF15	Too many arguments passed to XPATH function document-literal()	The number of parameters may vary only from 1 to 6.

Examples

Example 24.581. Simple reading of a standalone XML document

Read a short document from string

```
document-literal("
<html><body><p>Hello
</p></body></html>)
```

Example 24.582. Simple reading of a non-standalone document

Read a non-standalone document from local mirror but access its subdocuments as if it is retrieved directly from 'http://www.example.com/sales/prices.xml', so e.g. the subdocument that is referenced as 'termsandconditions.xml' is retrieved from 'http://www.example.com/sales/termsandconditions.xml'

```
document-literal('
<!DOCTYPE price-list SYSTEM "http://www.example.com/dtd/sales.dtd" [
<!ENTITY t_and_c SYSTEM "termsandconditions.xml">
<!ENTITY prices_oct2002 SYSTEM "prices/2002/oct.xml">
]>
<price-list>
&t_and_c;
&prices_oct2002;
</price-list>
',
'http://webcache.localdomain/examplesales/prices.xml' )
```

document()

xtree_doc()

xper_doc()

empty

empty — Returns true if given argument is an empty sequence, false if it is any single value or nonempty sequence.

Synopsis

```
boolean empty ( seq any );
```

Description

Returns true if given argument is an empty sequence, false if it is any single value or nonempty sequence.

Parameters

seq
: Sequence of values to be checked.

Return Types

Boolean

Errors

This function never returns any errors

Examples

Example 24.583.

```
if(empty(//table),'There are no tables in context node','There is at least one table')
```

See Also

count()

ends-with

ends-with — Returns true if the first argument string ends with the second argument string, and otherwise returns false.

Synopsis

```
boolean ends-with ( strg string ,
                    suffix string ) ;
```

Description

For two given strings, this function checks if the first string ends with characters of second string. If any argument is not a string, it is converted to string using rules from string() XPATH function. Thus if the second argument has no string value, the function returns true, because it will be converted to an empty string first.

Unlike start-with() XPATH function, this function is not described in XPATH 1.0 standard. To write portable XPATH expression, use substring().

Parameters

strg
: String whose first characters must be compared

prefix
: String whose characters must be compared with first characters of strg

Return Types

Boolean

Examples

Example 24.584.

```
ends-with('OpenLink Virtuoso', 'Virtuoso')
```

See Also

string() contains() starts-with()

every

every — Returns true if all items of given sequence matches given criterion.

Synopsis

```
boolean every ( varname string ,
                test_set sequence ,
                test_expn boolean ) ;
```

Description

The function creates a temporary local variable, whose name is specified by *varname* argument. Then, for every item of *test_set* sequence it calculates the *test_expn* boolean expression having set the created variable to that "current" item. If the value of expression is false, the function immediately returns false without processing the rest of *test_set* sequence. If all items of the sequence are probed without getting false, true is returned. (So if the sequence is empty, the function returns true).

In any case, temporary variable is destroyed on return.

This function is used in the implementation of "EVERY" logical operator in XQUERY, so you will probably use that operator in XQUERY expressions, not the function. This function may be useful in XPATH expressions and in XSLT stylesheets. It is not a part of library of standard XQUERY 1.0 functions.

Parameters

varname
: Name of temporary variable

test_set
: Sequence of items; these items will be tested by test_expn

test_expn
: Boolean expression which should be calculated for items of test_set .

Return Types

Boolean

Examples

Example 24.585.

This expression returns true if all reports have positive incomes recorded.

```
every('income_value', /report/income, $income_value > 0)
```

See Also

some()

except

except — Returns a difference of two sets

Synopsis

```
sequence except ( set1 sequence ,
                  set2 sequence ) ;
```

Description

The function returns an unordered sequence that consists of all distinct items from the first sequence that are missing in the second sequence.

Duplicate values from *set1* are removed, the decision whether two values duplicate each other is made according rules used by `distinct()` function.

Parameters

set1
: Sequence that contains items that can occur in the resulting set.

set2
: Sequence that contains items that can not occur in the resulting set.

Return Types

The function returns an unordered sequence of distinct values.

See Also

`union`

`intersect`

false

false — Returns false.

Synopsis

```
boolean false ( void);
```

Description

This function returns boolean constant "false".

Return Types

Boolean

See Also

true boolean

filter

filter — Composes trees of shallow copies of given XML entities.

Synopsis

```
node-set filter ( selection sequence );
```

Description

The function takes a single parameter which can be any expression. The function evaluates its argument and returns a shallow copy of the nodes that are selected by the argument, preserving any relationships that exist among these nodes. Duplicate nodes are removed before the processing.

The structure of the resulting node-set may be explained in the following way. First of all, all input entities are grouped by their documents, so we have a set of distinct documents and for every document we have a list of entities that refers to various nodes of the document. After that, every such document is processed separately, and the result of processing is a node-set; the union of these node-sets will be returned as the result of the call of filter() function. A copy of the document is made, and a "color" is assigned to every node of the copy: it's "black if the original node is listed in the *selection* sequence, otherwise it's "white". Then "white" nodes are removed from the copy, node after node: if a "white" node may be found, it is replaced with list of its children. Finally, we have a list of one or more "black" nodes whose descendants are all "black", too, and this list is added into the resulting node-set.

(The actual algorithm is much faster and much more complicated than the described one, but the result is identical.)

Note that this function is defined in XQuery standard, not in XPath, but in Virtuoso it may be used freely in expression of any kind.

Parameters

selection
: The sequence of nodes that should be included into the result

Return Types

Node-set

Errors

Table 24.142. Errors signalled by filter()

SQLState	Error Code	Error Text	Description
XP001	XPFB0	The argument of XQUERY function filter() must be a sequence of XML entities	According to the XQuery standard, the function should signal an error if input contains values other than XML entity.

Examples

Example 24.586. Composing table of contents

The following example is from the XQuery standard and it illustrates how filter() might be used to compute a table of contents for a document that contains many levels of nested sections. The query filters the document, retaining only section elements, title elements nested directly inside section elements, and the text of those title elements. Other elements, such as paragraphs and figure titles, are eliminated, leaving only the "skeleton" of the document. The example generates a table of contents for a document named "cookbook.xml".

```
<toc>
   {
```

```
    filter(document("cookbook.xml") //
       (section | section/title | section/title/text()))
    }
</toc>
```

See Also

shallow()

floor

floor — Returns the largest integer that is not greater than the argument.

Synopsis

```
integer floor ( num number );
```

Description

This function returns the largest (closest to positive infinity) number that is not greater than the argument and that is an integer. In other words, it "rounds down" the given value.

Parameters

num
: The value to be "rounded down"

Return Types

Examples

Example 24.587.

The following expressions are true:

```
floor(2.5) = 2
floor(2) = 2
floor(-2.5) = -3
floor(-2) = -2
```

ceiling() round()

for

for — Repeats some calculation for every item of a given sequence

Synopsis

```
any for ( varname string ,
          source_set sequence ,
          mapping_expn any ) ;
```

Description

The function creates a temporary local variable, whose name is specified by *varname* argument. Then, for every item of *source_set* sequence it calculates the value of *mapping_expn* expression having set the created variable to that "current" item. It returns the "flattened" sequence of values returned by *mapping_expn* in the same order as they are calculated. "Flattened" means that if *mapping_expn* returns an sequence, items of this sequence will be added into the end of resulting sequence, one by one, instead of adding one item of type "sequence".

The temporary variable is destroyed on return.

This function is used in the implementation of "FOR" control operator in XQUERY, so you will probably use that operator in XQUERY expressions, not the function. This function may be useful in XPATH expressions and in XSLT stylesheets. It is not a part of library of standard XQUERY 1.0 functions.

Parameters

varname
: Name of temporary variable

source_set
: Sequence of items; every item will cause one call of mapping_expn

mapping_expn
: An expression which should be calculated for items of source_set .

Return Types

Sequence

Examples

Example 24.588.

These two expressions are equivalent, but first may be used in any XPATH while second is written in XQUERY syntax

```
for('itm', /bid/item, 0.20 * $itm/price)
FOR $itm IN /bid/item RETURN 0.20 * $bid_item/price
```

See Also

let()

some()

every()

format-number

format-number

Synopsis

```
string format-number (   num number ,
                         format_pattern string
                         ,
                         decimal_format
                         string ) ;
```

Description

The function converts the *num* argument to a string using the format pattern string specified by the *format_pattern* and the decimal-format named by the *decimal_format* , or the default decimal-format, if there is no third argument.

The format pattern string is in the syntax specified by the JDK 1.1 DecimalFormat class. The following describes the structure of the pattern.

- The pattern consists of one or two subpatterns, first is for positive numbers and zero, second is for negative numbers. Two subpatterns are delimited by semicolon. If there is only one subpattern, - is prefixed to the positive subpattern.
- Every subpattern consists of optional prefix characters followed by an integer part followed by an optional fraction part followed by an optional suffix characters.
- Prefix and suffix characters are any Unicode characters except special formatting characters described below, while integer and fraction part consist only from that special formatting characters. (As an exception, special characters may appear in prefix in suffix parts if enclosed in single quotes.
- If fractional present, it starts from '.' character, and only one '.' may occur in the subformat. Thus it is easy to find where each part begins.

By default, the following characters are treated as special when used in the parts of the subpattern:

Table 24.143. Sub-pattern character substitutions

Symbol	Meaning
0	A digit, zero will be printed. 0 must be the last character of integer part.
#	A digit, zero will not be printed.
.	Placeholder for decimal separator in the beginning of fraction part.
,	Placeholder for grouping separator. It may appear only in integer part. All commas except the last will be ignored.
;	Separates formats. It may appear only once in the pattern.
-	Placeholder for negative prefix.
%	Indicates that the value must be multiplied by 100 and shown as percentage.
?	Indicates that the value must be multiplied by 1000 and shown as per mille.

Note that character '¤' have a special meaning in DecimalFormat of JDK 1.1, but not in XPATH.

The format pattern string may be in a localized notation. The *decimal_format* may determine what characters have a special meaning in the pattern (with the exception of the quote character, which is not localized). The *decimal_format* must be a QName, and a search will be performed for top-level <xsl:decimal-format> key whose "key" attribute is equal to *decimal_format* ; all names will be expanded before the search. It is an error if the stylesheet does not contain a declaration of the decimal-format with the specified expanded name.

Parameters

num
: Number to format.

format_pattern
: Format pattern which must be applied to the number.

decimal_format
: Name of <xsl:decimal-format> element which must be used to parse format pattern.

Return Types

String

Errors

Table 24.144. Errors signalled by

SQLState	Error Code	Error Text	Description
XS370	XS036	Number format ... is not defined in XPath function format-number()	The function is called outside an XSLT processor or the current stylesheet contains no format definition with the required name.

Examples

Example 24.589.

If the XSLT stylesheet defines format 'financial' as '###,###.00####', then the following returns '123,456.789':

```
format(123456.789, "financial")
```

function-available

function-available — Returns true if XPATH extension function with the requested name is defined in the XPATH Processor, otherwise returns false.

Synopsis

```
boolean function-available ( funname string );
```

Description

The function returns true if XPATH Processor can execute XPATH extension function with the name specified by *funname* argument. If such function is not defined, function-available returns false.

Parameters

funname
: The name of XPATH extension function

Return Types

Boolean

Examples

Example 24.590.

This expression should return false.

```
function-available('http://example.com/Virtuoso/nosuchfunction')
```

See Also

xpf_extension()

generate-id

generate-id — Returns a string that uniquely identifies the node.

Synopsis

```
string generate-id ( place node_set );
```

Description

The function returns a string that uniquely identifies the first node in the *place* argument node-set. The unique identifier will consist of ASCII alphanumeric characters and will start with an alphabetic character. Thus, the string is syntactically an XML name. It always generates the same identifier for the same node. It always generates different identifiers from different nodes. This function is under no obligation to generate the same identifiers each time a document is transformed. There is no guarantee that a generated unique identifier will be distinct from any unique IDs specified in the source document.

If the argument node-set is empty, the empty string is returned.

If the argument is omitted, it defaults to the context node.

Parameters

place
: Node-set whose first node is used as a key to generate a resulting ID

Return Types

String which is syntactically an XML name.

Examples

Example 24.591.

```
generate_id(.)
```

id

id — Returns an entities whose ID attributes are in the given list

Synopsis

```
sequence id ( ids any );
```

Description

The function gets a list of strings, where every string is a list of IDs delimited by whitespace characters. For every listed ID, the function checks if the document that contains the context entity also contains an entity with such ID; if the entity with the listed ID exists, it is added into the sequence.

To avoid searches of every ID inside the whole document, the function uses "ID cache" that is created if "IdCache=ENABLE" DTD configuration option is specified in the call of function that parses the XML document. In some cases, it is possible to build such cache on demand if it is not built by a parser, but it consumes time and in any case it requires the saved DTD information from the XML parser, so the parser should be specially configured anyway.

Note that any attribute of types ID, IDREF or IDREFS is a good input string for the function id(). So while XQuery "pointer operator" is not available in XPath expression, the id() function is a good replacement for it.

Parameters

ids
: The list of strings that consist of IDs

Return Types

Errors

The function ignores any sort of syntax errors on input.

Examples

Example 24.592. List errors in census data

List every person who is not a spouse of his own spouse.

```
document ("census.xml")//person[@spouse and not (. = id (id (@spouse)/person/@spouse)]
```

See Also

document()

if

if — If the boolean value is true then calculates one expression, otherwise calculates another expression.

Synopsis

```
any if ( test boolean ,
         then_branch any ,
         else_branch any ) ;
```

Description

This function calculates the value of *test* argument. If the value is true, the function calculates the *then_branch* expression and returns its value. If the value is false, the function calculates the *else_branch* expression and returns its value.

Note that unlike other programming languages, *else_branch* is required argument, not optional.

This function is used in the implementation of "IF" control operator in XQUERY, so you will probably use that operator in XQUERY expressions, not the function. This function may be useful in XPATH expressions and in XSLT stylesheets. It is not a part of library of standard XQUERY 1.0 functions.

Parameters

test
: Boolean value used to choose an expression to execute

then_branch
: Expression which is calculated if test argument is true

else_branch
: Expression which is calculated if test argument is false

Return Types

Any

Examples

Example 24.593.

These two expressions are equivalent, but first may be used in any XPATH while second is written in XQUERY syntax:

```
if (2 * 2 = 4, 'I think so', 'Unbelievable!')
IF 2 * 2 = 4 THEN 'I think so' ELSE 'Unbelievable!'
```

See Also

and() or()

intersect

intersect — Returns an intersect of two sets

Synopsis

```
sequence intersect ( set1 sequence ,
                     set2 sequence ) ;
```

Description

The function returns an unordered sequence that consists of all distinct items such that every of source sequences contains every of the resulting items.

Duplicates are removed, including duplicate occurrences of same value in one sequence, the decision whether two values duplicate each other is made according rules used by `distinct()` function.

Parameters

set1, set2
: Sequence that contains items of the resulting intersect.

Return Types

The function returns a sequence of distinct values.

See Also

`union`

`except`

is_after

is_after — Returns true if the given entity is after the second given entity in document order, otherwise returns false.

Synopsis

```
boolean is_after (   ent1 entity ,
                     ent2 entity
                     ) ;
```

Description

The function ensures that both *ent1* and *ent2* are XML entities and the returns true if *ent1* and *ent2* are both in the same XML document and *ent1* is strictly after *ent2* in document order. It returns false if one of them is not an entity but an empty node-set or if their documents differ or or if they're equal or if one of them is an ancestor of other or if *ent1* is simply before *ent2* in document order.

Parameters

ent1
: An XML entity or an node-set whose first node is compared.

ent2
: An XML entity or an node-set whose first node is compared.

Return Types

Boolean

Errors

Table 24.145. Errors signalled by is_after()

SQLState	Error Code	Error Text	Description
XP001	XPFB0	First argument of XPATH function is-before() or is-after() must be XML entity	The value that is neither an XML entity nor an empty node-set may not be compared using document order.
XP001	XPFB1	Second argument of XPATH function is-before() or is-after() must be XML entity	The value that is neither an XML entity nor an empty node-set may not be compared using document order.

Examples

Example 24.594.

Find all chapters that have title after table of content

```
/book/chapter[is-after(toc,title)]
```

See Also

is_before()

is_before

is_before — Returns true if the given entity is before the second given entity in document order, otherwise returns false.

Synopsis

```
boolean is_before ( ent1 entity ,
                    ent2 entity ) ;
```

Description

The function ensures that both *ent1* and *ent2* are XML entities and the returns true if *ent1* and *ent2* are both in the same XML document and *ent1* is strictly before *ent2* in document order. It returns false if one of them is not an entity but an empty node-set or if their documents differ or or if they're equal or if one of them is an ancestor of other or if *ent1* is simply after *ent2* in document order.

Parameters

ent1
: An XML entity or an node-set whose first node is compared.

ent2
: An XML entity or an node-set whose first node is compared.

Return Types

Boolean

Errors

Table 24.146. Errors signalled by is_before()

SQLState	Error Code	Error Text	Description
XP001	XPFB0	First argument of XPATH function is-after() or is-before() must be XML entity	The value that is neither an XML entity nor an empty node-set may not be compared using document order.
XP001	XPFB1	Second argument of XPATH function is-after() or is-before() must be XML entity	The value that is neither an XML entity nor an empty node-set may not be compared using document order.

Examples

Example 24.595.

Find all chapters that have table of content before title

```
/book/chapter[is-before(title,toc)]
```

See Also

is_after()

key

key — This XSLT 1.0 function is not implemented in the current version of Virtuoso.

Synopsis

```
string key ( keyname string ,
             keyvalues any ) ;
```

lang

lang — Returns true if the language of context node matches given language name.

Synopsis

```
boolean lang ( lang_name string );
```

Description

The lang function returns true or false depending on whether the language of the context node as specified by xml:lang attributes is the same as or is a sublanguage of the language specified by the argument string. The language of the context node is determined by the value of the xml:lang attribute on the context node, or, if the context node has no xml:lang attribute, by the value of the xml:lang attribute on the nearest ancestor of the context node that has an xml:lang attribute. If there is no such attribute, then lang returns false. If there is such an attribute, then lang returns true if the attribute value is equal to the argument ignoring case, or if there is some suffix starting with "-" such that the attribute value is equal to the argument ignoring that suffix of the attribute value and ignoring case.

Parameters

lang_name
: Name of the language

Return Types

Boolean

Examples

Example 24.596.

The expression lang("en") would return true if the context node is any of these five elements:

```
<para xml:lang="en"/>
<div xml:lang="en"><para/></div>
<para xml:lang="EN"/>
<para xml:lang="en-us"/>
```

See Also

last

last — Returns the context size from expression evaluation context.

Synopsis

```
number last ( void);
```

Description

Context size is the number of nodes in the node-set where the context node comes from. For the most popular case, when last() is used inside a predicate, and the predicate relates to some axis of the path, last() is the number of elements found by that axis at once; in other words, the number of elements to be tested by predicate.

Return Types

Positive integer.

Examples

Example 24.597. Call of last() inside a predicate

Find all waybills with more than one <address> child inside the <waybill> element.

```
//waybill/address[last()>1]
```

See Also

position() count()

let

let — Creates temporary variables and calculates an expression that uses these variables

Synopsis

```
any let ( var1name string ,
          var1value sequence ,
          var2name string ,
          var2value sequence ,
          ... ,
          varNname string ,
          varNvalue sequence ,
          retval any ) ;
```

Description

For every pair of arguments, the function calculates values of these arguments and then creates a new temporary local variable whose name is the string value of the first argument in pair and the value assigned is the value of the second argument in pair. Obviously, the argument for variable name is usually a constant string of alphanumeric characters. The expression for a value of variable number I may refer to variables created during steps 1 to I-1. When all pairs of arguments are turned into temporary variables, the last argument is calculated and its value is returned as the value of the whole expression.

Temporary variables are destroyed on return.

This function is used in the implementation of "LET" control operator in XQUERY, so you will probably use that operator in XQUERY expressions, not the function. This function may be useful in XPATH expressions and in XSLT stylesheets. It is not a part of library of standard XQUERY 1.0 functions.

Parameters

varIname
: Expression for the name for the I-th temporary variable

varIvalue
: Expression for the value for the I-th temporary variable

retval
: Expression for the value to be returned

Return Types

Any, depending on the type of `retval` expression.

Errors

Table 24.147. Errors signalled by let()

SQLState	Error Code	Error Text	Description
42000	XPF02	Wrong number of arguments for XPATH function let(), maybe internal XQuery error	The function should have odd number of arguments: even number of arguments that describe variables plus one for the returned expression.

Examples

Example 24.598.

These two expressions are equivalent, but first may be used in any XPATH while second is written in XQUERY syntax

```
let('baseprice', /item/price, 'discount', 0.20, $baseprice * (1.0 - $discount))
LET  $baseprice := /item/price, $discount := 0.20 RETURN $baseprice * (1.0 - $discount)
```

See Also

for()

list

list — Selects the first item of every argument sequence and returns the sequence of the selected items

Synopsis

```
sequence list ( seq1 sequence ,
                seq2 sequence ,
                ... ,
                seqN sequence ) ;
```

Description

This function calculates all given arguments from left to right, and creates a sequence which contains the first item of the first calculated sequence, then the first item of the second calculated sequence and so on. If the value of an argument is not a sequence, but a scalar, the scalar is treated as one-element sequence so it is added into the result. If the value of an argument is an empry sequence, nothing is added into the result (unlike function tuple() that adds an empty string in this case).

This function is not a part of XPATH 1.0 or XQUERY 1.0 libraries of standard functions.

Parameters

SeqI
: The sequence of items, first of its items will be used as I-tn item of the resulting sequence

Return Types

Sequence

Examples

Example 24.599.

Compose a sequence of the first title in the document, then the first abstract, then the first introduction

```
list(/title, /abstract, /intro)
```

See Also

append() tuple()

local-name

local-name — Returns the local part of the expanded name of the argument.

Synopsis

```
string local-name ( node_obj any );
```

Description

For given node, it returns local part of the node, i.e. the name of given attribute or element with namespace prefix removed. If the argument is node-set, first node of the node-set will be considered. Empty string is returned if the argument is an empty node-set, a node without name or if the argument is not a node.

If the argument is omitted, context node is used instead as if it is a node-set of one element.

Parameters

node_obj
: Node whose name is to be returned

Return Types

String

Examples

Example 24.600.

Find all elements whose names start with "ref..." prefix

```
//*[starts-with(local-name(),'ref')]
```

See Also

name() namespace-uri()

max

max — Returns maximum value among all its arguments.

Synopsis

```
number max ( arg1 any ,
             arg2 any ,
             ... ,
             argN any ) ;
```

Description

The function returns the maximum value among all values in all its arguments, For each node in every argument node-set, it converts the string-value of the node to a number. If some arguments are not node-sets, they are converted to numbers. The maximum number found is returned.

This function is not a part of XPATH 1.0 standard library.

Parameters

argI
: A node-set of nodes whose string values must be converted to numbers and added to the result, or single value.

Return Types

Table 24.148. Errors signalled by

SQLState	Error Code	Error Text	Description
XP001	XPF05	Nonempty sequence of values expected as argument of XPATH function max(); max() of nothing is senseless	This happens if the function is called without arguments, or with all arguments set to empty node-sets.

Examples

Example 24.601.

```
max(/report[@type="daily-sales"]/total)
```

See Also

sum avg min

min

min — Returns minimum value among all its arguments.

Synopsis

```
number min ( arg1 any ,
             arg2 any ,
             ... ,
             argN any ) ;
```

Description

The function returns the minimum value among all values in all its arguments, For each node in every argument node-set, it converts the string-value of the node to a number. If some arguments are not node-sets, they are converted to numbers. The minimum number found is returned.

This function is not a part of XPATH 1.0 standard library.

Parameters

argI
: A node-set of nodes whose string values must be converted to numbers and added to the result, or single value.

Return Types

Table 24.149. Errors signalled by min()

SQLState	Error Code	Error Text	Description
XP001	XPF04	Nonempty sequence of values expected as argument of XPATH function min(); min() of nothing is senseless	This happens if the function is called without arguments, or with all arguments set to empty node-sets.

Examples

Example 24.602.

```
min(/report[@type="daily-sales"]/total)
```

See Also

sum avg max

name

name — Returns the expanded name of the argument.

Synopsis

```
string name ( node_obj any );
```

Description

For given node, it returns extended name of the node, i.e. the name of given attribute or element with namespace prefix replaced with namespace URI string. If the argument is node-set, first node of the node-set will be considered. Empty string is returned if the argument is an empty node-set, a node without name or if the argument is not a node.

If the argument is omitted, context node is used instead as if it is a node-set of one element.

Parameters

node_obj
: Node whose name is to be returned.

Return Types

String

Examples

Example 24.603.

Find all elements whose namespace URIs or local names contain "html" substring

```
//*[contains(name(),'html')]
```

See Also

local-name() namespace_uri()

namespace-uri

namespace-uri — Returns the namespace URI of the extended name of the given node

Synopsis

```
string namespace-uri ( node_obj any );
```

Description

If given argument is a node, the function returns the URI string of the namespace specified in the name of node. If the argument is node-set, first node of the node-set will be considered. Empty string is returned if the argument is an empty node-set, a node without name or if the argument is not a node.

If the argument is omitted, context node is used instead as if it is a node-set of one element.

Parameters

node_obj
: Node whose namespace URI is to be returned.

Return Types

String

Examples

Example 24.604.

Find all elements whose namespace URIs contain "html" substring

```
//*[contains(namespace-uri(),'html')]
```

See Also

local-name() name()

normalize-space

normalize-space — Returns the argument string with whitespace normalized.

Synopsis

```
string normalize-space ( strg string );
```

Description

The function returns the argument string with whitespace normalized by stripping leading and trailing whitespace and replacing sequences of whitespace characters by a single space. Whitespace characters are the same as those allowed by the S production in XML, i.e. space (#x20), carriage returns (#xD), line feeds (#xA), and tabs (#x9). If the argument is omitted, it defaults to the context node converted to a string, in other words the string-value of the context node.

Parameters

strg
: A string to be normalized

Return Types

Examples

Example 24.605.

```
normalize-space('    too     many   spaces    ')
```

See Also

translate() replace()

not

not — Returns true if its argument is false, and false otherwise.

Synopsis

```
boolean not ( obj boolean );
```

Description

This function returns true if its argument is false, and false otherwise. If the argument is not a value of boolean type, it will be converted to boolean first.

Parameters

obj
: Boolean value

Return Types

Boolean

Examples

Example 24.606.

See Also

boolean()

number

number — Converts its argument to a number.

Synopsis

```
number number ( obj any );
```

Description

The number function converts its argument to a number as follows:

- A string that consists of decimal number and optional whitespaces is converted to the number recorded. Any other string is converted to NaN ("not-a-number" value). More precisely, a string that consists of optional whitespace followed by an optional plus or minus sign followed by a Number followed by whitespace is converted to the IEEE 754 number that is nearest (according to the IEEE 754 round-to-nearest rule) to the mathematical value represented by the string. Note that it differs from XPATH 1.0 standard where plus sign is not allowed before Number part of the string.
- Boolean true is converted to 1; boolean false is converted to 0.
- A node-set is first converted to a string as if by a call to the string function and then converted in the same way as a string argument.
- An object of a type other than the four basic types is converted to a number in a way that is dependent on that type.

If the argument is omitted, it defaults to a node-set with the context node as its only member.

Parameters

obj
: Value to be converted to a number.

Return Types

Number

Examples

Example 24.607.

```
number(' 3.1415926 ')
```

See Also

string() boolean()

or

or — Returns true if a value of some argument is true, otherwise returns false.

Synopsis

```
boolean or ( val1 boolean ,
             val2 boolean ,
             ... ,
             valN boolean ) ;
```

Description

This function calculates values of its arguments, from left to right. If the value of calculated parameter is true, the function returns true immediately, without calculating of the remaining parameters. If the list of arguments ends without any true value calculated, the function returns false (Thus it returns true when called without arguments).

The name of this function is the same as name of "or" XPATH and XQUERY operator. Thus it must be surrounded by double quotes when used in XPATH or XQUERY expressions. Moreover, this function is not a part of XPATH standard, so it cannot be used if portability is important.

Parameters

valI
: Value of boolean expression argument

Return Types

boolean

Examples

Example 24.608. Control over sequence of search operations

If two conditions must be checked, where one is simple and another is hard to calculate, then "and" may be used to calculate second condition only if first is false, to reduce average time of processing

```
"or" ( empty(authors),
  document(concat('http://www.lib20.org/findxml.cgi?isbn=',@isbn))/status[@outofprint='YES'] )
```

See Also

not and some

position

position — Returns the context position from expression evaluation context.

Synopsis

```
number position ( void);
```

Description

Context position is the number of nodes in the node-set where the context node comes from. For the most popular case, when position() is used inside a predicate, and the predicate relates to some axis of the path, position() is the number of calls of the predicate, including the "current" call which is in progress when the function is called. Thus, context position cannot be greater than context size.

Return Types

Positive integer.

Examples

Example 24.609. Explicit call of position() inside a predicate

For every waybill, find the last <address> child inside the <waybill> element.

```
//waybill/address[position() = last()]
```

Example 24.610. Implicit call of position() inside a predicate

For every article, find up to three first paragraphs of the first section.

```
//article/section[1]/paragraph[position()<=3]
```

See Also

last() count()

processXQuery

processXQuery — Calls an XQuery module from XPath expression, e.g. from some XSLT or BPEL code.

Synopsis

```
any processXQuery ( module_uri string ,
                    context entity ,
                    index integer ,
                    param1_name string ,
                    param1_value any ... ,
                    paramN_name string,
                    paramN_value any) ;
```

Description

This function takes a URI of an XQuery module and an XML entity and calls the module with the entity as a context. Depending on value of *index* parameter, either the result of the module is returned 'as is' or the sequence of results is returned.

Parameters can be passed to the module by specifying additional arguments to `processXQuery()` . The names of parameters should appear in argument list without the leading '$' sign. Unlike `xquery_eval()` function, parameter can not be ignored depending on the type of its value. If the same name appears more than once in the vector, the last name/value pair is used and all preceding pairs with this name are silently ignored. Obviously, names should be strings that are valid XPath variable names.

The XQuery standard does not offer a way of calling of a module from other XQuery expression. The reason is that there's no need for such calling if the code is designed properly. If an expression is re-used in various places then it should be turned into a function and placed into an XQuery library module; one should import the module and call the function instead of calling a non-library module. It is possible to use `processXQuery()` in XQuery expressions but it is much better to use library modules instead, and to use `processXQuery()` only for tricks in XPATH expressions.

For compatibility, the `processXQuery()` function can also be called as `http://schemas.oracle.com/xpath/extension:processXQuery()` .

Parameters

module_uri
: URI pointing to the location of an XQuery module. It can be absolute or relative. A relative module_uri should be resolved before use, this requires base URI information. Base URI can be declared explicitly by "__base_uri" parameter in XPATH or "declare base-uri" setter in XQuery. If not declared but the expression is a part of some stylesheet or XQuery module then the URI of module is used as a base URI. A run-time error is signalled if the URI is relative and the expression does not contain explicit declaration and the expression is neither in a stylesheet nor in a module.

index
: Result index. If omitted a value of 1 is assumed, meaning only the first result is returned. If a value of 0 is supplied then a (flatten) sequence of all results is returned. (Note that if a non-zero value is specified then the returned value still can be a sequence).

context
: XML entity that is the context node of module call. If the function is called with only one argument then the current context node of the processXQuery() call is used as a context of module call. (In any case, context size and context position of module call are always set to 1 and not inherited from call of processXQuery() .)

paramI_name
: Name of parameter to be passed to the XSLT engine for use in the transformation.

paramI_value
: Value of parameter with name specified by paramI_name .

Return Types

The type of return value depends on type of value returned by module.

Examples

Example 24.611. Call of XQuery in XSLT

Sample templates put the result of the call of module "mymodule.xq" for context node into the resulting document. This assumes that both the stylesheet and XQuery module "mymodule.xq" reside in the same directory so relative a URI "mymodule.xq" can be resolved using the URI of the stylesheet as base URI.

```
  <xsl:template match="myelement">
  <xsl:copy-of select="processXQuery('mymodule.xq')"/>
</xsl:template>
```

This is equivalent with the following template:

```
  <xsl:template match="myelement">
  <xsl:copy-of select="processXQuery('mymodule.xq', current(), 1)"/>
</xsl:template>
```

See Also

`xquery_eval()`

`processXSLT()`

`processXSQL()`

processXSLT

processXSLT — Applies stylesheet to given XML entity and returns the result.

Synopsis

```
entity processXSLT ( stylesheet_uri string ,
                     source entity ,
                     param1_name string ,
                     param1_value any ... ,
                     paramN_name string,
                     paramN_value any ) ;
```

Description

This function takes the URI of a stylesheet and an XML entity and produces an XML entity representing the transformation result of the given entity with the given stylesheet. The result tree is separate from the argument tree and the only reference to it is the returned entity. Errors occurring in the transformation will be signalled as SQL states, with XML or XSLT specific conditions beginning with XS or XP.

The stylesheet is applied to the value of *source* parameter. Obviously, *source* must be an entity. If *source* is not specified then the stylesheet is applied to the current entity.

Parameters can be passed to the stylesheet by specifying additional arguments to `processXSLT()` . The values can be referenced from inside XPath expressions in the stylesheet. The names of parameters should appear in argument list without the leading '$' sign. Unlike `xslt()` function, parameter can not be ignored depending on the type of its value. If the same name appears more than once in the vector, the last name/value pair is used and all preceding pairs with this name are silently ignored. Obviously, names should be strings that are valid XPath variable names.

The function uses the cache of compiled stylesheets, see description of `xslt()` Virtuoso/PL function for more details.

For compatibility, the `processXSLT()` function can also be called as `http://schemas.oracle.com/xpath/extension:processXSLT()` .

Parameters

stylesheet_uri
: URI pointing to the location of an XSL stylesheet. It can be absolute or relative. A relative stylesheet_uri should be resolved before use, this requires base URI information. The base URI can be declared explicitly with the "__base_uri" parameter in XPATH or "declare base-uri" setter in XQuery. If not declared but the expression is a part of some stylesheet or XQuery module then the URI of module is used as a base URI. A run-time error is signalled if the URI is relative and the expression does not contain explicit declaration and the expression is neither in a stylesheet nor in a module.

source
: XML entity that is the source of XSL transformation. If the function is called with only one argument then the context node is used as a source.

paramI_name
: Name of parameter to be passed to the XSLT engine for use in the transformation.

paramI_value
: Value of parameter with name specified by paramI_name .

Return Types

The function returns an XML entity that is the root entity of the resulting document of an XSL transformation.

Examples

Example 24.612. XSLT inside XQuery expression

The query composes a single document that contain a list of labels for parcels. Depending on destination country and the state value of the parcel, the query applies one of three stylesheets that make a label from the address data; the query makes a label from every item of sequence $orders.

```
<parcel-labels>
for $order in $orders let $customer := $customers/customer [ @CustId = $order/@CustId ] return
  if ($customer/address/@Country = "US")
    if ($order/sum >= 50.0)
      processXSLT ("file://registered-parcel.xsl", $customer/address, "value", $order/sum)
    else
      processXSLT ("file://plain-parcel.xsl", $customer/address)
  else
    processXSLT ("file://foreign-parcel.xsl", $customer/address, "value", $order/sum)
</parcel-labels>
```

See Also

`xslt()`

`processXQuery()`

`processXSQL()`

processXSQL

processXSQL — Executes XSQL page and returns the result.

Synopsis

```
entity processXSQL ( xsql_page_uri string );
```

Description

This function takes a URI of an XSQL page, compiles the page into a Virtuoso/PL procedure (if not compiled earlier) and executes the compiled procedure. The current entity is passed to the page procedure as "context XML" argument. The function returns the XML document composed by page procedure. The result tree is separate from the argument tree and the only reference to it is the returned entity.

For compatibility, the `processXSQL()` function can also be called as `http://schemas.oracle.com/xpath/extension:processXSQL()`.

Parameters

xsql_page_uri
: URI pointing to the location of an XSQL page. It can be absolute or relative. Relative xsql_page_uri should be resolved before use, this requires base URI information. Base URI can be declared explicitly by "__base_uri" parameter in XPATH or "declare base-uri" setter in XQuery. If this is not declared but the expression is a part of some stylesheet or XQuery module then the URI of the stylesheet or module is used as a base URI. A run-time error is signalled if the URI is relative and the expression does not contain explicit declaration and the expression is neither in a stylesheet nor in a module.

Return Types

The function returns an XML entity that is the root entity of the resulting document of an XSQL page.

Examples

Example 24.613. Simple call

The query passes its argument to the XSQL page and returns its result. This is the simplest way of calling an XSQL page.

```
processXSQL ("file://sample.xsql")
```

See Also

`processXSLT()`

`processXQuery()`

progn

progn — Calculates all given expressions and returns the result produced by the last one.

Synopsis

```
any progn ( expn1 any ,
            expn2 any ,
            ... ,
            expnN any ) ;
```

Description

This function calculates its first argument, then second argument and so on. The results of these calculations are not used, except the result of the last expression which is returned. The only useful application for this function is calling XPath extension functions for side effects.

This function is not a part of library of standard XQuery 1.0 functions.

Parameters

expn1, expn2, ... expnN
: Expressions to be calculated.

Return Types

Any (according to the type of *expnN*)

Examples

Example 24.614.

```
[xmlns:fileio='http://www.example.com/file-io']
if (function-available ('fileio:printf'),
  progn (
    fileio:open('greeting.txt', 'wt'),
    fileio:printf('Hello %s', /userinfo/name),
    fileio:close(),
    'File greeting.txt saved' ),
  'File greeting.txt not saved' ) )
```

See Also

if

for

let

replace

replace — Searches for an substring and replace its occurrences with other substring.

Synopsis

```
string replace ( txt string ,
                 search_strg string ,
                 replace_strg string ) ;
```

Description

The function searches for all occurrences of a *search_strg* in *txt* and replaces every occurrence with *replace_strg* . An error is signalled if *search_strg* is empty.

Parameters

txt
: Text to process.

search_strg
: Substring to search for txt .

replace_strg
: Substring to replace search_strg in txt .

Return Types

String.

Errors

Table 24.150. Errors signalled by

SQLState	Error Code	Error Text	Description
XP001	XPF08	Empty string passed as argument 2 to XPATH function replace()	It is impossible to search for an empty substring.
XP001	XPF14	The result of XPATH function replace() is too long	If the function replaces short substring with longer one, the result is longer than the original string and may exceed 10Mb limit.

Examples

Example 24.615.

Replace all occurrences of 'http://www.example.com/' with '/webrobot/'

```
replace(
  '<A HREF="http://www.example.com/index.html">Home</A>',
  'http://www.example.com/', '/webrobot/' )
```

See Also

translate

round

round — Returns the integer that is the nearest to the argument.

Synopsis

```
integer round ( num number );
```

Description

The function returns the number that is closest to the argument and that is an integer. If there are two such numbers, then the one that is closest to positive infinity is returned. If the argument is NaN, then NaN is returned. If the argument is positive infinity, then positive infinity is returned. If the argument is negative infinity, then negative infinity is returned.

Parameters

num
: The value to be rounded

Return Types

Examples

Example 24.616.

The following expressions are true:

```
round(2.4) = 2
round(2.5) = 3
round(2.6) = 3
round(-2.4) = -3
round(-2.5) = -2
round(-2.6) = -2
```

See Also

floor() ceiling()

serialize

serialize — Serializes a value of its argument following the rules of the host RDBMS.

Synopsis

```
string serialize ( obj any );
```

Description

The serialize() function converts an object to a string as follows:

- An empty sequence is converted to an empty string.
- A nonempty node-set is converted to a string by serialization of its first node.
- A non-attribute XML entity is serialized as if it is serialized by http() function. In other words, the result is a plain text of XML syntax. For an attribute XML entity, the value of attribute is returned.
- Values of other types are converted into strings as cast(... as varchar) do this in Virtuoso/PL, exactly.

If the argument is omitted, context node is converted instead as if it is a node-set of one element.

Parameters

obj
: Value to be converted into the string

Return Types

String

Errors

Examples

Example 24.617.

```
string(//title)
```

See Also

format_number()

serialize()

concat()

shallow

shallow — Returns a shallow copy of the given XML entity

Synopsis

```
entity shallow ( ent entity );
```

Description

The function returns a shallow copy of the given XML entity, i.e. a root of a new document that consists of only one node that is a copy of the given entity but have no children.

Parameters

ent
: The XML entity to copy

Return Types

The function returns an XML entity.

Errors

Table 24.151. Errors signalled by shallow()

SQLState	Error Code	Error Text	Description
XP001	XPFD6	The argument of XPATH function shallow() is not an entity	To match XQuery standard, the function signal an error if *ent* is not an entity.
XP001	XPFD7	Persistent XML entities are not supported by XPATH function shallow()	This is an artificial restriction that is to be removed in future versions of Virtuoso.

Examples

Example 24.618. Find Martha's spouse

The idea of the following sample is from W3C's XQuery Use Cases (case 1.9.4.1.). The query should find all persons whose name is "Marta" and return entities that describes their spouses, with removed information about children.

```
-- read the document, then...
    let $doc := document("census.xml")
-- for every person named "Martha"...
      for $m in $doc//person[@name="Martha"]
-- for all (i.e. 0 or 1) her spouses...
        for $s in $m/@spouse => person
-- return <person> element with attributes preserved but with children removed
          return shallow($s)
```

See Also

filter()

some

some — Returns true if at least one item of given sequence matches given criterion.

Synopsis

```
boolean some ( varname string ,
               test_set sequence ,
               test_expn boolean ) ;
```

Description

The function creates a temporary local variable, whose name is specified by *varname* argument. Then, for every item of *test_set* sequence it calculates the *test_expn* boolean expression having set the created variable to that "current" item. If the value of expression is true, the function immediately returns true without processing the rest of *test_set* sequence. If all items of the sequence are probed without getting true, false is returned. (So if the sequence is empty, the function returns false).

In any case, temporary variable is destroyed on return.

This function is used in the implementation of "SOME" logical operator in XQUERY, so you will probably use that operator in XQUERY expressions, not the function. This function may be useful in XPATH expressions and in XSLT stylesheets. It is not a part of library of standard XQUERY 1.0 functions.

Parameters

varname
: Name of temporary variable

test_set
: Sequence of items; these items will be tested by test_expn

test_expn
: Boolean expression which should be calculated for items of test_set .

Return Types

Boolean

Examples

Example 24.619.

This expression returns true if some reports have zero incomes recorded.

```
some('income_value', /report/income, $income_value = 0)
```

See Also

every()

starts-with

starts-with — Returns true if the first argument string starts with the second argument string, and otherwise returns false.

Synopsis

```
boolean starts-with ( strg string ,
                      prefix string ) ;
```

Description

For two given strings, this function checks if the first string starts with characters of second string. If any argument is not a string, it is converted to string using rules for string() XPATH function. Thus if the second argument has no string value, the function returns true, because it will be converted to an empty string first.

Parameters

strg
: String whose first characters must be compared

prefix
: String whose characters must be compared with first characters of strg

Return Types

Boolean

Examples

Example 24.620.

```
starts-with('OpenLink Virtuoso', 'OpenLink')
```

See Also

string() contains() ends-with()

string

string — Returns a string value of its argument.

Synopsis

```
string string ( obj any );
```

Description

The string() function converts an object to a string as follows:

- An empty sequence is converted to an empty string.
- A nonempty node-set is converted to a string by returning the string-value of the first node in the node-set. Note that the XPATH standard says that 'first' means 'first in document order' here, not 'first value returned'. For almost all queries, there is no difference between these two orders; it may be important only for node-sets calculated by so-called reverse-order axis. Moreover, the rure of standard is senseless if node-set contains nodes from more than one document. That is why the standard is violated here, intentionally.
- A nonempty sequence which is not a node-set is converted to a string by returning the string-value of the first node in the sequence.
- A NaN number is converted to the string 'NaN'.
- Zero is converted to the string '0'.
- Positive infinity is converted to the string 'Infinity'
- Negative infinity is converted to the string '-Infinity'
- Integer number is represented in decimal form with no decimal point and no leading zeros, preceded by a minus sign '-' if the number is negative.
- Non-integer number is represented in decimal form including a decimal point with at least one digit before the decimal point and at least one digit after the decimal point, preceded by a minus sign '-' if the number is negative; there must be no leading zeros before the decimal point apart possibly from the one required digit immediately before the decimal point; beyond the one required digit after the decimal point there will be be as many, but only as many, more digits as are needed to uniquely distinguish the number from all other IEEE 754 numeric values.
- The boolean false value is converted to the string 'false'. The boolean 'true' value is converted to the string 'true'.
- An object of a type other than the listed above is converted to a string in a way that is dependent on that type.

If the argument is omitted, context node is converted instead as if it is a node-set of one element.

Parameters

obj
: Value to be converted into the string

Return Types

String

Examples

Example 24.621. Examples

```
SQL> select xpath_eval ('string (//*)', xtree_doc ('<a>abc</a>')) ;
xpath_eval
VARCHAR
abc

SQL> select xpath_eval ('string (//title)', xtree_doc ('<doc><title>Simple test</title></doc>')) ;
xpath_eval
VARCHAR
Simple test

SQL> select xpath_eval ('string(.) div 21', xtree_doc ('<a>100</a>'))
```

```
xpath_eval
VARCHAR
4.761904761904762
No. of rows in result: 1

SQL> select xpath_eval ('string(//title) div 21', xtree_doc ('<a>100</a>'))
xpath_eval
VARCHAR
 0
No. of rows in result: 1

SQL> select xpath_eval ('string(//a) div 20', xtree_doc ('<a>100</a>'))
Query result:
xpath_eval
VARCHAR
 5
```

See Also

format_number()

serialize()

urlify()

concat()

string-length

string-length — Returns the number of characters in the string.

Synopsis

```
integer string-length ( strg string );
```

Description

The string-length() XPATH function returns the number of characters in the string. If the argument is omitted, it defaults to the context node converted to a string, in other words the string-value of the context node.

Parameters

strg
: The string whose length must be measured.

Return Types

Integer

Examples

Example 24.622.

The following expressions returns 5.

```
string-length('ABCDE')
```

See Also

xpf_string()

substring

substring — Returns the substring of the first argument starting at the position specified in the second argument with length specified in the third argument.

Synopsis

```
string substring ( strg string ,
                   start integer ,
                   length integer ) ;
```

Description

The substring() XPATH function returns the substring of the *strg* starting at the position specified in *start* argument with length specified in *length* argument. If *length* is not specified, it returns the substring starting at the position specified in the *start* argument and continuing to the end of the string.

XPATH 1.0 defines that "each character in the string... is considered to have a numeric position: the position of the first character is 1, the position of the second character is 2 and so on. This differs from Java and ECMAScript, in which the String.substring method treats the position of the first character as 0." The returned substring contains those characters for which the position of the character is greater than or equal to *start* and, if *length* is specified, less than the sum of *start* and *length* .

If *start* and/or *length* are not integers, they are converted to integers following rules for round() XPATH function, before doing any other processing. So they will be rounded first, and the sum of rounded values will be used as "end position"

If *start* is greater than or equal to the length of string, the empty string is returned. If *length* is specified and the sum of *start* is less than or equal to 1, the empty string is returned, too. Otherwise, the result string will contains some characters even if *start* is less than 1.

If *length* *start* is greater than or equal to the length of string, the empty string is returned.

Parameters

strg
: Source string. If the argument is not a string, it is converted to string first.

start
: Position of first character of the substring in the source string.

length
: Number of characters in the substring, if specified.

Return Types

String

Examples

Example 24.623.

The following expressions are all true:

```
substring("12345", 2, 3) = "234"
substring("12345", 2) = "2345"
substring("12345", 1.5, 2.6) = "234"
substring("12345", 0, 3) = "12"
substring("12345", -2, 5) = "12"
substring("12345", -2) = "12345"
```

See Also

substring-before() substring-after()

substring-after

substring-after — Returns the substring of the first argument string that follows the first occurrence of the second argument string in the first argument string.

Synopsis

```
string substring-after ( source_strg string ,
                         sub_strg string ) ;
```

Description

If the *source_strg* does not contain *sub_strg* , the function returns the empty string. Otherwise, it finds the first occurrence of *sub_strg* and returns the part of *source_strg* that follows the occurrence. If any argument is not a string, it is converted to string using rules for string() XPATH function.

Parameters

source_strg
: String where the search is performed

sub_strg
: String to search

Return Types

String

Examples

Example 24.624.

Extract time and timezone ("23:59:59 GMT" substring) from timestamp

```
substring-after('1999-12-31 23:59:59 GMT',' ')
```

See Also

string() substring() substring-after()

substring-before

substring-before — Returns the substring of the first argument string that precedes the first occurrence of the second argument string in the first argument string.

Synopsis

```
string substring-before ( source_strg string ,
                          sub_strg string ) ;
```

Description

If the *source_strg* does not contain *sub_strg* , the function returns the empty string. Otherwise, it finds the first occurrence of *sub_strg* and returns the part of *source_strg* that precedes the occurrence. If any argument is not a string, it is converted to string using rules for string() XPATH function.

Parameters

source_strg
: String where the search is performed

sub_strg
: String to search

Return Types

String

Examples

Example 24.625.

Extract year ("1999" substring) from ISO date string

```
substring-before('1999-12-31','-')
```

See Also

string() substring() substring-after()

sum

sum — Returns sum of all its arguments

Synopsis

```
number sum ( arg1 any ,
             arg2 any ,
             ... ,
             argN any ) ;
```

Description

The function returns the sum, for each node in every argument node-set, of the result of converting the string-values of the node to a number. If some arguments are not node-sets, they are converted to numbers first.

Note that this definition differs from XPATH 1.0 standard, where sum() function must have exactly one argument of type node-set. It is important that other XPATH processors may quietly ignore all arguments except the first one, producing unexpected results.

Being called without arguments, sum() will return zero.

Parameters

argI
: A node-set of nodes whose string values must be converted to numbers and added to the result, or single value.

Return Types

Examples

Example 24.626.

```
sum(/bill[@type="sale"]/total,/bill[@type="leasing"]/income)
```

See Also

avg max min

system-property

system-property — Returns a value of the system property identified by the name

Synopsis

```
object system-property ( property_qname varchar );
```

Description

The function returns an object representing the value of the system property identified by the name. If there is no such system property, the empty string is returned.

Parameters

property_qname
: a string that is a QName. The QName is expanded into a name using the namespace declarations in scope for the expression.

Return Types

String or double precision number.

Examples

Example 24.627. xsl:version

xsl:version is a number giving the version of XSLT implemented by the processor; this version returns 1.0.

```
[xmlns:xsl='http://www.w3.org/1999/XSL/Transform'] system-property('xsl:version')
```

Example 24.628. xsl:vendor

xsl:vendor is a string identifying the vendor of the XSLT processor; this version returns 'OpenLink Software'.

```
[xmlns:xsl='http://www.w3.org/1999/XSL/Transform'] system-property('xsl:vendor')
```

Example 24.629. xsl:vendor-url

xsl:vendor-url is a string containing a URL identifying the vendor of the XSLT processor; this version returns 'http://www.openlinksw.com'.

```
[xmlns:xsl='http://www.w3.org/1999/XSL/Transform'] system-property('xsl:vendor-url')
```

Example 24.630. xsl:product-name

xsl:product-name is a string containing a name of XSLT processor; this version returns 'OpenLink Virtuoso Server'.

```
[xmlns:xsl='http://www.w3.org/1999/XSL/Transform'] system-property('xsl:product-name')
```

Example 24.631. xsl:product-version

xsl:product-version is a string containing a version of XSLT processor implementation; the returned string may depend on OS, hardware and other parameters of installation.

```
[xmlns:xsl='http://www.w3.org/1999/XSL/Transform'] system-property('xsl:product-version')
```

See Also

`function_available` ()

text_contains

text_contains — Returns true if the text value of some node in the given node-set contains the text matching the given free-text query, otherwise returns false.

Synopsis

```
boolean text_contains ( scope node-set ,
                        query string ) ;
```

Description

This function calculates text values of nodes from the *scope* , and checks whether the current text value contains any fragment that matches the *query* . When the first match is found, the rest of the node-set is ignored the boolean 'true' is returned. If the node-set ends before any match is found, 'false' is returned.

The `text_contains()` function may be used only in XPath expressions that are arguments of `xcontains()` . This restriction is for optimization purposes. When Virtuoso executes an SQL statement that uses `xcontains()` , it performs some sophisticated free-text search, and it applies the XPath expression not to all available documents but only to documents that satisfied the free-text search criterion. Moreover, the server uses the intermediate free-text data to optimize the search inside a selected document.

Parameters

scope
: The node-set where the text search is performed.

query
: The text of the query.

Return Types

Returns a boolean: True or False.

When the first match is found, the rest of the node-set is ignored the boolean 'true' is returned. If the node-set ends before any match is found, 'false' is returned.

Errors

Table 24.152. Errors signalled by text-contains()

SQLState	Error Code	Error Text	Description
XP370	XPF11	XPATH function text-contains() is allowed only in special SQL predicate xcontains()	The XPath processor is called not by xcontains() but by some other way so it has no suitable free-text data.
XP001	XPF13	Unsupported combination of arguments in XPATH function text-contains()	The XPath processor has failed to built an execution plan for the free-text search.

Examples

Example 24.632.

xcontains predicate

translate

translate — Performs char-by-char translation of given string

Synopsis

```
string translate ( strg string ,
                   search_list string ,
                   replace_list string ) ;
```

Description

The function returns the *strg* with occurrences of characters in the *search_list* replaced by the character at the corresponding position in the *replace_list* . If there is a character in the *search_list* with no character at a corresponding position in the *replace_list* (because the *replace_list* is longer than the *replace_list*), then occurrences of that character in *strg* string are removed.

If a character occurs more than once in the *search_list* , then the first occurrence determines the replacement character. If the *replace_list* is longer than the *search_list* , then excess characters are ignored.

Two popular use cases for this function are case conversion and sorting with collation. For "to-upper" case conversion, the *search_list* consists of all lowercase characters of some language and the *replace_list* consists of all uppercase characters of that language. For "to-lower" case conversion, uppercase chars are in the *search_list* and lowercase are in the *replace_list* . For sorting with collation, the function must be used in "select" string expression attribute of <xsl:sort> element; the *search_list* consists of all characters reordered by collation and the *replace_list* consists of corresponding characters from "collation string".

Parameters

strg
: String that must be translated.

search_list
: String of characters that must be edited in the strg .

replace_list
: String of characters that must be inserted in the strg .

Return Types

String

Errors

Table 24.153. Errors signalled by translate()

SQLState	Error Code	Error Text	Description
XP001	XPF07	Too long string passed as argument 1 to XPATH function translate(), the result of translation is too long	Virtuoso cannot process strings that are longer than 10M. This limit may be exceed if UTF-8 representations of the replacement characters are longer than representations of replaced characters; even if the number of encoded characters remains the same or decrements.

Examples

Example 24.633. Trivial cases

The following expressions are true:

```
translate("abracadabra","abc","ABC") = "ABrACAdABrA".
translate("ab-ra-ca-dab-ra","abc-","ABC") = "ABrACAdABrA".
```

Example 24.634. Sorting with collation in XSL

The following <xsl:sort> will sort records by its titles, making no difference between spaces and punctuation marks. In addition, spaces will be normalized after the collation processing.

```
<xsl:key select="normalize-space(translate('@title','.,:;!?','      '))"/>
```

See Also

replace() normalize-space()

true

true — Returns true

Synopsis

```
boolean true ( void);
```

Description

This function returns boolean constant "true"

Return Types

Boolean

See Also

false boolean

tuple

tuple — Selects the first item of every argument sequence and returns the sequence of the selected items

Synopsis

```
sequence tuple ( seq1 sequence ,
                 seq2 sequence ,
                 ... ,
                 seqN sequence ) ;
```

Description

This function calculates all given arguments from left to right, and creates a sequence which contains the first item of the first calculated sequence, then the first item of the second calculated sequence and so on. If the value of an argument is not a sequence, but a scalar, the scalar is treated as one-element sequence so it is added into the result. If the value of an argument is an empry sequence, the empty string is added into the result.

This function is not a part of XPATH 1.0 or XQUERY 1.0 libraries of standard functions.

Parameters

SeqI
: The sequence of items, first of its items will be used as I-tn item of the resulting sequence

Return Types

Sequence

Examples

Example 24.635.

```
tuple(/title, /abstract, /intro)
```

See Also

append list

union

union — Returns an union of two or more sets

Synopsis

```
sequence union ( set1 sequence ,
                 set2 sequence ... ,
                 setN sequence ) ;
```

Description

The function returns an unordered sequence that consists of all distinct items from all given sets.

All duplicates are removed, including duplicate occurrences of same value in one sequence, thus the function works exactly as `distinct()` when only one parameter is passed.

Parameters

setI
: Sequence that contains items of the resulting union.

Return Types

The function returns an unordered sequence of distinct values.

See Also

`intersect`

`except`

unordered

unordered — Returns the given sequence in any order.

Synopsis

```
sequence unordered ( input sequence );
```

Description

The function takes a sequence, or more typically an expression that evaluates to a sequence, and indicates that the result sequence may be returned in any order.

Parameters

input
: The sequence of nodes

Return Types

Sequence

Examples

Example 24.636. Finding pairs of books

The following example is from the XQuery standard and it illustrates how to find pairs of books that have different titles but the same set of authors (possibly in a different order).

```
<bib>
{
   for $book1 in document("bib.xml")/bib/book,
       $book2 in document("bib.xml")/bib/book
   where $book1/title > $book2/title
   and $book1/author = $book2/author
   return
      <book-pair>
         { $book1/title, $book2/title }
      </book-pair>
}
</bib>
```

unparsed-entity-uri

unparsed-entity-uri — This XSLT 1.0 function is not implemented in the current version of Virtuoso.

Synopsis

```
string unparsed-entity-uri ( unparsed_entity_name string );
```

urlify

urlify — Converts its argument to a string and returns it in URL encoding.

Synopsis

```
string urlify ( obj string );
```

Description

The urlify() function encodes its argument string according to URI rules (i.e. whitespaces are replaced with plus signs and all special characters are replaced with '%XX' notation. This is especially useful for stylesheets that compose dynamic HTML documents with calculateable values of attributes like <A HREF=...>.

Parameters

obj
: Value to be formatted as URI

Return Types

String

See Also

string()

format_number()

serialize()

concat()

xmlview

xmlview — Returns the xml document corresponding to given XML view

Synopsis

xmlview (in *view_name* varchar) ;

Description

The function returns the output produced by an XML view as it was a content of some XML document accessed via document() XPath function. The result of the function call may be used as input of some path expression that select interesting parts of the full output of the XML view. The XQuery engine will translate the XPath expression into SQL statement in order to avoid redundant data access and to build whole XML tree.

This function may be used only in the header of FOR operator of XQuery. To specify the list of values of a variable, a path expression may be used that starts with the call of xmlview() function.

Parameters

view_name
: The name of xml view

Errors

Table 24.154. Errors signalled by xmlview

SQLState	Error Code	Error Text	Description
37000		Unknown view name is passed as argument of xmlview()	

Examples

Example 24.637.

The XQUERY expressions below are queries to the following XML view:

```
create xml view "cat" as
{
  "Demo"."demo"."Categories" c as "category" ("CategoryID", "Description" as "description")
      {
            "Demo"."demo"."Products" p as "product"  ("ProductName")
                on (p."CategoryID" = c."CategoryID")
      }
};
```

The first query returns all products with the attribute ProductName starting with "L". The second query returns categories with attribute CategoryID less than 10.

```
for $r in xmlview("cat")//product[@ProductName like "L%"] return $r
for $r in xmlview("cat")/category[@CategoryID<"10"] return $r
```

BPEL.BPEL.compile_script

BPEL.BPEL.compile_script — Compile a BPEL script source

Synopsis

BPEL.BPEL.compile_script (in *scp_id* int ,
in *vdir* varchar (default null) ,
in *opts* any (default null) ,
in *no_check* int (default 0)) ;

Parameters

scp_id
: int the BPEL process identifier to be compiled

vdir
: varchar virtual directory to be created for this process (absolute path)

opts
: any options to the virtual directory if specified

no_check
: int flag to check or not partner links, bu default before compilation function will check if every partner link have corresponding WSDL uploaded

Return Types

this function has no return value

Description

`BPEL.BPEL.compile_script` is used to compile BPEL script identified by scp_id and link to it all WSDL definitions have been associated to it.

Examples

Example 24.638. Simple example

The following will compile a BPEL script with identifier equals to 1

```
SQL> create procedure echo_deploy ()
{
  declare scp int;
  BPEL.BPEL.import_script ('file:/echo/bpel.xml', 'Echo', scp);
  BPEL.BPEL.compile_script (scp, '/Echo');
};
Done. -- 0 msec.
SQL> echo_deploy ();
Done. -- 2303 msec.
```

BPEL.BPEL.copy_script

BPEL.BPEL.copy_script — Makes a copy of an existing script

Synopsis

BPEL.BPEL.copy_script (in *scp_id* int);

Parameters

scp_id
: int the ID of the BPEL script to be copied

Return Types

returns a unique integer identifier for the script copy

Description

BPEL.BPEL.copy_script makes a copy of an existing script and put it in edit mode.

Examples

Example 24.639. Simple example

This will copy a script with identifier equal to 1, the copy have Id equal to 2

```
SQL> select BPEL.BPEL.copy_script (1);
unnamed
INTEGER
_______________________________________________________________________________

2

1 Rows. -- 1672 msec.
```

BPEL.BPEL.get_partner_links

BPEL.BPEL.get_partner_links — Returns a list of partner links used in the BPEL script

Synopsis

BPEL.BPEL.get_partner_links (in *scp_id* int);

Parameters

scp_id
: int the ID of BPEL script

Return Types

returns an XML document containing partner links

Description

BPEL.BPEL.get_partner_links The function is used for partner link names retrieval. It returns an XML document containing all partner links.

Examples

Example 24.640. Simple example

```
SQL> select BPEL.BPEL.get_partner_links (4);
callret
VARCHAR
_______________________________________________________________________________

<n0:partnerLinks xmlns:n0="http://schemas.xmlsoap.org/ws/2003/03/business-process/">
    <n0:partnerLink name="client" partnerLinkType="tns:LoanFlow" partnerRole="LoanFlowRequester

    <n0:partnerLink name="creditRatingService" partnerLinkType="services:CreditRatingService" p

    <n0:partnerLink name="UnitedLoanService" partnerLinkType="services:LoanService" myRole="Loa

    <n0:partnerLink name="StarLoanService" partnerLinkType="services:LoanService" myRole="LoanS
</n0:partnerLinks>

1 Rows. -- 88 msec.
```

BPEL.BPEL.instance_delete

BPEL.BPEL.instance_delete — delete a BPEL process instance

Synopsis

BPEL.BPEL.instance_delete (in *id* int);

Parameters

id
: int instance identifier

Return Types

this function has no return value

Description

BPEL.BPEL.instance_delete Deletes the instance, regardless of completion state or such. If there are waits for the instance the waits are flagged as deleted, not physically deleted. This will cause the reply message to be received instead of going to the unexpected messages queue.

Examples

Example 24.641. Simple example

The following will delete process instance with ID equal to 5

```
SQL> BPEL.BPEL.instance_delete (5);
Done. -- 10 msec.
```

BPEL.BPEL.purge_instance

BPEL.BPEL.purge_instance — removes old BPEL process instances

Synopsis

BPEL.BPEL.purge_instance (in *completed_before* datetime ,
in *make_archive* int (default 1)) ;

Parameters

completed_before
: datetime all instances completed before this date and time will be removed

make_archive
: int flag to archive or not instances before removal

Return Types

Description

`BPEL.BPEL.purge_instance` this will erase all instances completed before the datetime specified.

Examples

Example 24.642. Simple example

The following wil lremove all process instances completed before 10 of January 2004.

```
SQL> BPEL.BPEL.purge_instance (stringdate ('2004-01-10'));
Done. -- 10 msec.
```

BPEL.BPEL.script_delete

BPEL.BPEL.script_delete — Remove a BPEL process

Synopsis

BPEL.BPEL.script_delete (in *script* varchar ,
in *delete_instances* int) ;

Parameters

script
: int the identifier of the BPEL process to be deleted

delete_instances
: int this flag specifies to delete all instances of the given process

Return Types

this function has no return value

Description

`BPEL.BPEL.script_delete` Deletes all versions of the BPEL process and all related partner links, instances, sources etc. if delete_instances is false and there exist instances of at least one version of the script the function signals an error and does nothing

Examples

Example 24.643. Simple example

The following will delete script with ID equal of 3 and all it's instances

```
SQL> BPEL.BPEL.script_delete (5, 1);
Done. -- 10 msec.
```

BPEL.BPEL.script_obsolete

BPEL.BPEL.script_obsolete — mark a BPEL script as obsoleted

Synopsis

BPEL.BPEL.script_obsolete (in *script* varchar) ;

Parameters

script
varchar

Return Types

this function has no return value

Description

BPEL.BPEL.script_obsolete Marks the script as obsolete. This means that existing instances will complete but no new instances can be made. The effect can be reversed by going to edit mode and recompiling a new version which then becomes current. Directly after this function there will be no current version but there may be a version being edited.

Examples

Example 24.644. Simple example

```
SQL> BPEL.BPEL.script_obsolete (5);
Done. -- 10 msec.
```

BPEL.BPEL.script_source_update

BPEL.BPEL.script_source_update — Updates an existing script in BPEL repository

Synopsis

```
BPEL.BPEL.script_source_update (  in scp_id int ,
                                  in url varchar ,
                                  in content any );
```

Parameters

scp_id
: int the ID of the BPEL script to be updated with new source

url
: varchar the URL to the script source

content
: any as an alternative this is to specify script source directly.

Return Types

This function does not return a value

Description

`BPEL.BPEL.script_source_update` is used to update the script source of an already uploaded script. The script must be in edit mode in order to do that. The URL and content parameters works as in script_upload.

Examples

Example 24.645. Simple example

```
SQL> BPEL.BPEL.script_source_update (1, 'file:/LoanFlow.bpel', null);
Done. -- 10 msec.
```

BPEL.BPEL.script_upload

BPEL.BPEL.script_upload — Upload a new BPEL script source

Synopsis

BPEL.BPEL.script_upload (in *name* varchar ,
in *url* varchar ,
in *content* any) ;

Parameters

name
: varchar a human readable name for script

url
: varchar the URL to the script source

content
: any as an alternative to the URL, the content can be specified.

Return Types

returns an integer unique identifier for the uploaded script

Description

`BPEL.BPEL.script_upload` uploads a new BPEL script, makes expanded version, and put into edit mode. If content is supplied the function will not try to download or check the URL specified.

Examples

Example 24.646. Simple example

```
SQL> select BPEL.BPEL.script_upload ('LoanFlow', 'file:/LoanFlow.bpel', null);
unnamed
INTEGER
_______________________________________________________________________________

1
```

BPEL.BPEL.wsdl_upload

BPEL.BPEL.wsdl_upload — Uploads a WSDL description for a given BPEL script

Synopsis

```
BPEL.BPEL.wsdl_upload (  in scp_id int ,
                         in url varchar ,
                         in content any ,
                         in pl varchar default 'wsdl' ) ;
```

Parameters

scp_id
: int the BPEL script identifier

url
: varchar the URL to the WSDL description file.

content
: any default null the source of the WSDL file, this can be omitted then the function will try downloading the source from the URL specified

pl
: varchar default 'wsdl' the partner which is described by given WSDL. When this is a file describing the process itself the default value MUST be used.

Return Types

this function has no return value

Description

`BPEL.BPEL.wsdl_upload` uploads a WSDL description for a given partner link. The function if content is not specified this will download the content via the URL specified and will associate it with the specified partner link. Also after download the WSDL will be expanded to resolve includes in WSDL and XMLSchema namespaces.

Examples

Example 24.647. Simple example

```
SQL> BPEL.BPEL.wsdl_upload (1, 'file:/LoanFlow.wsdl', null, 'wsdl');
Done. -- 10 msec.
```

BPEL.BPEL.getVariableData

BPEL.BPEL.getVariableData — gets BPEL variable data within <bpelv:exec binding="SQL"> activity

Synopsis

BPEL.BPEL.getVariableData (in *var_name* varchar ,
in *part* varchar ,
in *query* varchar) ;

Parameters

var_name
: varchar the name of BPEL variable

part
: varchar default null the part of BPEL variable in question.

query
: varchar default null XPATH query for selecting data in the BPEL variable

Return Types

this function returns the selected data from the BPEL variable. This can be either an XML tree or a varchar or an integer.

Description

`BPEL.BPEL.getVariableData` Returns select by query expression data from part (if applicable) of the BPEL variable. If the variable is unknown, or if the XPATH expression signals an error, the appropriate error is signalled. This procedure may only be used in Virtuoso/PL code invoked from a BPEL process.

Examples

Example 24.648. Simple example

```
declare city, country varchar;
city := cast (BPEL.BPEL.getVariableData ('request',
                'req_payload',
                '/destRequest/city/text()');
```

BPEL.BPEL.setVariableData

BPEL.BPEL.setVariableData — sets BPEL variable data within code invoked from <bpelv:exec binding="SQL"> activity

Synopsis

```
BPEL.BPEL.setVariableData ( in var_name varchar ,
                            in value any ,
                            in part varchar ,
                            in query varchar ) ;
```

Parameters

var_name
: varchar the name of BPEL variable

value
: any the value to be set. Can be XML tree or varchar

part
: varchar default null the part of BPEL variable in question.

query
: varchar default null XPATH query for selecting data in the BPEL variable

Return Types

this function has no return value.

Description

`BPEL.BPEL.setVariableData` Sets the data selected by "query" in the part (named by "part" argument) of the BPEL variable. If there is no variable with such name or the query contains syntax errors or if its evaluation signals a run time error, the appropriate error is signalled. This procedure may only be used in Virtuoso/PL code invoked from a BPEL process.

Examples

Example 24.649. Simple example

```
declare country any;

...

if (country is null)
  BPEL.BPEL.setVariableData ('res',
        xtree_doc (']]&gt;<destResponse><country>Unknown</country></destResponse><![CDATA['),
        'repl_payload');
 else
  BPEL.BPEL.setVariableData ('res',
        country,
        'repl_payload',
        '/destResponse/country');
```

BPEL.BPEL.plink_get_option

BPEL.BPEL.plink_get_option — retrieving a partner link option

Synopsis

BPEL.BPEL.plink_get_option (in *script* varchar ,
in *plink* varchar ,
in *opt* varchar) ;

Parameters

script
: varchar name of a process that partner link belongs to

plink
: varchar name of the partner link

opt
: varchar name of the options to be retrieved

Return Types

The function returns a string or array of strings depending of the requested option.

Description

`BPEL.BPEL.plink_get_option` This function can be used to retrieve the options assigned to a particular partner link. These options are used to configure various Web Service protocols (see Protocol Support section in BPEL reference chapter). For available options see `plink_set_option()` function.

Examples

Example 24.650. Simple example

```
SQL> select BPEL.BPEL.plink_get_option ('WSSecho', 'service', 'wss-in-encrypt');
callret
VARCHAR
_______________________________________________________________________________

NONE
```

BPEL.BPEL.plink_set_option

BPEL.BPEL.plink_set_option — set value of a partner link option

Synopsis

```
BPEL.BPEL.plink_set_option (  in script varchar ,
                              in plink varchar ,
                              in opt varchar ,
                              in val any ) ;
```

Parameters

script
: varchar name of a process that partner link belongs to

plink
: varchar name of the partner link

opt
: varchar name of the options to be set

val
: any value of the option to be set

Return Types

The function has no return value

Description

`BPEL.BPEL.plink_set_option` This function is used to set an option of the specified partner link. The options are used to configure WS-Security, WS-Addressing and WS-Reliable Messaging protocols for sending and receiving messages to the given partner.

- *wsa* the version of namespace value for WS-Addressing protocol.
- *http-auth-uid* user name for basic HTTP authentication
- *http-auth-pwd* password for HTTP authentication
- *wss-priv-key* name of the private key to be used for signing the requests
- *wss-pub-key* name of the partner's public key to be used for encryption of the requests
- *wss-in-encrypt* incoming message XML data encryption policy
- *wss-in-signature* incoming messages XML signature policy
- *wss-in-signers* list of public key names which are trusted (empty list mean all are trusted)
- *wss-out-encrypt-key* type of the session key for outgoing message encryption
- *wss-out-signature-type* XML signature template type for signing the outgoing messages
- *wss-out-signature-function* in case of custom signature this option is a name of the PL function producing the template for XML signature
- *wsrm-in-type* WS-Reliable Messaging protocol usage for incoming messages
- *wsrm-out-type* WS-Reliable Messaging protocol usage for outgoing messages

Examples

Example 24.651. Simple example

```
SQL> BPEL.BPEL.plink_set_option  ('WSSecho', 'service', 'wss-in-encrypt', 'Mandatory');

Done. -- 16 msec.
```

BPEL.BPEL.import_script

BPEL.BPEL.import_script — Import a new BPEL process

Synopsis

BPEL.BPEL.import_script (in *base_uri* varchar ,
in *base_name* varchar ,
in *scp_id* int) ;

Parameters

base_uri
: varchar the URL to the bpel.xml which contains information for bpel and wsdl for process and its partnerlinks wsdl's urls.

base_name
: varchar a human readable name for process

scp_id
: int id of the process.

Description

`BPEL.BPEL.import_script` imports a new BPEL process or refetches the content of bpel, wsdl files and wsdl for partner links for a given process. In both cases the process is turned to mode "Edit". Urls of wsdl files must have absolute paths.

Examples

Example 24.652. Simple example

```
SQL>create procedure echo_import ()
   {
    declare scp int;
    BPEL.BPEL.import_script ('file:/echo/bpel.xml', 'Echo', scp);
   }
  ;

SQL> echo_import ();
Done. -- 10 msec.
```

GeometryType

GeometryType — returns EWKT type name of a shape.

Synopsis

GeometryType (in *shape* any);

Description

GeometryType function returns EWKT type name of a given shape.

Parameters

shape
: Geometry.

Return Types

Returns varchar.

Examples

Example 24.653. Simple example

```
SQL> DB.DBA.TTLP ('
<point2d>               <shape> "POINT(1 3)"^^<http://www.openlinksw.com/schemas/virtrdf#Geometry> .
<point4d>               <shape> "POINTZM(0 1 2 3)"^^<http://www.openlinksw.com/schemas/virtrdf#Geometry>

http_st_dxf_entity

http_st_dxf_entity — writes a DXF (Data Exchange Format) representation of shape into the given output session.

Synopsis

http_st_dxf_entity (in *shape* any ,
in *attrs* vector ,
in *sess* any) ;

Description

This function writes a DXF (Data Exchange Format) representation of shape into the given output session.

Parameters

shape
: If shape is null, the function returns without writing anything to the shape.

attrs
: vector of arbitrary DXF properties in form (tag1, value1, tag2, value2...) where tags are integer codes according to DXF specification; related values are not validated and are printed to the session as-is. Current version does not support ARCSTRINGs, CURVEs, nor CURVEPOLYGONs.

sess
: Output session.

Examples

Example 24.654. Simple example

```
create procedure Example_http_st_dxf_entity ()
{
  declare ses, ctx any;
  ses := string_output ();

  for (select a1, deserialize (Example_GEOM) as geom from Demo.Demo."Example_Countries") do
    http_st_dxf_entity (geom, vector (62, 0)), ses);
  string_to_file ('examples/Example_http_st_dxf_entity.dxf', ses, -2);
}
;
```

http_st_ewkt

http_st_ewkt — Writes a EWKT representation of a shape to the given session.

Synopsis

http_st_ewkt (in *shape* any ,
inout *sess* any) ;

Description

Writes a EWKT representation of a shape to the given session, a fast replacement for http (st_astext (shape), ses).

Parameters

shape
: A given shape.

sess
: Session.

Return Types

Returns any.

Examples

Example 24.655. Simple example

```
create procedure Example_http_st_ewkt ()
{
  declare g, ses, ctx, g_ewkt any;
  ses := string_output ();

  g := st_ewkt_read ('POLYGON
                      (
                        (1 3,2 4,1 5,0 4,1 3),
                        (1 3.5,1.5 4,1 4.5,0.5 4,1 3.5)
                      )
                     ');
  ses := string_output ();
  http_st_ewkt (g, ses);
}
;
```

st_ewkt_read

st_ewkt_read — Parses the given text as a EWKT and returns the parsed shape.

Synopsis

st_ewkt_read (in *ewkt_text* any);

Description

Parses the given text as a EWKT and returns the parsed shape.

Parameters

ewkt_text
: A given text to be parsed as EWKT.

Return Types

This function returns shape.

Examples

Example 24.656. Simple Use

```
select st_translate (
         st_ewkt_read ('POLYGON((1 3,2 4,1 5,0 4,1 3),
                                (1 3.5,1.5 4,1 4.5,0.5 4,1 3.5))'),
                       0.1, 0.2);
Query result:
geometry
 POLYGON((1.100000 3.200000,2.100000 4.200000,1.100000 5.200000,0.100000 4.200000,1.100000 3.200000),
         (1.100000 3.700000,1.600000 4.200000,1.100000 4.700000,0.600000 4.200000,1.100000 3.700000))
No. of rows in result: 1
```

`http_st_ewkt()`

postgis_proj_version

postgis_proj_version — Returns the version of v7proj4 plugin in use, as a string, for compatibility with PostGIS.

Synopsis

```
postgis_proj_version (  );
```

Description

Returns the version of the v7proj4 plugin in use, as a string, for compatibility with PostGIS.

Return Types

any

dist_from_point_to_line_segment

dist_from_point_to_line_segment — returns the distance between a point and a segment on a plane.

Synopsis

dist_from_point_to_line_segment (in *Xpoint* any ,
in *Ypoint* any ,
in *Xsegment1* any ,
in *Ysegment1* any ,
in *Xsegment2* any ,
in *Ysegment2* any) ;

Description

returns the distance between a point and a segment on a plane.

Parameters

Xpoint
: A X point

Ypoint
: A Y point

Xsegment1
: X Segment

Ysegment1
: Y Segment

Xsegment2
: X Segment

Ysegment2
: Y Segment

Return Types

Returns any.

Examples

Example 24.657. Simple Use

```
SQL> select dist_from_point_to_line_segment (5, 5, 0, 3, 4, 0)

4.6

SQL> select dist_from_point_to_line_segment (5, 0, 0, 3, 4, 0)

1

SQL> select dist_from_point_to_line_segment (5, -1, 0, 3, 4, 0)

1.414213562373095

ST_ExteriorRing

ST_ExteriorRing — Returns an external (the very first) ring of a polygon.

Synopsis

ST_ExteriorRing (in *poligon* any);

Description

Returns an external (the very first) ring of a polygon.

Parameters

poligon
: A given poligon from a type shape.

Return Types

Returns any.

Examples

Example 24.659. Simple Use

```
SQL> select ST_ExteriorRing (st_ewkt_read ('POLYGON((1 3,2 4,1 5,0 4,1 3),(1 3.5,1.5 4,1 4.5,0.5 4,1 3.5)

ST_GeometryN

ST_GeometryN — Given a 1-based index of a member of a MULTI... or ...COLLECTION shape, returns the member.

Synopsis

ST_GeometryN (in *shape* any ,
in *idx* any) ;

Description

Given a 1-based index of a member of a MULTI... or ...COLLECTION shape, returns the member.

Parameters

shape
: Shape.

idx
: Index.

Return Types

Returns any.

Examples

Example 24.660. Simple Use

```
SQL> select st_geometryn (
       st_geometryn (
         st_ewkt_read ('
           GEOMETRYCOLLECTION(
              POINT(0 0),

st_get_bounding_box

st_get_bounding_box — returns BOX2D that is a bounding box of a shape.

Synopsis

st_get_bounding_box (in *shape* any);

Description

returns BOX2D that is a bounding box of a shape.

Parameters

shape
: Shape.

Return Types

Returns any.

Examples

Example 24.661. Simple Use

```
SQL> SPARQL
SELECT bif:st_get_bounding_box(?o) ?o
FROM <http://geo-api-demo/>
WHERE { ?s ?p ?o }
ORDER BY ASC(str(?s))

st_get_bounding_box_n

st_get_bounding_box_n — Given a 1-based index of a member of a MULTI... or ...COLLECTION shape, returns the bounding box of a member.

Synopsis

st_get_bounding_box_n (in *shape* any ,
in *idx* any) ;

Description

Given a 1-based index of a member of a MULTI... or ...COLLECTION shape, returns the bounding box of a member. This is a fast equivalent of `st_get_bounding_box_n(ST_GeometryN (shape,idx))`.

Parameters

shape
: Shape

idx
: Index

Return Types

Returns any.

Examples

Example 24.662. Simple Use

```
SQL> select st_get_bounding_box_n (
               st_ewkt_read ('
                 GEOMETRYCOLLECTION(

haversine_deg_km

haversine_deg_km — Given latitudes and longitudes of two points in degrees, calculates the approximate distance between that points in kilometers

Synopsis

haversine_deg_km (in *lat1* double precision ,
in *long1* double precision ,
in *lat2* double precision ,
in *long2* double precision) ;

Description

The function calculates the approximate distance between two points, using haversine formula with an adjustment for case when points are ends of some diameter.

Note that the order of arguments is latitude-longitude, not longitude-latitude.

Parameters

lat1
: latitude

long1
: longitude

lat2
: latitude

long2
: longitude

Return Types

The function returns distance in kilometers as double precision.

Examples

Example 24.663. Simple example

```
-- select haversine_deg_km (-90,0,90,0)
haversine_deg_km
VARCHAR
_______________________________________________________________________________

20003.88915449353

-- select haversine_deg_km (0,0,0,180) - haversine_deg_km (-90,0,90,0)
temp
VARCHAR

ST_InteriorRingN

ST_InteriorRingN — Given a 1-based index of an interior ring of a polygon, returns the ring. Wrong index is not reported as an error and NULL is returned.

Synopsis

ST_InteriorRingN (in *poligon* any ,
in *idx* any) ;

Description

Given a 1-based index of an interior ring of a polygon, returns the ring. Wrong index is not reported as an error and NULL is returned.

Parameters

poligon
: A given poligon of a type shape.

idx
: Index.

Return Types

Returns any.

Examples

Example 24.664. Simple Use

```
SQL> select ST_InteriorRingN (st_ewkt_read ('POLYGON((1 3,2 4,1 5,0 4,1 3),(1 3.5,1.5 4,1 4.5,0.5 4,1 3.5

st_linestring

st_linestring — returns a linestring in default SRID

Synopsis

st_linestring (in *item1* any ,
in *item2* any ,
in *itemN* any) ;

Description

returns a linestring in default SRID, the coordinates of vertices are specified by arguments that are points, 2-, 3- or 4-item vectors of coordinates, linestrings, arcstrings or vectors of the above mentioned values. Repeating vertices are automatically removed, except the case of repeating vertices in the middle of a linestring/arcstring argument.

Parameters

item1
: Geometry.

item2
: Geometry.

itemN
: Geometry.

Return Types

Returns varchar.

Examples

Example 24.665. Simple Use

```
SQL> select st_linestring (st_point (11,22),
                           st_point (13, 24),
                           st_point (13,24),
                           st_point (15,26),

ST_M

ST_M — returns the M coordinate.

Synopsis

ST_M (in *g* any);

Description

returns the M coordinate. M is for mileage or the like. M equal to 245.3 could be 245.3 km of road or 0.3 distance from buoy 245 to buoy 246 or similar.

Parameters

g
: Geometry point

Return Types

Returns double precision.

Examples

Example 24.666. Simple Use

```
SELECT st_m( st_point (10, 20, 30, 40));
unnamed
DOUBLE PRECISION
40
```

st_may_intersect

st_may_intersect — checks whether bounding boxes of two shapes intersect or some of its points are within the specified proximity.

Synopsis

st_may_intersect (in *shape1* any ,
in *shape2* any ,
in *proximity* any) ;

Description

checks whether bounding boxes of two shapes intersect or some of its points are within the specified proximity. This is much faster than full `st_intersects()` check.

Parameters

shape1
: Given shape

shape2
: Given shape

proximity
: A proximity.

Return Types

Returns any.

Examples

Example 24.667. Simple Use

```
SQL> SPARQL
SELECT ?s1 ?s2
FROM <http://geo-api-demo/>
WHERE
  {
    ?s1 ?p1 ?o1 .
    ?s2 ?p2 ?o2 .
    FILTER (bif:st_may_intersect (?o1, ?o2))
  }
ORDER BY ASC(str(?s1)) ASC(str(?s2));

s1                              s2
ANY                             ANY

ST_MMax

ST_MMax — returns boundaries of a bounding box around a shape in cordinates.

Synopsis

ST_MMax (in *shape* any) ;

Description

returns boundaries of a bounding box around a shape. Bounding boxes around arcs are calculated in assumption that no one arc is longer than a half of full circle.

Parameters

shape
: A bounding box.

Return Types

Returns double precision.

Examples

Example 24.668. Simple Use

```

`ST_InteriorRingN()`

`ST_ExteriorRing()`

ST_Transform

ST_Transform — Transforms the given shape from its current spatial reference system to one specified by dest_srid.

Synopsis

ST_Transform (in *shape* any ,
in *dest_srid* any ,
in *origin_proj4_string* varchar ,
in *dest_proj4_string* varchar) ;

Description

Transforms the given shape from its current spatial reference system to one specified by dest_srid. Two optional arguments: the SRID of the resulting shape is set to dest_srid but the conversion is done by proj4 using origin_proj4_string for projection of original shape and dest_proj4_string for the result. If orig_proj4_string or dest_proj4_string argument is passed but is NULL instead of string, the projection corresponding to original or destination SRID is used. ST_Transform is provided by a separate plugin named v7proj4, as described below. When the plugin is loaded, functions like ST_Intersects() support pairs of arguments with different SRIDs by converting coords of second argument into the system of the first one, as required by OGC and GeoSPARQL.

Parameters

shape
: Geometry.

dest_srid
: Destination SRID.

origin_proj4_string
: String to be used for the projection.

dest_proj4_string
: String used for the destination result.

Return Types

Returns varchar.

Examples

Example 24.672. Simple Use

```
SQL> SELECT * FROM DB.DBA.SYS_V7PROJ4_SRIDS;

st_transform_by_custom_projection

st_transform_by_custom_projection — Performs a custom projection of shape, using the specified algorithm and algorithm-specific arguments.

Synopsis

st_transform_by_custom_projection (in *shape* any ,
in *algorithm_id* any) ;

Description

Performs a custom projection of shape, using the specified algorithm and algorithm-specific arguments.

Parameters

shape
: Geometry.

algorithm_id
: Algorithm -- Current version supports only one algorithm, st_transform_by_custom_projection (shape, 'OLAEAPS', long_of_center, lat_of_center) for Oblique Lampert Azimuthal Equal-Area Projection System with the specified center point.

Return Types

Returns varchar.

Examples

Example 24.673. Simple Use

```
select st_transform_by_custom_projection (
  st_ewkt_read ('POLYGON((1 3,2 4,1 5,0 4,1 3),
                         (1 3.5,1.5 4,1 4.5,0.5 4,1 3.5))'),

ST_Translate

ST_Translate — returns a copy of a shape with all coordinates shifted by the provided dX, dY and dZ.

Synopsis

ST_Translate (in *shape* any ,
in *dX* any ,
in *dY* any ,
in *dZ* any) ;

Description

returns a copy of a shape with all coordinates shifted by the provided dX, dY and dZ.

Parameters

shape
: Geometry.

dX
: X coordinate.

dY
: Y coordinate.

dZ
: Z coordinate.

Examples

Example 24.674. Simple Use

ST_TransScale

ST_TransScale — returns a copy of a shape with all coordinates shifted by the provided dX, dY and then multiplied by Xfactor and Yfactor.

Synopsis

ST_TransScale (in *shape* any ,
in *dX* any ,
in *dY* any ,
in *Xfactor* any ,
in *Yfactor* any) ;

Description

returns a copy of a shape with all coordinates shifted by the provided dX, dY and then multiplied by Xfactor and Yfactor. Different values for Xfactor and Yfactor will result in distorted arcs.

Parameters

shape
: Geometry.

dX
: X coordinate.

dY
: Y coordinate.

Xfactor
: X value to multiple by.

Yfactor
: Y value to multiple by.

Return Types

Returns any.

Examples

Example 24.675. Simple Use

```
SQL> DB.DBA.TTLP ('

ST_XMax

ST_XMax — returns maximum x boundaries of a bounding box around a shape.

Synopsis

ST_XMax (in *shape* any) ;

Description

returns boundaries of a bounding box around a shape. Bounding boxes around arcs are calculated in assumption that no one arc is longer than a half of full circle.

Parameters

shape
: A bounding box.

Return Types

Returns double precision.

ST_Zmflag

ST_Zmflag — returns bits indicating presence of Z and/or M coordinates.

Synopsis

ST_Zmflag (in *g* any);

Description

Returns bits indicating presence of Z and/or M coordinates. 0 means that the shape has only X and Y, 1 means that M is also in use (but not Z), 2 means Z but ont M, 3 is for both M and Z.

Parameters

g
: Geometry

Return Types

Returns integer.

Examples

Example 24.682. Simple Use

```
SELECT ST_Zmflag( st_point (10, 20, 30, 40));
unnamed
INTEGER
 3
```

ST_ZMin

ST_ZMin — returns minimum z boundaries of a bounding box around a shape.

Synopsis

ST_ZMin (in *shape* any) ;

Description

returns boundaries of a bounding box around a shape. Bounding boxes around arcs are calculated in ssumption that no one arc is longer than a half of full circle.

Parameters

shape
: A bounding box.

Return Types

Returns double precision.

Examples

Example 24.683. Simple Use
