```

16.9. RDF Insert Methods in Virtuoso

16.9.1. Using API functions

- Using the DB.DBA.TTLP() function
    - Note: use this function for loading Turtle
- Using the DB.DBA.TTLP_MT() function
    - Note: use this function for loading triples from file on multiple threads
- Using the DB.DBA.RDF_LOAD_RDFXML_MT() function
    - Note: Use this function for loading large resources when transactional integrity is not important (loading of a single resource may take more than one transaction)
- Using the DB.DBA.RDF_TTL2HASH() function
    - Note: use this function to get dictionary of triples in 'long valmode'.
- Using the DB.DBA.RDF_LOAD_RDFXML() function
    - For loading RDF/XML, the best way is to split the data to be loaded into multiple streams and load these in parallel using this function.

See more details for loading Performance Tuning specifics.

16.9.2. SPARQL endpoint REST API

With POST can be accomplished SPARQL Insert/Update etc.

The result is in the rdf_quad.

With GET Methods you can get the triples which are saved.

Examples:

Example 1:

Create a DAV collection xx for user demo with password demo.

Execute the following command:

```
curl -i -d "INSERT {<http://demo.openlinksw.com/DAV/home/demo_about.rdf>
<http://www.w3.org/1999/02/22-rdf-syntax-ns#type> <http://rdfs.org/sioc/ns#User>}" -u "demo:demo"
-H "Content-Type: application/sparql-query" http://example.com/DAV/xx/yy
```

The response should be:

```
HTTP/1.1 201 Created
Server: Virtuoso/05.00.3023 (Win32) i686-generic-win-32  VDB
Connection: Keep-Alive
Content-Type: text/html; charset=ISO-8859-1
Date: Fri, 28 Dec 2007 12:50:12 GMT
Accept-Ranges: bytes
MS-Author-Via: SPARQL
Content-Length: 0
```

The result in the DAV/xx location will be a new WebDAV resource with name "yy" containing the inserted RDF:

```
<?xml version="1.0" encoding="utf-8" ?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
xmlns:rdfs="http://www.w3.org/2000/01/rdf-schema#">
<rdf:Description
rdf:about="http://demo.openlinksw.com/DAV/home/demo_about.rdf">
<ns0pred:type xmlns:ns0pred="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
rdf:resource="http://rdfs.org/sioc/ns#User"/>
</rdf:Description>
</rdf:RDF>
```

Example 2:

Create a DAV collection, for ex. with name "test" for user (for ex. demo).

Execute the following command:

```
curl -i -d "INSERT IN GRAPH <http://mygraph.com>
{ <http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this>
  <http://www.w3.org/1999/02/22-rdf-syntax-ns#type>
  <http://rdfs.org/sioc/ns#User> .
  <http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this>
  <http://www.w3.org/2000/01/rdf-schema#label>
  <Kingsley Uyi Idehen> .
  <http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this>
  <http://rdfs.org/sioc/ns#creator_of>

<http://www.openlinksw.com/dataspace/kidehen@openlinksw.com/weblog/kidehen@openlinksw.com%27s%20BLOG%20%5
  } " -u "demo:demo" -H "Content-Type: application/sparql-query" http://example.com/DAV/home/demo/test/my
```

As result the response will be:

```
HTTP/1.1 201 Created
Server: Virtuoso/05.00.3023 (Win32) i686-generic-win-32  VDB
Connection: Keep-Alive
```

```
Content-Type: text/html; charset=ISO-8859-1
Date: Thu, 20 Dec 2007 16:25:25 GMT
Accept-Ranges: bytes
MS-Author-Via: SPARQL
Content-Length: 0
```

Now let's check the inserted triples. Go to the sparql endpoint, i.e. http://example.com/sparql and:

1. Enter for Default Graph URI:

   ```
   http://mygraph.com
   ```
2. Enter in the Query area:

   ```
   SELECT * WHERE {?s ?p ?o}
   ```
3. Click the button "Run Query"
4. As result will be shown the inserted triples:

   ```
   s                                                                    p
   http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this   http://www.w3.org/1999/02
   http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this   http://www.w3.org/2000/01
   http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this   http://rdfs.org/sioc/ns#c
   ```

16.9.3. HTTP PUT using Content-Type: application/rdf+xml

The URI in a PUT request identifies the entity enclosed with the request. Therefore using HTTP PUT is a more useful and meaningful command than using POST (which is more about submitting data to a script).

Example:

Suppose there is myfoaf.rdf file with the following content:

```
<rdf:RDF xmlns="http://www.example/jose/foaf.rdf#"
    xmlns:foaf="http://xmlns.com/foaf/0.1/"
    xmlns:log="http://www.w3.org/2000/10/swap/log#"
    xmlns:myfoaf="http://www.example/jose/foaf.rdf#"
    xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#">

    <foaf:Person rdf:about="http://www.example/jose/foaf.rdf#jose">
        <foaf:homepage rdf:resource="http://www.example/jose/"/>
        <foaf:knows rdf:resource="http://www.example/jose/foaf.rdf#juan"/>
        <foaf:name>Jose Jimen~ez</foaf:name>
        <foaf:nick>Jo</foaf:nick>
        <foaf:workplaceHomepage rdf:resource="http://www.corp.example/"/>
    </foaf:Person>

    <foaf:Person rdf:about="http://www.example/jose/foaf.rdf#juan">
        <foaf:mbox rdf:resource="mailto:juan@mail.example"/>
    </foaf:Person>

    <foaf:Person rdf:about="http://www.example/jose/foaf.rdf#julia">
        <foaf:mbox rdf:resource="mailto:julia@mail.example"/>
    </foaf:Person>

    <rdf:Description rdf:about="http://www.example/jose/foaf.rdf#kendall">
        <foaf:knows rdf:resource="http://www.example/jose/foaf.rdf#edd"/>
    </rdf:Description>
</rdf:RDF>
```

Now let's upload the myfoaf.rdf file to destination server demo.openlinksw.com for user demo:

```
curl -T myfoaf.rdf http://demo.openlinksw.com/DAV/home/demo/rdf_sink/myfoaf.rdf -u demo:demo
```

As result the response should be:

```
<!DOCTYPE HTML PUBLIC "-//IETF//DTD HTML 2.0//EN">
<HTML>
<HEAD>
  <TITLE>201 Created</TITLE>
```

```
</HEAD>
<BODY>
  <H1>Created</H1>
  Resource /DAV/home/demo/rdf_sink/ myfoaf.rdf has been created.
</BODY>
</HTML>
```

Then you can execute:

```
curl -F "query=SELECT DISTINCT ?p FROM <http://demo.openlinksw.com/DAV/home/demo/rdf_sink/> WHERE {?s ?p
```

The result should be:

```
<?xml version="1.0" ?>
<sparql xmlns="http://www.w3.org/2005/sparql-results#" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instan
 <head>
  <variable name="p"/>
 </head>
 <results distinct="false" ordered="true">
  <result>
   <binding name="p"><uri>http://www.w3.org/1999/02/22-rdf-syntax-ns#type</uri></binding>
  </result>
  <result>
   <binding name="p"><uri>http://xmlns.com/foaf/0.1/nick</uri></binding>
  </result>
  <result>
   <binding name="p"><uri>http://xmlns.com/foaf/0.1/name</uri></binding>
  </result>
  <result>
   <binding name="p"><uri>http://xmlns.com/foaf/0.1/homepage</uri></binding>
  </result>
  <result>
   <binding name="p"><uri>http://xmlns.com/foaf/0.1/knows</uri></binding>
  </result>
  <result>
   <binding name="p"><uri>http://xmlns.com/foaf/0.1/workplaceHomepage</uri></binding>
  </result>
  <result>
   <binding name="p"><uri>http://xmlns.com/foaf/0.1/mbox</uri></binding>
  </result>
 </results>
</sparql>
```

Other examples with curl:

```
curl -F "query=SELECT distinct ?Concept FROM <http://dbpedia.org> WHERE {?s a ?Concept} limit 10" http://

curl -F "query=SELECT distinct ?Concept FROM <http://example.com/dataspace/person/kidehen> WHERE {?s a ?C

curl -F "query=SELECT distinct ?Concept FROM <http://data.openlinksw.com/oplweb/product_family/virtuoso>

curl -F "query=SELECT distinct ?Concept FROM <http://openlinksw.com/dataspace/organization/openlink> WHER
```

16.9.4. SPARQL Insert using LOAD

SPARQL INSERT operation can be done using the LOAD features:

```
SPARQL INSERT INTO <..> { .... } [[FROM ...] { ... }]

SPARQL LOAD <x> [INTO <y>]

-- <ResourceURL> will be the Graph IRI of the loaded data:
SPARQL LOAD <ResourceURL>
```

Examples:

1. Load from ISQL:

```
SPARQL insert in graph <http://mygraph.com>
{
  <http://example.com/dataspace/Kingsley#this>
  <http://www.w3.org/1999/02/22-rdf-syntax-ns#type>
  <http://rdfs.org/sioc/ns#User> .

  <http://example.com/dataspace/Kingsley#this>
  <http://rdfs.org/sioc/ns#id>
  <Kingsley> .

  <http://example.com/dataspace/Caroline#this>
  <http://www.w3.org/1999/02/22-rdf-syntax-ns#type>
  <http://rdfs.org/sioc/ns#User> .

 <http://example.com/dataspace/Caroline#this>
  <http://rdfs.org/sioc/ns#id>
  <Caroline> .

   <http://example.com/dataspace/Matt#this>
  <http://www.w3.org/1999/02/22-rdf-syntax-ns#type>
  <http://rdfs.org/sioc/ns#User> .

  <http://example.com/dataspace/Matt#this>
  <http://rdfs.org/sioc/ns#id>
  <Matt> .

   <http://example.com/dataspace/demo#this>
  <http://www.w3.org/1999/02/22-rdf-syntax-ns#type>
  <http://rdfs.org/sioc/ns#User> .

  <http://example.com/dataspace/demo#this>
  <http://rdfs.org/sioc/ns#id>
  <demo> .};
```

2. Load from .rq file:

   a. Create DAV collection which is visible to public, for ex: http://example.com/DAV/tmp
   b. Upload to the DAV collection the following file for ex. with name listall.rq and with the following content:

```
SPARQL
PREFIX rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
PREFIX rdfs: <http://www.w3.org/2000/01/rdf-schema#>
PREFIX sioc: <http://rdfs.org/sioc/ns#>
SELECT ?x ?p ?o
FROM <http://mygraph.com>
WHERE
  {
    ?x rdf:type sioc:User .
    ?x ?p ?o.
    ?x sioc:id ?id .
    FILTER REGEX(str(?id), "^King")
  }
ORDER BY ?x
```

   c. Execute from ISQL the following command:

```
SQL>SPARQL
load bif:concat ("http://", bif:registry_get("URIQADefaultHost"), "/DAV/tmp/listall.rq") ir
```

   As result should be shown:

```
callret-0
VARCHAR
_______________________________________________________________________________

Load <http://example.com/DAV/tmp/listall.rq> into graph <http://myNewGraph.com> -- done

1 Rows. -- 321 msec.
```

3. Load from Resource URL:

```
SQL> SPARQL LOAD <http://www.w3.org/People/Berners-Lee/card#i>;
callret-0
VARCHAR
```

```
Load <http://www.w3.org/People/Berners-Lee/card#i> into graph <http://www.w3.org/People/Berners-Le

1 Rows. -- 703 msec.
SQL>
```

16.9.5. SPARQL Insert via /sparql endpoint

SPARQL INSERT operation can be sent to a web service endpoint as a single statement and executed in sequence.

Example:

Using the Virtuoso ISQL tool or using the /sparql UI at http://host:port/sparql, execute the following:

1. Insert into graph http://BookStore.com 3 triples:

```
SQL>SPARQL insert in graph <http://BookStore.com>
{ <http://www.dajobe.org/foaf.rdf#i> <http://purl.org/dc/elements/1.1/date> <1999-04-01T00:00:00>
  <http://www.w3.org/People/Berners-Lee/card#i> <http://purl.org/dc/elements/1.1/date> <1998-05-03
  <http://www.w3.org/People/Connolly/#me> <http://purl.org/dc/elements/1.1/date> <2001-02-08T00:00
```

2. As result will be shown the message:

```
SQL>Insert into <http://BookStore.com>
3 triples -- done
```

3. Next we will select all triples from the graph http://BookStore.com:

```
SQL>SPARQL SELECT * FROM <http://BookStore.com> WHERE {?s ?p ?o};
```

4. As result will be shown:

```
s                                                 p                                          o
VARCHAR                                           VARCHAR                                    VARCHAR
_______________________________________________________________________________________________

http://www.w3.org/People/Berners-Lee/card#i       http://purl.org/dc/elements/1.1/date       1998-05-03T
http://www.w3.org/People/Connolly/#me             http://purl.org/dc/elements/1.1/date       2001-02-08T
http://www.dajobe.org/foaf.rdf#i                  http://purl.org/dc/elements/1.1/date       1999-04-01T

3 Rows. -- 0 msec.
```

5. Now let's insert into graph another http://NewBookStore.com graph's values:

```
SQL>SPARQL
PREFIX dc:  <http://purl.org/dc/elements/1.1/>
PREFIX xsd: <http://www.w3.org/2001/XMLSchema#>
INSERT INTO GRAPH <http://NewBookStore.com> { ?book ?p ?v }
WHERE
  { GRAPH  <http://BookStore.com>
   { ?book dc:date ?date
     FILTER ( xsd:dateTime(?date) < xsd:dateTime("2000-01-01T00:00:00")).
     ?book ?p ?v.
   }
  };
```

6. As result will be shown:

```
callret-0
VARCHAR
_______________________________________________________________________________

Insert into <http://NewBookStore.com>, 2 triples -- done
```

7. Finally we will check the triples from the graph NewBookStore.com:

```
SQL> SPARQL
SELECT *
FROM <http://NewBookStore.com>
WHERE {?s ?p ?o};
```

8. As result will be shown:

```
s                                                p                                          o
VARCHAR                                          VARCHAR                                    VARCHAR
_______________________________________________________________________________________________

http://www.w3.org/People/Berners-Lee/card#i      http://purl.org/dc/elements/1.1/date       1998-05-03T00
http://www.dajobe.org/foaf.rdf#i                 http://purl.org/dc/elements/1.1/date       1999-04-01T00

2 Rows. -- 10 msec.
```

16.9.6. SPARQL Insert via SPARQL endpoint REST API and ODS wiki

With HTTP Post and ODS wiki can be written an rdf document and respectively to be performed over it INSERT/UPDATE action.

You can write to a file using SIOC terms for ODS-Wiki

You can check with sparql the inserted / updated triples in the Quad Store.

Example:

Suppose there is ODS user test3 with ODS password 1, which has testWiki wiki instance.

Execute the following:

```
curl -i -d "INSERT {<http://example.com/dataspace/test3/wiki/testWiki> <http://atomowl.org/ontologies/ato
```

As result we should have 2 files created:

- In the user DAV folder "DAV/home/test3/wiki/testWiki/" will be created a file "MyTest" with type "application/sparql-query". You can view the content of this file from the Conductor UI or from the user's Briefcase UI, path "DAV/home/test3/wiki/testWiki". Its content will be:

```
<?xml version="1.0" encoding="utf-8" ?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#" xmlns:rdfs="http://www.w3.org/200
<rdf:Description rdf:about="http://example.com/dataspace/test3/wiki/testWiki"><ns0pred:entry xmlns
<rdf:Description rdf:about="http://example.com/dataspace/test3/wiki/testWiki/MyTest"><ns0pred:labe
<rdf:Description rdf:about="http://example.com/dataspace/test3/wiki/testWiki/MyTest"><ns0pred:type
<rdf:Description rdf:about="http://example.com/dataspace/test3/wiki/testWiki/MyTest"><ns0pred:type
<rdf:Description rdf:about="http://example.com/dataspace/test3/wiki/testWiki/MyTest"><ns0pred:type
<rdf:Description rdf:about="http://example.com/dataspace/test3/wiki/testWiki/MyTest"><ns0pred:has_
<rdf:Description rdf:about="http://example.com/dataspace/test3/wiki/testWiki"><ns0pred:container_o
<rdf:Description rdf:about="http://example.com/dataspace/test3/wiki/testWiki"><ns0pred:contains xm
<rdf:Description rdf:about="http://example.com/dataspace/test3/wiki/testWiki/MyTest"><ns0pred:cont
<rdf:Description rdf:about="http://example.com/dataspace/test3/wiki/testWiki/MyTest"><ns0pred:topi
<rdf:Description rdf:about="http://example.com/dataspace/test3/wiki/testWiki/MyTest"><ns0pred:sour
</rdf:RDF>
```

- To the user's wiki instance will be added a new WikiWord "MyTest" with content the value of the SIOC term attribute "content":

```
<http://example.com/dataspace/test3/wiki/testWiki/MyTest> <http://rdfs.org/sioc/ns#content> <test>
i.e. the content will be "test".
```

Now let's check what data was inserted in the Quad Store:

1. Go to the sparql endpoint, i.e. for ex. to http://example.com/sparql
2. Enter for Default Graph URI:

```
http://example.com/DAV/home/test3/wiki/testWiki/MyTest
```

3. Enter for Query text:

```
SELECT * WHERE {?s ?p ?o}
```

4. Click the "Run Query" button.
5. As result will be shown the inserted triples:

```
s                                                                p
http://example.com/dataspace/test3/wiki/testWiki                 http://rdfs.org/sioc/ns#container_of
```

```
http://example.com/dataspace/test3/wiki/testWiki            http://atomowl.org/ontologies/atomrdf#
http://example.com/dataspace/test3/wiki/testWiki            http://atomowl.org/ontologies/atomrdf#

http://example.com/dataspace/test3/wiki/testWiki/MyTest  http://rdfs.org/sioc/ns#has_container
http://example.com/dataspace/test3/wiki/testWiki/MyTest  http://rdfs.org/sioc/ns#content
http://example.com/dataspace/test3/wiki/testWiki/MyTest  http://rdfs.org/sioc/ns#topic
http://example.com/dataspace/test3/wiki/testWiki/MyTest  http://atomowl.org/ontologies/atomrdf#sou
```

16.9.7. Using WebDAV

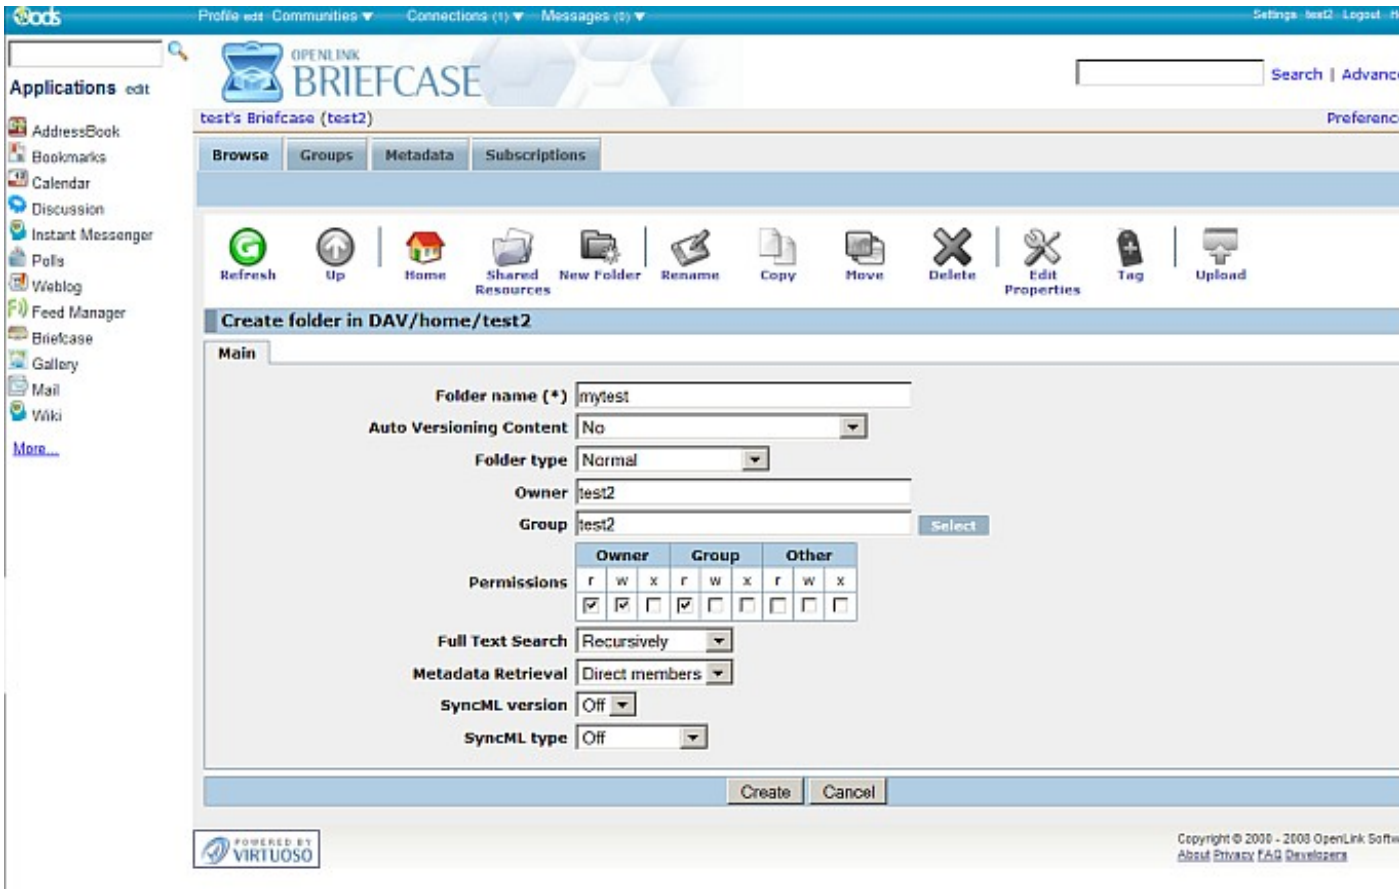
Example using WebDAV (mount folder to DAV and dump; if this is the rdf_sink the Quad Store is updated automatically, or you can load from DAV manually to quad store)

Example:

Example 1: Using ODS Briefcase

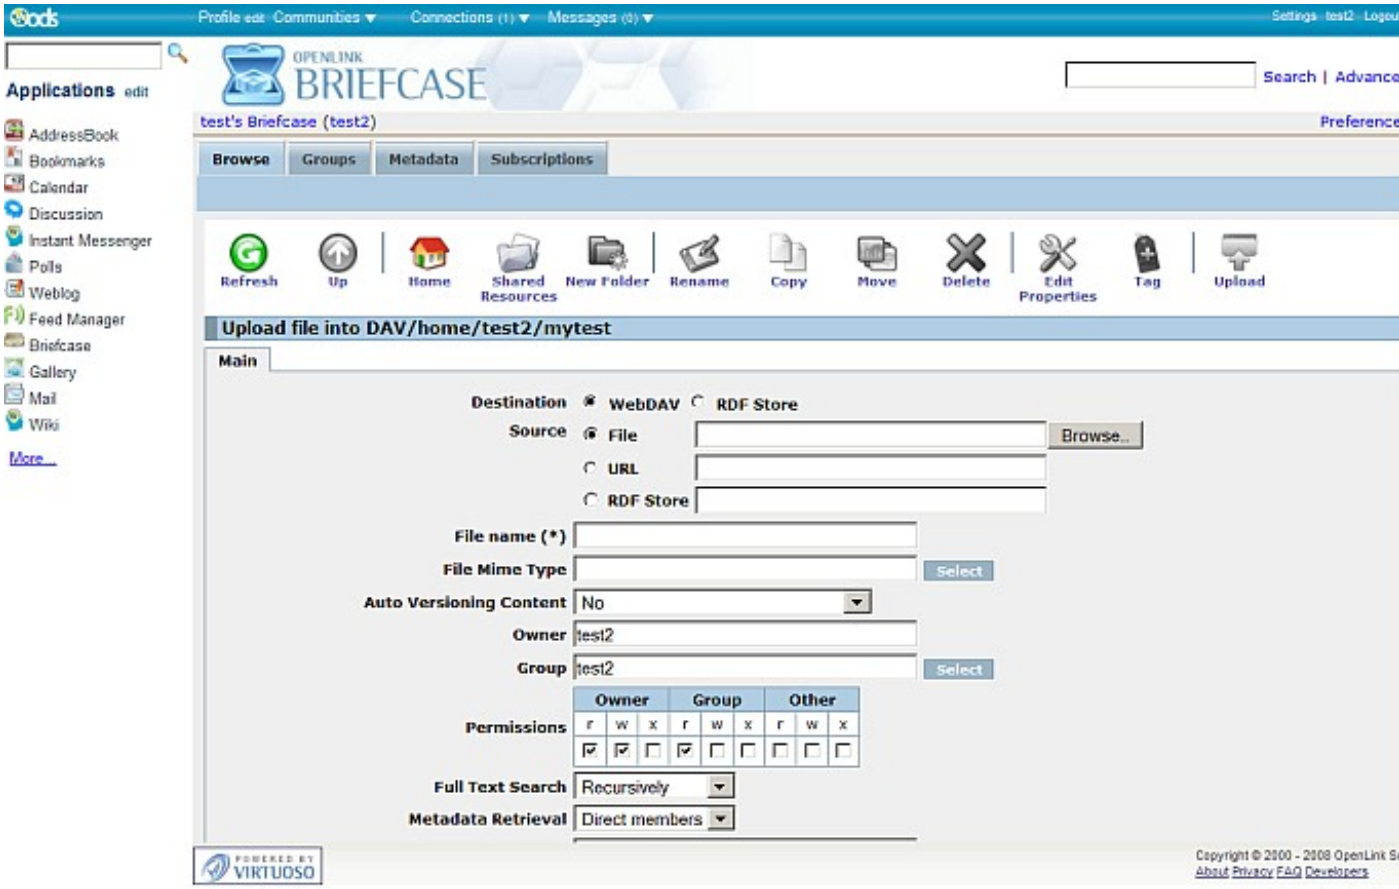
1. Go to your ods location, for ex. http://example.com/ods
2. Register user, for ex. user test1
3. Login if not already in ods
4. Go to ODS -> Briefcase
5. Go to ODS -> Briefcase
6. Click the "New folder" icon from the Main Briefcase horizontal navigation
7. Enter for name for ex. "mytest" and click the "Create" button.

Figure 16.81. Using Briefcase UI



8. Go to folder "mytest" and click the click the "Upload" icon from the Main Briefcase horizontal navigation
9. Enter for name for ex. "mytest" and click the "Create" button.

Figure 16.82. Using Briefcase UI



10. In the shown form set:

    - Destination: RDF Store
    - RDF graph name for ex. with the value: http://example.com/DAV/home/test2/mytest/
    - Select URL or File. For ex. you can select the following file with name jose.rdf:

```
<rdf:RDF xmlns="http://www.example/jose/foaf.rdf#"
    xmlns:foaf="http://xmlns.com/foaf/0.1/"
    xmlns:log="http://www.w3.org/2000/10/swap/log#"
    xmlns:myfoaf="http://www.example/jose/foaf.rdf#"
    xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#">

    <foaf:Person rdf:about="http://www.example/jose/foaf.rdf#jose">
        <foaf:homepage rdf:resource="http://www.example/jose/"/>
        <foaf:knows rdf:resource="http://www.example/jose/foaf.rdf#juan"/>
        <foaf:name>Jose Jimen~ez</foaf:name>
        <foaf:nick>Jo</foaf:nick>
        <foaf:workplaceHomepage rdf:resource="http://www.corp.example/"/>
    </foaf:Person>

    <foaf:Person rdf:about="http://www.example/jose/foaf.rdf#juan">
        <foaf:mbox rdf:resource="mailto:juan@mail.example"/>
    </foaf:Person>

    <foaf:Person rdf:about="http://www.example/jose/foaf.rdf#julia">
        <foaf:mbox rdf:resource="mailto:julia@mail.example"/>
    </foaf:Person>

    <rdf:Description rdf:about="http://www.example/jose/foaf.rdf#kendall">

        <foaf:knows rdf:resource="http://www.example/jose/foaf.rdf#edd"/>
    </rdf:Description>
</rdf:RDF>
```

11. You can also perform the steps from above by uploading the file in the rdf_sink folder i.e. in Briefcase it will be with this path: DAV/home/test2/rdf_sink and respectively the "RDF graph name" will have this value: http://host:port/DAV/home/username/rdf_sink/

Execute from ISQL or from the SPARQL endpoint the following query:

```
SELECT * FROM <http://example.com/DAV/home/test2/mytest/>
WHERE {?s ?p ?o}
```

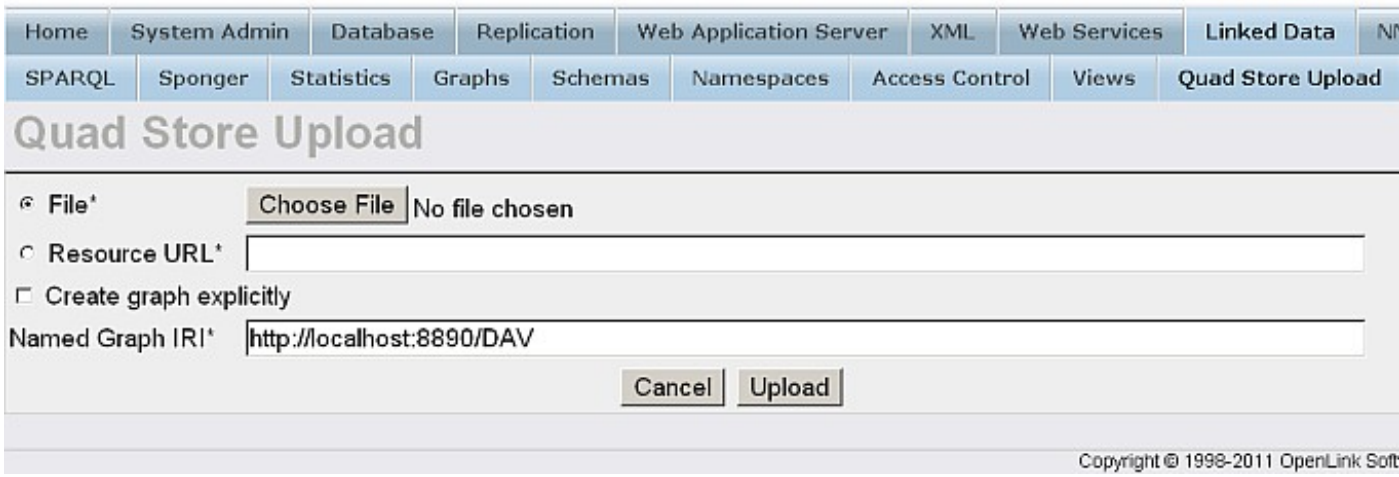
As result should be shown:

```
s                                        p                                                o
http://www.example/jose/foaf.rdf#jose    http://www.w3.org/1999/02/22-rdf-syntax-ns#type  http://xmlns.
http://www.example/jose/foaf.rdf#jose    http://xmlns.com/foaf/0.1/nick                   Jo
http://www.example/jose/foaf.rdf#jose    http://xmlns.com/foaf/0.1/name                   Jose Jimen~ez
http://www.example/jose/foaf.rdf#jose    http://xmlns.com/foaf/0.1/knows                  http://www.ex
http://www.example/jose/foaf.rdf#jose    http://xmlns.com/foaf/0.1/homepage               http://www.ex
http://www.example/jose/foaf.rdf#jose    http://xmlns.com/foaf/0.1/workplaceHomepage      http://www.co
http://www.example/jose/foaf.rdf#kendall http://xmlns.com/foaf/0.1/knows                  http://www.ex
http://www.example/jose/foaf.rdf#julia   http://www.w3.org/1999/02/22-rdf-syntax-ns#type  http://xmlns.
http://www.example/jose/foaf.rdf#julia   http://xmlns.com/foaf/0.1/mbox                   mailto:julia@
http://www.example/jose/foaf.rdf#juan    http://www.w3.org/1999/02/22-rdf-syntax-ns#type  http://xmlns.
http://www.example/jose/foaf.rdf#juan    http://xmlns.com/foaf/0.1/mbox                   mailto:juan@m
```

Example 2: Using Conductor UI

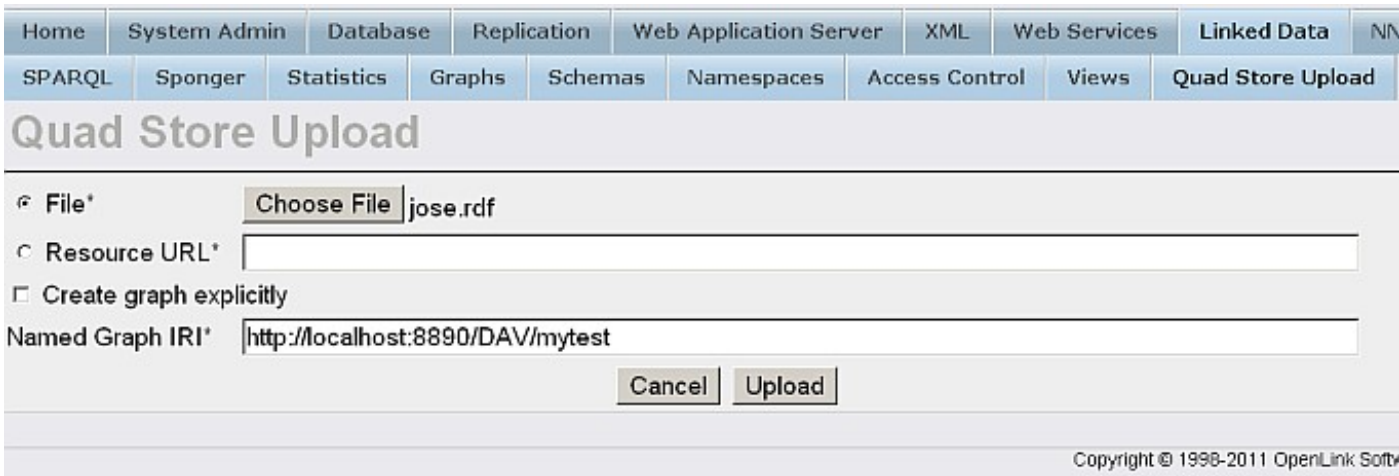
1. Go to Conductor UI, for ex. at http://example.com/conductor
2. Login as dba user
3. Go to Linked Data -> Quad Store Upload

Figure 16.83. Quad Store Upload



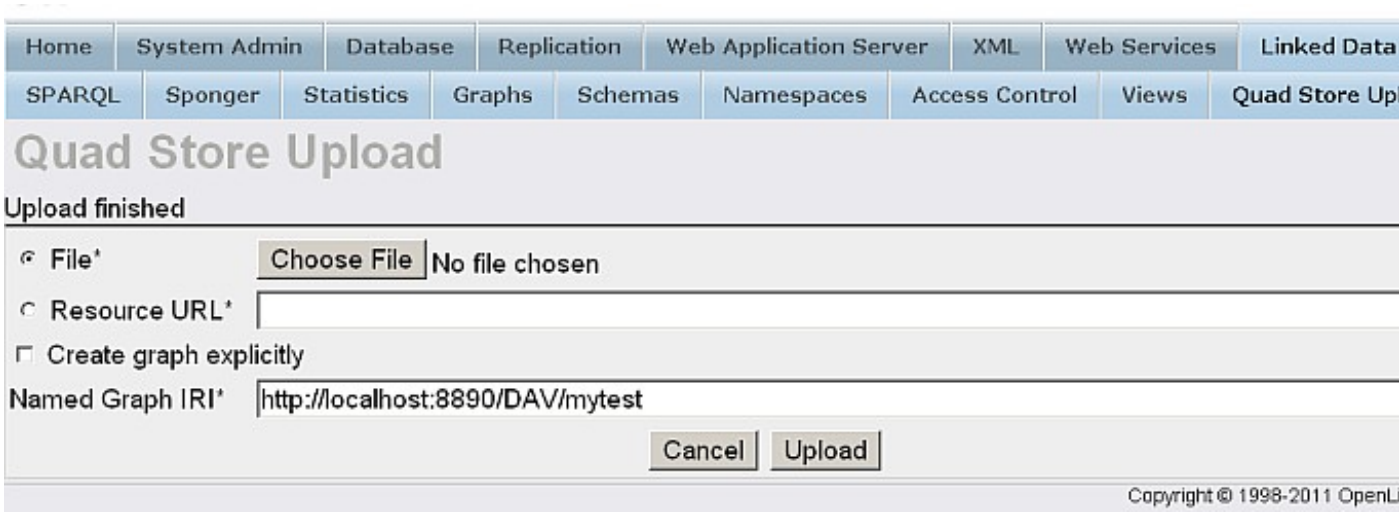
4. In the shown form click the "Browse" button in order to select a file, for ex. the file jose.rdf and set the "RDF IRI*"

Figure 16.84. Quad Store Upload



5. Click the "Upload" button.

Figure 16.85. Quad Store Upload



16.9.8. Using Virtuoso Crawler

Using Virtuoso Crawler (which includes the Sponger options so you crawl non-RDF but get RDF and this can go to the Quad Store).

Example:

1. Go to Conductor UI. For ex. at http://example.com/conductor :

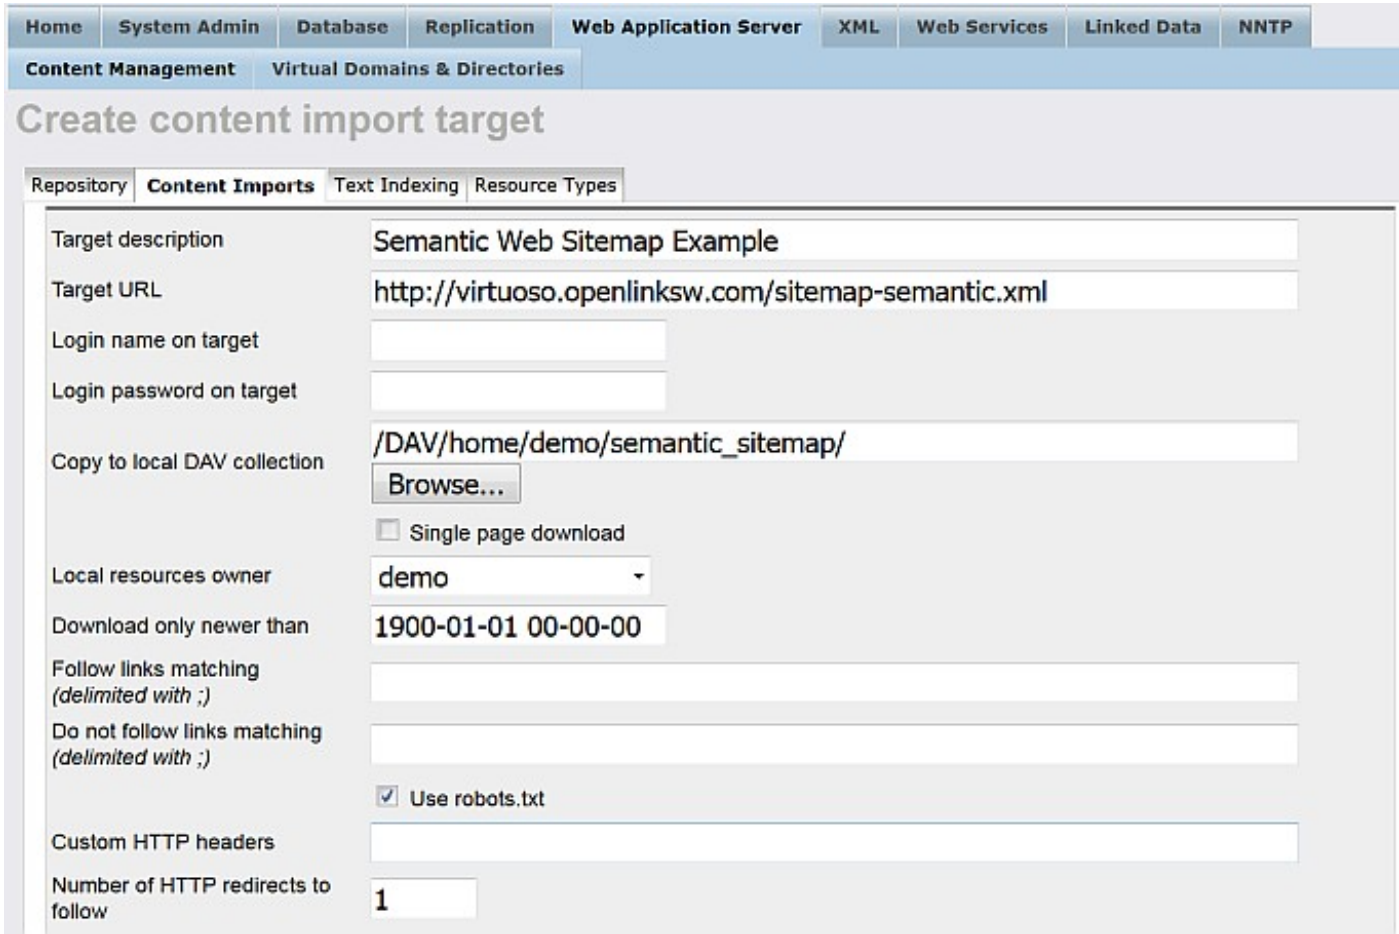
Figure 16.86. Using Virtuoso Crawler

2. Enter admin user credentials:

Figure 16.87. Using Virtuoso Crawler

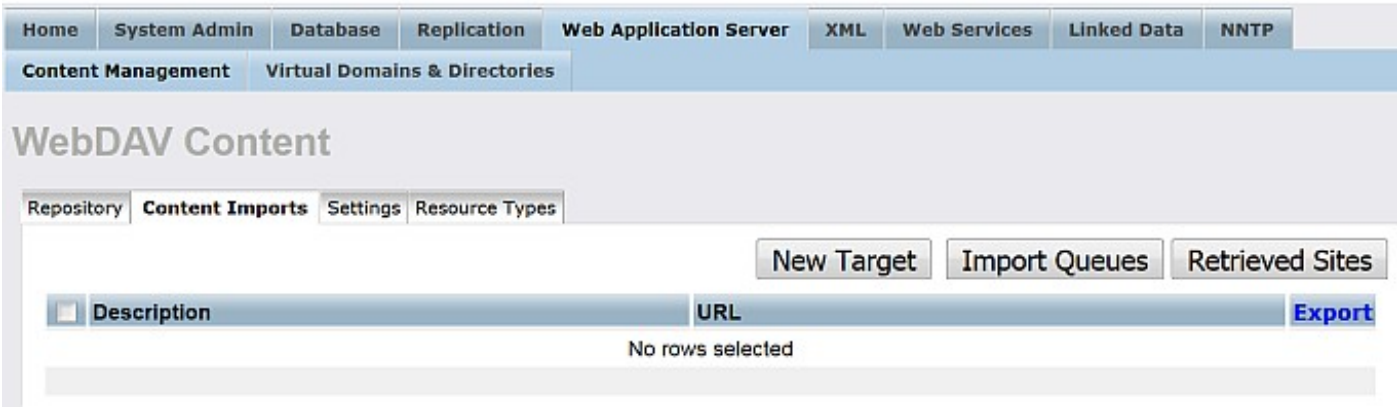
3. Go to tab Web Application Server:

Figure 16.88. Using Virtuoso Crawler



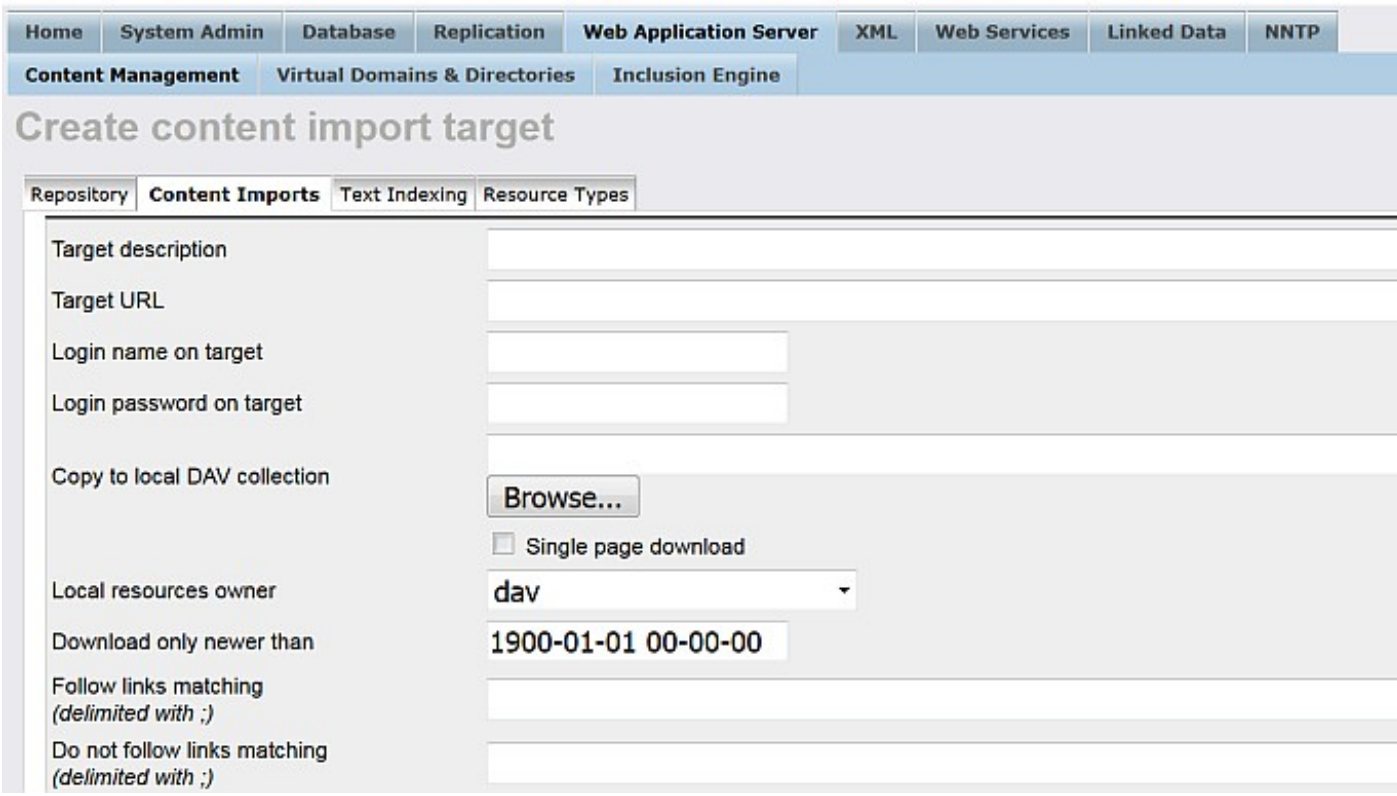
4. Go to tab Content Imports:

Figure 16.89. Using Virtuoso Crawler



5. Click the "New Target" button:

Figure 16.90. Using Virtuoso Crawler



6. In the shown form set respectively:

   a. "Target description": Tim Berners-Lee's electronic Business Card
   b. "Target URL": http://www.w3.org/People/Berners-Lee/ ;
   c. "Copy to local DAV collection " for ex.: /DAV/home/demo/my-crawling/ ;
   d. Choose from the list "Local resources owner": demo ;
   e. Leave checked by default the check-box "Store documents locally". -- Note: if "Store document locally" is not checked, then in this case no documents will be save as DAV resource and the specified DAV folder from above will not be used ;
   f. Check the check-box with label "Store metadata" ;
   g. Specify which cartridges to be involved by hatching their check-box ;
   h. Note: when selected "Convert Link", then all HREFs in the local stored content will be relative.

Figure 16.91. Using Virtuoso Crawler

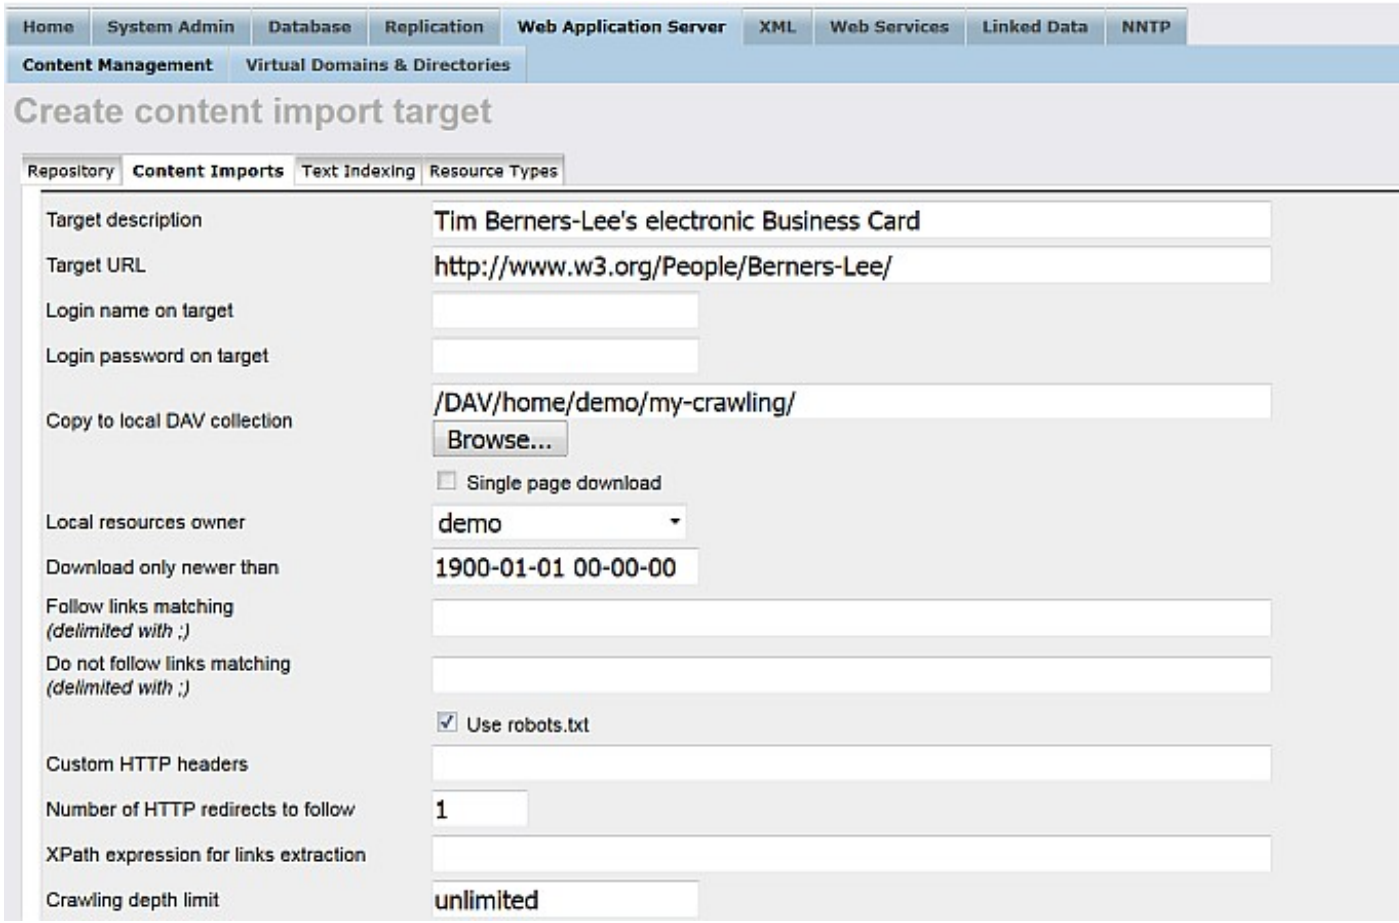


Figure 16.92. Using Virtuoso Crawler

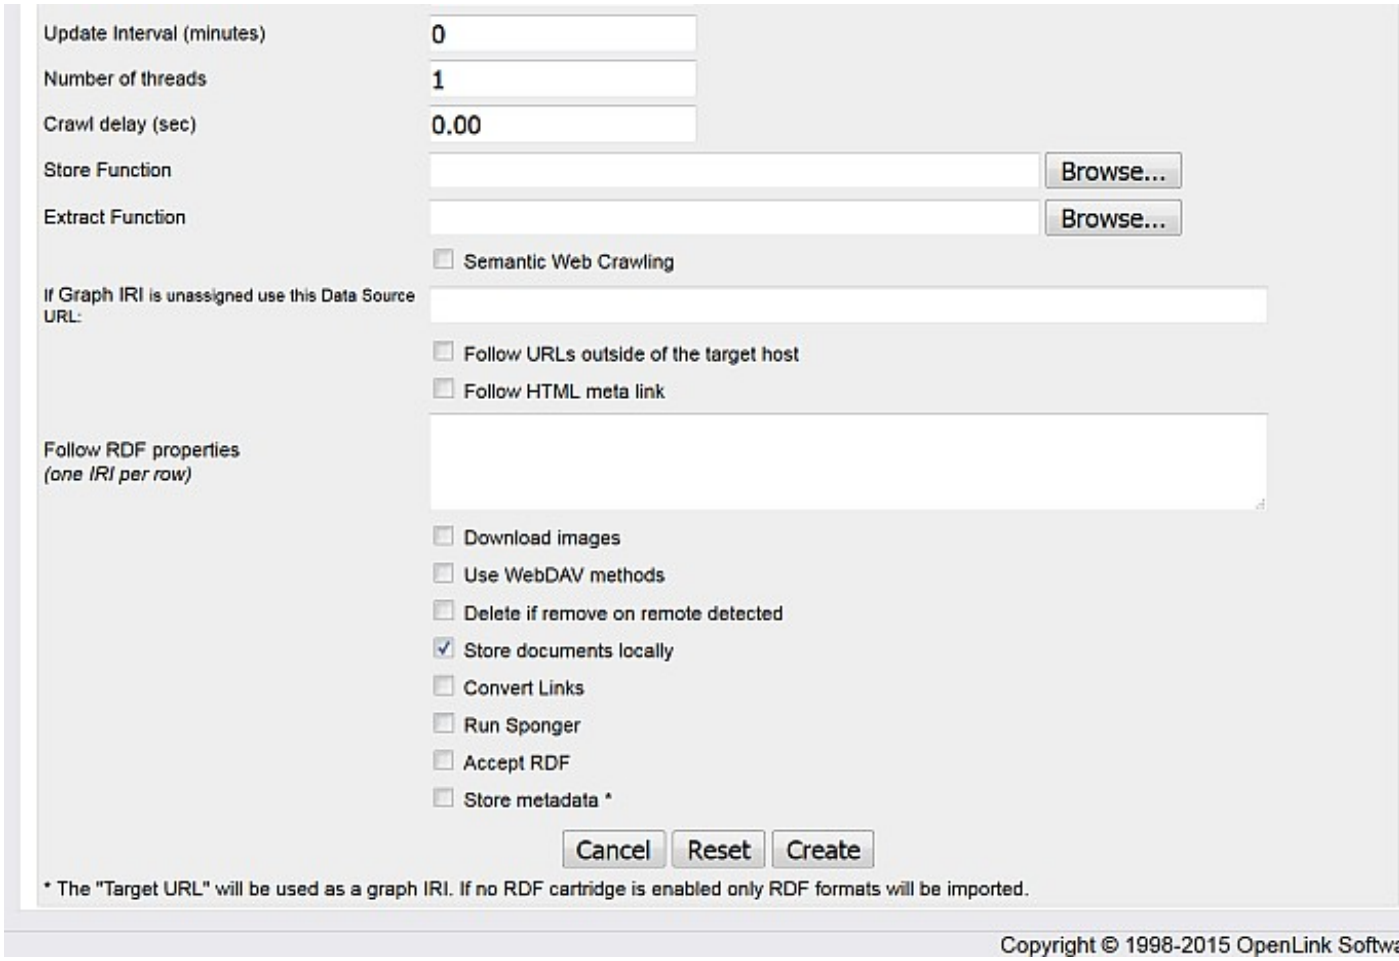
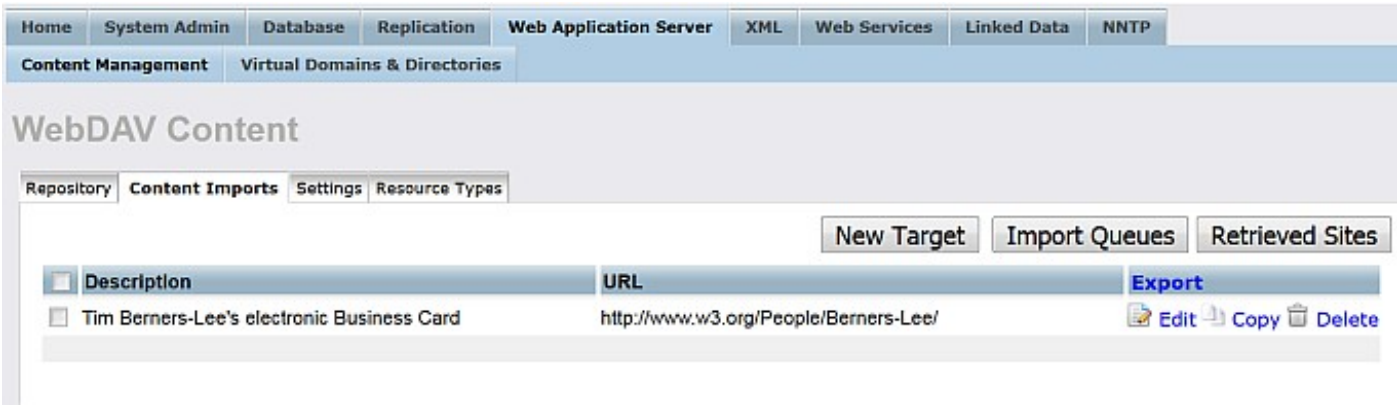


7. Click the button "Create":

Figure 16.93. Using Virtuoso Crawler

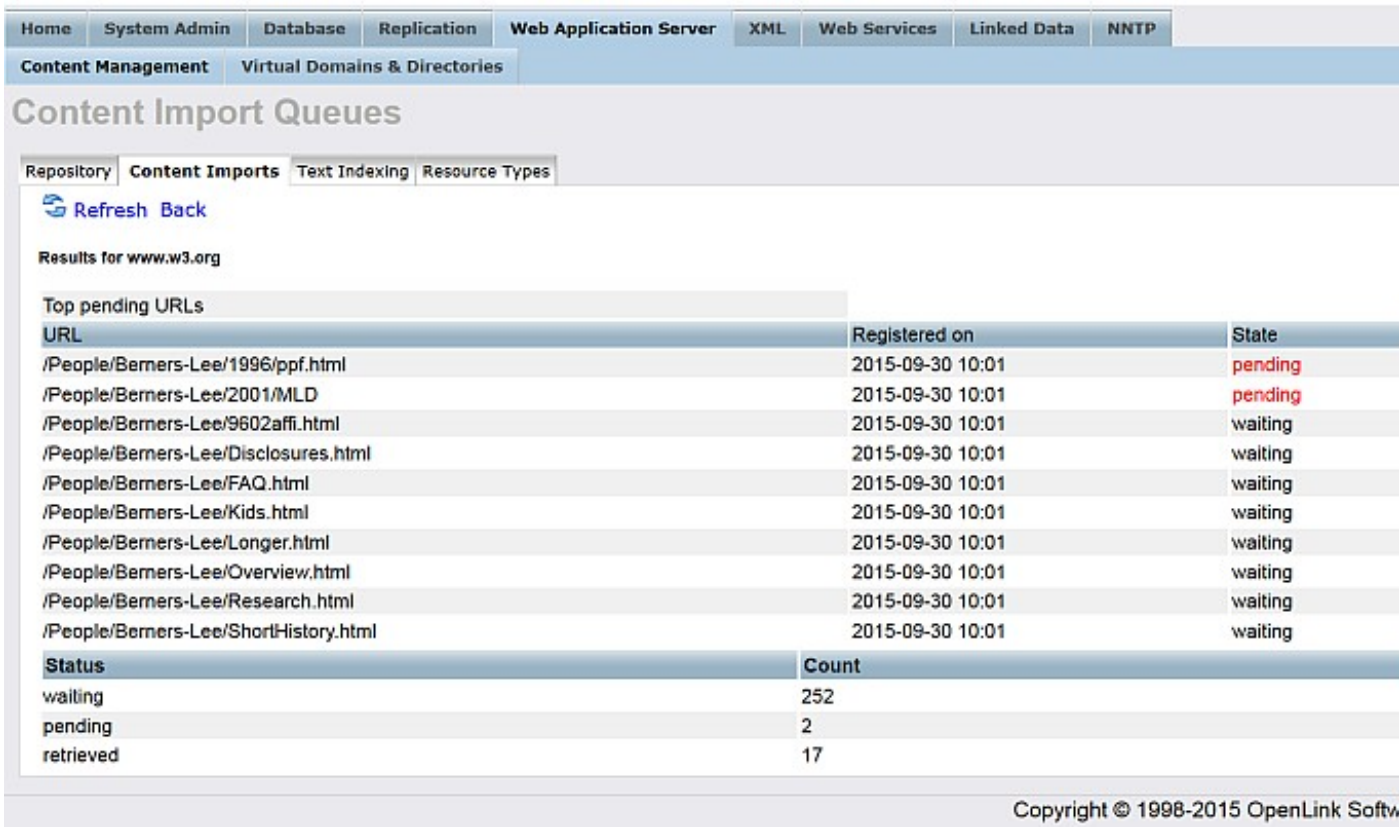


8. Click the button "Import Queues":

Figure 16.94. Using Virtuoso Crawler

9. For "Robot target" with label "Tim Berners-Lee's electronic Business Card" click "Run".
10. As result should be shown the number of the pages retrieved.

Figure 16.95. Using Virtuoso Crawler



Example: Use of schedular to interface Virtuoso Quad Store with PTSW using the following program:

```
create procedure PTSW_CRAWL ()
{
  declare xt, xp any;
  declare content, headers any;

  content := http_get ('http://pingthesemanticweb.com/export/', headers);
  xt := xtree_doc (content);
  xp := xpath_eval ('//rdfdocument/@url', xt, 0);
  foreach (any x in xp) do
    {
      x := cast (x as varchar);
      dbg_obj_print (x);
      {
        declare exit handler for sqlstate '*' {
          log_message (sprintf ('PTSW crawler can not load : %s', x));
        };
        sparql load ?:x into graph ?:x;
        update DB.DBA.SYS_HTTP_SPONGE set HS_LOCAL_IRI = x, HS_EXPIRATION = null WHERE HS_LOCAL_IRI = 'de
        commit work;
      }
    }
}
;

insert soft SYS_SCHEDULED_EVENT (SE_SQL, SE_START, SE_INTERVAL, SE_NAME)
        values ('DB.DBA.PTSW_CRAWL ()', cast (stringtime ('0:0') as DATETIME), 60, 'PTSW Crawling');
```

See Also:

Other Methods to Set Up the Content Crawler for RDF gathering.

16.9.9. Using SPARQL Query and Sponger (i.e. we Fetch the Network Resources in the FROM Clause or values for the graph-uri parameter in SPARQL protocol URLs)

Example:

Execute the following query:

```
SQL>SPARQL
SELECT ?id
FROM NAMED <http://www.openlinksw.com/dataspace/kidehen@openlinksw.com/weblog/kidehen@openlinksw.com%27s%
 OPTION (get:soft "soft", get:method "GET")
WHERE { GRAPH ?g { ?id a ?o } }
limit 10;
```

As result will be shown the retrieved triples:

```
id
VARCHAR
_______________________________________________________________________________

http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this
http://www.openlinksw.com/dataspace/kidehen@openlinksw.com/weblog/kidehen@openlinksw.com%27s%20BLOG%20%5B
http://www.openlinksw.com/dataspace/kidehen@openlinksw.com/weblog/kidehen@openlinksw.com%27s%20BLOG%20%5B
http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this

10 Rows. -- 20 msec.
```

16.9.10. Using Virtuoso PL APIs

Basic Sponger Cartridge Example

In the example script we implement a basic mapper which maps a text/plain mime type to an imaginary ontology, which extends the class Document from FOAF with properties 'txt:UniqueWords' and 'txt:Chars', where the prefix 'txt:' we specify as 'urn:txt:v0.0:'.

```
use DB;

create procedure DB.DBA.RDF_LOAD_TXT_META
        (
         in graph_iri varchar,
         in new_origin_uri varchar,
         in dest varchar,
         inout ret_body any,
         inout aq any,
         inout ps any,
         inout ser_key any
         )
{
  declare words, chars int;
  declare vtb, arr, subj, ses, str any;
  declare ses any;
  -- if any error we just say nothing can be done
  declare exit handler for sqlstate '*'
    {
      return 0;
    };
  subj := coalesce (dest, new_origin_uri);
  vtb := vt_batch ();
  chars := length (ret_body);
  -- using the text index procedures we get a list of words
  vt_batch_feed (vtb, ret_body, 1);
  arr := vt_batch_strings_array (vtb);
  -- the list has 'word' and positions array , so we must divide by 2
  words := length (arr) / 2;
  ses := string_output ();
  -- we compose a N3 literal
  http (sprintf ('<%s> <http://www.w3.org/1999/02/22-rdf-syntax-ns#type> <http://xmlns.com/foaf/0.1/Docum
  http (sprintf ('<%s> <urn:txt:v0.0:UniqueWords> "%d" .\n', subj, words), ses);
  http (sprintf ('<%s> <urn:txt:v0.0:Chars> "%d" .\n', subj, chars), ses);
```

```
  str := string_output_string (ses);
  -- we push the N3 text into the local store
  DB.DBA.TTLP (str, new_origin_uri, subj);
  return 1;
}
;

--
DELETE FROM DB.DBA.SYS_RDF_MAPPERS WHERE RM_HOOK = 'DB.DBA.RDF_LOAD_TXT_META';

INSERT SOFT DB.DBA.SYS_RDF_MAPPERS (RM_PATTERN, RM_TYPE, RM_HOOK, RM_KEY, RM_DESCRIPTION)
    VALUES ('(text/plain)', 'MIME', 'DB.DBA.RDF_LOAD_TXT_META', null, 'Text Files (demo)');

-- here we set order to some large number so don't break existing mappers
update DB.DBA.SYS_RDF_MAPPERS set RM_ID = 2000 WHERE RM_HOOK = 'DB.DBA.RDF_LOAD_TXT_META';
```

1. Paste the whole of this code into Conductor's iSQL interface and execute it to define and register the cartridge.
2. Create a simple text document with a .txt extension. For ex. with name: summary.txt
3. The .txt file must now be made Web accessible. A simple way to do this is to expose it as a WebDAV resource using Virtuoso's built-in WebDAV support:
    a. Log in to Virtuoso's ODS Briefcase application;
    b. Navigate to your Public folder;
    c. Upload your text document, ensuring that the file extension is .txt, the MIME type is set to text/plain and the file permissions are rw-r--r--.
    d. As result the file would be Web accessible via the URL http://cname/DAV/home/username/Public/summary.txt .
    e. Note: you can also check our live demo .
4. To test the mapper we just use /sparql endpoint with option 'Retrieve remote RDF data for all missing source graphs' to execute (for ex.):

```
SELECT *
FROM <http://cname/DAV/home/username/Public/summary.txt>
WHERE {?s ?p ?o}
```

5. Click the "Run Query" button.
6. As result should be shown the found triples, for ex.:

```
s                                                    p
http://cname/DAV/home/username/Public/summary.txt  http://www.w3.org/1999/02/22-rdf-syntax-ns#type
http://cname/DAV/home/username/Public/summary.txt  urn:txt:v0.0:UniqueWords
http://cname/DAV/home/username/Public/summary.txt  urn:txt:v0.0:Chars
```

Important: Setting Sponger Permissions

In order to allow the Sponger to update the local RDF quad store with triples constituting the fetched Network Resource structured data, the role "SPARQL_SPONGE" must be granted to the account "SPARQL", i.e., to the owner account of /sparql web service endpoint. This should normally be the case. If not, you must manually grant this permission. As with most Virtuoso DBA tasks, the Conductor provides the simplest means of doing this.

See Also:

- The DB.DBA.RDF_LOAD_RDFXML function to parse the content of RDF/XML text.
- The DB.DBA.TTLP_MT function to parse TTL (TURTLE or N3 resource).
- The gz_file_open function to retrieve content of a gzipped file and example for loading gzipped N3 and Turtle files.

16.9.11. Using SIMILE RDF Bank API

Virtuoso implements the HTTP-based Semantic Bank API that enables client applications to post to its RDF Triple Store. This method offers an alternative to using Virtuoso/PL functions or WebDAV uploads as the triples-insertion mechanism.

Example:

From your machine go to Firefox->Tools->PiggyBank->My Semantic Bank Accounts

Add in the shown form:

- For bank: address: http://demo.openlinksw.com/bank
- For account id: demo
- For password: demo

Go to http://demo.openlinksw.com/ods

Log in as user demo, password: demo

Go to the Weblog tab from the main ODS Navigation

Click on weblog instance name, for ex. "demo's Weblog".

When the weblog home page is loaded, click Alt + P.

As result is shown the "My PiggyBank" page with all the collected information presented in items.

For several of the items add Tags from the form "Tag" shown for each of them.

As result should be shown the message "Last updated: [here goes the date value].

You can also click "Save" and "Publish" for these items.

Go to http://demo.openlinksw.com/sparql

Enter for the "Default Graph URI" field: http://simile.org/piggybank/demo

Enter for the "Query text" text-area:

```
prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
prefix sioc: <http://rdfs.org/sioc/ns#>
SELECT *
FROM <http://simile.org/piggybank/demo>
WHERE {?s ?p  ?o}
```

Click "Run Query".

As results are shown the found results.

16.9.12. Using RDF NET

Example:

Execute the following query:

```
SQL> SELECT DB.DBA.HTTP_RDF_NET ('sparql load
"http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com"
into graph <http://www.openlinksw.com/>');
```

As result should be shown:

```
callret
VARCHAR
_______________________________________________________

<?xml version="1.0" ?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
xmlns:vcard="http://www.w3.org/2001/vcard-rdf/3.0#"
xmlns="http://example.org/book/" xmlns:dc="http://purl.org/dc/elements/1.1/"
xmlns:ns="http://example.org/ns#">
<rdf:Description>
<callret-0>Load <http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com>
into graph <http://www.openlinksw.com/> -- done</callret-0>
```

```
</rdf:Description>
</rdf:RDF>

1 Rows. -- 1982 msec.
```

16.9.13. Using the RDF Proxy (Sponger) Service

Triples can be inserted also using the Sponger Proxy URI Service. For more information and examples see here .

16.10. RDFizer Middleware (Sponger)

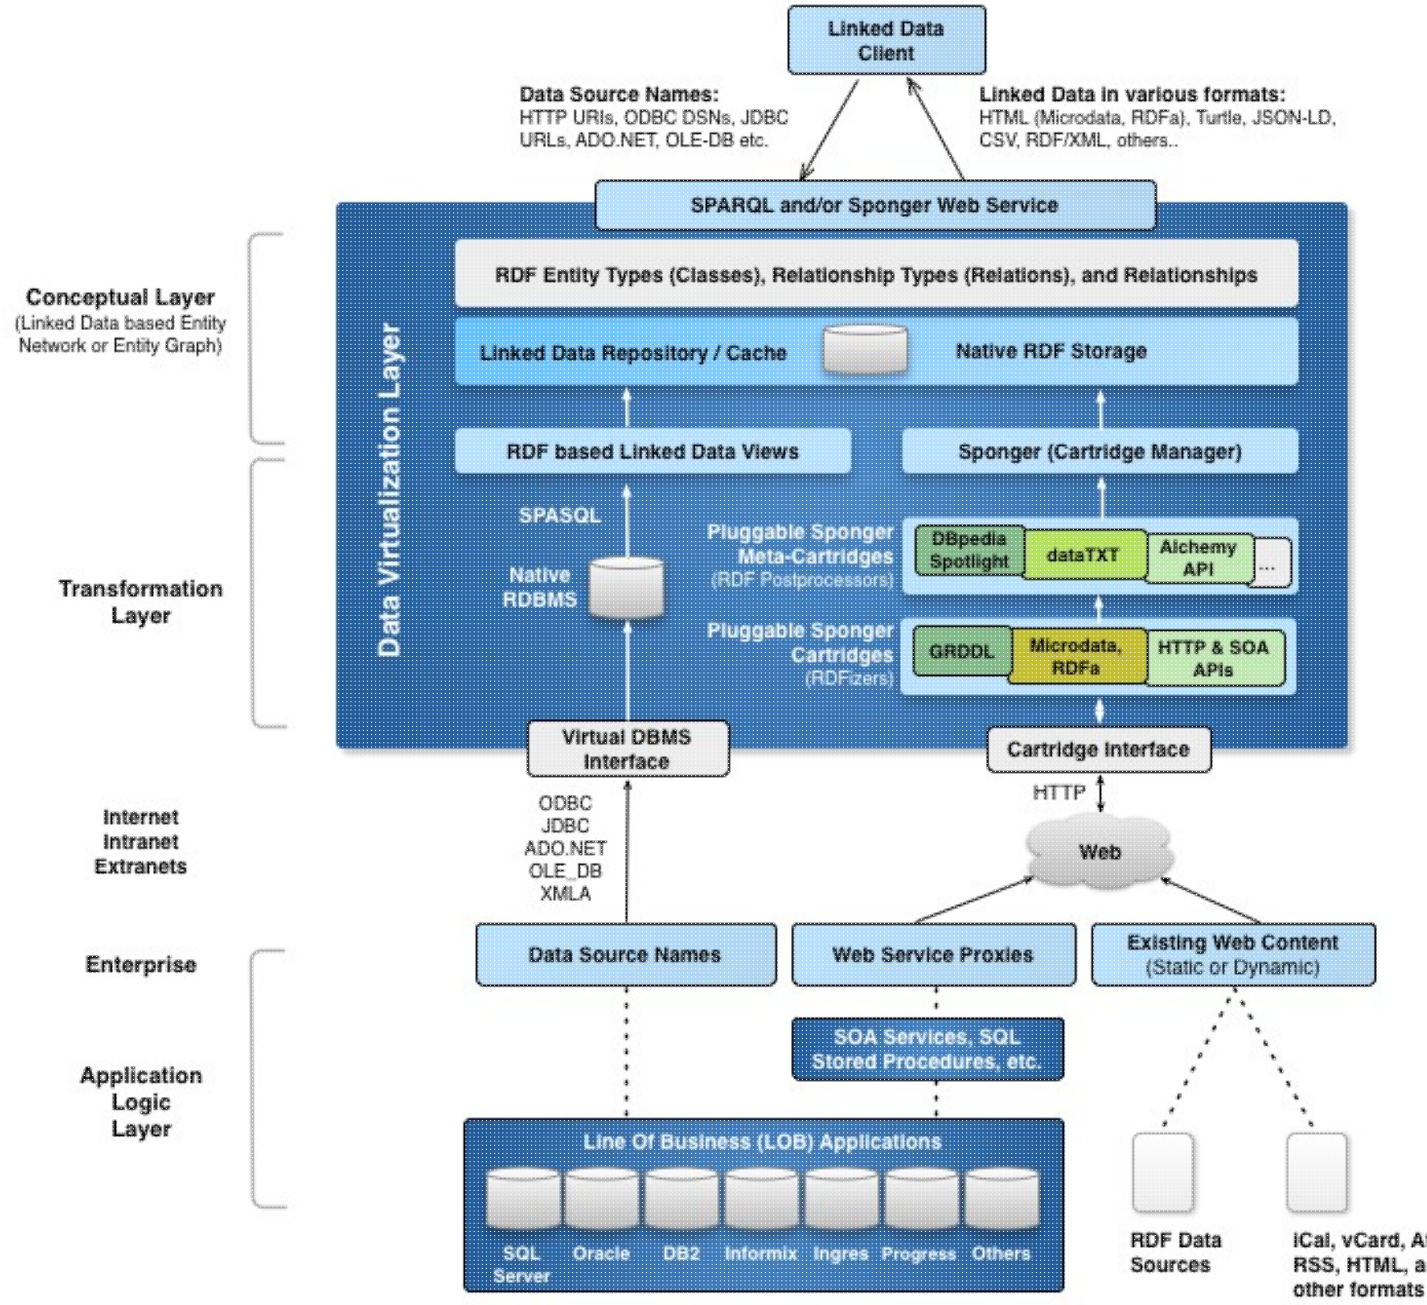
16.10.1. What Is The Sponger?

The Virtuoso Sponger is the Linked Data middleware component of Virtuoso that generates Linked Data from a variety of data sources, supporting a wide variety of data representation and serialization formats. The sponger is transparently integrated into Virtuoso's SPARQL Query Processor where it delivers URI de-referencing within SPARQL query patterns, across disparate data spaces. It also delivers configurable smart HTTP caching services. Optionally, it can be used by the Virtuoso Content Crawler to periodically populate and replenish data within the native RDF Quad Store.

The sponger is a fully fledged HTTP proxy service that is also directly accessible via SOAP or REST interfaces.

As depicted below, OpenLink's broad portfolio of Linked-Data-aware products supports a number of routes for creating or consuming Linked Data. The Sponger provides a key platform for developers to generate quality data meshes from unstructured or semi-structured data sources.

Figure 16.96. OpenLink Linked Data generation options



Architecturally, the Sponger is comprised of a number of Cartridges two types of cartridges: Extractor and Meta Cartridges. Extractor Cartridges focus on data extraction and transformation services while the Meta Cartridges provide lookups and joins across other linked data spaces and Web 2.0 APIs. Both cartridge types are themselves comprised of a data extractors and RDF Schema/Ontology Mapper components.

Cartridges are is highly customizable. Custom cartridges can be developed using any language supported by the Virtuoso Server Extensions API enabling structured linked data generation from resource types not available in the default Sponger Cartridge collection bundled -- as part of the Virtuoso Cartridges VAD package .

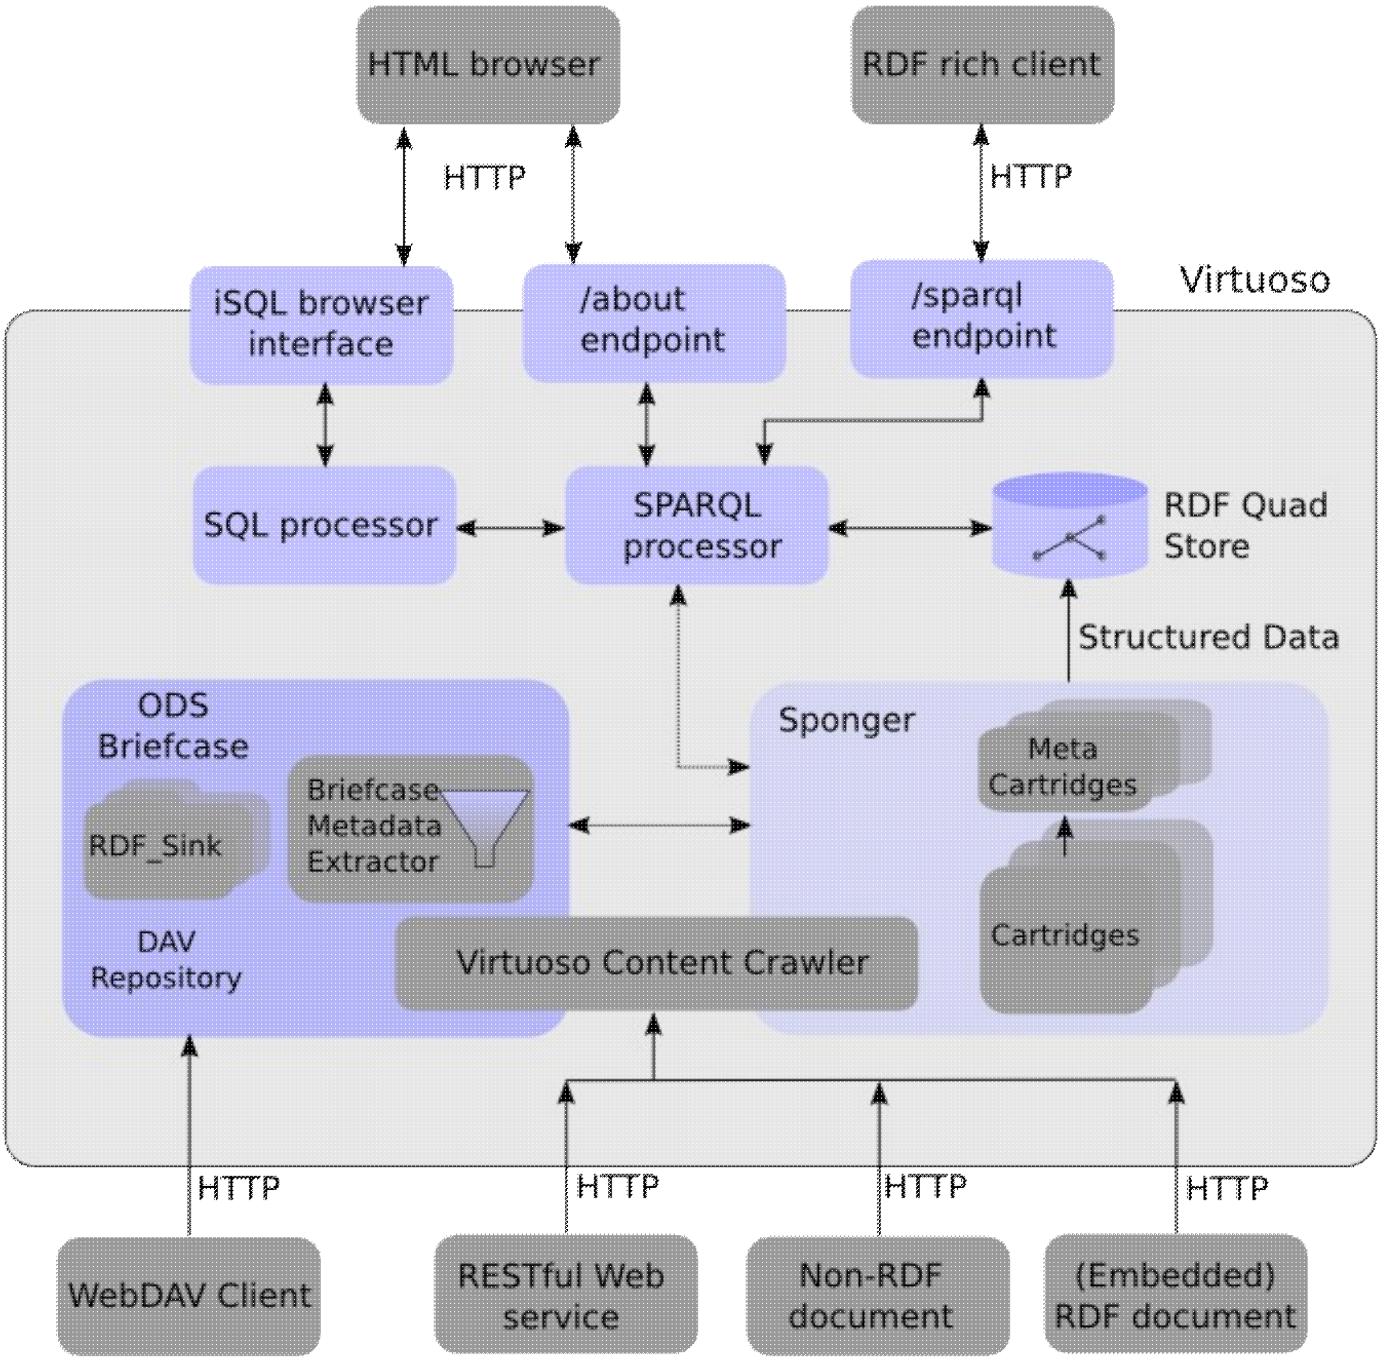
(Embedded) RDF document



16.10.2. Why is it Important?

A majority of the worlds data naturally resides in non RDF form at the current time. The Sponger delivers middleware that accelerates the bootstrap of the Semantic Data Web by generating RDF from non RDF data sources, unobtrusively. This "Swiss army knife" for on-the-fly Linked Data generation provides a bridge between the traditional Document Web and the Linked Data Web ("Data Web").

Sponging data from non-RDF Web sources and converting it to RDF exposes the data in a canonical form for querying and inference, and enables fast and easy construction of linked data driven mesh-ups as opposed to code driven Web 2.0 mash-ups.

The RDF extraction and instance data generation products that offer functionality demonstrated by the Sponger are also commonly referred to as RDFizers.

16.10.3. How Does It Work?

When an RDF aware client requests data from a network accessible resource via the Sponger the following events occur:

- A requests in made for data in RDF form, and if RDF is returned nothing further happens
- If RDF isn't returned, then the Sponger passes the data through a Metadata Extraction Pipeline process (using Metadata Extractors)
- The extracted data is transformed to RDF via a Mapping Pipeline process (RDF is extracted by way of Ontology matching and mapping) that results in RDF Entities (instance data) generation
- RDF Entities are returned to the client

The imported data forms a local cache and its invalidation rules conform to those of traditional HTTP clients (Web Browsers). Thus, expiration time is determined based on subsequent data fetches of the same resource (note: the first data load will record the 'expires' header) with current time compared to expiration time stored in the local cache. If HTTP 'expires' header data isn't returned by the source data server, then the "Sponger" will derive it's own invalidation time frame by evaluating the 'date' header and 'last-modified' HTTP headers. Irrespective of path taken, local cache invalidation is driven by an assessment of current time relative to recorded expiration time.

To manage the cache expiration, set the *MinExpiration* parameter in your Virtuoso.ini file.

Read full description of the parameter in the [SPARQL] ini section .

Designed with a pluggable architecture, the Sponger's core functionality is provided by Cartridges. Each cartridge includes Data Extractors which extract data from one or more data sources, and Ontology Mappers which map the extracted data to one or more ontologies/schemas, and route to producing RDF Linked Data.

The Schema Mappers are typically XSLT (e.g. GRDDL and other OpenLink Mapping Schemas) or Virtuoso PL based. The Metadata Extractors may be developed in Virtuoso PL, C/C++, Java, or any other language that can be integrated into the Virtuoso via it's server extensions APIs.

The Sponger also includes a pluggable name resolution mechanism that enables the development of Custom Resolvers for naming schemes (e.g. URNs) associated with protocols beyond HTTP. Examples of custom resolvers include:

- LSID
- DOI

16.10.4. Installation Steps

1. Download the Cartridges VAD package .
2. Install the cartridges_dav.vad package by using the Conductor UI or by using iSQL:

```
SQL> DB.DBA.VAD_INSTALL('tmp/cartridges_dav.vad',0);
SQL_STATE  SQL_MESSAGE
VARCHAR  VARCHAR
_______________________________________________________________________________

00000    No errors detected
00000    Installation of "Linked Data Cartridges" is complete.
00000    Now making a final checkpoint.
00000    Final checkpoint is made.
00000    SUCCESS

6 Rows. -- 1078 msec.
```

3. Cartridge Configuration

    - Extractor Cartridges
    - Meta Cartridges

See Also: Cartridges Package content description.

16.10.5. Using The Sponger

The Sponger can be invoked via the following mechanisms:

1. Virtuoso SPARQL query processor
2. RDF Proxy Service
3. OpenLink RDF client applications
4. ODS-Briefcase (Virtuoso WebDAV)

   - a component of the OpenLink Data Spaces distributed collaborative application platform
5. Directly via Virtuoso PL

SPARQL Query Processor IRI Dereferencing

The Sponger is transparently integrated into the Virtuoso SPARQL query processor, where it supports IRI dereferencing.

Virtuoso extends the SPARQL Query Language such that it is possible to download RDF resources from a given IRI, parse, and then store the resulting triples in a graph, with all three operations performed during the SPARQL query-execution process. The IRI/URI of the graph used to store the triples is usually equal to the URL where the resources are downloaded from, consequently the feature is known as "IRI/URI dereferencing". If a SPARQL query instructs the SPARQL processor to retrieve the target graph into local storage, then the SPARQL sponger will be invoked.

The SPARQL extensions for IRI dereferencing are described below. Essentially these enable downloading and local storage of selected triples either from one or more named graphs, or based on a proximity search from a starting URI for entities matching the select criteria and also related by the specified predicates, up to a given depth. For full details see section Linked Data - IRI Dereferencing .

Note: For brevity, any reference to URI/IRIs above or in subsequent sections implies an HTTP URI/IRI, where IRI is an internationalized URI. Similarly, in the context of the Sponger, the term IRI in the Virtuoso reference documentation should be taken to mean an HTTP IRI.

SPARQL Extensions for IRI Dereferencing of FROM Clauses

In addition to the "define get:..." SPARQL extensions for IRI dereferencing in FROM clauses, Virtuoso supports dereferencing SPARQL IRIs used in the WHERE clause (graph patterns) of a SPARQL query via a set of "define input:grab-..." pragmas.

Consider an RDF resource which describes a member of a contact list, user1, and also contains statements about other users, user2 anduser3 , known to him. Resource user3 in turn contains statements about user4 and so on. If all the data relating to these users were loaded into Virtuoso's RDF database, the query to retrieve the details of all the users could be quite simple. e.g.:

```
sparql
prefix foaf: <http://xmlns.com/foaf/0.1/>
prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
select ?id ?firstname ?nick
where
  {
    graph ?g
      {
        ?id rdf:type foaf:Person .
        ?id foaf:firstName ?firstname .
        ?id foaf:knows ?fn .
        ?fn foaf:nick ?nick .
      }
   }
limit 10;
```

But what if some or all of these resources were not present in Virtuoso's quad store? The highly distributed nature of the Linked Data Web makes it highly likely that these interlinked resources would be spread across several data spaces. Virtuoso's 'input:grab-...' extensions to SPARQL enable IRI dereferencing in such a way that all appropriate Network resources are loaded, i.e. "being fetched", during query execution, even if some of the Network resources are not known beforehand. For any particular resource matched, and if necessary downloaded, by the query, it is possible to download related resources via a designated predicate path(s) to a specifiable depth i.e. number of 'hops', distance, or degrees of separation (i.e compute Transitive Closures in SPARQL).

Using Virtuoso's 'input:grab-' pragmas to enable sponging, the above query might be recast to:

```
sparql
define input:grab-var "?more"
define input:grab-depth 10
define input:grab-limit 100
define input:grab-base "http://www.openlinksw.com/dataspace/kidehen@openlinksw.com/weblog/kidehen@openlin
prefix foaf: <http://xmlns.com/foaf/0.1/>
prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
prefix rdfs: <http://www.w3.org/2000/01/rdf-schema#>

select ?id ?firstname ?nick
where {
    graph ?g {
                ?id rdf:type foaf:Person .
                ?id foaf:firstName ?firstname .
                ?id foaf:knows ?fn .
                ?fn foaf:nick ?nick .
                optional { ?id rdfs:SeeAlso ?more }
              }
}
limit 10;
```

Another example showing a designated predicate traversal path via the input:grab-seealso extension is:

```
sparql
define input:grab-iri <http://www.openlinksw.com/dataspace/kidehen@openlinksw.com/weblog/kidehen@openlink
define input:grab-var "id"
define input:grab-depth 10
define input:grab-limit 100
define input:grab-base "http://www.openlinksw.com/dataspace/kidehen@openlinksw.com/weblog/kidehen@openlin
define input:grab-seealso <foaf:maker>
prefix foaf: <http://xmlns.com/foaf/0.1/>

select ?id
where
  {
    graph ?g
      {
        ?id a foaf:Person .
      }
  }
limit 10;
```

A list of the input:grab pragmas is given below:

- input:grab-var specifies the name of the SPARQL variable whose values should be used as IRIs of resources that should be downloaded.
- input:grab-iri specifies an IRI that should be retrieved before executing the rest of the query, if it is not in the quad store already. (This pragma can be included multiple times).
- input:grab-seealso (or its synonym input:grab-follow-predicate) specifies a predicate IRI to be used when traversing a graph. (This pragma can be included multiple times).
- input:grab-limit sets the maximum number of resources (graph subject or object nodes) to be retrieved from a target graph.
- input:grab-depth sets the maximum 'degrees of separation' or links (predicates) between nodes in the target graph.
- input:grab-all "yes" instructs the SPARQL processor to dereference everything related to the query. All variables and literal IRIs in the query become values for input:grab-var and input:grab-iri. The resulting performance may be very bad.
- input:grab-base specifies the base IRI to use when converting relative IRIs to absolute. (Default: empty string).
- input:grab-destination overrides the default IRI dereferencing and forces all retrieved triples to be stored in the specified graph.
- input:grab-loader identifies the procedure used to retrieve each resource via HTTP, parse and store it. (Default: DB.DBA.RDF_SPONGE_UP)
- input:grab-resolver identifies the procedure that resolves IRIs and determines the HTTP method of retrieval. (Default: DB.DBA.RDF_GRAB_RESOLVER_DEFAULT)

SPARQL Processor Usage Example

Network Resource Fetch can be performed directly from within the SPARQL processor.

After logging into Virtuoso's Conductor interface, the following query can be issued from the Interactive SQL (iSQL) panel:

```
sparql
define get:uri "http://www.ivan-herman.net/foaf.html"
define get:soft "soft"
select * from <http://mygraph> where {?s ?p ?o}
```

Here the sparql keyword invokes the SPARQL processor from the SQL interface and the RDF data fetched from page http://www.ivan-herman.net/foaf.html is loaded into the local RDF quad store as graph http://mygraph .

The new graph can then be queried using the basic SPARQL client normally available in a default Virtuoso installation at http://example.com/sparql/. e.g.:

```
select * from <http://mygraph> where {?s ?p ?o}
```

RDF Proxy Service

The Sponger's functionality is also exposed via an in-built REST style Web service. This web service takes a target URL and either returns the content "as is" or tries to transform (by sponging) to RDF. Thus, the proxy service can be used as a 'pipe' for RDF browsers to browse non-RDF sources.

When the cartridges package is installed, Virtuoso reserves the path '/about/[id|data|rdf|html]/http/' for Sponger Proxy URI Service. For example, if a Virtuoso installation on host example.com listens for HTTP requests on port 8080 then client applications should use a 'service endpoint' string equal to 'http://example.com:8080/about/[id|data|rdf|html]/http/'. If the cartridges package is not installed, then the service uses the path '/proxy/rdf/'.

Note: The old Sponger Proxy URI Service pattern '/proxy/' is now deprecated.

Example 1

The following URLs return information about musician John Cale, gleaned from the MusicBrainz music metadatabase, rendered as RDF or HTML respectively. (The Network Resource fetched data is available in the HTML rendering through the foaf:primaryTopic property.)

- http://demo.openlinksw.com/about/rdf/http://musicbrainz.org/artist/72c090b6-a68e-4cb9-b330-85278681a714.html
- http://demo.openlinksw.com/about/html/http/musicbrainz.org/artist/72c090b6-a68e-4cb9-b330-85278681a714.html

Example 2

The file http://www.ivan-herman.net/foaf.html contains a short profile of the W3C Semantic Web Activity Lead Ivan Herman. This XHTML file contains RDF embedded as RDFa. Running the file through the Sponger via Virtuoso's RDF proxy service extracts the embedded FOAF data as pure RDF, as can be seen by executing:

```
$ curl -L -H "Accept:application/rdf+xml" http://linkeddata.uriburner.com/about/id/entity/http/www.ivan-h
<?xml version="1.0" encoding="utf-8" ?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#" xmlns:rdfs="http://www.w3.org/2000/01/rd
  <rdf:Description rdf:about="http://linkeddata.uriburner.com/about/id/http/www.ivan-herman.net/foaf.html
  <rdf:Description rdf:nodeID="b145981159"><rdf:rest rdf:nodeID="b145981158"/></rdf:Description>
  <rdf:Description rdf:about="http://linkeddata.uriburner.com/about/id/entity/http/www.mendeley.com/profi
  etc ..
  <rdf:Description rdf:nodeID="b145981130"><http-voc:elementName xmlns:http-voc="http://www.w3.org/2006/h
</rdf:RDF>
```

(linkeddata.uriburner.com hosts a public Virtuoso instance.) Though this example demonstrates the action of the /about/id/entity/ service quite transparently, it is a basic and unwieldy way to view RDF. As described earlier, the OpenLink Data Explorer uses the same proxy service to provide a more polished means to extract and view fetched RDF data.

Usage of the Sponger Middleware via REST patterns

Delegation and proxies are part of the Internet and Web's federated architecture. Thus, developers of RESTful applications benefit immensely from the ability to leverage Sponger functionality via delegation to it as a proxy.

The following table presents list of the supported URL parameters:

Table 16.9.

Parameter	Value	Description	Example
refresh	clean	*Usage* : for overwriting. The 'clean' usage explicitly clears the graph i.e. will cause the Sponger to drop cache even if it is marked to be in the fly. Thus, if fetched cache by some reason is left in some inconsistent state like shutdown during Network Resource fetching, then 'clean' is required as it doesn't check cache state. *Note* : must be used with caution as other threads may be doing fetching of network resources at same time.	Explicitly clear the graph
sponger:get	add	*Usage* : Add new triples to named graphs, progressively. This is the default value for the parameter sponger:get. May be used together with refresh=<seconds> to overwrite the expiration in the cache.	Add new triples and refresh on every 10 seconds
sponger:get	soft	*Usage* : Network Resource Fetch data subject to cache invalidation mode and associated rules of instance. May be used together with refresh=<seconds> to overwrite the expiration in the cache.	Network Resource Fetch data with option *soft* and refresh on every 10 seconds
sponger:get	replace	*Usage* : Replace subject to cache invalidation mode and rules, but coverage includes non fetched triples if such exist in a given named graph. may be used together with refresh=<seconds> to overwrite the expiration in the cache.	Replace data and refresh on every 10 seconds

OpenLink RDF Client Applications

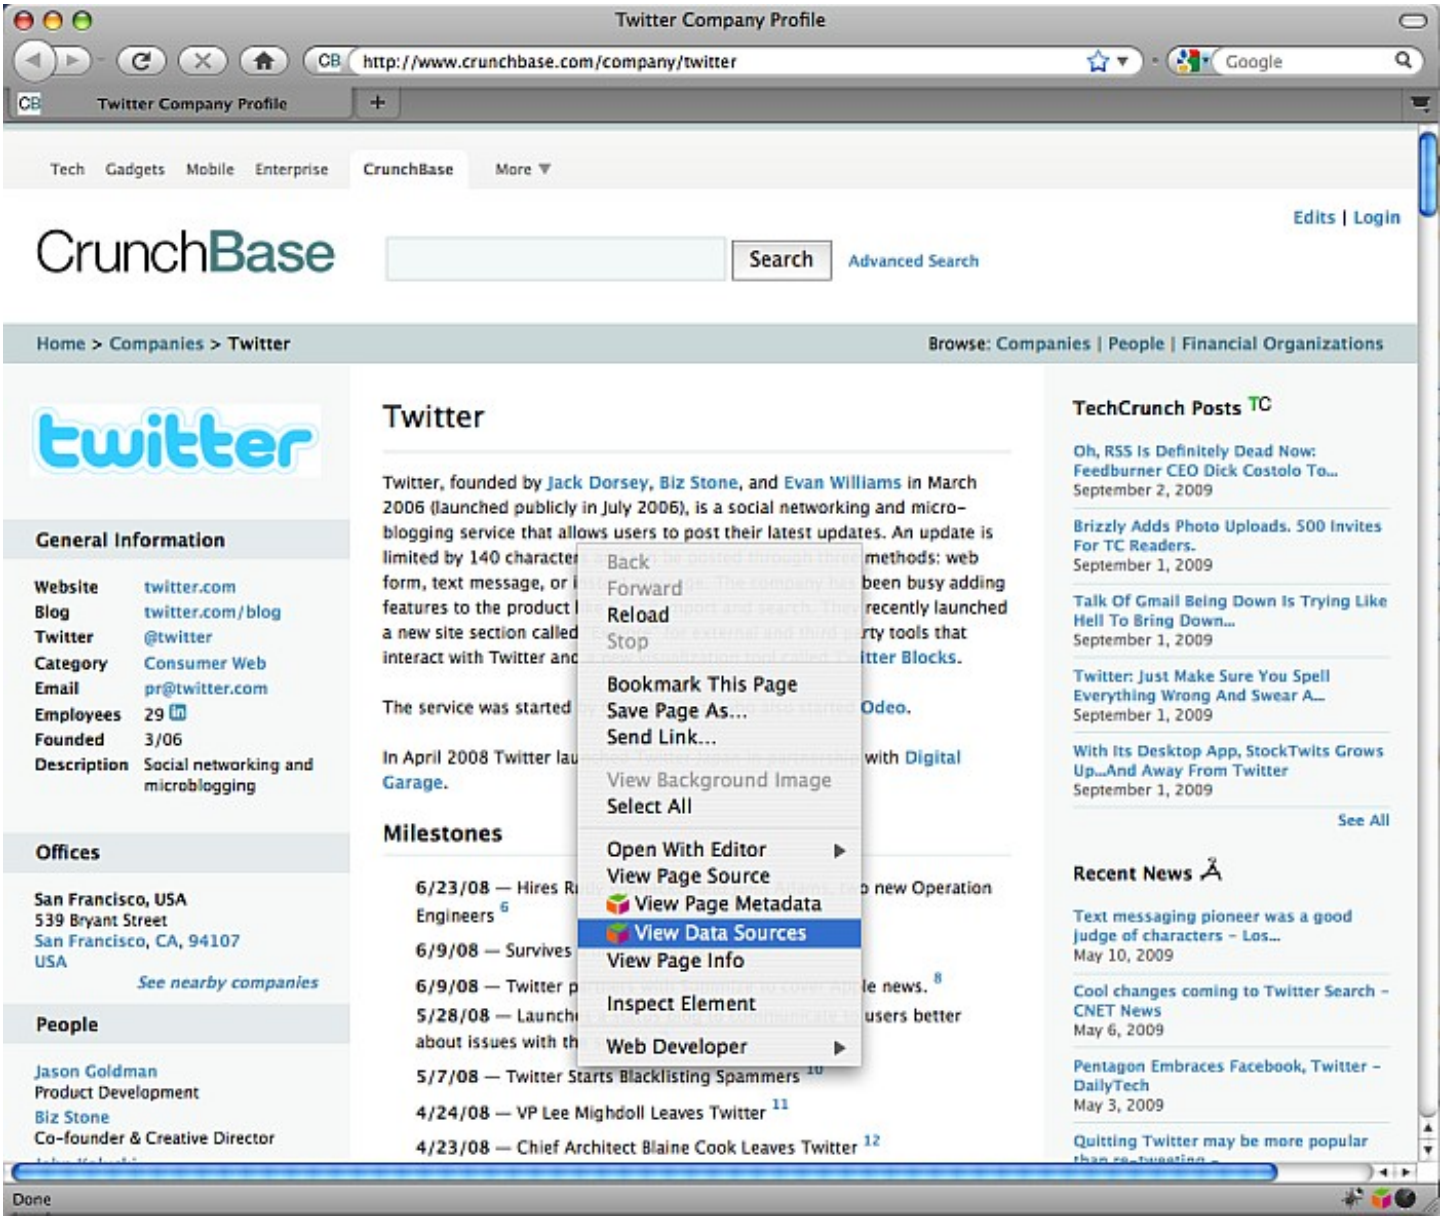
OpenLink currently provides two main RDF client applications:

- OpenLink Data Explorer (ODE)
- iSPARQL

ODE is a Linked Data explorer packaged as a Firefox plugin (support for other browsers is planned). iSPARQL is an interactive AJAX-based SPARQL query builder with support for SPARQL QBE, bundled as part of the OpenLink Ajax Toolkit (OAT). Both RIA clients utilise sponging extensively.

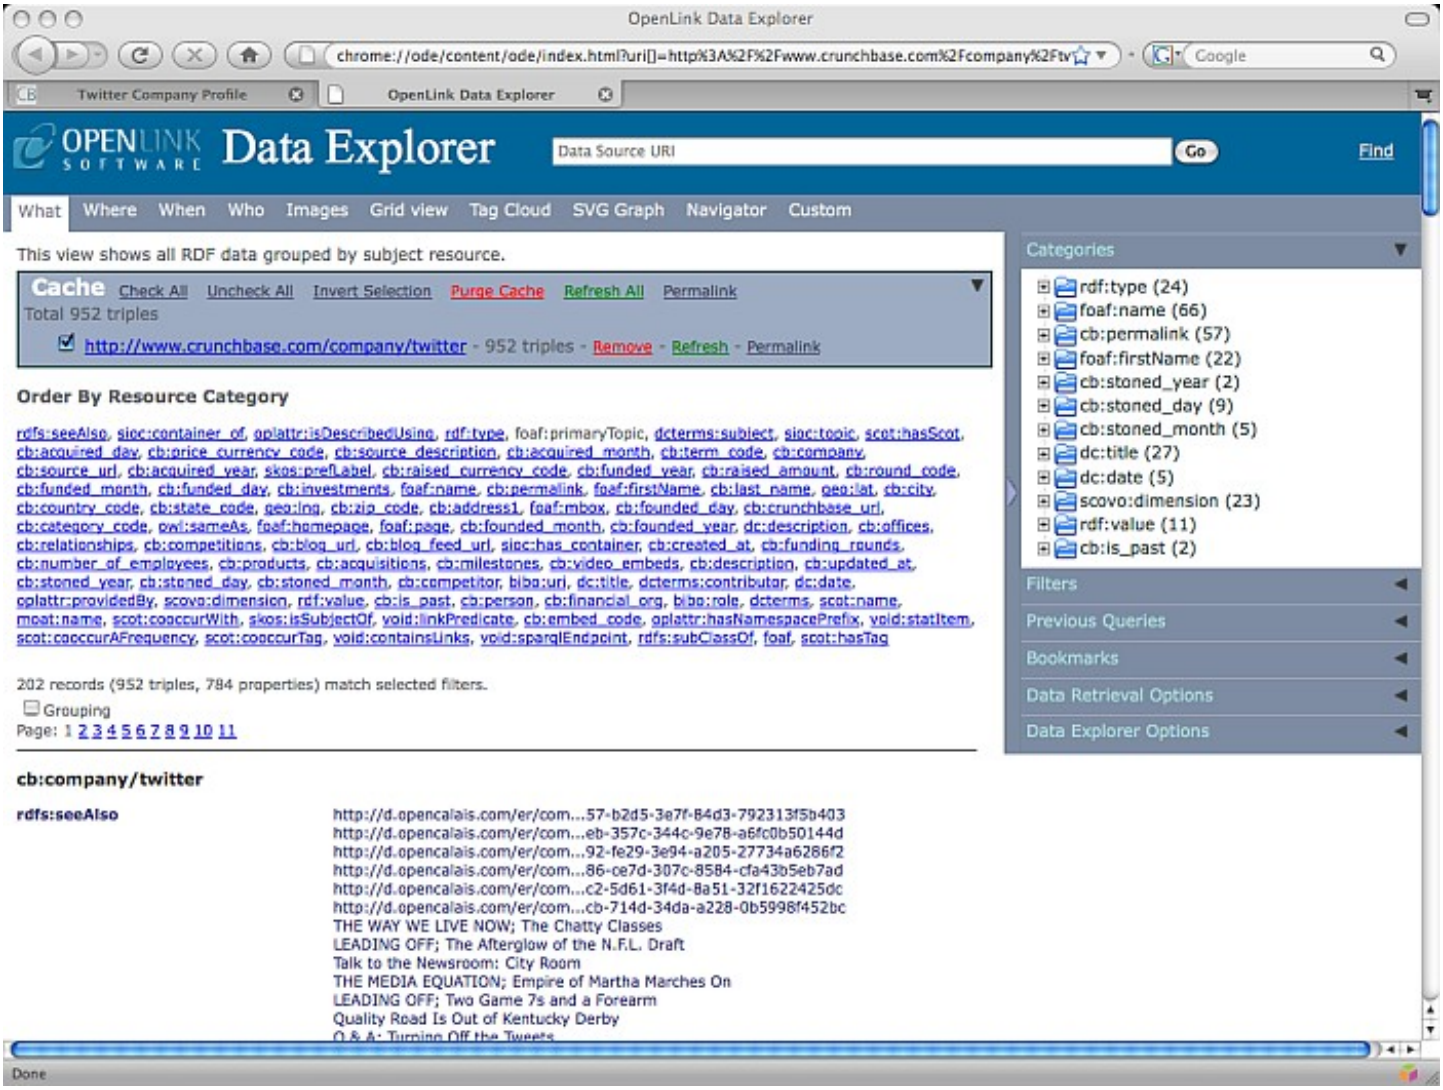
The ODE plugin is dual faceted - RDF data can be viewed and explored natively, through its integral RDF browser, or, as described above, rendered as HTML through ODE's 'View Page Metadata' option. The screenshots below show ODE's RDF browser being launched through the 'View Linked Data Sources' popup menu.

Figure 16.98. Launching ODE's RDF browser



The RDF browser then displays RDF data fetched via the Crunchbase cartridge.

Figure 16.99. ODE RDF browser displaying Crunchbase network resource fetched data



iSPARQL directs queries to the configured SPARQL endpoint. When targetting a Virtuoso /sparql service, Virtuoso specific sponging options can be enabled through the 'Preferences' dialog box.

The iSPARQL sponger settings are appended to SPARQL queries through the 'should-sponge' query parameter. These are translated to IRI dereferencing pragmas on the server as follows:

Table 16.10.

iSPARQL sponging setting	/sparql endpoint: "should-sponge" query parameter value	SPARQL processor directives
Use only local data	N/A	N/A
Retrieve remote RDF data for all missing source graphs	soft	define get:soft "soft"
Retrieve all missing remote RDF data that might be useful	grab-all	define input:grab-all "yes" define input:grab-depth 5 define input:grab-limit 100
Retrieve all missing remote RDF data that might be useful including seeAlso references	grab-seealso	define input:grab-all "yes" define input:grab-depth 5 define input:grab-limit 200 define input:grab-seealso <http://www.w3.org.2000/01/rdf-schema#seeAlso> define input:grab-seealso <http://xmlns.com/foaf/0.1/seeAlso>
Try to download all referenced resources	grab-everything	define input:grab-all "yes" define input:grab-intermediate "yes" define input:grab-depth 5 define input:grab-limit 500 define input:grab-seealso

iSPARQL sponging setting	/sparql endpoint: "should-sponge" query parameter value	SPARQL processor directives
		<http://www.w3.org/2000/01/rdf-schema#seeAlso> define input:grab-seealso <http://xmlns.com/foaf/0.1/seeAlso>

ODS-Briefcase (Virtuoso WebDAV)

ODS-Briefcase is a component of OpenLink Data Spaces (ODS), a new generation distributed collaborative application platform for creating Semantic Web presence via Data Spaces derived from weblogs, wikis, feed aggregators, photo galleries, shared bookmarks, discussion forums and more. It is also a high level interface to the Virtuoso WebDAV repository.

ODS-Briefcase offers file-sharing functionality that includes the following features:

- Web brower-based interactions
- Web Services (direct use of the HTTP based WebDAV protocol)
- SPARQL query language support - all WebDAV resources are exposed as SIOC ontology instance data (RDF data sets)

When resources or documents are put into the ODS Briefcase and are made publicly readable (via a Unix-style +r permission or ACL setting) and the resource in question is of a supported content type, metadata is automatically extracted at file upload time.

Note: ODS-Briefcase extracts metadata from a wide array of file formats, automatically.

The extracted metadata is available in two forms, pure WebDAV and RDF (with RDF/XML or N3/Turtle serialization options), that is optionally synchronized with the underlying Virtuoso Quad Store.

All public readable resources in WebDAV have their owner, creation time, update time, size and tags published, plus associated content type dependent metadata. This WebDAV metadata is also available in RDF form as a SPARQL queriable graph accessible via the SPARQL protocol endpoint using the WebDAV location as the RDF data set URI (graph or data source URI).

You can also use a special RDF_Sink folder to automate the process of uploading RDF resources files into the Virtuoso Quad Store via WebDAV or raw HTTP. The properties of the special folder control whether sponging (RDFization) occurs. Of course, by default, this feature is enabled across all Virtuoso and ODS installations (with an ODS-Briefcase Data Space instance enabled).

Raw HTTP Example for Extracting Metadata using CURL

```
Username: demo
Password: demo
Source File: wine.rdf
Destination Folder:
http://demo.openlinksw.com/DAV/home/demo/rdf_sink/
Content Type: application/rdf+xml

$ curl -v -T wine.rdf -H content-type:application/rdf+xml http://demo.openlinksw.com/DAV/home/demo/rdf_si
```

Finally, you can also get RDF data into Virtuoso's Quad Store via WebDAV using the Virtuoso Web Crawler utility (configurable via the Virtuoso Conductor UI). This feature also provides the ability to enable or disable Sponging as depicted below.

Sponger and ODS-Briefcase Structured Data Extractor Interrelationship

As the Sponger and ODS-Briefcase both extract structured data, what is the relationship between these two facilities?

The principal difference between the two is that the Sponger is anRDF data crawler & generator, whereas Briefcase's structured data extractor is a WebDAV resourcefilter. The Briefcase structured data extractor is aimed at providing RDF data from WebDAV resources. Thus, if none of the available Sponger cartridges are able to extract metadata and produce RDF structured data, the Sponger calls upon the Briefcase extractor as the last resort in the RDF structured data generation pipeline.

Figure 16.100. Conductor's content import configuration panel

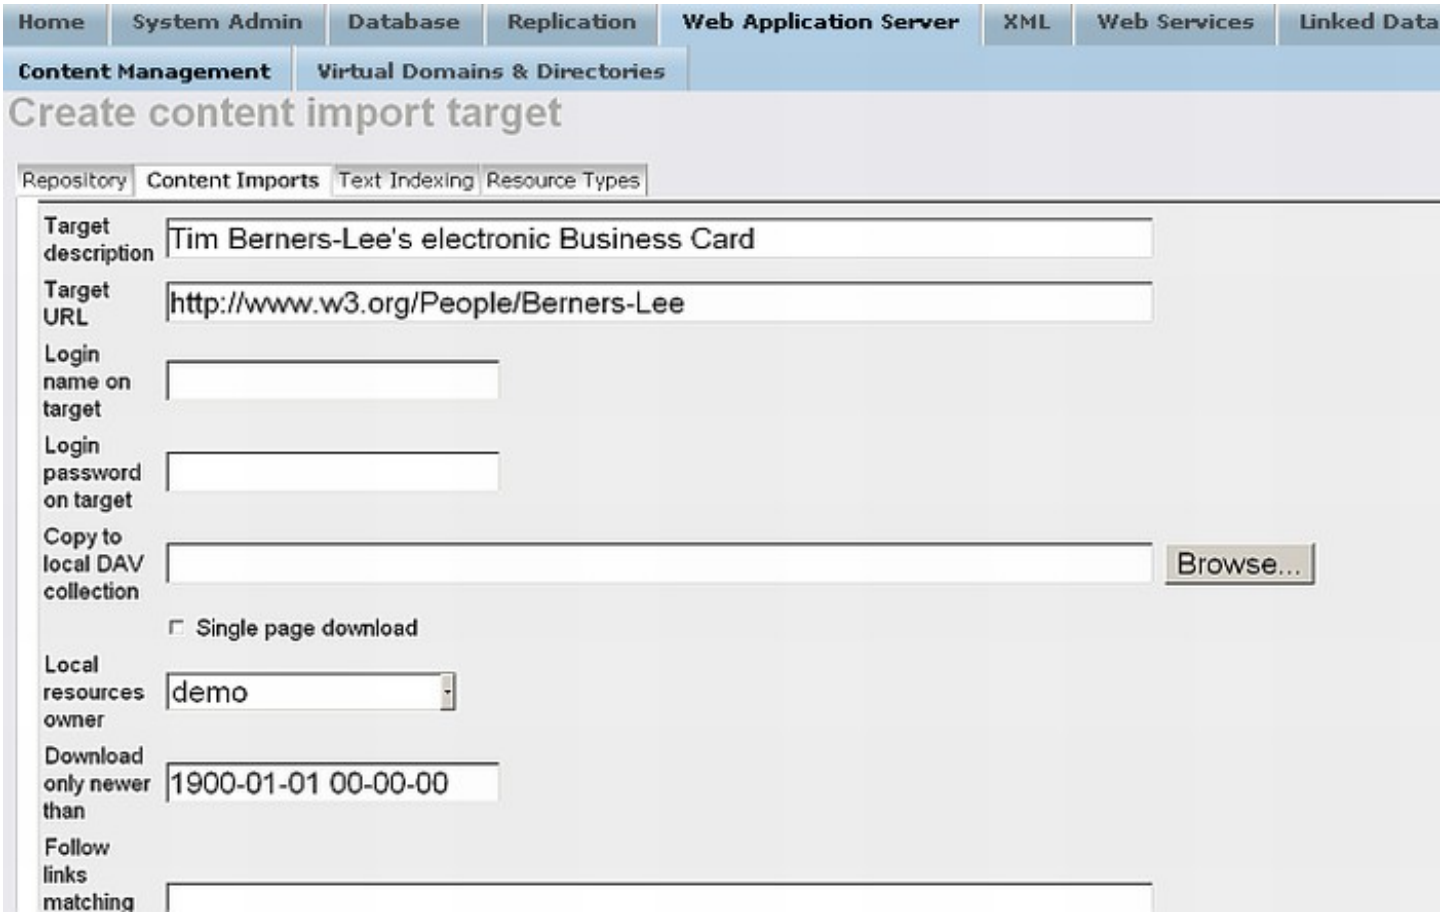


Figure 16.101. Conductor's content import configuration panel

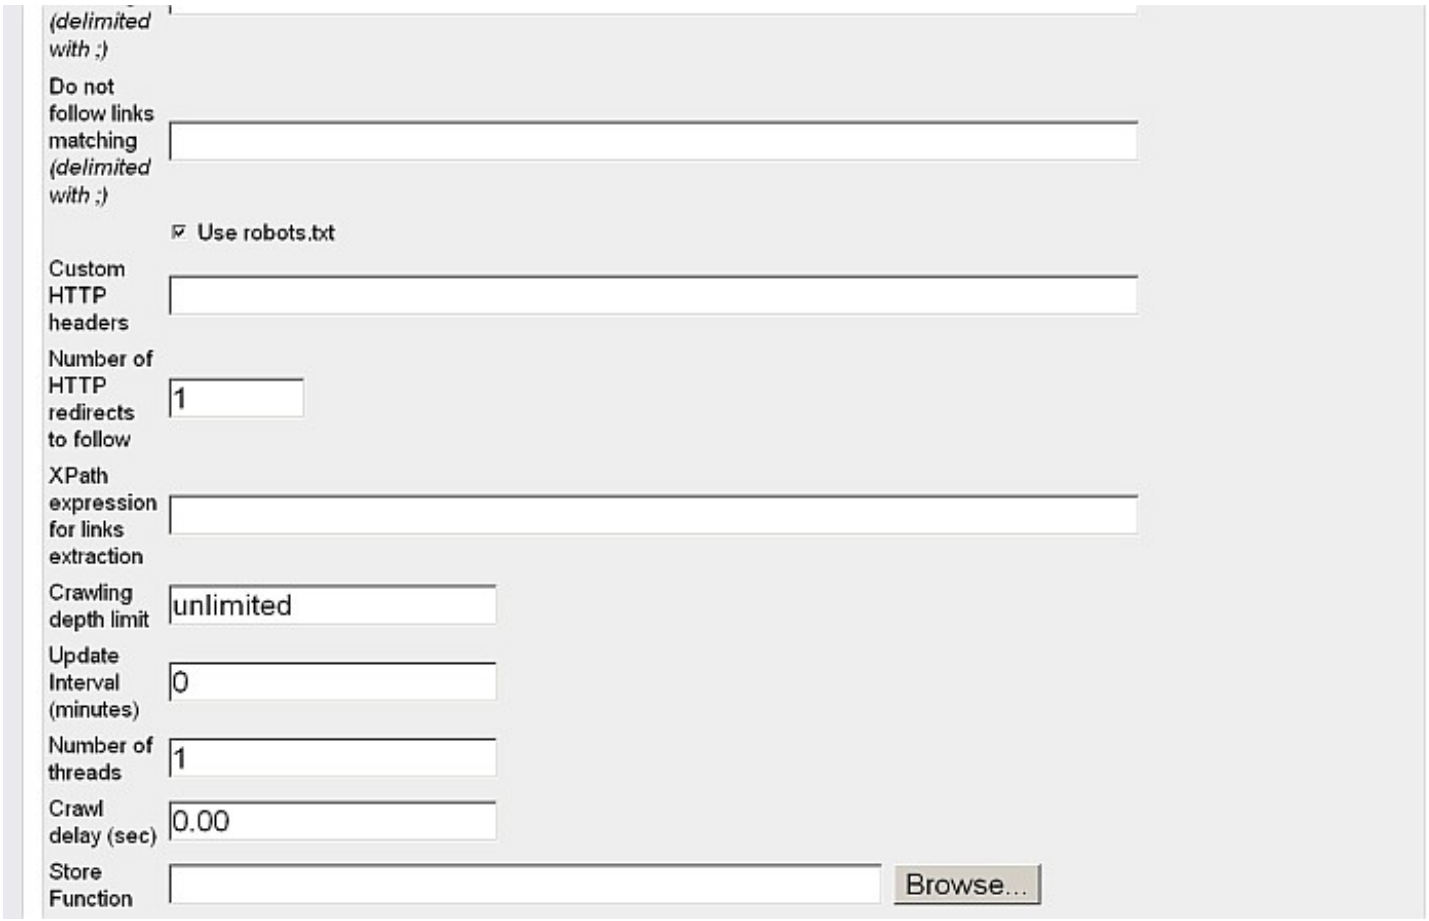

Figure 16.102. Conductor's content import configuration panel

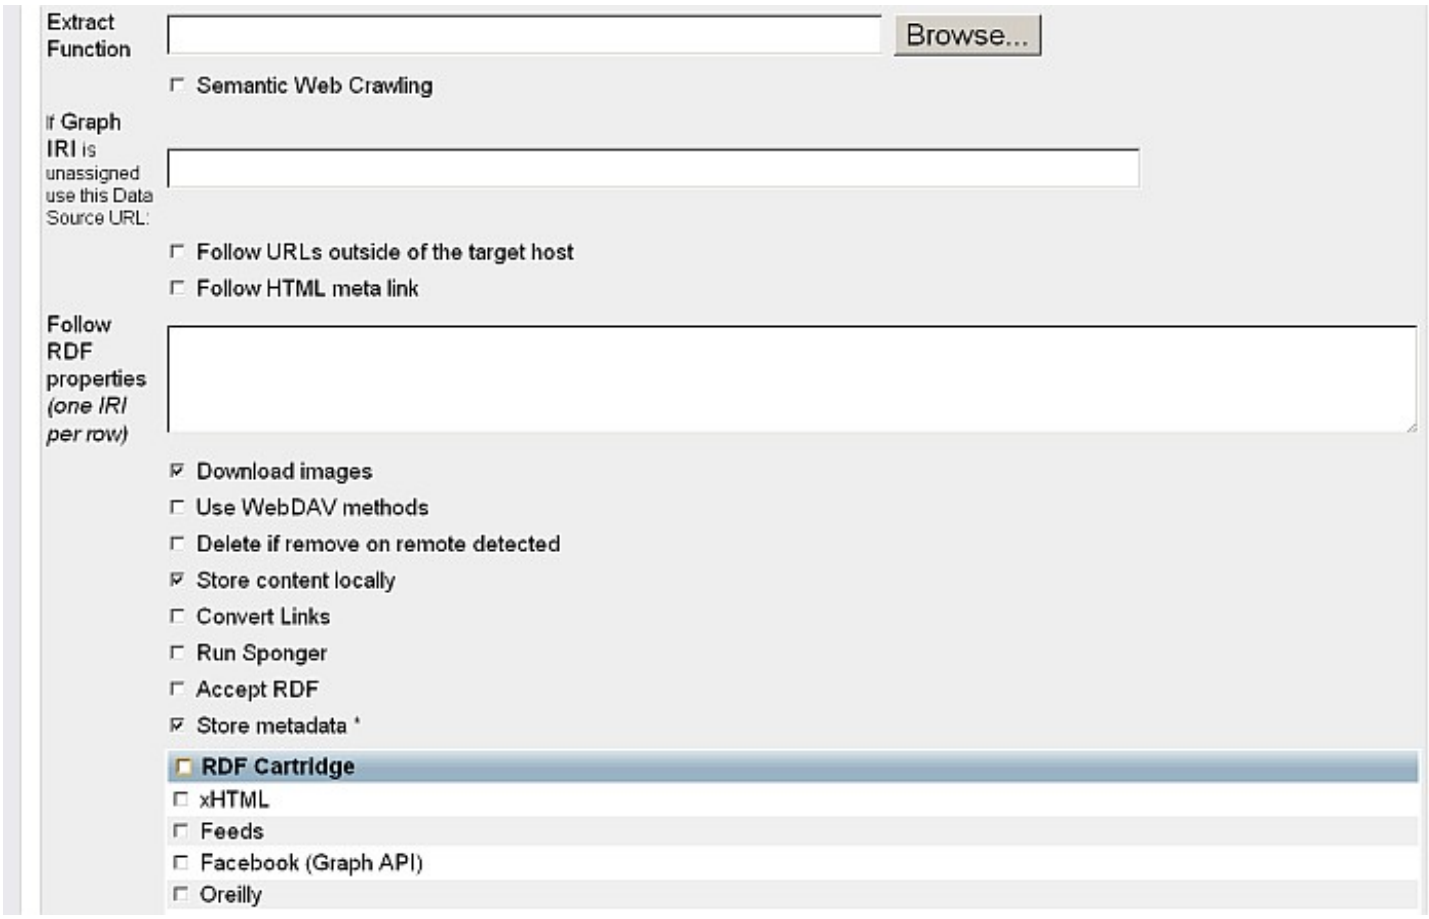

Figure 16.103. Conductor's content import configuration panel

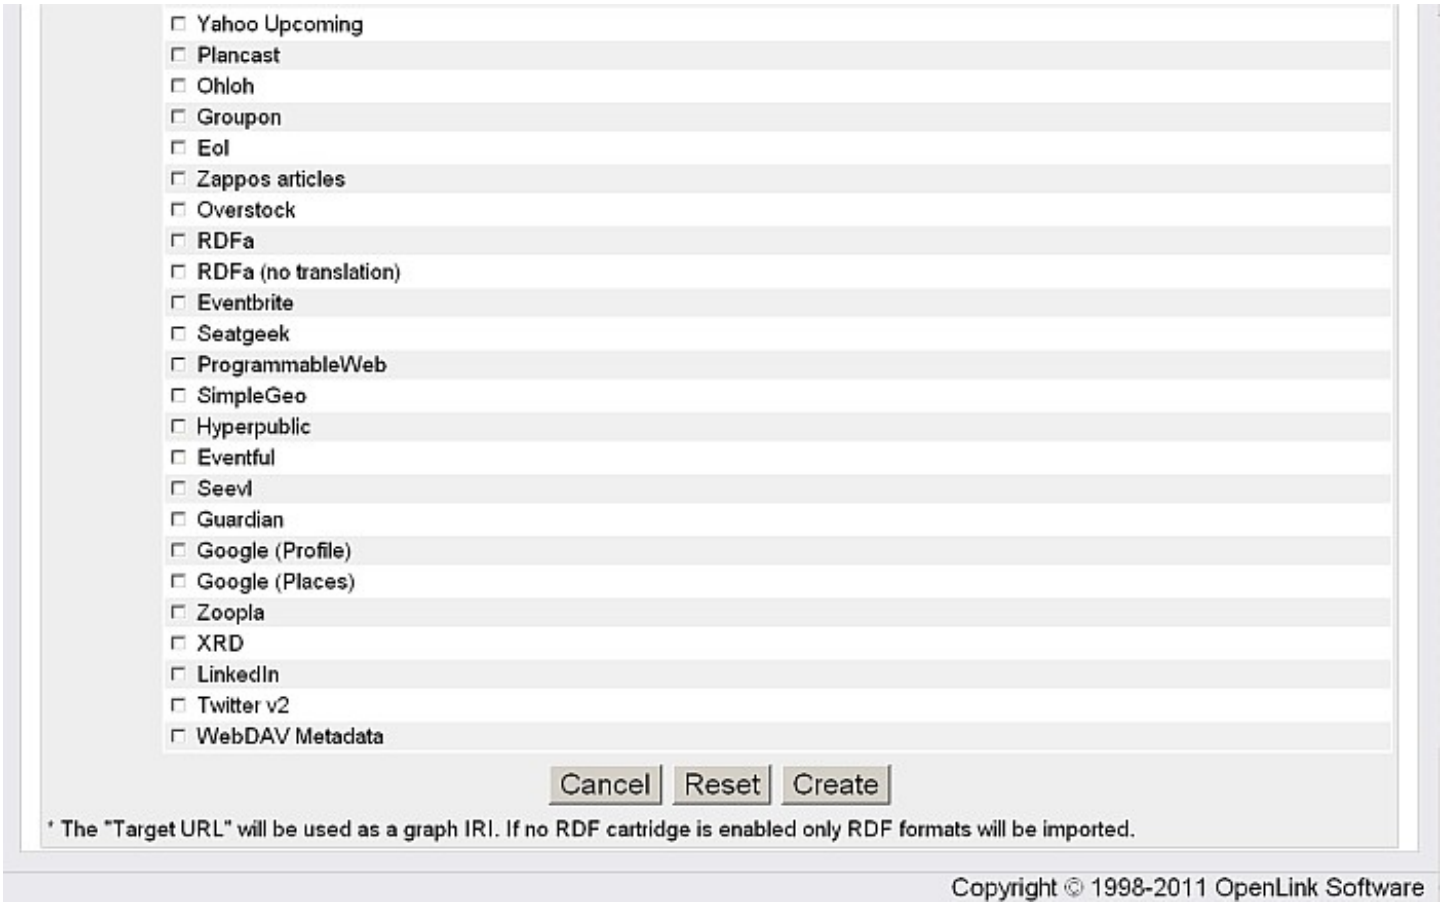

Directly via Virtuoso PL

Sponger cartridges are invoked through a cartridge hook which provides a Virtuoso PL entry point to the packaged functionality. Should you wish to utilize the Sponger from your own Virtuoso PL procedures, you can do so by calling these hook routines directly. Full details of the hook function prototype and how to define your own cartridges are presented here .

16.10.6. Consuming the Generated RDF Structured Data

The generated RDF-based structured data (RDF) can be consumed in a number of ways, depending on whether or not the data is persisted in Virtuoso's RDF Quad Store.

If the data is persisted, it can be queried through the Virtuoso SPARQL endpoint associated with any Virtuoso instance: /sparql. The RDF is exposed in a graph typically identified using a URL matching the source resource URL from which the RDF data was generated. Naturally, any SQL query can also access this, since SPARQL can be freely intermixed with SQL via Virtuoso's SPASQL (SPARQL inside SQL) functionality. RDF data is also accessible through Virtuoso's implementation of the URIQA protocol.

If not persisted, as is the case with the RDF Proxy Service, the data can be consumed by an RDF aware Web client, e.g. an RDF browser such as the OpenLink Data Explorer (ODE).

16.10.7. RDF Cartridges Use Cases

This section contains examples of Web resources which can be transformed by RDF Cartridges. It also states where additional setup for given cartridges is needed i.e. keys account names etc.

Service based:

- amazon

```
needs: api key
example: http://www.amazon.com/gp/product/0553383043
```

- ebay

```
needs: account, api-key

URN handlers

Table 16.11. URN handlers List

URN handler	Sample URI	Resource Description	Linked Data View	Linked Data Graph	Needs
LSID	urn:lsid:ubio.org:namebank:12292	HTML Representation	Linked Data View	Data Explorer View	none
DOI	doi:10.1038/35057062	HTML Representation	Linked Data View	Data Explorer View	Needs hslookup plugin, relevant html, pdf, xml etc. mappers enabled.
OAI	oai:dcmi.ischool.washington.edu:article/8	HTML Representation	Linked Data View	Data Explorer View	none

SPARQL IRI Dereferencing

The Virtuoso SPARQL engine (called for brevity just SPARQL below) supports IRI Dereferencing, however it understands only RDF data, that is it can retrieve only files containing RDF/XML, turtle or N3 serialized RDF data, if format is unknown it will try mapping with built-in WebDAV metadata extractor. In order to extend this feature with dereferencing web or file resources which naturally don't have RDF data (like PDF, JPEG files for example) is provided a special mechanism in SPARQL engine. This mechanism is called RDF mappers for translation of non-RDF data files to RDF.

In order to instruct the SPARQL to call a RDF mapper it needs to be registered and it will be called for a given URL or MIME type pattern. In other words, when unknown for SPARQL format is received during URL dereferencing process, it will look into a special registry (a table) to match either the MIME type or IRI using a regular expression, if match is found the mapper function will be called.

Sponger Proxy service

Sponger functionality is also exposed via Virtuoso's "/proxy/rdf/" endpoint, as an in-built REST style Web service available in any Virtuoso standard installation. This web service takes a target URL and either returns the content "as is" or tries to transform (by sponging) to RDF. Thus, the proxy service can be used as a 'pipe' for RDF browsers to browse non-RDF sources.

For more information see RDF Sponger Proxy service

Cache Invalidation

To clear cache on all values of HS_LOCAL_IRI of the SYS_HTTP_SPONGE table use:

```
SPARQL clear graph <A-Named-Graph>;
```

16.10.8. Cartridge Architecture

What is a Cartridge?

See full description here

Extractor Cartridges

An Extractor Cartridge processes a Resource of a given format, extracting RDF according to rules appropriate to that format. External data does not come into play; only the content of the Resource fed to the Sponger.

Supported Standard Non-RDF Data Formats

These Cartridges handle open formats - typically community-developed, openly-documented, and freely-licensed data structures.

Table 16.12.

Supported Vendor-specific Non-RDF Data Formats

These Cartridges handle closed formats - typically proprietary; sometimes undocumented; possibly licensed to no-one except the format originator. Sometimes data may not be parsed as desired or expected, as many of these Cartridges have required reverse-engineering of the data format in question.

Meta Cartridges

A Meta Cartridge submits a Resource to a third-party Web Service for processing. Returned RDF supplements the RDF generated by Extractor and other Meta Cartridges. Locally generated RDF may also be submitted to the third-party services, instead-of or in-addition-to the original Resource itself.

Default Sponger behavior is for all installed Meta Cartridges to be brought to bear on all submitted Resources:

Meta Cartridge Usage via REST Request

Description.vsp underlies the /about/html/ page, and accepts the parameters described below.

Table 16.15.

Parameter	Value	Description	Example
@Lookup@		The type of lookup	
	No Value	When value is not given (i.e., *@Lookup@=*), all will work as if the parameter were not present. %BR% The "Lookup" name is chosen to distinguish between parameters belonging to the URL being processed, and parameters for the Sponger.	Refresh the graph with all current cartridges, either type
	0	NLP meta only	Execute only NLP meta extraction
	-2	Keywords-based only	Execute only keywords-based meta extraction
	x,y...	A list of meta cartridges to be executed, by their unique IDs. The ID column can be found in *Conductor -> Linked Data -> Sponger -> Meta Cartridges*	Execute only CNET (ID=19) and NYT: The TimesTags (ID=22) meta cartridges
refresh=0,1,2 etc.		*Usage* : for cache invalidation. When used 1 or larger number (n), adds *get:refresh "N"* (explicit refresh interval in seconds) as a directive to Sponger. A refresh of zero ("0") seconds will make a new graph on the next lookup with the '*@Lookup@* ' parameter value.	Refresh the graph with all current cartridges
refresh=clean		*Usage* : for overwriting. The 'clean' usage explicitly clears the graph i.e. will cause the Sponger to drop cache even if it is marked to be in the fly. Thus, if network resource fetched cache by some reason is left in some inconsistent state like shutdown during the fetching, then 'clean' is required as it doesn't check cache state. *Note* : must be used with caution as other threads may be doing Network Resource Fetch at same time.	

Meta Cartridges Parametrized Examples

All examples in the table below start from the same Resource, http://www.news.com, and submit it to the Sponger for processing with the single listed Meta Cartridge.

It can be informative to start by seeing what the results would be with no Meta Cartridges at all .

If you have a lot of time to spare, you may want to see what the results would be with all Meta Cartridges combined . As may be obvious, this must wait for each of the above services to respond, so it may take quite some time to return.

16.10.9. Sponger Programmers Guide

The Sponger forms part of the extensible RDF framework built into Virtuoso Universal Server. A key component of the Sponger's pluggable architecture is its support for Sponger Cartridges, which themselves are comprised of an Entity Extractor and an Ontology Mapper. Virtuoso bundles numerous pre-written cartridges for RDF data extraction from a wide range of data sources. However, developers are free to develop their own custom cartridges. This programmer's guide describes how.

The guide is a companion to the Virtuoso Sponger whitepaper. The latter describes the Sponger in depth, its architecture, configuration, use and integration with other Virtuoso facilities such as the Open Data Services (ODS) application framework. This guide focuses solely on custom cartridge development.

Configuration of CURIEs used by the Sponger

For configuring CURIEs used by the Sponger which is exposed via Sponger clients such as "description.vsp" - the VSP based information resource description utility, you can use the `xml_set_ns_decl` function.

Here is sample example to add curie pattern:

```
-- Example link: http://linkeddata.uriburner.com/about/rdf/http://twitter.com/guykawasaki/status/11449455
XML_SET_NS_DECL ('uriburner',
                 'http://linkeddata.uriburner.com/about/rdf/http://',
                 2);
```

Cartridge Architecture

The Sponger is comprised of cartridges which are themselves comprised of an entity extractor and an ontology mapper. Entities extracted from non-RDF resources are used as the basis for generating structured data by mapping them to a suitable ontology. A cartridge is invoked through its cartridge hook, a Virtuoso/PL procedure entry point and binding to the cartridge's entity extractor and ontology mapper.

Entity Extractor

When an RDF aware client requests data from a network accessible resource via the Sponger the following events occur:

- A request is made for data in RDF form (explicitly via HTTP Accept Headers), and if RDF is returned nothing further happens.
- If RDF isn't returned, the Sponger passes the data through a

  Entity Extraction Pipeline

  (using Entity Extractors).
- The extracted data is transformed into RDF via a

  Mapping Pipeline

  . RDF instance data is generated by way of ontology matching and mapping.
- RDF instance data (aka. RDF Structured Linked Data) are returned to the client.

Extraction Pipeline

Depending on the file or format type detected at ingest, the Sponger applies the appropriate entity extractor. Detection occurs at the time of content negotiation instigated by the retrieval user agent. The normal extraction pipeline processing is as follows:

- The Sponger tries to get RDF data (including N3 or Turtle) directly from the dereferenced URL. If it finds some, it returns it, otherwise, it continues.
- If the URL refers to a HTML file, the Sponger tries to find "link" elements referring to RDF documents. If it finds one or more of them, it adds their triples into a temporary RDF graph and continues its processing.
- The Sponger then scans for microformats or GRDDL. If either is found, RDF triples are generated and added to a temporary RDF graph before continuing.
- If the Sponger finds eRDF or RDFa data in the HTML file, it extracts it from the HTML file and inserts it into the RDF graph before continuing.
- If the Sponger finds it is talking with a web service such as Google Base, it maps the API of the web service with an ontology, creates triples from that mapping and includes the triples into the temporary RDF graph.
- The next fallback is scanning of the HTML header for different Web 2.0 types or RSS 1.1, RSS 2.0, Atom, etc.
- Failing those tests, the scan then uses standard Web 1.0 rules to search in the header tags for metadata (typically Dublin Core) and transform them to RDF and again add them to the temporary graph. Other HTTP response header data may also be transformed to RDF.
- If nothing has been retrieved at this point, the ODS-Briefcase metadata extractor is tried.
- Finally, if nothing is found, the Sponger will return an empty graph.

Ontology Mapper

Sponger ontology mappers peform the the task of generating RDF instance data from extracted entities (non-RDF) using ontologies associated with a given data source type. They are typically XSLT (using GRDDL or an in-built Virtuoso mapping scheme) or Virtuoso/PL based. Virtuoso comes preconfigured with a large range of ontology mappers contained in one or more Sponger cartridges.

Cartridge Registry

To be recognized by the SPARQL engine, a Sponger cartridge must be registered in the Cartridge Registry by adding a record to the table DB.DBA.SYS_RDF_MAPPERS, either manually via DML, or more easily through Conductor, Virtuoso's browser-based administration console, which provides a UI for adding your own cartridges. (Sponger configuration using Conductor is described in detail later.) The SYS_RDF_MAPPERS table definition is as follows:

```
create table "DB"."DBA"."SYS_RDF_MAPPERS"
(
"RM_ID" INTEGER IDENTITY,  -- cartridge ID. Determines the order of the cartridge's invocation in the Spo
"RM_PATTERN" VARCHAR,  -- a REGEX pattern to match the resource URL or MIME type
"RM_TYPE" VARCHAR,  -- which property of the current resource to match: "MIME" or "URL"
"RM_HOOK" VARCHAR,  -- fully qualified Virtuoso/PL function name
"RM_KEY" LONG VARCHAR,  -- API specific key to use
"RM_DESCRIPTION" LONG VARCHAR,  -- cartridge description (free text)
"RM_ENABLED" INTEGER,  -- a 0 or 1 integer flag to exclude or include the cartridge from the Sponger proc
"RM_OPTIONS" ANY,  -- cartridge specific options
"RM_PID" INTEGER IDENTITY,
PRIMARY KEY ("RM_PATTERN", "RM_TYPE")
);
```

Cartridge Invocation

The Virtuoso SPARQL processor supports IRI dereferencing via the Sponger. If a SPARQL query references non-default graph URIs, the Sponger goes out (via HTTP) to Fetch the Network Resource data source URIs and inserts the extracted RDF data into the local RDF quad store. The Sponger invokes the appropriate cartridge for the data source type to produce RDF instance data. If none of the registered cartridges are capable of handling the received content type, the Sponger will attempt to obtain RDF instance data via the in-built WebDAV metadata extractor.

Sponger cartridges are invoked as follows:

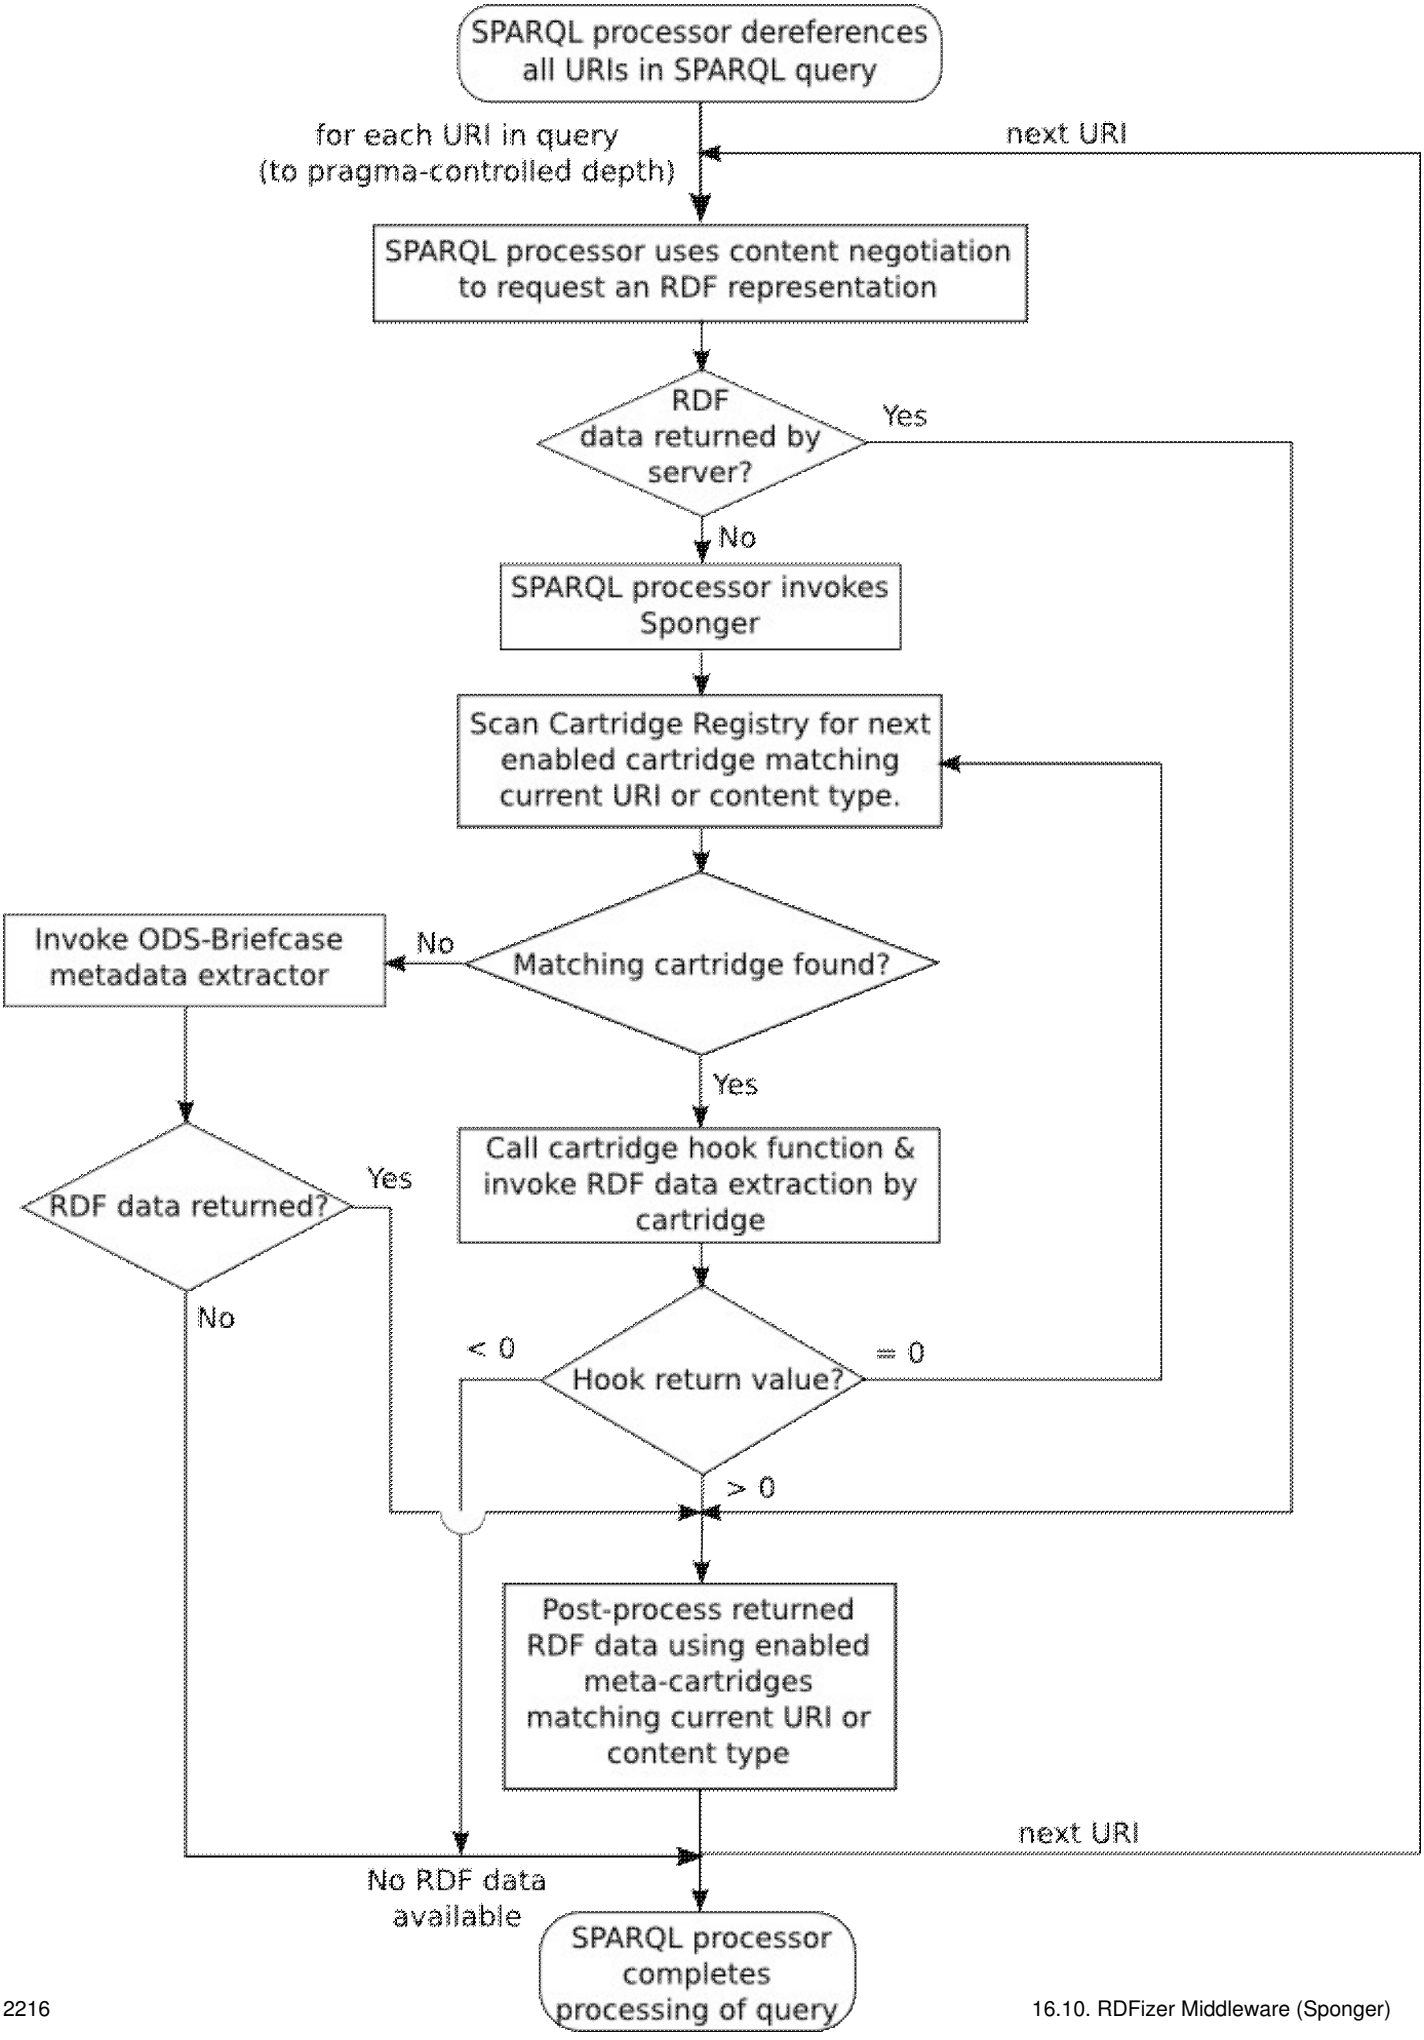
When the SPARQL processor dereferences a URI, it plays the role of an HTTP user agent (client) that makes a content type specific request to an HTTP server via the HTTP request's Accept headers. The following then occurs:

- If the content type returned is RDF then no further transformation is needed and the process stops. For instance, when consuming an (X)HTML document with a GRDDL profile, the profile URI points to a data provider that simply returns RDF instance data.
- If the content type is not RDF (i.e. application/rdf+xml or text/rdf+n3), for instance 'text/plain', the Sponger looks in the Cartridge Registry iterating over every record for which the RM_ENABLED flag is true, with the look-up sequence ordered on the RM_ID column values. For each record, the processor tries matching the content type or URL against the RM_PATTERN value and, if there is match, the function specified in RM_HOOK column is called. If the function doesn't exist, or signals an error, the SPARQL processor looks at next record.
    - If the hook returns zero, the next cartridge is tried. (A cartridge function can return zero if it believes a subsequent cartridge in the chain is capable of extracting more RDF data.)
    - If the result returned by the hook is negative, the Sponger is instructed that no RDF was generated and the process stops.
    - If the hook result is positive, the Sponger is informed that structured data was retrieved and the process stops.
- If none of the cartridges match the source data signature (content type or URL), the ODS-Briefcase WebDAV metadata extractor and RDF generator is called.

Meta-Cartridges

The above describes the RDF generation process for 'primary' Sponger cartridges. Virtuoso also supports another cartridge type - a 'meta-cartridge'. Meta-cartridges act as post-processors in the cartridge pipeline, augmenting entity descriptions in an RDF graph with additional information gleaned from 'lookup' data sources and web services. Meta-cartridges are described in more detail in a later section.

Figure 16.104. Meta-Cartridges



SPARQL processor dereferences all URIs in SPARQL query

No RDF data available
SPARQL processor completes processing of query

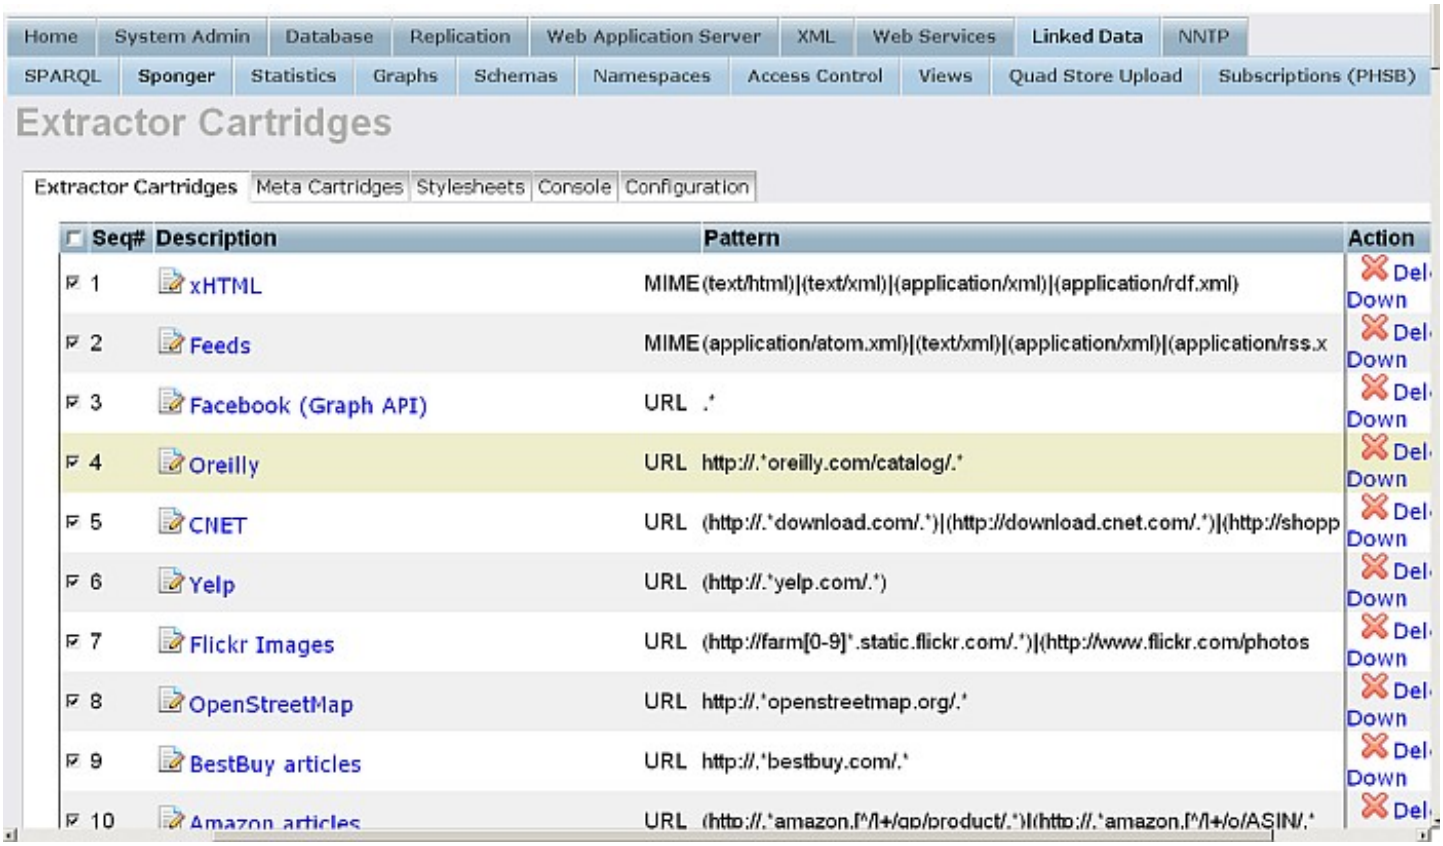
Cartridges Bundled with Virtuoso

Cartridges VAD

Virtuoso supplies a number of prewritten cartridges for extracting RDF data from a variety of popular Web resources and file types. The cartridges are bundled as part of the cartridges_dav VAD (Virtuoso Application Distribution).

To see which cartridges are available, look at the 'Linked Data' screen in Conductor. This can be reached through the Linked Data -> Sponger -> Extractor Cartridges and Meta Cartridges menu items.

Figure 16.105. RDF Cartridges



To check which version of the cartridges VAD is installed, or to upgrade it, refer to Conductor's 'VAD Packages' screen, reachable through the 'System Admin' > 'Packages' menu items.

The latest VADs for the closed source releases of Virtuoso can be downloaded from the downloads area on the OpenLink website. Select either the 'DBMS (WebDAV) Hosted' or 'File System Hosted' product format from the 'Distributed Collaborative Applications' section, depending on whether you want the Virtuoso application to use WebDAV or native filesystem storage. VADs for Virtuoso Open Source edition (VOS) are available for download from the VOS Wiki.

Example Source Code

For developers wanting example cartridge code, the most authoritative reference is the cartridges VAD source code itself. This is included as part of the VOS distribution. After downloading and unpacking the sources, the script used to create the cartridges, and the associated stylesheets can be found in:

- <vos root>/binsrc/rdf_mappers/rdf_mappers.sql
- <vos root>/binsrc/rdf_mappers/xslt/*.xsl

Alternatively, you can look at the actual cartridge implementations installed in your Virtuoso instance by inspecting the cartridge hook function used by a particular cartridge. This is easily identified from the 'Cartridge name' field of Conductor's 'RDF Cartridges' screen, after selecting the cartridge of interest. The hook function code can be viewed from the 'Schema Objects' screen under the 'Database' menu, by locating the function in the 'DB' > 'Procedures' folder. Stylesheets used by the cartridges are

installed in the WebDAV folder DAV/VAD/cartridges/xslt. This can be explored using Conductor's WebDAV interface. The actual rdf_mappers.sql file installed with your system can also be found in the DAV/VAD/cartridges folder.

Custom Cartridge

Virtuoso comes well supplied with a variety of Sponger cartridges and GRDDL filters. When then is it necessary to write your own cartridge?

In the main, writing a new cartridge should only be necessary to generate RDF from a REST-style Web service not supported by an existing cartridge, or to customize the output from an existing cartridge to your own requirements. Apart from these circumstances, the existing Sponger infrastructure should meet most of your needs. This is particularly the case for document resources.

Document Resources

We use the term document resource to identify content which is not being returned from a Web service. Normally it can broadly be conceived as some form of document, be it a text based entity or some form of file, for instance an image file.

In these cases, the document either contains RDF, which can be extracted directly, or it holds metadata in a supported format which can be transformed to RDF using an existing filter.

The following cases should all be covered by the existing Sponger cartridges:

- embedded or linked RDF
- RDFa, eRDF and other popular microformats extractable directly or via GRDDL
- popular syndication formats (RSS 2.0 , Atom, OPML , OCS , XBEL)

GRDDL

GRDDL (Gleaning Resource Descriptions from Dialects of Languages) is mechanism for deriving RDF data from XML documents and in particular XHTML pages. Document authors may associate transformation algorithms, typically expressed in XSLT, with their documents to transform embedded metadata into RDF.

The cartridges VAD installs a number of GRDDL filters for transforming popular microformats (such as RDFa, eRDF or hCalendar) into RDF. The available filters can be viewed, or configured, in Conductor's 'GRDDL Filters for XHTML' screen. Navigate to the 'RDF Cartridges' screen using the 'RDF' > 'RDF Cartridges' menu items, then SELECT the 'GRDDL Mappings' tab to display the 'GRDDL Filters for XHTML' screen. GRDDL filters are held in the WebDAV folder /DAV/VAD/rdf_cartridges/xslt/ alongside other XSLT templates. The Conductor interface allows you to add new GRDDL filters should you so wish.

For an introduction to GRDDL, try the GRDDL Primer . To underline GRDDL's utility, the primer includes an example of transforming Excel spreadsheet data, saved as XML, into RDF.

A comprehensive list of stylesheets for transforming HTML and non-HTML XML dialects is maintained on the ESW Wiki. The list covers a range of microformats, syndication formats and feedlists.

To see which Web Services are already catered for, view the list of cartridges in Conductor's 'RDF Cartridges' screen.

Creating Custom Cartridges

The Sponger is fully extensible by virtue of its pluggable cartridge architecture. New data formats can be fetched by creating new cartridges. While OpenLink is active in adding cartridges for new data sources, you are free to develop your own custom cartridges. Entity extractors can be built using Virtuoso PL, C/C++, Java or any other external language supported by Virtuoso's Server Extension API. Of course, Virtuoso's own entity extractors are written in Virtuoso PL.

The Anatomy of a Cartridge

Cartridge Hook Prototype

Every Virtuoso PL hook function used to plug a custom Sponger cartridge into the Virtuoso SPARQL engine must have a parameter list with the following parameters (the names of the parameters are not important, but their order and presence are):

- *in graph_iri varchar*

  : the IRI of the graph being retrieved/crawled
- *in new_origin_uri varchar*

  : the URL of the document being retrieved
- *in dest varchar*

  : the destination/target graph IRI
- *inout content any*

  : the content of the retrieved document
- *inout async_queue any*

  : if the PingService initialization parameter has been configured in the [SPARQL] section of the virtuoso.ini file, this is a pre-allocated asynchronous queue to be used to call the ping service
- *inout ping_service any*

  : the URL of a ping service, as assigned to the PingService parameter in the [SPARQL] section of the virtuoso.ini configuration file. PingTheSemanticWeb is an example of a such a service.
- *inout api_key any*

  : a string value specific to a given cartridge, contained in the RC_KEY column of the DB.DBA.SYS_RDF_CARTRIDGES table. The value can be a single string or a serialized array of strings providing cartridge specific data.
- *inout opts any*

  : cartridge specific options held in a Virtuoso/PL vector which acts as an array of key-value pairs.

Return Value

If the hook procedure returns zero the next cartridge will be tried. If the result is negative the sponging process stops, instructing the SPARQL engine that nothing was retrieved. If the result is positive the process stops, this time instructing the SPARQL engine that RDF data was successfully retrieved.

If your cartridge should need to test whether other cartridges are configured to handle a particular data source, the following extract taken from the RDF_LOAD_CALAIS hook procedure illustrates how you might do this:

```
if (xd is not null)
{
  -- Sponging successful. Load network resource data being fetched in the Virtuoso Quad Store:
  DB.DBA.RM_RDF_LOAD_RDFXML (xd, new_origin_uri, coalesce (dest, graph_iri));
  flag := 1;
}

declare ord any;
ord := (SELECT RM_ID FROM DB.DBA.SYS_RDF_MAPPERS WHERE
         RM_HOOK = 'DB.DBA.RDF_LOAD_CALAIS');
for SELECT RM_PATTERN FROM DB.DBA.SYS_RDF_MAPPERS WHERE
  RM_ID > ord and RM_TYPE = 'URL' and RM_ENABLED = 1 ORDER BY RM_ID do
{
  if (regexp_match (RM_PATTERN, new_origin_uri) is not null)
    -- try next candidate cartridge
    flag := 0;
}
return flag;
```

Specifying the Target Graph

Two cartridge hook function parameters contain graph IRIs, graph_iri and dest. graph_iri identifies an input graph being crawled. dest holds the IRI specified in any input:grab-destination pragma defined to control the SPARQL processor's IRI dereferencing. The pragma overrides the default behaviour and forces all retrieved triples to be stored in a single graph, irrespective of their graph of origin.

So, under some circumstances depending on how the Sponger has been invoked and whether it is being used to crawl an existing RDF graph, or derive RDF data from a non-RDF data source, dest may be null.

Consequently, when loading network resource being fetched as RDF data into the quad store, cartridges typically specify the graph to receive the data using the coalesce function which returns the first non-null parameter. e.g.

```
DB.DBA.RDF_LOAD_RDFXML (xd, new_origin_uri, coalesce (dest, graph_iri));
```

Here xd is an RDF/XML string holding the fetched RDF.

Specifying & Retrieving Cartridge Specific Options

The hook function prototype allows cartridge specific data to be passed to a cartridge through the RM_OPTIONS parameter, a Virtuoso/PL vector which acts as a heterogeneous array.

In the following example, two options are passed, 'add-html-meta' and 'get-feeds' with both values set to 'no'.

```
insert soft DB.DBA.SYS_RDF_MAPPERS (
  RM_PATTERN, RM_TYPE, RM_HOOK, RM_KEY, RM_DESCRIPTION, RM_OPTIONS
)
values (
  '(text/html)|(text/xml)|(application/xml)|(application/rdf.xml)',
  'MIME', 'DB.DBA.RDF_LOAD_HTML_RESPONSE', null, 'xHTML',
  vector ('add-html-meta', 'no', 'get-feeds', 'no')
);
```

The RM_OPTIONS vector can be handled as an array of key-value pairs using the get_keyword function. get_keyword performs a case sensitive search for the given keyword at every even index of the given array. It returns the element following the keyword, i.e. the keyword value.

Using get_keyword, any options passed to the cartridge can be retrieved using an approach similar to that below:

```
create procedure DB.DBA.RDF_LOAD_HTML_RESPONSE (
  in graph_iri varchar, in new_origin_uri varchar, in dest varchar,
  inout ret_body any, inout aq any, inout ps any, inout _key any,
  inout opts any )
{
  declare get_feeds, add_html_meta;
  ...
  get_feeds := add_html_meta := 0;
  if (isarray (opts) and 0 = mod (length(opts), 2))
  {
    if (get_keyword ('get-feeds', opts) = 'yes')
      get_feeds := 1;
    if (get_keyword ('add-html-meta', opts) = 'yes')
      add_html_meta := 1;
  }
  ...
```

XSLT - The Fulchrum

XSLT is the fulchrum of all OpenLink supplied cartridges. It provides the most convenient means of converting structured data extracted from web content by a cartridge's Entity Extractor into RDF.

Virtuoso's XML Infrastructure & Tools

Virtuoso's XML support and XSLT support are covered in detail in the on-line documentation. Virtuoso includes a highly capable XML parser and supports XPath, XQuery, XSLT and XML Schema validation.

Virtuoso supports extraction of XML documents from SQL datasets. A SQL long varchar, long xml or xmltype column in a database table can contain XML data as text or in a binary serialized format. A string representing a well-formed XML entity can be converted into an entity object representing the root node.

While Sponger cartridges will not normally concern themselves with handling XML extracted from SQL data, the ability to convert a string into an in-memory XML document is used extensively. The function xtree_doc(string) converts a string into such

a document and returns a reference to the document's root. This document together with an appropriate stylesheet forms the input for the transformation of the extracted entities to RDF using XSLT. The input string to xtree_doc generally contains structured content derived from a web service.

Virtuoso XSLT Support

Virtuoso implements XSLT 1.0 transformations as SQL callable functions. The xslt() Virtuoso/PL function applies a given stylesheet to a given source XML document and returns the transformed document. Virtuoso provides a way to extend the abilities of the XSLT processor by creating user defined XPath functions. The functions xpf_extension() and xpf_extension_remove() allow addition and removal of XPath extension functions.

General Cartridge Pipeline

The broad pipeline outlined here reflects the steps common to most cartridges:

- Redirect from the requested URL to a Web service which returns XML
- Stream the content into an in-memory XML document
- Convert it to the required RDF/XML, expressed in the chosen ontology, using XSLT
- Encode the RDF/XML as UTF-8
- Load the RDF/XML into the quad store

The MusicBrainz cartridge typifies this approach. MusicBrainz is a community music metadatabase which captures information about artists, their recorded works, and the relationships between them. Artists always have a unique ID, so the URL http://musicbrainz.org/artist/4d5447d7-c61c-4120-ba1b-d7f471d385b9.html takes you directly to entries for John Lennon.

If you were to look at this page in your browser, you would see that the information about the artist contains no RDF data. However, the cartridge is configured to intercept requests to URLs of the form http://musicbrainz.org/([^/]*)/([^.]*) and redirect to the cartridge to Fetch all the available information on the given artist, release, track or label.

The cartridge extracts entities by redirecting to the MusicBrainz XML Web Service using as the basis for the initial query the item ID, e.g. an artist or label ID, extracted from the original URL. Stripped to its essentials, the core of the cartridge is:

```
webservice_uri := sprintf ('http://musicbrainz.org/ws/1/%s/%s?type=xml&inc=%U',
                                    kind, id, inc);
content := RDF_HTTP_URL_GET (webservice_uri, '', hdr, 'GET', 'Accept: */*');
xt := xtree_doc (content);
...
xd := DB.DBA.RDF_MAPPER_XSLT (registry_get ('_cartridges_path_') || 'xslt/mbz2rdf.xsl', xt);
...
xd := serialize_to_UTF8_xml (xd);
DB.DBA.RM_RDF_LOAD_RDFXML (xd, new_origin_uri, coalesce (dest, graph_iri));
```

In the above outline, RDF_HTTP_URL_GET sends a query to the MusicBrainz web service, using query parameters appropriate for the original request, and retrieves the response using Network Resource Fetch.

The returned XML is parsed into an in-memory parse tree by xtree_doc. Virtuoso/PL function RDF_MAPPER_XSLT is a simple wrapper around the function xslt which sets the current user to dba before returning an XML document transformed by an XSLT stylesheet, in this case mbz2rdf.xsl. Function serialize_to_UTF8_xml changes the character set of the in-memory XML document to UTF8. Finally, RM_RDF_LOAD_RDFXML is a wrapper around RDF_LOAD_RDFXML which parses the content of an RDF/XML string into a sequence of RDF triples and loads them into the quad store. XSLT stylesheets are usually held in the DAV/VAD/cartridges/xslt folder of Virtuoso's WebDAV store. registry_get('cartridges_path') returns the Cartridges VAD path, 'DAV/VAD/cartridges', from the Virtuoso registry.

Error Handling with Exit Handlers

Virtuoso condition handlers determine the behaviour of a Virtuoso/PL procedure when a condition occurs. You can declare one or more condition handlers in a Virtuoso/PL procedure for general SQL conditions or specific SQLSTATE values. If a statement in your procedure raises an SQLEXCEPTION condition and you declared a handler for the specific SQLSTATE or SQLEXCEPTION condition the server passes control to that handler. If a statement in your Virtuoso/PL procedure raises an SQLEXCEPTION condition, and you have not declared a handler for the specific SQLSTATE or the SQLEXCEPTION condition, the server passes the exception to the calling procedure (if any). If the procedure call is at the top-level, then the exception is signaled to the calling client.

A number of different condition handler types can be declared (see the Virtuoso reference documentation for more details.) Of these, exit handlers are probably all you will need. An example is shown below which handles any SQLSTATE. Commented out is a debug statement which outputs the message describing the SQLSTATE.

```
create procedure DB.DBA.RDF_LOAD_SOCIALGRAPH (in graph_iri varchar, ...)
{
  declare qr, path, hdr any;
  ...
  declare exit handler for sqlstate '*'
  {
    -- dbg_printf ('%s', __SQL_MESSAGE);
    return 0;
  };
  ...
  -- data extraction and mapping successful
  return 1;
}
```

Exit handlers are used extensively in the Virtuoso supplied cartridges. They are useful for ensuring graceful failure when trying to convert content which may not conform to your expectations. The RDF_LOAD_FEED_SIOC procedure (which is used internally by several cartridges) shown below uses this approach:

```
-- /* convert the feed in rss 1.0 format to sioc */
create procedure DB.DBA.RDF_LOAD_FEED_SIOC (in content any, in iri varchar, in graph_iri varchar, in is_d
{
  declare xt, xd any;
  declare exit handler for sqlstate '*'
    {
      goto no_sioc;
    };
  xt := xtree_doc (content);
  xd := DB.DBA.RDF_MAPPER_XSLT (
      registry_get ('_cartridges_path_') || 'xslt/feed2sioc.xsl', xt,
      vector ('base', graph_iri, 'isDiscussion', is_disc));
  xd := serialize_to_UTF8_xml (xd);
  DB.DBA.RM_RDF_LOAD_RDFXML (xd, iri, graph_iri);
  return 1;
no_sioc:
  return 0;
}
```

Loading RDF into the Quad Store

RDF_LOAD_RDFXML & TTLP

The two main Virtuoso/PL functions used by the cartridges for loading RDF data into the Virtuoso quad store are DB.DBA.TTLP and DB.DBA.RDF_LOAD_RDFXML. Multithreaded versions of these functions, DB.DBA.TTLP_MT and DB.DBA.RDF_LOAD_RDFXML_MT, are also available.

RDF_LOAD_RDFXML parses the content of an RDF/XML string as a sequence of RDF triples and loads then into the quad store. TTLP parses TTL (Turtle or N3) and places its triples into quad storage. Ordinarily, cartridges use RDF_LOAD_RDFXML. However there may be occasions where you want to insert statements written as TTL, rather than RDF/XML, in which case you should use TTLP.

See Also:

- Loading RDF using API functions

Attribution

Many of the OpenLink supplied cartridges actually use RM_RDF_LOAD_RDFXML to load data into the quad store. This is a thin wrapper around RDF_LOAD_RDFXML which includes in the generated graph an indication of the external ontologies being used. The attribution takes the form:

```
<ontologyURI> a opl:DataSource .
<spongedResourceURI> rdfs:isDefinedBy <ontologyURI> .
```

```
<ontologyURI> opl:hasNamespacePrefix "<ontologyPrefix>" .
```

where prefix opl: denotes the ontology http://www.openlinksw.com/schema/attribution#.

Deleting Existing Graphs

Before loading network resource fetched RDF data into a graph, you may want to delete any existing graph with the same URI. To do so, select the 'RDF' > 'List of Graphs' menu commands in Conductor, then use the 'Delete' command for the appropriate graph. Alternatively, you can use one of the following SQL commands:

```
SPARQL CLEAR GRAPH
-- or
DELETE FROM DB.DBA.RDF_QUAD WHERE G = DB.DBA.RDF_MAKE_IID_OF_QNAME (graph_iri)
```

Proxy Service Data Expiration

When the Proxy Service is invoked by a user agent, the Sponger records the expiry date of the imported data in the table DB.DBA.SYS_HTTP_SPONGE. The data invalidation rules conform to those of traditional HTTP clients (Web browsers). The data expiration time is determined based on subsequent data fetches of the same resource. The first data retrieval records the 'expires' header. On subsequent fetches, the current time is compared to the expiration time stored in the local cache. If HTTP 'expires' header data isn't returned by the source data server, the Sponger will derive its own expiration time by evaluating the 'date' header and 'last-modified' HTTP headers.

Ontology Mapping

After extracting entities from a web resource and converting them to an in-memory XML document, the entities must be transformed to the target ontology using XSLT and an appropriate stylesheet. A typical call sequence would be:

```
xt := xtree_doc (content);
...
xd := DB.DBA.RDF_MAPPER_XSLT (registry_get ('_cartridges_path_') || 'xslt/mbz2rdf.xsl', xt);
```

Because of the wide variation in the data mapped by cartridges, it is not possible to present a typical XSL stylesheet outline. The Examples section presented later includes detailed extracts from the MusicBrainz? cartridge's stylesheet which provide a good example of how to map to an ontology. Rather than attempting to be an XSLT tutorial, the material which follows offers some general guidelines.

Passing Parameters to the XSLT Processor

Virtuoso's XSLT processor will accept default values for global parameters from the optional third argument of the xslt() function. This argument, if specified, must be a vector of parameter names and values of the form vector(name1, value1,... nameN, valueN), where name1 ... nameN must be of type varchar, and value1 ... valueN may be of any Virtuoso datatype, but may not be null.

This extract from the Crunchbase cartridge shows how parameters may be passed to the XSLT processor. The function RDF_MAPPER_XSLT (in xslt varchar, inout xt any, in params any := null) passes the parameters vector directly to xslt().

```
xt := DB.DBA.RDF_MAPPER_XSLT (
registry_get ('_cartridges_path_') || 'xslt/crunchbase2rdf.xsl', xt,
vector ('baseUri', coalesce (dest, graph_iri), 'base', base, 'suffix', suffix)
);
```

The corresponding stylesheet crunchbase2rdf.xsl retrieves the parameters baseUri, base and suffix as follows:

```
...
<xsl:output method="xml" indent="yes" />
  <xsl:variable name="ns">http://www.crunchbase.com/</xsl:variable>
  <xsl:param name="baseUri" />
  <xsl:param name="base"/>
  <xsl:param name="suffix"/>

  <xsl:template name="space-name">
...
```

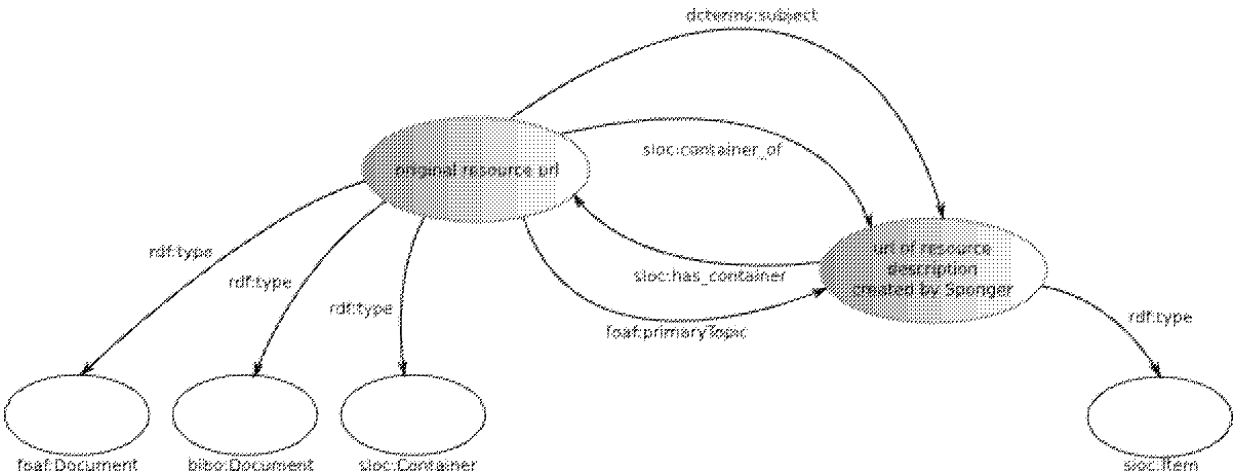
An RDF Description Template

Defining A Generic Resource Description Wrapper

Many of the OpenLink cartridges create a resource description formed to a common "wrapper" template which describes the relationship between the (usually) non-RDF source network resource being fetched and the RDF description generated by the Sponger. The wrapper is appropriate for resources which can broadly be conceived as documents. It provides a generic minimal description of the source document, but also links to the much more detailed description provided by the Sponger. So, instead of just emitting a resource description, the Sponger factors the container into the generated graph constituting the RDF description.

The template is depicted below:

Figure 16.106. Template



To generate an RDF description corresponding to the wrapper template, a stylesheet containing the following block of instructions is used. This extract is taken from the eBay cartridge's stylesheet, ebay2rdf.xsl. Many of the OpenLink cartridges follow a similar pattern.

```
  <xsl:param name="baseUri"/>
  ...
  <xsl:variable name="resourceURL">
      <xsl:value-of select="$baseUri"/>
  </xsl:variable>
  ...

<xsl:template match="/">
      <rdf:RDF>
          <rdf:Description rdf:about="{$resourceURL}">
              <rdf:type rdf:resource="Document"/>
              <rdf:type rdf:resource="Document"/>
              <rdf:type rdf:resource="Container"/>
              <sioc:container_of rdf:resource="{vi:proxyIRI ($resourceURL)}"/>
              <foaf:primaryTopic rdf:resource="{vi:proxyIRI ($resourceURL)}"/>
              <dcterms:subject rdf:resource="{vi:proxyIRI ($resourceURL)}"/>
          </rdf:Description>
          <rdf:Description rdf:about="{vi:proxyIRI ($resourceURL)}">
              <rdf:type rdf:resource="Item"/>
              <sioc:has_container rdf:resource="{$resourceURL}"/>
              <xsl:apply-templates/>
          </rdf:Description>
      </rdf:RDF>
  </xsl:template>
  ...
```

Using SIOC as a Generic Container Model

The generic resource description wrapper just described uses SIOC to establish the container/contained relationship between the source resource and the generated graph. Although the most important classes for the generic wrapper are obviously Container and Item, SIOC provides a generic data model of containers, items, item types, and associations between items which can be combined with other vocabularies such as FOAF and Dublin Core.

SIOC defines a number of other classes, such as User, UserGroup, Role, Site, Forum and Post. A separate SIOC types module (T-SIOC) extends the SIOC Core ontology by defining subclasses and subproperties of SIOC terms. Subclasses include: AddressBook, BookmarkFolder, Briefcase, EventCalendar, ImageGallery, Wiki, Weblog, BlogPost, Wiki plus many others.

OpenLink Data Spaces (ODS) uses SIOC extensively as a data space "glue" ontology to describe the base data and containment hierarchy of all the items managed by ODS applications (Data Spaces). For example, ODS-Weblog is an application of type sioc:Forum. Each ODS-Weblog application instance contains blogs of type sioct:Weblog. Each blog is a sioc:container_of posts of type sioc:Post.

Generally, when deciding how to describe resources handled by your own custom cartridge, SIOC provides a useful framework for the description which complements the SIOC-based container model adopted throughout the ODS framework.

Naming Conventions for Sponger Generated Descriptions

As can be seen from the stylesheet extract just shown, the URI of the resource description generated by the Sponger to describe the network resource being fetched, is given by the function {vi:proxyIRI ($resourceURL)} where resourceURL is the URL of the original network resource being fetched. proxyIRI is an XPath extension function defined in rdf_mappers.sql as

```
xpf_extension ('http://www.openlinksw.com/virtuoso/xslt/:proxyIRI', 'DB.DBA.RDF_SPONGE_PROXY_IRI');
```

which maps to the Virtuoso/PL procedure DB.DBA.RDF_SPONGE_PROXY_IRI. This procedure in turn generates a resource description URI which typically takes the form: http://<hostName:port>/about/html/http/<resourceURL>#this

Registering & Configuring Cartridges

Once you have developed a cartridge, you must register it in the Cartridge Registry to have the SPARQL processor recognize and use it. You should have compiled your cartridge hook function first by issuing a "create procedure DB.DBA.RDF_LOAD_xxx ..." command through one of Virtuoso's SQL interfaces. You can create the required Cartridge Registry entry either by adding a row to the SYS_REF_MAPPERS table directly using SQL, or by using the Conductor UI.

Using SQLs

If you choose register your cartridge using SQL, possibly as part of a Virtuoso/PL script, the required SQL will typically mirror one of the following INSERT commands.

Below, a cartridge for OpenCalais is being installed which will be tried when the MIME type of the network resource data being fetched is one of text/plain, text/xml or text/html. (The definition of the SYS_RDF_MAPPERS table was introduced earlier in section 'Cartridge Registry'.)

```
insert soft DB.DBA.SYS_RDF_MAPPERS (
  RM_PATTERN, RM_TYPE, RM_HOOK, RM_KEY, RM_DESCRIPTION, RM_ENABLED)
values (
  '(text/plain)|(text/xml)|(text/html)', 'MIME', 'DB.DBA.RDF_LOAD_CALAIS',
  null, 'Opencalais', 1);
```

As an alternative to matching on the content's MIME type, candidate cartridges to be tried in the conversion pipeline can be identified by matching the data source URL against a URL pattern stored in the cartridge's entry in the Cartridge Registry.

```
insert soft DB.DBA.SYS_RDF_MAPPERS (
  RM_PATTERN, RM_TYPE, RM_HOOK, RM_KEY, RM_DESCRIPTION, RM_OPTIONS)
values (
  '(http://api.crunchbase.com/v/1/.*)|(http://www.crunchbase.com/.*)', 'URL',
  'DB.DBA.RDF_LOAD_CRUNCHBASE', null, 'CrunchBase', null);
```

The value of RM_ID to set depends on where in the cartridge invocation order you want to position a particular cartridge. RM_ID should be set lower than 10028 to ensure the cartridge is tried before the ODS-Briefcase (WebDAV) metadata extractor, which is always the last mapper to be tried if no preceding cartridge has been successful.

```
UPDATE DB.DBA.SYS_RDF_MAPPERS
SET RM_ID = 1000
WHERE RM_HOOK = 'DB.DBA.RDF_LOAD_BIN_DOCUMENT';
```

Using Conductor

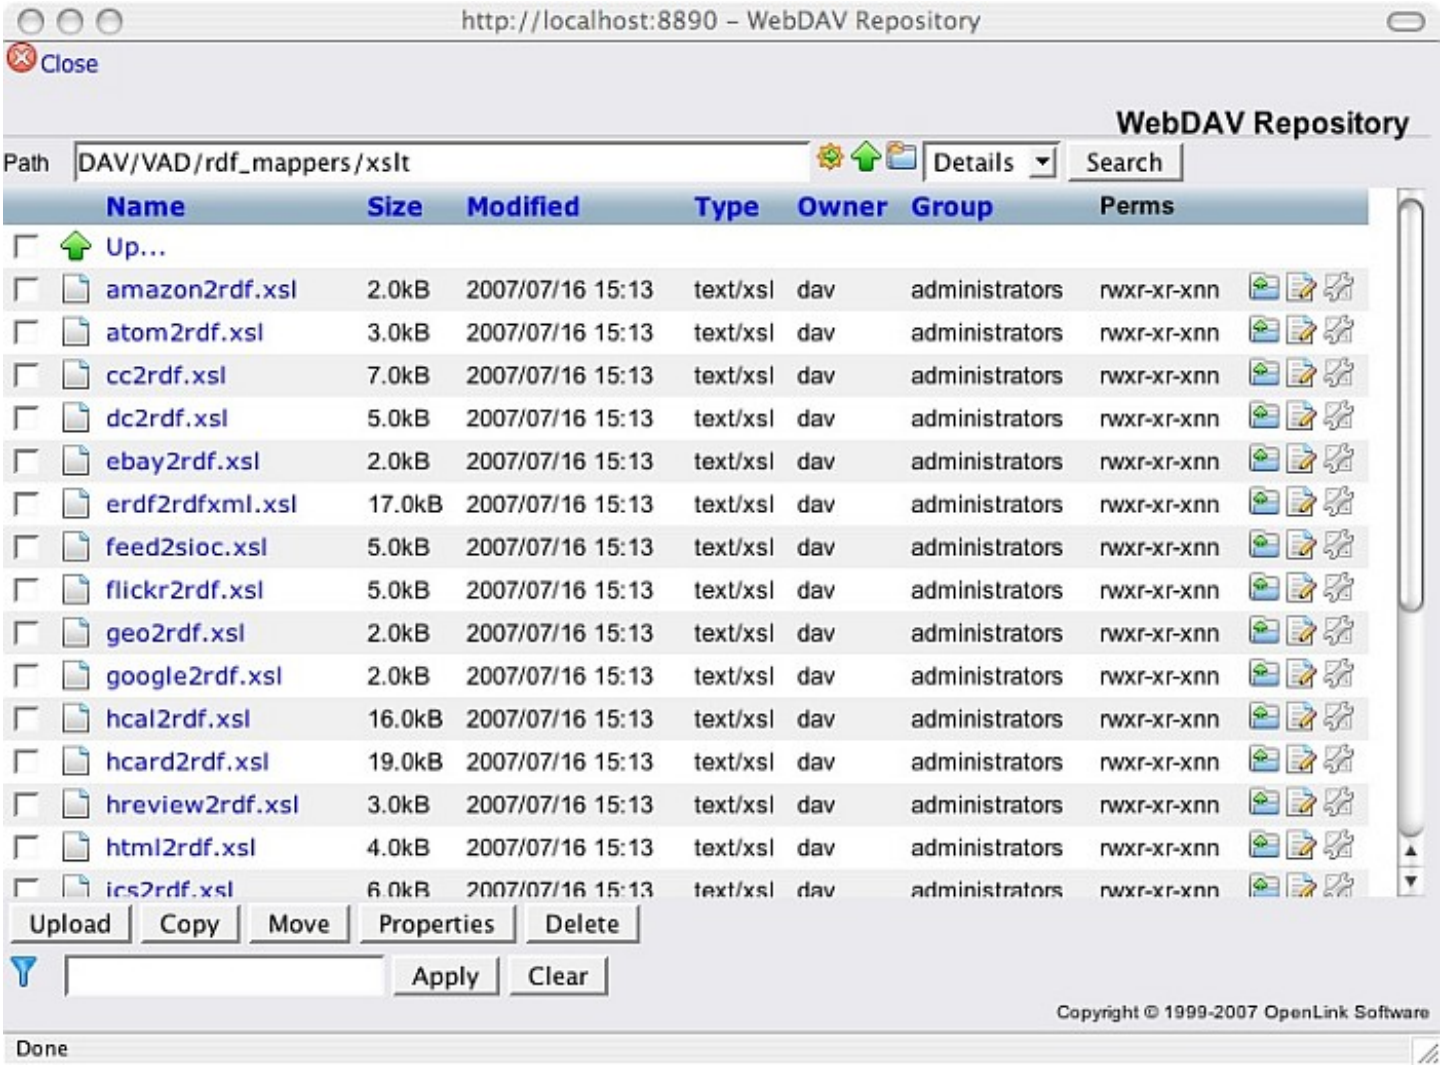
Cartridges can be added manually using the 'Add' panel of the 'RDF Cartridges' screen.

Figure 16.107. RDF Cartridges

Installing Stylesheets

Although you could place your cartridge stylesheet in any folder configured to be accessible by Virtuoso, the simplest option is to upload them to the DAV/VAD/cartridges/xslt folder using the WebDAV browser accessible from the Conductor UI.

Figure 16.108. WebDAV browser



Should you wish to locate your stylesheets elsewhere, ensure that the DirsAllowed setting in the virtuoso.ini file is configured appropriately.

Setting API Key

Some Cartridges require and API account and/or API Key to be provided for accessing the required service. This can be done from the Linked Data -> Sponger tab of the Conductor by selecting the cartridge from the list provided, entering the API Account and API Key in the dialog at the bottom of the page and click update to save, as indicated in the screenshot below:

Figure 16.109. Registering API Key

For example, for the service Flickr developers must register to obtain a key. See http://developer.yahoo.com/flickr/. In order to cater for services which require an application key, the Cartridge Registry SYS_RDF_MAPPERS table includes an RM_KEY column to store any key required for a particular service. This value is passed to the service's cartridge through the _key parameter of the cartridge hook function.

Alternatively a cartridge can store a key value in the virtuoso.ini configuration file and retrieve it in the hook function.

Flickr Cartridge

This example shows an extract from the Flickr cartridge hook function DB.DBA.RDF_LOAD_FLICKR_IMG and the use of an API key. Also, commented out, is a call to cfg_item_value() which illustrates how the API key could instead be stored and retrieved from the SPARQL section of the virtuoso.ini file.

```
create procedure DB.DBA.RDF_LOAD_FLICKR_IMG (
in graph_iri varchar, in new_origin_uri varchar, in dest varchar,
inout _ret_body any, inout aq any, inout ps any, inout _key any,
inout opts any )
{
declare xd, xt, url, tmp, api_key, img_id, hdr, exif any;
declare exit handler for sqlstate '*'
{
 return 0;
};
tmp := sprintf_inverse (new_origin_uri,
  'http://farm%s.static.flickr.com/%s/%s_%s.%s', 0);
img_id := tmp[2];
api_key := _key;
--cfg_item_value (virtuoso_ini_path (), 'SPARQL', 'FlickrAPIkey');
if (tmp is null or length (tmp) <> 5 or not isstring (api_key))
  return 0;
url :=  sprintf('http://api.flickr.com/services/rest/?method=flickr.photos.getInfo&photo_id=%s&api_key=%s
tmp := http_get (url, hdr);
```

MusicBrainz Example: A Music Metadatabase

To illustrate some of the material presented so far, we'll delve deeper into the MusicBrainz cartridge mentioned earlier.

MusicBrainz XML Web Service

The cartridge extracts data through the MusicBrainz XML Web Service using, as the basis for the initial query, an item type and MBID (MusicBrainz ID) extracted from the original URI submitted to the RDF proxy. A range of item types are supported including artist, release and track.

Using the album "Imagine" by John Lennon as an example, a standard HTML description of the album (which has an MBID of f237e6a0-4b0e-4722-8172-66f4930198bc) can be retrieved direct from MusicBrainz using the URL:

```
http://musicbrainz.org/release/f237e6a0-4b0e-4722-8172-66f4930198bc.html
```

Alternatively, information can be extracted in XML form through the web service. A description of the tracks on the album can be obtained with the query:

```
http://musicbrainz.org/ws/1/release/f237e6a0-4b0e-4722-8172-66f4930198bc?type=xml&inc=tracks
```

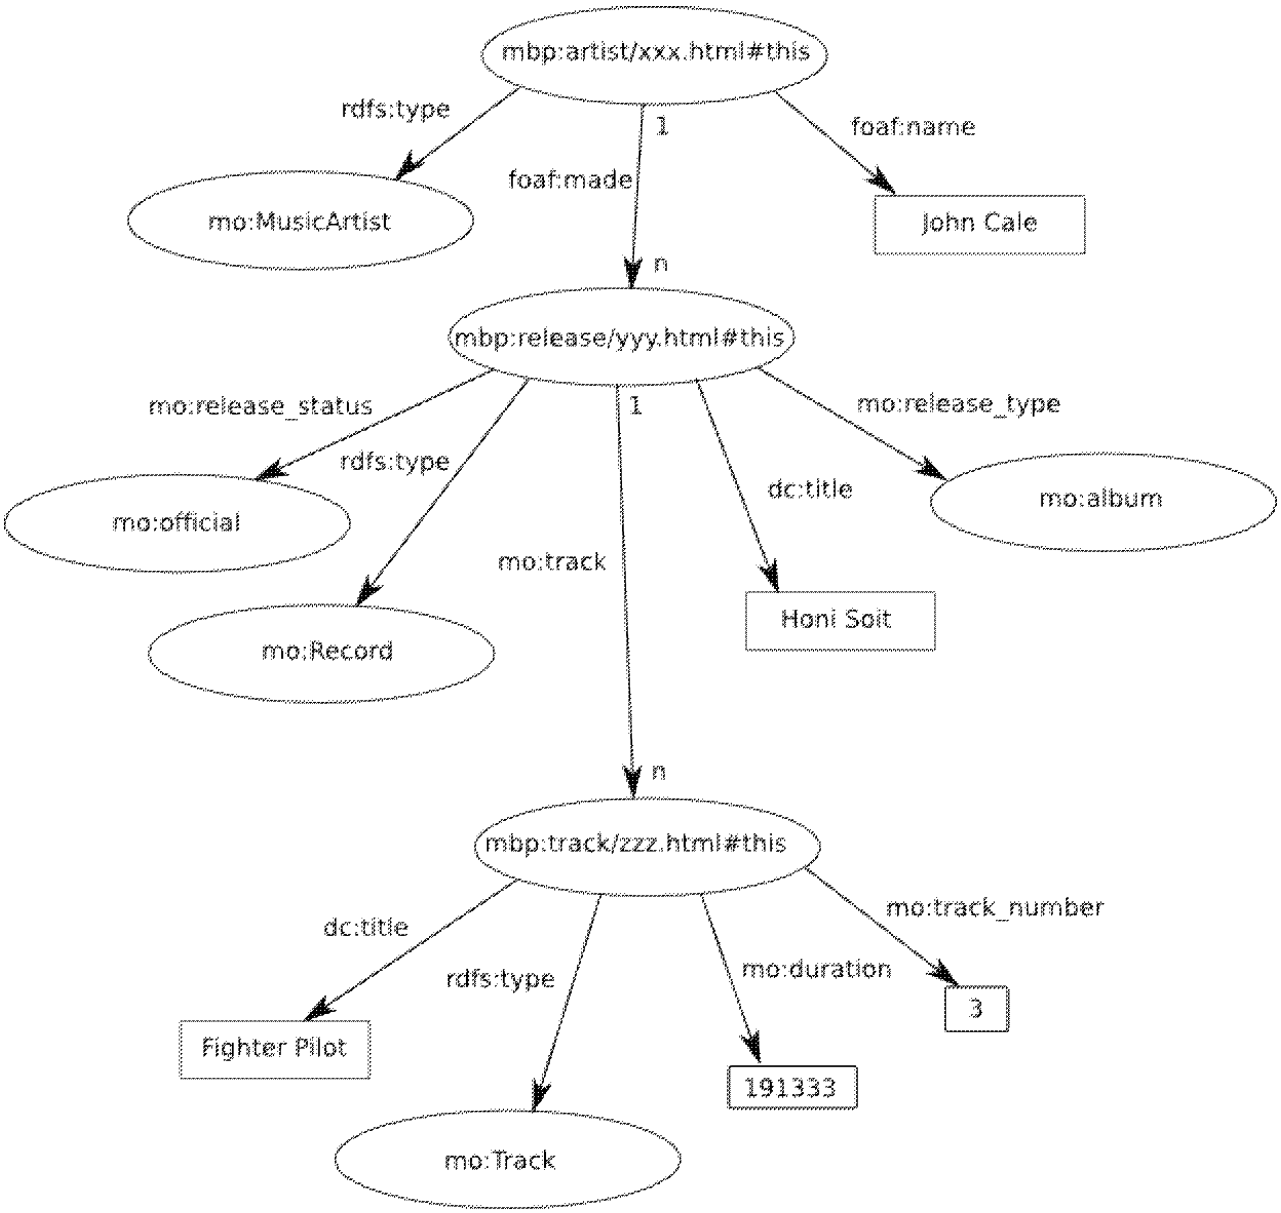
The XML returned by the web service is shown below (only the first two tracks are shown for brevity):

```
<?xml version="1.0" encoding="UTF-8"?>
  <metadata xmlns="http://musicbrainz.org/ns/mmd-1.0#"
   xmlns:ext="http://musicbrainz.org/ns/ext-1.0#">
    <release
xml:id="f237e6a0-4b0e-4722-8172-66f4930198bc" type="Album Official" >
      <title>Imagine</title>
        <text-representation language="ENG" script="Latn"/>
        <asin>B0000457L2</asin>
        <track-list>
          <track
xml:id="b88bdafd-e675-4c6a-9681-5ea85ab99446">
            <title>Imagine</title>
```

```
              <duration>182933</duration>
            </track>
            <track
xml:id="b38ce90d-3c47-4ccd-bea2-4718c4d34b0d">
              <title>Crippled Inside</title>
              <duration>227906</duration>
            </track>
            . . .
          </track-list>
        </release>
    </metadata>
```

Although, as shown above, MusicBrainz defines its own XML Metadata Format to represent music metadata, the MusicBrainz sponger converts the raw data to a subset of the Music Ontology , an RDF vocabulary which aims to provide a set of core classes and properties for describing music on the Semantic Web. Part of the subset used is depicted in the following RDF graph (representing in this case a John Cale album).

Figure 16.110. RDF graph



mbp: http://localhost:8890/proxy/rdf/http://musicbrainz.org/
mo: http://purl.org/ontology/mo/
dc: http://purl.org/dc/elements/1.1/
rdfs: http://www.w3.org/2000/01/rdf-schema#
foaf: http://xmlns.com/foaf/0.1/

Artist ID: xxx = 72c090b6-a68e-4cb9-b330-85278681a714b330b
Release ID: yyy = 9d0cadc4-69cd-4692-b6c4-9458522733e1
Track ID: zzz = 94cd2383-c828-4835-9c83-645148379136

With the prefix mo: denoting the Music Ontology at http://purl.org/ontology/mo/, it can be seen that artists are represented by instances of class mo:Artist, their albums, records etc. by instances of class mo:Release and tracks on these releases by class mo:Track. The property foaf:made links an artist and his/her releases. Property mo:track links a release with the tracks it contains

RDF Output

An RDF description of the album can be obtained by sponging the same URL, i.e. by submitting it to the Sponger's proxy interface using the URL:

```
http://demo.openlinksw.com/about/rdf/http://musicbrainz.org/release/f237e6a0-4b0e-4722-8172-66f4930198bc.
```

The extract below shows part of the (reorganized) RDF output returned by the Sponger for "Imagine". Only the album's title track is included.

```
<?xml version="1.0" encoding="utf-8" ?>

Cartridge Hook Function

The cartridge's hook function is listed below. It is important to note that MusicBrainz supports a variety of query types, each of which returns a different set of information, depending on the item type being queried. Full details can be found on the MusicBrainz? site. The sponger cartridge is capable of handling all the query types supported by MusicBrainz? and is intended to be used in a drill-down scenario, as would be the case when using an RDF browser such as the OpenLink Data Explorer (ODE) . This example focuses primarily on the types release and track.

```
create procedure DB.DBA.RDF_LOAD_MBZ (
  in graph_iri varchar, in new_origin_uri varchar, in dest varchar,
  inout _ret_body any, inout aq any, inout ps any, inout _key any,
  inout opts any)
{
  declare kind, id varchar;
  declare tmp, incs any;
  declare uri, cnt, hdr, inc, xd, xt varchar;
  tmp := regexp_parse ('http://musicbrainz.org/([^/]*)/([^\.]+)', new_origin_uri, 0);
  declare exit handler for sqlstate '*'
  {
    -- dbg_printf ('%s', __SQL_MESSAGE);
    return 0;
  };
  if (length (tmp) < 6)
    return 0;

  kind := subseq (new_origin_uri, tmp[2], tmp[3]);
  id :=   subseq (new_origin_uri, tmp[4], tmp[5]);
  incs := vector ();
  if (kind = 'artist')
    {
      inc := 'aliases artist-rels label-rels release-rels track-rels url-rels';
      incs :=
        vector (
        'sa-Album', 'sa-Single', 'sa-EP', 'sa-Compilation', 'sa-Soundtrack',
        'sa-Spokenword', 'sa-Interview', 'sa-Audiobook', 'sa-Live', 'sa-Remix', 'sa-Other'
        , 'va-Album', 'va-Single', 'va-EP', 'va-Compilation', 'va-Soundtrack',

        'va-Spokenword', 'va-Interview', 'va-Audiobook', 'va-Live', 'va-Remix', 'va-Other'
        );
    }
  else if (kind = 'release')
    inc := 'artist counts release-events discs tracks artist-rels label-rels release-rels track-rels url-
  else if (kind = 'track')
    inc := 'artist releases puids artist-rels label-rels release-rels track-rels url-rels';
  else if (kind = 'label')
    inc := 'aliases artist-rels label-rels release-rels track-rels url-rels';
  else
    return 0;
  if (dest is null)
    DELETE FROM DB.DBA.RDF_QUAD WHERE G = DB.DBA.RDF_MAKE_IID_OF_QNAME (graph_iri);
  DB.DBA.RDF_LOAD_MBZ_1 (graph_iri, new_origin_uri, dest, kind, id, inc);
  DB.DBA.TTLP (sprintf ('<%S> <http://xmlns.com/foaf/0.1/primaryTopic> <%S> .\n<%S> a <http://xmlns.com/f
        new_origin_uri, DB.DBA.RDF_SPONGE_PROXY_IRI (new_origin_uri), new_origin_uri),
        '', graph_iri);
  foreach (any inc1 in incs) do
    {
      DB.DBA.RDF_LOAD_MBZ_1 (graph_iri, new_origin_uri, dest, kind, id, inc1);
    }
  return 1;
};
```

The hook function uses a subordinate procedure RDF_LOAD_MBZ_1:

```
create procedure DB.DBA.RDF_LOAD_MBZ_1 (in graph_iri varchar, in new_origin_uri varchar,
```

```
   in dest varchar, in kind varchar, in id varchar, in inc varchar)
{
  declare uri, cnt, xt, xd, hdr any;
  uri := sprintf ('http://musicbrainz.org/ws/1/%s/%s?type=xml&inc=%U', kind, id, inc);
  cnt := RDF_HTTP_URL_GET (uri, '', hdr, 'GET', 'Accept: */*');
  xt := xtree_doc (cnt);
  xd := DB.DBA.RDF_MAPPER_XSLT (registry_get ('_cartridges_path_') || 'xslt/mbz2rdf.xsl', xt,
        vector ('baseUri', new_origin_uri));
  xd := serialize_to_UTF8_xml (xd);
  DB.DBA.RM_RDF_LOAD_RDFXML (xd, new_origin_uri, coalesce (dest, graph_iri));
};
```

XSLT Stylesheet

The key sections of the MusicBrainz XSLT template relevant to this example are listed below. Only the sections relating to an artist, his releases, or the tracks on those releases, are shown.

```
<!DOCTYPE xsl:stylesheet [

        </mo:Track>
    </xsl:template>

    ...

  <xsl:template match="text()"/>
</xsl:stylesheet>
```

Entity Extractor & Mapper Component

Used to extract RDF from a Web Data Source the Virtuoso Sponger Cartridge RDF Extractor consumes services from: Virtuoso PL, C/C++, Java based RDF Extractors

The RDF mappers provide a way to extract metadata from non-RDF documents such as HTML pages, images Office documents etc. and pass to SPARQL sponger (crawler which retrieve missing source graphs). For brevity further in this article the "RDF mapper" we simply will call "mapper".

The mappers consist of PL procedure (hook) and extractor, where extractor itself can be built using PL, C or any external language supported by Virtuoso server.

Once the mapper is developed it must be plugged into the SPARQL engine by adding a record in the table DB.DBA.SYS_RDF_MAPPERS.

If a SPARQL query instructs the SPARQL processor to retrieve target graph into local storage, then the SPARQL sponger will be invoked. If the target graph IRI represents a dereferenceable URL then content will be retrieved using content negotiation. The next step is the content type to be detected:

- If RDF and no further transformation such as GRDDL is needed, then the process would stop.
- If such as 'text/plain' and is not known to have metadata, then the SPARQL sponger will look in the DB.DBA.SYS_RDF_MAPPERS table by order of RM_ID and for every matching URL or MIME type pattern (depends on column RM_TYPE) will call the mapper hook.
    - If hook returns zero the next mapper will be tried;
    - If result is negative the process would stop instructing the SPARQL nothing was retrieved;
    - If result is positive the process would stop instructing the SPARQL that metadata was retrieved.

Virtuoso/PL based Extractors

PL hook requirements:

Every PL function used to plug a mapper into SPARQL engine must have following parameters in the same order:

- in graph_iri varchar: the graph IRI which is currently retrieved
- in new_origin_uri varchar: the URL of the document retrieved
- in destination varchar: the destination graph IRI
- inout content any: the content of the document retrieved by SPARQL sponger
- inout async_queue any: an asynchronous queue, can be used to push something to execute on background if needed.
- inout ping_service any: the value of [SPARQL] - PingService INI parameter, could be used to configure a service

notification such as pingthesemanticweb.com
- inout api_key any: a plain text id single key value or serialized vector of key structure, basically the value of RM_KEY column of the DB.DBA.SYS_RDF_MAPPERS table.

Note: the names of the parameters are not important, but their order and presence are!

Example Implementation:

In the example script below we implement a basic mapper, which maps a text/plain mime type to an imaginary ontology, which extends the class Document from FOAF with properties 'txt:UniqueWords' and 'txt:Chars', where the prefix 'txt:' we specify as 'urn:txt:v0.0:'.

```
use DB;

create procedure DB.DBA.RDF_LOAD_TXT_META
 (
  in graph_iri varchar,
  in new_origin_uri varchar,
  in dest varchar,
  inout ret_body any,
  inout aq any,
  inout ps any,
  inout ser_key any
  )
{
  declare words, chars int;
  declare vtb, arr, subj, ses, str any;
  declare ses any;
  -- if any error we just say nothing can be done
  declare exit handler for sqlstate '*'
    {
      return 0;
    };
  subj := coalesce (dest, new_origin_uri);
  vtb := vt_batch ();
  chars := length (ret_body);

  -- using the text index procedures we get a list of words
  vt_batch_feed (vtb, ret_body, 1);
  arr := vt_batch_strings_array (vtb);

  -- the list has 'word' and positions array, so we must divide by 2
  words := length (arr) / 2;
  ses := string_output ();

  -- we compose a N3 literal
  http (sprintf ('<%s> <http://www.w3.org/1999/02/22-rdf-syntax-ns#type> <http://xmlns.com/foaf/0.1/Docum
  http (sprintf ('<%s> <urn:txt:v0.0:UniqueWords> "%d" .\n', subj, words), ses);
  http (sprintf ('<%s> <urn:txt:v0.0:Chars> "%d" .\n', subj, chars), ses);
  str := string_output_string (ses);

  -- we push the N3 text into the local store
  DB.DBA.TTLP (str, new_origin_uri, subj);
  return 1;
};

DELETE FROM DB.DBA.SYS_RDF_MAPPERS WHERE RM_HOOK = 'DB.DBA.RDF_LOAD_TXT_META';

INSERT SOFT DB.DBA.SYS_RDF_MAPPERS (RM_PATTERN, RM_TYPE, RM_HOOK, RM_KEY, RM_DESCRIPTION)
VALUES ('(text/plain)', 'MIME', 'DB.DBA.RDF_LOAD_TXT_META', null, 'Text Files (demo)');

-- here we set order to some large number so don't break existing mappers
update DB.DBA.SYS_RDF_MAPPERS
SET RM_ID = 2000
WHERE RM_HOOK = 'DB.DBA.RDF_LOAD_TXT_META';
```

To test the mapper we just use /sparql endpoint with option 'Retrieve remote RDF data for all missing source graphs' to execute:

```
SELECT *
FROM <URL-of-a-txt-file>
```

```
WHERE { ?s ?p ?o }
```

It is important that the SPARQL_UPDATE role to be granted to "SPARQL" account in order to allow local repository update via Network Resource Fetch feature.

Authentication in Sponger

To enable usage of user defined authentication, there are added more parameters to the /proxy/rdf and /sparql endpoints. So to use it, the RDF browser and iSPARQL should send following url parameters:

- for /proxy/rdf endpoint:

```
'login=<account name>'
```

- for /sparql endpoint:

```
get-login=<account name>
```

Registry

The table DB.DBA.SYS_RDF_MAPPERS is used as registry for registering RDF mappers.

```
create table DB.DBA.SYS_RDF_MAPPERS (
    RM_ID integer identity,         -- mapper ID, designate order of execution
    RM_PATTERN varchar,             -- a REGEX pattern to match URL or MIME type
    RM_TYPE varchar default 'MIME', -- what property of the current resource to match: MIME or URL are su
    RM_HOOK varchar,                -- fully qualified PL function name e.q. DB.DBA.MY_MAPPER_FUNCTION
    RM_KEY  long varchar,           -- API specific key to use
    RM_DESCRIPTION long varchar,    -- Mapper description, free text
    RM_ENABLED integer default 1,   -- a flag 0 or 1 integer to include or exclude the given mapper from
    primary key (RM_TYPE, RM_PATTERN))
;
```

The current way to register/update/unregister a mapper is just a DML statement e.g. NSERT/UPDATE/DELETE.

Execution order and processing

When SPARQL retrieves a resource with unknown content it will look in the mappers registry and will loop over every record having RM_ENABLED flag true. The sequence of look-up is based on ordering by RM_ID column. For every record it will either try matching the MIME type or URL against RM_PATTERN value and if there is match the function specified in RM_HOOK column will be called. If the function doesn't exists or signal an error the SPARQL will look at next record.

When it stops looking? It will stop if value returned by mapper function is positive or negative number, if the return is negative processing stops with meaning no RDF was supplied, if return is positive the meaning is that RDF data was extracted, if zero integer is returned then SPARQL will look for next mapper. The mapper function also can return zero if it is expected next mapper in the chain to get more RDF data.

If none of the mappers matches the signature (MIME type nor URL) the built-in WebDAV metadata extractor will be called.

Extension function

The mapper function is a PL stored procedure with following signature:

```
THE_MAPPER_FUNCTION_NAME (
        in graph_iri varchar,
        in origin_uri varchar,
        in destination_uri varchar,
        inout content varchar,
        inout async_notification_queue any,
        inout ping_service any,
        inout keys any
        )
{
   -- do processing here
   -- return -1, 0 or 1 (as explained above in Execution order and processing section)
}
;
```

Parameters

- graph_iri - the target graph IRI
- origin_uri - the current URI of processing
- destination_uri - get:destination value
- content - the resource content
- async_notification_queue - if INI parameter PingService is specified in SPARQL section in the INI file, this is a pre-allocated asynchronous queue to be used to call ping service
- ping_service - the URL of the ping service configured in SPARQL section in the INI in PingService parameter
- keys - a string value contained in the RM_KEY column for given mapper, can be single string or serialized array, generally can be used as mapper specific data.

Return value

- 0 - no data was retrieved or some next matching mapper must extract more data
- 1 - data is retrieved, stop looking for other mappers
- -1 - no data is retrieved, stop looking for more data

Cartridges package content

The Virtuoso supply as a cartridges_dav.vad VAD package a cartridge for extracting RDF data from certain popular Web resources and file types. It can be installed (if not already) using VAD_INSTALL function, see the VAD chapter in documentation on how to do that.

HTTP-in-RDF

Maps the HTTP request response to HTTP Vocabulary in RDF, see http://www.w3.org/2006/http#.

This mapper is disabled by default. If it's enabled , it must be first in order of execution.

Also it always will return 0, which means any other mapper should push more data.

HTML

This mapper is composite, it looking for metadata which can specified in a HTML pages as follows:

- Embedded/linked RDF
  - scan for meta in RDF

    ```
    <link rel="meta" type="application/rdf+xml"
    ```
  - RDF embedded in xHTML (as markup or inside XML comments)
- Micro-formats
  - GRDDL - GRDDL Data Views: RDF expressed in XHTML and XML: http://www.w3.org/2003/g/data-view#
  - eLinked Data - http://purl.org/NET/erdf/profile
  - RDFa
  - hCard - http://www.w3.org/2006/03/hcard
  - hCalendar - http://dannyayers.com/microformats/hcalendar-profile
  - hReview - http://dannyayers.com/micromodels/profiles/hreview
  - relLicense - CC license: http://web.resource.org/cc/schema.rdf
  - Dublin Core (DCMI) - http://purl.org/dc/elements/1.1/
  - geoURL - http://www.w3.org/2003/01/geo/wgs84_pos#
  - Google Base - OpenLink Virtuoso specific mapping
  - Ning Metadata
- Feeds extraction
  - RSS/Linked Data - SIOC & AtomOWL
  - RSS 1.0 - RSS/RDF, SIOC & AtomOWL
  - Atom 1.0 - RSS/RDF, SIOC & AtomOWL
- xHTML metadata transformation using FOAF (foaf:Document) and Dublin Core properties (dc:title, dc:subject etc.)

The HTML page mapper will look for RDF data in order as listed above, it will try to extract metadata on each step and will return positive flag if any of the above step give a RDF data. In case where page URL matches some of other RDF mappers listed in registry it will return 0 so next mapper to extract more data. In order to function properly, this mapper must be executed before any other specific mappers.

Flickr URLs

This mapper extracts metadata of the Flickr images, using Flickr REST API. To function properly it must have configured key. The Flickr mapper extracts metadata using: CC license, Dublin Core, Dublin Core Metadata Terms, GeoURL, FOAF, EXIF: http://www.w3.org/2003/12/exif/ns/ ontology.

Amazon URLs

This mapper extracts metadata for Amazon articles, using Amazon REST API. It needs a Amazon API key in order to be functional.

eBay URLs

Implements eBay REST API for extracting metadata of eBay articles, it needs a key and user name to be configured in order to work.

Open Office (OO) documents

The OO documents contains metadata which can be extracted using UNZIP, so this extractor needs Virtuoso unzip plugin to be configured on the server.

Yahoo traffic data URLs

Implements transformation of the result of Yahoo traffic data to RDF.

iCal files

Transform iCal files to RDF as per http://www.w3.org/2002/12/cal/ical# .

Binary content, PDF, PowerPoint

The unknown binary content, PDF and MS PowerPoint files can be transformed to RDF using Aperture framework (http://aperture.sourceforge.net/). This mapper needs Virtuoso with Java hosting support, Aperture framework and MetaExtractor.class installed on the host system in order to work.

The Aperture framework & MetaExtractor.class must be installed on the system before to install the Cartridges VAD package . If the package is already installed, then to activate this mapper you can just re-install the VAD.

Setting-up Virtuoso with Java hosting to run Aperture framework

- Install a Virtuoso binary which includes built-in Java hosting support (The executable name will indicate whether the required hosting support is built in - a suitably enabled executable will include javavm in the name, for example virtuoso-javavm-t, rather than virtuoso-t).
- Download the Aperture framework from http://aperture.sourceforge.net.
- Unpack the contents of the framework's lib directory into an 'aperture' subdirectory of the Virtuoso working directory, i.e. of the directory containing the database and virtuoso.ini files.
- Ensure the Virtuoso working directory includes a 'lib' subdirectory containing the file MetaExtractor.class. (At the current time MetaExtractor.class in not included in the cartridges VAD. Please contact OpenLink Technical Support to obtain a copy.)
- In the [Parameters] section of the virtuoso.ini configuration file:
    - Add the line (linebreaks have been inserted for clarity):

```
JavaClasspath = lib:aperture/DFKIUtils2.jar:aperture/JempBox-0.2.0.jar:aperture/activation-
aperture/ant-compression-utils-1.7.1.jar:aperture/aperture-1.2.0.jar:aperture/aperture-exam
aperture/applewrapper-0.2.jar:aperture/bcmail-jdk14-132.jar:aperture/bcprov-jdk14-132.jar:a
aperture/commons-lang-2.3.jar:aperture/demork-2.1.jar:aperture/flickrapi-1.0.jar:aperture/f
```

```
aperture/ical4j-1.0-beta4.jar:aperture/infsail-0.1.jar:aperture/jacob-1.10.jar:aperture/jai
aperture/jcl104-over-slf4j-1.5.0.jar:aperture/jpim-0.1-aperture-1.jar:aperture/junit-3.8.1.
aperture/metadata-extractor-2.4.0-beta-1.jar:aperture/mstor-0.9.11.jar:aperture/nrlvalidato
aperture/osgi.core-4.0.jar:aperture/pdfbox-0.7.4-dev-20071030.jar:aperture/poi-3.0.2-FINAL-
aperture/rdf2go.api-4.6.2.jar:aperture/rdf2go.impl.base-4.6.2.jar:aperture/rdf2go.impl.sesa
aperture/slf4j-api-1.5.0.jar:aperture/slf4j-jdk14-1.5.0.jar:aperture/unionsail-0.1.jar:aper
```

    - Ensure DirsAllowed includes directories /tmp, (or the temporary directory for the host operating system), lib and aperture.
- Start the Virtuoso server with java hosting support
- Configure the cartridge either by installing the cartridges VAD or, if the VAD is already installed, by executing procedure DB.DBA.RDF_APERTURE_INIT.
- During the VAD installation process, RDF_APERTURE_INIT() configures the Aperture cartridge. If you look in the list of available cartridges under the RDF > Sponger tab in Conductor, you should see an entry for 'Binary Files'.

To check the cartridge has been configured, connect with Virtuoso's ISQL tool:

- Issue the command:

```
SQL> SELECT udt_is_available('APERTURE.DBA.MetaExtractor');
```

- Copy a test PDF document to the Virtuoso working directory, then execute:

```
SQL> SELECT APERTURE.DBA."MetaExtractor"().getMetaFromFile ('some_pdf_in_server_working_dir.pdf',

... some RDF data should be returned ...
```

You should now be able to Fetch all Network Resource document types supported by the Aperture framework, (using one of the standard Sponger invocation mechanisms, for instance with a URL of the form http://example.com/about/rdf/http://targethost/targetfile.pdf), subject to the MIME type pattern filters configured for the cartridge in the Conductor UI. By default the Aperture cartridge is registered to match MIME types (application/octet-stream)|(application/pdf)|(application/mspowerpoint). To Fetch all the Network Resource MIME types Aperture is capable of handling, changed the MIME type pattern to 'application/.*'.

Important: The installation guidelines presented above have been verified on Mac OS X with Aperture 1.2.0. Some adjustment may be needed for different operating systems or versions of Aperture.

Examples & tutorials

How to write own RDF mapper? Look at Virtuoso tutorial on this subject http://demo.openlinksw.com/tutorial/rdf/rd_s_1/rd_s_1.vsp .

Meta-Cartridges

So far the discussion has centered on 'primary' cartridges. However, Virtuoso supports an alternative type of cartridge, a 'meta-cartridge'. The way a meta-cartridge operates is essentially the same as a primary cartridge, that is it has a cartridge hook function with the same signature and its inserts data into the quad store through entity extraction and ontology mapping as before. Where meta-cartridges differ from primary cartridges is in their intent and their position in the cartridge invocation pipeline.

The purpose of meta-cartridges is to enrich graphs produced by other (primary) cartridges. They serve as general post-processors to add additional information about selected entities in an RDF graph. For instance, a particular meta-cartridge might be designed to search for entities of type 'umbel:Country' in a given graph, and then add additional statements about each country it finds, where the information contained in these statements is retrieved from the web service targeted by the meta-cartridge. One such example might be a 'World Bank' meta-cartridge which adds information relating to a country's GDP, its exports of goods and services as a percentage of GDP etc; retrieved using the World Bank web service API . In order to benefit from the World Bank meta-cartridge, any primary cartridge which might generate instance data relating to countries should ensure that each country instance it handles is also described as being of rdf:type 'umbel:Country'. Here, the UMBEL (Upper Mapping and Binding Exchange Layer) ontology is used as a data-source-agnostic classification system. It provides a core set of 20,000+ subject concepts which act as "a fixed set of reference points in a global knowledge space". The use of UMBEL in this way serves to decouple meta-cartridges from primary cartridges and data source specific ontologies.

Virtuoso includes two default meta-cartridges which use UMBEL and OpenCalais to augment source graphs.

Registration

Meta-cartridges must be registered in the RDF_META_CARTRIDGES table, which fulfills a role similar to the SYS_RDF_MAPPERS table used by primary cartridges. The structure of the table, and the meaning and use of its columns, are similar to SYS_RDF_MAPPERS. The meta-cartridge hook function signature is identical to that for primary cartridges.

The RDF_META_CARTRIDGES table definition is as follows:

```
create table DB.DBA.RDF_META_CARTRIDGES (
MC_ID INTEGER IDENTITY,          -- meta-cartridge ID. Determines the order of the
                                    meta-cartridge's invocation in the Sponger
                                  processing chain
MC_SEQ INTEGER IDENTITY,
MC_HOOK VARCHAR,                        -- fully qualified Virtuoso/PL function name
MC_TYPE VARCHAR,
MC_PATTERN VARCHAR,              -- a REGEX pattern to match resource URL or
                                            MIME type
MC_KEY VARCHAR,                  -- API specific key to use
MC_OPTIONS ANY,                  -- meta-cartridge specific options
MC_DESC LONG VARCHAR,            -- meta-cartridge description (free text)
MC_ENABLED INTEGER               -- a 0 or 1 integer flag to exclude or include
                                            meta-cartridge from Sponger processing chain
);
```

(At the time of writing there is no Conductor UI for registering meta-cartridges, they must be registered using SQL. A Conductor interface for this task will be added in due course.)

Invocation

Meta-cartridges are invoked through the post-processing hook procedure RDF_LOAD_POST_PROCESS which is called, for every document retrieved, after RDF_LOAD_RDFXML loads fetched data into the Quad Store.

Cartridges in the meta-cartridge registry (RDF_META_CARTRIDGES) are configured to match a given MIME type or URI pattern. Matching meta-cartridges are invoked in order of their MC_SEQ value. Ordinarily a meta-cartridge should return 0, in which case the next meta-cartridge in the post-processing chain will be invoked. If it returns 1 or -1, the post-processing stops and no further meta-cartridges are invoked.

The order of processing by the Sponger cartridge pipeline is thus:

1. Try to get RDF in the form of TTL or RDF/XML. If RDF is retrieved if go to step 3
2. Try generating RDF through the Sponger primary cartridges as before
3. Post-process the RDF using meta-cartridges in order of their MC_SEQ value. If a meta-cartridge returns 1 or -1, stop the post-processing chain.

Notice that meta-cartridges may be invoked even if primary cartridges are not.

Example - A Campaign Finance Meta-Cartridge for Freebase

Note

The example which follows builds on a Freebase Sponger cartridge developed prior to the announcement of Freebase's support for generating Linked Data through the endpoint http://rdf.freebase.com/ . The OpenLink cartridge has since evolved to reflect these changes. A snapshot of the Freebase cartridge and stylesheet compatible with this example can be found here .

Freebase is an open community database of the world's information which serves facts and statistics rather than articles. Its designers see this difference in emphasis from article-oriented databases as beneficial for developers wanting to use Freebase facts in other websites and applications.

Virtuoso includes a Freebase cartridge in the cartridges VAD. The aim of the example cartridge presented here is to provide a lightweight meta-cartridge that is used to conditionally add triples to graphs generated by the Freebase cartridge, if Freebase is describing a U.S. senator.

New York Times Campaign Finance (NYTCF) API

The New York Times Campaign Finance (NYTCF) API allows you to retrieve contribution and expenditure data based on United States Federal Election Commission filings. You can retrieve totals for a particular presidential candidate, see aggregates by ZIP

code or state, or get details on a particular donor.

The API supports a number of query types. To keep this example from being overly long, the meta-cartridge supports just one of these - a query for the candidate details. An example query and the resulting output follow:

Query:

```
http://api.nytimes.com/svc/elections/us/v2/president/2008/finances/candidates/obama,barack.xml?api-key=xx
```

Result:

```

```

Sponging Freebase

Using OpenLink Data Explorer

The following instructions assume you have the OpenLink Data Explorer (ODE) browser extension installed in your browser.

An HTML description of Barack Obama can be obtained directly from Freebase by pasting the following URL into your browser: http://www.freebase.com/view/en/barack_obama

To view RDF data fetched from this page, select 'Linked Data Sources' from the browser's 'View' menu. An OpenLink Data Explorer interface will load in a new tab.

Clicking on the 'Barack Obama' link under the 'Person' category displayed by ODE fetches RDF data using the Freebase cartridge. Click the 'down arrow' adjacent to the 'Barack Obama' link to explore the retrieved data.

Assuming your Virtuoso instance is running on port 8890 on localhost, the list of data caches displayed by ODE should include: http://example.com/about/html/http/www.freebase.com/view/en/barack_obama#this

The information displayed in the rest of the page relates to the entity instance identified by this URI. The prefix http://example.com/about/html/http/ prepended to the original URI indicates that the Sponger Proxy Service has been invoked. The Sponger creates an associated entity instance (identified by the above URI with the #this suffix) which holds network resource information being fetched about the original entity.

Using the Command Line

As an alternative to ODE, you can perform Network Resource Fetch from the command line with the command:

```
curl -H "Accept: text/xml" "http://example.com/about/html/http/www.freebase.com/view/en/barack_obama"
```

To view the results, you can use Conductor's browser-based SPARQL interface (e.g. http://example.com/sparql) to query the resulting graph generated by the Sponger, http://www.freebase.com/view/en/barack_obama.

Installing the Meta-Cartridge

To register the meta-cartridge, a procedure similar to the following can be used:

```
create procedure INSTALL_RDF_LOAD_NYTCF ()
{
  -- delete any previous NYTCF cartridge installed as a primary cartridge
  DELETE FROM SYS_RDF_MAPPERS WHERE RM_HOOK = 'DB.DBA.RDF_LOAD_NYTCF';
  -- register in the meta-cartridge post-processing chain
  INSERT SOFT DB.DBA.RDF_META_CARTRIDGES (MC_PATTERN, MC_TYPE, MC_HOOK,
    MC_KEY, MC_DESC, MC_OPTIONS)
    VALUES (
    'http://www.freebase.com/view/.*',
    'URL', 'DB.DBA.RDF_LOAD_NYTCF', '2c1d95a62e5fxxxxx', 'Freebase NYTCF',
    vector ());
};
```

Looking at the list of cartridges in Conductor's 'RDF Cartridges' screen, you will see that the Freebase cartridge is configured by default to perform Network Resource Fetch of URIs which match the pattern "http://www.freebase.com/view/.*" The meta-cartridge is configured to match on the same URI pattern.

To use the Campaign Finance API, you must register and request an API key. The script above shows an invalid key. Replace it with your own key before executing the procedure.

NYTCF Meta-Cartridge Functions

The meta-cartridge function definitions are listed below. They can be executed by pasting them into Conductor's iSQL interface.

```
-- New York Times: Campaign Finance Web Service
-- See http://developer.nytimes.com/docs/campaign_finance_api

-- DB.DBA.RDF_NYTCF_LOOKUP is in effect a lightweight lookup cartridge that is used
-- to conditionally add triples to graphs generated by the Wikipedia and
-- Freebase cartridges. These cartridges call on RDF_NYTCF_LOOKUP when
-- handling an entity of rdf:type yago:Congressman109955781. The NYTCF lookup
-- cartridge (aka a metacartridge) is used to return campaign finance data
-- for the candidate in question retrieved from the New York Times Campaign
-- Finance web service.
create procedure DB.DBA.RDF_NYTCF_LOOKUP(
  in candidate_id any,          -- id of candidate
  in graph_iri varchar,         -- graph into which the additional campaign finance triples should be loa
  in api_key varchar            -- NYT finance API key
)
{
  declare version, campaign_type, year any;
  declare nyt_url, hdr, tmp any;
  declare xt, xd any;

  -- Common parameters - The NYT API only supports the following values at present:
  version := 'v2';
  campaign_type := 'president';
  year := '2008';

  -- Candidate summaries
  -- nyt_url := sprintf('http://api.nytimes.com/svc/elections/us/%s/%s/%s/finances/totals.xml?api-key=%s'
  --    version, campaign_type, year, api_key);

  -- Candidate details
  nyt_url := sprintf('http://api.nytimes.com/svc/elections/us/%s/%s/%s/finances/candidates/%s.xml?api-key
        version, campaign_type, year, candidate_id, api_key);

  tmp := http_client_ext (nyt_url, headers=>hdr, proxy=>connection_get ('sparql-get:proxy'));
  if (hdr[0] not like 'HTTP/1._ 200 %')
    signal ('22023', trim(hdr[0], '\r\n'), 'DB.DBA.RDF_LOAD_NYTCF_LOOKUP');
```

```
  xd := xtree_doc (tmp);

}
;
```

NYTCF Meta-Cartridge Stylesheet

The XSLT stylesheet, nyctf2rdf.xsl, used by the meta-cartridge to transform the base Campaign Finance web service output to RDF is shown below. RDF_NYCTF_LOOKUP() assumes the stylesheet is located alongside the other stylesheets provided by the cartridges VAD in the Virtuoso WebDAV folder DAV/VAD/cartridges/xslt. You should create nyctf2rdf.xsl here from the following listing. The WebDAV Browser interface in Conductor provides the easiest means to upload the stylesheet.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE xsl:stylesheet [
<!ENTITY rdf "http://www.w3.org/1999/02/22-rdf-syntax-ns#">
<!ENTITY nyt "http://www.nytimes.com/">
]>

<xsl:stylesheet
    version="1.0"

          </nyt:date_coverage_from>
          <nyt:date_coverage_to rdf:datatype="date">
           <xsl:value-of select="date_coverage_to"/>
          </nyt:date_coverage_to>
      </rdf:Description>
    </xsl:template>

  <xsl:template match="text()|@*"/>
</xsl:stylesheet>
```

The stylesheet uses the prefix nyt: (http://www.nytimes.com) for the predicates of the augmenting triples. This has been used purely for illustration - you may prefer to define your own ontology for RDF data derived from New York Times APIs.

Testing the Meta-Cartridge

After creating the required Virtuoso/PL functions and installing the stylesheet, you should be able to test the meta-cartridge by sponging a Freebase page as described earlier using ODE or the command line. For instance:

- http://www.freebase.com/view/en/barack_obama , or
- http://www.freebase.com/view/en/hillary_rodham_clinton

You should see campaign finance data added to the graph created by the Sponger in the form of triples with predicates starting http://www.nytimes.com/xxx, e.g. http://www.nytimes.com/net_primary_contribution.

How The Meta-Cartridge Works

The comments in the meta-cartridge code detail how the cartridge works. In brief:

Given the URI of the graph being created by the Freebase cartridge, RDF_MQL_RESOURCE_IS_SENATOR checks if the resource described by Freebase is a U.S. senator. Only then does it make sense to query for campaign finance data from the

NYTCF data space.

To test for senators, the procedure starts by looking for two statements in the Freebase cartridge output similar to:

```
<rdf:Description rdf:about="http://example.com/about/rdf/http://www.freebase.com/view/en/barack_obama#thi
  <rdf:type rdf:resource="http://xmlns.com/foaf/0.1/Person"/>
  <rdfs:seeAlso rdf:resource="http://en.wikipedia.org/wiki/Barack_Obama"/>
   ...
```

where the graph generated by the Sponger will be

```
<http://www.freebase.com/view/en/barack_obama>
```

To test whether a resource is a senator, RDF_MQL_RESOURCE_IS_SENATOR

- Checks whether the Freebase resource is of rdf:type foaf:Person
- Extracts the person's name from the Wikipedia URI referenced by rdfs:seeAlso
- Uses the extracted name to build a URI to DBpedia's description of the person.
- Queries the DBpedia description to see if the person is of rdf:type yago:Senator110578471 (YAGO is a semantic knowledge base which provides a core set of concepts which in turn are used by DBpedia.)

Only if this is the case is the RDF_NYTCF_LOOKUP routine called to query for and return campaign finance data for the candidate. The form of the query and the resulting XML output from the Campaign Finance service were presented earlier.

Sponger Queue API

Functions

- *DB.DBA.RDF_SPONGER_QUEUE_ADD*

  : This function is available when rdf cartridges vad is installed.

  ```
  DB.DBA.RDF_SPONGER_QUEUE_ADD  (url, options);
  ```

  - *url*

    : the URI to perform Network Resource Fetch
  - *options*

    : an array usually typical sponger pragmas, for ex:

    ```
    vector ('get:soft',  'soft',  'refresh_free_text',  1);
    ```

REST Web service

The Sponger REST Web service has the following characteristics:

- endpoint: http://cname/about/service
- parameters:
  - op=add: type of operation, for now addition to the queue is supported
  - uris=[json array]: an array of URIs to be added to the sponger queue, the format is JSON array, for example:

    ```
    { "uris":["http://www.amazon.co.uk/Hama-Stylus-Input-Apple-iPad/dp/B003O0OM0C", "http://ww
    ```

The service will return a json encoded result of the number of items added, for example:

```
{ "result":2 }
```

In case of error a JSON with error text will be returned and http status 500.

cURL example

1. Assume file.txt which contains URL encoded JSON string:

```
uris=%7B%20%22uris%22%3A%5B%22http%3A%2F%2Fwww.amazon.co.uk%2FHama-Stylus-Input-Apple-iPad%2Fdp%2F
```

2. Execute the following command:

```
curl -i -d@file.txt http://cname/about/service?op=add
HTTP/1.1 200 OK
Server: Virtuoso/06.02.3129 (Darwin) i686-apple-darwin10.0.0  VDB
Connection: Keep-Alive
Date: Thu, 05 May 2011 12:06:24 GMT
Accept-Ranges: bytes
Content-Type: applcation/json; charset="UTF-8"
Content-Length: 14

{ "result":2 }
```

Virtuoso functions usage examples

String Functions

sprintf_inverse

```
tmp := sprintf_inverse (new_origin_uri, 'http://farm%s.static.flickr.com/%s/%s_%s.%s', 0);
img_id := tmp[2];
```

split_and_decode

```
request_hdr := headers[0];
response_hdr := headers[1];
host := http_request_header (request, 'Host');
tmp := split_and_decode (request_hdr[0], 0, '\0\0 ');

http_method := tmp[0];
url := tmp[1];
protocol_version := substring (tmp[2], 6, 8);
tmp := rtrim (response_hdr[0], '\r\n');
tmp := split_and_decode (response_hdr[0], 0, '\0\0 ');
```

Retrieving URLs

http_get

```
url := sprintf('http://api.flickr.com/services/rest/?i"??
        method=flickr.photos.getInfo&photo_id=%s&api_key=%s', img_id, api_key);
tmp := http_get (url, hdr);
if (hdr[0] not like 'HTTP/1._ 200 %')
  signal ('22023', trim(hdr[0], '\r\n'), 'RDFXX');
xd := xtree_doc (tmp);
```

DB.DBA.RDF_HTTP_URL_GET

A wrapper around http_get. Retrieves a URL using the specified HTTP method (defaults to GET). The function can handle proxies, redirects (up to fifteen) and HTTPS.

```
uri := sprintf ('http://musicbrainz.org/ws/1/%s/%s?type=xml&inc=%U',
        kind, id, inc);
cnt := RDF_HTTP_URL_GET (uri, '', hdr, 'GET', 'Accept: */*');
xt := xtree_doc (cnt);
xd := DB.DBA.RDF_MAPPER_XSLT (registry_get ('_cartridges_path_') || 'xslt/mbz2rdf.xsl', xt, vector ('base
```

http_request_header

```
content := RDF_HTTP_URL_GET (rdf_url, new_origin_uri, hdr, 'GET',
                'Accept: application/rdf+xml, text/rdf+n3, */*');
ret_content_type := http_request_header (hdr, 'Content-Type', null, null);
```

Handling Non-XML Response Content

json_parse : Parses JSON content into a tree.

```
url := sprintf ('http://www.freebase.com/api/service/mqlread?queries=%U', qr);
  content := http_get (url, hdr);
  tree := json_parse (content);
  tree := get_keyword ('ROOT', tree);
  tree := get_keyword ('result', tree);
```

Writing Arbitrarily Long Text

http

```
-- Writing N3 to a string output stream using function http(), parsing the N3 into a graph, then loading
ses := string_output ();
http ('@prefix opl: <http://www.openlinksw.com/schema/attribution#> .\n', ses);
http ('@prefix rdfs: <http://www.w3.org/2000/01/rdf-schema#> .\n', ses);
...
DB.DBA.TTLP (ses, base, graph);
DB.DBA.RDF_LOAD_RDFXML (strg, base, graph);
```

string_output

```
ses := string_output ();
cnt := http_get (sprintf ('http://download.finance.yahoo.com/d/quotes.csv?s=%U&f=nsbavophg&e=.csv',
    symbol));
arr := rdfm_yq_parse_csv (cnt);
http ('<quote stock="NASDAQ">', ses);
foreach (any q in arr) do
  {
    http_value (q[0], 'company', ses);
    http_value (q[1], 'symbol', ses);
    ...
  }
  http ('</quote>', ses);
  content := string_output_string (ses);
  xt := xtree_doc (content);
```

string_output_string

XML & XSLT

xtree_doc

```
content := RDF_HTTP_URL_GET (uri, '', hdr, 'GET', 'Accept: */*');
xt := xtree_doc (content);
```

xpath_eval

```
profile := cast (xpath_eval ('/html/head/@profile', xt) as varchar);
```

DB.DBA.RDF_MAPPER_XSLT

```
tmp := http_get (url);
xd := xtree_doc (tmp);
xt := DB.DBA.RDF_MAPPER_XSLT (
        registry_get ('_cartridges_path_') || 'xslt/atom2rdf.xsl',
        xd, vector ('baseUri', coalesce (dest, graph_iri)));
```

Character Set Conversion

serialize_to_UTF8_xml

```
xt := DB.DBA.RDF_MAPPER_XSLT (
        registry_get ('_cartridges_path_') || 'xslt/crunchbase2rdf.xsl',
        xt, vector ('baseUri', coalesce (dest, graph_iri), 'base', base,
        'suffix', suffix));
```

```
xd := serialize_to_UTF8_xml (xt);
DB.DBA.RM_RDF_LOAD_RDFXML (xd, new_origin_uri, coalesce (dest, graph_iri));
```

Loading Data Into the Quad Store

DB.DBA.RDF_LOAD_RDFXML

```
content := RDF_HTTP_URL_GET (uri, '', hdr, 'GET', 'Accept: */*');
xt := xtree_doc (content);
xd := DB.DBA.RDF_MAPPER_XSLT (
        registry_get ('_cartridges_path_') || 'xslt/mbz2rdf.xsl',
        xt, vector ('baseUri', new_origin_uri));
xd := serialize_to_UTF8_xml (xd);
DB.DBA.RM_RDF_LOAD_RDFXML (xd, new_origin_uri, coalesce (dest, graph_iri));
```

DB.DBA.TTLP

```
sess := string_output ();
...
http (sprintf ('<http://dbpedia.org/resource/%s>
        <http://xbrlontology.com/ontology/finance/stock_market#hasCompetitor>
        <http://dbpedia.org/resource/%s> .\n',
        symbol, x), sess);
http (sprintf ('<http://dbpedia.org/resource/%s>
        <http://www.w3.org/2000/01/rdf-schema#isDefinedBy>
        <http://finance.yahoo.com/q?s=%s> .\n',
         x, x), sess);
content := string_output_string (sess);
DB.DBA.TTLP (content, new_origin_uri, coalesce (dest, graph_iri));
```

PingTheSemanticWeb RDF Notification Service

PingtheSemanticWeb (PTSW) is a repository for RDF documents. The PTSW web service archives the location of recently created or updated RDF documents on the Web. It is intended for use by crawlers or other types of software agents which need to know when and where the latest updated RDF documents can be found. They can request a list of recently updated documents as a starting location to crawl the Semantic Web.

You may find this service useful for publicizing your own RDF content. Content authors can notify PTSW that an RDF document has been created or updated by pinging the service with the URL of the document. The Sponger supports this facility through the async_queue and ping_service parameters of the cartridge hook function, where the ping_service parameter contains the ping service URL as configured in the SPARQL section of the virtuoso.ini file:

```
[SPARQL]
...
PingService = http://rpc.pingthesemanticweb.com/
...
```

The configured ping service can be called using an asynchronous request and the RDF_SW_PING procedure as illustrated below.

```
create procedure DB.DBA.RDF_LOAD_HTML_RESPONSE (
```

```
  in graph_iri varchar, in new_origin_uri varchar, in dest varchar,
  inout ret_body any, inout async_queue any, inout ping_service any,
  inout _key any, inout opts any )
{
  ...
  if ( ... and async_queue is not null)
    aq_request (async_queue, 'DB.DBA.RDF_SW_PING',
                vector (ping_service, new_origin_uri));
```

For more details refer to section Asynchronous Execution and Multithreading in Virtuoso/PL

Main Namespaces used by OpenLink Cartridges

A list of the main namespaces / ontologies used by OpenLink-provided Sponger cartridges is given below. Some of these ontologies may prove useful when creating your own cartridges.

- - http://www.openlinksw.com/virtuoso/xslt/
- - http://example.com/schemas/XHTML#
- rdf: http://www.w3.org/1999/02/22-rdf-syntax-ns#
- rdfs: http://www.w3.org/2000/01/rdf-schema#
- dc: http://purl.org/dc/elements/1.1/
- dcterms: http://purl.org/dc/terms/
- foaf: http://xmlns.com/foaf/0.1/
- sioc: http://rdfs.org/sioc/ns#
- sioct: http://rdfs.org/sioc/types#
- skos: http://www.w3.org/2004/02/skos/core#
- bibo: http://purl.org/ontology/bibo/

Freebase Cartridge & Stylesheet

Snapshots of the Freebase cartridge and stylesheet compatible with the meta-cartridge example presented earlier in this document can be found below.

DB.DBA.RDF_LOAD_MQL:

```
--no_c_escapes-
create procedure DB.DBA.RDF_LOAD_MQL (in graph_iri varchar, in new_origin_uri varchar,  in dest varchar,
    inout _ret_body any, inout aq any, inout ps any, inout _key any, inout opts any)
{
  declare qr, path, hdr any;
  declare tree, xt, xd, types any;
  declare k, cnt, url, sa varchar;

  hdr := null;
  sa := '';
  declare exit handler for sqlstate '*'
    {
      --dbg_printf ('%s', __SQL_MESSAGE);
      return 0;
    };

  path := split_and_decode (new_origin_uri, 0, '%\0/');
  if (length (path) < 1)
    return 0;
  k := path [length(path) - 1];
  if (path [length(path) - 2] = 'guid')
    k := sprintf ('"id":"/guid/%s"', k);
  else
  {
    if (k like '#%')
        k := sprintf ('"id":"%s"', k);
    else
      {
        sa := DB.DBA.RDF_MQL_GET_WIKI_URI (k);
    k := sprintf ('"key":"%s"', k);
  }
  }
  qr := sprintf ('{"ROOT":{"query":[{%s, "type":[]}]}}', k);
```

```
  url := sprintf ('http://www.freebase.com/api/service/mqlread?queries=%U', qr);
  cnt := http_get (url, hdr);
  tree := json_parse (cnt);
  xt := get_keyword ('ROOT', tree);
  if (not isarray (xt))
    return 0;
  xt := get_keyword ('result', xt);
  types := vector ();
  foreach (any tp in xt) do
    {
      declare tmp any;
      tmp := get_keyword ('type', tp);
      types := vector_concat (types, tmp);
    }
  --types := get_keyword ('type', xt);
  DELETE FROM DB.DBA.RDF_QUAD WHERE g =  iri_to_id(new_origin_uri);
  foreach (any tp in types) do
    {
      qr := sprintf ('{"ROOT":{"query":{%s, "type":"%s", "*":[]}}}', k, tp);
      url := sprintf ('http://www.freebase.com/api/service/mqlread?queries=%U', qr);
      cnt := http_get (url, hdr);
      --dbg_printf ('%s', cnt);
      tree := json_parse (cnt);
      xt := get_keyword ('ROOT', tree);
      xt := DB.DBA.MQL_TREE_TO_XML (tree);
      --dbg_obj_print (xt);
      xt := DB.DBA.RDF_MAPPER_XSLT (registry_get ('_cartridges_path_') || 'xslt/mql2rdf.xsl', xt,
        vector ('baseUri', coalesce (dest, graph_iri), 'wpUri', sa));
      sa := '';
      xd := serialize_to_UTF8_xml (xt);
--      dbg_printf ('%s', xd);
      DB.DBA.RM_RDF_LOAD_RDFXML (xd, new_origin_uri, coalesce (dest, graph_iri));
    }
  return 1;
}
```

mql2rdf.xsl:

```
<?xml version="1.0" encoding="UTF-8"?>

```

Using Python to perform Virtuoso Sponging

This section contains the generic steps to use Python language to extend the Virtuoso Sponger.

1. Build the latest Python hosting module. It will introduce a new function `python_exec ()` The parameters of python_exec are :

   - string containing a python code, it should define one or more functions, see remarks below
   - string containing name of function to be called
   - list of parameters for the function

   For Example:

   ```
   python_exec (file_to_string ('spoonge.py'), 'rdf4uri', 'http://url..', 'http://base...');
   ```

   The above means call the rdf4uri ('http://url..', 'http://base...') function from spoonge.py file. It is importnat to know that python_exec is restricted to DBA only group and that the python source should not have __main__ or this to be restricted in python code to not be called . Any print etc. for stdout/stderr will go on server console if server is on foreground. Can be used for debug for example but not for real work.

   The function is supposed to return just single string, don't try to return multiple results, this will not work in this revision.
2. Setup the Virtuoso server INI to include python module:

   ```
   ...
   [Plugins]
   LoadPath = ../lib
   Load1    = Hosting, hosting_python.so
   ...
   ```
3. Download and install the rdflib package from http://www.rdflib.net/ Note before to build, disable Zope interface in rdflib as this not work with C-API correctly. Or make sure Python has no Zope interfaces installed. To disable the zope in rdflib, just comment out following in <rdflibhome>/rdflib/__init__.py:

   ```
    36 #from rdflib.interfaces import IIdentifier, classImplements
    37 #classImplements(URIRef, IIdentifier)
    38 #classImplements(BNode, IIdentifier)
    39 #classImplements(Literal, IIdentifier)
   ```

   Then do:

   ```
   perl setup.py build
   perl setup.py --user install
   ```
4. Get an example of python code for sponger like: http://www.ebusiness-unibw.org/wiki/Python4Spongers and make sure you disable the last lines which not suitable for calling inside Sponger:

   ```
   ...
   #if __name__ == '__main__':
   #       rdf_xml = rdf4uri(uri='http://www.amazon.com/Apple-touch-Generation-NEWEST-MODEL/dp/B002M3
   #       print rdf_xml
   ```

Store the python code in sponge.py in server working directory. Make sure this directory is allowed to read in DirsAllowed INI setting.

5. Create a procedure and register with Sponger:

```
-- THIS IS FOR DEMO PURPOSE ONLY

-- for demo purposes we delete all other cartridges registrations to see effect from only this car
delete from DB.DBA.SYS_RDF_MAPPERS;
delete from DB.DBA.RDF_META_CARTRIDGES;

-- register cartridge
insert soft DB.DBA.SYS_RDF_MAPPERS (RM_PATTERN, RM_TYPE, RM_HOOK, RM_KEY, RM_DESCRIPTION)
        values ('(http://.*amazon.[^/]+/[^/]+/dp/[^/]+(/.*)?)', 'URL', 'DB.DBA.RDF_LOAD_PYTHON_AMA

-- the cartridge stored procedure itself
create procedure DB.DBA.RDF_LOAD_PYTHON_AMAZON_ARTICLE (in graph_iri varchar, in new_origin_uri va
    inout _ret_body any, inout aq any, inout ps any, inout _key any, inout opts any)
{
  declare result any;
  -- we check first python hosting is capable to run code
  if (__proc_exists ('python_exec', 2) is null)
    return 0;
  -- handle any error
  declare exit handler for sqlstate '*'
    {
      -- log the error
      DB.DBA.RM_RDF_SPONGE_ERROR (current_proc_name (), graph_iri, dest, __SQL_MESSAGE);
      return 0;
    };
  -- call the python code
  result := python_exec (file_to_string ('sponge.py'), 'rdf4uri', new_origin_uri);
  -- in case of python error we will get integer zero, so we check
  if (not isstring (result))
    return 0;
  -- for demo purpose we delete all from this graph
  delete from DB.DBA.RDF_QUAD where G = DB.DBA.RDF_MAKE_IID_OF_QNAME (graph_iri);
  -- load the results
  DB.DBA.RDF_LOAD_RDFXML (result, new_origin_uri, coalesce (dest, graph_iri), 0);
  return 1;
}
;
```

6. Test the Sponger code like this:

```
sparql define get:soft "soft" select * from <http://www.amazon.com/Apple-touch-Generation-NEWEST-M
```

16.10.10. Sponger and Nanotations

Situation Analysis

Since the advent of blogging, it has been clear to everyone that posts require augmentation in order to truly function as rapid-fire meme vectors. For instance, could you imagine early blog posts without tagging?

Today, we've evolved from early literal tagging (which didn't scale an iota) to wide use of `@handles` and `#hastags` . Basically, `@handles` are social network specific HTTP URIs that denote Agents (People, Organizations, and Bots) while `#hashtags` are HTTP URIs that denote Topics.

Problem: Looking at the picture above, in regards to productively encoding and decoding information via the World Wide Web medium, it should be obvious that `@handles` and `#hashtags` are basically the digital equivalents of nouns. And as a consequence, we are basically trying to replicate the power of natural language sentences without critical components such as verbs (connectors) and adjectives (classifiers).

A Solution: Leverage the power of an existing language, based on open standards, that already delivers the power of natural language without being limited by the physical constraints of paper (as a mechanism for sentence persistence and exchange).

This is where RDF comes into play. It is an open standards based language for constructing digital sentences that pack the same (or even more power) its natural language equivalents. Through the power of RDF it is possible to create micro-annotations (aka. Nanotations) that are embeddable in any kind of text based documents. Naturally, the aforementioned claim doesn't apply to every

RDF notation, which is why RDF-Turtle is the vehicle we've chosen to unleash the full power of RDF and the Semantic Web it enables when digital sentences take the form of Linked Open Data.

What is Nanotation?

Nanotation is a mechanism for using embedded digital sentences to enhance blog posts, forum discussion posts, tweets (and other micro-blogging posts), HTML, and plain text document. In addition, it turns each of the aforementioned document types into end-user oriented conduits for contributing data to public and/or private Linked Open Data clouds, on a piecemeal basis -- i.e., you turn curating and publishing Linked Open Data Cloud into a productive crowd-sourced jigsaw puzzle game.

Why is it important?

Being able to say anything, about anything, whenever, and from wherever, in a manner that's both machine and human comprehensible has always sat at the very foundations of the Semantic Web Project's value proposition. Unfortunately, confusion about RDF -- the powerful language that drives the notion of a global Semantic Web -- lead to a general bottom-up misconception whereby most perceive it as a document content format rather that an abstract language (system of signs, syntax, and semantics) exploitable using a wide variety of notations.

How do I use it?

Due to the compact nature of RDF-Turtle notation, it is possible to embed RDF statements into any text based content. The only requirements are as follows:

- Use the following as a marker for embedded RDF-Turtle based RDF statements:

```
## Turtle Start ##
## {Trutle-based-RDF-statements}
## Turtle End ##
```

- Honor the use of <> to indicate reference identifiers (absolute or relative)
- Optionally treat `@handle` as an HTTP URIs that denote Agents -- for a given data space (e.g., Twitter, LinkedIn, Facebook, Google+ etc..)
- Optionally treat `#hashtag` as an HTTP URI that denotes a Topic -- ditto .

Basic Rules (authors and processing engines)

As per natural language sentences we have the following parts:

1. *Subject*

   -- statement focal point
2. *Predicate*

   -- connection, association, link
3. *Object*

   -- value of the connection, association, link.

Each sentence subject, predicate, object is denoted (named or referred to) using an identifier (word, phrase, or term). If you want to generate Linked Data that flows across data spaces your best bet is to denote (refer to) sentence subject, predicate, and object (optionally) using identifiers that function like terms -- by using HTTP URIs.

Use prefixes to shorten RDF-Turtle statements:

```
@prefix foaf: <http://xmlns.com/foaf/0.1/> .
```

Enables statements such as:

```
<>
a foaf:Document .
```

Examples

1. Most basic Nanotation:

```
<> a <#Document> .
<> <#topic> <#Nanotation>.
```

2. More sophisticated Nanotation that leverages terms from existing vocabularies:

```
<> a foaf:Document .
<> foaf:topic <#Nanotation>  .
```

3. More sophisticated Nanotation that leverages commas and semicolons for statement brevity e.g. when multiple sentences have a common Subject:

```
<>
a foaf:Document;
foaf:topic <#Nanotation>.
```

4. When multiple sentences have a common Subject and Predicate but varying list of Objects:

```
<>
a foaf:Document;
foaf:topic <#Nanotation>, <#SemanticWeb>, <#LinkedData>.
```

5. Incorporation of Pronouns into RDF sentence:

```
<> a foaf:Document .
<> foaf:maker [a foaf:Person;
               foaf:name "Kingsley Idehen"  ] .
```

6. Processor (parser) hint markers that help Nanotation processors negate seriously mangled HTML content:

```
## Turtle Start ##

<>
a foaf:Document;
foaf:topic <#Nanotation>, <#SemanticWeb>, <#LinkedData>.

## Turtle End ##
```

Nanotation Processor Usage

A nanotation processer is an application or service that's capable of consuming text content enhanced with RDF-Turtle based nanotations. Virtuoso's in-built Linked Data Transformation middleware (aka "Sponger") is an example of an application that supports nanotation. Likewise, our URIBurner service which is a free public service driven by an instance of Virtuoso with the Sponger module enabled:

- When using your own instance of Virtuoso, the Sponger service is invoked via the URL pattern:

```
http://{cname-of-virtuoso-host-machine}/sponger
```

- When using the public URIBurner service , the Sponger services is invoked via the URL:

```
http://linkeddata.uriburner.com/
```

- Note: Either approach outlined above will lead you to an HTML page that contains an input field into which you can type or paste an HTTP-accessible document URL. Alternatively you can use the following URI patterns:

```
http://{cname-of-virtuoso-host-machine}/about/html/{document-http-uri}
```

In all cases, you will end up with an HTML document that includes RDF statements that describe the processed document in a manner that also reveals all the embedded nanotations.

Virtuoso Sponger Implementation Notes

The Sponger treats resources transferred over HTTP as a duality of both a container document and a primary entity. When a resource is deemed to be an HTML document, the document is treated as the primary entity. Otherwise, where the domain is well known, a custom extractor cartridge populates the primary entity with data arising from API calls and the HTML content is regarded as secondary, relegated to the container document. For example, G+ posts are recognized and the Sponger concentrates on presenting the timestamp, body, tags and links and other features of a post.

When sponging an HTTP resource, multiple extractor cartridges might be brought to bear. Consequently, there may be multiple triples containing the entity's content.

The Turtle Sniffer is implemented as a Metacartridge, i.e it runs after all the extractor cartridges have run, augmenting data in the graph. It uses SPARQL inference to collate predicates that constitute "content" for this purpose, along with the HTTP request content (if any), flattening each to plain text.

Currently, the list of potential content predicates is:

- `bibo:content` (e.g. arising from the HTML+Variants extractor cartridge)
- `bibo:abstract`
- `oplgplus:annotation` (used by Google+ for text when sharing items)

For each of these contents, it checks if it matches the patterns:

```
## Nanotation Start ## .... ## Nannotation End ##

## Turtle Start ## .... ## Turtle Stop ##

{.... } (note: only applies to tweets on Twitter)
```

If a content contains one or more nanotation blocks, each block is parsed in turn as Turtle; if not, it attempts to parse the content item as Turtle in entirety.

The HTTP document content is only inspected in case of no triples having been extracted by prior means.

Optionally (enabled by default) each triple may be reified, i.e an rdf:Statement entity created to describe its subject, predicate and object, so you can identify triples arising from nanotations as entities labelled 'Embedded Turtle Statement' and a number in the graph.

Domain-Aware Tag and User Expansion

The Turtle Sniffer expands the patterns `#word` and `@word` when they appear in URI (<>) or double quotes (""), in the context of the domain of the URI being sponged.

For example, a Tweet containing the nanotation:

```
## Nannotation Start ##
<@kidehen> foaf:name "Kingsley Idehen" ;
           foaf:knows <@openlink> ;
           scot:has_tag <#Data> .
## Nannotation End ##
```

will be expanded to a Turtle string:

```
<https://twitter.com/kidehen> foaf:name "Kingsley Idehen" ;
  foaf:knows <https://twitter.com/openlink> ;
  scot:has_tag <https://twitter.com/hashtag/Data#this> .
```

We recognize custom URI formats for users and tags in the contexts of Facebook, Twitter, G+, LinkedIn and Delicious.

Note that the word must appear within quotes -- this is to avoid confusion with Turtle's @prefix directive (which is not a user!) and problems that would be caused by performing similar expansions within a quoted sentence.

Live Examples

- RDF statement about Privacy;
- RDFs usage re. property/predicate description;
- owl:sameAs relation inserted into a Google+ Post;
- Heavy duty RDF statements in a Facebook post;
- Another Facebook post that puts Ted Nelsons talk on documents and hypertext into contemporary context;
- A tweet reply demonstrating multiple embedded nanotation blocks and tags.

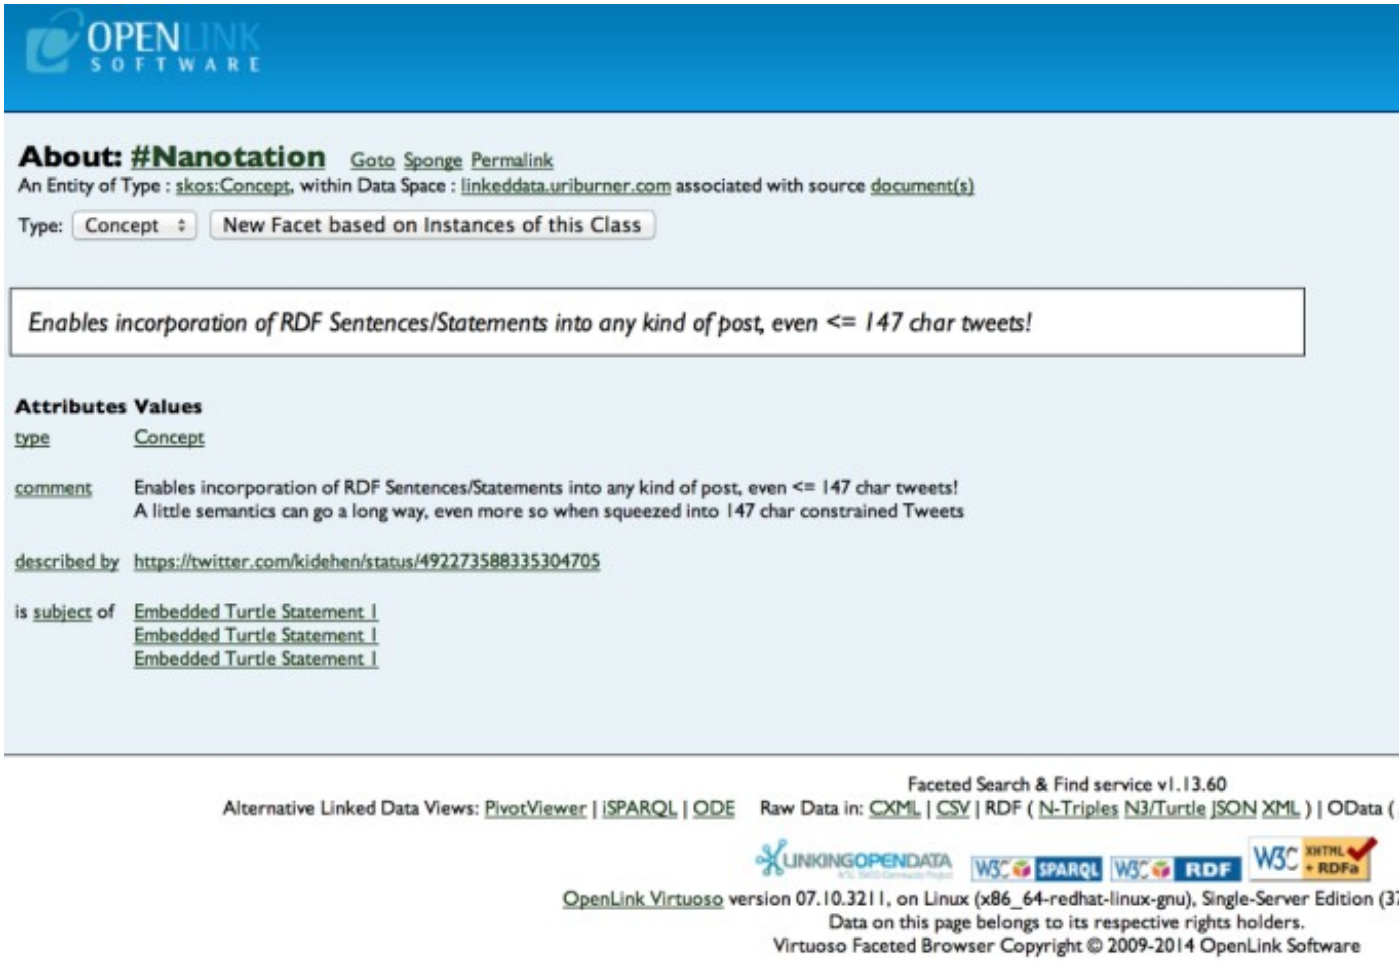
Nanotation generated 5-Star Linked Open Data (via URIBurner - a Nanotation Processor) Examples

- Various Nanotations from 28th July 2014;
- Various Nanotations from 27th July 2014;
- Various Nanotations from 25th July 2014;
- A tweet reply demonstrating multiple embedded nanotation blocks and tags.

Faceted Browser Nanotation Examples

- Nanotation based RDF statement that describes Nannotation:

Figure 16.111. Faceted Browser Nanotation RDF

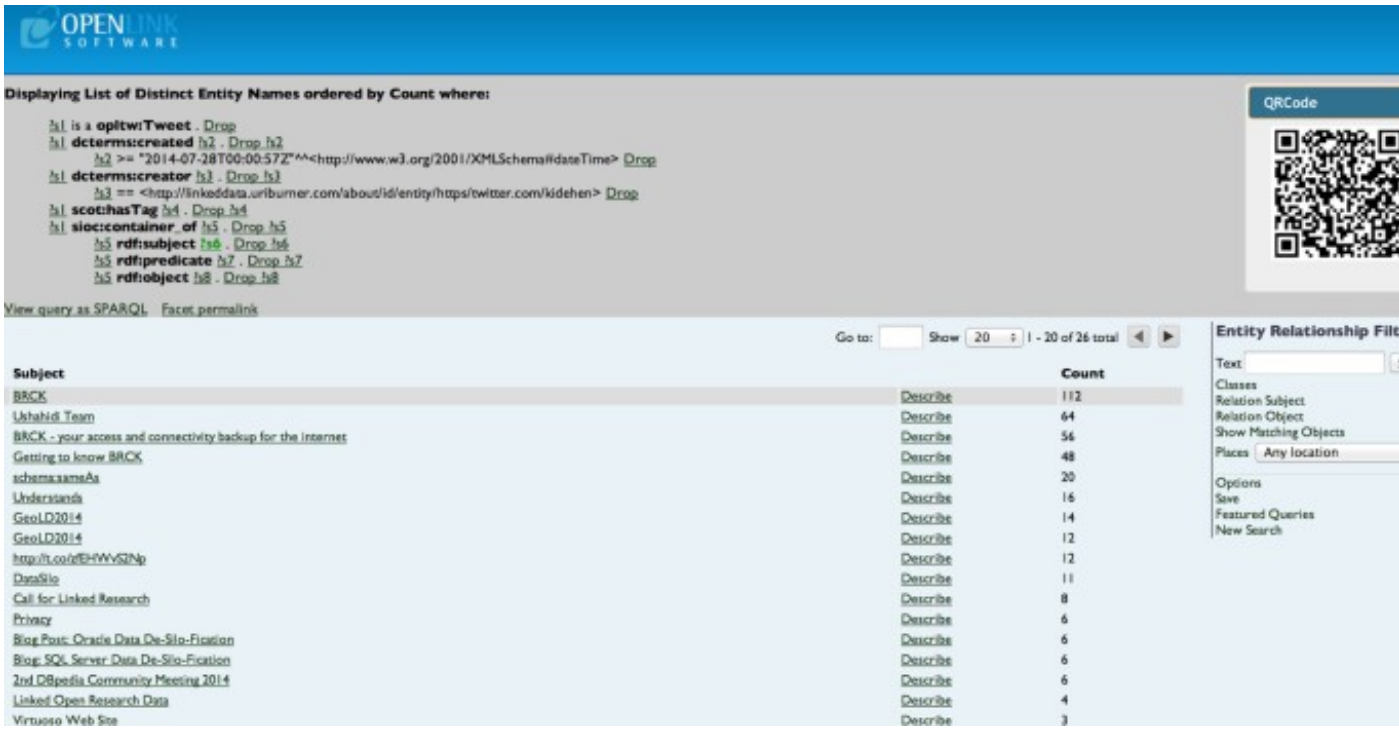


- Nanotation that represents a "Hat Tip" relationship type:

Figure 16.112. Faceted Browser Nanotation Hat Tip Type

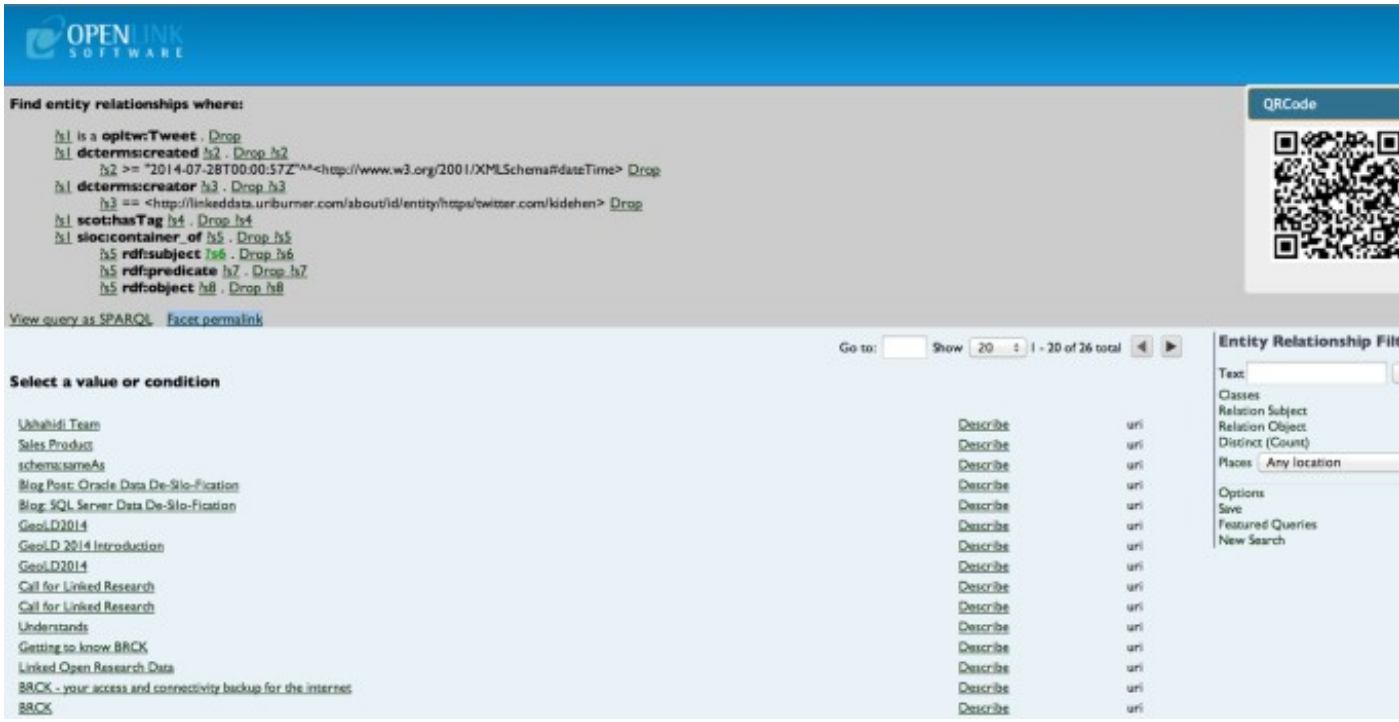
- Nanotation generated RDF statements aggregated by Subject:

Figure 16.113. Faceted Browser Nanotation RDF Aggregation by Subject



- Nanotation generated RDF statements by Subject:

Figure 16.114. Faceted Browser Nanotation Generation by Subject



16.10.11. Sponger Usage Examples

- SPARQL Processor Usage Example
- RDF Proxy Service Example
- Browsing & Exploring Linked Data View Example Using ODE
- Browsing & Exploring Linked Data View Example Using iSPARQL
- Basic Sponger Cartridge Example
- HTTP Example for Extracting Metadata using CURL
- RESTFul Interaction Examples
- Flickr Cartridge Example
- MusicBrainz Metadatabase Example

16.11. Virtuoso Faceted Browser Installation and configuration

16.11.1. Prerequisites

Requires Virtuoso 6.0 TP1 or higher for use.

16.11.2. Pre Installation

Note : This step is not required for Virtuoso Release 6.1 and above builds

If you have an existing Virtuoso 6.x installation, and your Quad Store has greater than 10K worth of triples, please perform the following steps:

1. Run the following commands using the Virtuoso isql program before installing the Faceted Browser VAD:

```
drop index RDF_QUAD_OPGS;
drop index RDF_QUAD_POGS;
drop index RDF_QUAD_GPOS;
drop index RDF_QUAD_OGPS;

checkpoint;

create table R2 (G iri_id_8, S iri_id_8, P iri_id_8, O any, primary key (S, P, O, G));
```

```
alter index R2 on R2 partition (S int (0hexffff00));

log_enable (2);

INSERT INTO R2 (G, S, P, O) select G, S, P, O FROM rdf_quad;

DROP TABLE RDF_QUAD;
ALTER TABLE r2 rename RDF_QUAD;

checkpoint;

create bitmap index RDF_QUAD_OPGS on RDF_QUAD (O, P, G, S) partition (O varchar (-1, 0hexffff));
create bitmap index RDF_QUAD_POGS on RDF_QUAD (P, O, G, S) partition (O varchar (-1, 0hexffff));
create bitmap index RDF_QUAD_GPOS on RDF_QUAD (G, P, O, S) partition (O varchar (-1, 0hexffff));

checkpoint;
```

Note this step may take sometime depending on how many triples are already in your Quad Store.

16.11.3. VAD Package Installation

1. Download and install the Virtuoso Faceted Browser VAD package using the Conductor System Admin - > Packages tab.

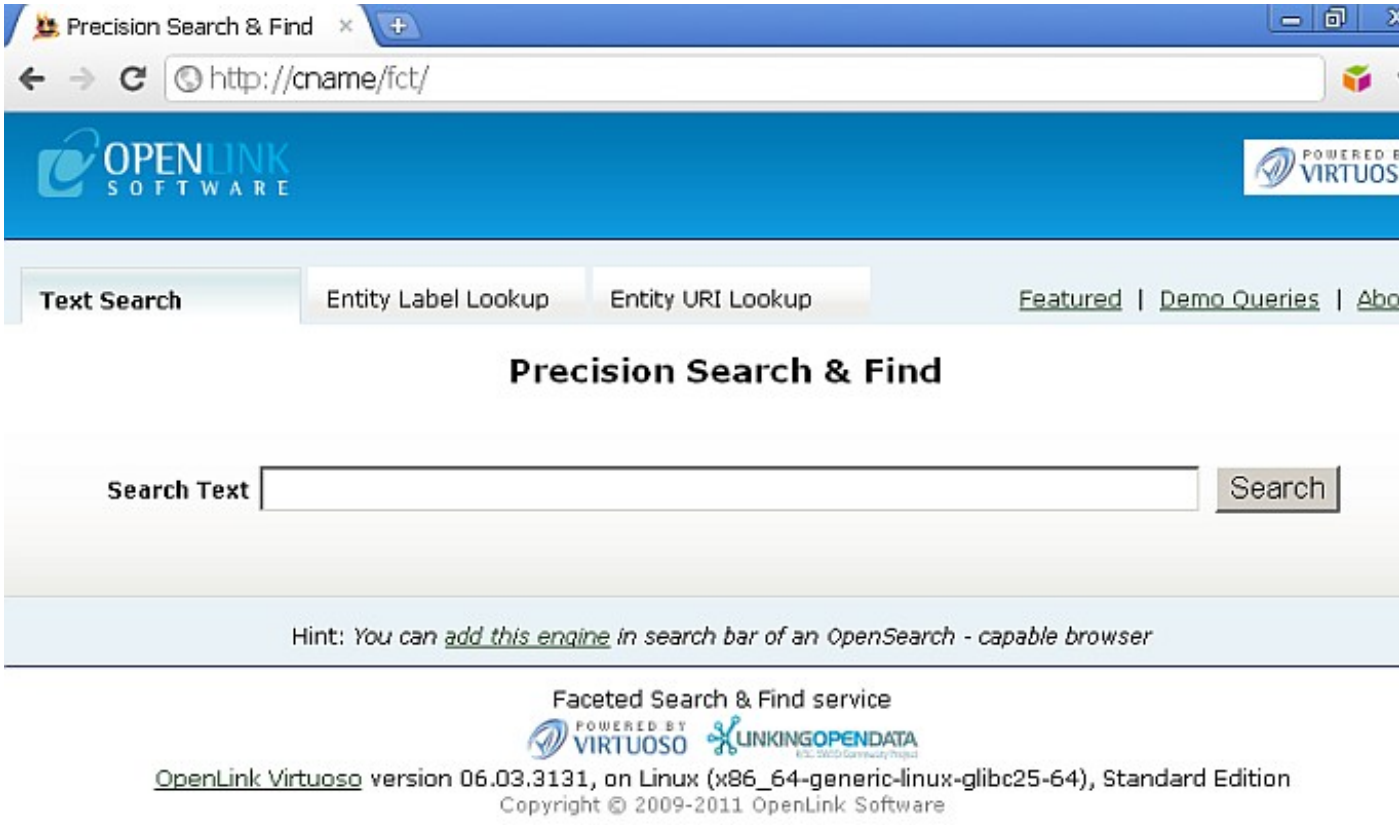
   Figure 16.115. Install the FCT package

2. The HTML interface of the Faceted Browser Engine is exposed at:

   http://<cname>/fct

   , where "cname" is the hostname:portno your Virtuoso instance is running on.

   Figure 16.116. FCT HTML interface



3. The Faceted Browser Engine exposes a REST API at the endpoint:

   http://<cname>/fct/service

   .

   See Also:
   - Virtuoso APIs for Faceted REST services
   - Faceted Web Service and Linked Data

16.11.4. Post Installation

1. Build Full Text Indexes by running the following commands using the Virtuoso

   isql

   program:

   ```
   RDF_OBJ_FT_RULE_ADD (null, null, 'All');
   VT_INC_INDEX_DB_DBA_RDF_OBJ ();
   ```

2. Run the following procedure using the Virtuoso

   isql

   program to populate label lookup tables periodically and activate the

   Label

   text box of the

   Entity Label Lookup

tab:

```
urilbl_ac_init_db()
```

3. Run the following procedure using the Virtuoso

   isql

   program to calculate the IRI ranks. Note this should be run periodically as the data grows to re-rank the IRIs.

```
s_rank()
```

4. Perform Network Resource Fetch of some data to load some RDF triples in the quad store. This can easily be done using the Virtuoso

   description.vsp

   page which provides a hypertext description of RDF Linked Data, by describing the following page for example (or one of your choice):

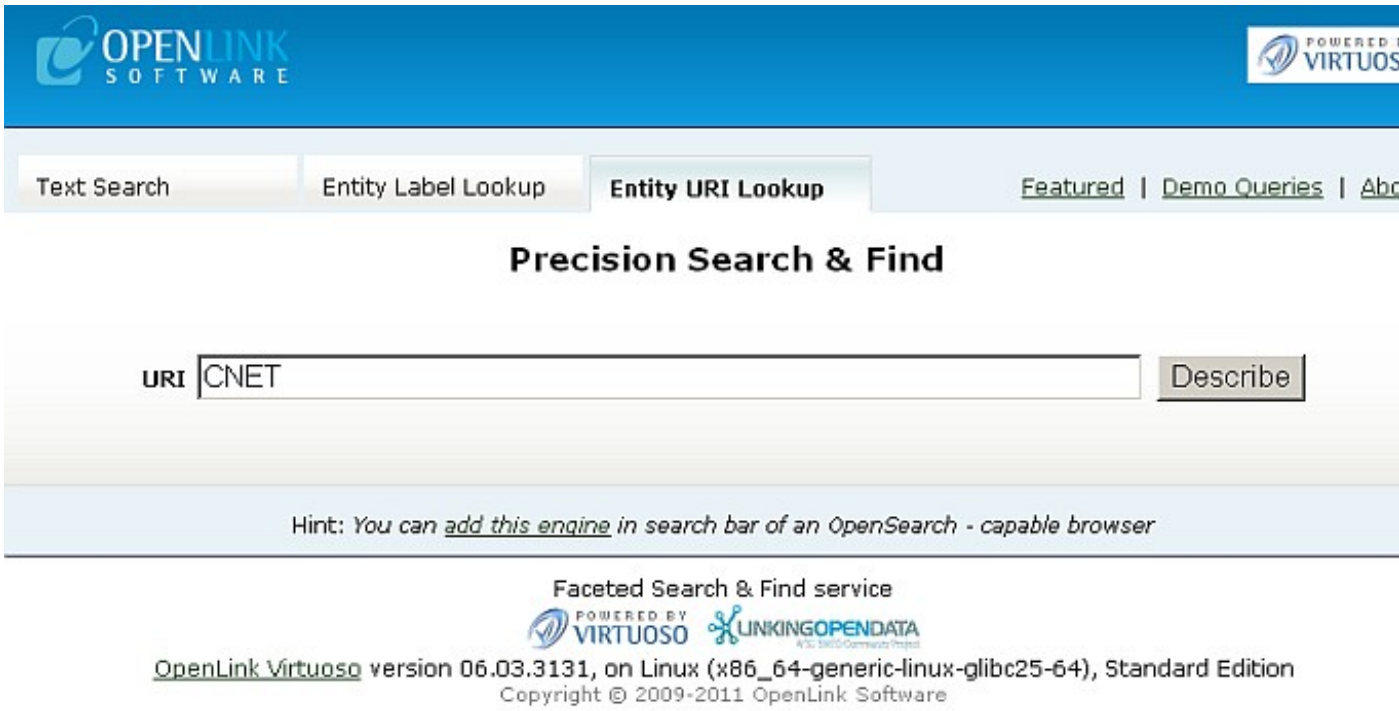
```
http://cname/about/html/http/news.cnet.com
```

Figure 16.117. Network Resource Fetch data

Figure 16.118. Network Resource Fetch data

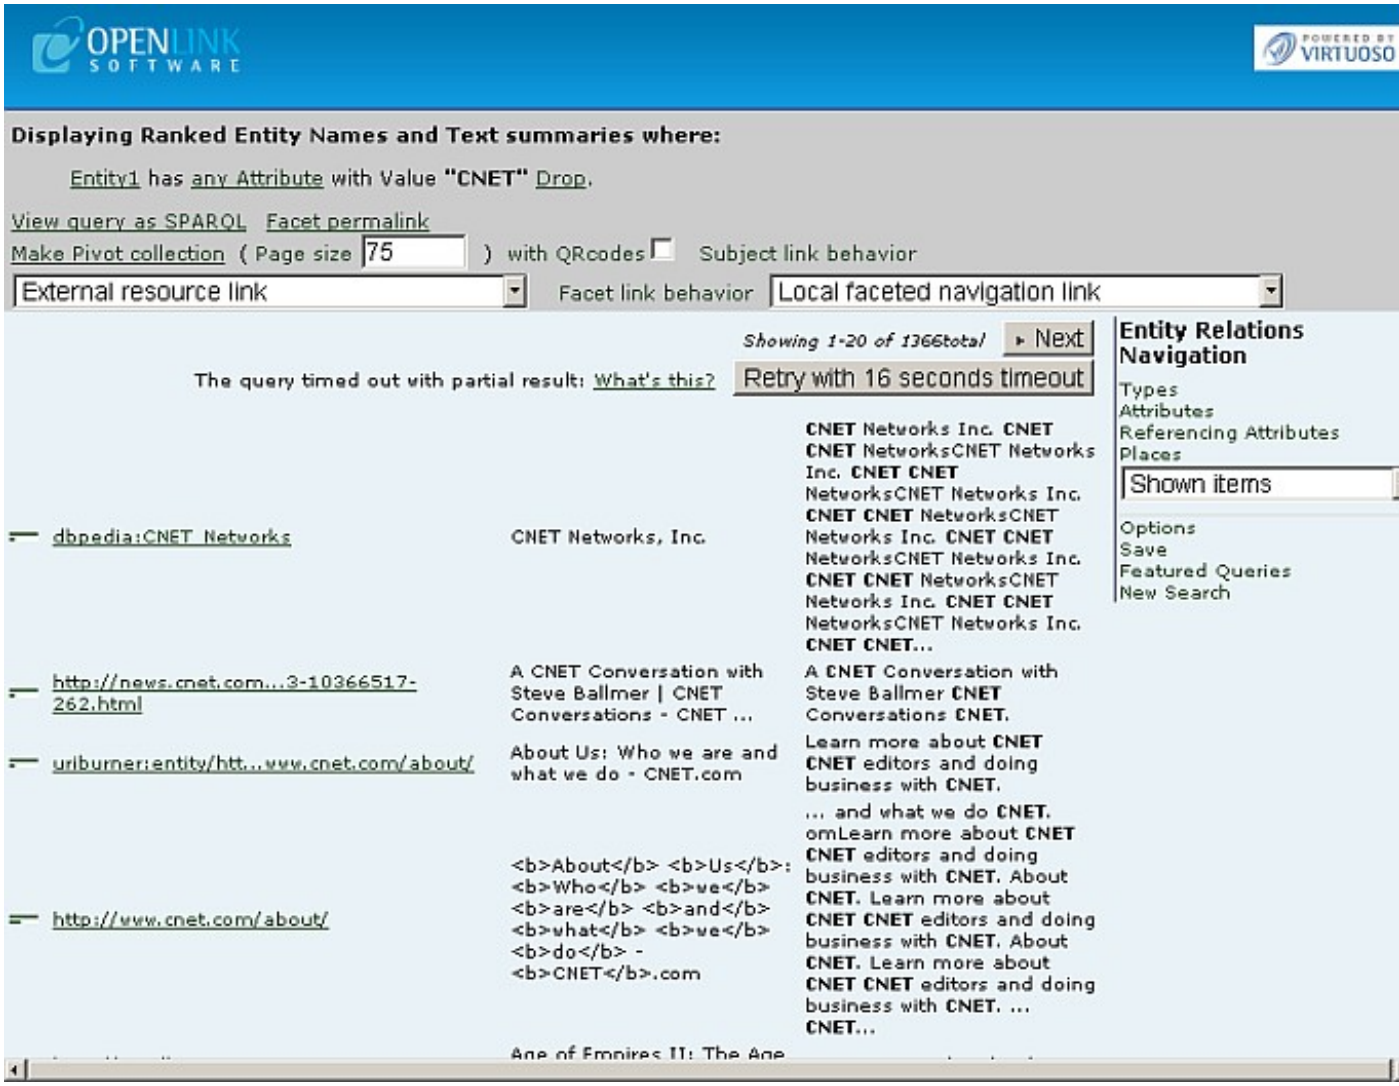
5. Use the Faceted Browser Search and Find User Interface to search for information on "CNET":

Figure 16.119. Faceted Browser Search



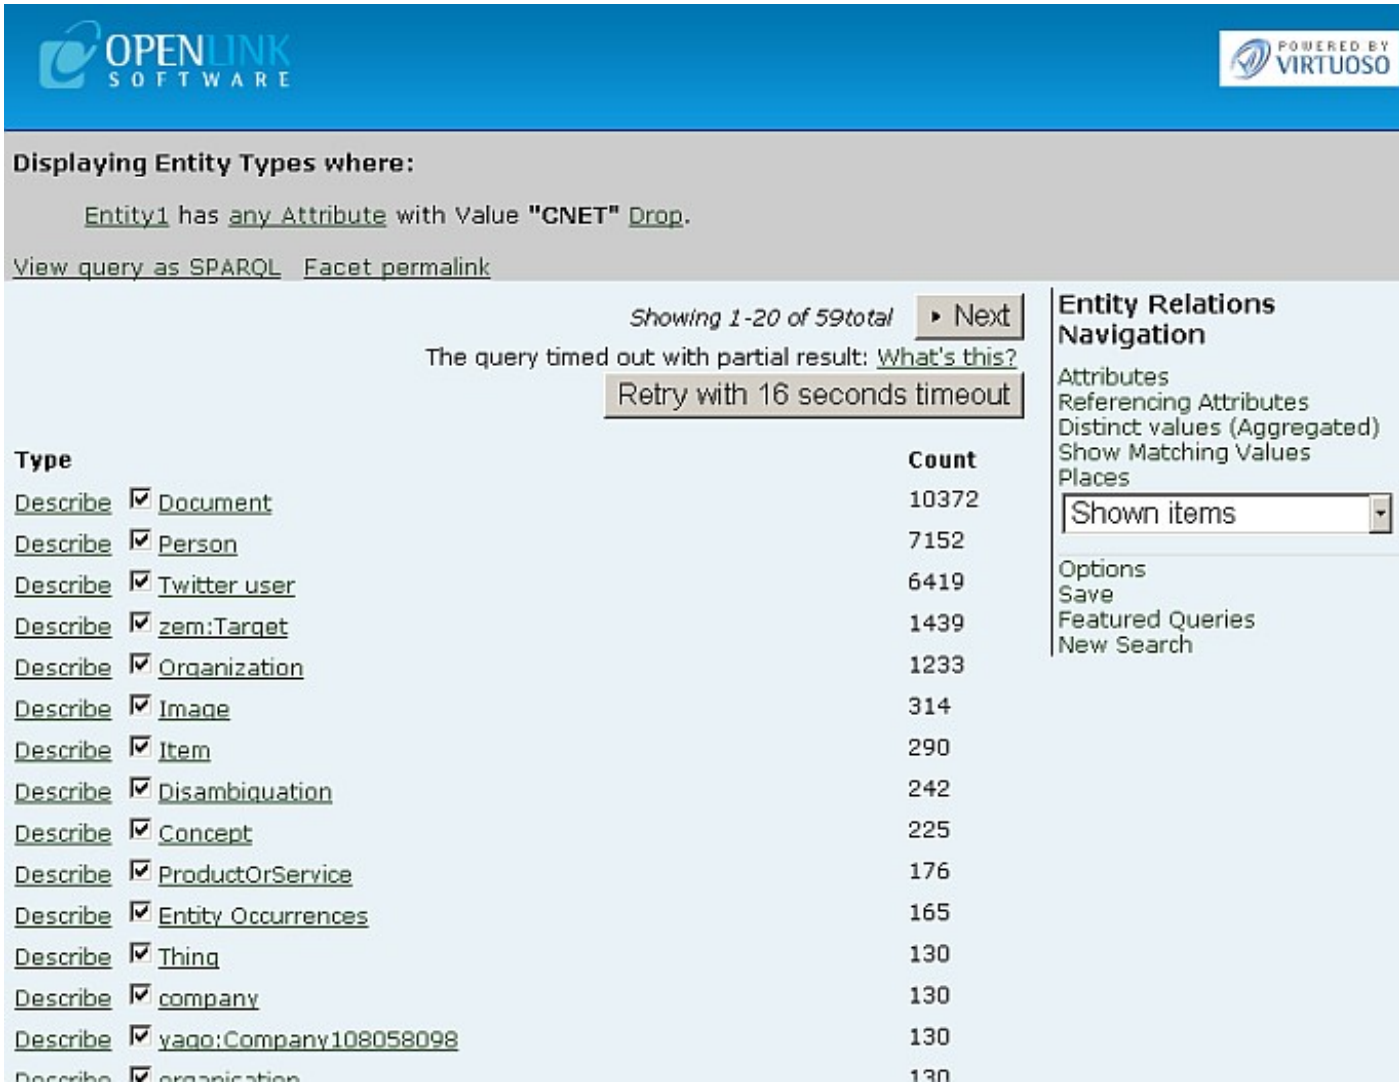
6. Results of the following form should be returned for the network resource data being fetched.

Figure 16.120. Faceted Browser Search Results



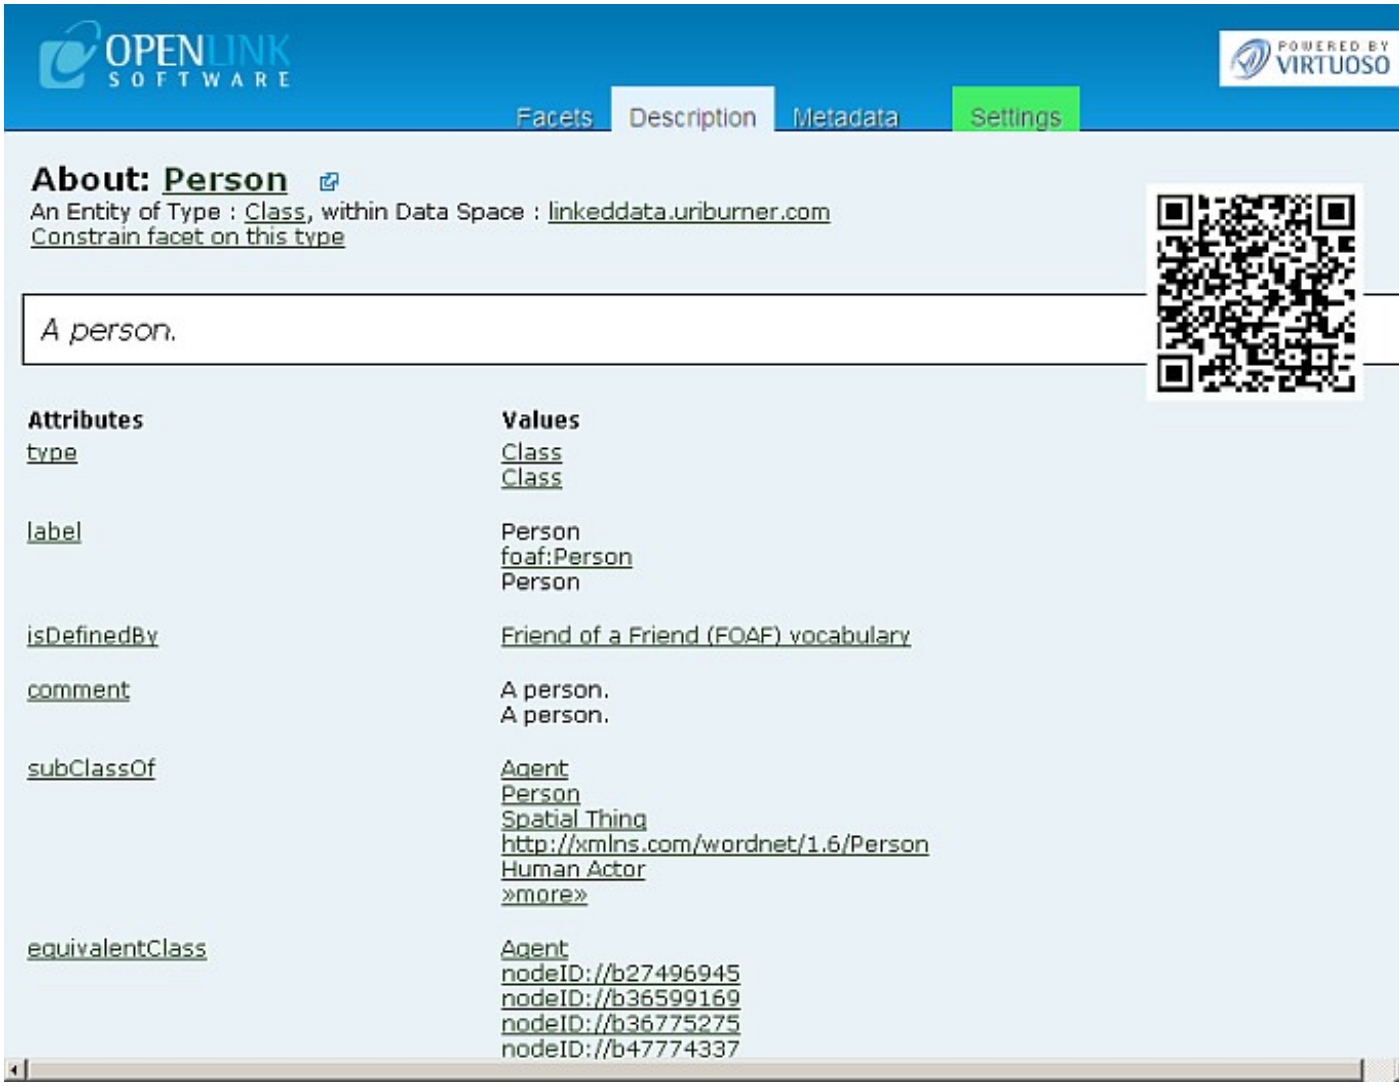
7. Click "Types" link shown at the right vertical Navigation
8. Results of the classes/properties should be returned:

Figure 16.121. Results of the classes/properties



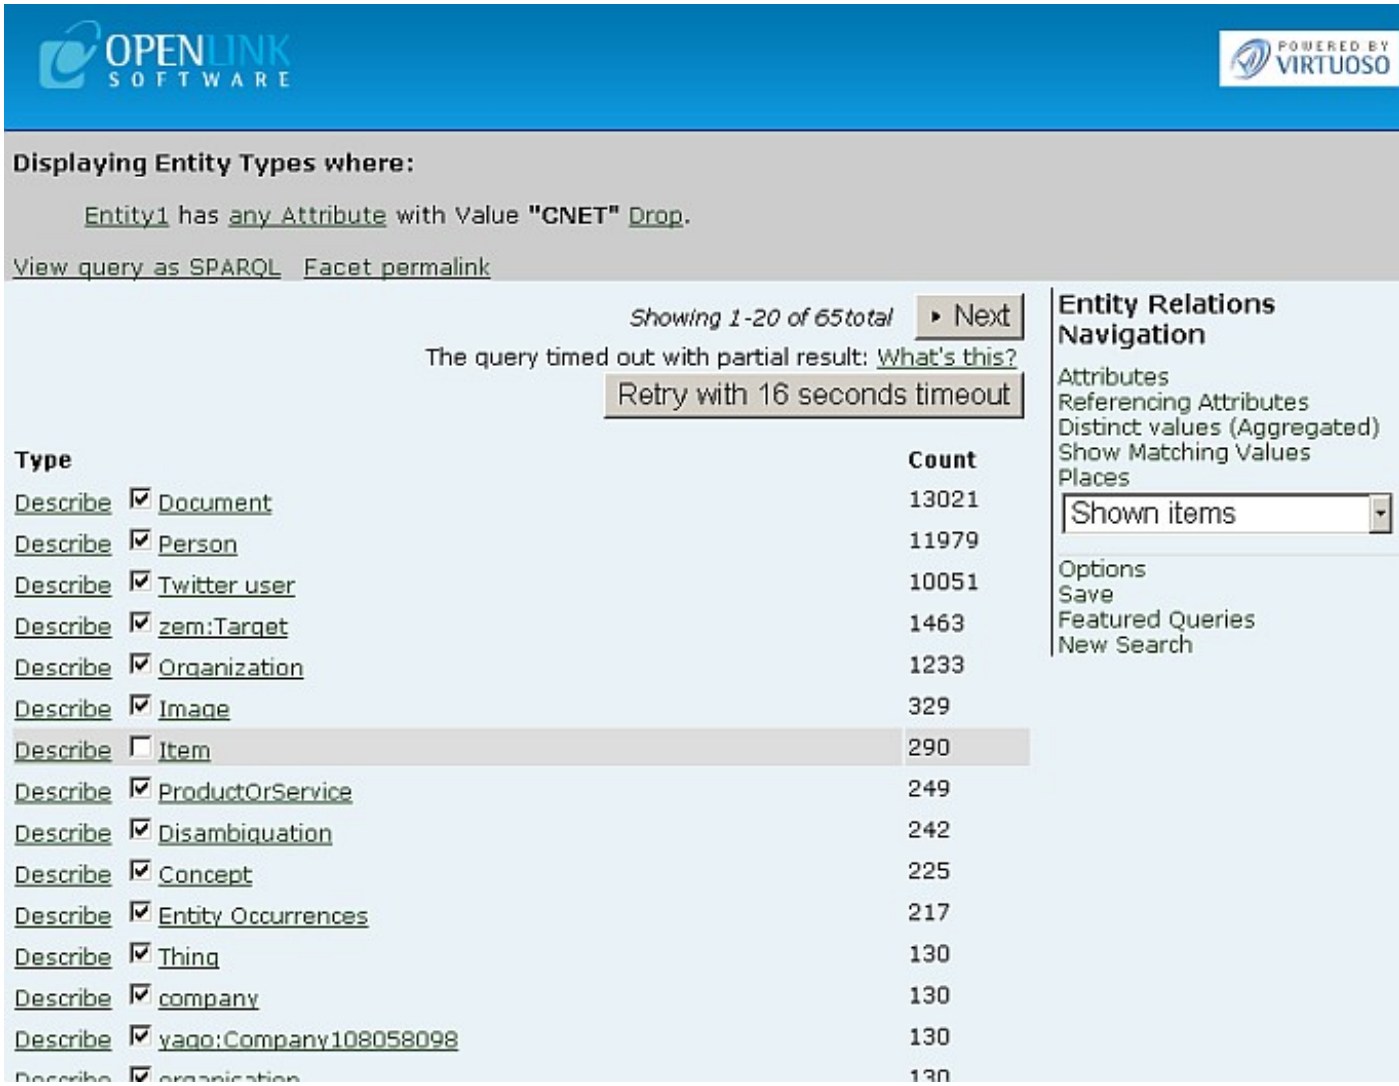
9. To get Type description, click "Describe" link for a given type, for ex. "Person".
10. A list of attributes and values should be presented for the given resource. Note that automatically is generated QRCode image for the described entity.

Figure 16.122. Results of the classes/properties



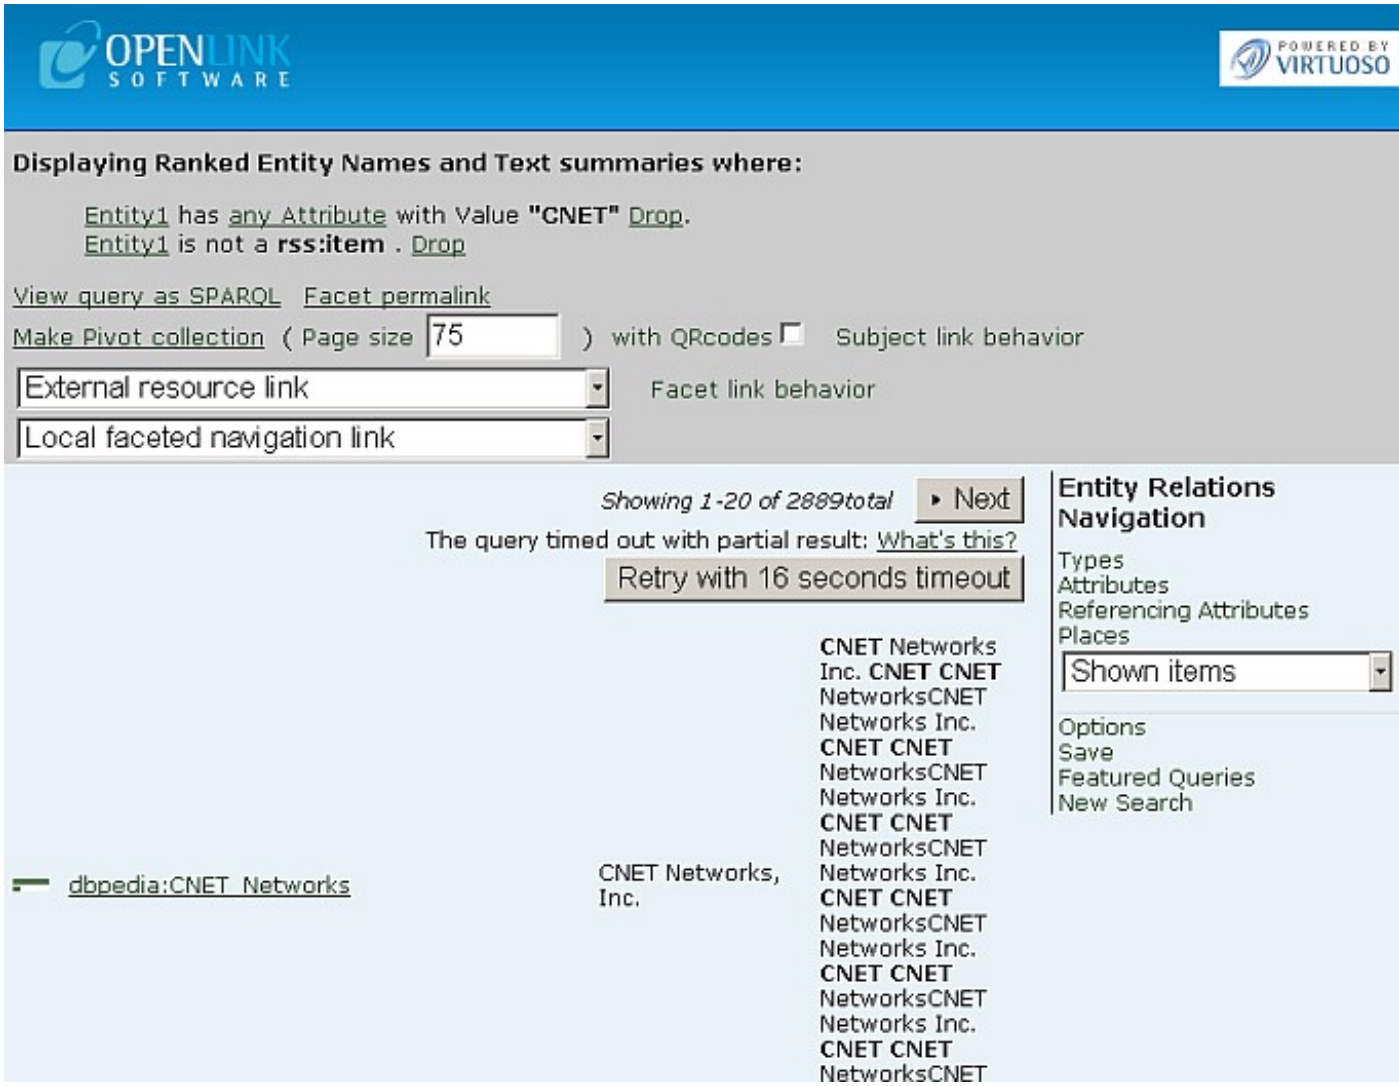
11. Return back to the Attributes list from above by going to the "Facets" tab.
12. To exclude a type, un-tick the checkbox associated with the type:

Figure 16.123. Exclude Type(s)



13. Click the Type URI link
14. Results of excluding the Type(s) should be shown:

Figure 16.124. Results of Excluded Type(s)



15. The Faceted Browser Web service endpoint can also be queried to obtain the same results:

```
$ more cnet.xml
<?xml version="1.0"?>
<query xmlns="http://openlinksw.com/services/facets/1.0" inference="" same-as="">
  <text>CNET</text>
  <view type="text" limit="20" offset=""/>
</query>

$ curl -H "Content-Type: text/xml" -d @cnet.xml  http://cname/fct/service
<fct:facets xmlns:fct="http://openlinksw.com/services/facets/1.0/">
<fct:sparql>    SELECT ?s1 as ?c1, (bif:search_excerpt (bif:vector ('CNET'), ?o1)) as ?c2, ?sc, ?r
<fct:time>16</fct:time>

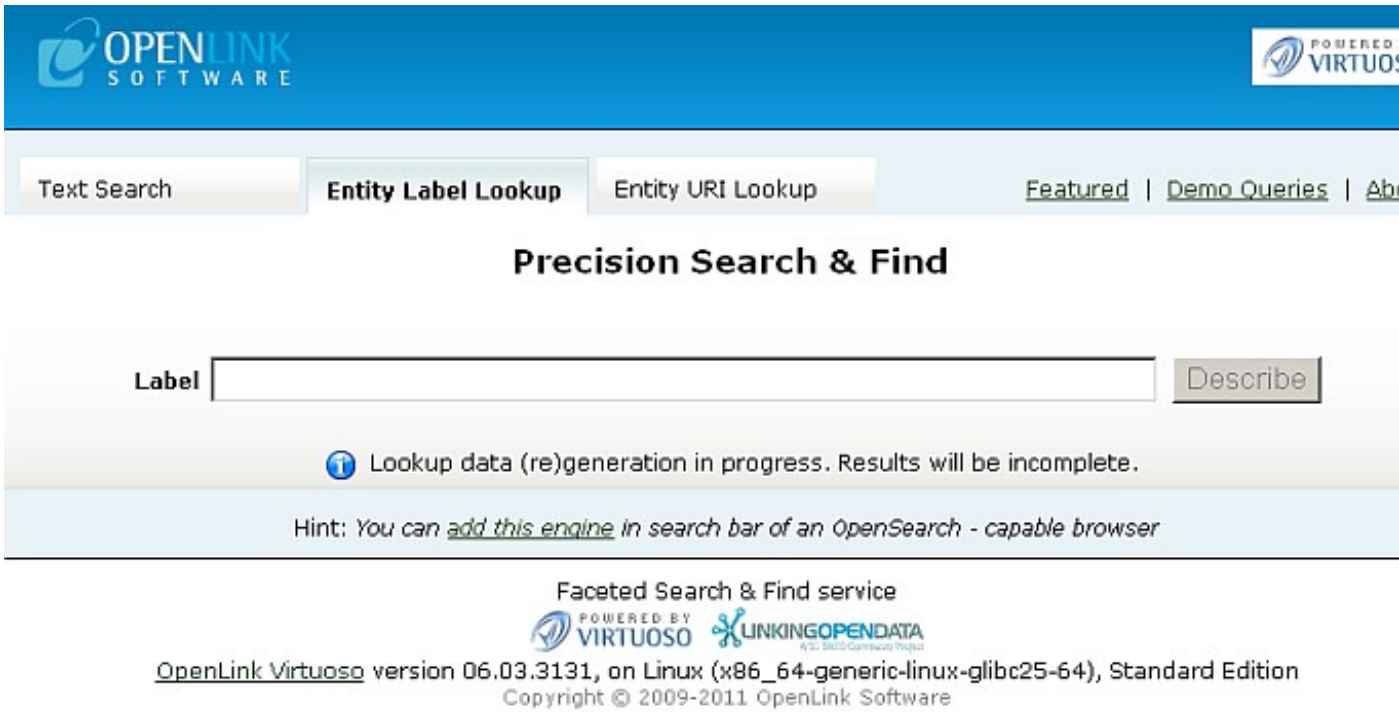
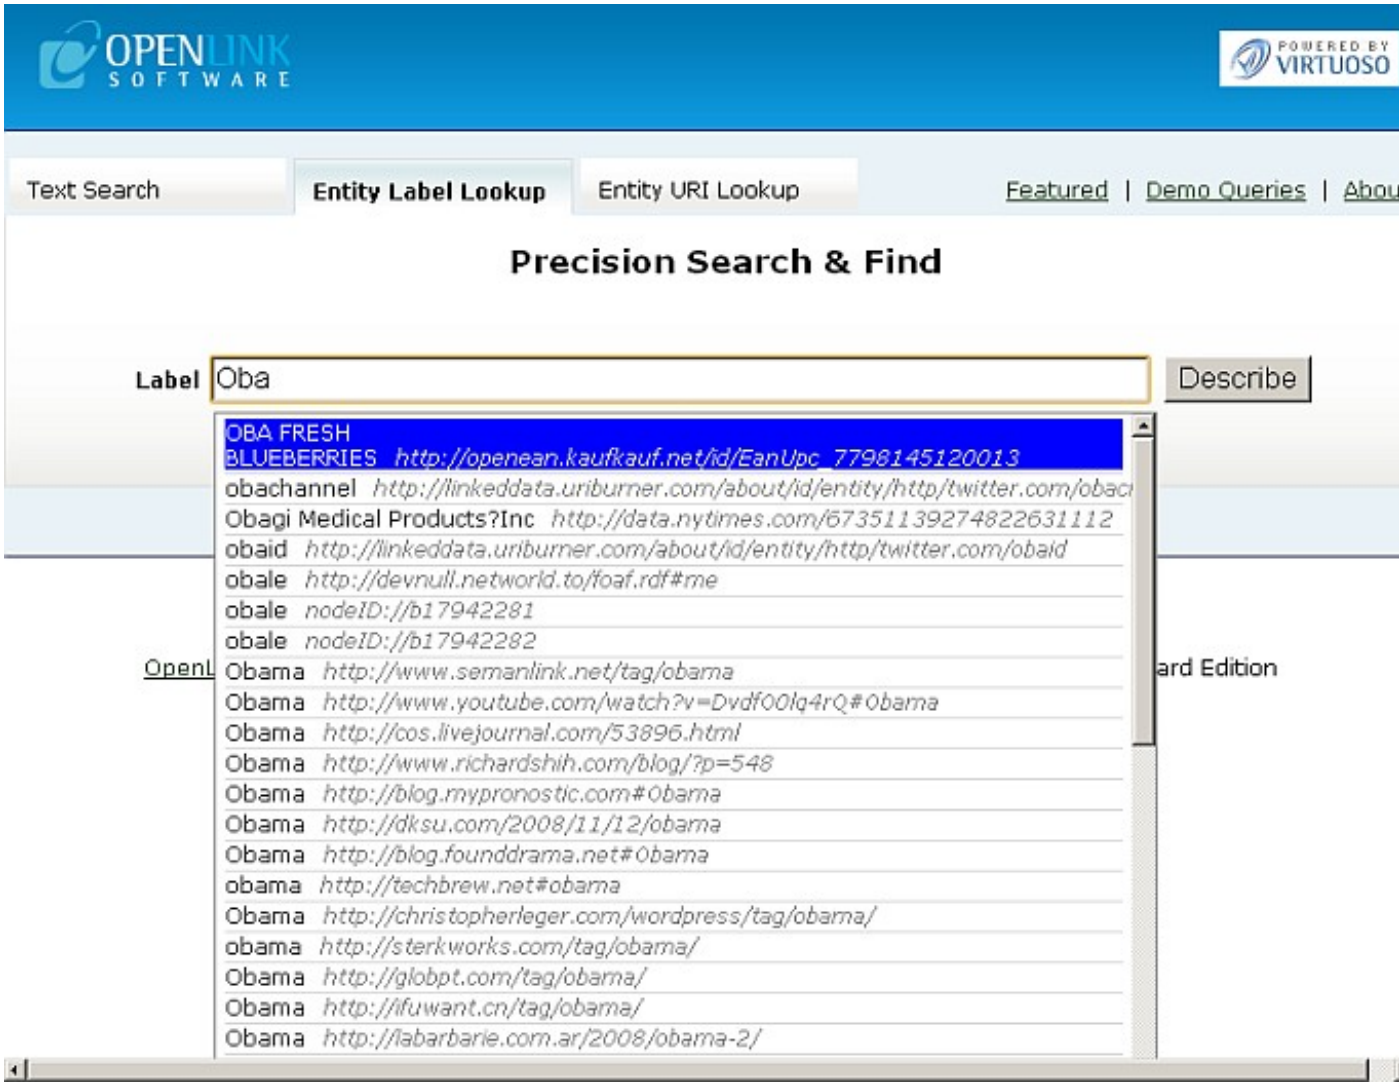
16. Click "New search" from the Entity Relations Navigation and go to "Entity Label Lookup" tab:

Figure 16.125. Query Faceted Browser Web service endpoint



17. In the Label auto-complete text box of the Entity Label Lookup tab, enter the name of an rdfs label to be Described:

Figure 16.126. Select a URI from the list of available Labels



18. Select a URI from the list of available Labels to obtain a description of the URI:

Figure 16.127. Select a URI from the list of available Labels

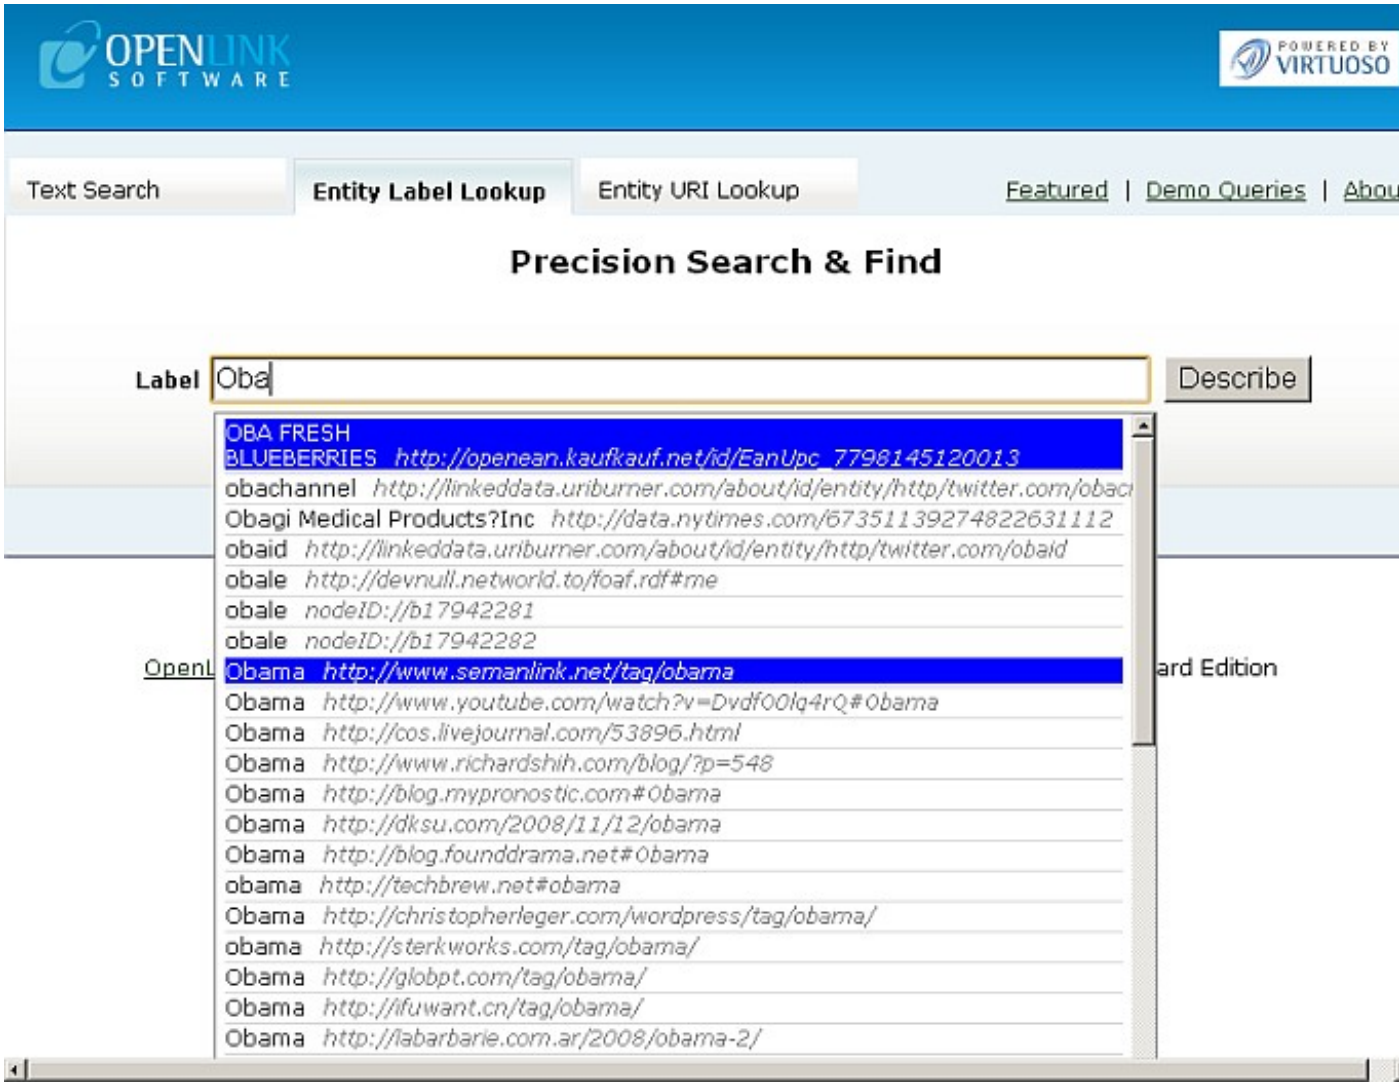


Figure 16.128. Select a URI from the list of available Labels

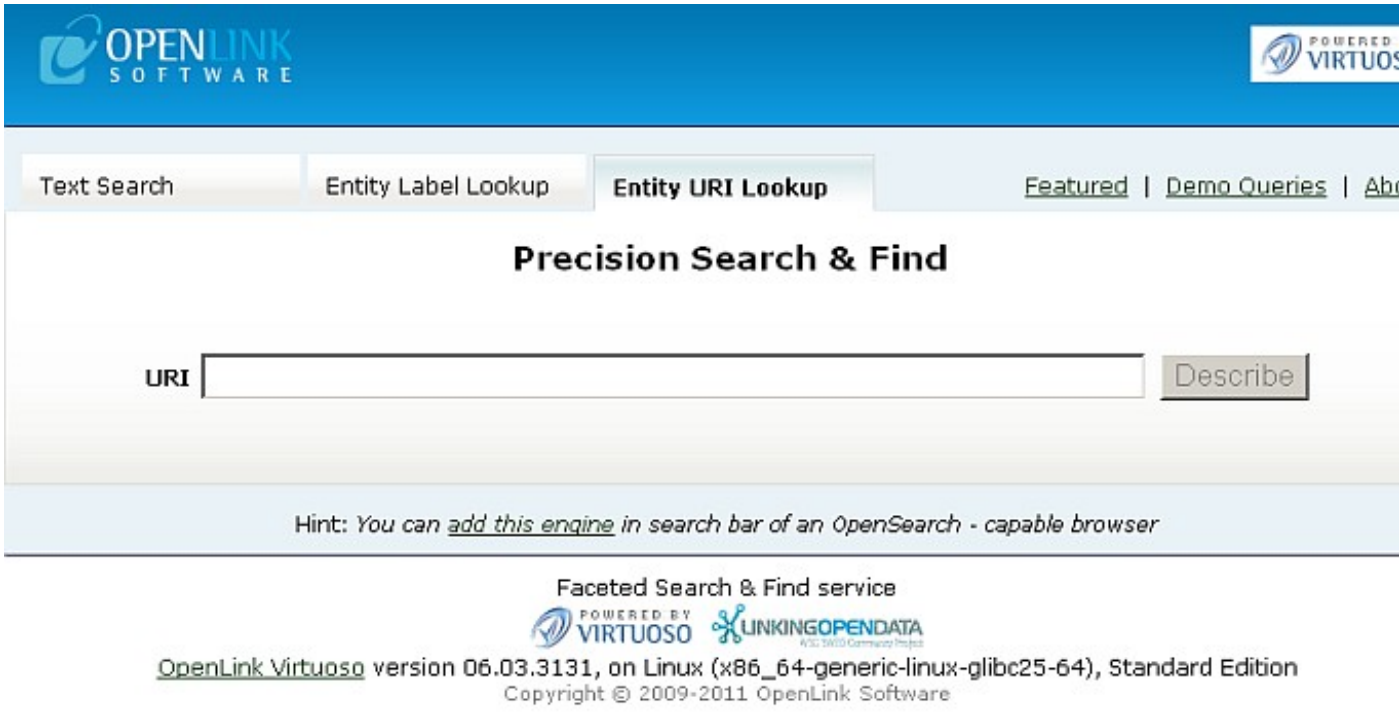
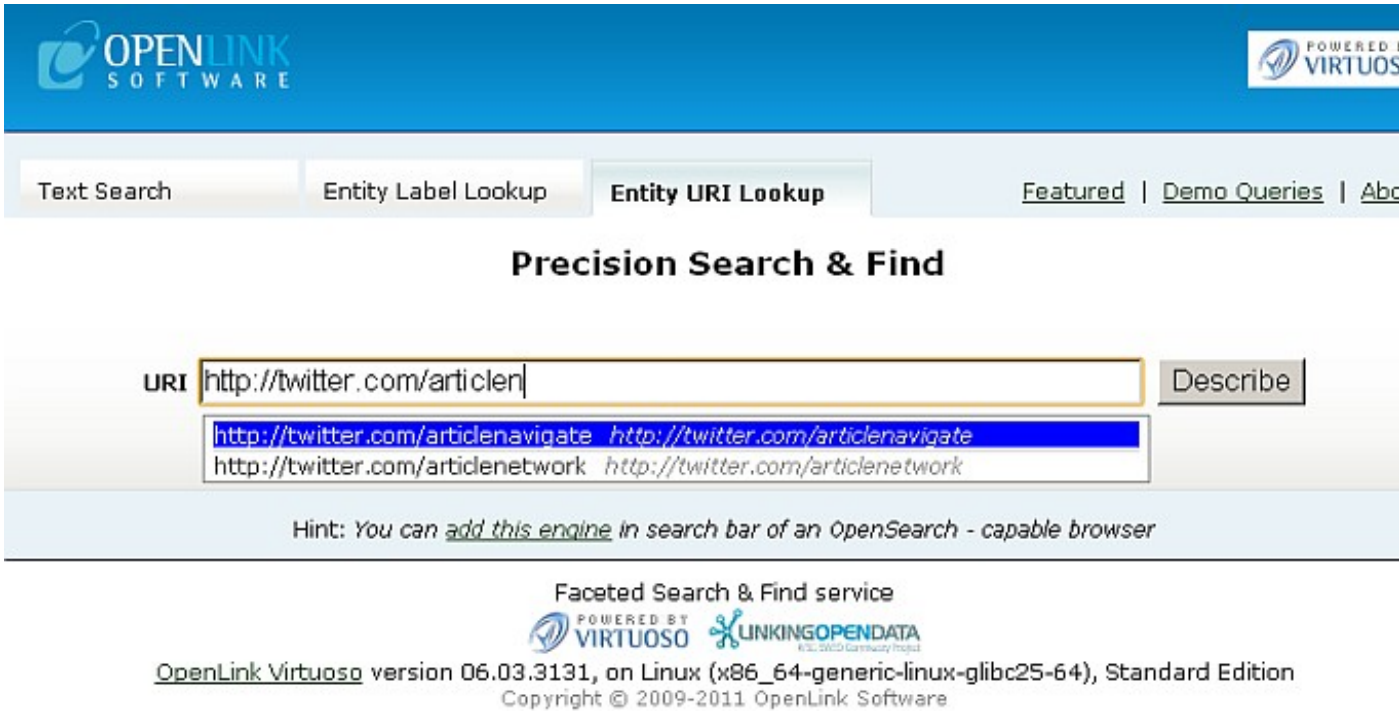
19. Click "Facets" and go to "Entity URI Lookup" tab:

Figure 16.129. Enter URI



20. In the URI auto-complete text box of the Entity URI Lookup tab enter the name URI to be Described:

Figure 16.130. Enter URI



21. Select a URI from the list of available Labels to obtain a description of the URI:

Figure 16.131. Obtain a description of the URI

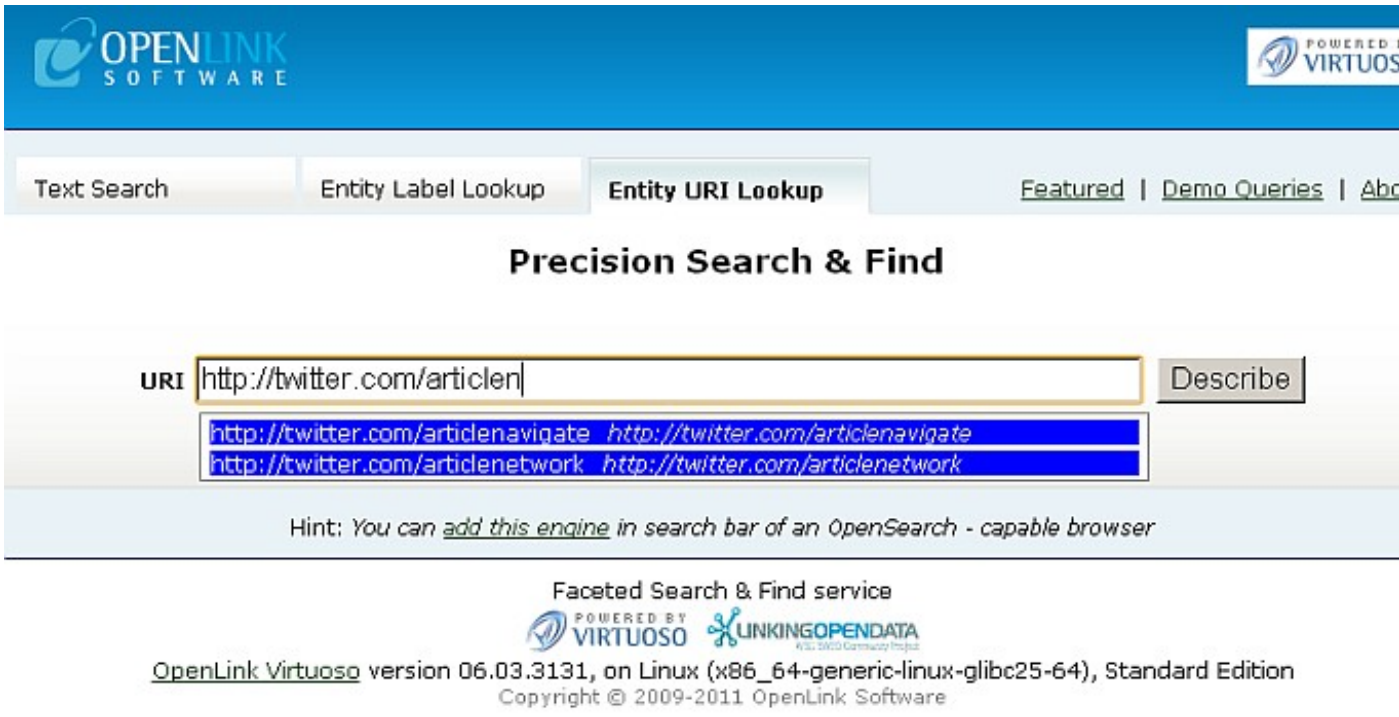


Figure 16.132. Obtain a description of the URI

22. If data is loaded into the quad store via DML functions (TTLP, RDF_LOAD_RDFXML etc.) the following procedure needs to run from

    isql

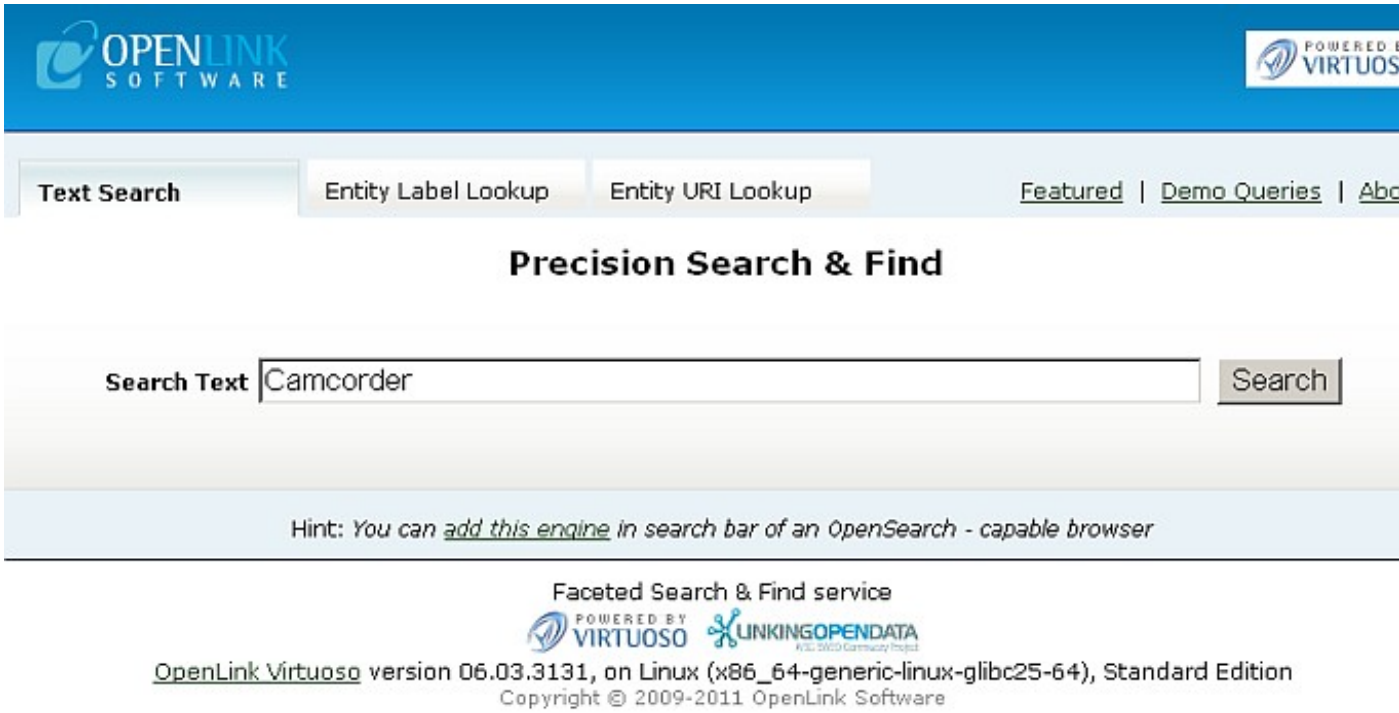
    to build the free text indexes required each time:

    ```
    VT_INC_INDEX_DB_DBA_RDF_OBJ ()
    ```

16.11.5. URI Labels

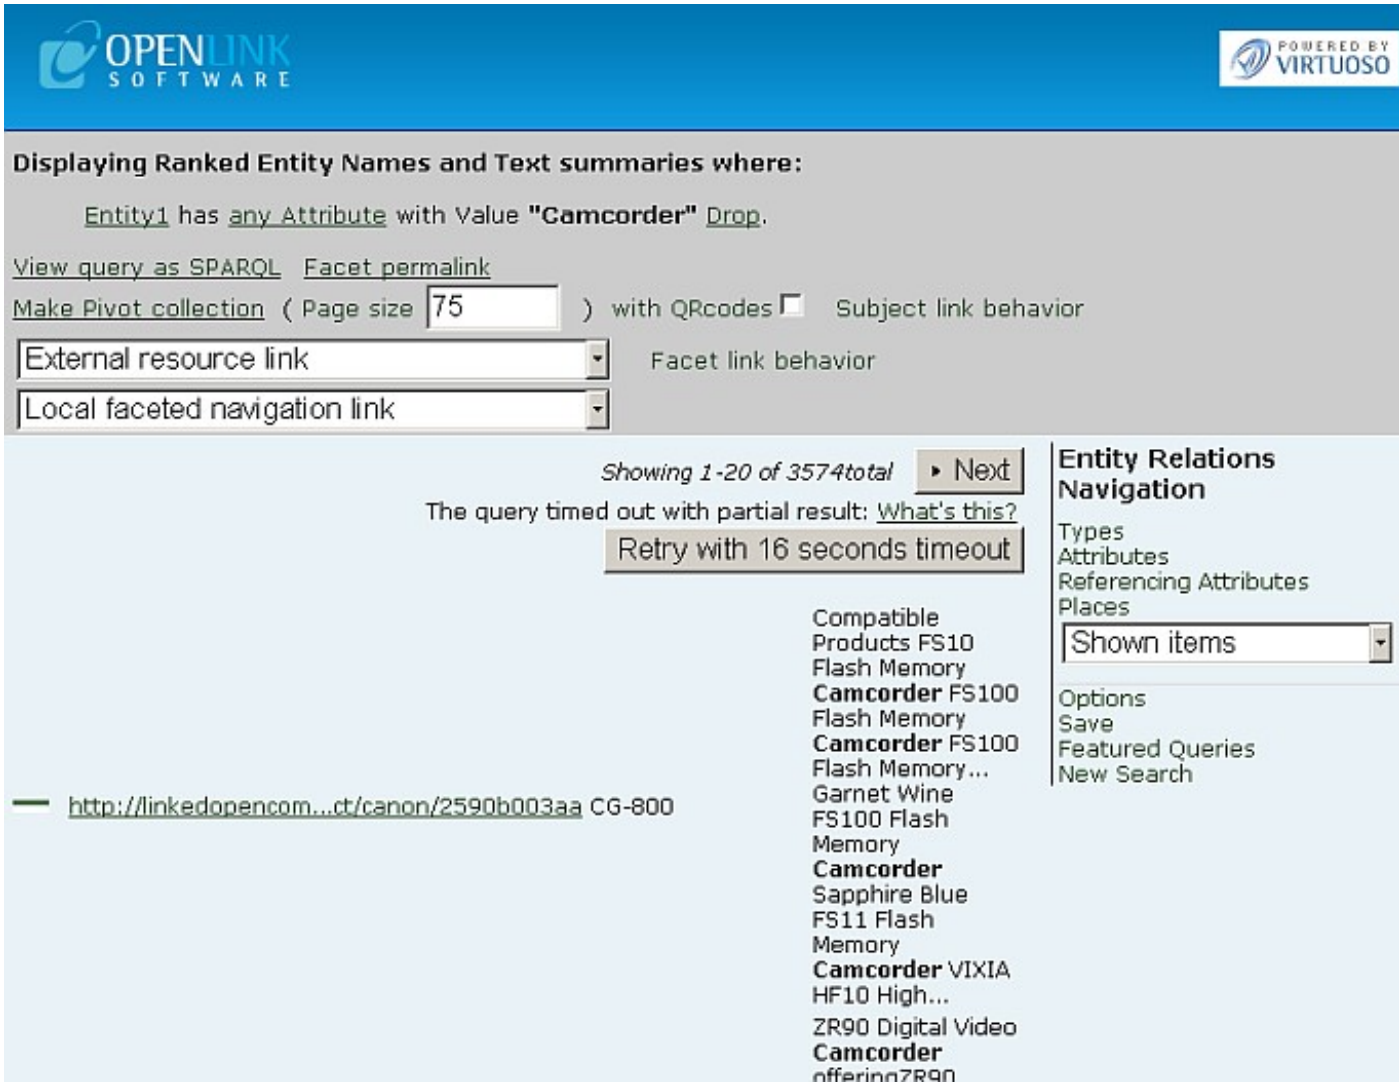
1. Go to http://cname/fct
2. Enter a free text search pattern (for example, "Camcorder" as consumer product), and click Search:

Figure 16.133. URI Labels



3. Your initial query results page will display a list of literal value snippets where for each URL will be displayed a label:

Figure 16.134. URI Labels



4. Click for ex. on the URL link of the first row result.
5. The product description page should be shown and a list of Attributes and Values will be presented. An URL label of the product also will be shown: "Charges Lithium Ion 800 series batteries":

Figure 16.135. URI Labels

Figure 16.136. URI Labels

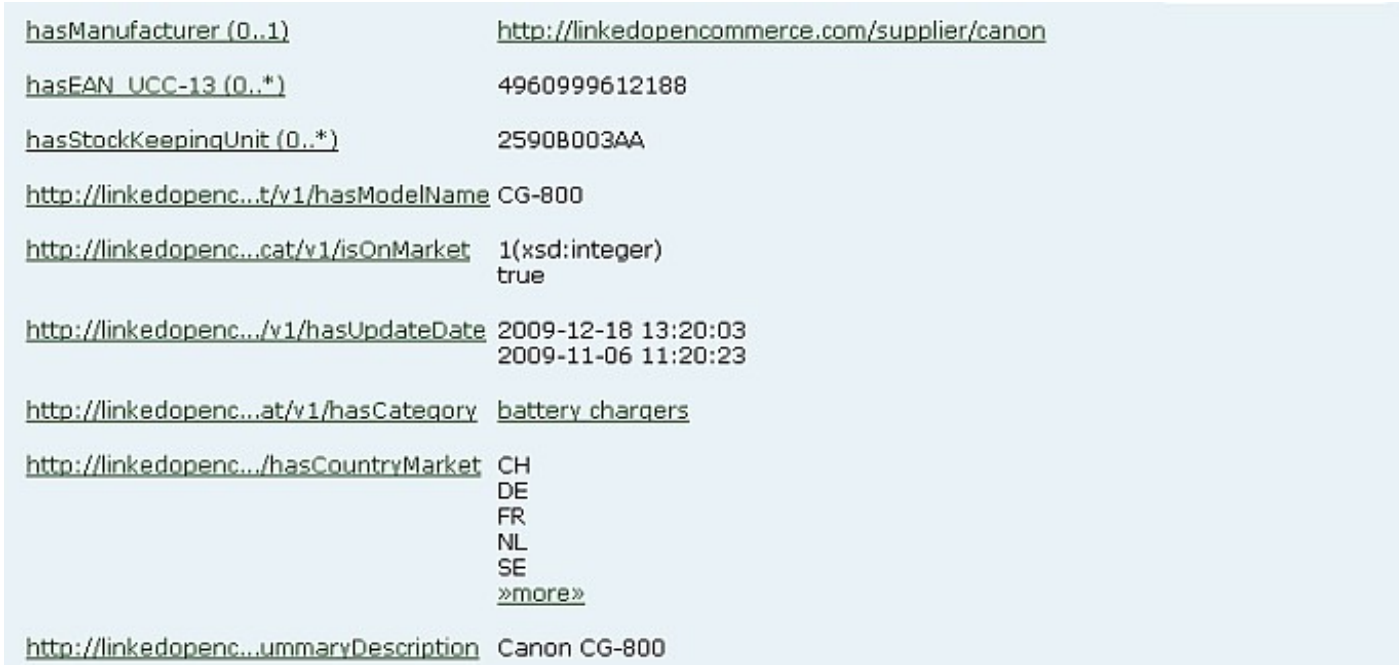


Figure 16.137. URI Labels

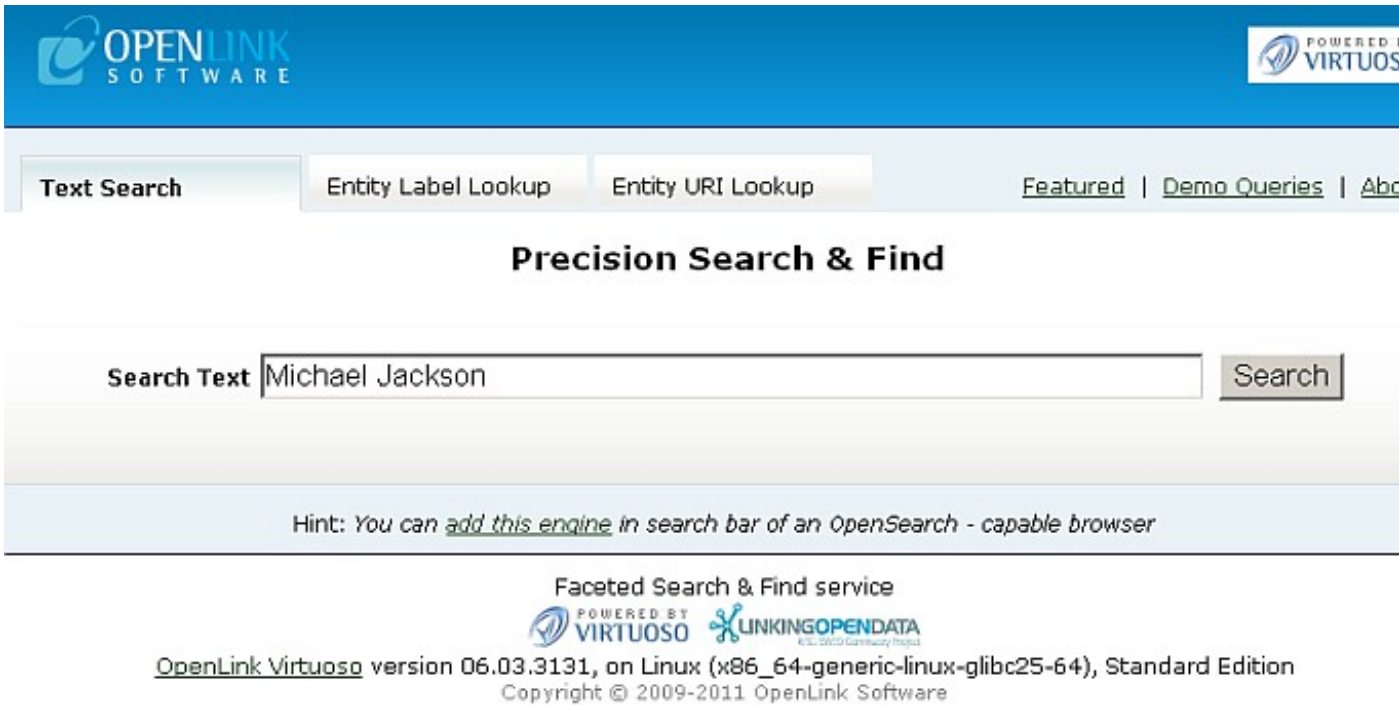
16.11.6. Usage Statistics

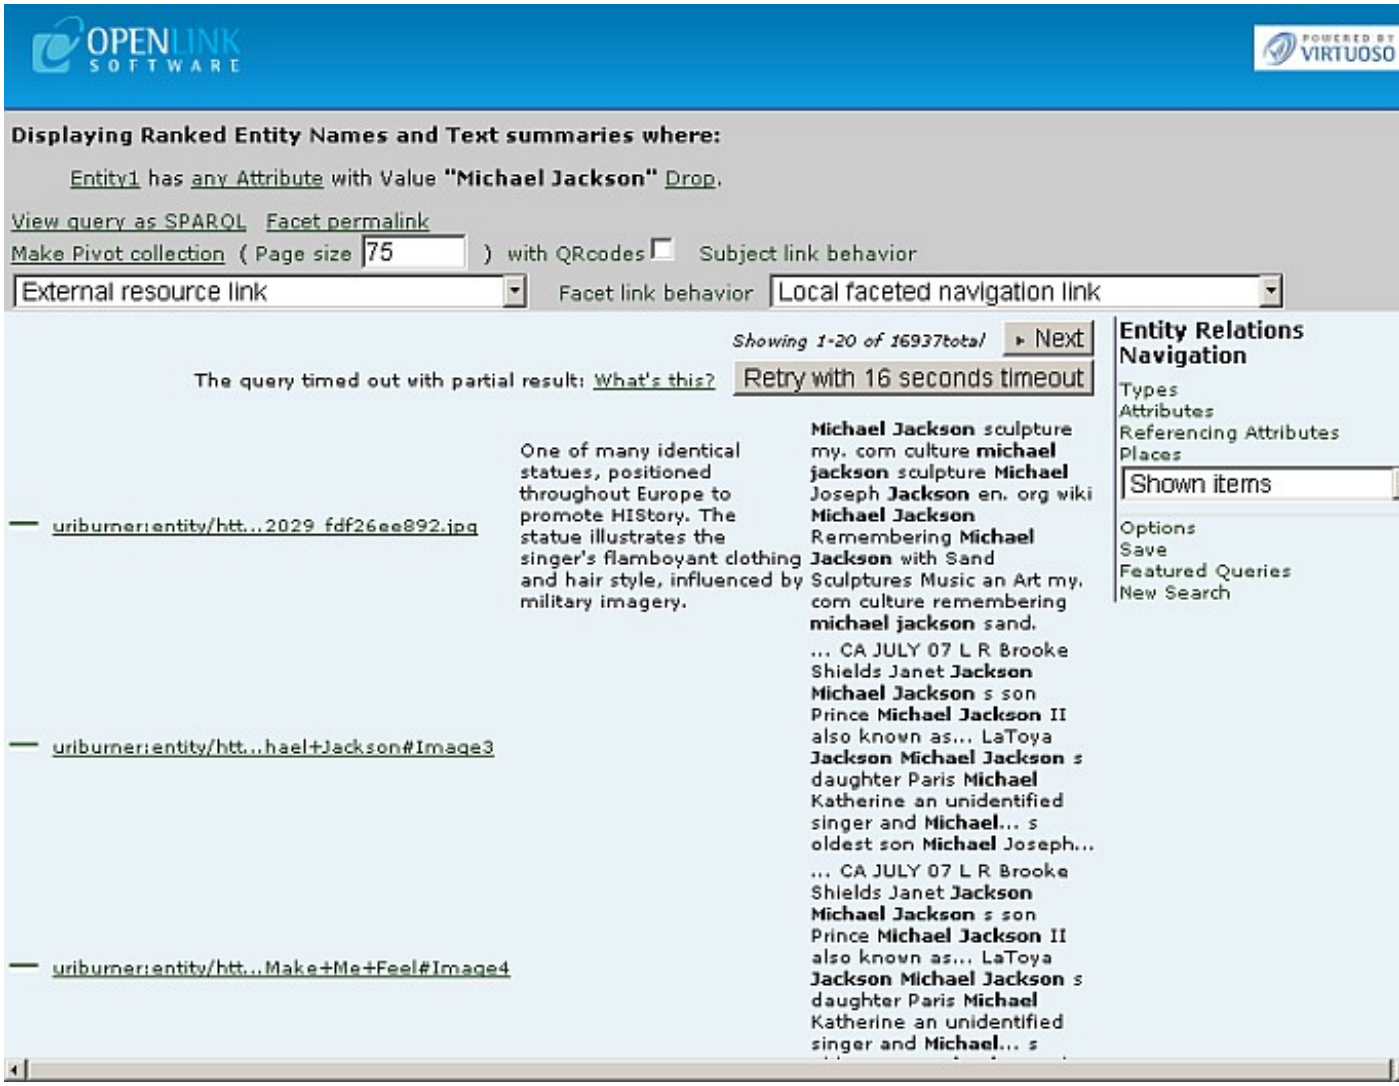
1. Use the Faceted Browser Search and Find User Interface to search for information on "Michael Jackson":

Figure 16.138. Usage Statistics



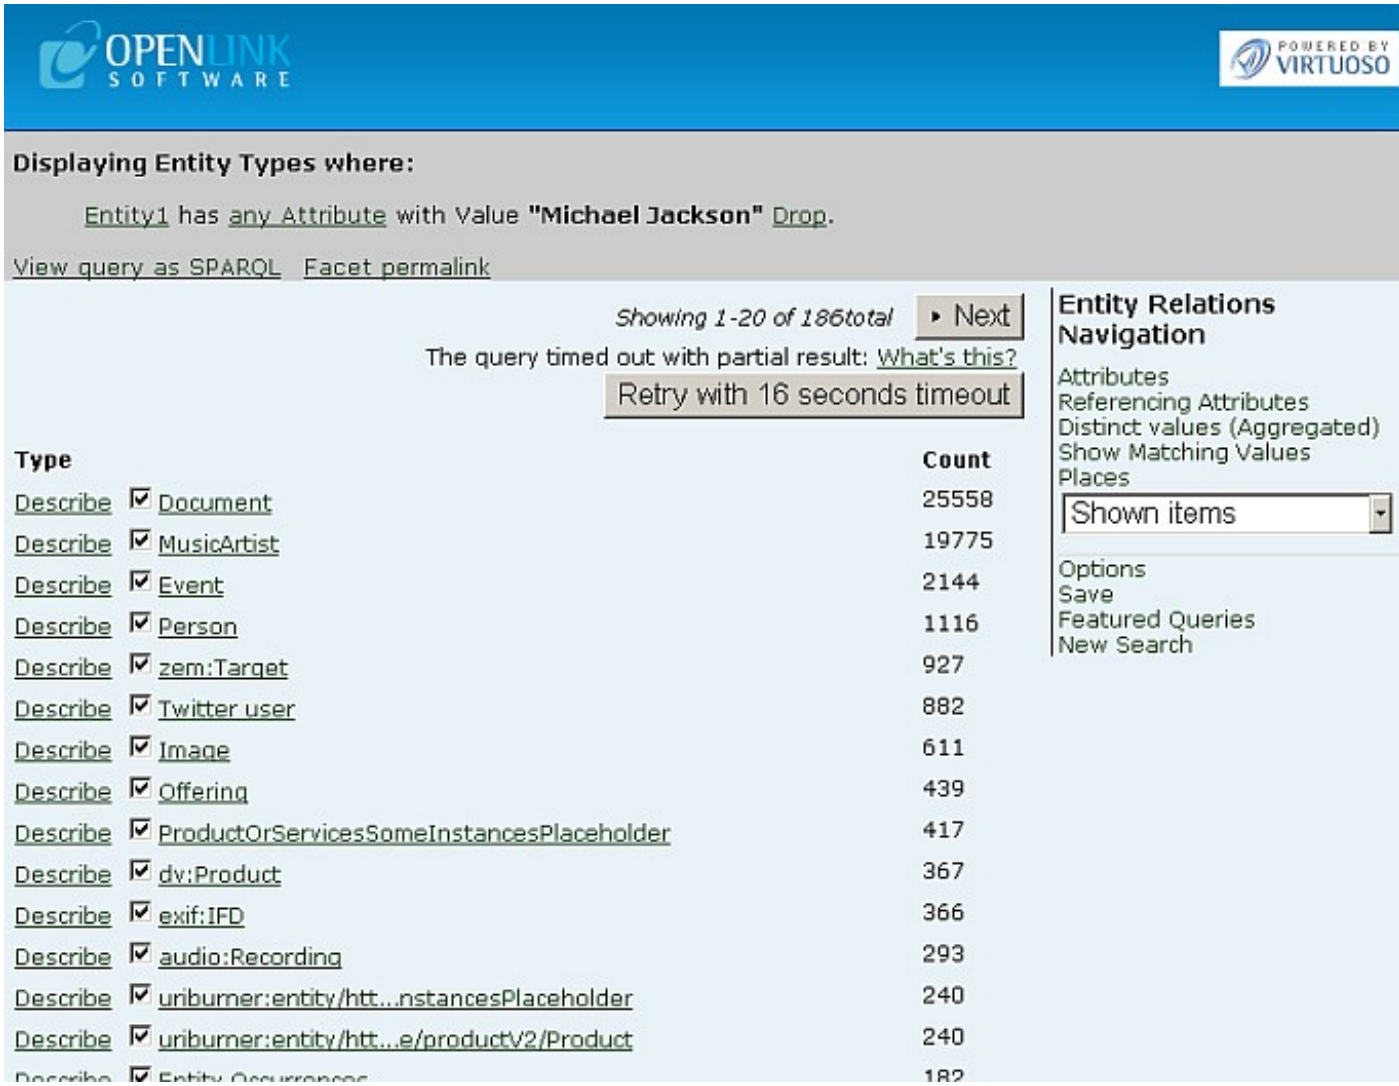
2. Results of the following form should be returned for the network resource data being fetched.

Figure 16.139. Usage Statistics



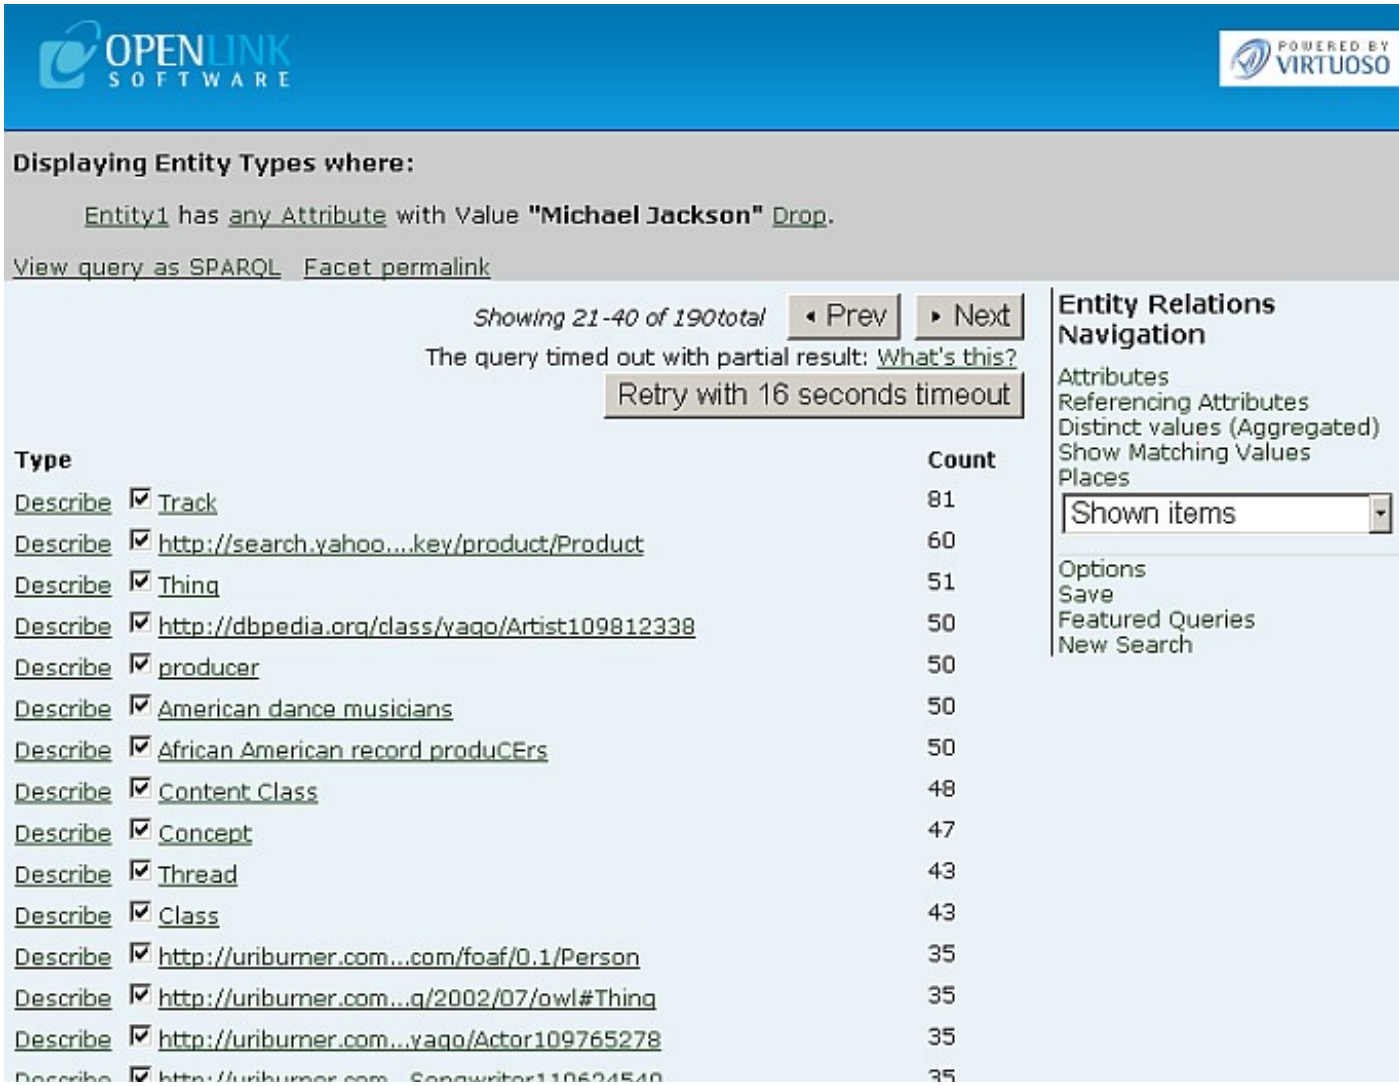
3. Click the "Types" link under "Entity Relations Navigation".
4. Results about "Michael Jackson" as Type/Label/Count list should be displayed:

Figure 16.140. Usage Statistics



5. You can navigate amongst the search results pages by using the "Prev" and "Next" buttons. Click for ex. "Next":

Figure 16.141. Usage Statistics



6. Click a type link, for ex.:

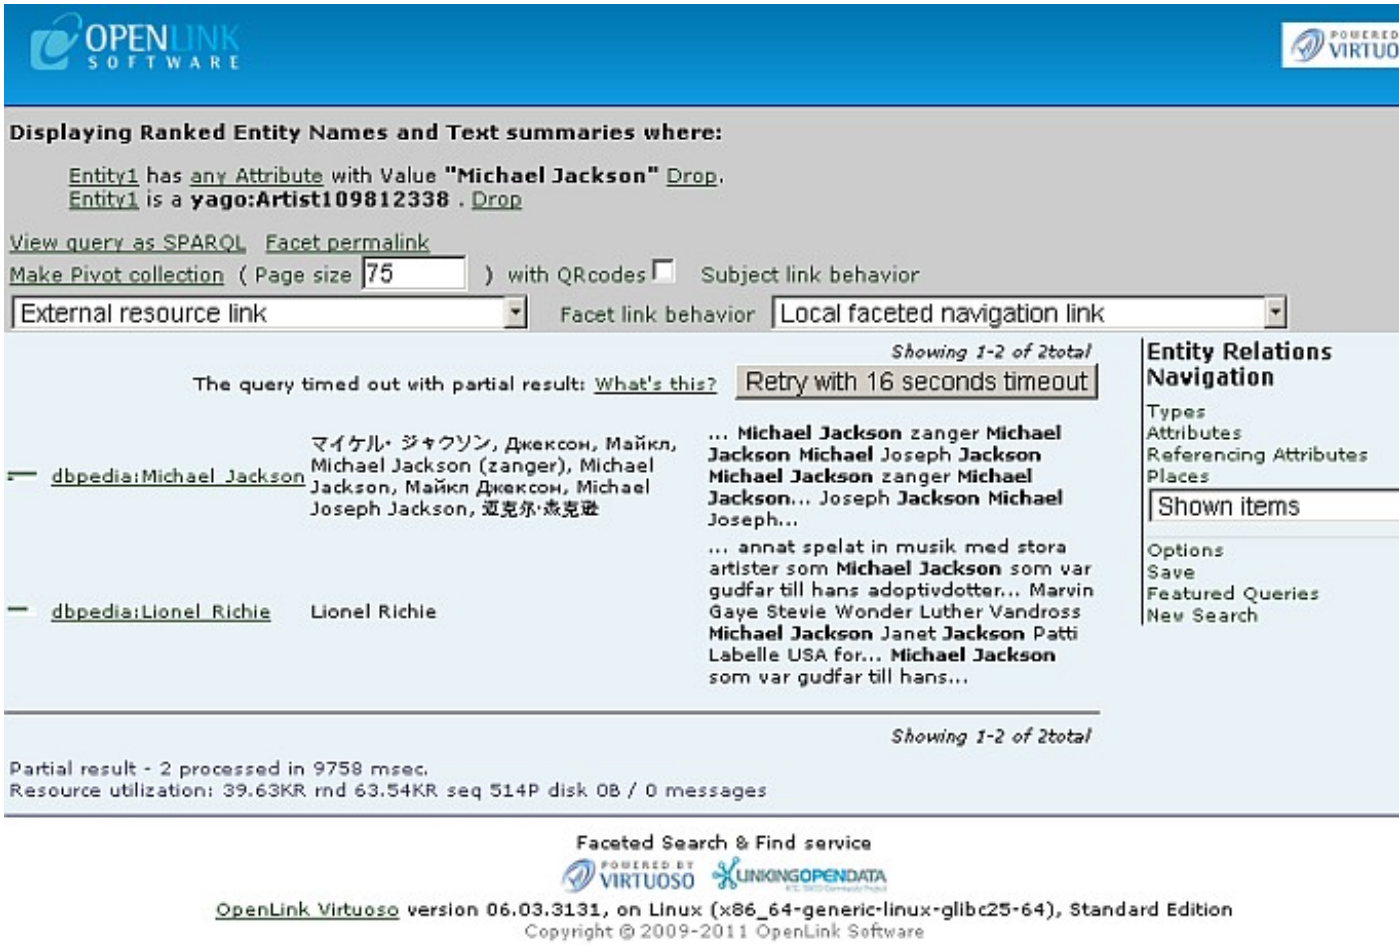
```
http://dbpedia.org/class/yago/Artist109812338
```

7. Should be shown type results and:

```
Displaying Ranked Entity Names and Text summaries where:

Entity1 has any Attribute with Value "Michael Jackson" Drop.
Entity1 is a yago:Artist109812338 . Drop
```

Figure 16.142. Usage Statistics



8. Click the link:

   ```
   dbpedia:Michael_Jackson
   ```

9. Results about "Michael Jackson" as Attribute/Value list should be presented:

Figure 16.143. Usage Statistics

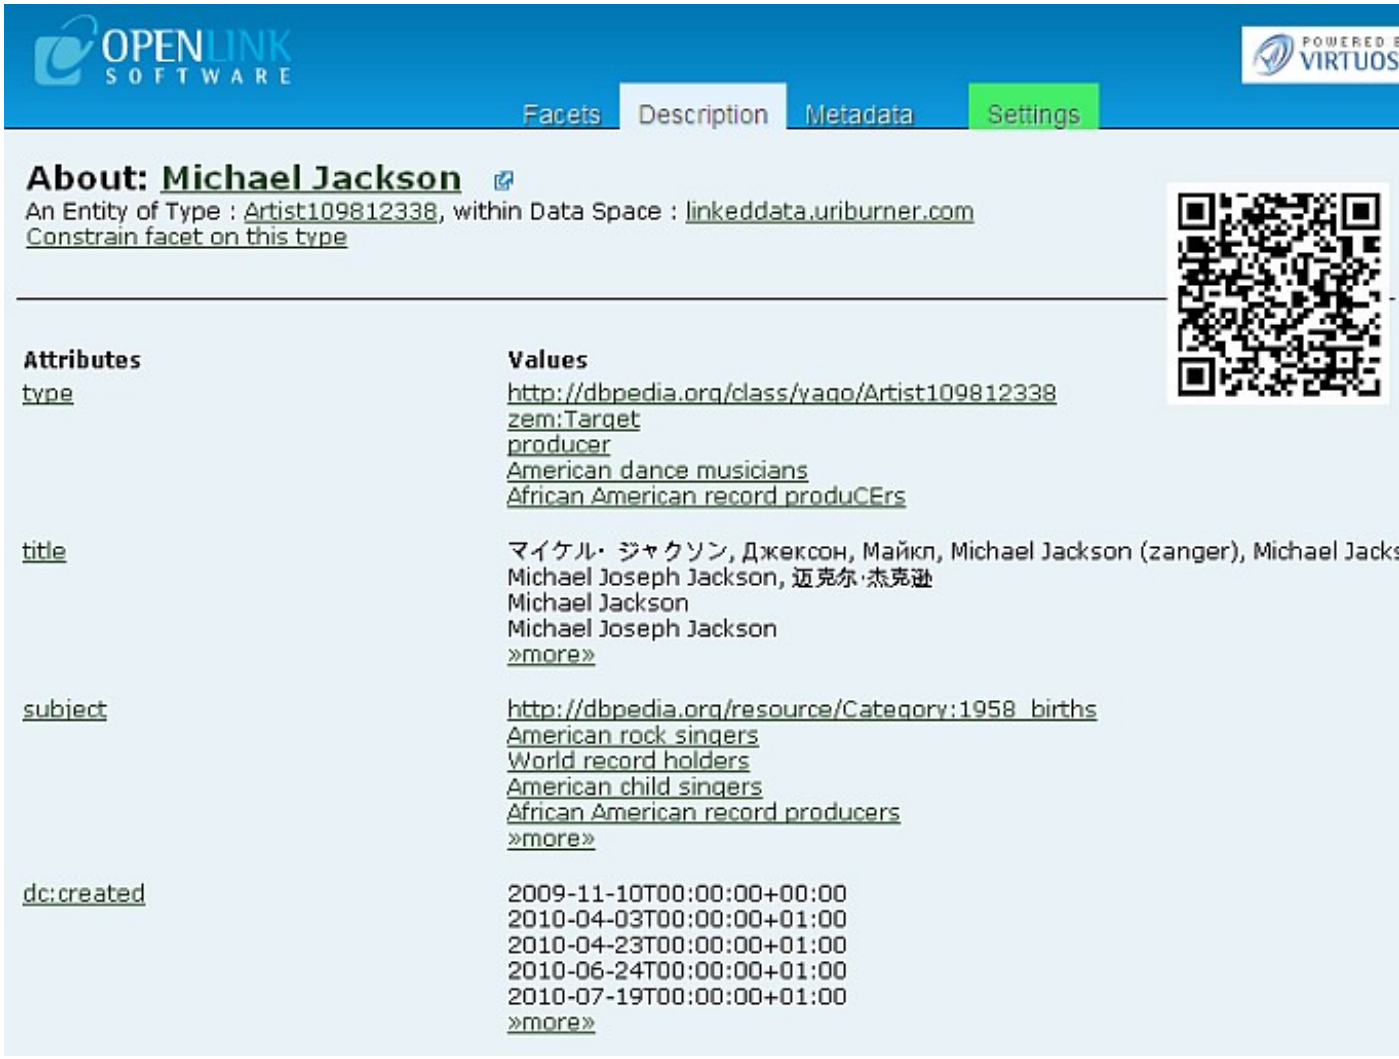


Figure 16.144. Usage Statistics

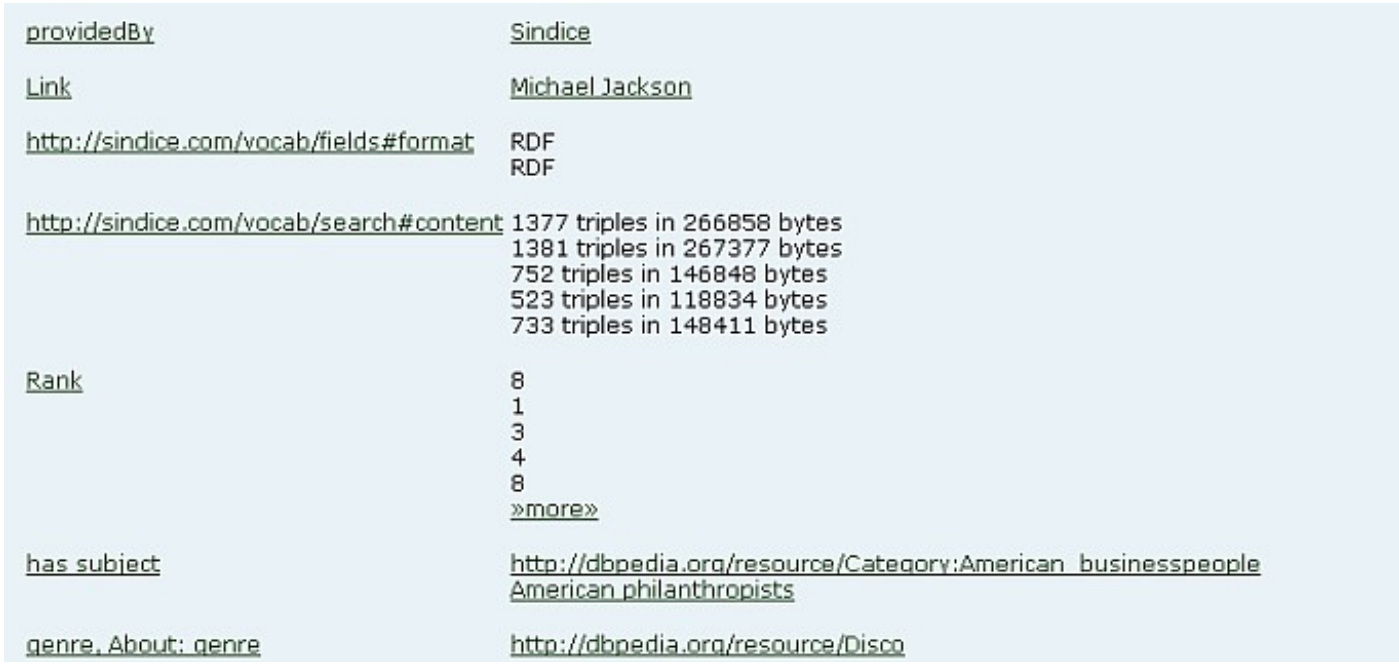

Figure 16.145. Usage Statistics

Figure 16.146. Usage Statistics

10. You can navigate amongst the search results pages by using the "First", "Prev", "Next" and "Last" buttons. Click for ex. "Last":

Figure 16.147. Usage Statistics

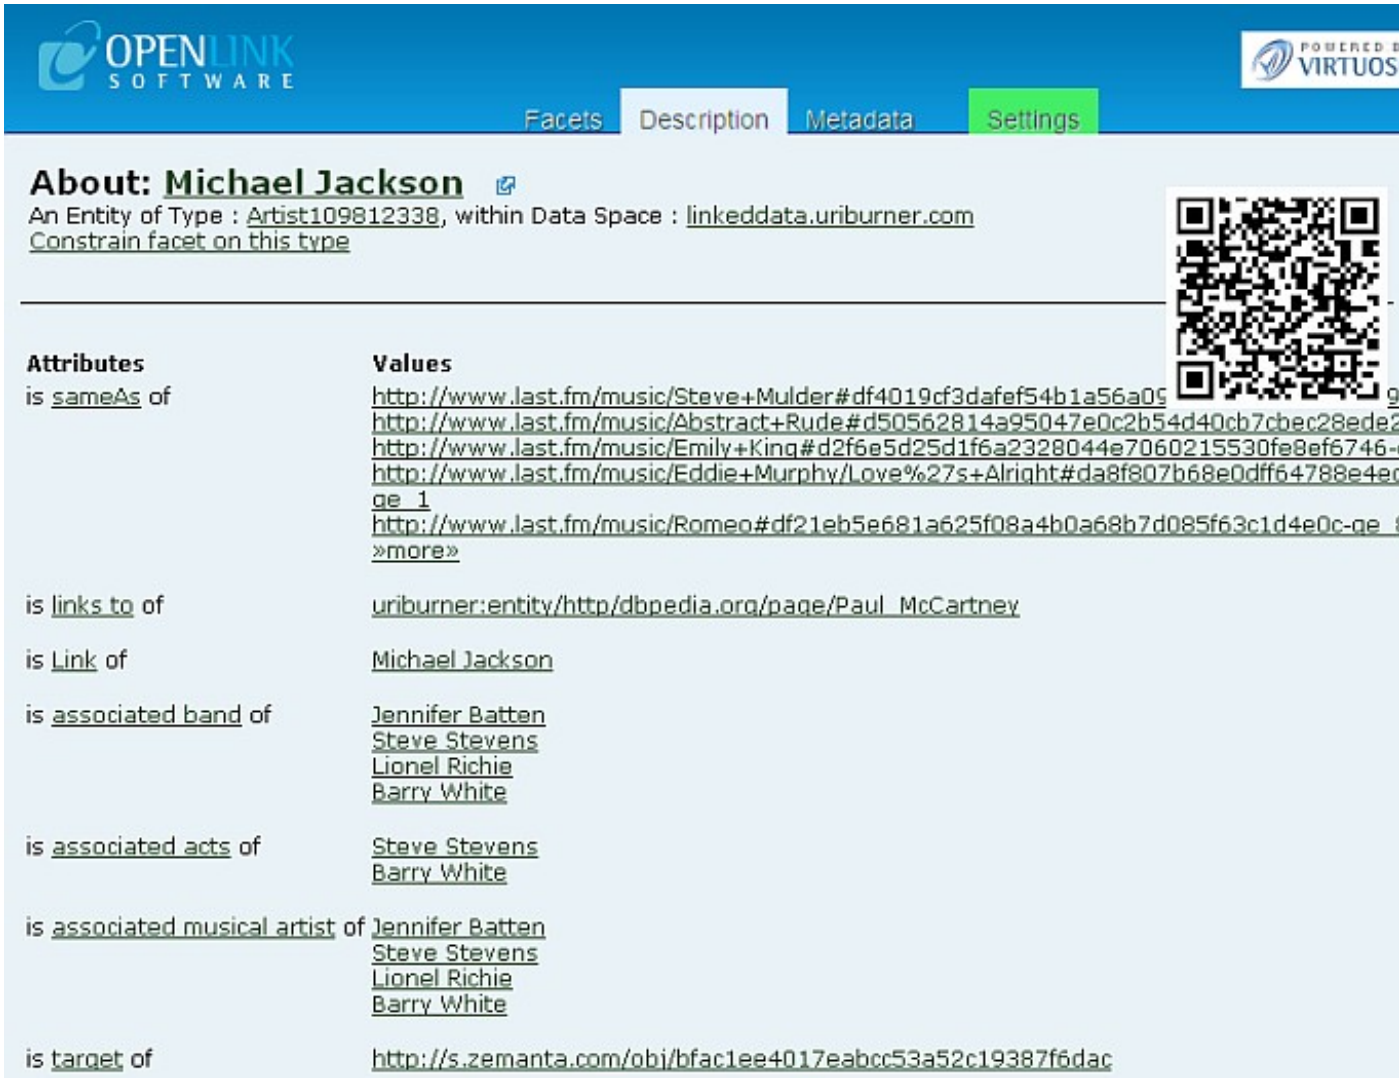

Figure 16.148. Usage Statistics

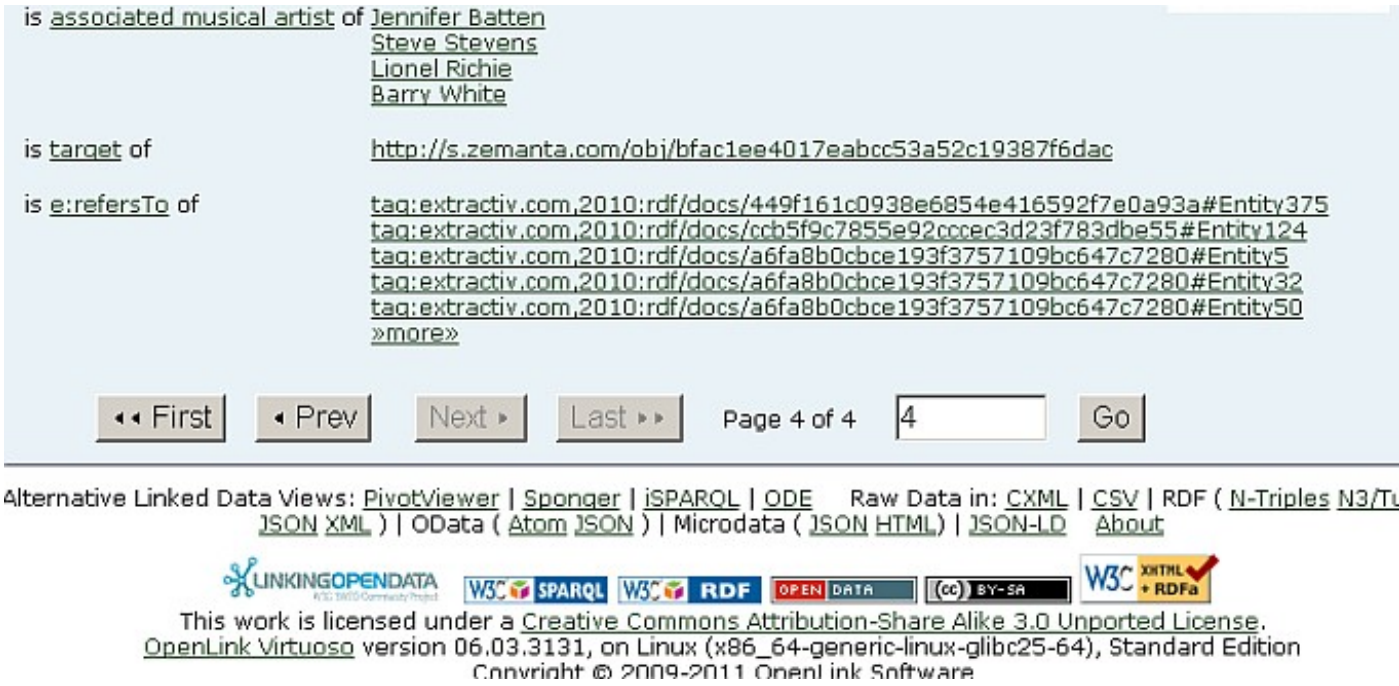
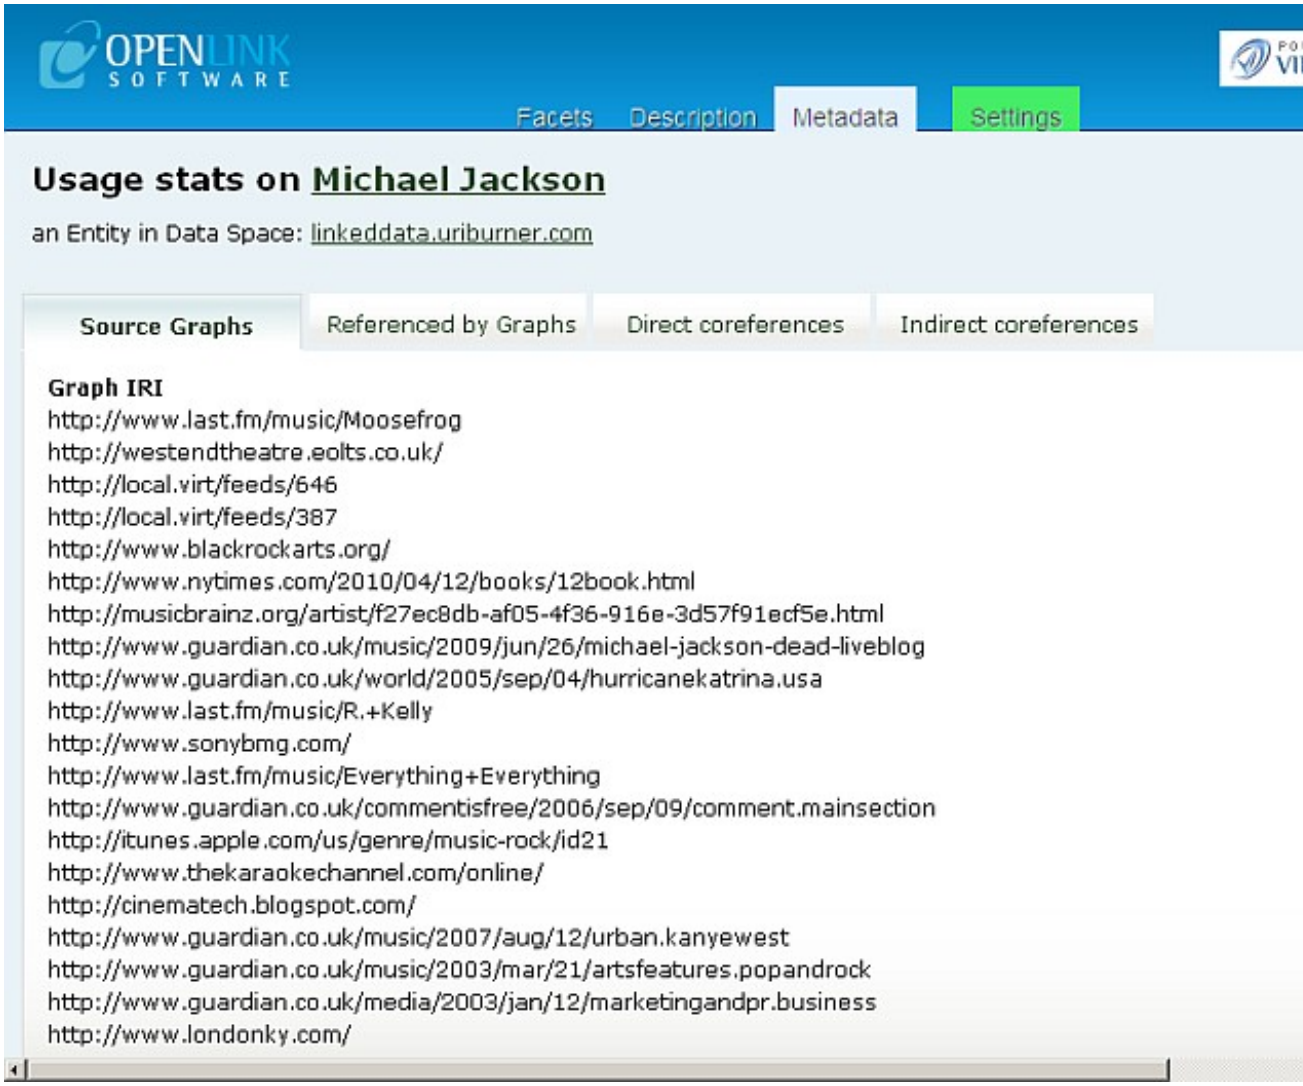


11. "Metadata" tab.
12. Results of usage statistics for "Michael Jackson" grouped in 4 tabs should be shown:

a. Referenced by Graphs: shows how many times the URI is found as subject in the relevant graph(s):

```
SPARQL
SELECT ?g count (*)
where
  {
    graph ?g { <URI> ?p ?o }
  }
group by ?g
order by desc 2
limit 20
```

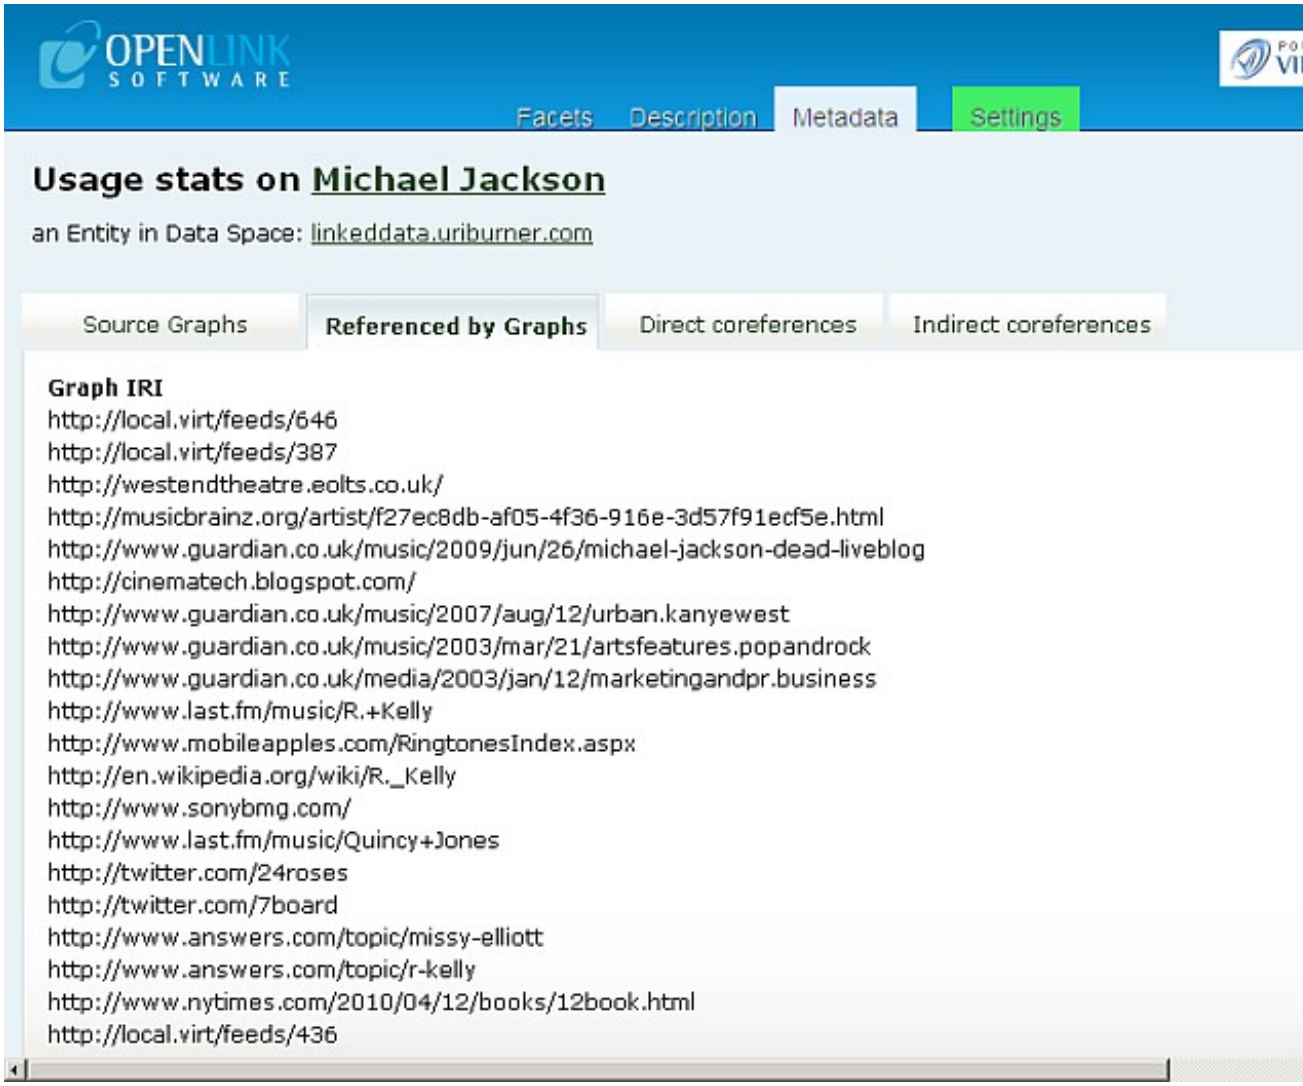
Figure 16.149. Usage Statistics



b. Source Graphs: shows how many times the URI is found as object in the relevant graph(s):

```
SPARQL
SELECT ?g count (*)
where
  {
    graph ?g { ?s ?p <URI>  }
  }
group by ?g
order by desc 2
limit 20
```

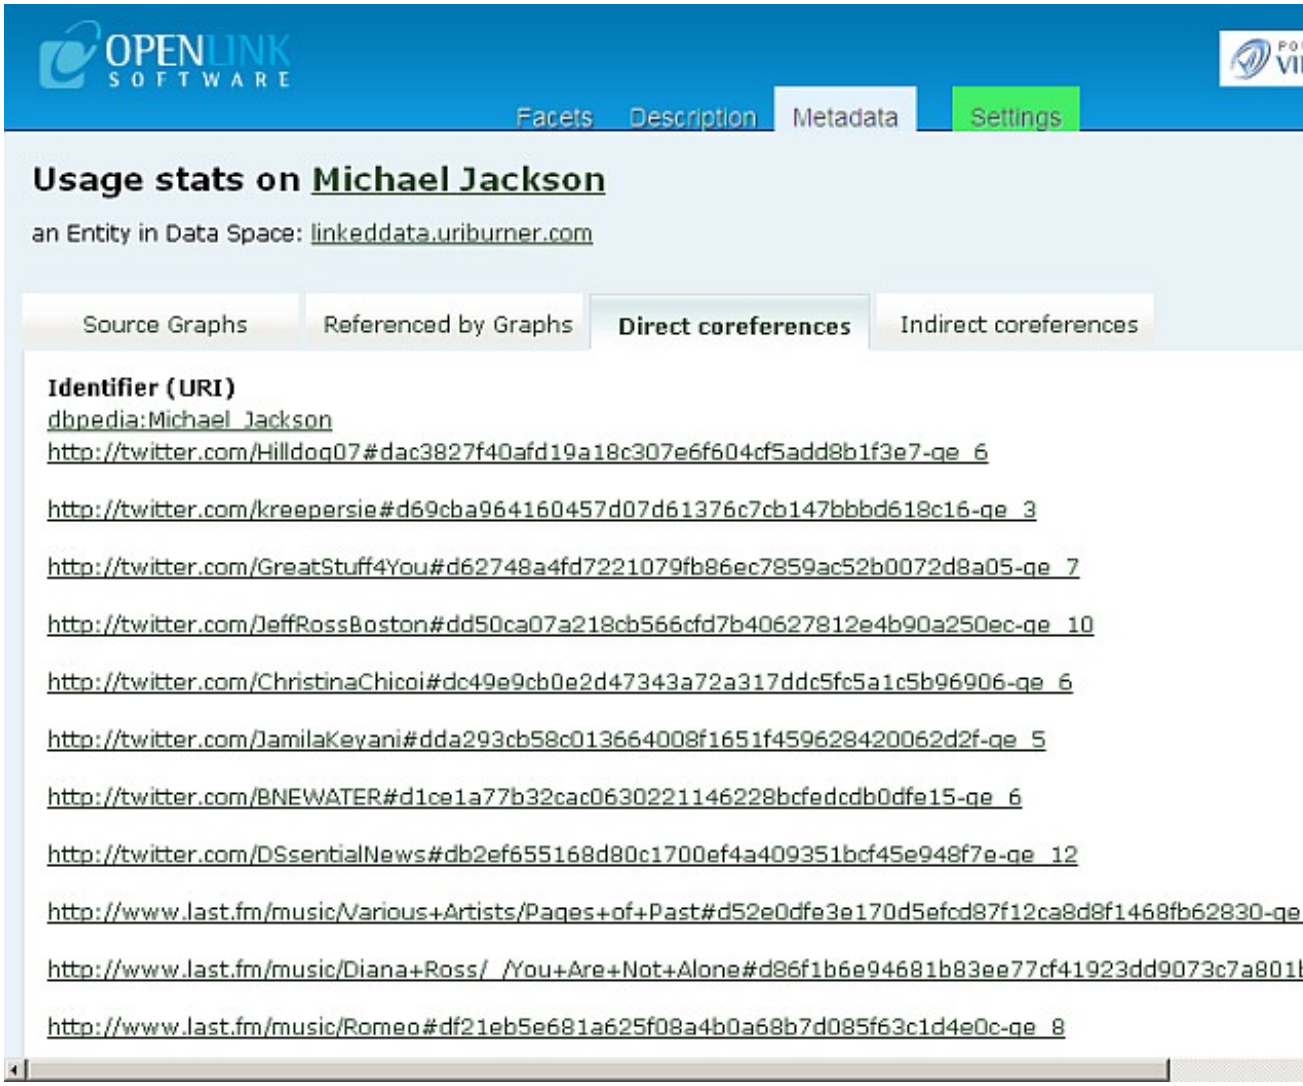
Figure 16.150. Usage Statistics



c. Direct co-references: shows results as subject and calculated rank, based on running transitive closure over owl:sameAs of the URI in subject or object:

```
SPARQL
SELECT ?syn ( sql:rnk_scale (<LONG::IRI_RANK> (?syn)))
where
  {
    { SELECT ?s ?syn
      where
       {
         {?syn owl:sameAs ?s } union {?s owl:sameAs ?syn}
       }
    }
    option (transitive, t_distinct, t_min (0), T_in (?s), t_out (?syn)) . filter (!isliter
  }
order by desc 2
limit 20
```

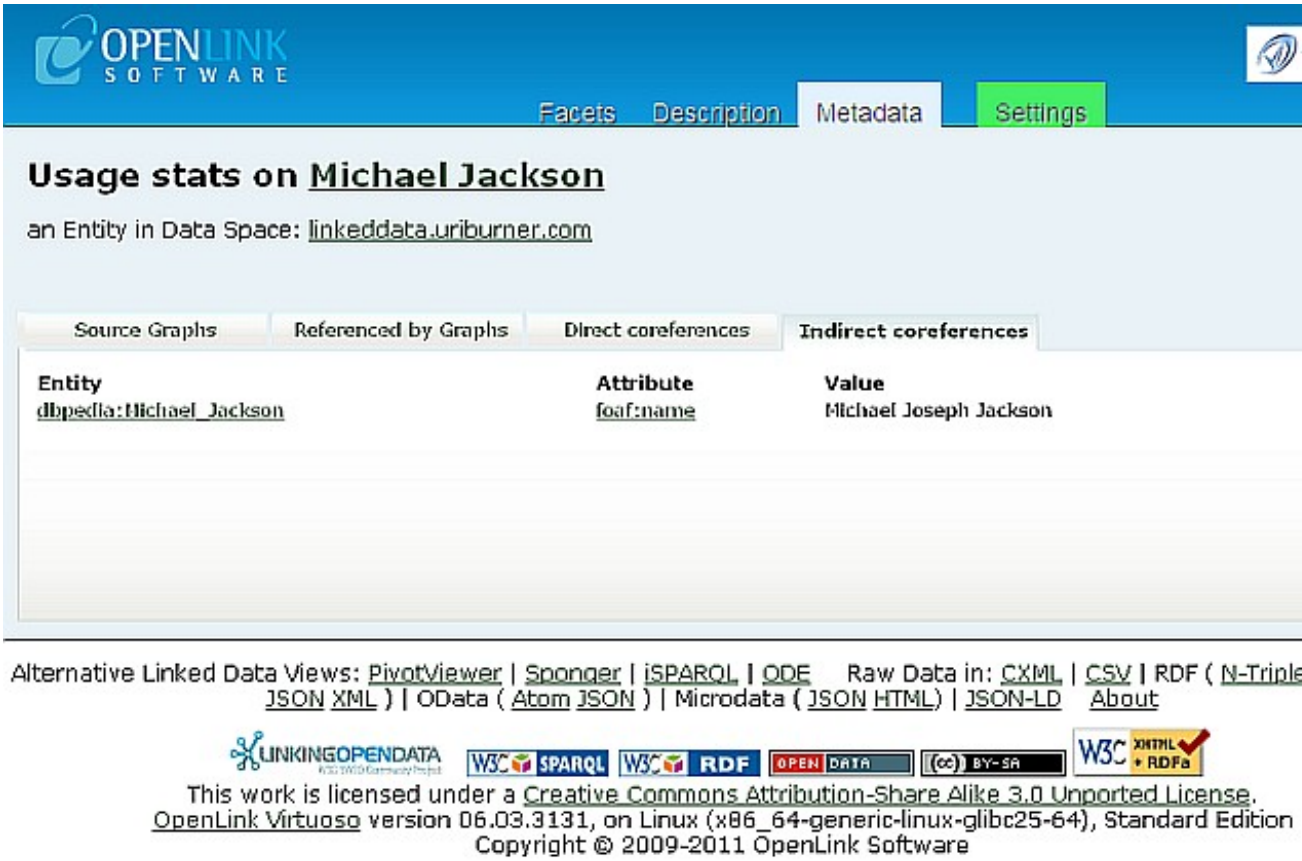
Figure 16.151. Usage Statistics



d. Indirect co-references: shows expanded results for objects concur with the URI by IFP:

```
SPARQL
SELECT distinct ?syn ?p ?o (sql:rnk_scale (<LONG::IRI_RANK> (?syn)))
where
  { <URI> ?p ?o .  filter (0 != (<LONG::bif:rdf_is_sub> ("b3sifp", ?p, lod:ifp_like, 3))) .
    ?syn ?p ?o .
}
order by desc 4
limit 20
```

Figure 16.152. Usage Statistics



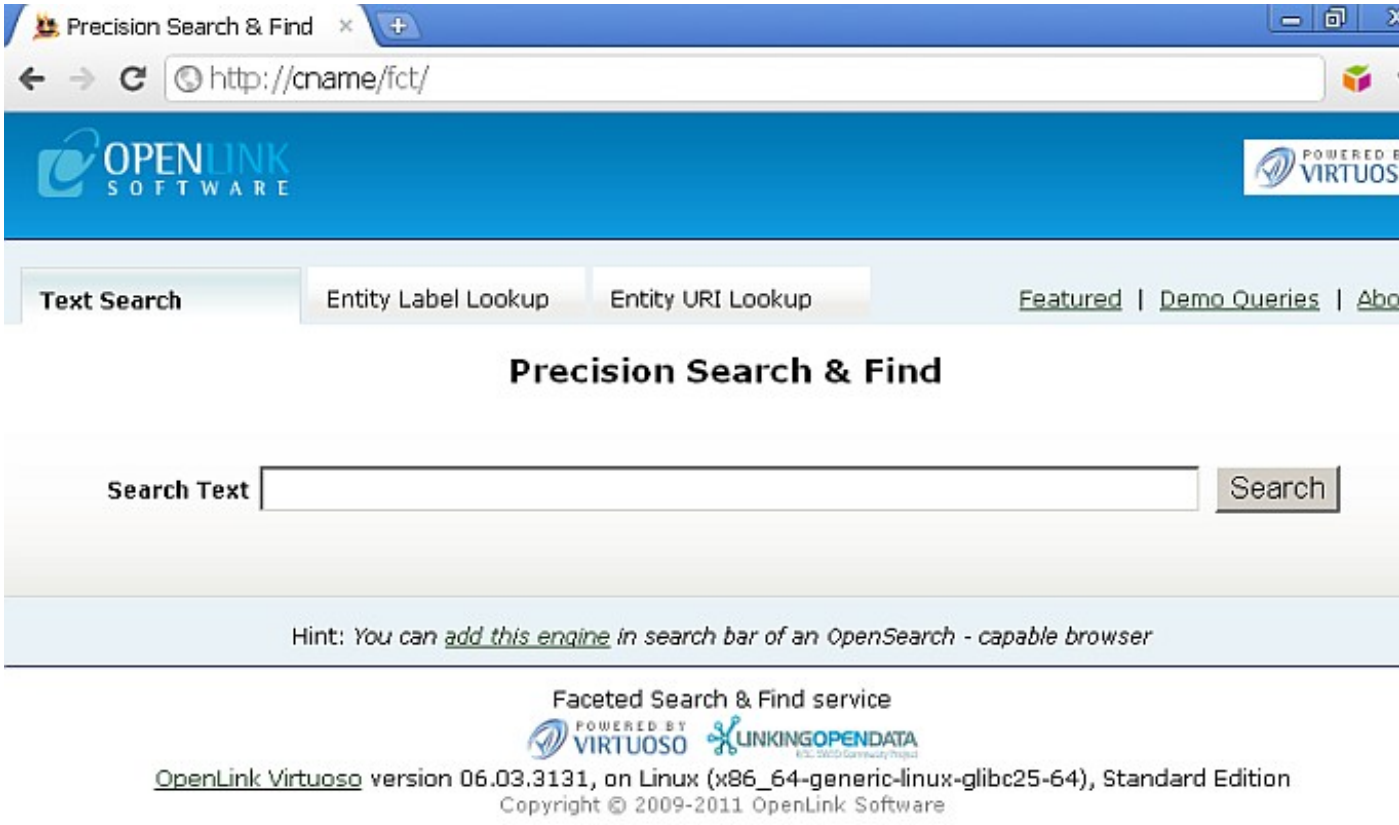
16.11.7. Examples

Faceted Browsing Sample using LOD Cloud Cache data space

The following example demonstrates a simple scenario of tracking Kingsley Idehen's conversations across the Web, using the Virtuoso Faceted Browser hosted on LOD.

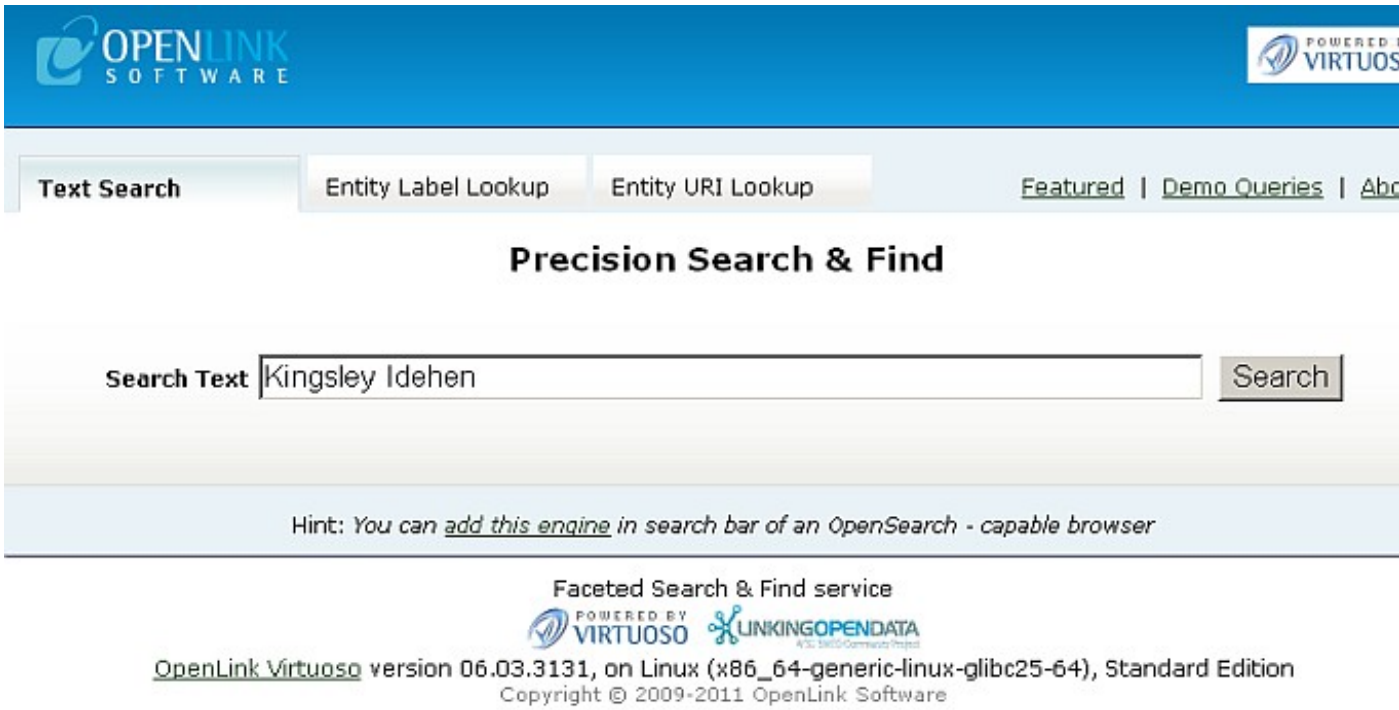
1. Go to http://lod.openlinksw.com/fct/

Figure 16.153. Faceted Navigation Example



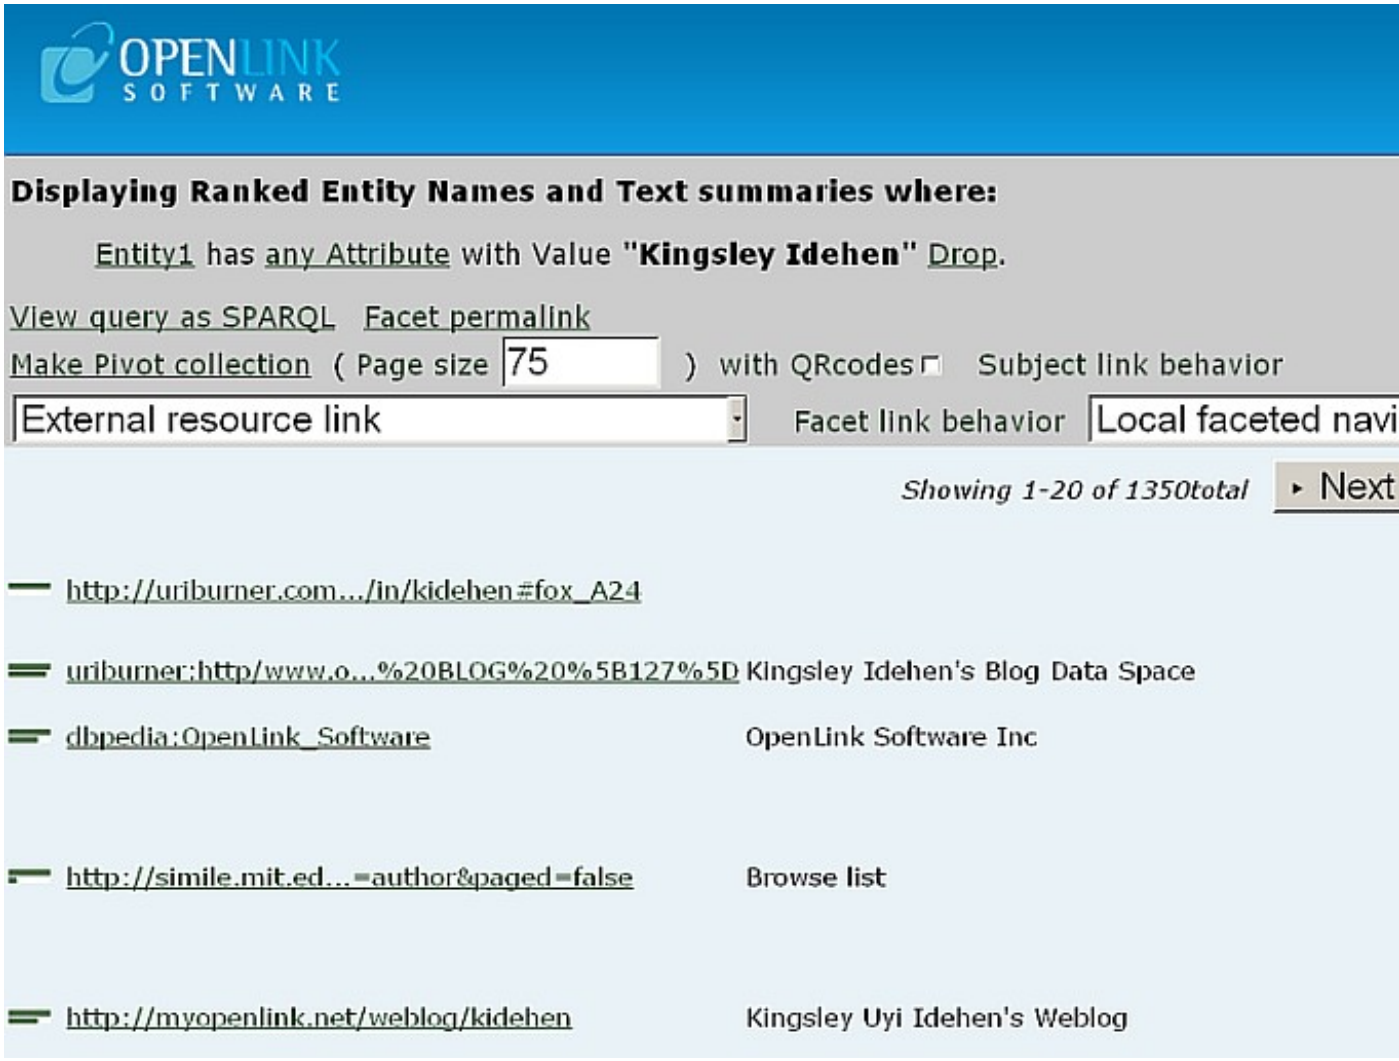
2. Enter a free text search pattern (for example, "Kingsley Idehen"), and click Search

Figure 16.154. Faceted Navigation Example



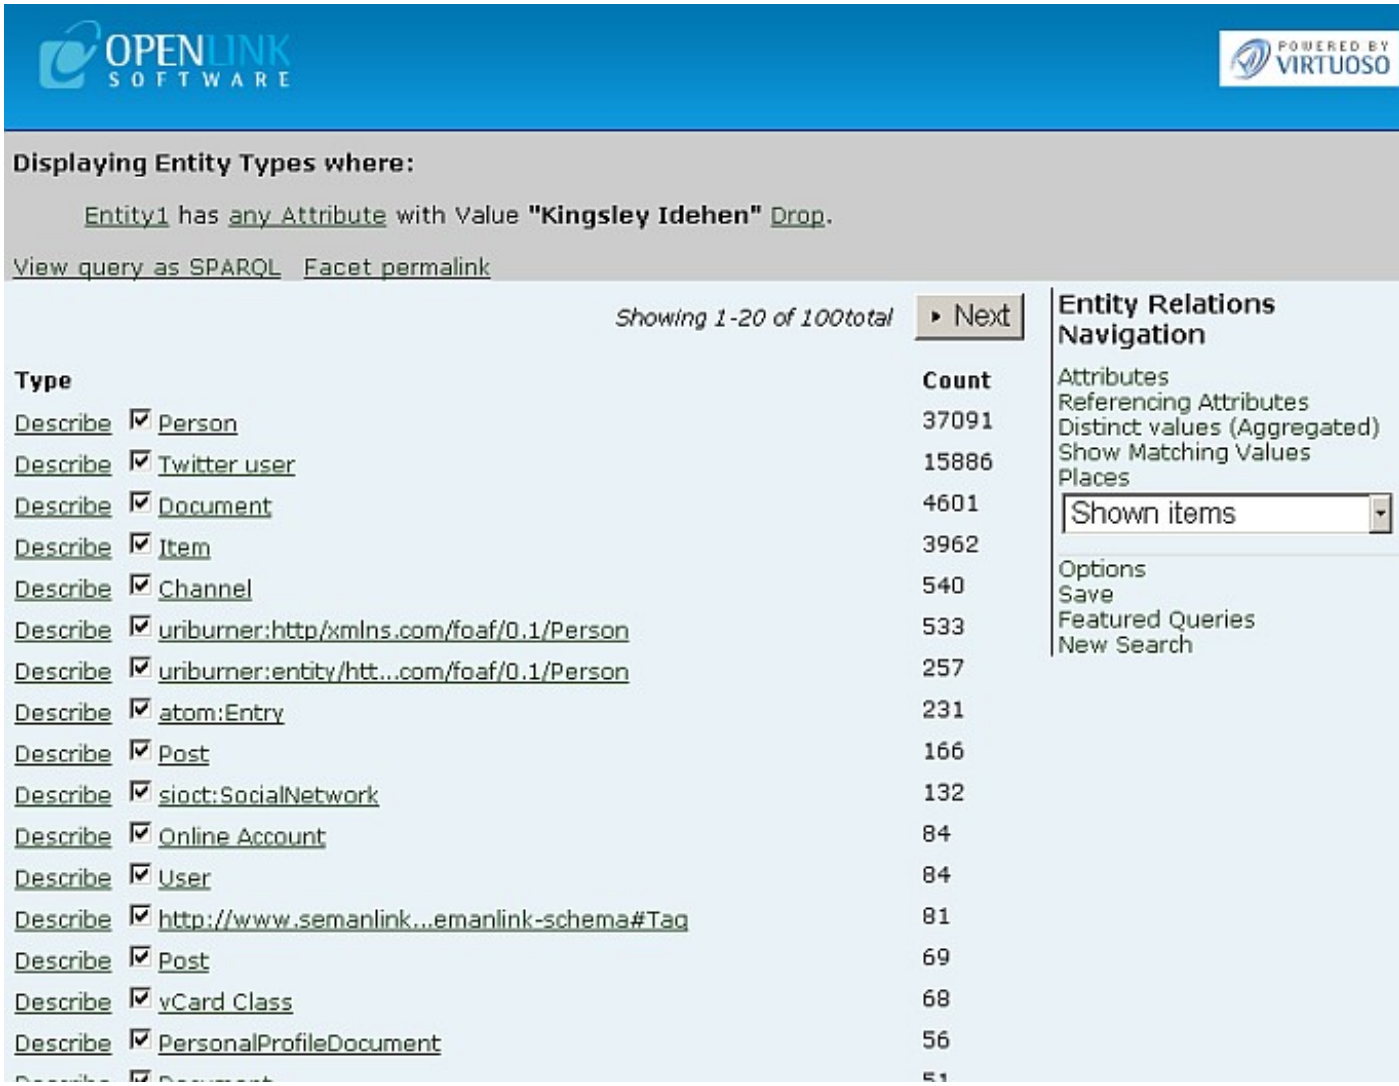
3. Your initial query results page will display a list of literal value snippets from property values associated with the query text pattern

Figure 16.155. Faceted Navigation Example



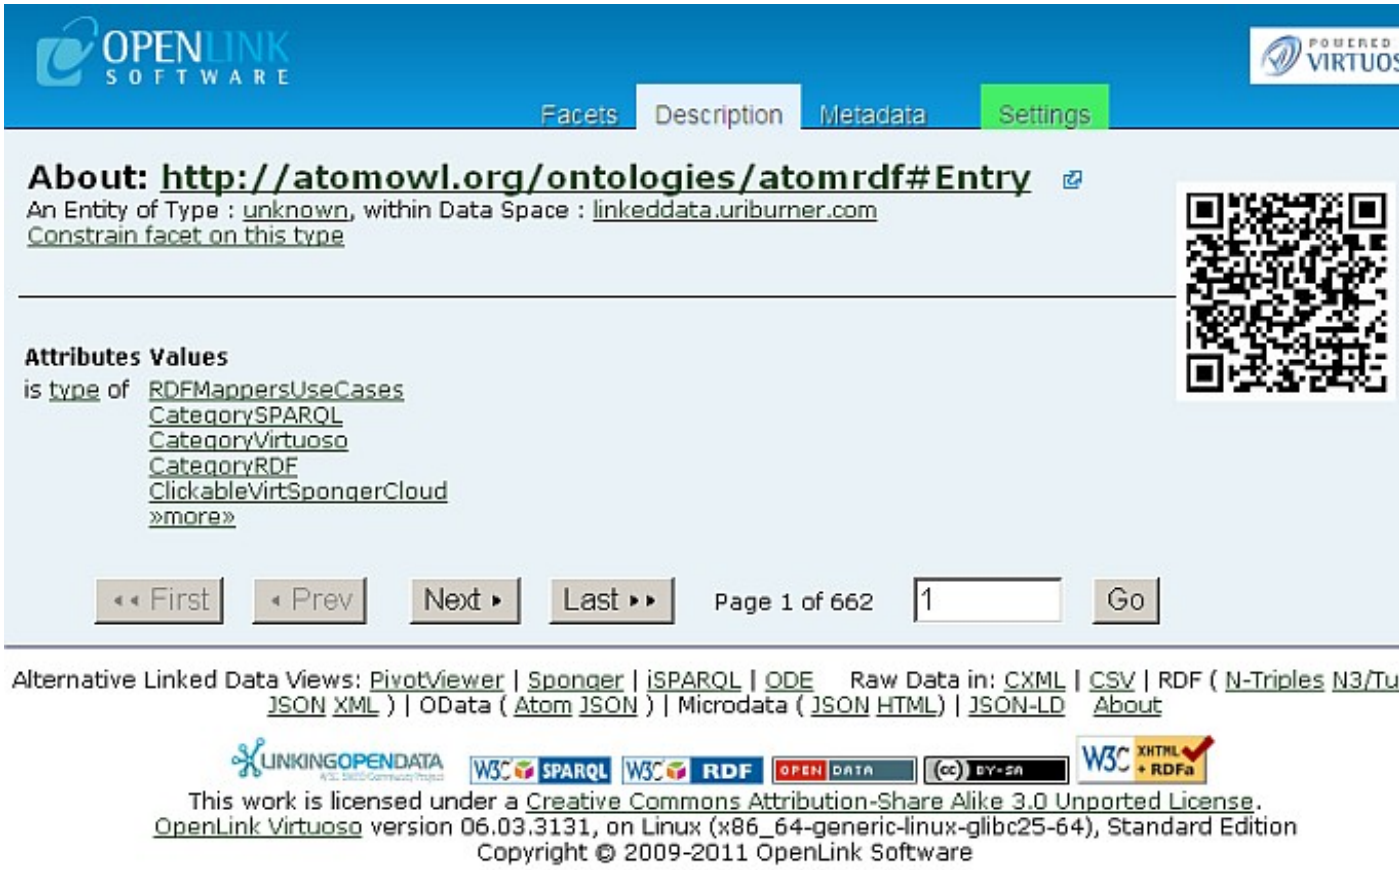
4. Using the Navigation section on the right, click on "Types", which alters the contents of the query results area by presenting CURIE based hyperlinks for each of the Entity Types associated with Property values that contains the query text pattern

Figure 16.156. Faceted Navigation Example



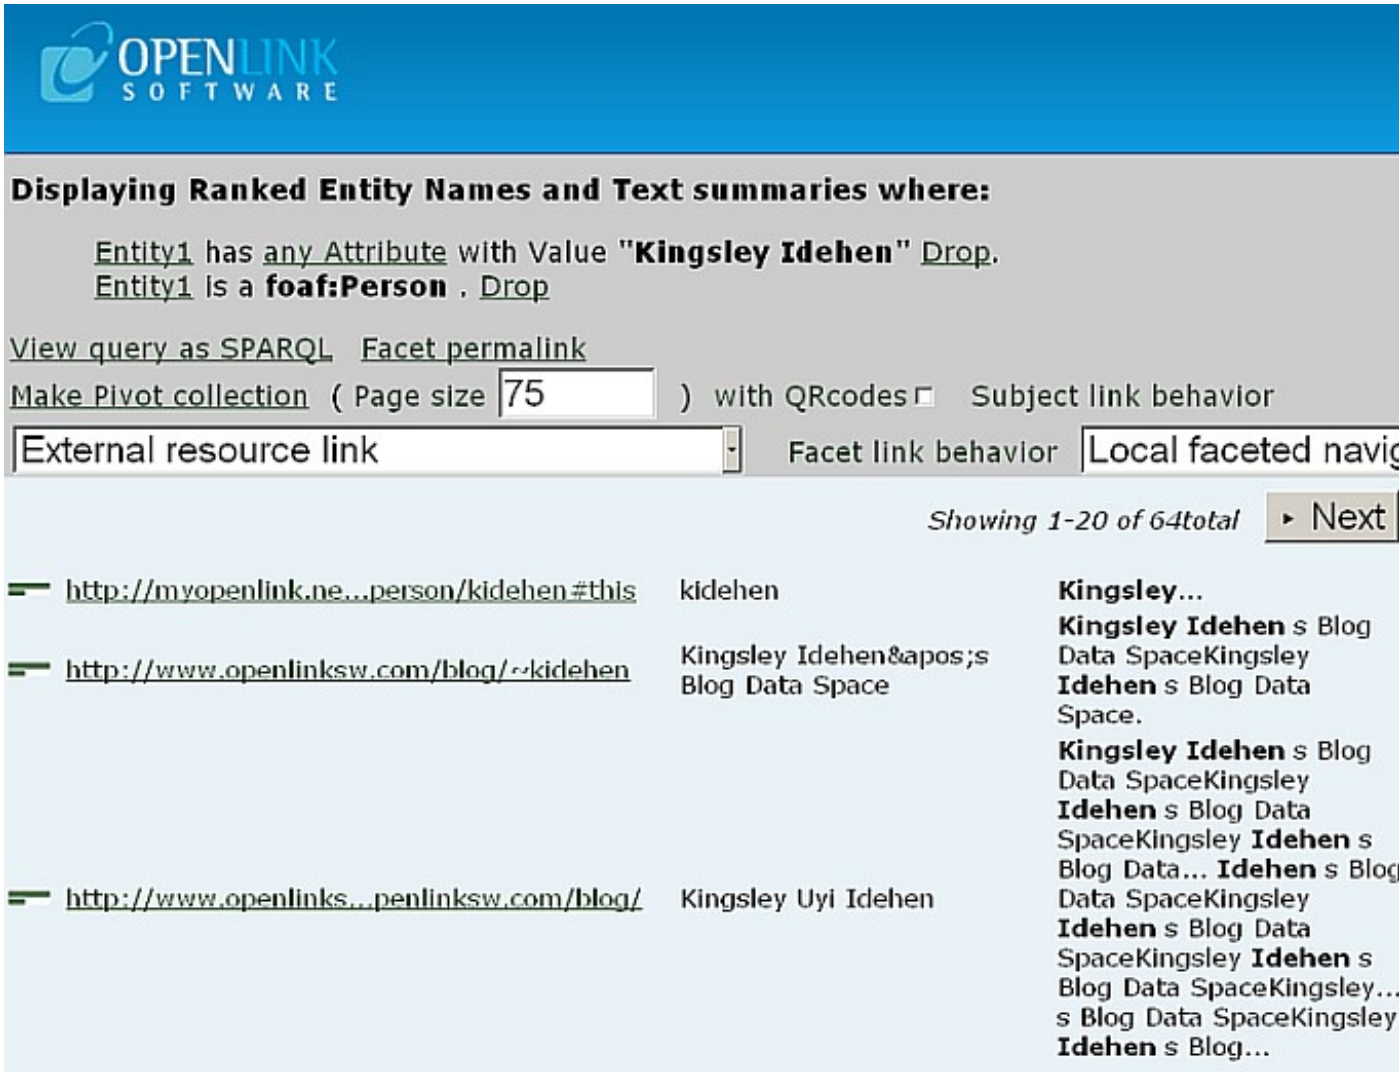
5. You can perform *Describe* for a given found type, by clicking the "Describe" link in the "Type" column. For ex, for "atom:Entry" the produced describe type page would show a list of Attributes and Values + automatically generated QRCode image:

Figure 16.157. Faceted Navigation Example



6. Click "Facets" tab to return to the Types content page from the previous step.
7. Click on the "foaf:Person" link to narrow the result set down to Entities of this Type, un-hatch the checkbox beside this link for Negation (filtering out) based on this Entity Type

Figure 16.158. Faceted Navigation Example



- For Negation (filtering out) based on this Entity Type un-hatch the check-box shown besides the link:

Figure 16.159. Faceted Navigation Example

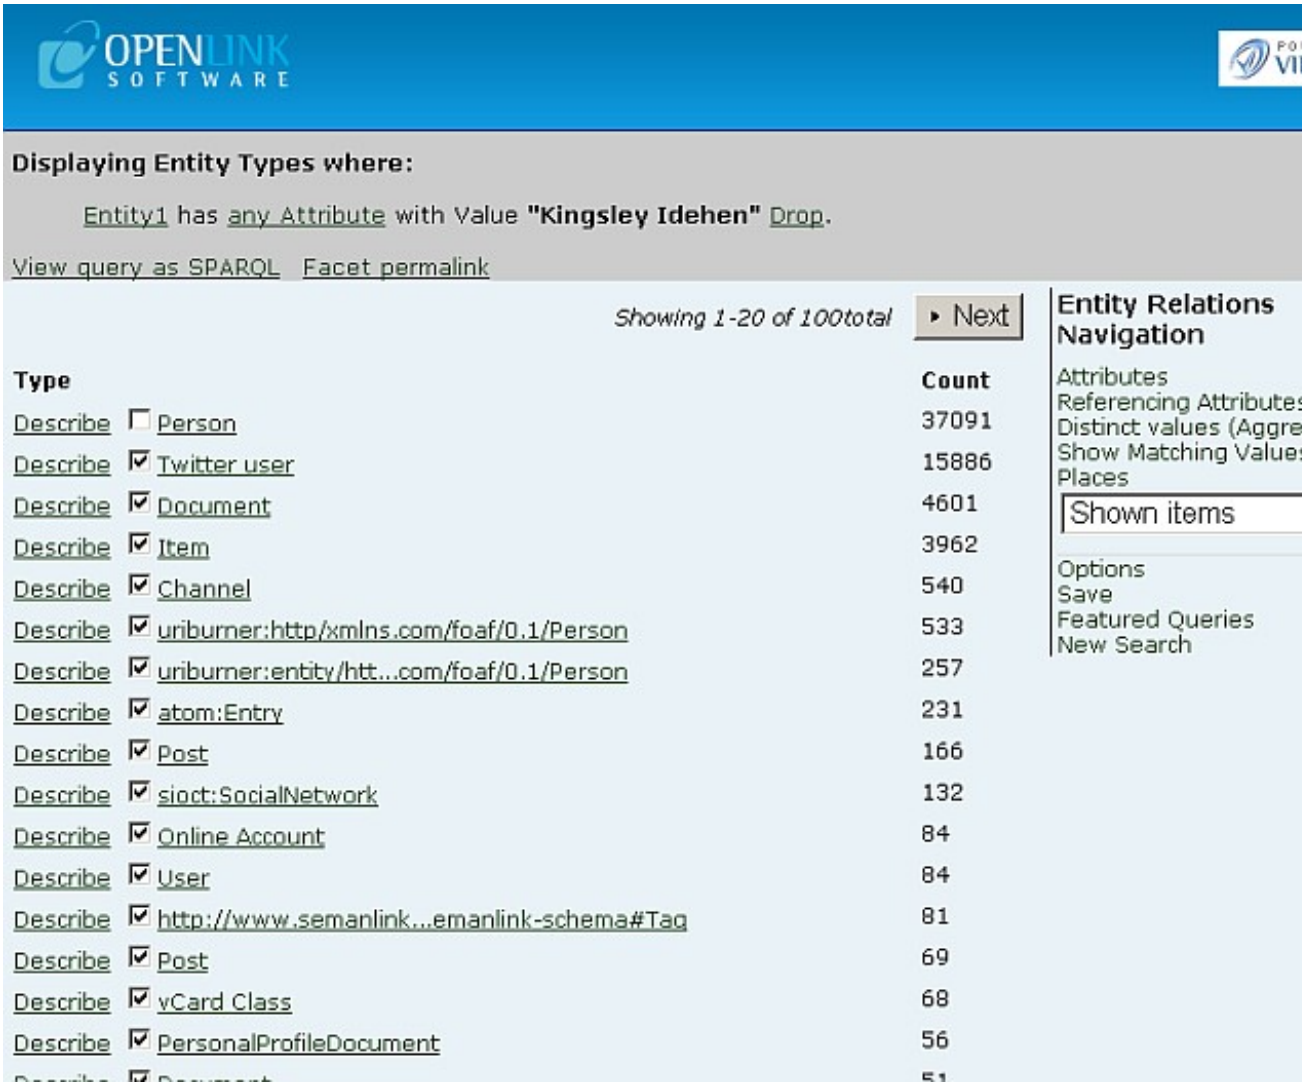


Figure 16.160. Faceted Navigation Example

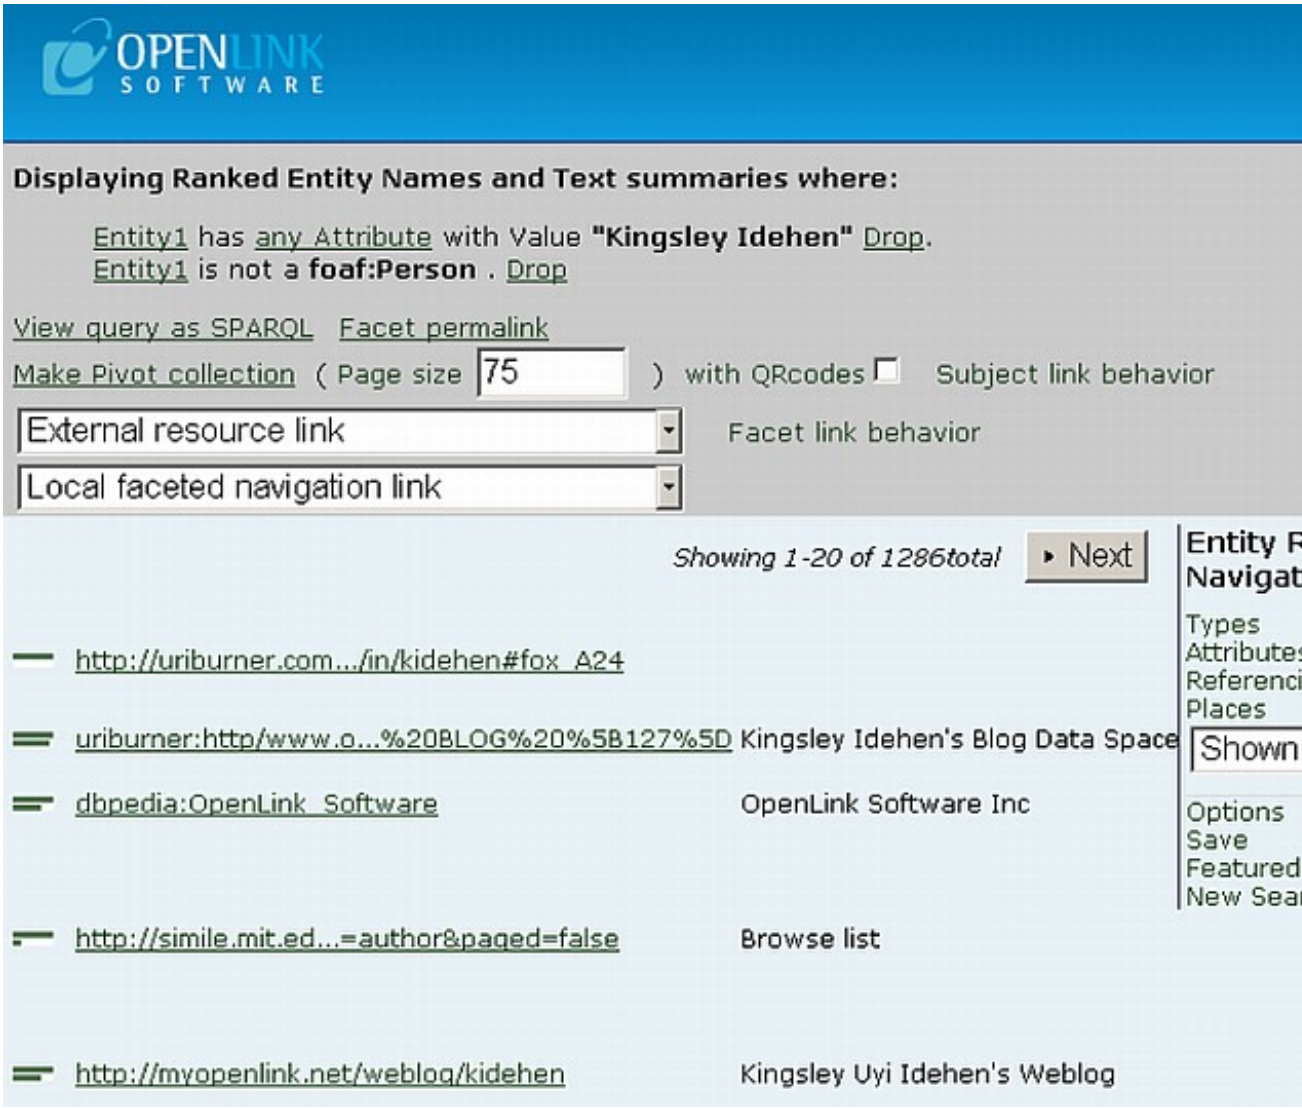
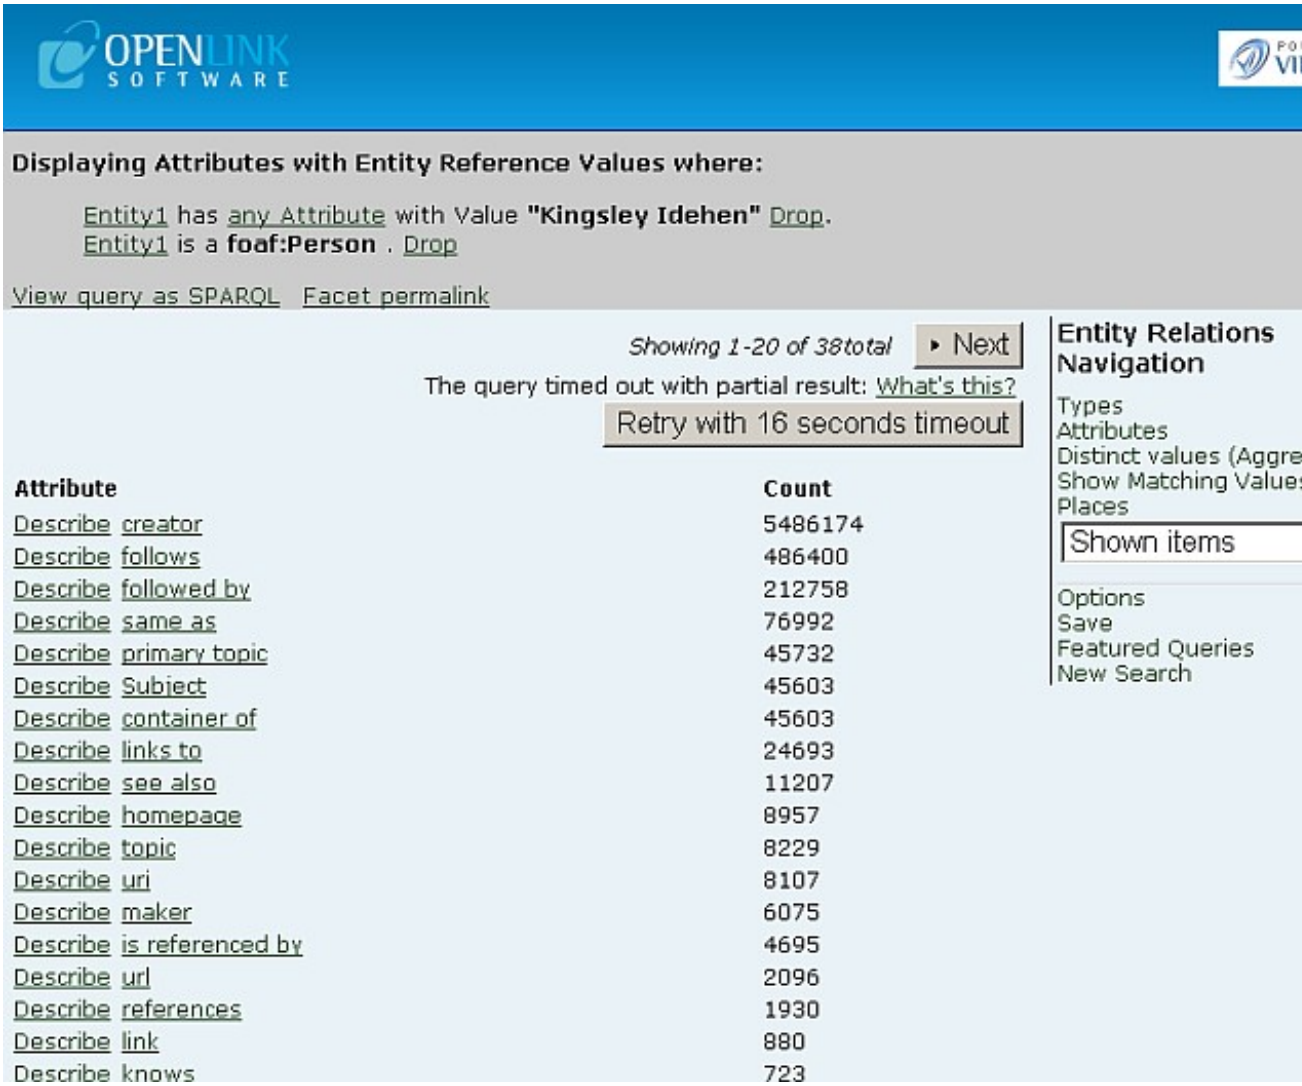


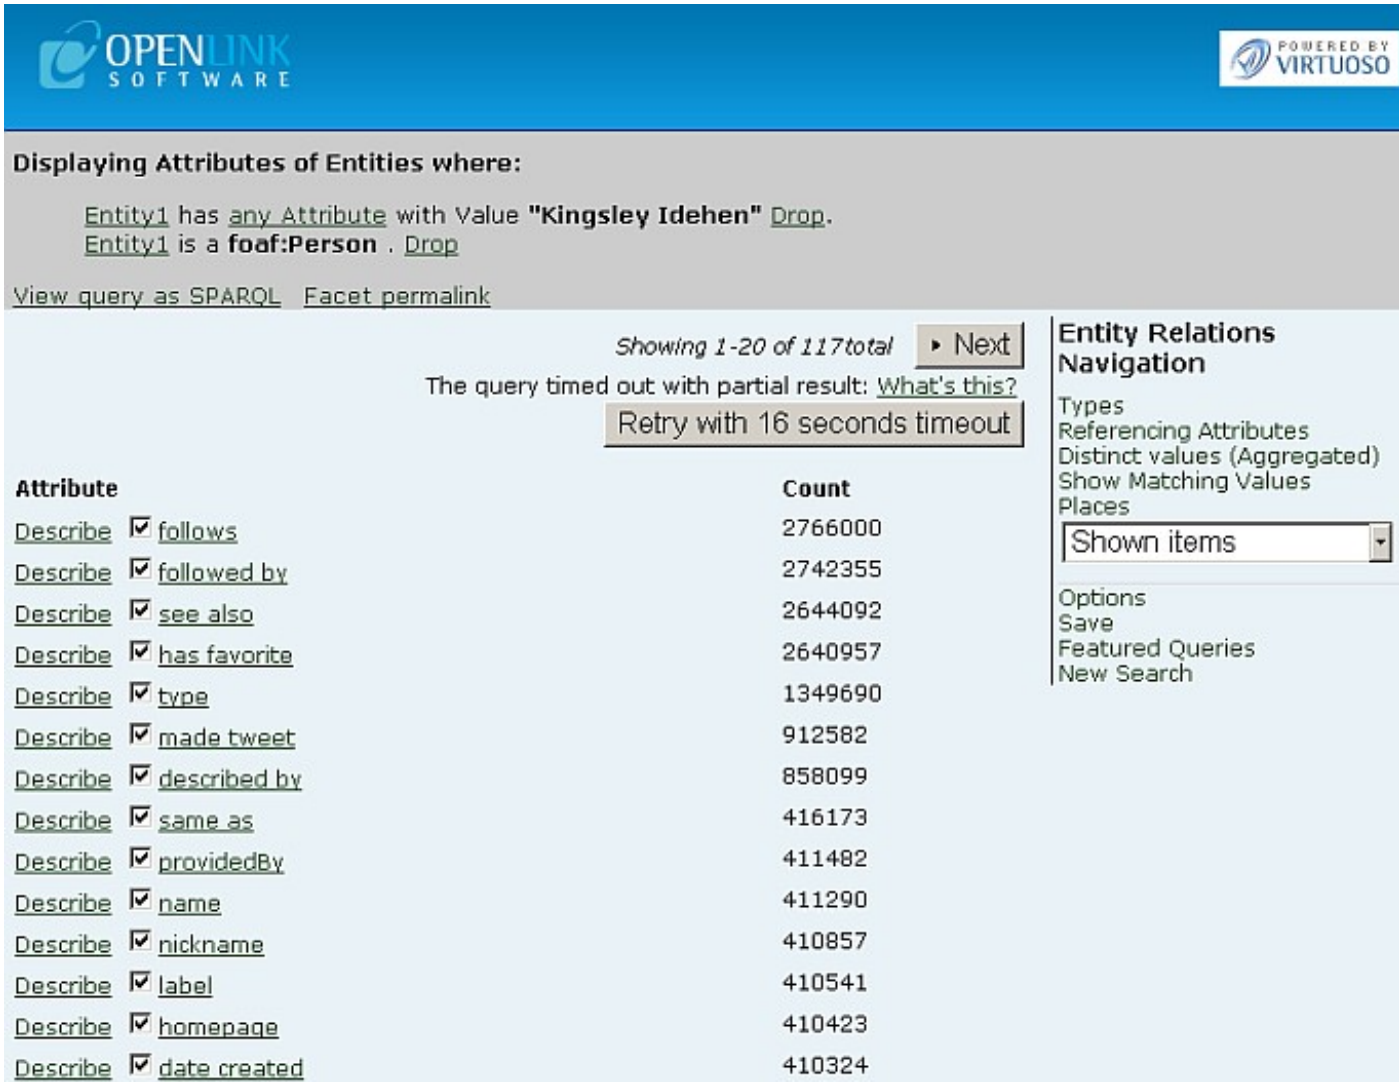
- You can filter further, by switching (pivoting) to the a Property based view, by returning to the Navigation section and then clicking on "Properties" or "Referencing Properties" links; in either case, you have further filtering of based on the combination of Properties and Entities where Entities in the result-set contain values matching the query text pattern

Figure 16.161. Faceted Navigation Example



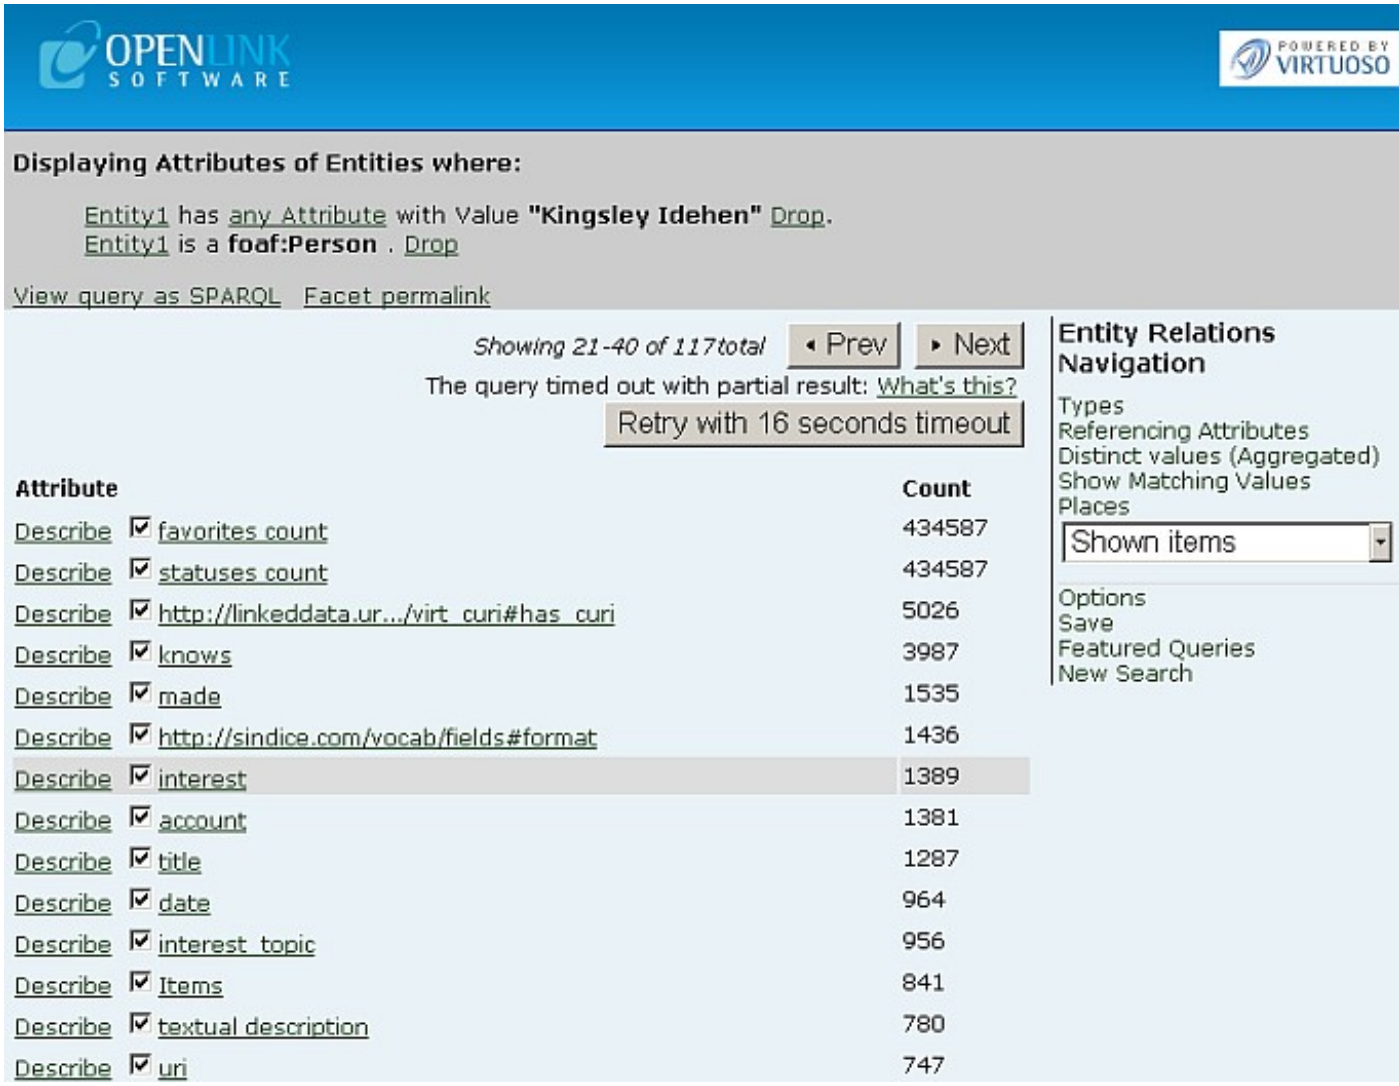
8. From "Entity Relations Navigation" click "Attributes".

Figure 16.162. Faceted Navigation Example



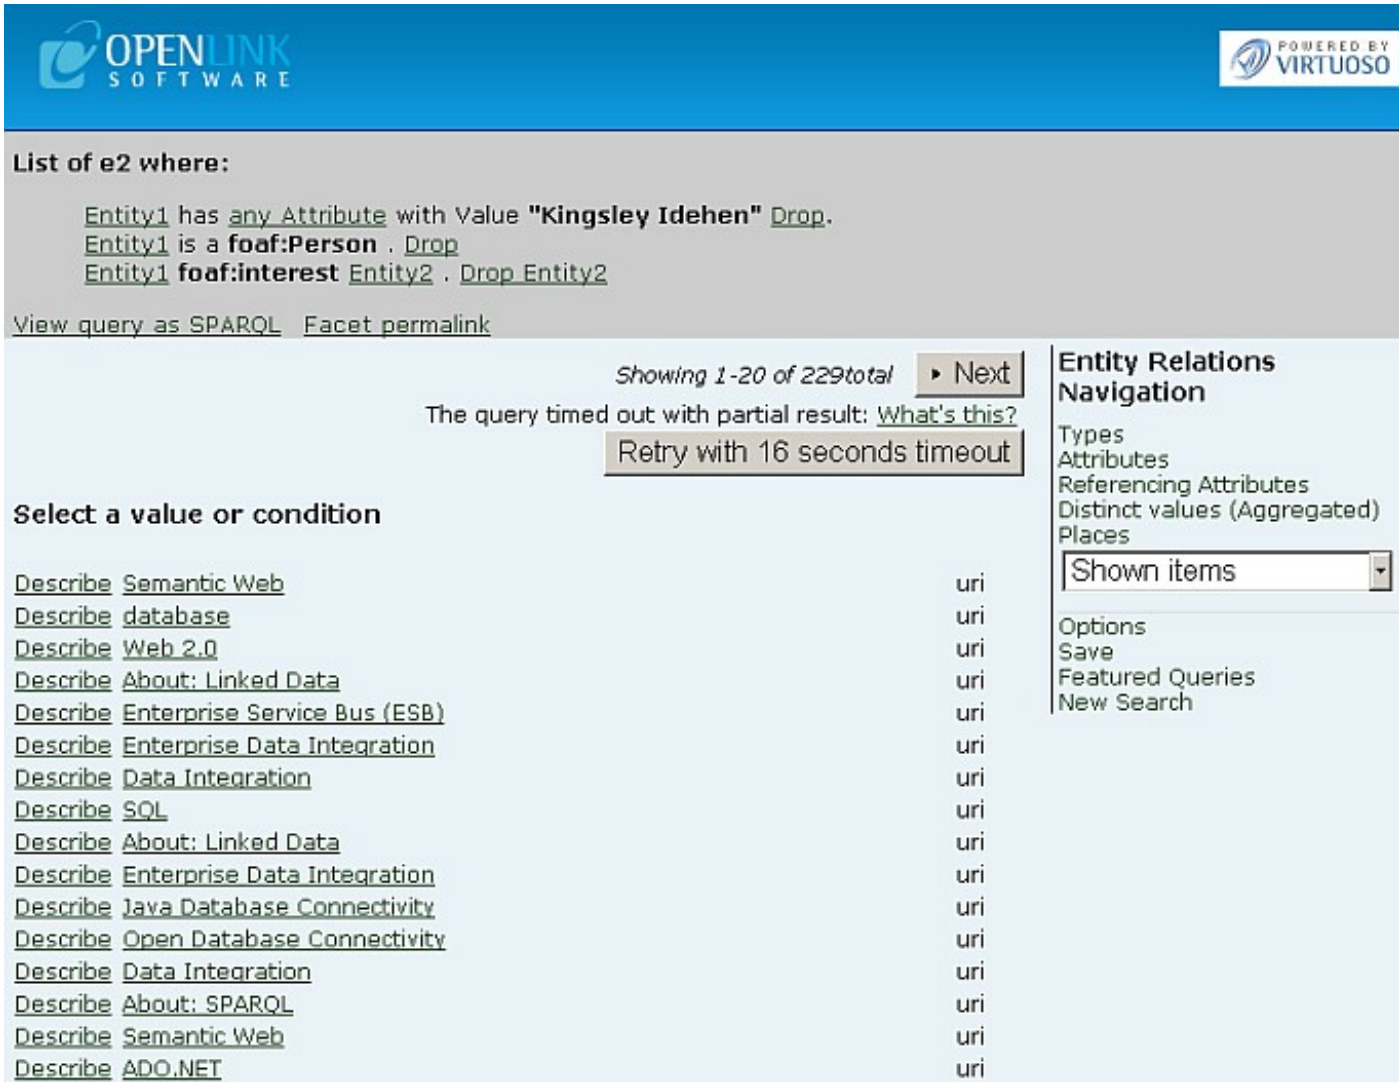
9. You can navigate amongst the search results pages by using the "Prev" and "Next" buttons. Click for ex. "Next":

Figure 16.163. Faceted Navigation Example



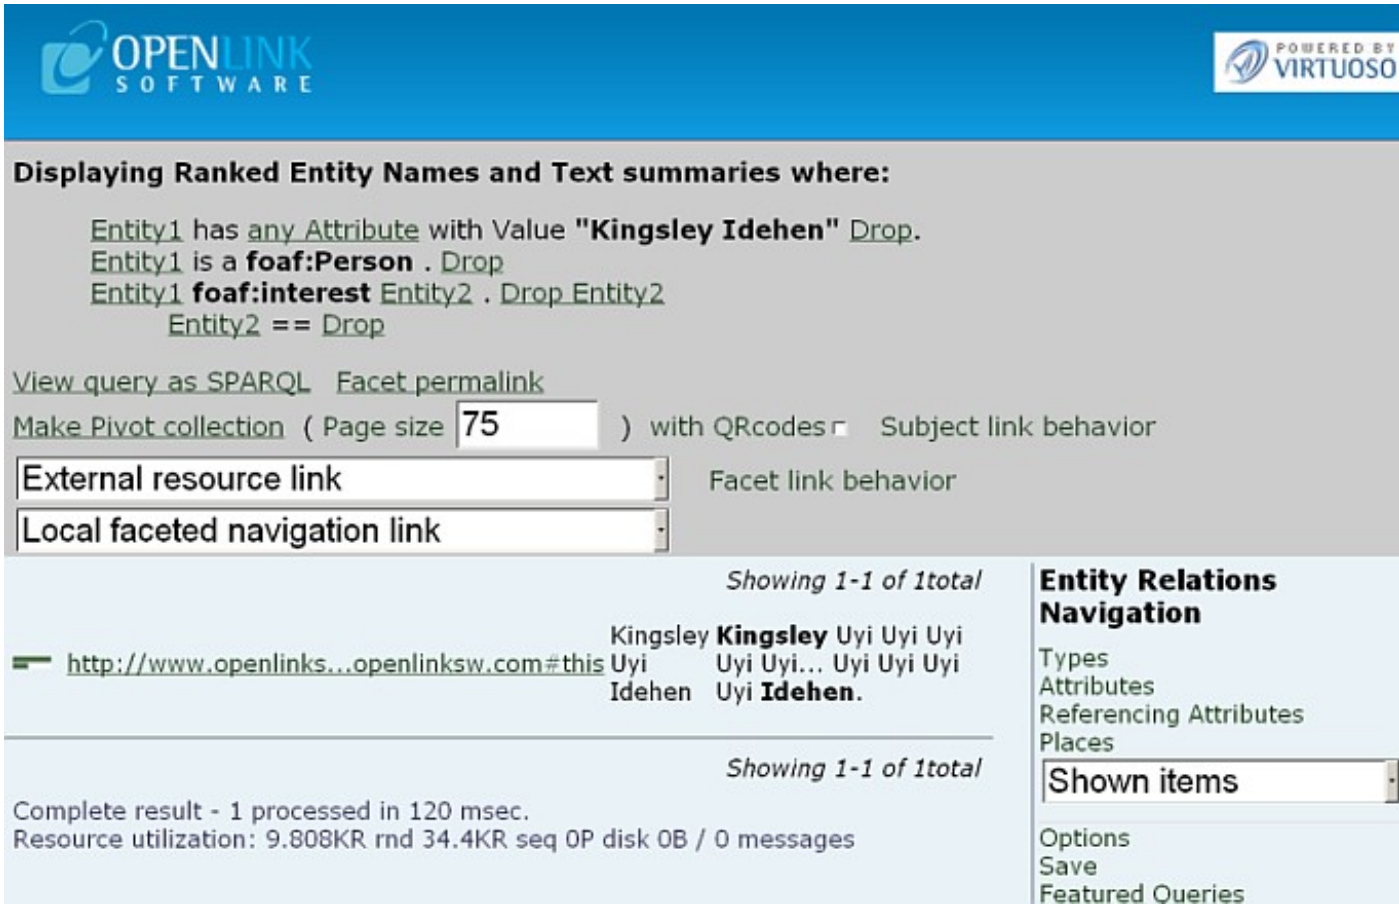
10. From the list of Property Types, click on the "foaf:interest" link to filter further, based on the values of this property:

Figure 16.164. Faceted Navigation Example



11. From the list of "foaf:interest" Values, click on "About:Linked Data", which filters the result-set further to display reveal Entity Identifier Links (Generic HTTP URIs) and Labels for each "foaf:Person" associated with the property "foaf:interest", in the LOD data space:

Figure 16.165. Faceted Navigation Example



12. Click on one of the HTTP URIs in the filtered results-set to obtain a detailed structured description of a given Entity i.e. about the person Kingsley Uyi Idehen. Each listed Property is a

    Link

    ; thus, each Property is a link to other structured Entity descriptions. Additionally, a QRCode image will be produced automatically for the given entity:

    Figure 16.166. Faceted Navigation Example

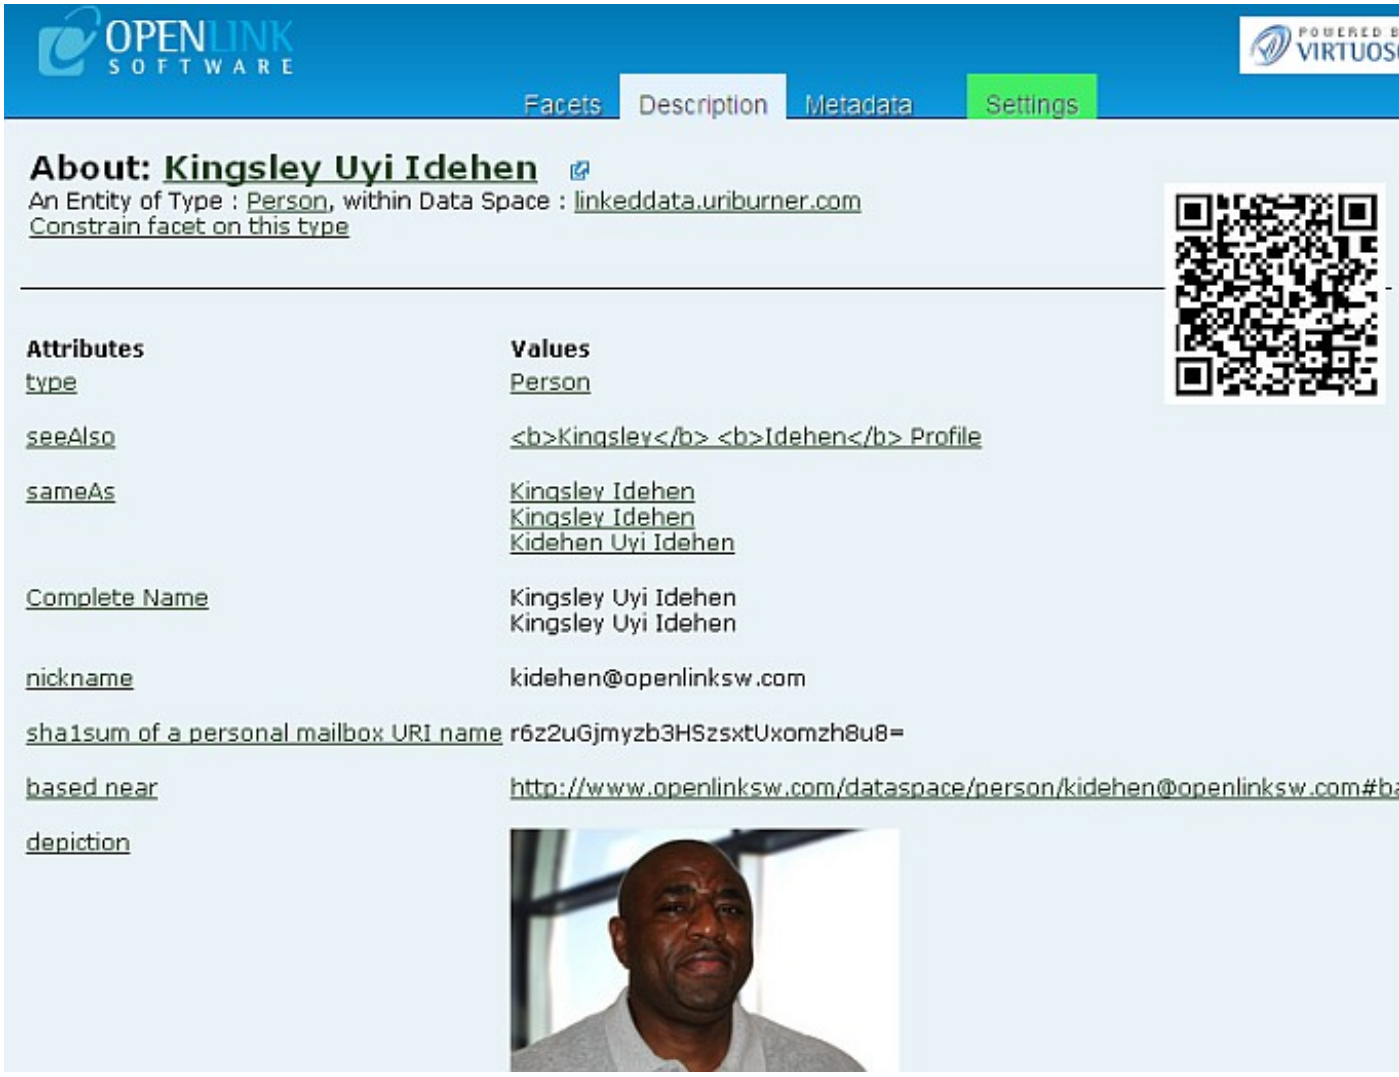


Figure 16.167. Faceted Navigation Example

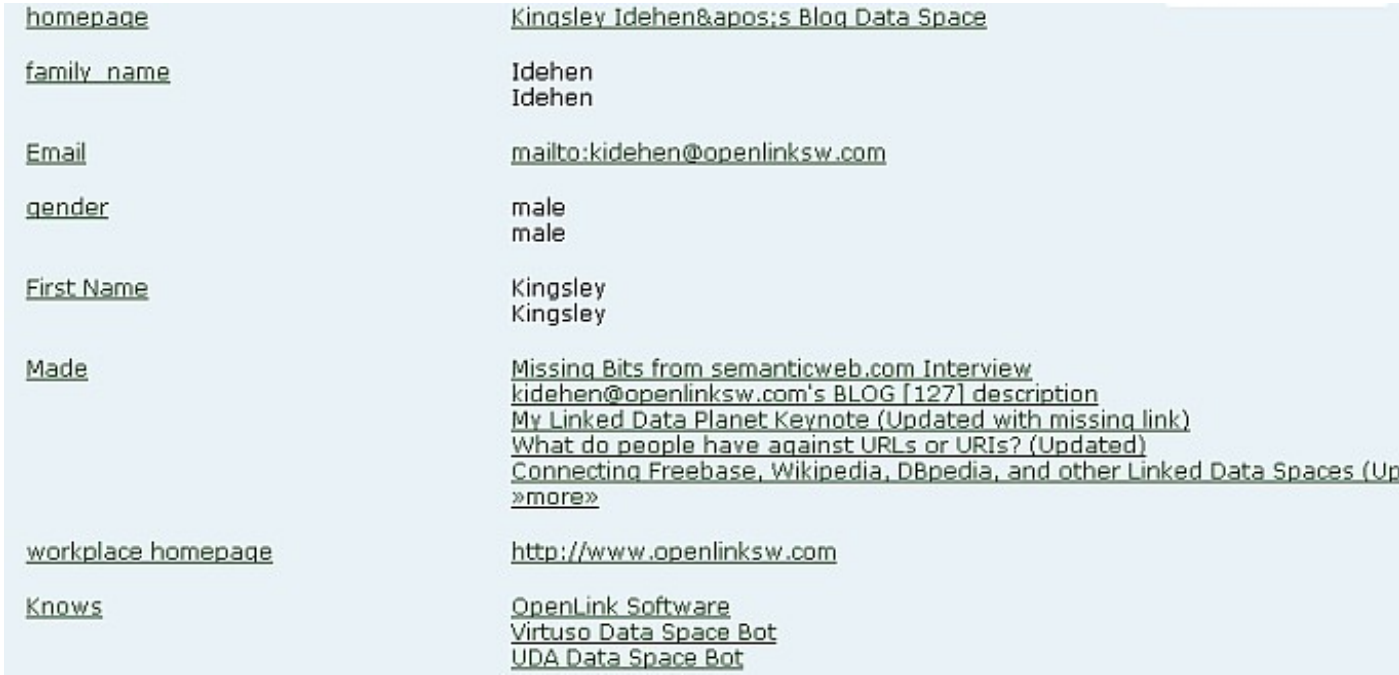

Figure 16.168. Faceted Navigation Example

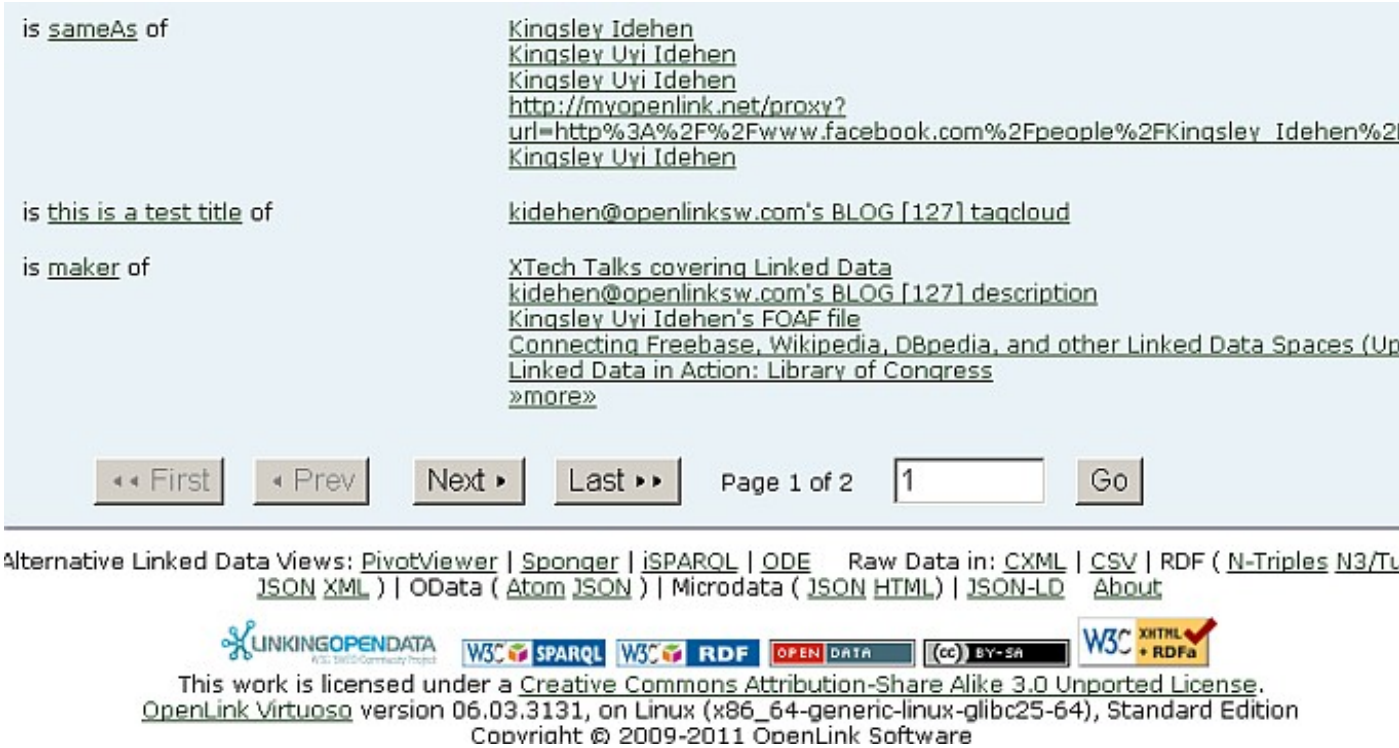
Figure 16.169. Faceted Navigation Example



13. You can navigate amongst the search results pages by using the "First", "Prev", "Next" and "Last" buttons. Click for ex. "Last":

Figure 16.170. Faceted Navigation Example

Figure 16.171. Faceted Navigation Example

14. Click on " *Metadata* " link to get a summary view of this Linked Data Space, "Source" and "Reference" graphs are akin to saying "Table X" and "Table Y" where each table is the container of Records re. RDBMS or Worksheet re. Spreadsheet.:

Figure 16.172. Faceted Navigation Example

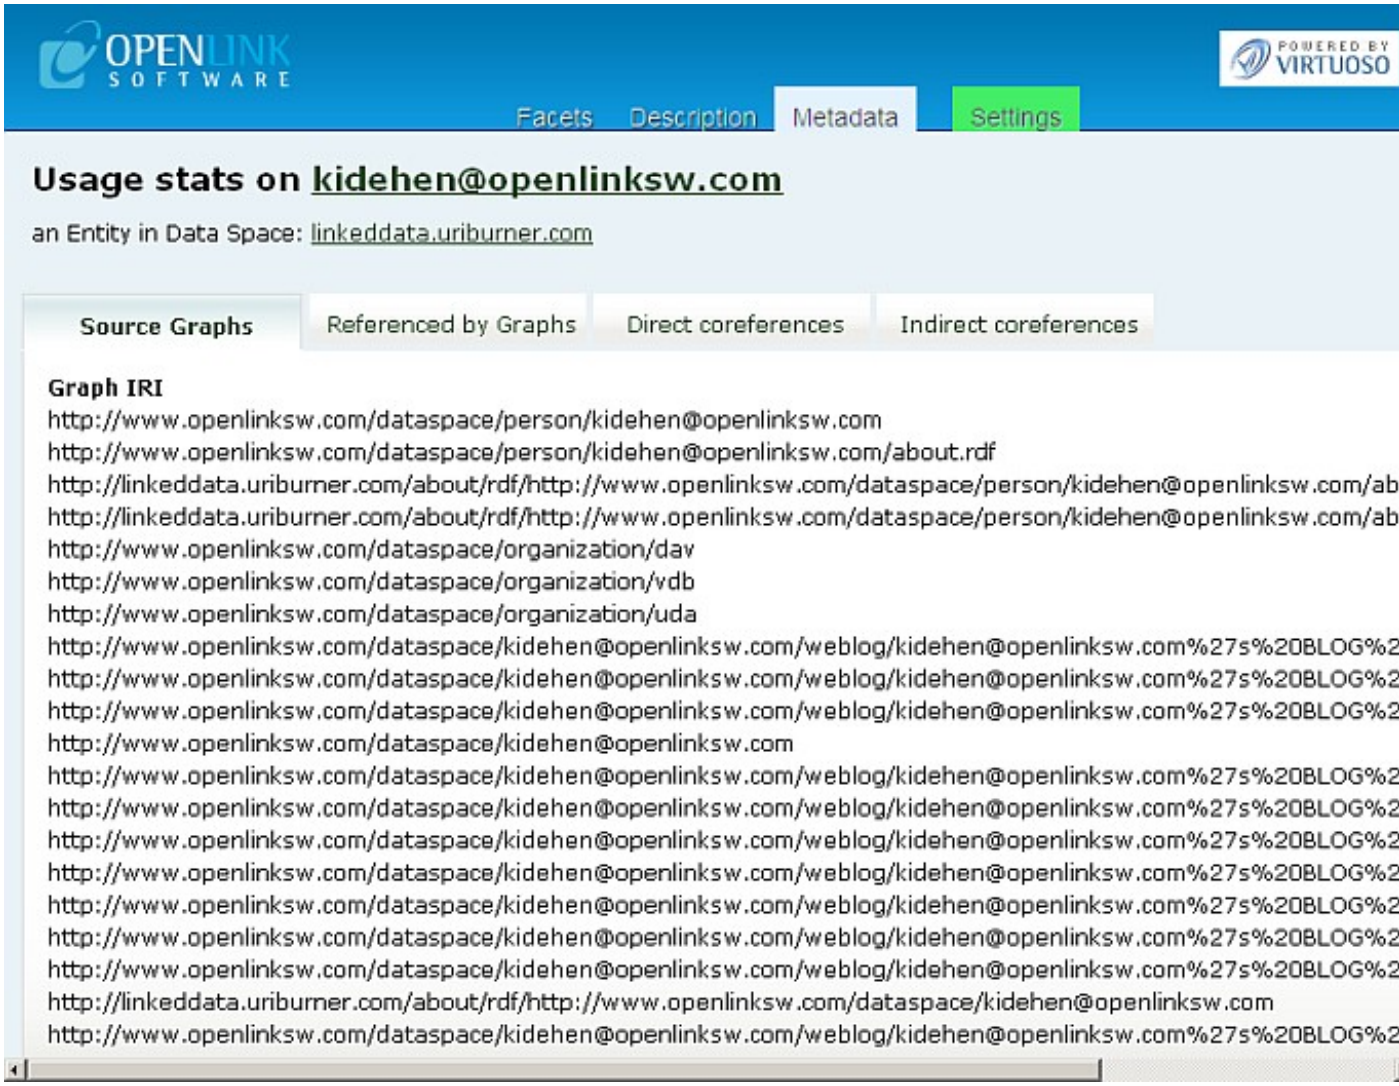


Figure 16.173. Faceted Navigation Example

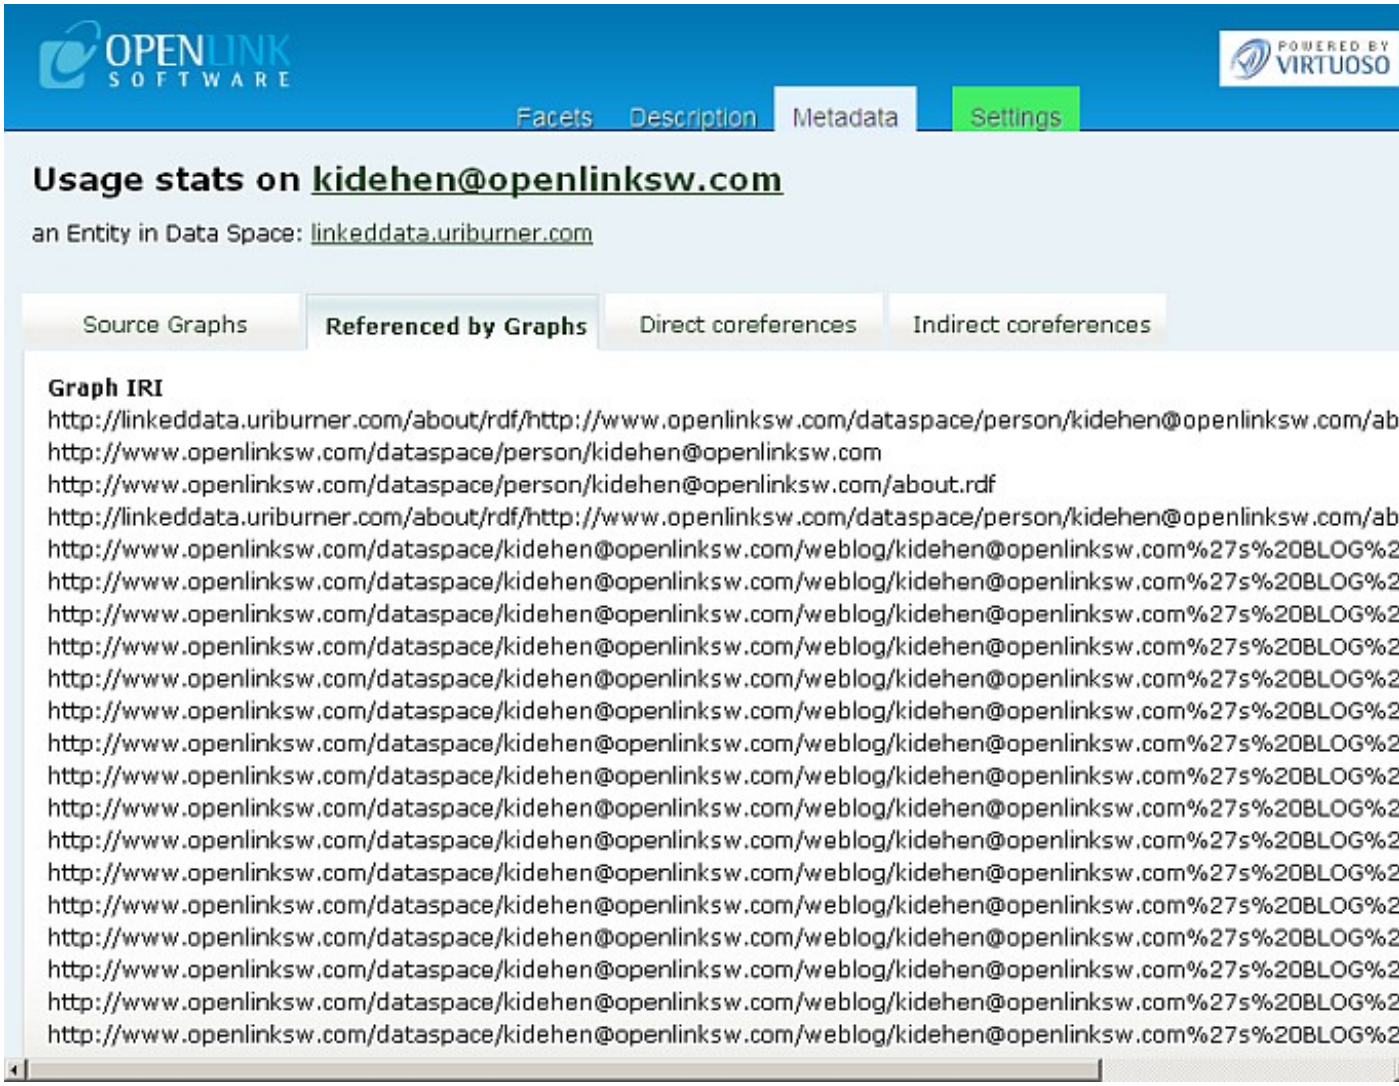

15. "Direct" and "InDirect" coreferences show other references (Identifiers) that relate associated with Kingsley Idehen (like saying: here are his other names or his know by this name in this other place):

Figure 16.174. f21 Navigation Example

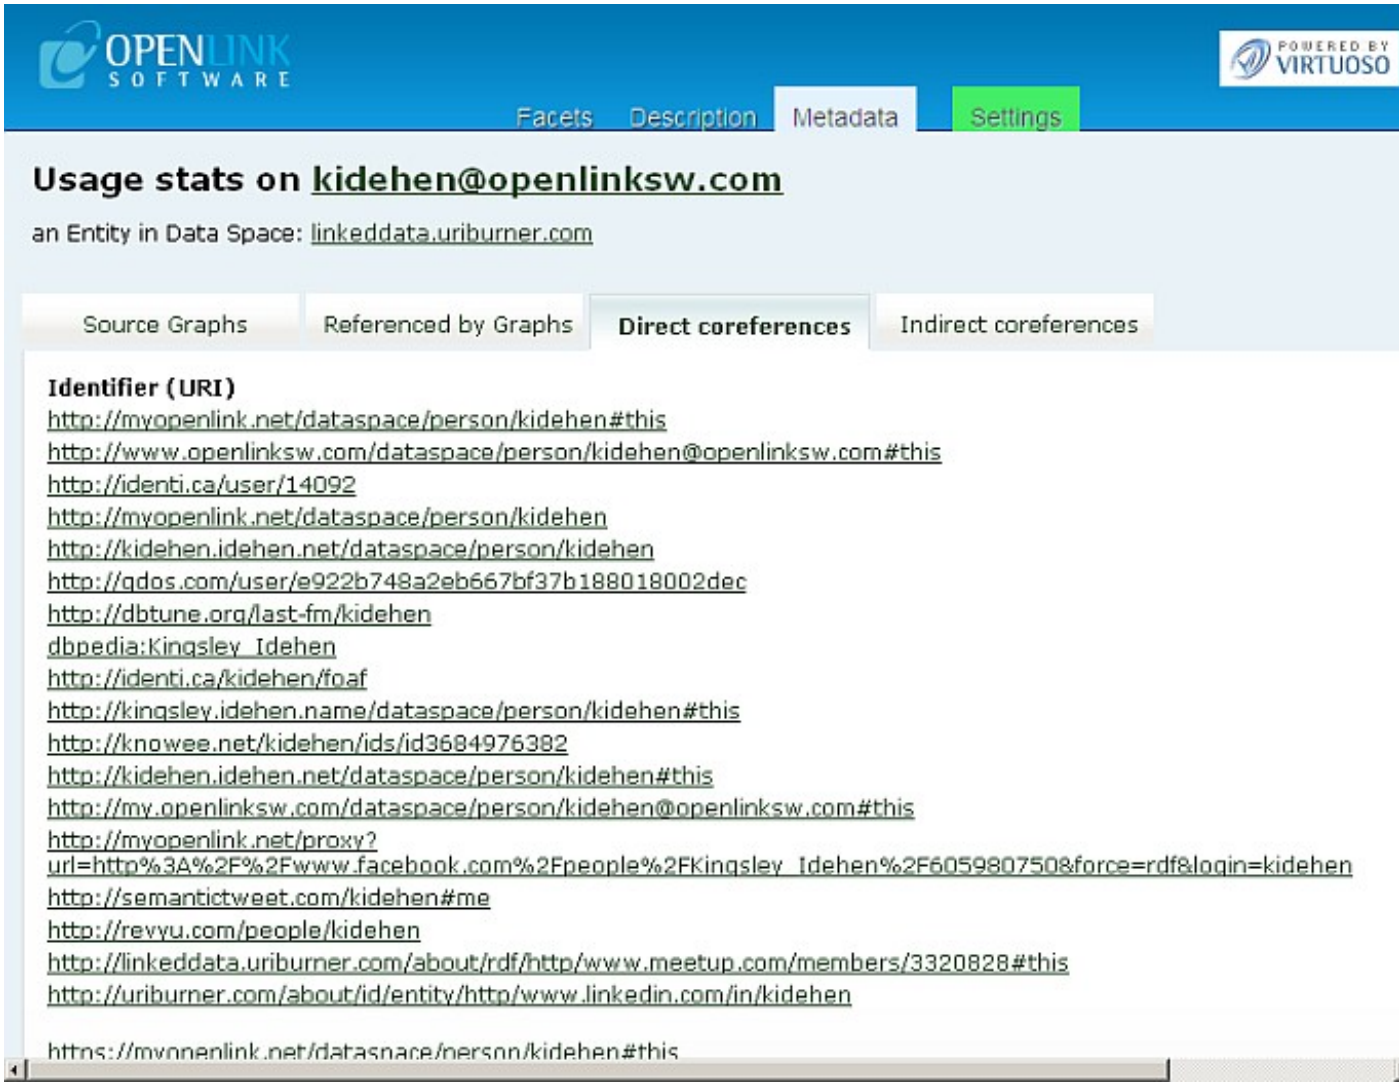

Figure 16.175. Faceted Navigation Example

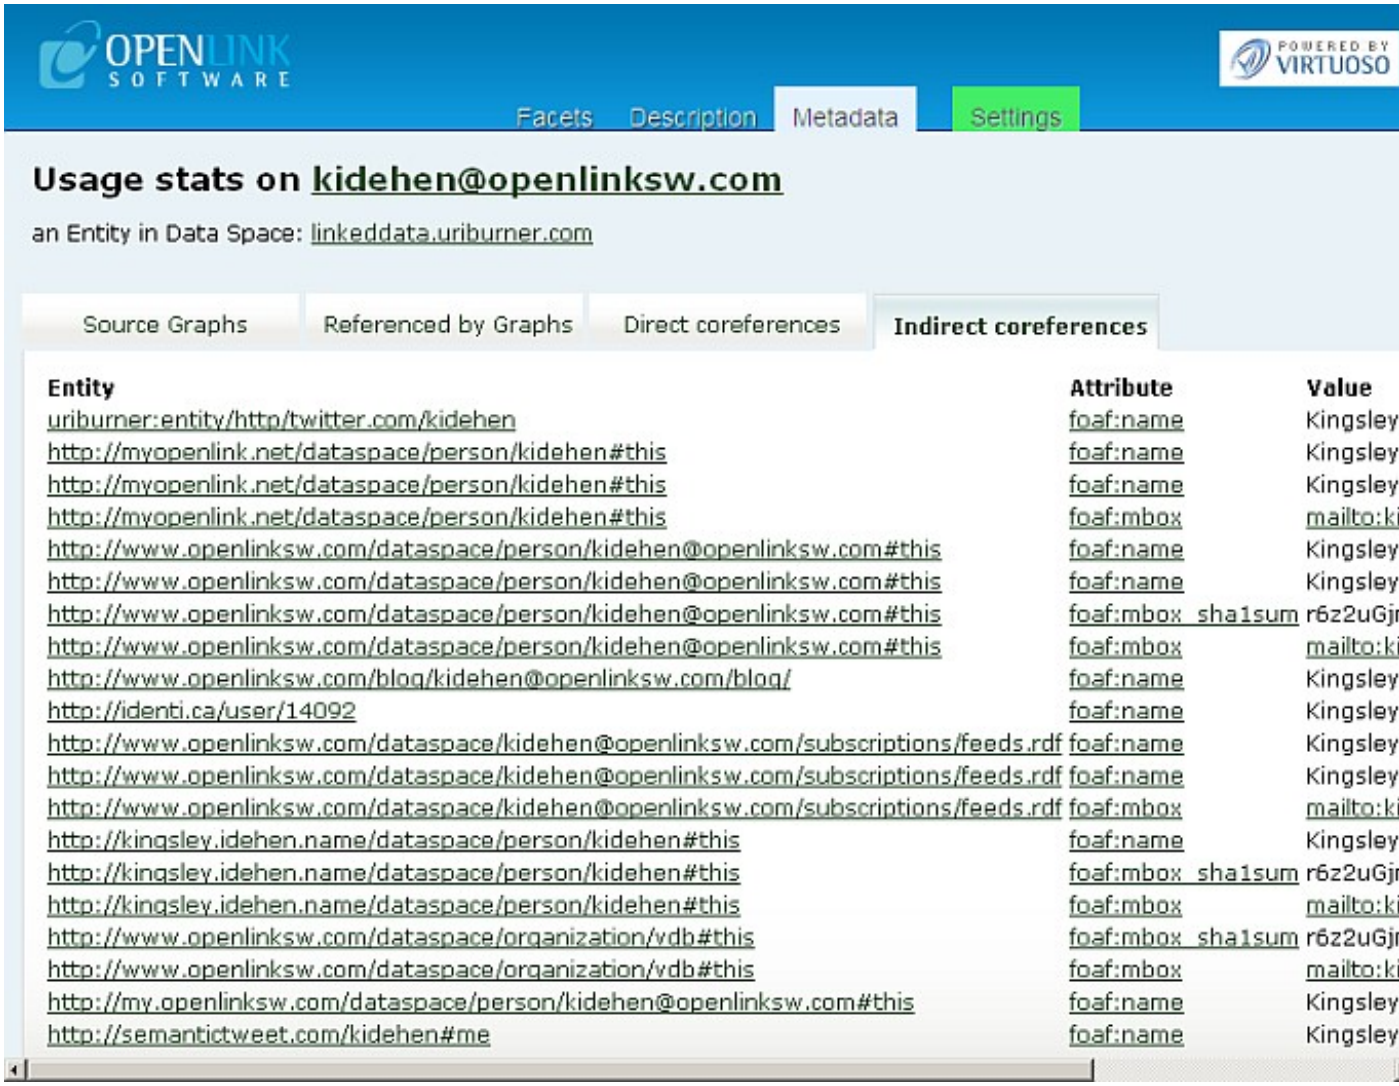
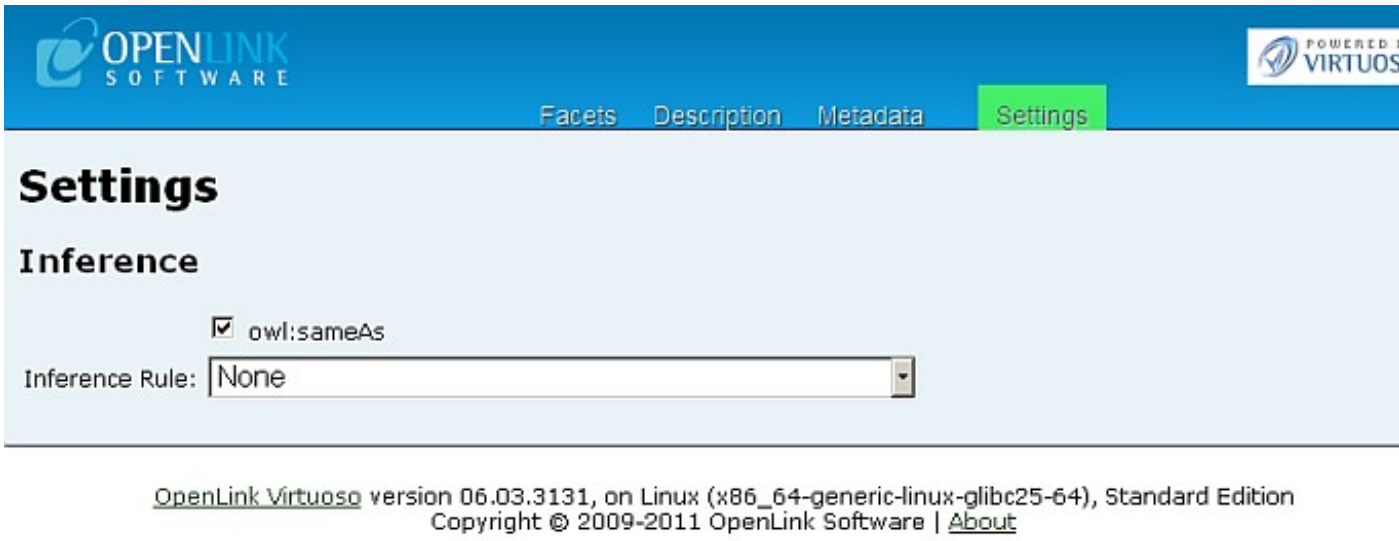


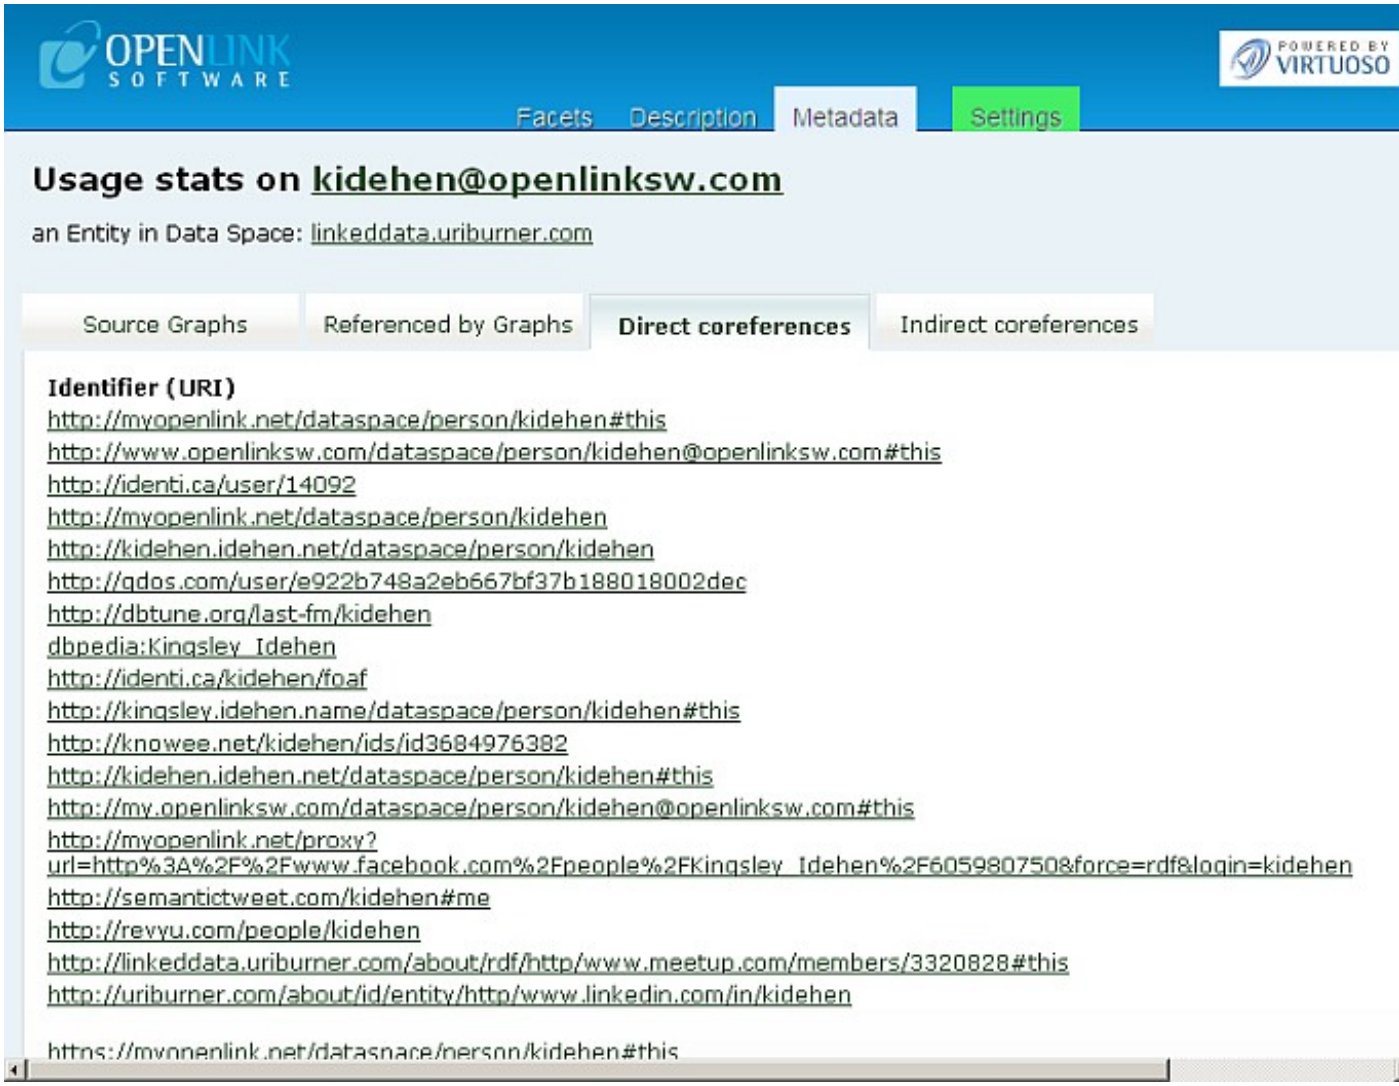
16. Click on "Settings" check "owl:sameAs" and it sets a context mode for the session (meaning: a set of rules to take place):

Figure 16.176. Faceted Navigation Example



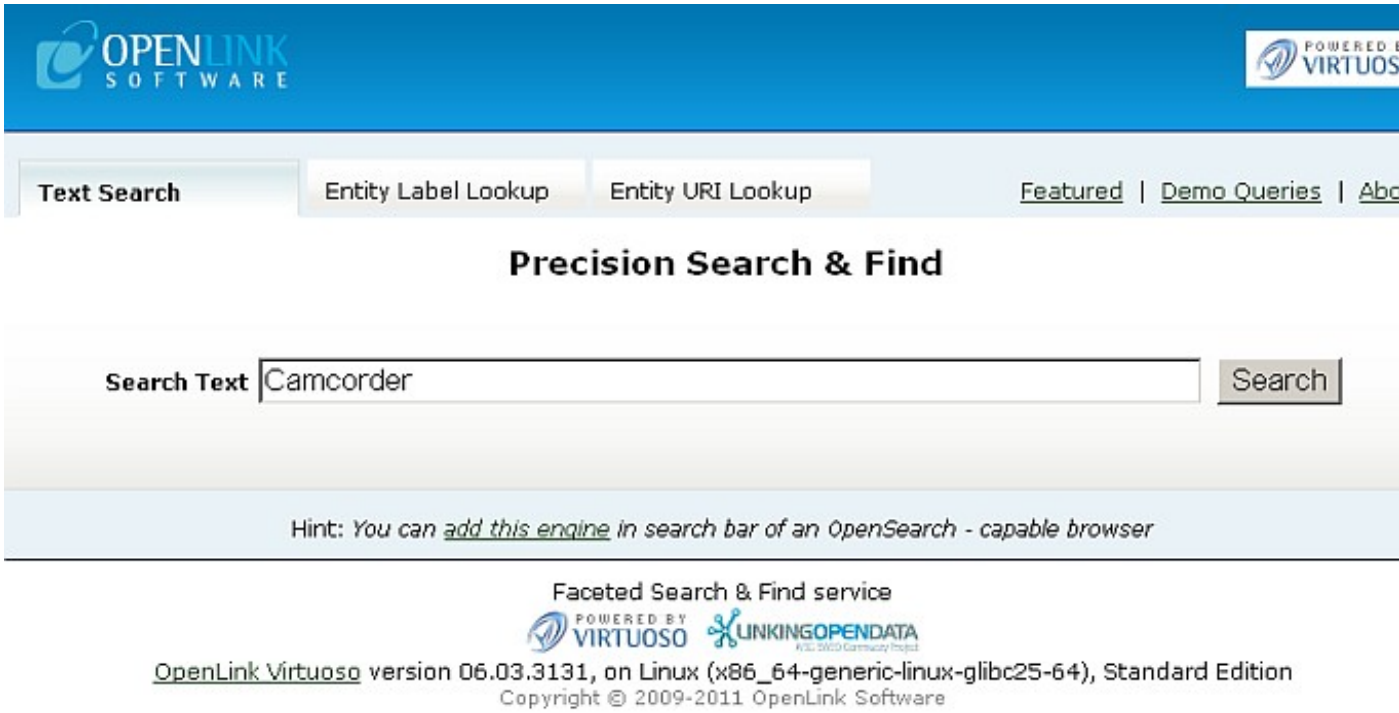
17. Go back to the "Direct Co-reference" tab:

Figure 16.177. Faceted Navigation Example



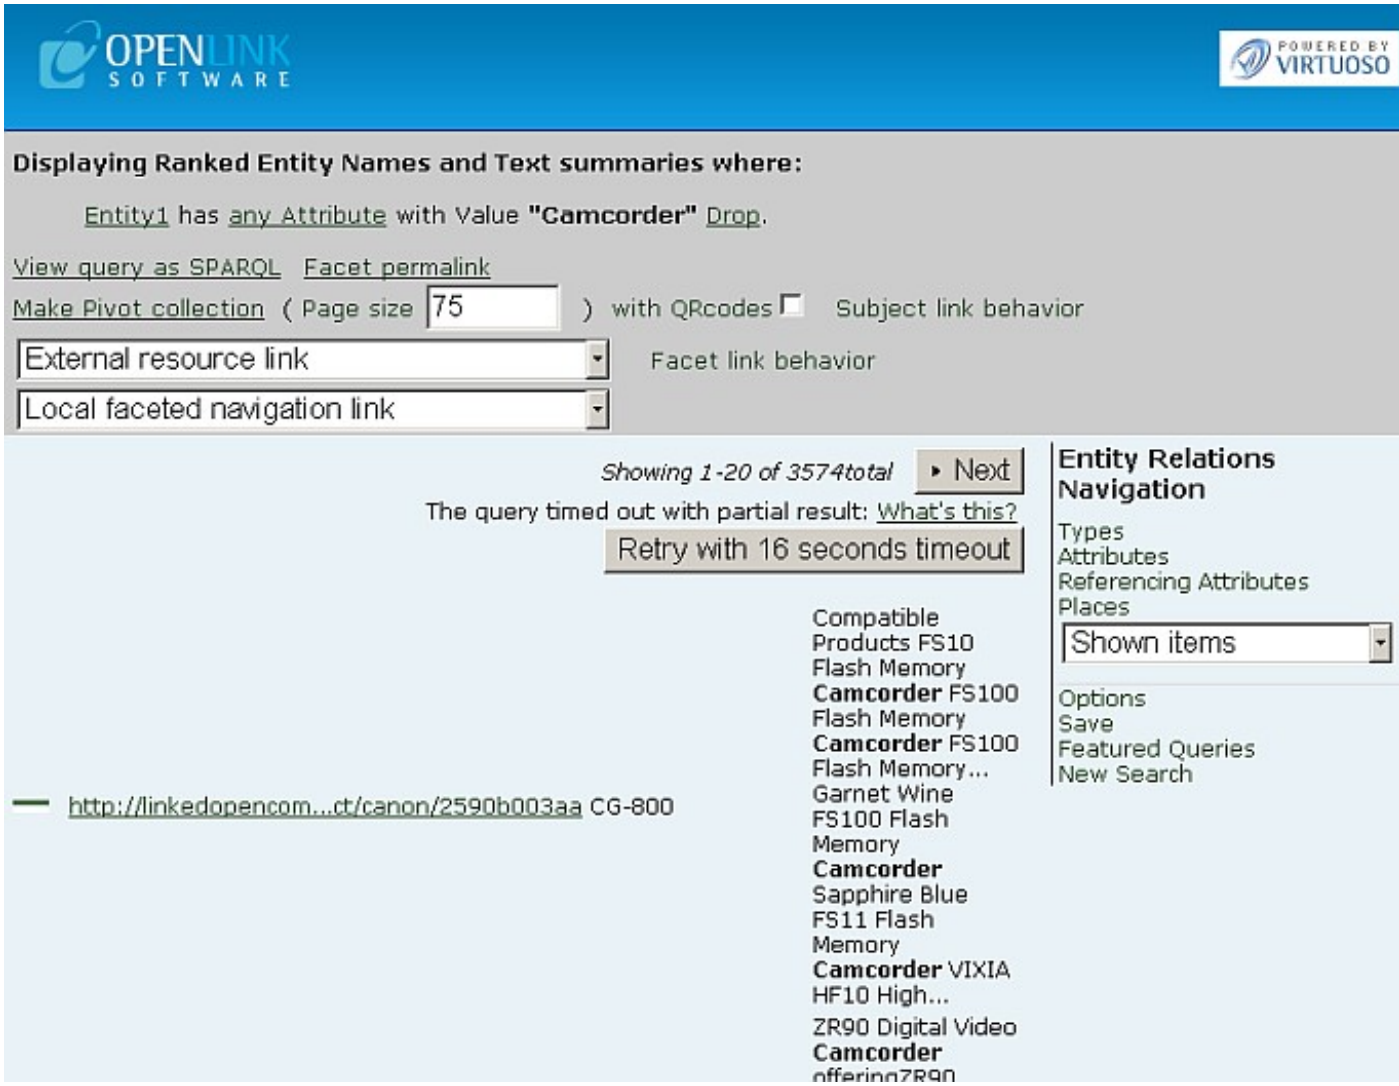
18. As result each link will unveil a union (combination) of all the the data associated with all Kingsley Idehen's other Identifiers (other Names in other places), i.e., they all show the same data.
19. Go to "Facets" and then from "Entity Relations Navigation" click "New Search".
20. Enter a free text search pattern (for example, " `Camcorder` " as consumer product), and click Search:

Figure 16.178. Faceted Navigation Example



21. Your initial query results page will display a list of literal value snippets where for each URI will be displayed a label:

Figure 16.179. Faceted Navigation Example



22. Click for ex. on the URL link ofthe first row result.
23. The product description page should be shown and a list of Attributes and Values will be presented. An URI label of the product also will be shown: "CG-800":

Figure 16.180. Faceted Navigation Example

Figure 16.181. Faceted Navigation Example

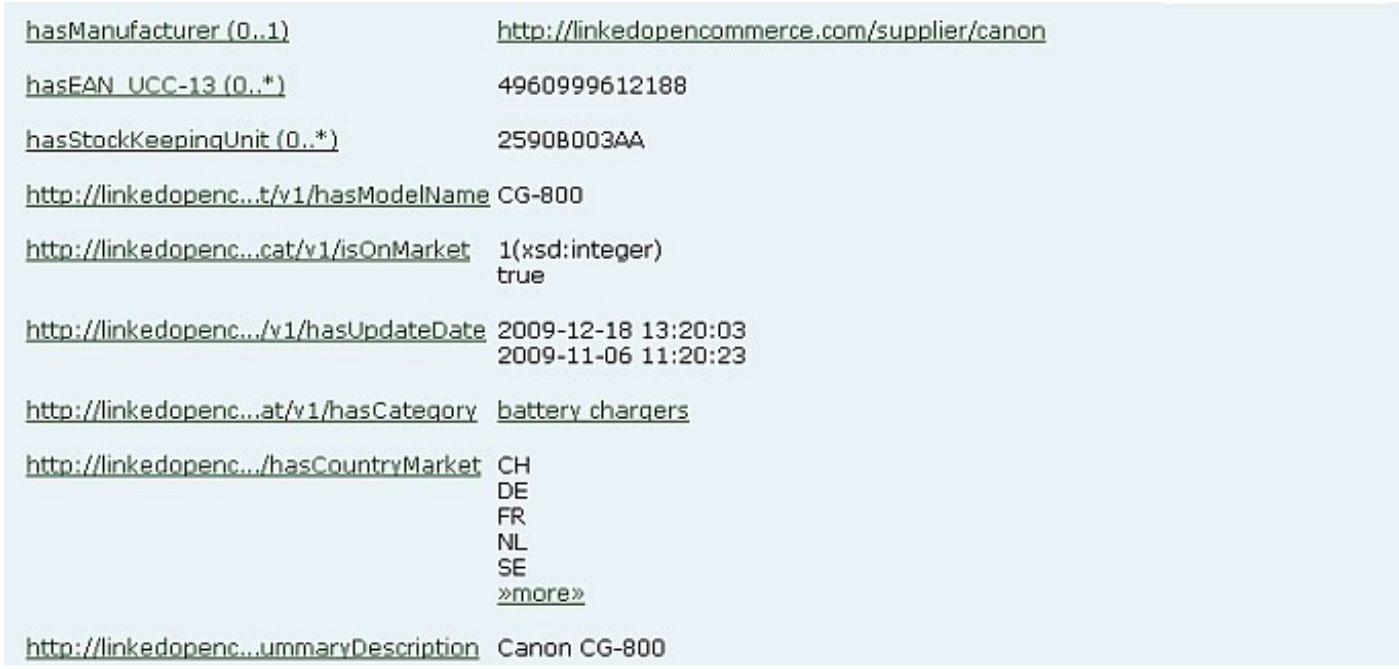


Figure 16.182. Faceted Navigation Example

16.12. Virtuoso Faceted Web Service

The Virtuoso Faceted web service is a general purpose RDF query facility for facet based browsing. It takes an XML description of the view desired and generates the reply as an XML tree containing the requested data. The user agent or a local web page can use XSLT for rendering this for the end user. The selection of facets and values is represented as an XML tree. The rationale for this is the fact that such a representation is easier to process in an application than the SPARQL source text or a parse tree of SPARQL and more compactly captures the specific subset of SPARQL needed for faceted browsing. The web service returns the SPARQL source text also, thus this can serve as a basis for and-crafted queries.

The top element of the tree is <query>, it must be in namespace "http://openlinksw.com/services/facets/1.0/".

This has the following attributes:

- graph="graph_iri" - default is search in all graphs but system defaults may override this
- timeout="no_of_msec" - default is no timeout, but system defaults may override this
- inference="name" where name is a name of an inference context declared with rdfs_rule_set.
- same-as="boolean" - If "boolean" is "yes", then owl:sameAs links will be considered in the query evaluation.

The result is a tree of the form:

```
<facets xmlns="http://openlinksw.com/services/facets/1.0/">
<result><row><column datatype="..." shortform="..." xml:lang="..">...</column></row></result>
<time>msecs</time>
<complete>yes or no</complete>
<db-activity>resource use string</db-activity>
<sparql>sparql statement text</sparql>
</facets>
```

By convention, the first column is the subject selected by the view element, typically a URI, the second a label of the URI and the third, if present, is either a count or a search summary.

The first column's text child is the text form of the value. The column element has the following attributes qualifying this further:

- datatype - The xsd type of the value. If this is a URI, the datatype is "uri"
- shortform - If the value is a URI, this is an abbreviated form where known namespaces are replaced with their prefixes and very long URI's are truncated preserving start and end.
- xml:lang - if the value is a language tagged string, this is the language

The query has the top level element <query>. The child elements of this represent conditions pertaining to a single subject. A join is expressed with the property or property-of element. This has in turn children which state conditions on a property of the first subject. property and property-of elements can be nested to an arbitrary depth and many can occur inside one containing element. In this way, tree-shaped structures of joins can be expressed.

Expressing more complex relationships, such as intermediate grouping, subqueries, arithmetic or such requires writing the query in SPARQL. The XML format is a shorthand for easy automatic composition of queries needed for showing facets, not a replacement for SPARQL.

A facet query contains a single view element. This specifies which subject of the joined subjects is shown. Its attributes specify the manner of viewing, e.g. list of distinct values, distinct values with occurrence counts, properties or classes of the selected subjects etc.

The top query element or any property or property-of element can have the following types of children:

```
<text property="iri">text pattern</text>
```

The subject has an O that matches the text pattern. If property is given, the text pattern must occur in a value of this property. If not specified, any property will do. The value "none" for property is the same as not specifying a property. This is restricted to occurring directly under the top level query element.

```
<class iri="iri" inference="ctx_name" />
```

The S must be an instance of this class. If inference is specified then option (input:inference "ctx_name" is added and applies to this pattern alone.

```
<property iri="iri" same_as="yes" inference="ctx_name">
```

The child elements of this are conditions that apply to the value of this property of the S that is in scope in the enclosing <query> or <property> element. If same_as is present, then option (input:same-as "yes") is added to the triple pattern which specifies this property. If inference is present, then option (input:inference "ctx_name") is added to the triple pattern for the property.

```
<property-of iri="iri" same_as="yes" inference="ctx_name" >
```

The child elements of this are conditions that apply to an S which has property "iri" whose object is the S in scope in the enclosing <query> or <property> element. The options are otherwise the same as with property.

```
<value datatype="type" xml:lang="lng" op="= | < | > | >= | <=">value </value>
```

When this occurs inside <property> or <property-of> this means that the property in scope has the specified relation to the value. type and language can be used for XML typed or language tagged literals. The "uri" type means that the value is a qualified name of a URI. If this occurs directly under the <query> element, this means that the query starts with a fixed subject. If this is so, then there must be property or propertyof elements or the view element must specify properties or classes, list is not allowed as a view type. This is so because the query must have at least one triple pattern.

```
<view type="view" limit="n" offset="n" >
```

This may occur once inside a <query> element but may occur either at top level or inside property or property-of elements. This specifies what which subject is presented in the result set.

The type can be:

- "properties"

```
SPARQL
SELECT ?p count (*) { ?this_s ?p ?any_o ...}
GROUP BY ?p
ORDER BY DESC 2
LIMIT l OFFSET 0
```

- "properties-in"

```
SPARQL
SELECT ?p count (*) { ?any_s ?p ?this_s ... }
GROUP BY ?p
ORDER BY DESC 2
LIMIT L OFFSET 0
```

- "classes"

```
SPARQL
SELECT ?c count (*)
WHERE { ?xx a ?c ... }
GROUP BY ?c
ORDER BY DESC 2
LIMIT l OFFSET 0
```

- "text"

```
SPARQL
SELECT DISTINCT ?s (bif:search_excerpt (sql:search_terms (""pattern"), ?o)) ...
LIMIT 1 OFFSET 0
```

- "list"

```
SPARQL
SELECT DISTINCT ?s long::sql:fct_label (?s) ...
LIMIT 1 OFFSET 0
```

- "list-count"

```
SPARQL
SELECT ?s COUNT (*) ....
GROUP BY ?s
ORDER BY DESC 2
```

- "alphabet"

```
SPARQL
SELECT (sql:subseq (?s, 0, 1)) count (*) ...
GROUP BY (sql:subseq (?s, 0, 1))
ORDER BY 1
```

- "geo"

```
SPARQL
SELECT DISTINCT ?lat ?long ?s
WHERE ?s geo:lat ?lat . ?s geo:long ?long . ... }
```

- "years"

```
SPARQL
SELECT sql::year (?s) count (*) ...
GROUP BY (bif:year (?s))
ORDER BY 1
OFFSET 0 LIMIT 1
```

- "months"

```
SPARQL
SELECT sql::round_month (?s) count (*) ...
GROUP BY (sql:round_month (?s))
ORDER BY 1 OFFSET 0 LIMIT 1
```

- "weeks"

```
SPARQL
SELECT sql::round_week (?s) COUNT (*) ...
GROUP BY (sql:round_week (?s))
ORDER BY 1 OFFSET 0 LIMIT 1
```

- "describe"

```
SPARQL describe ?s ... OFFSET 0 LIMIT 1
```

16.12.1. Customizing

The following types of customization will be generally useful:

- Resource accounting and limitations, managing access and login
- Localization, choice of labels shown with class/property/instance URI's
- Adding types of views, for example timelines, map or business graphics
- Controlling navigation, for example choosing what type of view is initially presented when opening a given property.
- Page layout, captions, help texts, etc.

The source code is divided in two SQL files and a number of XSLT sheets. The file facet.sql has the code for the web service. The facet_view.sql file contains the procedures for the sample HTML interface.

16.12.2. Examples

Note: in all examples the default namespace xmlns="http://openlinksw.com/services/facets/1.0/" is omitted for brevity.

For people called Mike:

```
<query>
  <text>Mike</text>
  <view type="text"/>
</query>
```

To open the list of people who Mike knows:

```
<query>
  <text>Mike</text>
  <view type="properties"/>
</query>
```

To show the list of subjects Mike knows:

```
<query>
  <text>Mike</text>
  <property iri="foaf:knows>
    <view type="list" />
  </property>
</query>
```

To show the properties of people Mike knows:

```
<query>
  <text>Mike</text>
  <property iri="foaf:knows>
    <view type="properties" />
  </property>
</query>
```

To show the names:

```
<query>
  <text>Mike</text>
  <property iri="foaf:knows>
    <property iri="foaf:name>
      <view type="list" />
    </property>
  </property>
</query>
```

To specify one named Joe:

```
<query>
  <text>Mike</text>
  <property iri="foaf:knows>
     <property iri="foaf:name>
        <value>Joe</value>
     </property>
    <view type="properties" />
  </property>
</query>
```

This lists the properties of the friends of Mike that are called Joe.

To show the Mikes that know a Joe, one would change the shown variable in the navigation and get:

```
<query>
  <text>Mike</text>
  <property iri="foaf:knows>
    <property iri="foaf:name>
      <value>Joe</value>
```

```
    </property>
   </property>
   <view type="text" />
</query>
```

This would be the search summaries of subjects with Mike in some field that know a subject with name Joe.

Now to specify that Mike must be a member of a discussion board:

```
<query>
  <text>Mike</text>
  <property iri="foaf:knows>
    <property iri="foaf:name>
     <value>Joe</value>
   </property>
  </property>
  <view type="property-in" />
</query>
```

This lists the properties of triples whom object is Mike. Pick sioc:member_of

```
<query>
  <text>Mike</text>
  <property iri="foaf:knows>
    <property iri="foaf:name>
      <value>Joe</value>
    </property>
  </property>
  <property-of iri="sioc:member_of>
    <view type="list" />
  </property-of>
</query>
```

This would show things where Mike is a member. To specify that the thing must be a forum:

```
<query>
  <text>Mike</text>
  <property iri="foaf:knows>
    <property iri="foaf:name>
      <value>Joe</value>
    </property>
  </property>
  <property-of iri="sioc:member_of>
    <view type="classes" />
  </property-of>
</query>
```

This shows classes of things where Mike is a member Clicking on sioc:Forum gives:

```
<query>
  <text>Mike</text>
  <property iri="foaf:knows>
    <property iri="foaf:name>
      <value>Joe</value>
    </property>
  </property>
  <property-of iri="sioc:member_of>
    <class iri="sioc:Forum" />
    <view type="classes"/>
  </property-of>
</query>
```

The view stays with classes, but now scoped to the classes of things where Mike is a member that are instances of sioc:Forum.

To go look at the list of Mikes with the added restriction, click the shown variable in the navigation and set it to s1.

```
<query>
  <text>Mike</text>
  <property iri="foaf:knows>
    <property iri="foaf:name>
```

```
        <value>Joe</value>
      </property>
    </property>
    <property-of iri="sioc:member_of>
     <class iri="sioc:Forum" />
    </property-of>
    <view type="list"/>
  </query>
```

To say that Joe must also have a geekCode, One clicks the shown variable and sets it to s2 and the view to properties.

```
  <query>
    <text>Mike</text>
    <property iri="foaf:knows>
      <property iri="foaf:name>
        <value>Joe</value>
      </property>
      <view type="properties"/>
    </property>
    <property-of iri="sioc:member_of>
      <class iri="sioc:Forum" />
     </property-of>
  </query>
```

Pick geekCode

```
  <query>
    <text>Mike</text>
    <property iri="foaf:knows>
      <property iri="foaf:name>
        <value>Joe</value>
      </property>
      <property iri="geekCode">
        <view type="list"/>
      </property>
    </property>
    <property-of iri="sioc:member_of>
      <class iri="sioc:Forum" />
    </property-of>
  </query>
```

We specify no restriction on the geekCode. Click the shown variable to take the focus back to Mike.

```
  <query>
    <text>Mike</text>
    <property iri="foaf:knows>
      <property iri="foaf:name>
        <value>Joe</value>
      </property>
      <property iri="geekCode"></property>
    </property>
    <property-of iri="sioc:member_of>
      <class iri="sioc:Forum" />
    </property-of>
    <view type="text"/>
  </query>
```

16.12.3. WebService Interface

REST interface

The Virtuoso Faceted web service provide following REST interface:

Service description:

- Endpoint: http://<cname>/fct/service for ex. http://lod.openlinksw.com/fct/service
- HTTP method: POST
- Content-Type: MUST be 'text/xml'
- The entity body must be XML document with top element 'query' as described above.

- The request response namespace MUST be "http://openlinksw.com/services/facets/1.0"

Error conditions:

The all error conditions are reported via 'Error explanation'

Files:

The facet_svc.sql contains web service code and virtual directory mapping, and it uses fct_req.xsl & fct_resp.xsl as request & response filters.

Example:

Using CURL program

```
curl -H "Content-Type: text/xml" -d @post.xml  http://lod.openlinksw.com/fct/service
```

Where 'post.xml' document contains query document:

```
<?xml version="1.0"?>
<query xmlns="http://openlinksw.com/services/facets/1.0" inference="" same-as="">
  <text> Seattle Mariners traveled all the way to Japan to watch</text>
  <view type="text" limit="20" offset=""/>
</query>
```

Produces following response:

```
<fct:facets xmlns:fct="http://openlinksw.com/services/facets/1.0/">
<fct:sparql>   SELECT distinct ?s1 as ?c1, (bif:search_excerpt (bif:vector ('THE', 'MARINERS', 'WAY', 'SE
<fct:time>116</fct:time>
<fct:complete>yes</fct:complete>
<fct:db-activity>   134R rnd  9.488KR seq      0P disk  8.966MB /    602 messages</fct:db-activity>
 <fct:result>
  <fct:row>
    <fct:column datatype="url" shortform="http://bobdupuy.mlbl...ld_baseball__6.html">http://bobdupuy.mlb
    <fct:column />
    <fct:column><span class="srch_xerpt">... While Chuck Armstrong president of <b>the</b> <b>Seattle</b>
  </fct:row>
  <fct:row>
    <fct:column datatype="url" shortform="http://bobdupuy.mlbl...ld_baseball__6.html">http://bobdupuy.mlb
    <fct:column />
    <fct:column><span class="srch_xerpt">Orlando While Chuck Armstrong president of <b>the</b> <b>Seattle
  </fct:row>
 </fct:result>
</fct:facets>
```

Virtuoso APIs for Faceted REST services

The Virtuoso APIs for FCT REST services are Virtuoso Stored Procedures that enable faceted browsing over Linked Data hosted in the RDF Quad Store. This also includes Linked Data that is progressively added to the Quad Store via URI de-referencing.

They enable the use Virtuoso's VSP/VSPX technology to produce (X)HTML-based Linked Data explorer pages that are endowed with high-performance (in-process) faceted browsing capability.

You can use this API with Virtuoso SQL calls that provide data to your VSP/VSPX, ASP.NET, PHP, etc., -based interfaces using ODBC, JDBC, ADO.NET, or XMLA connectivity (SPASQL) to Virtuoso.

API Definition

```
CREATE PROCEDURE
fct_exec
  (
    IN  tree     ANY ,
    IN  timeout  INT
  )
{
  DECLARE  start_time,
```

```
          view3,
          inx,
          n_rows      INT     ;
  DECLARE  sqls,
          msg,
          qr,
          qr2,

Example

The following example shows how to use the fct_exec APi in vsp page to perform a "text" search for the word "Mike" assuming this exists in your Virtuoso RDF store (if not amend the query in the fct_example.vsp code sample below to search for text known to exist).

1. The service can be used in the following sample fct_example.vsp:

```
<?vsp

declare txt, reply, tree any;
```

```
declare timeout int;

tree := xtree_doc ('
  <query>
    <text>Mike</text>
    <view type="text"/>
  </query>
');

timeout := 3000;
reply := fct_exec (tree, timeout);

txt := string_output ();

http_value (xslt ('virt://WS.WS.SYS_DAV_RES.RES_FULL_PATH.RES_CONTENT:/DAV/fct_example.xsl',
                  reply,
                  vector ()),
                  null, txt);

http (txt);
?>
```

2. The xsl:

```
<?xml version="1.0" encoding="utf-8"?>

<xsl:stylesheet
    version="1.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
  <xsl:output method="html" encoding="ISO-8859-1"/>
  <xsl:variable name="rowcnt" select="count(/facets/result/row)"/>

  <xsl:template match="facets">
    <div
xml:id="res">
      <xsl:if test="/facets/complete = 'yes' and /facets/processed = 0 and $rowcnt = 0">
        <div class="empty_result">
          Nothing found.
        </div>
      </xsl:if>
      <xsl:for-each select="/facets/result">
        <xsl:call-template name="render-result"/>
      </xsl:for-each>
    </div>
    <!-- #res -->

  </xsl:template>

  <xsl:template name="render-result">
    <table class="result" border="1">
      <thead>
        <tr>
          <th>Entity</th>
          <th>Title</th>
          <th>Text excerpt</th>
        </tr>
      </thead>
      <tbody>
        <xsl:for-each select="row">
          <tr>
            <td class="rnk">
              <xsl:for-each select="column[@datatype='trank' or @datatype='erank']">

SOAP interface

The facet web service is also available via SOAP protocol.

The request message contains single element 'query' with syntax explained earlier. Also the SOAPAction HTTP header should be '#query' . After successful evaluation of the query, the service will return a SOAP envelope containing in the Body element single 'facets' element described above.

Example:

This example shows execution of same command as in example for REST interface here it using SOAP:

Request message:

```
<SOAP:Envelope xmlns:SOAP="http://schemas.xmlsoap.org/soap/envelope/">
  <SOAP:Body>
    <query xmlns="http://openlinksw.com/services/facets/1.0/" inference="" same-as="">
      <text>Seattle Mariners traveled all the way to Japan to watch</text>
      <view type="text" limit="20" offset="0"/>
    </query>
  </SOAP:Body>
</SOAP:Envelope>
```

Response message:

```
<SOAP:Envelope xmlns:SOAP="http://schemas.xmlsoap.org/soap/envelope/">
  <SOAP:Body>
    <fct:facets xmlns:fct="http://openlinksw.com/services/facets/1.0/">

          </fct:row>
        </fct:result>
      </fct:facets>
    </SOAP:Body>
  </SOAP:Envelope>
```

16.13. Linked Data

There are many cases when RDF data should be retrieved from remote sources only when really needed. E.g., a scheduling application may read personal calendars from personal sites of its users. Calendar data expire quickly, so there's no reason to frequently re-load them in hope that they are queried before expired.

Virtuoso extends SPARQL so it is possible to download RDF resource from a given IRI, parse them and store the resulting triples in a graph, all three operations will be performed during the SPARQL query execution. The IRI of graph to store triples is usually equal to the IRI where the resource is download from, so the feature is named "IRI dereferencing" There are two different use cases for this feature. In simple case, a SPARQL query contains *from* clauses that enumerate graphs to process, but there are no triples in *DB.DBA.RDF_QUAD* that correspond to some of these graphs. The query execution starts with dereferencing of these graphs and the rest runs as usual. In more sophisticated case, the query is executed many times in a loop. Every execution produces a partial result. SPARQL processor checks for IRIs in the result such that resources with that IRIs may contain relevant data but not yet loaded into the *DB.DBA.RDF_QUAD* . After some iteration, the partial result is identical to the result of the previous iteration, because there's no more data to retrieve. As the last step, SPARQL processor builds the final result set.

16.13.1. IRI Dereferencing For FROM Clauses, "define get:..." Pragmas

Virtuoso extends SPARQL syntax of *from* and *from named* clauses. It allows additional list of options at end of clause: *option (param1 value1, param2 value2, ...)* where parameter names are QNames that start with *get:* prefix and values are "precode" expressions, i.e. expressions that does not contain variables other than external parameters. Names of allowed parameters are listed below.

- *get:soft*

  is the retrieval mode, supported values are "soft" and "replacing". If the value is "soft" then the SPARQL processor will not even try to retrieve triples if the destination graph is non-empty. Other

  get:...

  parameters are useless without this one.
- *get:uri*

  is the IRI to retrieve if it is not equal to the IRI of the

  from

  clause. These can be used if data should be retrieved from a mirror, not from original resource location or in any other case when the destination graph IRI differs from the location of the resource.
- ```
  SQL>SPARQL
  define get:uri "http://example.com/dataspace/person/kidehen"
  SELECT ?id
  FROM NAMED <http://www.openlinksw.com/dataspace/kidehen@openlinksw.com/weblog/kidehen@openlinksw.c
  WHERE { graph ?g { ?id a ?o } }
  LIMIT 10;

  id

10 Rows. -- 10 msec.
```

- *get:method*

  is the HTTP method that should be used to retrieve the resource, supported methods are "GET" for plain HTTP and "MGET" for URIQA web service endpoint. By default, "MGET" is used for IRIs that end with "/" and "GET" for everything else.
- *get:refresh*

  is the maximum allowed age of the cached resource, no matter what is specified by the server where the resource resides. The value is an positive integer (number of seconds). Virtuoso reads HTTP headers and uses "Date", "ETag", "Expires", "Last-Modified", "Cache-Control" and "Pragma: no-cache" fields to calculate when the resource should be reloaded, this value can become smaller due to

  get:refresh

  but can not be incremented.
- ```

```

- It can make text shorter and it is especially useful when the query text comes from client but the parameter should have a fixed value due to security reasons: the values set by *define get:*... can not be redefined inside the query and the application may prevent the text with desired pragmas before the execution.

  Note that the user should have *SPARQL_UPDATE* role in order to execute such a query. By default SPARQL web service endpoint is owned by *SPARQL* user that have *SPARQL_SELECT* but not *SPARQL_UPDATE* . It is possible in principle to grant *SPARQL_UPDATE* to *SPARQL* but this breaches the whole security of the RDF storage.
- *FROM CLAUSE with options*

  : options in OPTION() list should be delimited with commas. grab options are not allowed as they are global for the query. Only specific 'get:xxx' options are useful here.

```
SQL>SPARQL
PREFIX foaf: <http://xmlns.com/foaf/0.1/>
SELECT DISTINCT ?friend
FROM NAMED  <http://example.com/dataspace/person/kidehen>
```

```
OPTION (get:soft "soft", get:method "GET")
WHERE

16.13.2. IRI Dereferencing For Variables, "define input:grab-..." Pragmas

Consider a set of personal data such that one resource can list many persons and point to resources where that persons are described in more details. E.g. resource about *user1* describes the user and also contain statements that *user2* and *user3* are persons and more data can be found in *user2.ttl* and *user3.ttl* , *user3.ttl* can contain statements that *user4* is also person and more data can be found in *user4.ttl* and so on. The query should find as many users as it is possible and return their names and e-mails.

If all data about all users were loaded into the database, the query could be quite simple:

```
SQL>SPARQL
prefix foaf: <http://xmlns.com/foaf/0.1/>
prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
SELECT ?id ?firstname ?nick
where
  {
    graph ?g
      {
        ?id rdf:type foaf:Person.
        ?id foaf:firstName ?firstname.
        ?id foaf:knows ?fn .
        ?fn foaf:nick ?nick.
      }
   }
limit 10;

id                                                    firstname  nick
VARCHAR                                               VARCHAR    VARCHAR

The IRI dereferencing is controlled by the following pragmas:

- *input:grab-var*

  specifies a name of variable whose values should be used as IRIs of resources that should be downloaded. It is not an error if the variable is sometimes unbound or gets values that can not be converted to IRIs (e.g., integers) -- bad values are silently ignored. It is also not an error if the IRI can not be retrieved, this makes IRI retrieval somewhat similar to "best effort union" in SQL. This pragma can be used more than once to specify many variable names. It is not an error if values of different variables result in same IRI or a variable gets same value many times -- no one IRI is retrieved more than once.
- *input:grab-iri*

  specifies an IRI that should be retrieved before executing the rest of the query, if it is not in the

  DB.DBA.RDF_QUAD

  already. This pragma can be used more than once to specify many IRIs. The typical use of this pragma is querying a set of related resources when only one "root" resource IRI is known but even that resource is not loaded.
- ```
  SQL>SPARQL
    define input:storage ""
    define input:grab-iri <http://www.openlinksw.com/dataspace/kidehen@openlinksw.com/weblog/kidehen
    define input:grab-var "id"
    define input:grab-depth 10
    define input:grab-limit 100
    define input:grab-base "http://www.openlinksw.com/dataspace/kidehen@openlinksw.com/weblog/kidehe
  SELECT ?id

10 Rows. -- 530 msec.
```

- *input:grab-all*

  is the simplest possible way to enable the feature but the resulting performance can be very bad. It turns all variables and IRI constants in all graph, subject and object fields of all triple patterns of the query into values for

  input:grab-var

  and

  input:grab-iri

  , so the SPARQL processor will dereference everything what might be related to the text of the query.

```
SQL>SPARQL
  define input:grab-all "yes"
  define input:grab-depth 10

10 Rows. -- 660 msec.
```

- *input:grab-seealso*

  (and synonym

  input:grab-follow-predicate

) specifies an IRI of an predicate similar to foaf:seeAlso. Predicates of that sort suggest location of resources that contain more data about predicate subject. The IRI dereferencing routine may use these predicates to find additional IRIs for loading resources. This is especially useful when the text of the query comes from remote client and may lack triple patterns like

optional { ?id <SeeAlso> ?more }

from the previous example. The use of

input:grab-seealso

makes the SPARQL query nondeterministic, because the order and the number of retrieved documents will depend on execution plan and they may change from run to run. This pragma can be used more than once to specify many IRIs, but this feature is costly. Every additional predicate may result in significant number of lookups in the RDF storage, affecting total execution time.

- ```
  SQL>SPARQL
    define input:grab-iri <http://www.openlinksw.com/dataspace/kidehen@openlinksw.com/weblog/kidehen
    define input:grab-var "id"
    define input:grab-depth 10

  9 Rows. -- 105 msec.
  ```

- *input:grab-limit*

  should be an integer that is a maximum allowed number of resource retrievals. The default value is pretty big (few millions of documents) so it is strongly recommended to set smaller value. Set it even if you're absolutely sure that the set of resources is small, because program errors are always possible. All resource downloads are counted, both successful and failed, both forced by

  input:grab-iri

  and forced by

  input:grab-var

  . Nevertheless, all constant IRIs specified by

  input:grab-iri

  (or
  ```

input:grab-all

) are downloaded before the first check of the

input:grab-limit

counter, so this limit will never prevent from downloading "root" resources.

- *input:grab-depth*

  should be an integer that is a maximum allowed number of query iterations. Every iteration may find new IRIs to retrieve, because resources loaded on previous iteration may add these IRIs to

  DB.DBA.RDF_QUAD

  and make result set longer. The default value is 1, so the SPARQL processor will retrieve only resources explicitly named in "root" resources or in quad that are in the database before the query execution.
- *input:grab-base*

  specifies a base IRI used to convert relative IRIs into absolute. The default is an empty string.
- ```
  SQL>SPARQL
    define input:grab-depth 10
    define input:grab-limit 100
    define input:grab-var "more"
    define input:grab-base "http://www.openlinksw.com/dataspace/kidehen@openlinksw.com/weblog/kidehe
    prefix foaf: <http://xmlns.com/foaf/0.1/>
  SELECT ?id
  where
    {
      graph ?g
       {
         ?id a foaf:Person .
         optional { ?id foaf:maker ?more }
       }
    }
  limit 10;

  id

  ```
- *input:grab-resolver*

  is a name of procedure that resolve IRIs and determines the HTTP method of retrieval. The default is name of

  DB.DBA.RDF_GRAB_RESOLVER_DEFAULT()

  procedure that is described below. If other procedure is specified, the signature should match to the default one.
- *input:grab-destination*

  is to override the default behaviour of the IRI dereferencing and store all retrieved triples in a single graph. This is convenient when there's no logical difference where any given triple comes from, and changes in remote resources will only add triples but not make cached triples obsolete. A SPARQL query is usually faster when all graph IRIs are fixed and there are no graph group patterns with an unbound graph variable, so storing everything in one single graph is worth considering.
  ```

- *input:grab-loader*

  is a name of procedure that retrieve the resource via HTTP, parse it and store it. The default is name of

  DB.DBA.RDF_SPONGE_UP()

  procedure; this procedure also used by IRI dereferencing for FROM clauses. You will probably never need to write your own procedure of this sort but some Virtuoso plugins will provide ready-to-use functions that will retrieve non-RDF resources and extract their metadata as triples or will implement protocols other than HTTP.

Default resolver procedure is *DB.DBA.RDF_GRAB_RESOLVER_DEFAULT()* . Note that the function produce two absolute URIs, *abs_uri* and *dest_uri* . Default procedure returns two equal strings, but other may return different values, e.g., return primary and permanent location of the resource as *dest_uri* and the fastest known mirror location as *abs_uri* thus saving HTTP retrieval time. It can even signal an error to block the downloading of some unwanted resource.

```
DB.DBA.RDF_GRAB_RESOLVER_DEFAULT (
  in base varchar,         -- base IRI as specified by input:grab-base pragma
  in rel_uri varchar,      -- IRI of the resource as it is specified by input:grab-iri or a value of a va
  out abs_uri varchar,     -- the absolute IRI that should be downloaded
  out dest_uri varchar,    -- the graph IRI where triples should be stored after download
  out get_method varchar ) -- the HTTP method to use, should be "GET" or "MGET".
```

16.13.3. URL rewriting

URL rewriting is the act of modifying a source URL prior to the final processing of that URL by a Web Server.

The ability to rewrite URLs may be desirable for many reasons that include:

- Changing Web information resource URLs on the a Web Server without breaking existing bookmarks held in User Agents (e.g., Web browsers)
- URL compaction where shorter URLs may be constructed on a conditional basis for specific User Agents (e.g. Email clients)
- Construction of search engine friendly URLs that enable richer indexing since most search engines cannot process parameterized URLs effectively.

Using URL Rewriting to Solve Linked Data Deployment Challenges

URI naming schemes don't resolve the challenges associated with referencing data. To reiterate, this is demonstrated by the fact that the URIs http://demo.openlinksw.com/Northwind/Customer/ALFKI and http://demo.openlinksw.com/Northwind/Customer/ALFKI#this both appear as http://demo.openlinksw.com/Northwind/Customer/ALFKI to the Web Server, since data following the fragment identifier "#" never makes it that far.

The only way to address data referencing is by pre-processing source URIs (e.g. via regular expression or sprintf substitutions) as part of a URL rewriting processing pipeline. The pipeline process has to take the form of a set of rules that cater for elements such as HTTP Accept headers, HTTP response code, HTTP response headers, and rule processing order.

An example of such a pipeline is depicted in the table below.

Table 16.17. Pre-processing source URIs

URI Source(Regular Expression Pattern)	HTTP Accept Headers(Regular Expression)	HTTPResponse Code	HTTP Response Headers	Rule Processing Order
/Northwind/Customer/([^#]*)	None (meaning default)	200 or 303 redirect to a resource with default representation.	None	Normal (order irrelevant)
/Northwind/Customer/([^#]*)	(text/rdf.n3)	(application/rdf.xml)	303 redirect to location of a descriptive and associated resource (e.g. RESTful Web	None

URI Source(Regular Expression Pattern)	HTTP Accept Headers(Regular Expression)	HTTPResponse Code	HTTP Response Headers	Rule Processing Order
			Service that returns desired representation)	
/Northwind/Customer/([^#]*)	(text/html)	(application/xhtml.xml)	406 (Not Acceptable)or303 redirect to location of resource in requested representation	Vary: negotiate, acceptAlternates: {"ALFKI" 0.9 {type application/rdf+xml}}

The source URI patterns refer to virtual or physical directories for ex. at http://demo.openlinksw.com/. Rules can be placed at the head or tail of the pipeline, or applied in the order they are declared, by specifying a Rule Processing Order of First, Last, or Normal, respectively. The decision as to which representation to return for URI http://demo.openlinksw.com/Northwind/Customer/ALFKI is based on the MIME type(s) specified in any Accept header accompanying the request.

In the case of the last rule, the Alternates response header applies only to response code 406. 406 would be returned if there were no (X)HTML representation available for the requested resource. In the example shown, an alternative representation is available in RDF/XML.

When applied to matching HTTP requests, the last two rules might generate responses similar to those below:

```
$ curl -I -H "Accept: application/rdf+xml" http://demo.openlinksw.com/Northwind/Customer/ALFKI

HTTP/1.1 303 See Other
Server: Virtuoso/05.00.3016 (Solaris) x86_64-sun-solaris2.10-64 PHP5
Connection: close
Content-Type: text/html; charset=ISO-8859-1
Date: Mon, 16 Jul 2007 22:40:03 GMT
Accept-Ranges: bytes
Location: /sparql?query=CONSTRUCT+{+%3Chttp%3A//demo.openlinksw.com/Northwind/Customer/ALFKI%23this%3E+%3
Content-Length: 0
```

In the cURL exchange depicted above, the target Virtuoso server redirects to a SPARQL endpoint that retrieves an RDF/XML representation of the requested entity.

```
$ curl -I -H "Accept: text/html" http://demo.openlinksw.com/Northwind/Customer/ALFKI

HTTP/1.1 406 Not Acceptable
Server: Virtuoso/05.00.3016 (Solaris) x86_64-sun-solaris2.10-64 PHP5
Connection: close
Content-Type: text/html; charset=ISO-8859-1
Date: Mon, 16 Jul 2007 22:40:23 GMT
Accept-Ranges: bytes
Vary: negotiate,accept
Alternates: {"ALFKI" 0.9 {type application/rdf+xml}}
Content-Length: 0
```

In this second cURL exchange, the target Virtuoso server indicates that there is no resource to deliver in the requested representation. It provides hints in the form of an alternate resource representation and URI that may be appropriate, i.e., an RDF/XML representation of the requested entity.

The Virtuoso Rules-Based URL Rewriter

Virtuoso provides a URL rewriter that can be enabled for URLs matching specified patterns. Coupled with customizable HTTP response headers and response codes, Data-Web server administrators can configure highly flexible rules for driving content negotiation and URL rewriting. The key elements of the URL rewriter are:

- Rewriting rule
- Each rule describes how to parse a single source URL, and how to compose the URL of the page ultimately returned in the "Location:" response headers
- Every rewriting rule is uniquely identified internally (using IRIs).

- Two types of rule are supported, based on the syntax used to describe the source URL pattern matching: sprintf-based and regex-based.
- Rewrite rules list
- A named ordered list of rewrite rules or rule lists where rules of the list are processed from top to bottom or in line with processing pipeline precedence instructions
- Configuration API
- The rewriter configuration API defines functions for creating, dropping, and enumerating rules and rule lists.
- Virtual hosts and virtual paths
- URL rewriting is enabled by associating a rewrite rules list with a virtual directory

Virtual Domains (Hosts) & Directories

A Virtuoso virtual directory maps a logical path to a physical directory that is file system or WebDAV based. This mechanism allows physical locations to be hidden or simply reorganised. Virtual directory definitions are held in the system table DB.DBA.HTTP_PATH. Virtual directories can be administered in three basic ways:

- Using the Visual Administration Interface via a Web browser;
- Using the functions vhost_define() and vhost_remove(); and
- Using SQL statements to directly update the HTTP_PATH system table.

"Nice" URLs vs. "Long" URLs

Although we are approaching the URL Rewriter from the perspective of deploying linked data, the Rewriter was developed with additional objectives in mind. These in turn have influenced the naming of some of the formal argument names in the Configuration API function prototypes. In the following sections, long URLs are those containing a query string with named parameters; nice (aka. source) URLs have data encoded in some other format. The primary goal of the Rewriter is to accept a nice URL from an application and convert this into a long URL, which then identifies the page that should actually be retrieved.

Rule Processing Mechanics

When an HTTP request is accepted by the Virtuoso HTTP server, the received nice URL is passed to an internal path translation function. This function takes the nice URL and, if the current virtual directory has a url_rewrite option set to an existing ruleset name, tries to match the corresponding rulesets and rules; that is, it performs a recursive traversal of any rulelist associated with it. For every rule in the rulelist, the same logic is applied (only the logic for regex-based rules is described; that for sprintf-based rules is very similar):

- The input for the rule is the resource URL as received from the HTTP header, i.e., the portion of the URL from the first '/' after the host:port fields to the end of the URL.
- The input is normalized.
- The input is matched against the rule's regex. If the match fails, the rule is not applied and the next rule is tried. If the match succeeds, the result is a vector of values.
- If the URL contains a query string, the names and values of the parameters are decoded by split_and_decode().
- The names and values of any parameters in the request body are also decoded.
- The destination URL is composed
- The value of each parameter in the destination URL is taken from (in order of priority)
- The value of a parameter in the match result;
- The value of a named parameter in the query string of the input nice URL;
- If the original request was submitted by the POST method, the value of a named parameter in the body of the POST request; or
- if a parameter value cannot be derived from one of these sources, the rule is not applied and the next rule is tried.

The path translation function described above is internal to the Web server, so its signature is not appropriate for Virtuoso/PL calls and thus is not published. Virtuoso/PL developers can harness the same functionality using the DB.DBA.URLREWRITE_APPLY API call.

Enabling URL Rewriting via the Virtuoso Conductor UI

Virtuoso is a full-blown HTTP server in its own right. The HTTP server functionality co-exists with the product core (i.e., DBMS Engine, Web Services Platform, WebDAV filesystem, and other components of the Universal Server). As a result, it has the ability to multi-home Web domains within a single instance across a variety of domain name and port combinations. In addition, it also enables the creation of multiple virtual directories per domain.

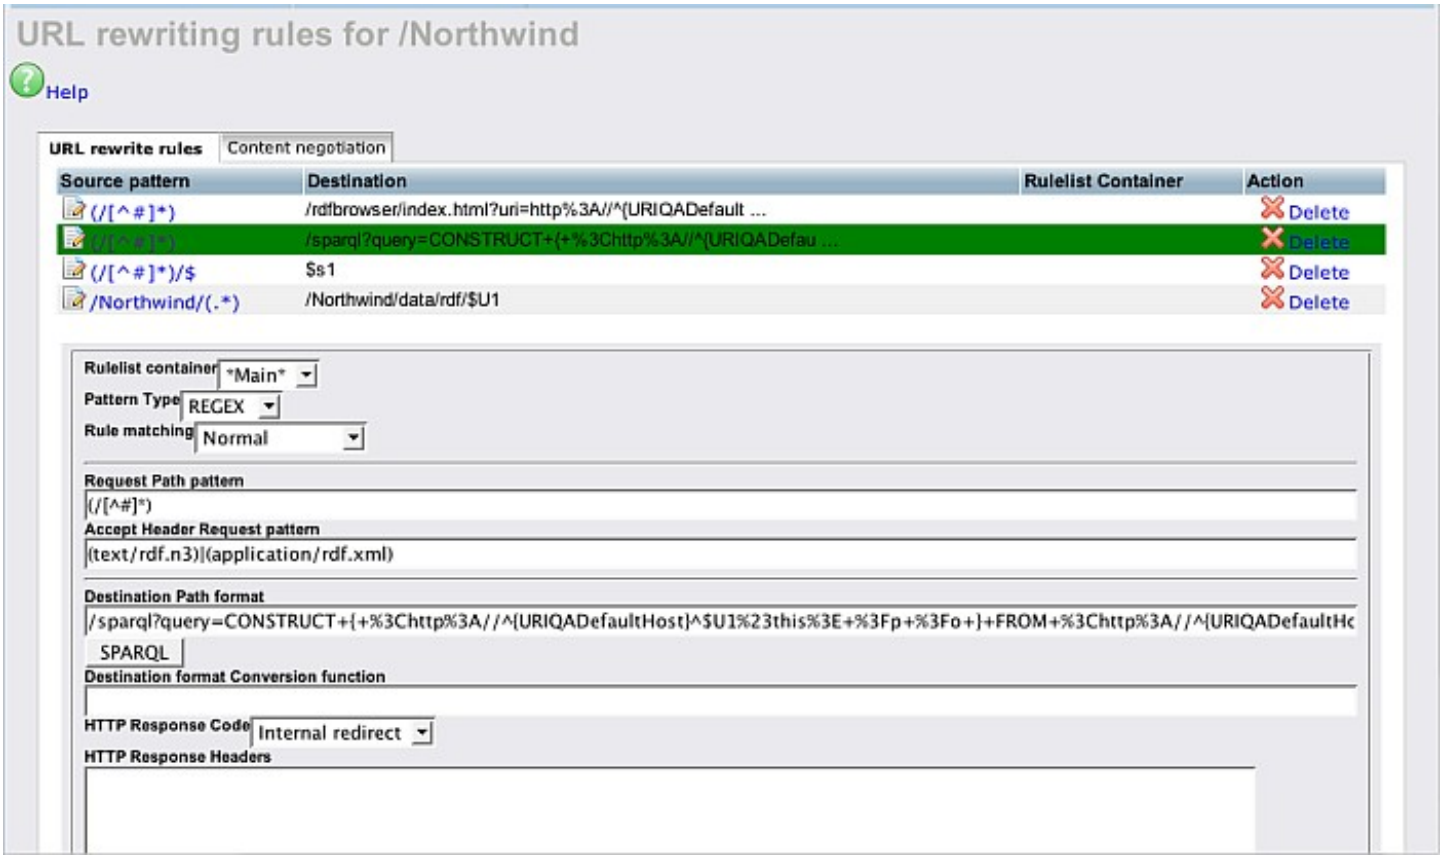
In addition to the basic functionality, Virtuoso facilitates the association of URL Rewriting rules with the virtual directories associated with a hosted Web domain.

In all cases, Virtuoso enables you to configure virtual domains, virtual directories and URL rewrite rules for one or more virtual directories, via the (X)HTML-based Conductor Admin User Interface or a collection of Virtuoso Stored Procedure Language (PL)-based APIs.

The steps for configuring URL Rewrite rules via the Virtuoso Conductor are as follows:

- Assuming you are using the local demonstration database, load http://example.com/conductor into your browser, and then proceed through the Conductor as follows:
- Click the "Web Application Server", and "Virtual Domains & Directories" tabs
- Pick the domain that contains the virtual directories to which the rules are to be applied (in this case the default was taken)
- Click on the "URL-rewrite" link to create, delete, or edit a rule as shown below:
- Create a Rule for HTML Representation Requests (via SPARQL SELECT Query)
- Create a Rule for RDF Representation Requests (via SPARQL CONSTRUCT Query)
- Then save and exit the Conductor, and test your rules with curl or any other User Agent.

Figure 16.184. URL-rewrite UI using Conductor



Enabling URL Rewriting via Virtuoso PL

The vhost_define()API is used to define virtual hosts and virtual paths hosted by the Virtuoso HTTP server. URL rewriting is enabled through this function's opts parameter. opts is of type ANY, e.g., a vector of field-value pairs. Numerous fields are recognized for controlling different options. The field value url_rewrite controls URL rewriting. The corresponding field value is the IRI of a rule list to apply.

Configuration API

Virtuoso includes the following functions for managing URL rewriting rules and rule lists. The names are self-explanatory.

```
-- Deletes a rewriting rule
DB.DBA.URLREWRITE_DROP_RULE
```

```
-- Creates a rewriting rule which uses sprintf-based pattern matching
DB.DBA.URLREWRITE_CREATE_SPRINTF_RULE

-- Creates a rewriting rule which uses regular expression (regex) based pattern matching
DB.DBA.URLREWRITE_CREATE_REGEX_RULE

-- Deletes a rewriting rule list
DB.DBA.URLREWRITE_DROP_RULELIST

-- Creates a rewriting rule list
DB.DBA.URLREWRITE_CREATE_RULELIST

-- Lists all the rules whose IRI match the specified 'SQL like' pattern
DB.DBA.URLREWRITE_ENUMERATE_RULES

-- Lists all the rule lists whose IRIs match the specified 'SQL like' pattern
DB.DBA.URLREWRITE_ENUMERATE_RULELISTS
```

Creating Rewriting Rules

Rewriting rules take two forms: sprintf-based or regex-based. When used for nice URL to long URL conversion, the only difference between them is the syntax of format strings. The reverse long to nice conversion works only for sprintf-based rules, whereas regex-based rules are unidirectional.

For the purposes of describing how to make dereferenceable URIs for linked data, we will stick with the nice to long conversion using regex-based rules.

Regex rules are created using the *URLREWRITE_CREATE_REGEX_RULE()* function.

Example - URL Rewriting For the Northwind Linked Data View

The Northwind schema is comprised of commonly understood SQL Tables that include: Customers, Orders, Employees, Products, Product Categories, Shippers, Countries, Provinces etc.

An Linked Data View of SQL data is an RDF named graph (RDF data set) comprised of RDF Linked Data (triples) stored in a Virtuoso Quad Store (the native RDF Data Management realm of Virtuoso).

In this example we are going interact with Linked Data deployed into the Data-Web from a live instance of Virtuoso, which uses the URL Rewrite rules from the prior section.

The components used in the example are as follows:

- Virtuoso SPARQL Endpoint: http://demo.openlinksw.com/sparql
- Named RDF Graph: http://demo.openlinksw.com/Northwind
- Entity ID - http://demo.openlinksw.com/Northwind/Customer/ALFKI#this
- Information Resource: http://demo.openlinksw.com/Northwind/Customer/ALFKI
- Interactive SPARQL Query Builder (iSPARQL) - http://demo.openlinksw.com/DAV/JS/isparql/index.html

Northwind URL Rewriting Verification Using curl

The curl utility provides a useful tool for verifying HTTP server responses and rewriting rules. The curl exchanges below show the URL rewriting rules defined for the Northwind RDF view being applied.

Example 1:

```
$ curl -I -H "Accept: text/html" http://demo.openlinksw.com/Northwind/Customer/ALFKI

HTTP/1.1 303 See Other
Server: Virtuoso/05.00.3016 (Solaris) x86_64-sun-solaris2.10-64 PHP5
Connection: close
Content-Type: text/html; charset=ISO-8859-1
Date: Tue, 14 Aug 2007 13:30:02 GMT
Accept-Ranges: bytes
Location: http://demo.openlinksw.com/about/html/http/demo.openlinksw.com/Northwind/Customer/ALFKI
Content-Length: 0
```

Example 2:

```
$ curl -I -H "Accept: application/rdf+xml" http://demo.openlinksw.com/Northwind/Customer/ALFKI

HTTP/1.1 303 See Other
Server: Virtuoso/05.00.3016 (Solaris) x86_64-sun-solaris2.10-64 PHP5
Connection: close
Content-Type: text/html; charset=ISO-8859-1
Date: Tue, 14 Aug 2007 13:30:22 GMT
Accept-Ranges: bytes
Location: /sparql?query=CONSTRUCT+{+%3Chttp%3A//demo.openlinksw.com/Northwind/Customer/ALFKI%23this%3E+%3
Content-Length: 0
```

Example 3:

```
$ curl -I -H "Accept: text/html" http://demo.openlinksw.com/Northwind/Customer/ALFKI#this

HTTP/1.1 404 Not Found
Server: Virtuoso/05.00.3016 (Solaris) x86_64-sun-solaris2.10-64 PHP5
Connection: Keep-Alive
Content-Type: text/html; charset=ISO-8859-1
Date: Tue, 14 Aug 2007 13:31:01 GMT
Accept-Ranges: bytes
Content-Length: 0
```

The output above shows how RDF entities from the Data-Web, in this case customer ALFKI, are exposed in the Document Web. The power of SPARQL coupled with URL rewriting enables us to produce results in line with the desired representation. A SPARQL SELECT or CONSTRUCT query is used depending on whether the requested representation is text/html or application/rdf+xml, respectively.

The 404 response in Example 3 indicates that no HTML representation is available for entity ALFKI#this. In most cases, a URI of this form (containing a '#' fragment identifier) will not reach the server. This example supposes that it does: i.e., the RDF client and network routing allows the suffixed request. The presence of the #this suffix implicitly states that this is a request for a data resource in the Data-Web realm, not a document resource from the Document Web.2

Rather than return 404, we could instead choose to construct our rewriting rules to perform a 303 redirect, so that the response for ALFKI#this in Example 3 becomes the same as that for ALFKI in Example 1.

Transparent Content Negotiation

So as not to overload our preceding description of Linked Data deployment with excessive detail, the description of content negotiation presented thus far was kept deliberately brief. This section discusses content negotiation in more detail.

HTTP/1.1 Content Negotiation

Recall that a resource (conceptual entity) identified by a URI may be associated with more than one representation (e.g. multiple languages, data formats, sizes, resolutions). If multiple representations are available, the resource is referred to as negotiable and each of its representations is termed a variant. For instance, a Web document resource, named 'ALFKI' may have three variants: alfki.xml, alfki.html and alfki.txt all representing the same data. Content negotiation provides a mechanism for selecting the best variant.

As outlined in the earlier brief discussion of content negotiation, when a user agent requests a resource, it can include with the request Accept headers (Accept, Accept-Language, Accept-Charset, Accept-Encoding etc.) which express the user preferences and user agent capabilities. The server then chooses and returns the best variant based on the Accept headers. Because the selection of the best resource representation is made by the server, this scheme is classed as server-driven negotiation.

Transparent Content Negotiation

An alternative content negotiation mechanism is Transparent Content Negotiation (TCN), a protocol defined by RFC2295 . TCN offers a number of benefits over standard HTTP/1.1 negotiation, for suitably enabled user agents.

RFC2295 introduces a number of new HTTP headers including the Negotiate request header, and the TCN and Alternates response headers. (Krishnamurthy et al. note that although the HTTP/1.1 specification reserved the Alternates header for use in agent driven negotiation, it was not fully specified. Consequently under a pure HTTP/1.1 implementation as defined by RFC2616, server-driven content negotiation is the only option. RFC2295 addresses this issue.)

Deficiencies of HTTP/1.1 Server-Driven Negotiation

Weaknesses of server-driven negotiation highlighted by RFCs 2295 and 2616 include:

- Inefficiency - Sending details of a user agent's capabilities and preferences with every request is very inefficient, not least because very few Web resources have multiple variants, and expensive in terms of the number of Accept headers required to fully describe all but the most simple browser's capabilities.
- Server doesn't always know 'best' - Having the server decide on the 'best' variant may not always result in the most suitable resource representation being returned to the client. The user agent might often be better placed to decide what is best for its needs.

Variant Selection By User Agent

Rather than rely on server-driven negotiation and variant selection by the server, a user agent can take full control over deciding the best variant by explicitly requesting transparent content negotiation through the Negotiate request header. The negotiation is 'transparent' because it makes all the variants on the server visible to the agent.

Under this scheme, the server sends the user agent a list, represented in an Alternates header, containing the available variants and their properties. The user agent can then choose the best variant itself. Consequently, the agent no longer needs to send large Accept headers describing in detail its capabilities and preferences. (However, unless caching is used, user-agent driven negotiation does suffer from the disadvantage of needing a second request to obtain the best representation. By sending its best guess as the first response, server driven negotiation avoids this second request if the initial best guess is acceptable.)

Variant Selection By Server

As well as variant selection by the user agent, TCN allows the server to choose on behalf of the user agent if the user agent explicitly allows it through the Negotiate request header. This option allows the user agent to send smaller Accept headers containing enough information to allow the server to choose the best variant and return it directly. The server's choice is controlled by a 'remote variant selection algorithm' as defined in RFC2296.

Variant Selection By End-User

A further option is to allow the end-user to select a variant, in case the choice made by negotiation process is not optimal. For instance, the user agent could display an HTML-based 'pick list' of variants constructed from the variant list returned by the server. Alternatively the server could generate this pick list itself and include it in the response to a user agent's request for a variant list. (Virtuoso currently responds this way.)

Transparent Content Negotiation in Virtuoso HTTP Server

The following section describes the Virtuoso HTTP server's TCN implementation which is based on RFC2295, but without "Feature" negotiation. OpenLink's RDF rich clients, iSparql and the OpenLink RDF Browser, both support TCN. User agents which do not support transparent content negotiation continue to be handled using HTTP/1.1 style content negotiation (whereby server-side selection is the only option - the server selects the best variant and returns a list of variants in an Alternates response header).

Describing Resource Variants

In order to negotiate a resource, the server needs to be given information about each of the variants. Variant descriptions are held in SQL table HTTP_VARIANT_MAP. The descriptions themselves can be created, updated or deleted using Virtuoso/PL or through the Conductor UI. The table definition is as follows:

```
create table DB.DBA.HTTP_VARIANT_MAP (
  VM_ID integer identity, -- unique ID
  VM_RULELIST varchar, -- HTTP rule list name
  VM_URI varchar, -- name of requested resource e.g. 'page'
  VM_VARIANT_URI varchar, -- name of variant e.g. 'page.xml', 'page.de.html' etc.
  VM_QS float, -- Source quality, a number in the range 0.001-1.000, with 3 digit precision
  VM_TYPE varchar, -- Content type of the variant e.g. text/xml
  VM_LANG varchar, -- Content language e.g. 'en', 'de' etc.
  VM_ENC varchar, -- Content encoding e.g. 'utf-8', 'ISO-8892' etc.
  VM_DESCRIPTION long varchar, -- a human readable description about the variant e.g. 'Profile in RDF for
  VM_ALGO int default 0, -- reserved for future use
  primary key (VM_RULELIST, VM_URI, VM_VARIANT_URI)
 )
```

```
create unique index HTTP_VARIANT_MAP_ID on DB.DBA.HTTP_VARIANT_MAP (VM_ID)
```

Configuration using Virtuoso/PL

Two functions are provided for adding or updating, or removing variant descriptions using Virtuoso/PL:

```
-- Adding or Updating a Resource Variant:
DB.DBA.HTTP_VARIANT_ADD (
  in rulelist_uri varchar, -- HTTP rule list name
  in uri varchar, -- Requested resource name e.g. 'page'
  in variant_uri varchar, -- Variant name e.g. 'page.xml', 'page.de.html' etc.
  in mime varchar, -- Content type of the variant e.g. text/xml
  in qs float := 1.0, -- Source quality, a floating point number with 3 digit precision in 0.001-1.000 ra
  in description varchar := null, -- a human readable description of the variant e.g. 'Profile in RDF for
  in lang varchar := null, -- Content language e.g. 'en', 'bg'. 'de' etc.
  in enc varchar := null -- Content encoding e.g. 'utf-8', 'ISO-8892' etc.
)

--Removing a Resource Variant
DB.DBA.HTTP_VARIANT_REMOVE (
  in rulelist_uri varchar, -- HTTP rule list name
  in uri varchar, -- Name of requested resource e.g. 'page'
  in variant_uri varchar := '%' -- Variant name filter
)
```

Configuration using Conductor UI

The Conductor 'Content negotiation' panel for describing resource variants and configuring content negotiation is depicted below. It can be reached by selecting the 'Virtual Domains & Directories' tab under the 'Web Application Server' menu item, then selecting the 'URL rewrite' option for a logical path listed amongst those for the relevant HTTP host, e.g. '{Default Web Site}'

The input fields reflect the supported 'dimensions' of negotiation which include content type, language and encoding. Quality values corresponding to the options for 'Source Quality' are as follows:

Table 16.18. Source Quality

Source Quality	Quality Value
perfect representation	1.000
threshold of noticeable loss of quality	0.900
noticeable, but acceptable quality reduction	0.800
barely acceptable quality	0.500
severely degraded quality	0.300
completely degraded quality	0.000

Variant Selection Algorithm

When a user agent instructs the server to select the best variant, Virtuoso does so using the selection algorithm below:

If a virtual directory has URL rewriting enabled (has the 'url_rewrite' option set), the web server:

- Looks in DB.DBA.HTTP_VARIANT_MAP for a VM_RULELIST matching the one specified in the 'url_rewrite' option
- If present, it loops over all variants for which VM_URI is equal to the resource requested
- For every variant it calculates the source quality based on the value of VM_QS and the source quality given by the user agent
- If the best variant is found, it adds TCN HTTP headers to the response and passes the VM_VARIANT_URI to the URL rewriter
- If the user agent has asked for a variant list, it composes such a list and returns an 'Alternates' HTTP header with response code 300
- If no URL rewriter rules exist for the target URL, the web server returns the content of the dereferenced VM_VARIANT_URI.

The server may return the best-choice resource representation or a list of available resource variants. When a user agent requests transparent negotiation, the web server returns the TCN header "choice". When a user agent asks for a variant list, the server

returns the TCN header "list".

Examples

In this example we assume the following files have been uploaded to the Virtuoso WebDAV server, with each containing the same information but in different formats:

- /DAV/TCN/page.xml - a XML variant
- /DAV/TCN/page.html - a HTML variant
- /DAV/TCN/page.txt - a text variant

We add TCN rules and define a virtual directory:

```
DB.DBA.HTTP_VARIANT_ADD ('http_rule_list_1', 'page', 'page.html','text/html', 0.900000, 'HTML variant');
DB.DBA.HTTP_VARIANT_ADD ('http_rule_list_1', 'page', 'page.txt', 'text/plain', 0.500000, 'Text document')
DB.DBA.HTTP_VARIANT_ADD ('http_rule_list_1', 'page', 'page.xml', 'text/xml', 1.000000, 'XML variant');
DB.DBA.VHOST_DEFINE (lpath=>'/DAV/TCN/',
                     ppath=>'/DAV/TCN/',
                     is_dav=>1,
                     vsp_user=>'dba',
                     opts=>vector ('url_rewrite', 'http_rule_list_1'));
```

Having done this we can now test the setup with a suitable HTTP client, in this case the curl command line utility. In the following examples, the curl client supplies Negotiate request headers containing content negotiation directives which include:

- "trans" - The user agent supports transparent content negotiation for the current request.
- "vlist" - The user agent requests that any transparently negotiated response for the current request includes an Alternates header with the variant list bound to the negotiable resource. Implies "trans".
- "*" - The user agent allows servers and proxies to run any remote variant selection algorithm.

The server returns a TCN response header signalling that the resource is transparently negotiated and either a choice or a list response as appropriate.

In the first curl exchange, the user agent indicates to the server that, of the formats it recognizes, HTML is preferred and it instructs the server to perform transparent content negotiation. In the response, the Vary header field expresses the parameters the server used to select a representation, i.e. only the Negotiate and Accept header fields are considered.

```
$ curl -i -H "Accept: text/xml;q=0.3,text/html;q=1.0,text/plain;q=0.5,*/*;
q=0.3" -H "Negotiate: *" http://example.com/DAV/TCN/page
HTTP/1.1 200 OK Server: Virtuoso/05.00.3021 (Linux) i686-pc-linux-gnu
VDB Connection: Keep-Alive Date: Wed, 31 Oct 2007 15:43:18
GMT Accept-Ranges: bytes TCN: choice Vary: negotiate,accept
Content-Location: page.html Content-Type: text/html
ETag: "14056a25c066a6e0a6e65889754a0602"
Content-Length: 49
<html> <body> some html </body> </html>
```

Next, the source quality values are adjusted so that the user agent indicates that XML is its preferred format.

```
$ curl -i -H "Accept: text/xml,text/html;q=0.7,text/plain;q=0.5,*/*;q=0.3" -H "Negotiate:
*" http://example.com/DAV/TCN/page HTTP/1.1 200 OK Server: Virtuoso/05.00.3021
(Linux) i686-pc-linux-gnu VDB Connection: Keep-Alive Date: Wed, 31 Oct 2007
15:44:07 GMT Accept-Ranges: bytes TCN: choice Vary: negotiate,accept
Content-Location: page.xml Content-Type: text/xml ETag:
"8b09f4b8e358fcb7fd1f0f8fa918973a" Content-Length: 39

<?xml version="1.0" ?> <a>some xml</a>
```

In the final example, the user agent wants to decide itself which is the most suitable representation, so it asks for a list of variants. The server provides the list, in the form of an Alternates response header, and, in addition, sends an HTML representation of the list so that the end user can decide on the preferred variant himself if the user agent is unable to.

```
$ curl -i -H "Accept: text/xml,text/html;q=0.7,text/plain;q=0.5,*/*;q=0.3" -H "Negotiate:
vlist" http://example.com/DAV/TCN/page HTTP/1.1 300 Multiple Choices Server:

Example of *DOI*

In order to execute correctly queries with doi resolver you need to have:

- the handle.dll file accessible from your system. For ex. you can put it in the Virtuoso bin folder where the rest of the server components are.
- in your Virtuoso database ini file in section Plugins added the hslookup.dll file, which location should be in the plugins folder under your Virtuoso server installation. For ex:

```
[Plugins]
LoadPath = ./plugin
...
Load6    = plain,hslookup
```

```
SQL>SPARQL
define get:soft "soft"
SELECT *
FROM <doi:10.1045/march99-bunker>
WHERE { ?s ?p ?o } ;

16.13.5. Faceted Views over Large-Scale Linked Data

Faceted views over structured and semi structured data have been popular in user interfaces for some years. Deploying such views of arbitrary linked data at arbitrary scale has been hampered by lack of suitable back end technology. Many ontologies are also quite large, with hundreds of thousands of classes.

Also, the linked data community has been concerned with the processing cost and potential for denial of service presented by public SPARQL end points.

This section discusses how we use Virtuoso Cluster Edition for providing interactive browsing over billions of triples, combining full text search, structured querying and result ranking. We discuss query planning, run-time inferencing and partial query evaluation. This functionality is exposed through SPARQL, a specialized web service and a web user interface.

The transition of the web from a distributed document repository into a universal, ubiquitous database requires a new dimension of scalability for supporting rich user interaction. If the web is the database, then it also needs a query and report writing tool to match. A faceted user interaction paradigm has been found useful for aiding discovery and query of variously structured data. Numerous implementations exist but they are chiefly client side and are limited in the data volumes they can handle.

At the present time, linked data is well beyond prototypes and proofs of concept. This means that what was done in limited specialty domains before must now be done at real world scale, in terms of both data volume and ontology size. On the schema, or T box side, there exist many comprehensive general purpose ontologies such as Yago[1], OpenCyc[2], Umbel[3] and the DBpedia[4] ontology and many domain specific ones, such as [5]. For these to enter into the user experience, the platform must be able to support the user's choice of terminology or terminologies as needed, preferably without blow up of data and concomitant slowdown.

Likewise, in the LOD world, many link sets have been created for bridging between data sets. Whether such linkage is relevant will depend on the use case. Therefore we provide fine grained control over which owl:sameAs assertions will be followed, if any.

Against this background, we discuss how we tackle incremental interactive query composition on arbitrary data with Virtuoso Cluster .

Using SPARQL or a web/web service interface, the user can form combinations of text search and structured criteria, including joins to an arbitrary depth. If queries are precise and select a limited number of results, the results are complete. If queries would select tens of millions of results, partial results are shown.

The system being described is being actively developed as of this writing, early March of 2009 and is online at http://lod.openlinksw.com/. The data set is a combination of DBpedia, MusicBrainz, Freebase, UniProt, NeuroCommons, Bio2RDF, and web crawls from PingTheSemanticWeb.com.

The hardware consists of two 8-core servers with 16G RAM and 4 disks each. The system runs on Virtuoso 6 Cluster Edition. All application code is written in SQL procedures with limited client side Ajax, the Virtuoso platform itself is in C.

The facets service allows the user to start with a text search or a fixed URI and to refine the search by specifying classes, property values etc., on the selected subjects or any subjects referenced therefrom.

This process generates queries involving combinations of text and structured criteria, often dealing with property and class hierarchies and often involving aggregation over millions of subjects, specially at the initial stages of query composition. To make this work with in interactive time, two things are needed:

1. a query optimizer that can almost infallibly produce the right join order based on cardinalities of the specific constants in the query
2. a query execution engine that can return partial results after a timeout.

It is often the case, specially at the beginning of query formulation, that the user only needs to know if there are relatively many or few results that are of a given type or involve a given property. Thus partially evaluating a query is often useful for producing this information. This must however be possible with an arbitrary query, simply citing precomputed statistics is not enough.

It has for a long time been a given that any search-like application ranks results by relevance. Whenever the facets service shows a list of results, not an aggregation of result types or properties, it is sorted on a composite of text match score and link density.

The section is divided into the following parts:

- SPARQL query optimization and execution adapted for run time inference over large subclass structures.
- Resolving identity with inverse functional properties
- Ranking entities based on graph link density
- SPARQL partial query evaluation for displaying partial results in fixed time
- a facets web service providing an XML interface for submitting queries, so that the user interface is not required to parse SPARQL
- a sample web interface for interacting with this
- sample queries and their evaluation times against combinations of large LOD data sets

Processing Large Hierarchies in SPARQL

Virtuoso has for a long time had built-in superclass and superproperty inference. This is enabled by specifying the *DEFINE input:inference "context"* option, where context is previously declared to be all subclass, subproperty, equivalence, inverse functional property and same as relations defined in a given graph. The ontology file is loaded into its own graph and this is then used to construct the context. Multiple ontologies and their equivalences can be loaded into a single graph which then makes another context which holds the union of the ontology information from the merged source ontologies.

Let us consider a sample query combining a full text search and a restriction on the class of the desired matches:

```
DEFINE  input:inference  "yago"
PREFIX  cy:  <http://dbpedia.org/class/yago/>
SELECT DISTINCT ?s1 AS ?c1
                ( bif:search_excerpt
                  ( bif:vector ( 'Shakespeare' ), ?o1 )
                ) AS ?c2
WHERE
  {
    ?s1  ?s1textp ?o1                          .
    FILTER
```

```
      ( bif:contains (?o1, '"Shakespeare"') ) .
    ?s1  a        cy:Performer110415638
  }
LIMIT 20
```

This selects all Yago performers that have a property that contains "Shakespeare" as a whole word.

The *DEFINE input:inference "yago"* clause means that subclass, subproperty and inverse functions property statements contained in the inference context called yago are considered when evaluating the query. The built-in function *bif:search_excerpt* makes a search engine style summary of the found text, highlighting occurrences of Shakespeare.

The *bif:contains* function in the filter specifies the full text search condition on ?o1.

This query is a typical example of queries that are executed all the time when a user refines a search. We will now look at how we can make an efficient execution plan for the query. First, we must know the cardinalities of the search conditions.

To see the count of subclasses of Yago performer, we can do:

```
SPARQL
PREFIX  cy:  <http://dbpedia.org/class/yago/>
SELECT COUNT (*)
FROM <http://dbpedia.org/yago.owl>
WHERE
  {
    ?s  rdfs:subClassOf  cy:Performer110415638
    OPTION (TRANSITIVE, T_DISTINCT)
  }
```

There are 4601 distinct subclasses, including indirect ones. Next we look at how many Shakespeare mentions there are:

```
SPARQL
SELECT COUNT (*)
WHERE
  {
    ?s  ?p  ?o .
    FILTER
      ( bif:contains (?o, 'Shakespeare') )
  }
```

There are 10267 subjects with Shakespeare mentioned in some literal.

```
SPARQL
DEFINE input:inference "yago"
PREFIX cy: <http://dbpedia.org/class/yago/>
SELECT COUNT (*)
WHERE
  {
    ?s1  a  cy:Performer110415638
  }
```

There are 184885 individuals that belong to some subclass of performer.

This is the data that the SPARQL compiler must know in order to have a valid query plan. Since these values will wildly vary depending on the specific constants in the query, the actual database must be consulted as needed while preparing the execution plan. This is regular query processing technology but is now specially adapted for deep subclass and subproperty structures.

Conditions in the queries are not evaluated twice, once for the cardinality estimate and once for the actual run. Instead, the cardinality estimate is a rapid sampling of the index trees that reads at most one leaf page.

Consider a B tree index, which we descend from top to the leftmost leaf containing a match of the condition. At each level, we count how many children would match and always select the leftmost one. When we reach a leaf, we see how many entries are on the page. From these observations, we extrapolate the total count of matches.

With this method, the guess for the count of performers is 114213, which is acceptably close to the real number. Given these numbers, we see that it makes sense to first find the full text matches and then retrieve the actual classes of each and see if this class is a subclass of performer. This last check is done against a memory resident copy of the Yago hierarchy, the same copy that

was used for enumerating the subclasses of performer.

However, the query

```
SPARQL
DEFINE input:inference "yago"
PREFIX cy: <http://dbpedia.org/class/yago/>
SELECT DISTINCT ?s1 AS ?c1,
                ( bif:search_excerpt
                  ( bif:vector ('Shakespeare'), ?o1 )
                ) AS ?c2
WHERE
  {
    ?s1  ?s1textp  ?o1                          .
    FILTER
      ( bif:contains (?o1, '"Shakespeare"') )   .
    ?s1  a          cy:ShakespeareanActors
  }
```

will start with Shakespearean actors since this is a leaf class with only 74 instances and then check if the properties contain Shakespeare and return their search summaries.

In principle, this is common cost based optimization but is here adapted to deep hierarchies combined with text patterns. An unmodified SQL optimizer would have no possibility of arriving at these results.

The implementation reads the graphs designated as holding ontologies when first needed and subsequently keeps a memory based copy of the hierarchy on all servers. This is used for quick iteration over sub/superclasses or properties as well as for checking if a given class or property is a subclass/property of another. Triples with OWL predicates *equivalentClass* , *equivalentProperty* and *sameAs* are also cached in the same data structure if they occur in the ontology graphs.

Also cardinality estimates for members of classes near the root of the class hierarchy take some time since a sample of each subclass is needed. These are cached for some minutes in the inference context, so that repeated queries will not redo the sampling.

Inverse Functional Properties and Same As

Specially when navigating social data, as in FOAF and SIOC spaces, there are many blank nodes that are identified by properties only. For this, we offer an option for automatically joining to subjects which share an IFP value with the subject being processed. For example, the query for the friends of friends of Kjetil Kjernsmo returns empty:

```
SPARQL
SELECT COUNT (?f2)
WHERE
  {
    ?s   a             foaf:Person          ;
         ?p            ?o                   ;
         foaf:knows    ?f1                  .
    ?o   bif:contains  "'Kjetil Kjernsmo'"  .
    ?f1  foaf:knows    ?f2
  }
```

But with the option

```
SPARQL
DEFINE input:inference "b3sifp"
SELECT COUNT (?f2)
WHERE
  {
    ?s   a             foaf:Person          ;
         ?p            ?o                   ;
         foaf:knows    ?f1                  .
    ?o   bif:contains  "'Kjetil Kjernsmo'"  .
    ?f1  foaf:knows    ?f2
  }
```

we get 4022. We note that there are many duplicates since the data is blank nodes only, with people easily represented 10 times. The context *b3sifp* simple declares that *foaf:name* and *foaf:mbox* sha1sum should be treated as inverse functional properties (IFP).

The name is not an IFP in the actual sense but treating it as such for the purposes of this one query makes sense, otherwise nothing would be found.

This option is controlled by the choice of the inference context, which is selectable in the interface discussed below.

The IFP inference can be thought of as a transparent addition of a subquery into the join sequence. The subquery joins each subject to its synonyms given by sharing IFPs. This subquery has the special property that it has the initial binding automatically in its result set. It could be expressed as:

```
SPARQL
SELECT ?f
WHERE
  {
    ?k foaf:name "Kjetil Kjernsmo"  .
    {
      SELECT ?org ?syn
      WHERE
        {
          ?org ?p ?key  .
          ?syn ?p ?key  .
          FILTER
            ( bif:rdf_is_sub
                ( "b3sifp", ?p, <b3s:any_ifp>, 3 )
              &&
              ?syn  !=  ?org
            )
        }
    }
    OPTION
      (
        TRANSITIVE ,
        T_IN (?org),
        T_OUT (?syn),
        T_MIN (0),
        T_MAX (1)
      )
    FILTER ( ?org = ?k ) .
    ?syn foaf:knows ?f .
  }
```

It is true that each subject shares IFP values with itself but the transitive construct with 0 minimum and 1 maximum depth allows passing the initial binding of *?org* directly to *?syn* , thus getting first results more rapidly. The *rdf_is_sub* function is an internal that simply tests whether *?p* is a subproperty of *b3s:any_ifp* .

Internally, the implementation has a special query operator for this and the internal form is more compact than would result from the above but the above could be used to the same effect.

Our general position is that identity criteria are highly application specific and thus we offer the full spectrum of choice between run time and precomputing. Further, weaker identity statements than sameness are difficult to use in queries, thus we prefer identity with semantics of *owl:sameAs* but make this an option that can be turned on and off query by query.

Entity Ranking

It is a common end user expectation to see text search results sorted by their relevance. The term entity rank refers to a quantity describing the relevance of a URI in an RDF graph.

This is a sample query using entity rank:

```
SPARQL
PREFIX  yago:  <http://dbpedia.org/class/yago/>
PREFIX  prop:  <http://dbpedia.org/property/>
SELECT DISTINCT ?s2 AS ?c1
WHERE
  {
    ?s1  ?s1textp      ?o1                    .
    ?o1  bif:contains  'Shakespeare'          .
    ?s1  a             yago:Writer110794014   .
    ?s2  prop:writer   ?s1
```

```
  }
ORDER BY DESC ( <LONG::IRI_RANK> (?s2) )
LIMIT 20
OFFSET 0
```

This selects works where a writer with Shakespeare in some property is the writer.

Here the query returns subjects, thus no text search summaries, so only the entity rank of the returned subject is used. We order text results by a composite of text hit score and entity rank of the RDF subject where the text occurs. The entity rank of the subject is defined by the count of references to it, weighed by the rank of the referrers and the outbound link count of referrers. Such techniques are used in text based information retrieval.

Example with Entity Ranking and Score

```
## Searching over labels, with text match
## scores and additional ranks for each
## iri / resource:

SELECT ?s ?page ?label
  ?textScore AS ?Text_Score_Rank
  ( <LONG::IRI_RANK> (?s) ) AS ?Entity_Rank
WHERE
  {
    ?s foaf:page ?page ;
     rdfs:label ?label .
    FILTER( lang( ?label ) = "en" ) .
    ?label bif:contains 'adobe and flash'
    OPTION (score ?textScore ) .
  }
```

One interesting application of entity rank and inference on IFPs and *owl:sameAs* is in locating URIs for reuse. We can easily list synonym URIs in order of popularity as well as locate URIs based on associated text. This can serve in application such as the Entity Name Server

Entity ranking is one of the few operations where we take a precomputing approach. Since a rank is calculated based on a possibly long chain of references, there is little choice but to precompute. The precomputation itself is straightforward enough: First all outbound references are counted for all subjects. Next all ranks of subjects are incremented by 1 over the referrer's outbound link count. On successive iterations, the increment is based on the rank increment the referrer received in the previous round.

The operation is easily partitioned, since each partition increments the ranks of subjects it holds. The referrers are spread throughout the cluster, though. When rank is calculated, each partition accesses every other partition. This is done with relatively long messages, referee ranks are accessed in batches of several thousand at a time, thus absorbing network latency.

On the test system, this operation performs a single pass over the corpus of 2.2 billion triples and 356 million distinct subjects in about 30 minutes. The operation has 100% utilization of all 16 cores. Adding hardware would speed it up, as would implementing it in C instead of the SQL procedures it is written in at present.

The main query in rank calculation is:

```
SPARQL
SELECT O            ,
       P            ,
       iri_rank (S)
FROM rdf_quad TABLE
OPTION (NO CLUSTER)
WHERE isiri_id(O)
ORDER BY O
```

This is the SQL cursor iterated over by each partition. The no cluster option means that only rows in this process's partition are retrieved. The RDF_QUAD table holds the RDF quads in the store, i.e., triple plus graph. The S, P, O columns are the subject, predicate, and object respectively. The graph column is not used here. The textttiri rank is a partitioned SQL function. This works by using the S argument to determine which cluster node should run the function. The specifics of the partitioning are declared elsewhere. The calls are then batched for each intended recipient and sent when the batches are full. The SQL compiler automatically generates the relevant control structures. This is like an implicit map operation in the map-reduce terminology.

An SQL procedure loops over this cursor, adds up the rank and when seeing a new O, the added rank is persisted into a table. Since links in RDF are typed, we can use the semantics of the link to determine how much rank is transferred by a reference. With extraction of named entities from text content, we can further place a given entity into a referential context and use this as a weighting factor. This is to be explored in future work. The experience thus far shows that we greatly benefit from Virtuoso being a general purpose DBMS, as we can create application specific data structures and control flows where these are efficient. For example, it would make little sense to store entity ranks as triples due to space consumption and locality considerations. With these tools, the whole ranking functionality took under a week to develop.

Note: In order to use the IRI_RANK feature you need to have the Facet (fct) vad package installed as the procedure is part of this vad.

Query Evaluation Time Limits

When scaling the Linked Data model, we have to take it as a given that the workload will be unexpected and that the query writers will often be unskilled in databases. Insofar possible, we wish to promote the forming of a culture of creative reuse of data. To this effect, even poorly formulated questions deserve an answer that is better than just timeout.

If a query produces a steady stream of results, interrupting it after a certain quota is simple. However, most interesting queries do not work in this way. They contain aggregation, sorting, maybe transitivity.

When evaluating a query with a time limit in a cluster setup, all nodes monitor the time left for the query. When dealing with a potentially partial query to begin with, there is little point in transactionality. Therefore the facet service uses read committed isolation. A read committed query will never block since it will see the before-image of any transactionally updated row. There will be no waiting for locks and timeouts can be managed locally by all servers in the cluster.

Thus, when having a partitioned count, for example, we expect all the partitions to time out around the same time and send a ready message with the timeout information to the cluster node coordinating the query. The condition raised by hitting a partial evaluation time limit differs from a run time error in that it leaves the query state intact on all participating nodes. This allows the timeout handling to come fetch any accumulated aggregates.

Let us consider the query for the top 10 classes of things with "Shakespeare" in some literal. This is typical of the workload generated by the faceted browsing web service:

```
SPARQL
DEFINE  input:inference  "yago"
SELECT ?c
       COUNT (*)
WHERE
  {
    ?s  a             ?c             ;
        ?p            ?o             .
    ?o  bif:contains  "Shakespeare"
  }
GROUP BY ?c
ORDER BY DESC 2
LIMIT 10
```

On the first execution with an entirely cold cache, this times out after 2 seconds and returns:

```
?c                                      COUNT (*)
yago:class/yago/Entity100001740         566
yago:class/yago/PhysicalEntity100001930 452
yago:class/yago/Object100002684         452
yago:class/yago/Whole100003553          449
yago:class/yago/Organism100004475       375
yago:class/yago/LivingThing100004258    375
yago:class/yago/CausalAgent100007347    373
yago:class/yago/Person100007846         373
yago:class/yago/Abstraction100002137    150
yago:class/yago/Communicator109610660   125
```

The next repeat gets about double the counts, starting with 1291 entities.

With a warm cache, the query finishes in about 300 ms (4 core Xeon, Virtuoso 6 Cluster) and returns:

```
?c                                        COUNT (*)
yago:class/yago/Entity100001740           13329
yago:class/yago/PhysicalEntity100001930   10423
yago:class/yago/Object100002684           10408
yago:class/yago/Whole100003553            10210
yago:class/yago/LivingThing100004258       8868
yago:class/yago/Organism100004475          8868
yago:class/yago/CausalAgent100007347       8853
yago:class/yago/Person100007846            8853
yago:class/yago/Abstraction100002137       3284
yago:class/yago/Entertainer109616922       2356
```

It is a well known fact that running from memory is thousands of times faster than from disk.

The query plan begins with the text search. The subjects with "Shakespeare" in some property get dispatched to the partition that holds their class. Since all partitions know the class hierarchy, the superclass inference runs in parallel, as does the aggregation of the group by. When all partitions have finished, the process coordinating the query fetches the partial aggregates, adds them up and sorts them by count.

If a timeout occurs, it will most likely occur where the classes of the text matches are being retrieved. When this happens, this part of the query is reset, but the aggregate states are left in place. The process coordinating the query then goes on as if the aggregates had completed. If there are many levels of nested aggregates, each timeout terminates the innermost aggregation that is still accumulating results, thus a query is guaranteed to return in no more than n timeouts, where n is the number of nested aggregations or subqueries.

Faceted Web Service and Linked Data

The Virtuoso Faceted Web Service is a general purpose RDF query facility for Faceted based browsing. It takes an XML description of the view desired and generates the reply as an XML tree containing the requested data. The user agent or a local web page can use XSLT for rendering this for the end user. The selection of facets and values is represented as an XML tree. The rationale for this is the fact that such a representation is easier to process in an application than the SPARQL source text or a parse tree of SPARQL and more compactly captures the specific subset of SPARQL needed for faceted browsing. All such queries internally generate SPARQL and the SPARQL generated is returned with the results. One can therefore use this is a starting point for hand crafted queries.

The query has the top level element. The child elements of this represents conditions pertaining to a single subject. A join is expressed with the property or propertyof element. This has in turn children which state conditions on a property of the first subject. Property and propertyof elements can be nested to an arbitrary depth and many can occur inside one containing element. In this way, tree-shaped structures of joins can be expressed.

Expressing more complex relationships, such as intermediate grouping, subqueries, arithmetic or such requires writing the query in SPARQL. The XML format is for easy automatic composition of queries needed for showing facets, not a replacement for SPARQL.

Consider composing a map of locations involved with Napoleon. Below we list user actions and the resulting XML query descriptions.

- Enter in the search form "Napoleon":

```
<query inference="" same-as="" view3="" s-term="e" c-term="type">
  <text>napoleon</text>
  <view type="text" limit="20" offset="" />
</query>
```

- Select the "types" view:

```
<query inference="" same-as="" view3="" s-term="e" c-term="type">
  <text>napoleon</text>
  <view type="classes" limit="20" offset="0" location-prop="0" />
</query>
```

- Choose "MilitaryConflict" type:

```
<query inference="" same-as="" view3="" s-term="e" c-term="type">
  <text>napoleon</text>
  <view type="classes" limit="20" offset="0" location-prop="0" />
  <class iri="yago:ontology/MilitaryConflict" />
```

```
</query>
```

- Choose "NapoleonicWars":

```
<query inference="" same-as="" view3="" s-term="e" c-term="type">
  <text>napoleon</text>
  <view type="classes" limit="20" offset="0" location-prop="0" />
  <class iri="yago:ontology/MilitaryConflict" />
  <class iri="yago:class/yago/NapoleonicWars" />
</query>
```

- Select "any location" in the select list beside the "map" link; then hit "map" link:

```
<query inference="" same-as="" view3="" s-term="e" c-term="type">
  <text>napoleon</text>
  <class iri="yago:ontology/MilitaryConflict" />
  <class iri="yago:class/yago/NapoleonicWars" />
  <view type="geo" limit="20" offset="0" location-prop="any" />
</query>
```

This last XML fragment corresponds to the below text of SPARQL query:

```
SPARQL
SELECT ?location AS ?c1
       ?lat1     AS ?c2
       ?lng1     AS ?c3
WHERE
  {
    ?s1        ?s1textp  ?o1                              .
    FILTER
      ( bif:contains (?o1, '"Napoleon"') )  .
    ?s1        a         <yago:ontology/MilitaryConflict>  .
    ?s1        a         <yago:class/yago/NapoleonicWars>  .
    ?s1        ?anyloc   ?location                         .
    ?location  geo:lat   ?lat1                             ;
               geo:long  ?lng1
  }
LIMIT 200
OFFSET 0
```

The query takes all subjects with some literal property with "Napoleon" in it, then filters for military conflicts and Napoleonic wars, then takes all objects related to these where the related object has a location. The map has the objects and their locations.

voiD Discoverability

A long awaited addition to the LOD cloud is the Vocabulary of Interlinked Data (voiD). Virtuoso automatically generates voiD descriptions of data sets it hosts. Virtuoso incorporates an SQL function *rdf_void_gen* which returns a Turtle representation of a given graph's voiD statistics.

Test System and Data

The test system consists of two 2x4 core Xeon 5345, 2.33 GHz servers with 16G RAM and 4 disks each. The machines are connected by two 1Gbit Ethernet connections. The software is Virtuoso 6 Cluster. The Virtuoso server is split into 16 partitions, 8 for each machine. Each partition is managed by a separate server process.

The test database has the following data sets:

- DBpedia 3.2
- MusicBrainz
- Bio2RDF
- NeuroCommons
- UniProt

- Freebase (95M triples)
- PingTheSemanticWeb (1.6M miscellaneous files from http://www.pingthesemanticweb.com/).

Ontologies:

- Yago
- OpenCyc
- Umbel
- DBpedia

The database is 2.2 billion triples with 356 million distinct URIs.

16.14. Inference Rules & Reasoning

16.14.1. Introduction

Virtuoso SPARQL can use an inference context for inferring triples that are not physically stored. This functionality applies to physically stored quads and not to virtual triples generated from relational data with Linked Data Views. Such an inference context can be built from one or more graphs containing RDF Schema triples. The supported RDF Schema or OWL constraints are imported from these graphs and are grouped together into rule bases. A rule base is a persistent entity that can be referenced by a SPARQL query or end point. Queries running with a given rule base work as if the triples asserted by this rule base were included in the graph or graphs accessed by the query.

As of version 5.0, Virtuoso recognizes *rdfs:subClassOf* and *rdfs:subPropertyOf* . owl:sameAs is considered for arbitrary subjects and objects if specially enabled by a pragma in the query. As of 5.00.3031, owl:sameAs, owl:equivalentClass and owl:equivalentProperty are also considered when determining subclass or subproperty relations. If two classes are equivalent, they share all instances, subclasses and superclasses directly or indirectly stated in the data for either class. Other RDF Schema or OWL information is not taken into account.

16.14.2. Making Rule Sets

Since RDF Schema and OWL schemas are RDF graphs, these can be loaded into the triple store. Thus, in order to use such a schema as query context, one first loads the corresponding document into the triple store using ttlp() or rdf_load_rdfxml() or related functions. After the schema document is loaded, one can add the assertions there into an inference context with the rdfs_rule_set() function. This function specifies a logical name for the rule set plus a graph URI. It is possible to combine multiple schema graphs into a single rule set. A single schema graph may also independently participate in multiple rule sets.

The *DB.DBA.SYS_RDF_SCHEMA* table contains information for all RDF rule sets in a Virtuoso instance. This table may be queried to, for instance, verify rdfs_rule_set() activity:

```
CREATE TABLE DB.DBA.SYS_RDF_SCHEMA (
  RS_NAME VARCHAR,  -- The name of the rdf rule set
  RS_URI  VARCHAR,  -- The name of the graph
  RS_G    VARCHAR,  -- Column for system usage only
  PRIMARY KEY (RS_NAME, RS_URI))
)
```

16.14.3. Changing Rule Sets

Changing a rule set affects queries made after the change. Some queries may have been previously compiled and will not be changed as a result of modifying the rule set. When a rule set is changed, i.e. when *rdfs_rule_set* is called with the first argument set to a pre-existing rule set's name, all the graphs associated with this name are read and the relevant facts are added to a new empty rule set. Thus, if triples are deleted from or added to the graphs comprising the rule set, calling *rdfs_rule_set* will refresh the rule set to correspond to the state of the stored graphs.

16.14.4. Subclasses and Subproperties

Virtuoso SPARQL supports RDF Schema subclasses and subproperties.

The predicates *rdfs:subClassOf* and *rdfs:subPropertyOf* are recognized when they appear in graphs included in a rule set. When such a rule set is specified as a context for a SPARQL query, the following extra triples are generated as needed.

For every *?s rdf:type ?class* , a triple *?s rdf:type ?superclass* is considered to exist, such that *?superclass* is a direct or indirect superclass of *?class* . Direct superclasses are declared with the *rdfs:subClassOf* predicate in the rule set graph. Transitivity of superclasses is automatically taken into account, meaning that if a is a superclass of b and b a superclass of c, then a is a superclass of c also. Cyclic superclass relations are not allowed. If such occur in the rule set data, the behavior is undefined but will not involve unterminating recursion.

For every *?s ?subpredicate ?o* , a triple *?s ?superpredicate ?o* is considered to exist if the rule context declares *?superpredicate* to be a superpredicate of *?predicate* . This is done by having the triple *?subpredicate rdfs:subPropertyOf ?superpredicate* as part of the graphs making up the rule context. Transitivity is observed, thus if a is a subpredicate of b and b a subpredicate of c, then a is also a subpredicate of c.

Two methods can be used for typical recursions, transitivity on inference and plain transitive patterns (or subqueries).

The advantage of inference is that queries are short and one inference rule set may be maintained for numerous queries.

If queries are about trees of classes or properties, or about equivalences of nodes, consider using inference rule sets.

Transitive patterns are inconvenient and may easily result in queries that runs too long or hard to debug, but they're unavoidable in traversing social networks or plain querying of RDF lists.

So consider a rule set, a handful of nodes with classes from the rule set and a couple of RDF Lisp-style lists defined on demo.openlinksw.com:

```
SQL> SPARQL CLEAR GRAPH <http://example.com/2/owl>;
callret-0
VARCHAR
_______________________________________________________________________________

Clear <http://example.com/2/owl>  -- done

1 Rows. -- 0 msec.

SQL> TTLP (' @prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>  .
  @prefix rdfs: <http://www.w3.org/2000/01/rdf-schema#>  .
  @prefix owl: <http://www.w3.org/2002/07/owl#>  .
  @prefix e: <http://example.com/e/>  .
  e:c1 rdfs:subClassOf e:c1or2 .
  e:c2 rdfs:subClassOf e:c1or2 .
  e:c1-10 rdfs:subClassOf e:c1 .
  e:c1-20 rdfs:subClassOf e:c1 .
  e:c2-30 rdfs:subClassOf e:c2 .
  e:c2-40 rdfs:subClassOf e:c2 .
  ', 'http://example.com/2/owl', 'http://example.com/2/owl' );

Done. -- 0 msec.
```

You can also use the SPARUL equivalent variant:

```
SPARQL
PREFIX rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
PREFIX rdfs: <http://www.w3.org/2000/01/rdf-schema#>
PREFIX owl: <http://www.w3.org/2002/07/owl#>
PREFIX e: <http://example.com/e/>

INSERT IN GRAPH <http://example.com/2/owl>
  {
    e:c1 rdfs:subClassOf e:c1or2 .
    e:c2 rdfs:subClassOf e:c1or2 .
    e:c1-10 rdfs:subClassOf e:c1 .
    e:c1-20 rdfs:subClassOf e:c1 .
```

```
    e:c2-30 rdfs:subClassOf e:c2 .
    e:c2-40 rdfs:subClassOf e:c2 .
  } ;
```

Define the inference rule:

```
SQL> rdfs_rule_set ('http://example.com/2/owl', 'http://example.com/2/owl');

Done. -- 0 msec.

SQL> SPARQL CLEAR GRAPH <http://example.com/2/data> ;
callret-0
VARCHAR
_______________________________________________________________________________

Clear <http://example.com/2/data>  -- done

1 Rows. -- 0 msec.

SQL>  TTLP ('
  @prefix e: <http://example.com/e/>  .
  @prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>  .
  @prefix owl: <http://www.w3.org/2002/07/owl#>  .
  e:s1 a e:c1 ; e:p1 "Value of p1 for s1" .

  e:s1-20 a e:c1-20 ; e:p1 "Value of p1 for s1-20" .
  e:s2-30 a e:c2-30 ; e:p1 "Value of p1 for s2-30" .
  e:s2-40 a e:c2-40 ; e:p1 "Value of p1 for s2-40" .
  e:lists
       rdf:_1 ( e:list1-item1 e:list1-item2 e:list1-item3 ) ;
       rdf:_2 (
           [ e:p2 "Value of p2 of item1 of list2" ; e:p3 "Value of p3 of item1 of list2" ]
           [ e:p2 "Value of p2 of item2 of list2" ; e:p3 "Value of p3 of item2 of list2" ]
           [ e:p2 "Value of p2 of item3 of list2" ; e:p3 "Value of p3 of item3 of list2" ] ) .
  ', 'http://example.com/2/data', 'http://example.com/2/data' );

Done. -- 0 msec.
```

You can also use the SPARUL equivalent variant:

```
SPARQL
PREFIX e: <http://example.com/e/>
PREFIX rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
PREFIX owl: <http://www.w3.org/2002/07/owl#>

INSERT IN GRAPH <http://example.com/2/data>
  {
    e:s1 a e:c1 ; e:p1 "Value of p1 for s1" .
    e:s2 a e:c2 ; e:p1 "Value of p1 for s2" .
    e:s1-10 a e:c1-10 ; e:p1 "Value of p1 for s1-10" .
    e:s1-20 a e:c1-20 ; e:p1 "Value of p1 for s1-20" .
    e:s2-30 a e:c2-30 ; e:p1 "Value of p1 for s2-30" .
    e:s2-40 a e:c2-40 ; e:p1 "Value of p1 for s2-40" .
    e:lists
      rdf:_1 ( e:list1-item1 e:list1-item2 e:list1-item3 ) ;
      rdf:_2 (
           [ e:p2 "Value of p2 of item1 of list2" ; e:p3 "Value of p3 of item1 of list2" ]
           [ e:p2 "Value of p2 of item2 of list2" ; e:p3 "Value of p3 of item2 of list2" ]
           [ e:p2 "Value of p2 of item3 of list2" ; e:p3 "Value of p3 of item3 of list2" ] )
  };
```

SPARQL DESCRIBE works fine with inference, deriving additional type information:

```
DEFINE input:inference <http://example.com/2/owl>
DESCRIBE <http://example.com/e/s1>
FROM <http://example.com/2/data>

fmtaggret-
LONG VARCHAR
_______________________________________________________________________________
```

```
@prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>  .
@prefix ns1: <http://example.com/e/>  .
ns1:s1 rdf:type ns1:c1or2 ,
ns1:c1 ;
ns1:p1 "Value of p1 for s1" .

1 Rows. -- 0 msec.
```

Example links against Virtuoso Demo Server SPARQL Endpoint with SPARQL Protocol URLs:

Querying is simple as well:

```
SQL>SPARQL DEFINE input:inference <http://example.com/2/owl>
PREFIX e:<http://example.com/e/>
SELECT *
FROM <http://example.com/2/data>
WHERE
  {
    ?s a e:c1or2 ;
          e:p1 ?o
  }

s                           o
VARCHAR                     VARCHAR
_____________________________

http://example.com/e/s1     Value of p1 for s1
http://example.com/e/s1-10  Value of p1 for s1-10
http://example.com/e/s1-20  Value of p1 for s1-20
http://example.com/e/s2-30  Value of p1 for s2-30
http://example.com/e/s2-40  Value of p1 for s2-40
http://example.com/e/s2     Value of p1 for s2

6 Rows. -- 0 msec.
```

```
SQL>SPARQL DEFINE input:inference <http://example.com/2/owl>
PREFIX e:<http://example.com/e/>
SELECT * FROM <http://example.com/2/data>
WHERE
  {
    ?s a e:c1 ;
```

```
        e:p1 ?o
  }

s                           o
VARCHAR                     VARCHAR
_______________________________

http://example.com/e/s1     Value of p1 for s1
http://example.com/e/s1-10  Value of p1 for s1-10
http://example.com/e/s1-20  Value of p1 for s1-20

3 Rows. -- 0 msec.
```

Example links against Virtuoso Demo Server SPARQL Endpoint with SPARQL Protocol URLs:

- View results page
- View editor page

However you should care about duplicates if both types and properties are queried: the join will result in all combinations of types and property values.

```
SQL>SPARQL DEFINE input:inference <http://example.com/2/owl>
PREFIX e:<http://example.com/e/>
SELECT * FROM <http://example.com/2/data>
WHERE
  {
    ?s a ?t ;
     e:p1 ?o
  }

s                           t                           o
VARCHAR                     VARCHAR                     VARCHAR
_______________________________

http://example.com/e/s1     http://example.com/e/c1     Value of p1 for s1
http://example.com/e/s1     http://example.com/e/c1or2  Value of p1 for s1
http://example.com/e/s1-10  http://example.com/e/c1-10  Value of p1 for s1-10
http://example.com/e/s1-10  http://example.com/e/c1     Value of p1 for s1-10
http://example.com/e/s1-10  http://example.com/e/c1or2  Value of p1 for s1-10
http://example.com/e/s1-20  http://example.com/e/c1-20  Value of p1 for s1-20
http://example.com/e/s1-20  http://example.com/e/c1     Value of p1 for s1-20

Transitive queries are convenient as SPARQL 1.1 "predicate+" equivalent. The equivalent of "predicate*" requires the use of a union:

```
SQL>SPARQL PREFIX e:<http://example.com/e/>
SELECT ?item
FROM <http://example.com/2/data>
WHERE
  {
    {
      ?lists rdf:_1 ?node
    }
    UNION
```

```
    {
      ?lists rdf:_1 ?l .
      ?l rdf:rest ?node option (transitive) .
    }
    ?node rdf:first ?item
  }

item
VARCHAR
_______________________________________________________________________________

http://example.com/e/list1-item1
http://example.com/e/list1-item2
http://example.com/e/list1-item3

3 Rows. -- 0 msec.
```

Example links against Virtuoso Demo Server SPARQL Endpoint with SPARQL Protocol URLs:

- View results page
- View editor page

```
SQL> SPARQL PREFIX e:<http://example.com/e/>
SELECT ?p ?o
FROM <http://example.com/2/data>
WHERE
  {
    {
      ?lists rdf:_2 ?node
    }
    UNION
    {
      ?lists rdf:_2 ?l .
      ?l rdf:rest ?node option (transitive) .
    }
    ?node rdf:first ?item .
    ?item ?p ?o
  }

p                         o
VARCHAR                   VARCHAR
_________________________

http://example.com/e/p2   Value of p2 of item1 of list2
http://example.com/e/p3   Value of p3 of item1 of list2
http://example.com/e/p2   Value of p2 of item2 of list2
http://example.com/e/p3   Value of p3 of item2 of list2
http://example.com/e/p2   Value of p2 of item3 of list2
http://example.com/e/p3   Value of p3 of item3 of list2

6 Rows. -- 0 msec.
```

Example links against Virtuoso Demo Server SPARQL Endpoint with SPARQL Protocol URLs:

- View results page
- View editor page

Note that the result set can be in order of items in the list, but it don't have to. If the order should be preserved, then fix the direction of transitive scan, get step number as a variable, order by that variable.

```
-- Line 82:
SQL> SPARQL PREFIX e:<http://example.com/e/>
SELECT ?p ?o bif:coalesce(?step_no, 0)
FROM <http://example.com/2/data>
WHERE
  {
    {
      ?lists rdf:_2 ?node
    }
    UNION
```

```
    {
      ?lists rdf:_2 ?l .
      ?l rdf:rest ?node OPTION (transitive, t_direction 1, t_step("step_no") as ?step_no) .
    }
    ?node rdf:first ?item .
    ?item ?p ?o
  }
ORDER BY ASC (?step_no)

p                        o                              callret-2
VARCHAR                  VARCHAR                        VARCHAR

16.14.5. OWL sameAs Support

Virtuoso has limited support for the OWL sameAs predicate.

If sameAs traversal is enabled and a triple pattern with a given subject or object is being matched, all the synonyms of the S and O will be tried and results generated for all the tried bindings of S and O. The set of synonyms is generated at run time by following all owl:sameAs triples where the IRI in question is either the subject or the object. These are followed recursively from object to subject and subject to object until the complete transitive closure is generated. All sameAs triples from all the graphs applicable to instantiating the triple pattern at hand are considered.

Thus for example:

The inital SPARQL query:

```
SQL>SPARQL
prefix foaf: <http://xmlns.com/foaf/0.1/>
prefix owl: <http://www.w3.org/2002/07/owl#>
prefix sioc: <http://rdfs.org/sioc/ns#>
SELECT *
from <http://example.com/dataspace>
where
 {
    ?person a foaf:Person FILTER REGEX(?person ,"http://example.com/dataspace/person/kidehen#this").
    ?person foaf:name ?name .
    ?person owl:sameAs ?sameas .
  }
limit 8;
person                                              name             sameas
VARCHAR                                             VARCHAR          VARCHAR
_____________________________________________________________________________

http://example.com/dataspace/person/kidehen#this  Kingsley Idehen  http://www.openlinksw.com/dataspace/pe
http://example.com/dataspace/person/kidehen#this  Kingsley Idehen  http://my.openlinksw.com/dataspace/per
http://example.com/dataspace/person/kidehen#this  Kingsley Idehen  http://kidehen.idehen.net/dataspace/pe
http://example.com/dataspace/person/kidehen#this  Kingsley Idehen  http://qdos.com/user/e922b748a2eb667bf
http://example.com/dataspace/person/kidehen#this  Kingsley Idehen  http://knowee.net/kidehen/ids/id368497
http://example.com/dataspace/person/kidehen#this  Kingsley Idehen  http://dbpedia.org/resource/Kingsley_I
http://example.com/dataspace/person/kidehen#this  Kingsley Idehen  http://identi.ca/user/14092
http://example.com/dataspace/person/kidehen#this  Kingsley Idehen  http://myopenlink.net/proxy?url=http%3

8 Rows. -- 181 msec.
```

So if we have:

```
<http://example.com/dataspace/person/kidehen#this>      <http://www.w3.org/2002/07/owl#sameAs> <http://ww
<http://example.com/dataspace/person/kidehen#this>      <http://xmlns.com/foaf/0.1/name>           Kingsl
```

and we instantiate *?s <http://xmlns.com/foaf/0.1/name> "Kingsley Idehen"* we get *?s* bound to *<http://example.com/dataspace/person/kidehen#this>* .

If we instantiate *<http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this> <http://xmlns.com/foaf/0.1/name> ?l* we get *?l* bound to *"Kingsley Idehen"* because the subject was given and it was expanded to its synonyms.

If binding a variable in a pattern where the variable was free, we do not expand the value to the complete set of its synonyms.

Same-as expansion is enabled in a query by *define input:same-as "yes"* in the beginning of the SPARQL query. This has a significant run time cost but is in some cases useful when joining data between sets which are mapped to each other with same-as.

We note that the number of same-as expansions will depend on the join order used for the SPARQL query. The compiler does not know the number of synonyms and cannot set the join order accordingly. Regardless of the join order we will however get at least one IRI of the each synonym set as answer. Also when interactively navigating a graph with a browser, the same-as expansion will take all synonyms into account.

For getting the complete entailment of same-as, a forward chaining approach should be used, effectively asserting all the implied triples.

OWL sameAs Example

```
SQL>SPARQL
DEFINE input:same-as "yes"
SELECT *
WHERE
 {
   ?s <http://xmlns.com/foaf/0.1/name> "Kingsley Idehen" .
 }
LIMIT 10;

16.14.6. Implementation

Triples entailed by subclass or subproperty statements in an inference context are not physically stored. Such triples are added to the result set by the query run time as needed. Also queries involving subclass or subproperty rules are not rewritten into unions of all the possible triple patterns that might imply the pattern that is requested. Instead, the SQL compiler adds special nodes that iterate over subclasses or subproperties at run time. The cost model also takes subclasses and subproperties into account when determining the approximate cardinality of triple patterns.

In essence, Virtuoso's support for subclasses and subproperties is backward chaining, i.e. it does not materialize all implied triples but rather looks for the basic facts implying these triples at query evaluation time.

16.14.7. Enabling Inferencing

In a SPARQL query, the define input:inference clause is used to instruct the compiler to use the rules in the named rule set. For example:

```
SQL> rdfs_rule_set ('sample', 'rule_graph');

SQL> SPARQL
define input:inference "sample"
SELECT *
FROM <g>
WHERE {?s ?p ?o};
```

will include all the implied triples in the result set, using the rules in the sample rule set.

Inference can be enabled triple pattern by triple pattern. This is done with the option (inference 'rule_set') clause after the triple pattern concerned. Specifying option (inference none) will disable inference for the pattern concerned while the default inference context applies to the rest of the patterns. Note that the keyword is input:inference in the query header and simply inference in the option clause. See the examples section below for examples.

In SQL, if RDF_QUAD occurs in a select from clause, inference can be added with the table option *WITH* , as follows:

```
SPARQL
SELECT *
FROM rdf_quad table OPTION (with 'sample')
WHERE g = iri_to_id ('xx', 0);
```

This is about the same as:

```
SPARQL
define input:inference "sample"
SELECT *
FROM <xx>
WHERE {?s ?p ?o}
```

16.14.8. Examples

Example for loading data space instance data Triples into a Named Graph for schema/ontology data

The following example shows how to load data space instance data Triples into a Named Graph: <http://example.com/test>, for schema/ontology data called: <http://example.com/schema/test> that expresses assertions about subclasses and subproperties.

```
ttlp ('
   <http://example.com/dataspace>                                <http://www.w3.org/1999/02/22-rdf-syntax-
   <http://example.com/dataspace/test2/weblog/test2tWeblog>  <http://www.w3.org/1999/02/22-rdf-syntax-ns#
   <http://example.com/dataspace/discussion/oWiki-test1Wiki> <http://www.w3.org/1999/02/22-rdf-syntax-ns#
   <http://example.com/dataspace>                               <http://rdfs.org/sioc/ns#link>
   <http://example.com/dataspace/test2/weblog/test2tWeblog>  <http://rdfs.org/sioc/ns#link>
   <http://example.com/dataspace/discussion/oWiki-test1Wiki> <http://rdfs.org/sioc/ns#link>
   ', '', 'http://example.com/test');

ttlp (' @prefix rdfs: <http://www.w3.org/2000/01/rdf-schema#> .
  <http://rdfs.org/sioc/ns#Space> rdfs:subClassOf <http://www.w3.org/2000/01/rdf-schema#Resource> .
  <http://rdfs.org/sioc/ns#Container> rdfs:subClassOf <http://rdfs.org/sioc/ns#Space> .
  <http://rdfs.org/sioc/ns#Forum> rdfs:subClassOf <http://rdfs.org/sioc/ns#Container> .
  <http://rdfs.org/sioc/types#Weblog> rdfs:subClassOf <http://rdfs.org/sioc/ns#Forum> .
  <http://rdfs.org/sioc/types#MessageBoard> rdfs:subClassOf <http://rdfs.org/sioc/ns#Forum> .
  <http://rdfs.org/sioc/ns#link> rdfs:subPropertyOf <http://rdfs.org/sioc/ns> .
  ', '', 'http://example.com/schema/test');

rdfs_rule_set ('http://example.com/schema/property_rules1', 'http://example.com/schema/test');
```

This defines the rule context http://example.com/schema/property_rules1 that is initialized from the contents of graph http://example.com/schema/test.

```
SQL>SPARQL
define input:inference "http://example.com/schema/property_rules1"
```

```
SELECT ?s
FROM <http://example.com/test>
WHERE {?s <http://www.w3.org/1999/02/22-rdf-syntax-ns#type>  <http://rdfs.org/sioc/ns#Space> };
s
VARCHAR
_______________________________________________________________________________

http://example.com/dataspace/test2/weblog/test2tWeblog
http://example.com/dataspace/discussion/oWiki-test1Wiki
http://example.com/dataspace

3 Rows. -- 0 msec.
```

This returns the instances of http://rdfs.org/sioc/ns#Space. Since http://rdfs.org/sioc/types#Weblog and http://rdfs.org/sioc/types#MessageBoard are subclasses of http://rdfs.org/sioc/ns#Space, instances of http://rdfs.org/sioc/ns#Space, http://rdfs.org/sioc/types#Weblog and http://rdfs.org/sioc/types#MessageBoard are all returned. This results in the subjects http://example.com/dataspace, http://example.com/dataspace/test2/weblog/test2tWeblog and http://example.com/dataspace/discussion/oWiki-test1Wiki.

```
SQL>SELECT id_to_iri (s)
FROM rdf_quad table option (with 'http://example.com/schema/property_rules1')
WHERE g = iri_to_id ('http://example.com/test',0)
  AND p = iri_to_id ('http://www.w3.org/1999/02/22-rdf-syntax-ns#type', 0)
  AND o = iri_to_id ('http://rdfs.org/sioc/ns#Space', 0);
callret
VARCHAR
_______________________________________________________________________________

http://example.com/dataspace/test2/weblog/test2tWeblog
http://example.com/dataspace/discussion/oWiki-test1Wiki
http://example.com/dataspace

3 Rows. -- 10 msec.
```

This is the corresponding SQL query, internally generated by the SPARQL query.

Below we first look for all instances of http://rdfs.org/sioc/ns#Space with some property set to http://example.com/dataspace/test2/weblog/test2tWeblog. We get the subject http://example.com/dataspace/test2/weblog/test2tWeblog and the properties http://rdfs.org/sioc/ns#link and http://rdfs.org/sioc/ns. The join involves both subclass and subproperty inference. Then we turn off the inference for the second pattern and only get the property http://rdfs.org/sioc/ns#link. Then we do the same but now specify that inference should apply only to the first triple pattern.

```
SQL>SPARQL
define input:inference  "http://example.com/schema/property_rules1"
SELECT *
FROM <http://example.com/test>
WHERE
  {
    ?s ?p <http://rdfs.org/sioc/ns#Space> .
    ?s ?p1 <http://example.com/dataspace/test2/weblog/test2tWeblog> .

```

Pure SPARQL Example

```
-- Query aimed at Fantasy Novel via query scoped to the "Fiction" class of
-- which it is a subclass in the Yago Hierarchy

SQL>SPARQL
define input:inference "http://dbpedia.org/resource/inference/rules/yago#"
PREFIX rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
PREFIX dbpedia: <http://dbpedia.org/property/>
PREFIX yago: <http://dbpedia.org/class/yago/>
SELECT ?s
FROM <http://dbpedia.org>
WHERE {
?s a <http://dbpedia.org/class/yago/Fiction106367107> .
?s dbpedia:name "The Lord of the Rings"@en .
};
s
VARCHAR
_______________________________________________________________________________

http://dbpedia.org/resource/The_Lord_of_the_Rings
http://dbpedia.org/resource/The_Lord_of_the_Rings
http://dbpedia.org/resource/The_Lord_of_the_Rings
http://dbpedia.org/resource/The_Lord_of_the_Rings

4 Rows. -- 150 msec.
```

Example for equivalence between classes

This example is based on UMBEL and DBpedia integration:

```
-- Load UMBEL & DBpedia Instance Level Cross-Links (owl:sameAs) Triples
SELECT ttlp_mt (file_to_string_output ('umbel_dbpedia_linkage_v071.n3'), '', 'http://dbpedia.org');

-- Load UMBEL and DBpedia Type (rdf:type) association Triples
SELECT ttlp_mt (file_to_string_output ('umbel_dbpedia_types_v071.n3'), '', 'http://dbpedia.org');

--- Load UMBEL Subject Concept Class Hierarchy into a Named Graph
SELECT ttlp_mt (file_to_string_output ('umbel_class_hierarchy_v071.n3'), '', 'http://dbpedia.org/resource

--- load UMBEL Subject Concepts Instance Data
SELECT ttlp_mt (file_to_string_output ('umbel_subject_concepts.n3'), '', 'http://dbpedia.org/resource/cla

--- Load UMBEL Abstract Concepts Instance Data
SELECT ttlp_mt (file_to_string_output ('umbel_abstract_concepts.n3'), '', 'http://dbpedia.org/resource/cl

-- Load UMBEL External Ontology Mapping into a Named Graph
SELECT ttlp_mt (file_to_string_output ('umbel_external_ontologies_linkage.n3'), '', 'http://dbpedia.org/r

-- Create UMBEL Inference Rules

rdfs_rule_set ('http://dbpedia.org/resource/inference/rules/umbel#', 'http://dbpedia.org/resource/classes
```

Now let's execute the following queries:

```
SQL>SPARQL define input:inference "http://dbpedia.org/resource/inference/rules/umbel#"
prefix umbel: <http://umbel.org/umbel/sc/>
PREFIX dbpedia: <http://dbpedia.org/property/>
prefix opencyc: <http://sw.opencyc.org/2008/06/10/concept/en/>
SELECT ?s
where
{
 ?s a opencyc:Motorcycle.
 ?s dbpedia:name ?n.
 ?n bif:contains "BMW".
};

16.14.9. Identity With Inverse Functional Properties

A graph used used with rdfs_rule_set may declare certain properties to be inversely functional. If one or more inverse functional properties (IFP's) are declared in the inference context used with the query, enabled with define input:inference = "context_name", then the following semantics apply:

1. If a literal is compared with an IRI, then the literal is substituted by all the subject IRI's where this literal occurs as a value of an IFP.
2. If two IRI's are compared for equality, they will be considered the same if there is an IFP P such that the same P has the same value on both subjects.
3. If an IRI is processed for distinctness in either distinct or group by, the IRI is first translated to be the IRI with the lowest ID among all IRI's that share an IFP value with this IRI.

Thus, if two IRI's are compared for distinctness, they will count as one if there is an IFP P with the same value with both IRI's. Literal data types are not translated into IRI's even if these literals occurred as IFP values of some subject.

It is possible to declare that specific values, even if they occur as values of an IFP in more than onme subject do not constitute identity between the subjects. For example, if two subjects were inferred to be the same because they had the same foaf:mbox_sha1sum, the SHA1 hash of mailto:// would be excluded. Two individuals have an email address that has a common default value are not the same.

In an ontology graph, a property IRI is declared to be inversely functional by making it an instance of the owl:InverseFunctionalProperty class. A value of an IFP can be declared null, i.e. sharing the value does not imply identity by by giving the IFP IRI a <http://www.openlinksw.com/schemas/virtrdf#nullIFPValue> property with the value to be ignored as the object.

Example

```
SQL>ttlp ('
<john1> a <person> .
<john2> a <person> .
<mary> a <person> .
<mike> a <person> .
<john1> <name> "John" .
<john2> <name> "John" .
<john1> <address> "101 A street" .
<john2> <address> "102 B street" .
<john2> <knows> <mike> .
<john1> <http://www.w3.org/2002/07/owl#sameAs> <john2> .
<mary> <knows> "John" .
<mike> <knows> <john1> .
<mike> <knows> <john2> .
<john1> <name> "Tarzan" .
<mike> <nam> "Tarzan" .
', '', 'ifps');

SQL>ttlp ('
<name> a <http://www.w3.org/2002/07/owl#InverseFunctionalProperty> .
<name> <http://www.openlinksw.com/schemas/virtrdf#nullIFPValue> "Tarzan" .
', '', 'ifp_list');

SQL>rdfs_rule_set ('ifps', 'ifp_list');

SQL>SPARQL define input:inference "ifps"  SELECT * FROM <ifps> WHERE {<john1> ?p ?o};

p                                                                                o
VARCHAR                                                                          VARCHAR
_______________________________________________________________________________

address                                                                          101 A street
name                                                                             John
http://www.w3.org/2002/07/owl#sameAs                                             john2
http://www.w3.org/1999/02/22-rdf-syntax-ns#type                                  person
name                                                                             Tarzan
name                                                                             John
knows                                                                            mike
http://www.w3.org/1999/02/22-rdf-syntax-ns#type                                  person
address                                                                          102 B street
```

We see that we get the properties of <john2> also.

```
SQL>SPARQL define input:inference "ifps" SELECT distinct ?p FROM <ifps> WHERE { ?p a <person>};

john2
mike
mary
```

We see that we get only one John. But John is not the same as Mike because they share the name Tarzan which is not considered as implying identity. Which John we get is a matter of which gets the lowest internal ID. This is variable and arbitrary at load time but once loaded this is permanent as long as the set of subjects with the name John does not change.

16.14.10. Inference Rules and SPARQL with Transitivity Option

- See example with an inference rule to cater data being skos:broader based, which is no longer transitive.
- See example with an inference rule to find entities that are subcategories of Protestant Churches, no deeper than 3 levels within the concept scheme hierarchy, filtered by a specific subcategory.

16.14.11. Inference Rules, OWL Support and Relationship Ontology

This section provides queries usage for inference rules, owl support and Relationship Vocabulary.

Example 1

Example based on Relationship Vocab:

```
## Verify Ontology Data is in Quad Store
## Ontology: <http://vocab.org/relationship/> (Relationship Ontology)
## Use pragma to put latest in Quad store.

DEFINE get:soft "replace"
SELECT *
FROM <http://vocab.org/relationship/>
WHERE {?s ?p ?o}

## Clean up

CLEAR GRAPH <urn:owl.tests>

## Create Instance Data for Relationship Ontology
PREFIX rel: <http://purl.org/vocab/relationship/>

INSERT into GRAPH <urn:owl.tests>
  {
    <http://dbpedia.org/resource/Prince_William_of_Wales> rel:siblingOf <http://dbpedia.org/resource/Prin
    <http://dbpedia.org/resource/Elizabeth_Bowes-Lyon> rel:ancestorOf <http://dbpedia.org/resource/Elizab
    <http://dbpedia.org/resource/Elizabeth_II_of_the_United_Kingdom> rel:ancestorOf
    <http://dbpedia.org/resource/Charles%2C_Prince_of_Wales>.
    <http://dbpedia.org/resource/Charles%2C_Prince_of_Wales> rel:ancestorOf <http://dbpedia.org/resource/
  };

## Verify

SELECT *
FROM  <urn:owl.tests>
WHERE
  {
    ?s ?p ?o
  }

## Create an  Inference Rule that references the Relationship Ontology Named Graph

rdfs_rule_set ('urn:owl.tests', 'http://vocab.org/relationship') ;

## Verify Rule's existence

SELECT * FROM SYS_RDF_SCHEMA ;
```

Example 2

```
## Test owl:TransitiveProperty Reasoning
## Start with a specific URI
## Goal: See inferred Triples
## In this case, relationship between: <http://dbpedia.org/resource/Elizabeth_Bowes-Lyon>
## and her descendants: Queen Elizabeth, Prince Charles, Prince William, and Prince Harry)

DEFINE input:inference 'urn:owl.tests'
PREFIX rel: <http://purl.org/vocab/relationship/>
SELECT *
FROM <urn:owl.tests>
WHERE
  {
```

```
    <http://dbpedia.org/resource/Elizabeth_Bowes-Lyon> rel:ancestorOf ?o
  }
```

Example 3

```
## Test owl:SymmetricalProperty Reasoning
## Should show same result irrespective of rel:siblingOf URI in Subject or Object slots of Triple

DEFINE input:inference 'urn:owl.tests'
PREFIX rel: <http://purl.org/vocab/relationship/>
PREFIX foaf: <http://xmlns.com/foaf/0.1/>

SELECT *
FROM <urn:owl.tests>
WHERE
  {
    <http://dbpedia.org/resource/Prince_William_of_Wales> rel:siblingOf ?o
  }

## OR

DEFINE input:inference 'urn:owl.tests'
PREFIX rel: <http://purl.org/vocab/relationship/>
PREFIX foaf: <http://xmlns.com/foaf/0.1/>

SELECT *
FROM <urn:owl.tests>
WHERE
  {
    ?s rel:siblingOf <http://dbpedia.org/resource/Prince_William_of_Wales>
  }
```

Example 4

```
## Test owl:inverseOf Reasoning
## Should show triples exposing the inverseOf relation.
## In this case rel:ancestorOf instance data triples exist,so the system must infer rel:descendant Of tri

DEFINE input:inference 'urn:owl.tests'
PREFIX rel: <http://purl.org/vocab/relationship/>

SELECT *
FROM <urn:owl.tests>
WHERE
  {
    <http://dbpedia.org/resource/Elizabeth_II_of_the_United_Kingdom> rel:descendantOf ?o
  }

## OR with Transitivity Option applied

DEFINE input:inference 'urn:owl.tests'
PREFIX rel: <http://purl.org/vocab/relationship/>

SELECT *
FROM <urn:owl.tests>
WHERE
  {
    <http://dbpedia.org/resource/Prince_William_of_Wales> rel:descendantOf ?o
    OPTION (T_DISTINCT)
  }
```

Example 5

```
## Test owl:inverseOf Reasoning
## Should show triples exposing the inverseOf relation.
## In this case rel:employedBy instance data triples exist,
## the system must infer rel:employerOf triples.

DEFINE input:inference 'urn:owl.tests'
PREFIX rel: <http://purl.org/vocab/relationship/>

SELECT *
```

```
FROM <urn:owl.tests>
WHERE
  {
    ?s rel:employerOf ?o
  }
```

Example 6

Example based on Relationship Vocab and SKOS

Assume the following test10.rdf file:

```
<?xml version="1.0" encoding="UTF-8"?>
<rdf:RDF
        xmlns:rdfs="http://www.w3.org/2000/01/rdf-schema#"
        xmlns:daml="http://www.daml.org/2001/03/daml+oil#"
        xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"

  {
    <http://www.turnguard.com/ElectroPop> skos:broaderTransitive ?o
    OPTION  (T_DISTINCT).
  }
```

16.15. RDF and Geometry

A geometry may occur as an object of an RDF quad. The SQL MM functions can then be used for geospatial queries.

For geometry functions, see the SQL Geometry support section .

A geometry may occur as an object value in an RDF quad. In such a case, the bare geometry object is not used but instead a special RDF typed literal is made with the type virtrdf:Geometry. Such a literal is automatically indexed in an R tree index containing all distinct geometries occurring in any quad of any graph under any predicate. Normally, WGS84, SRID 4326 is the SRID of any such geometry.

In this section, the geo namespace prefix is used to mean <http://www.w3.org/2003/01/geo/wgs84_pos#>.

The preferred way of adding geometries to RDF graphs is with the ttlp and related functions which parse a text string in the Turtle syntax and insert the result in a graph.

For example:

```
ttlp ('@prefix virtrdf: <http://www.openlinksw.com/schemas/virtrdf#>
<point> geo:geometry "point(1.2 22.4"^^virtrdf:Geometry .',
'xxx', 'graph');
```

A typed literal whose text is a WKT representation of a geometry and whose type is virtrdf:geometry creates a geometry object and adds it to the R tree index of all RDF geometries.

Geometries can be queried with geometry predicates, st_intersects, st_contains and st_within, as follows. As usual, the bif: namespace is used since these are SQL built-in functions.

```
SQL>
SPARQL
SELECT ?c COUNT (*)
WHERE
  {
    ?m geo:geometry ?geo .
    ?m a ?c .
    FILTER (bif:st_intersects (?geo, bif:st_point (0, 52), 100))
  }
GROUP BY ?c
ORDER BY DESC 2;

c                                                    callret-1
VARCHAR                                              VARCHAR

This would be the cities within 20 km of 0, 52, ordered by increasing distance from this point.

When SPARQL is called from SQL, the geometries can be bound to SQL variables as anything else returned from SPARQL. The *st_* functions can then be used for retrieving properties of these objects.

16.15.1. Programmatic Manipulation of Geometries in RDF

The `ttlp` function is the preferred way of inserting geometries. The more are inserted at one time, the more efficient the operation is. This loader function will also deal with cluster message optimization.

For deleting quads with geometries, normal SPARUL operations apply.

A geometry occurring in an RDF quad object is a member of the RDF box data type. This data type stands for a typed RDF literal. The type of all geometries is 256. This is mapped to a URI in the RDF_DATATYPE system table.

A geometry does not occur directly in the object position of a quad. It is referenced by an id that is stored in the RDF typed literal box and references RO_ID of the RDF_OBJ system table. To translate a geometry into a RDF box that can be stored, do as in the example below:

```
INSERT INTO RDF_QUAD (g, s, p, o)
VALUES (
         "g",
         "s",
         iri_to_id ('http://www.w3.org/2003/01/geo/wgs84_pos#geometry'),
         DB.DBA.rdf_geo_add (rdf_box (st_point (lng, lat), 256, 257, 0, 1)));
```

The DB.DBA.RDF_GEO_ADD function looks if an identical geometry already exists and if so assigns the existing id to it. If the geometry is new, it gets a new ID and is stored in the RDF literals table RDF_OBJ. At this time it is also automatically inserted into the RDF geometry index.

In a cluster situation one should use the dpipe mechanism for inserting into RDF quad so as to get large numbers of inserts into a single message. This is essential for performance.

16.15.2. Creating Geometries From RDF Data

Many data sets use the geo:lat and geo:long properties for describing a position. Virtuoso comes with a function for converting these properties into geometries. This operation reads through all graphs and for each subject with at least one geo:lat and geo:long, a point geometry is made for each distinct lat/long pair where lat and long are in the same graph. It should not happen in practice that a single subject has multiple lats or long within one graph. If this still happens, a geometry is made for each combination. The geometry is added to the subject with the lat and long as the value of the geo:geometry property. This is added to the same graph where the lat and long were.

The SQL procedure DB.DBA.RDF_GEO_FILL () performs this operation. This is performed in parallel on multiple threads and is optimized for cluster execution. This is done without transaction logging and is not transactional. To make the result persistent, the operator should do an explicit checkpoint. This is done by executing:

```
SQL>cl_exec ('checkpoint');
```

on any process of a cluster or single server. Otherwise the result may be lost if the server terminates abnormally before an automatic checkpoint is made.

The DB.DBA.RDF_GEO_FILL procedure may in principle be called several times but it will read every lat and long in the database. This is inefficient if there are large numbers of geometries.

Application logic must generally be used for constructing geometries and adding these to RDF subjects. It is easiest for the application to construct a text representation of the geometries in TTL and to use the `ttlp` function for loading this.

16.15.3. Using Geometries With Existing Databases

The geometry feature is compatible with any Virtuoso 6 databases. Once geometries are used, the database should not be opened with a server older than the one used for first inserting geometries, older servers will consider the storage format a physical corruption.

16.15.4. GEO Spatial Examples

Example 1

```
## Get All Stuff For Given Coordinates
SQL>SPARQL
SELECT ?c COUNT (*)
WHERE
   {
     ?m geo:geometry ?geo .

```

16.16. RDF Replication

Tables of RDF storage, such as DB.DBA.RDF_QUAD and DB.DBA.RDF_OBJ, can not be replicated in a usual way, because it's content is cached in memory in special ways and synchronized with values outside these tables, such as current values of special sequence objects.

Moreover, same IRI may have different internal IRI_IDs on different boxes, because the assigned IDs vary if new IRIs appear in data in different order. Similarly, there will be different IDs of RDF literal, datatypes and languages, blocking any attempt of one-to-one replication between RDF storages.

However, a special asynchronous RDF replication makes it possible to configure a "publisher" Virtuoso instance to keep the log of changes in some RDF graphs and subscribe some Virtuoso instances to replay all these changes.

Configuration functions are quite straightforward.

RDF graphs to replicate are all members of <http://www.openlinksw.com/schemas/virtrdf#rdf_repl_graph_group> graph group. That group can be filled in with graphs like any other graph group, but it is better to get the advantage of proper security check made by `DB.DBA.RDF_REPL_GRAPH_INS()` that inserts a graph to the group and `DB.DBA.RDF_REPL_GRAPH_DEL()` that removes a graph from the group.

Only publicly readable graphs can be replicated, an error is signalled otherwise, and it is better to know about a security issue as early as possible.

The `DB.DBA.RDF_REPL_START()` function starts the RDF replication at the publishing side. It creates replication "publication" named '__rdf_repl' and makes a log file '__rdf_repl.log' to record changes in replicated graphs. If the replication has been started before then an error is signalled; passing value 1 for parameter "quiet" elimintaes the error so the incorrect call has no effect at all. If the replication is enabled then the value of registry variable 'DB.DBA.RDF_REPL' indicates the moment of replication start.

The `DB.DBA.RDF_REPL_START()` function performs a security check before starting the replication to check.

The `DB.DBA.RDF_REPL_STOP()` stops the RDF replication at the publishing side. It calls `repl_unpublish()` but does not make empty reates replication "publication" named '__rdf_repl' and makes a log file '__rdf_repl.log' to record changes in replicated graphs.

Replication is asynchronous and the order of insertion and removal operations at the subscriber's side may not match the order at the publisher. As a result, it is not recommended to make few subscriptions that writes changes of few publishers into one common graph. A client-side application can force the synchronuzation by calling `DB.DBA.RDF_REPL_SYNC()` that acts like `repl_sync()` but for an RDF subscription. `DB.DBA.RDF_REPL_SYNC()` will not only initial synchronisation but also wait for the end of subscription to guarantee that the total effect of INSERT and DELETE operations is correct even if these operations were made in an order that differs from the original one.

16.17. RDF Performance Tuning

For RDF query performance, we have the following possible questions:

- Is the Virtuoso process properly configured to handle big data sets?
- Is the graph always specified?

- Are public web service endpoints protected against bad queries?
- Are there patterns where only a predicate is given?
- Is there a bad query plan because of cost model error?

16.17.1. General

When running with large data sets, one should configure the Virtuoso process to use between 2/3 to 3/5 of system RAM and to stripe storage on all available disks. See NumberOfBuffers , MaxDirtyBuffers , and Striping INI file parameters.

```
; default installation
NumberOfBuffers          = 2000
MaxDirtyBuffers          = 1200
```

Typical sizes for the NumberOfBuffers and MaxDirtyBuffers (3/4 of NumberOfBuffers) parameters in the Virtuoso configuration file (virtuoso.ini) for various memory sizes are as follows, with each buffer consisting of 8K bytes:

Table 16.19. recommended NumberOfBUffers and MaxDirtyBuffers

System RAM	NumberOfBuffers	MaxDirtyBuffers
2 GB	170000	130000
4 GB	340000	250000
8 GB	680000	500000
16 GB	1360000	1000000
32 GB	2720000	2000000
48 GB	4000000	3000000
64 GB	5450000	4000000

Also, if running with a large database, setting MaxCheckpointRemap to 1/4th of the database size is recommended. This is in pages, 8K per page.

16.17.2. RDF Index Scheme

Starting with version 6.00.3126, the default RDF index scheme consists of 2 full indices over RDF quads plus 3 partial indices. This index scheme is generally adapted to all kinds of workloads, regardless of whether queries generally specify a graph. As indicated the default index scheme in Virtuoso is almost always applicable as is, whether one has a RDF database with very large numbers of small graphs or just one or a few large graphs. With Virtuoso 7 the indices are column-wise by default, which results in them to consuming usually about 1/3 of the space the equivalent row-wise structures would consume.

Alternate indexing schemes are possible but will not be generally needed. For upgrading old databases with a different index scheme see the corresponding documentation.

The index scheme consists of the following indices:

- *PSOG*

  - primary key
- *POGS*

  - bitmap index for lookups on object value.
- *SP*

  - partial index for cases where only S is specified.
- *OP*

  - partial index for cases where only O is specified.
- *GS*

  - partial index for cases where only G is specified.

This index scheme is created by the following statements:

```
CREATE TABLE DB.DBA.RDF_QUAD (
  G IRI_ID_8,
  S IRI_ID_8,
  P IRI_ID_8,
  O ANY,
  PRIMARY KEY (P, S, O, G)
  )
ALTER INDEX RDF_QUAD ON DB.DBA.RDF_QUAD
  PARTITION (S INT (0hexffff00));

CREATE DISTINCT NO PRIMARY KEY REF BITMAP INDEX RDF_QUAD_SP
  ON RDF_QUAD (S, P)
  PARTITION (S INT (0hexffff00));

CREATE BITMAP INDEX RDF_QUAD_POGS
  ON RDF_QUAD (P, O, G, S)
  PARTITION (O VARCHAR (-1, 0hexffff));

CREATE DISTINCT NO PRIMARY KEY REF BITMAP INDEX RDF_QUAD_GS
  ON RDF_QUAD (G, S)
  PARTITION (S INT (0hexffff00));

CREATE DISTINCT NO PRIMARY KEY REF INDEX RDF_QUAD_OP
  ON RDF_QUAD (O, P)
  PARTITION (O VARCHAR (-1, 0hexffff));
```

The idea is to favor queries where the predicate is specified in triple patterns. The entire quad can be efficiently accessed when `P` and at least one of `S` and `O` are known. This has the advantage of clustering data by the predicate which improves working set. A page read from disk will only have entries pertaining to the same predicate; chances of accessing other entries of the page are thus higher than if the page held values for arbitrary predicates. For less frequent cases where only `S` is known, as in `DESCRIBE` , the distinct `P` s of the `S` are found in the `SP` index. These `SP` pairs are then used for accessing the `PSOG` index to get the `O` and `G` . For cases where only the `G` is known, as when dropping a graph, the distinct `S` s of the `G` are found in the `GS` index. The `P` s of the `S` are then found in the `SP` index. After this, the whole quad is found in the `PSOG` index.

The `SP` , `OP` , and `GS` indices do not store duplicates. If an `S` has many values of the `P` , there is only one entry. Entries are not deleted from `SP` , `OP` , or `GS` . This does not lead to erroneous results since a full index (that is, either `POSG` or `PSOG`) is always consulted in order to know if a quad actually exists. When updating data, most often a graph is entirely dropped and a substantially similar graph inserted in its place. The `SP` , `OP` , and `GS` indices get to stay relatively unaffected.

Still, over time, especially if there are frequent updates and values do not repeat between consecutive states, the `SP` , `OP` , and `GS` indices will get polluted, which may affect performance. Dropping and recreating the index will remedy this situation.

In cases where this is not practical, the index scheme should only have full indices; i.e., each key holds all columns of the primary key of the quad. This will be the case if the `DISTINCT NO PRIMARY KEY REF` options are not specified in the `CREATE INDEX` statement. In such cases, all indices remain in strict sync across deletes.

Many RDF workloads have bulk-load and read-intensive access patterns with few deletes. The default index scheme is optimized for these. With these situations, this scheme offers significant space savings, resulting in better working set. Typically, this layout takes 60-70% of the space of a layout with 4 full indices.

16.17.3. Index Scheme Selection

The indexes in place on the `RDF_QUAD table` can greatly affect the performance of SPARQL queries, as can be determined by running the `STATISTICS` command on the table as follows:

```
SQL> STATISTICS DB.DBA.RDF_QUAD;
Showing SQLStatistics of table(s) 'DB.DBA.RDF_QUAD'
TABLE_QUALIFIER  TABLE_OWNER      TABLE_NAME       NON_UNIQUE  INDEX_QUALIFIER  INDEX_NAME       TYPE
VARCHAR          VARCHAR          VARCHAR          SMALLINT    VARCHAR          VARCHAR          SMALLINT
_______________________________________________________________________________

DB               DBA              RDF_QUAD         NULL        NULL             NULL             0
DB               DBA              RDF_QUAD         0           DB               RDF_QUAD         3
DB               DBA              RDF_QUAD         0           DB               RDF_QUAD         3
DB               DBA              RDF_QUAD         0           DB               RDF_QUAD         3
```

```
DB              DBA             RDF_QUAD        0       DB              RDF_QUAD        3
DB              DBA             RDF_QUAD        1       DB              RDF_QUAD_GS     3

DB              DBA             RDF_QUAD        1       DB              RDF_QUAD_SP     3

15 Rows. -- 24 msec.
SQL>
```

With only one index (`OGPS`) created by default, if the graph is always given, as with one or more `FROM` or `FROM NAMED` clauses, and there are no patterns where only graph and predicate are given, then the default indices should be sufficient. If predicate and graph are given but subject is not, then it is sometimes useful to add:

```
CREATE BITMAP INDEX RDF_QUAD_PGOS
  ON DB.DBA.RDF_QUAD (G, P, O, S)
  PARTITION (O VARCHAR (-1, 0hexffff));
```

Note: If the server version is pre-5.0.7, leave out the partitioning clause.

Making the `PGOS` index can help in some cases even if it is not readily apparent from the queries that one is needed. This is so, for example, if the predicate by itself is selective; i.e., there is a predicate that occurs in only a few triples.

There is one known application scenario that requires a small alteration to the default index scheme. If the application has a large number of small graphs, e.g. millions of graphs of tens or hundreds of triples each, and it commonly happens that large numbers of graphs contain exactly the same triple, for example the same triple is found in 100000 or one million graphs, then some operations will become inefficient with the default index scheme. In specific, dropping a graph may have to scan through large amounts of data in order to find the right quad to delete from the set of quads that differ only in the graph.

This will affect a graph replace and a graph drop or generally any deletion that falls on a quad of the described sort. If this is the situation in the application, then dropping the `RDF_QUAD_GS` distinct projection and replacing it with a covering index that starts with `G` is appropriate:

```
Drop index RDF_QUAD_GS;
Create column index RDF_QUAD_GPSO on RDF_QUAD (G, P, S, O) partition (S int (0hexffff00);
```

The partition clause only affects cluster settings and is ignored in the single server case. Partitioning on `S` is usually better than on `O` since the distribution of `S` is generally less skewed than that of `O` . That is, there usually are some very common `O` values (e.g. class "thing"). This will increase space consumption by maybe 25% compared to the default scheme.

16.17.4. Manage Public Web Service Endpoints

Public web service endpoints have proven to be sources of especially bad queries. While local application developers can obtain instructions from database administrators and use ISQL access to the database to tune execution plans, "external" clients do not know details of configuration and/or lack appropriate skills. The most common problem is that public endpoints usually get requests that do not mention the required graph, because the queries were initially written for use with triple stores. If the web service provides access to a single graph (or to a short list of graphs), then it is strongly recommended to configure it by adding a row into `DB.DBA.SYS_SPARQL_HOST` .

```
create table DB.DBA.SYS_SPARQL_HOST (
  SH_HOST       varchar not null primary key, -- host mask
  SH_GRAPH_URI varchar,                 -- default graph uri
  SH_USER_URI   varchar,                  -- reserved for any use in applications
  SH_BASE_URI varchar,                  -- for future use (not used currently) to set BASE in sparql quer
  SH_DEFINES long varchar,              -- additional defines for requests
  PRIMARY KEY (SH_HOST)
)
```

You can find detailed descriptions of the table columns here .

The idea is that if the client specifies the default graph in the request, or uses named graphs and group graph patterns, then he is probably smarter than average and will provide meaningful queries. If no graph names are specified, then the query will benefit from preset graph because this will give the compiler some more indexes to choose from -- indexes that begin with `G` .

Sometimes web service endpoints are used to access data of only one application, not all data in the system. In that case, one may wish to declare a separate storage that consists of only RDF Views made by that application and `define input:storage` in the appropriate row of `DB.DBA.SYS_SPARQL_HOST` .

16.17.5. Erroneous Cost Estimates and Explicit Join Order

The selectivity of triple patterns is determined at query compile time from sampling the data. It is possible that misleading data is produced. To see if the cardinality guesses are generally valid, look at the query plan with the `explain` () function.

Below is a sample from the LUBM qualification data set in the Virtuoso distribution. After running *make test* in *binsrc/test/lubm* , there is a loaded database with the data. Start a server in the same directory to see the data.

```
SQL> EXPLAIN
  ('SPARQL
  PREFIX  ub:  <http://www.lehigh.edu/~zhp2/2004/0401/univ-bench.owl#>
  SELECT *
  FROM <lubm>
  WHERE { ?x  rdf:type  ub:GraduateStudent }
  ');

REPORT
VARCHAR
_______________________________________________________________________________

{

Precode:
      0: $25 "callret" := Call __BOX_FLAGS_TWEAK (<constant (lubm)>, <constant (1)>)
      5: $26 "lubm" := Call DB.DBA.RDF_MAKE_IID_OF_QNAME_SAFE ($25 "callret")
      12: $27 "callret" := Call __BOX_FLAGS_TWEAK (<constant (http://www.w3.org/1999/02/22-rdf-syntax-ns#
      17: $28 "-ns#type" := Call DB.DBA.RDF_MAKE_IID_OF_QNAME_SAFE ($27 "callret")
      24: $29 "callret" := Call __BOX_FLAGS_TWEAK (<constant (http://www.lehigh.edu/~zhp2/2004/0401/univ-
      29: $30 "owl#GraduateStudent" := Call DB.DBA.RDF_MAKE_IID_OF_QNAME_SAFE ($29 "callret")
      36: BReturn 0
from DB.DBA.RDF_QUAD by RDF_QUAD_OGPS    1.9e+03 rows
Key RDF_QUAD_OGPS  ASC ($32 "s-3-1-t0.S")
<col=415 O = $30 "owl#GraduateStudent"> , <col=412 G = $26 "lubm"> , <col=414 P = $28 "-ns#type">
row specs: <col=415 O LIKE <constant (T)>>

Current of: <$34 "<DB.DBA.RDF_QUAD s-3-1-t0>" spec 5>

After code:
      0: $35 "x" := Call ID_TO_IRI ($32 "s-3-1-t0.S")
      5: BReturn 0
Select ($35 "x", <$34 "<DB.DBA.RDF_QUAD s-3-1-t0>" spec 5>)
}

22 Rows. -- 1 msec.
```

This finds the graduate student instances in the LUBM graph. First the query converts the IRI literals to IDs. Then, using a match of `OG` on `OGPS` , it finds the IRIs of the graduate students. Then, it converts the IRI ID to return to the string form.

The cardinality estimate of 1.9e+03 rows is on the `FROM` line.

Doing an `EXPLAIN()` on the queries will show the cardinality estimates. To drill down further, one can split the query into smaller chunks and see the estimates for these, up to doing it at the triple pattern level. To indicate a variable that is bound but whose value is not a literal known at compile time, one can use the parameter marker *??* .

```
SQL> EXPLAIN
  ('
      SPARQL
      DEFINE  sql:table-option "order"
      PREFIX  ub:  <http://www.lehigh.edu/~zhp2/2004/0401/univ-bench.owl#>
      SELECT *
```

```
        FROM <lubm>
        WHERE { ?x  rdf:type  ?? }
    ');
```

This will not know the type but will know that a type will be provided. So instead of guessing 1900 matches, this will guess a smaller number, which is obviously less precise. Thus literals are generally better.

In some cases, generally to work around an optimization error, one can specify an explicit *JOIN* order. This is done with the *sql:select-option "order"* clause in the SPARQL query prefix:

```
SQL> SELECT SPARQL_to_sql_text
  ('
      DEFINE sql:select-option "order"
      PREFIX  ub:  <http://www.lehigh.edu/~zhp2/2004/0401/univ-bench.owl#>
      SELECT *
      FROM <lubm>
      WHERE
        {
          ?x  rdf:type        ub:GraduateStudent                                    .
          ?x  ub:takesCourse  <http://www.Department0.University0.edu/GraduateCourse0>
        }
  ');
```

shows the SQL text with the order option at the end.

If an estimate is radically wrong then this should be reported as a bug.

If there is a `FROM` with a `KEY` on the next line and no column specs then this is a full table scan. The more columns are specified the less rows will be passed to the next operation in the chain. In the example above, there are three columns whose values are known before reading the table and these columns are leading columns of the index in use so column specs are:

```
<col=415 O = $30 "owl#GraduateStudent"> ,
<col=412 G = $26 "lubm"> ,
<col=414 P = $28 "-ns#type">
```

Note

Note: A `KEY` with only a row spec is a full table scan with the row spec applied as a filter. This is usually not good unless this is specifically intended.

If queries are compiled to make full table scans when this is not specifically intended, this should be reported as a bug. The `explain ()` output and the query text should be included in the report.

Consider:

```
SQL> EXPLAIN
  ('
      SPARQL
      DEFINE sql:select-option "order, loop"
      PREFIX  ub:  <http://www.lehigh.edu/~zhp2/2004/0401/univ-bench.owl#>
      SELECT *
      FROM <lubm>
      WHERE
        {
          ?x  ub:takesCourse  ?c                  .
          ?x  rdf:type        ub:GraduateStudent
        }
  ');
```

One will see in the output that the first table access is to retrieve all in the LUBM graph which take some course and then later to check if this is a graduate student. This is obviously not the preferred order but the *sql:select-option "order"* forces the optimizer to join from left to right.

It is very easy to end up with completely unworkable query plans in this manner but if the optimizer really is in error, then this is the only way of overriding its preferences. The effect of *sql:select-option* is pervasive, extending inside unions, optionals, subqueries etc. within the statement.

We note that if, in the above query, both the course taken by the student and the type of the student are given, the query compilation will be, at least for all non-cluster cases, an index intersection. This is not overridden by the `sql:select-option` clause since an index intersection is always a safe guess, regardless of the correctness of the cardinality guesses of the patterns involved.

Translate and Analyze modes for analyzing sparql queries

Virtuoso Release 6.4 ISQL offers 2 new modes for analyzing sparql queries:

1. Translate a sparql query into the correspondent sql:

```
SQL> SET SPARQL_TRANSLATE ON;
SQL> SELECT * FROM <graph> WHERE {?S a ?O};
SQL> SET SPARQL_TRANSLATE OFF;
```

2. Analyze a given SQL query:

```
SQL> SET EXPLAIN ON;
SQL> SELECT * FROM TABLE WHERE field = 'text';
SQL> SET EXPLAIN OFF;
```

   - `explain` () is much more difficult to use since you cannot just cut and past a query as all quotes need to be doubled inside the `explain (' ... ')` :

```
SQL> explain('select * from table where field = ''text''');
```

Here is simple example of how to combine the two options to get a full explain plan for a simple SPARQL query:

1. Assume the following query:

```
SELECT *
FROM <http://dbpedia.org>
WHERE
  {
    ?s a ?o
  }
LIMIT 10
```

2. Connect using the ISQL command line tool to your database and execute:

```
SQL> SET BLOBS ON;                        -- in case output is very large
SQL> SET SPARQL_TRANSLATE ON;
SQL> SELECT * FROM <http://dbpedia.org> WHERE {?s a ?o} LIMIT 10;

SPARQL_TO_SQL_TEXT
VARCHAR
_______________________________________________________________________________

SELECT TOP 10 __id2i ( "s_1_0-t0"."S" ) AS "s",
  __ro2sq ( "s_1_0-t0"."O" ) AS "o"
FROM DB.DBA.RDF_QUAD AS "s_1_0-t0"
WHERE "s_1_0-t0"."G" = __i2idn ( __bft( 'http://dbpedia.org' , 1))
  AND  "s_1_0-t0"."P" = __i2idn ( __bft( 'http://www.w3.org/1999/02/22-rdf-syntax-ns#type' , 1))
OPTION (QUIETCAST)

1 Rows. -- 1 msec.

SQL> SET SPARQL_TRANSLATE OFF;
```

3. Use mouse to select the above query output and paste it after the `SET EXPLAIN ON;` command. After pasting in the command, followed by the ENTER key:

```
SQL> SET EXPLAIN ON;
SQL> SELECT TOP 10 __id2i ( "s_1_0-t0"."S" ) AS "s", __ro2sq ( "s_1_0-t0"."O" ) AS "o"
 FROM DB.DBA.RDF_QUAD AS "s_1_0-t0"
 WHERE "s_1_0-t0"."G" = __i2idn ( __bft( 'http://dbpedia.org' , 1))
   AND  "s_1_0-t0"."P" = __i2idn ( __bft( 'http://www.w3.org/1999/02/22-rdf-syn tax-ns#type' , 1))
 OPTION (QUIETCAST)
;

REPORT
```

```
VARCHAR
_______________________________________________________________________________

{
from DB.DBA.RDF_QUAD by RDF_QUAD_POGS    4.5e+05 rows
Key RDF_QUAD_POGS  ASC ($22 "s_1_0-t0.S", $21 "s_1_0-t0.O")
 inlined <col=556 P =  #type >
row specs: <col=554 G =  #http://dbpedia.org >

After code:
      0: $25 "s" := Call __id2i ($22 "s_1_0-t0.S")
      5: $26 "o" := Call __ro2sq ($21 "s_1_0-t0.O")
      10: BReturn 0
Select (TOP  10 ) ($25 "s", $26 "o", <$24 "<DB.DBA.RDF_QUAD s_1_0-t0>" spec 5>)
}

13 Rows. -- 1 msec.

SQL> SET EXPLAIN OFF;
```

16.17.6. Using "swappiness" parameter (Linux only)

For Linux users only , there is a kernel tuning parameter called "`swappiness` " that controls how much the kernel favors swap over RAM.

When hosting large data sets, it is recommended that this parameter be changed from its default value of 60 to something closer to 10, to reduce the amount of swapping that takes place on the server. Useful tidbits regarding swappiness include:

- The swappiness setting is found in the file `/proc/sys/vm/swappiness` .
- The command `/sbin/sysctl vm.swappiness` can be used to view its setting.
- The command `/sbin/sysctl -w vm.swappiness=10` can be used to change its value.
- Adding `vm.swappiness = 10` to the file `/etc/sysctl.conf` will force the value to be set at machine boot time.

16.17.7. Get All Graphs

In order to get all graphs URIs, one might use the Virtuoso `DB.DBA.SPARQL_SELECT_KNOWN_GRAPHS()` built-in function.

16.17.8. Rename RDF Graph and RDF Graph Groups

A RDF Graph in the Virtuoso Quad Store can be renamed without copying each assertion from the old graph to the new graph using a SQL statement, this being what the Conductor "rename" option does, which is:

```
UPDATE DB.DBA.RDF_QUAD TABLE OPTION (index RDF_QUAD_GS)
   SET g = iri_to_id ('new')
 WHERE g = iri_to_id ('old', 0);
```

Note: this operation must be run in row-autocommit mode i.e. log_enable (3), and then restore back to the default logging mode of 1.

For Virtuoso Graph Groups two tables need to be updated:

```
UPDATE DB.DBA.RDF_GRAPH_GROUP_MEMBER
   SET RGGM_GROUP_IID = iri_to_id ('new')
 WHERE RGGM_GROUP_IID = iri_to_id (old)
```

and

```
UPDATE DB.DBA.RDF_GRAPH_GROUP
   SET RGG_IID = iri_to_id ('new') , RGG_IRI = 'new'
 WHERE RGG_IRI = 'old'
```

16.17.9. Dump and Reload Graphs

What?

How to export RDF model data from Virtuoso's Quad Store.

Why?

Every DBMS needs to offer a mechanism for bulk export and import of data.

Virtuoso supports dumping and reloading graph model data (e.g., RDF), as well as relational data (e.g., SQL) (discussed elsewhere).

How?

We have created stored procedures for the task. The dump procedures leverage SPARQL to facilitate selective data dump(s) from one or more Named Graphs, each denoted by an IRI.

Dump One Graph

The procedure dump_one_graph can be used to dump any single Named Graph.

Parameters

- IN

  srcgraph

  VARCHAR -- source graph
- IN

  out_file

  VARCHAR -- output file
- IN

  file_length_limit

  INTEGER -- maximum length of dump files

Procedure source

```
CREATE PROCEDURE dump_one_graph
  ( IN  srcgraph           VARCHAR
  , IN  out_file           VARCHAR
  , IN  file_length_limit  INTEGER  := 1000000000
  )
  {
    DECLARE  file_name     VARCHAR;
    DECLARE  env,  ses           ANY;
    DECLARE  ses_len
          ,  max_ses_len
          ,  file_len
          ,  file_idx      INTEGER;
   SET ISOLATION = 'uncommitted';
   max_ses_len  := 10000000;
   file_len     := 0;
   file_idx     := 1;
   file_name    := sprintf ('%s%06d.ttl', out_file, file_idx);
   string_to_file ( file_name || '.graph',
                    srcgraph,
                    -2
                  );
    string_to_file ( file_name,
                     sprintf ( '# Dump of graph <%s>, as of %s\n@base <> .\n',
                               srcgraph,
                               CAST (NOW() AS VARCHAR)
                             ),
```

```
                    -2
                  );
    env := vector (dict_new (16000), 0, '', '', '', 0, 0, 0, 0, 0);
    ses := string_output ();
    FOR (SELECT * FROM ( SPARQL DEFINE input:storage ""
                         SELECT ?s ?p ?o { GRAPH `iri(?:srcgraph)` { ?s ?p ?o } }
                       ) AS sub OPTION (LOOP)) DO
       {
         http_ttl_triple (env, "s", "p", "o", ses);
         ses_len := length (ses);
         IF (ses_len > max_ses_len)
           {
             file_len := file_len + ses_len;
             IF (file_len > file_length_limit)
               {
                 http (' .\n', ses);
                 string_to_file (file_name, ses, -1);
                 gz_compress_file (file_name, file_name||'.gz');
                 file_delete (file_name);
                 file_len := 0;
                 file_idx := file_idx + 1;
                 file_name := sprintf ('%s%06d.ttl', out_file, file_idx);
                 string_to_file ( file_name,
                                  sprintf ( '# Dump of graph <%s>, as of %s (part %d)\n@base <> .\n',
                                            srcgraph,
                                            CAST (NOW() AS VARCHAR),
                                            file_idx),
                                  -2
                                );
                  env := VECTOR (dict_new (16000), 0, '', '', '', 0, 0, 0, 0, 0);
               }
             ELSE
               string_to_file (file_name, ses, -1);
             ses := string_output ();
           }
       }
     IF (LENGTH (ses))
       {
         http (' .\n', ses);
         string_to_file (file_name, ses, -1);
         gz_compress_file (file_name, file_name||'.gz');
         file_delete (file_name);
       }
   }
;
```

To load the procedure into Virtuoso, it can simply be copied and pasted into the Virtuoso `isql` command line tool or Interactive SQL UI of the Conductor and executed.

Example

Call the `dump_one_graph` procedure with appropriate arguments:

```
$ pwd
/Applications/OpenLink Virtuoso/Virtuoso 6.1/database

$ grep DirsAllowed virtuoso.ini
DirsAllowed              = ., ../vad,

$ /opt/virtuoso/bin/isql 1111
Connected to OpenLink Virtuoso
Driver: 06.01.3127 OpenLink Virtuoso ODBC Driver
OpenLink Interactive SQL (Virtuoso), version 0.9849b.
Type HELP; for help and EXIT; to exit.
SQL> dump_one_graph ('http://daas.openlinksw.com/data#', './data_', 1000000000);
Done. -- 1438 msec.

$
As a result, a dump of the graph <http://daas.openlinksw.com/data#> will be found in the files data_XX
```

```
$ ls
data_000001.ttl
data_000002.ttl
....
data_000001.ttl.graph
```

Dump Multiple Graphs

The *dump_graphs* procedure can be used to dump all the graphs in a Virtuoso server to a set of turtle (.ttl) data files in the specified dump directory.

Parameters

The procedure dump_graphs has the following parameters:

- IN

  dir

  VARCHAR -- dump directory
- IN

  file_length_limit

  INTEGER -- maximum length of dump files

Note: The dump directory must be included in the DirsAllowed parameter of the Virtuoso configuration file (virtuoso.ini), or the Virtuoso server will not be able to create or access the data files.

Source

The procedure *dump_graphs* has the following source:

```
CREATE PROCEDURE dump_graphs
  ( IN  dir               VARCHAR  :=  'dumps'   ,
    IN  file_length_limit INTEGER  :=  1000000000
  )
  {
    DECLARE inx INT;
    inx := 1;
    SET ISOLATION = 'uncommitted';
    FOR ( SELECT *
            FROM ( SPARQL DEFINE input:storage ""
                   SELECT DISTINCT ?g { GRAPH ?g { ?s ?p ?o } .
                                        FILTER ( ?g != virtrdf: )
                                      }
                 ) AS sub OPTION ( LOOP )) DO
      {
        dump_one_graph ( "g",
                         sprintf ('%s/graph%06d_', dir, inx),
                         file_length_limit
                       );
        inx := inx + 1;
      }
  }
;
```

Example

1. Call the

   dump_graphs

   procedure:

   ```
   $ pwd
   ```

```
/Applications/OpenLink Virtuoso/Virtuoso 6.1/database

$ grep DirsAllowed virtuoso.ini
DirsAllowed              = ., ../vad, ./dumps

$ /opt/virtuoso/bin/isql 1111
Connected to OpenLink Virtuoso
Driver: 06.01.3127 OpenLink Virtuoso ODBC Driver
OpenLink Interactive SQL (Virtuoso), version 0.9849b.
Type HELP; for help and EXIT; to exit.
SQL> dump_graphs();

Done. -- 998 msec.
SQL> quit;
```

2. As a result, a dump of the graph will be found in the files dumps/data_XX (located in your Virtuoso db folder):

```
<verbatim>
$ ls dumps
graph000001_000001.ttl          graph000005_000001.ttl
graph000001_000001.ttl.graph    graph000005_000001.ttl.graph
graph000002_000001.ttl          graph000006_000001.ttl
graph000002_000001.ttl.graph    graph000006_000001.ttl.graph
graph000003_000001.ttl          graph000007_000001.ttl
graph000003_000001.ttl.graph    graph000007_000001.ttl.graph
graph000004_000001.ttl          graph000008_000001.ttl
graph000004_000001.ttl.graph    graph000008_000001.ttl.graph
```

Load Graphs

The stored procedure *load_graphs* procedure performs a bulk load from a file.

Parameters

The procedure load_graphs has the following parameters:

- IN

  dir

  VARCHAR -- dump directory

Note: The dump directory must be included in the DirsAllowed parameter of the Virtuoso configuration file (virtuoso.ini), or the Virtuoso server will not be able to create or access the data files.

Source

The procedure *load_graphs* has the following source:

```
CREATE PROCEDURE load_graphs
  ( IN  dir  VARCHAR := 'dumps/' )
{
  DECLARE arr ANY;
  DECLARE g VARCHAR;

  arr := sys_dirlist (dir, 1);
  log_enable (2, 1);
  FOREACH (VARCHAR f IN arr) DO
    {
      IF (f LIKE '*.ttl')
        {
          DECLARE CONTINUE HANDLER FOR SQLSTATE '*'
            {
              log_message (sprintf ('Error in %s', f));
            };
          g := file_to_string (dir || '/' || f || '.graph');
          DB.DBA.TTLP_MT (file_open (dir || '/' || f), g, g, 255);
        }
    }
  EXEC ('CHECKPOINT');
}
```

```
;
```

Example

```
$ /opt/virtuoso/bin/isql 1112
Connected to OpenLink Virtuoso
Driver: 06.01.3127 OpenLink Virtuoso ODBC Driver
OpenLink Interactive SQL (Virtuoso), version 0.9849b.
Type HELP; for help and EXIT; to exit.
SQL> load_graphs();

Done. -- 2392 msec.
SQL>
```

16.17.10. RDF dumps from Virtuoso Quad store hosted data into NQuad dumps

What?

How to export RDF model data from Virtuoso's Quad Store in NQuad format.

Why?

When exporting RDF model data from Virtuoso's Quad Store, having the ability to retain and reflect Named Graph IRI based data partitioning is provide significant value to a variety of application profiles.

How?

We have created stored procedures for the task. The dump procedure *dump_nquads* leverage SPARQL to facilitate data dump(s) for all graphs excluding the predefined "virtrdf:" one.

Dump NQuads

Parameters

The procedure *dump_nquads* has the following parameters:

- IN

  dir

  VARCHAR -- folder where the dumps will be stored
- IN

  outstart_fromfile

  INTEGER -- output start from number n
- IN

  file_length_limit

  INTEGER -- maximum length of dump files
- IN

  comp

  INTEGER -- when set to 0, then no gzip will be done. By default is set to 1.

Source

The procedure *dump_nquads* has the following source:

```
create procedure dump_nquads (in dir varchar := 'dumps', in start_from int := 1, in file_length_limit int
{
  declare inx, ses_len int;
```

```
  declare file_name varchar;
  declare env, ses any;

  inx := start_from;
  set isolation = 'uncommitted';
  env := vector (0,0,0);
  ses := string_output (10000000);
  for (select * from (sparql define input:storage "" select ?s ?p ?o ?g { graph ?g { ?s ?p ?o } . filter
    {
      declare exit handler for sqlstate '22023'
        {
          goto next;
        };
      http_nquad (env, "s", "p", "o", "g", ses);
      ses_len := length (ses);
      if (ses_len >= file_length_limit)
        {
          file_name := sprintf ('%s/output%06d.nq', dir, inx);
          string_to_file (file_name, ses, -2);
          if (comp)
            {
              gz_compress_file (file_name, file_name||'.gz');
              file_delete (file_name);
            }
          inx := inx + 1;
          env := vector (0,0,0);
          ses := string_output (10000000);
        }
      next:;
    }
  if (length (ses))
    {
      file_name := sprintf ('%s/output%06d.nq', dir, inx);
      string_to_file (file_name, ses, -2);
      if (comp)
        {
          gz_compress_file (file_name, file_name||'.gz');
          file_delete (file_name);
        }
      inx := inx + 1;
      env := vector (0,0,0);
    }
}
;
```

Example

This example demonstrates calling the *dump_nquads* procedure in order to dump all graphs in a compressed nquad dumps, each uncompressed with length 10Mb (./dumps/output000001.nq.gz) :

```
SQL> dump_nquads ('dumps', 1, 10000000, 1);
```

16.17.11. Dump Linked Data View Graph to n3

The RDF_QM_TREE_DUMP procedure and its associated procedures below are used for dumping one or more RDFView Graphs in a Virtuoso server to a set of turtle ttl dataset files in the specified dump directory. The dump generation is made as fast as possible by grouping mappings by underlying tables so many properties from neighbor database columns can be extracted in one table scan. The size of the generated files is limited to 5MB. The dump process creates internal stored procedures; their texts are saved in file .dump_procedures.sql in the directory of dump files for debugging purposes.

Note that the dump directory must be included in the `DirsAllowed` parameter of the Virtuoso configuration file (e.g., `virtuoso.ini`), or the server will not be allowed to create nor access the dataset file(s).

The Virtuoso RDF bulk loader scripts can then be used to load the dumped datasets for the RDFView graphs directly into a Virtuoso RDF QUAD store.

Parameters

- in *dest_dir*

  VARCHAR - dump directory
- in *graph_iri*

  VARCHAR - IRI of the graph to be dumped; triples from other graphs will be excluded. If NULL, then there's no restriction by graph.
- in *storage*

  VARCHAR - IRI of the quad map storage to use. NULL means use default storage.
- in *root*

  VARCHAR - IRI of the quad map to use, e.g., an IRI of an Linked Data View (or its part). NULL means use all Linked Data Views of the storage (and the default mapping as well).

Procedure Code

```
CREATE PROCEDURE DB.DBA.RDF_QM_TREE_DUMP
  ( in  dest_dir  VARCHAR,
    in  graph_iri VARCHAR := NULL,
    in  storage   VARCHAR := NULL,
    in  root      VARCHAR := NULL
  )

16.17.12. Loading RDF

There are many functions for loading RDF text, in RDF/XML and Turtle.

For loading RDF/XML, the best way is to split the data to be loaded into multiple streams and load these in parallel using `RDF_LOAD_RDFXML ()` . To avoid running out of rollback space for large files and in order to have multiple concurrent loads not interfere with each other, the row autocommit mode should be enabled.

For example,

```
log_enable (2);
-- switch row-by-row autocommit on and logging off for this session
DB.DBA.RDF_LOAD_RDFXML (file_to_string_output ('file.xml'), 'base_uri', 'target_graph');
-- more files here ...
checkpoint;
```

Loading a file with text like the above with isql will load the data. Since the transaction logging is off, make a manual checkpoint at the end to ensure that data is persisted upon server restart since there is no roll forward log.

If large amounts of data are to be loaded, run multiple such streams in parallel. One may have for example 6 streams for 4 cores. This means that if up to two threads wait for disk, there is still work for all cores.

Having substantially more threads than processors or disks is not particularly useful.

There exist multithreaded load functions which will load one file on multiple threads: the DB.DBA.TTLP_MT() function and the DB.DBA.RDF_LOAD_RDFXML_MT() function . Experience shows that loading multiple files on one thread per file is better.

For loading Turtle, some platforms may have a non-reentrant Turtle parser. This means that only one load may run at a time. One can try this by calling `ttlp ()` from two sessions at the same time. If these do not execute concurrently, then the best way may be to try `ttlp_mt` and see if this runs faster than a single threaded ttlp call.

RDF Bulk Load Utility

The RDF loader utility facilitates parallel bulk loading of multiple RDF files. The utility maintains a database table containing a list of files to load and the status of each file, whether not loaded, loaded or loaded with error. The table also records load start and end times.

One must have a dba group login for using this and the virtuoso.ini file access control list must be set up so that the Virtuoso server can open the files to load.

Files are added to the load list with the function `ld_dir` :

```
ld_dir (in dir_path varchar, in file_mask varchar, in target_graph varchar);
```

The file mask is a SQL like pattern to match against the files in the directory. For example:

```
ld_dir ('/data8/2848260', '%.gz', 'http://bsbm.org');
```

would load the RDF in all files ending in .gz from the directory given as first parameter. The RDF would be loaded in the http://bsbm.org graph.

If NULL is given for the graph, each file may go to a different graph specified in a separate file with the name of the RDF source file plus the extension .graph.

A .graph file contains the target graph URI without any other content or whitespace.

The layout of the load_list table is as follows:

```
create table DB.DBA.LOAD_LIST (
  ll_file varchar,
  ll_graph varchar,
  ll_state int default 0, -- 0 not started, 1 going, 2 done
  ll_started datetime,
  ll_done datetime,
  ll_host int,
  ll_work_time integer,
  ll_error varchar,
  primary key (ll_file))
alter index LOAD_LIST on DB.DBA.LOAD_LIST partition (ll_file varchar)
create index LL_STATE on DB.DBA.LOAD_LIST (ll_state, ll_file, ll_graph) partition (ll_state int)
;
```

This table may be checked at any time during bulk load for the progress of the load. ll_state is 1 for files being loaded and 2 for files whose loading has finished. ll_error is NULL if the load finished without error, else it is the error message.

In order to load data from the files in load_list, run as dba:

```
DB.DBA.rdf_loader_run ();
```

One may run several of these commands on parallel sessions for better throughput.

On a cluster one can do:

```
cl_exec ('rdf_ld_srv ()');
```

This will start one rdf_loader_run() on each node of the cluster. Note that in such a setting all the server processes must see the same files at the same path.

On an isql session one may execute rdf_loader_run () & several times, forking a new isql for each such command, similarly to what a Unix shell does.

Because this load is non-transactional and non-logged, one must do an explicit checkpoint after the load to guarantee a persistent state.

On a single server do:

```
checkpoint;
```

On a cluster do:

```
cl_exec ('checkpoint');
```

The server(s) are online and can process queries and transactions while a bulk load is in progress. Periodic checkpoints may occur during the load but the state is guaranteed to be consistent only after running a checkpoint after all the bulk load threads have finished.

A bulk load should not be forcibly stopped. To make a controlled stop, run:

```
rdf_load_stop ();
```

This will cause the files being loaded at the time to finish load but no new loads will start until explicitly started with rdf_loader_run() .

Specially note that on a cluster the database will be inconsistent if one server process does a checkpoint and another does not. Thus guaranteeing a checkpoint on all is necessary. This is easily done with an isql script with the following content:

```
ld_dir ('/data8/2848260', '%.gz', 'http://bsbm.org');

-- Record CPU time
select getrusage ()[0] + getrusage ()[1];

rdf_loader_run () &
rdf_loader_run () &
rdf_loader_run () &
rdf_loader_run () &
rdf_loader_run () &
rdf_loader_run () &
rdf_loader_run () &
rdf_loader_run () &

wait_for_children;
checkpoint;

-- Record CPU time
select getrusage ()[0] + getrusage ()[1];
```

For a cluster, the equivalent is:

```
ld_dir ('/data8/2848260', '%.gz', 'http://bsbm.org');

cl_exec ('DB.DBA.RDF_LD_SRV (2)');

cl_exec ('checkpoint');
```

rdf_loader_run() recognizes several file types, including .ttl, .nt, .xml, .rdf, .owl, .nq, .n4, and others. Internally the function uses `DB.DBA.ttlp()` or `DB.DBA.rdf_load_rdfxml` , as appropriate.

See the next section for detailed description of the rdf_loader_run() function.

Loading LOD RDF data

To load the rdf data to LOD instance, perform the following steps:

- Configure & start cluster
- Execute the file:

```
--
--  $Id$
--
--  Alternate RDF index scheme for cases where G unspecified
--
--  This file is part of the OpenLink Software Virtuoso Open-Source (VOS)
--  project.
--
--  Copyright (C) 1998-2024 OpenLink Software

--
--

drop index RDF_QUAD_OGPS;
checkpoint;
```

```
create table R2 (G iri_id_8, S iri_id_8, P iri_id_8, O any, primary key (S, P, O, G))
alter index R2 on R2 partition (S int (0hexffff00));

log_enable (2);
insert into R2 (G, S, P, O) SELECT G, S, P, O from rdf_quad;

drop table RDF_QUAD;
alter table r2 rename RDF_QUAD;
checkpoint;
create bitmap index RDF_QUAD_OPGS on RDF_QUAD (O, P, G, S) partition (O varchar (-1, 0hexffff));
create bitmap index RDF_QUAD_POGS on RDF_QUAD (P, O, G, S) partition (O varchar (-1, 0hexffff));
create bitmap index RDF_QUAD_GPOS on RDF_QUAD (G, P, O, S) partition (O varchar (-1, 0hexffff));

checkpoint;
```

- Execute:

```
SQL>cl_exec ('checkpoint);
```

- Execute ld_dir ('directory' , 'mask' , 'graph'), for ex:

```
SQL>ld_dir ('/dbs/data', '*.gz', 'http://dbpedia.org');
```

- Execute on every node with separate client:

```
SQL>rdf_loader_run();
```

Loading UniProt RDF data

To load the uniprot data, create a function for example such as:

```
create function DB.DBA.UNIPROT_LOAD (in log_mode integer := 1)
{
  DB.DBA.RDF_LOAD_RDFXML_MT (file_to_string_output('filename1'),'http://base_uri_1', 'destination_graph_1
  DB.DBA.RDF_LOAD_RDFXML_MT (file_to_string_output('filename2'),'http://base_uri_2', 'destination_graph_2
  ...
  DB.DBA.RDF_LOAD_RDFXML_MT (file_to_string_output('filename9'),'http://base_uri_9', 'destination_graph_9
}
```

If you are starting from blank database and you can drop it and re-create in case of error signaled, use it this way:

```
checkpoint;
checkpoint_interval(6000);
DB.DBA.UNIPROT_LOAD (0),
checkpoint;
checkpoint_interval(60);
```

If the database contains important data already and there's no way to stop it and backup before the load then use:

```
checkpoint;
checkpoint_interval(6000);
DB.DBA.UNIPROT_LOAD (),
checkpoint;
checkpoint_interval(60);
```

Note that the 'number of threads' parameter of DB.DBA.RDF_LOAD_RDFXML() mentions threads used to process data from file, an extra thread will read the text and parse it, so for 4 CPU cores there's no need in parameter value greater than 3. Three processing threads per one parsing tread is usually good ratio because parsing is usually three times faster than the rest of loading so CPU loading is well balanced. If for example you are using 2 x Quad Xeon, then you can choose between 8 single-threaded parsers or 2 parsers with 3 processing threads each. With 4 cores you may simply load file after file with 3 processing threads. The most important performance tuning is to set the [Parameters] section of virtuoso configuration file:

```
NumberOfBuffers = 1000000
MaxDirtyBuffers = 800000
MaxCheckpointRemap = 1000000
DefaultIsolation = 2
```

Note: these numbers are reasonable for 16 GB RAM Linux box. Usually when there are no such massive operations as loading huge database, you can set up the values as:

```
NumberOfBuffers = 1500000
```

```
MaxDirtyBuffers = 1200000
MaxCheckpointRemap = 1500000
DefaultIsolation = 2
```

See Also:

Virtuoso Configuration Options

Tip:

Thus after loading all data you may wish to shutdown, tweak and start server again. If you have ext2fs or ext3fs filesystem, then it's better to have enough free space on disk not to make it more than 80% full. When it's almost full it may allocate database file badly, resulting in measurable loss of disk access speed. That is not Virtuoso-specific fact, but a common hint for all database-like applications with random access to big files.

Here is an example of using awk file for splitting big file smaller ones:

```
BEGIN {
        file_part=1000
        e_line = "</rdf:RDF>"
        cur=0
        cur_o=0
        file=0
        part=file_part
      }
        {
            res_file_i="res/"FILENAME
            line=$0
            s=$1
            res_file=res_file_i"_"file".rdf"

            if (index (s, "</rdf:Description>") == 1)
            {
                cur=cur+1
                part=part-1
            }

            if (part > 0)
            {
                print line >> res_file
            }

            if (part == 0)
            {
#               print "==================== " cur
                print line >> res_file
                print e_line >> res_file
                close (res_file)
                file=file+1
                part=file_part
                res_file=res_file_i"_"file".rdf"
                system ("cp beg.txt " res_file)
            }
        }
END { }
```

Loading DBPedia RDF data

You can use the following script as an example for loading DBPedia RDF data in Virtuoso:

```
#!/bin/sh

PORT=$1
USER=$2
PASS=$3
file=$4
g=$5
LOGF=`basename $0`.log

if [ -z "$PORT" -o -z "$USER" -o -z "$PASS" -o -z "$file" -o -z "$g" ]
then
  echo "Usage: `basename $0` [DSN] [user] [password] [ttl-file] [graph-iri]"
```

```
  exit
fi

if [ ! -f "$file" -a ! -d "$file" ]
then
    echo "$file does not exists"
    exit 1
fi

mkdir READY 2>/dev/null
rm -f $LOGF $LOGF.*

echo "Starting..."
echo "Logging into: $LOGF"

DOSQL ()
{
    isql $PORT $USER $PASS verbose=on banner=off prompt=off echo=ON errors=stdout exec="$1" > $LOGF
}

LOAD_FILE ()
{
    f=$1
    g=$2
    echo "Loading $f (`cat $f | wc -l` lines) `date \"+%H:%M:%S\"`" | tee -a $LOG

    DOSQL "ttlp_mt (file_to_string_output ('$f'), '', '$g', 17); checkpoint;" > $LOGF

    if [ $? != 0 ]
    then
        echo "An error occurred, please check $LOGF"
        exit 1
    fi

    line_no=`grep Error $LOGF | awk '{ match ($0, /line [0-9]+/, x) ; match (x[0], /[0-9]+/, y); print y[
    newf=$f.part
    inx=1
    while [ ! -z "$line_no" ]
    do
        cat $f |  awk "BEGIN { i = 1 } { if (i==$line_no) { print \$0; exit; } i = i + 1 }"  >> bad.nt
        line_no=`expr $line_no + 1`
        echo "Retrying from line $line_no"
        echo "@prefix rdfs: <http://www.w3.org/2000/01/rdf-schema#> ." > tmp.nt
        cat $f |  awk "BEGIN { i = 1 } { if (i>=$line_no) print \$0; i = i + 1 }"  >> tmp.nt
        mv tmp.nt $newf
        f=$newf
        mv $LOGF $LOGF.$inx
        DOSQL "ttlp_mt (file_to_string_output ('$f'), '', '$g', 17); checkpoint;" > $LOGF

        if [ $? != 0 ]
        then
            echo "An error occurred, please check $LOGF"
            exit 1
        fi
        line_no=`grep Error $LOGF | awk '{ match ($0, /line [0-9]+/, x) ; match (x[0], /[0-9]+/, y); prin
        inx=`expr $inx + 1`
    done
    rm -f $newf 2>/dev/null
    echo "Loaded.  "
}

echo "========================================"
echo "Loading started."
echo "========================================"

if [ -f "$file" ]
then
    LOAD_FILE $file $g
    mv $file READY 2>> /dev/null
elif [ -d "$file" ]
then
    for ff in `find $file -name '*.nt'`
    do
```

```
        LOAD_FILE $ff $g
        mv $ff READY 2>> /dev/null
    done
else
   echo "The input is not file or directory"
fi
echo "======================================="
echo "Final checkpoint."
DOSQL "checkpoint;" > temp.res
echo "======================================="
echo "Check bad.nt file for skipped triples."
echo "======================================="

exit 0
```

Loading Bio2RDF data

The shell script below was used to import files in n3 notation into OpenLink Virtuoso RDF storage.

When an syntax error it will cut content from next line and will retry. This was used on ubuntu linux to import bio2rdf and freebase dumps.

Note it uses gawk, so it must be available on system where is tried. Also for recovery additional disk space is needed at max the size of original file.

```
#!/bin/bash

PASS=$1
f=$2
g=$3

# Usage
if [ -z "$PASS" -o -z "$f" -o -z "$g" ]
then
  echo "Usage: $0 [password] [ttl-file] [graph-iri]"
  exit
fi

if [ ! -f "$f" ]
then
    echo "$f does not exists"
    exit
fi

# Your port here
PORT=1111  #`inifile -f dbpedia.ini -s Parameters -k ServerPort`
if test -z "$PORT"
then
    echo "Cannot find INI and inifile command"
    exit
fi

# Initial run
isql $PORT dba $PASS verbose=on banner=off prompt=off echo=ON errors=stdout exec="ttlp_mt (file_to_string

# If disconnect etc.
if [ $? != 0 ]
then
    echo "An error occurred, please check $0.log"
    exit
fi

# Check for error
line_no=`grep Error $0.log | awk '{ match ($0, /line [0-9]+/, x) ; match (x[0], /[0-9]+/, y); print y[0]
newf=$f.part
inx=1

# Error recovery
while [ ! -z "$line_no" ]
do
```

```
    cat $f |  awk "BEGIN { i = 0 } { if (i==$line_no) { print \$0; exit; } i = i + 1 }"  >> bad.nt
    line_no=`expr $line_no + 1`
    echo "Retrying from line $line_no"
    cat $f |  awk "BEGIN { i = 0 } { if (i>=$line_no) print \$0; i = i + 1 }"  > tmp.nt
    mv tmp.nt $newf
    f=$newf
    mv $0.log $0.log.$inx
    # Run the recovered part
    isql $PORT dba $PASS verbose=on banner=off prompt=off echo=ON errors=stdout exec="ttlp_mt (file_to_st

    if [ $? != 0 ]
    then
        echo "An error occurred, please check $0.log"
        exit
    fi
   line_no=`grep Error $0.log | awk '{ match ($0, /line [0-9]+/, x) ; match (x[0], /[0-9]+/, y); print y[
   inx=`expr $inx + 1`
done
```

16.17.13. Using SPARUL

Since SPARUL updates are generally not meant to be transactional, it is best to run these in `log_enable (2)` mode, which commits every operation as it is done. This prevents one from running out of rollback space. Also for bulk updates, transaction logging can be turned off. If so, one should do a manual checkpoint after the operation to ensure persistence across server restart since there is no roll forward log.

To have a roll forward log and row by row autocommit, one may use `log_enable (3)` . This will write constantly into the log which takes extra time. Having no logging and doing a checkpoint when the whole work is finished is faster.

Many SPARUL operations can be run in parallel in this way. If they are independent with respect to their input and output, they can run in parallel and row by row autocommit will ensure they do not end up waiting for each others' locks.

16.17.14. DBpedia Benchmark

We ran the DBpedia benchmark queries again with different configurations of Virtuoso. Comparing numbers given by different parties is a constant problem. In the case reported here, we loaded the full DBpedia 3, all languages, with about 198M triples, onto Virtuoso v5 and Virtuoso Cluster v6, all on the same 4 core 2GHz Xeon with 8G RAM. All databases were striped on 6 disks. The Cluster configuration was with 4 processes in the same box. We ran the queries in two variants:

- With graph specified in the SPARQL FROM clause, using the default indices.
- With no graph specified anywhere, using an alternate indexing scheme.

The times below are for the sequence of 5 queries. As there is a query in the set that specifies no condition on S or O and only P, thus cannot be done with the default indices With Virtuoso v5. With Virtuoso Cluster v6 it can, because v6 is more space efficient. So we added the index:

```
create bitmap index rdf_quad_pogs on rdf_quad (p, o, g, s);
```

Table 16.20.

	Virtuoso v5 with gspo, ogps, pogs	Virtuoso Cluster v6 with gspo, ogps	Virtuoso Cluster v6 with gspo, ogps, pogs
cold	210 s	136 s	33.4 s
warm	0.600 s	4.01 s	0.628 s

Now let us do it without a graph being specified. Note that alter index is valid for v6 or higher. For all platforms, we drop any existing indices, and:

```
create table r2 (g iri_id_8, s, iri_id_8, p iri_id_8, o any, primary key (s, p, o, g))
alter index R2 on R2 partition (s int (0hexffff00));

log_enable (2);
insert into r2 (g, s, p, o) SELECT g, s, p, o from rdf_quad;
```

```
drop table rdf_quad;
alter table r2 rename RDF_QUAD;
create bitmap index rdf_quad_opgs on rdf_quad (o, p, g, s) partition (o varchar (-1, 0hexffff));
create bitmap index rdf_quad_pogs on rdf_quad (p, o, g, s) partition (o varchar (-1, 0hexffff));
create bitmap index rdf_quad_gpos on rdf_quad (g, p, o, s) partition (o varchar (-1, 0hexffff));
```

The code is identical for v5 and v6, except that with v5 we use iri_id (32 bit) for the type, not iri_id_8 (64 bit). We note that we run out of IDs with v5 around a few billion triples, so with v6 we have double the ID length and still manage to be vastly more space efficient.

With the above 4 indices, we can query the data pretty much in any combination without hitting a full scan of any index. We note that all indices that do not begin with s end with s as a bitmap. This takes about 60% of the space of a non-bitmap index for data such as DBpedia.

If you intend to do completely arbitrary RDF queries in Virtuoso, then chances are you are best off with the above index scheme.

Table 16.21.

	Virtuoso v5 with gspo, ogps, pogs	Virtuoso Cluster v6 with gspo, ogps, pogs
warm	0.595 s	0.617 s

The cold times were about the same as above, so not reproduced.

It is in the SPARQL spirit to specify a graph and for pretty much any application, there are entirely sensible ways of keeping the data in graphs and specifying which ones are concerned by queries. This is why Virtuoso is set up for this by default.

On the other hand, for the open web scenario, dealing with an unknown large number of graphs, enumerating graphs is not possible and questions like which graph of which source asserts x become relevant. We have two distinct use cases which warrant different setups of the database, simple as that.

The latter use case is not really within the SPARQL spec, so implementations may or may not support this.

Once the indices are right, there is no difference between specifying a graph and not specifying a graph with the queries considered. With more complex queries, specifying a graph or set of graphs does allow some optimizations that cannot be done with no graph specified. For example, bitmap intersections are possible only when all leading key parts are given.

The best warm cache time is with v5; the five queries run under 600 ms after the first go. This is noted to show that all-in-memory with a single thread of execution is hard to beat.

Cluster v6 performs the same queries in 623 ms. What is gained in parallelism is lost in latency if all operations complete in microseconds. On the other hand, Cluster v6 leaves v5 in the dust in any situation that has less than 100% hit rate. This is due to actual benefit from parallelism if operations take longer than a few microseconds, such as in the case of disk reads. Cluster v6 has substantially better data layout on disk, as well as fewer pages to load for the same content.

This makes it possible to run the queries without the pogs index on Cluster v6 even when v5 takes prohibitively long.

The purpose is to have a lot of RAM and space-efficient data representation.

For reference, the query texts specifying the graph are below. To run without specifying the graph, just drop the FROM <http://dbpedia.org> from each query. The returned row counts are indicated below each query's text.

```
SQL>SPARQL
SELECT ?p ?o
FROM <http://dbpedia.org>
WHERE
  {
    <http://dbpedia.org/resource/Metropolitan_Museum_of_Art> ?p ?o .
  };

p                                                                                o
VARCHAR                                                                          VARCHAR

16.17.15. RDF Store Benchmarks

Introduction

In a particular RDF Store Benchmarks there is difference if the queries are executed with specified graph or with specified multiple graphs. As Virtuoso is quad store, not triple store with many tables, it runs queries inefficiently if graphs are specified and there are no additional indexes except pre-set GSPO and OGPS. Proper use of the FROM clause or adding indexes with graph column will contribute for better results.

Using bitmap indexes

If is known in advance for the current RDF Store Benchmarks that some users will not indicate specific graphs then should be done:

- either create indexes with graph in last position
- or load everything into single graph and specify it somewhere in querying application.

Both methods do not require any changes in query texts

- For users using Virtuoso 5 is strongly recommended is the usage of additional bitmap indexes:

```
SQL> create bitmap index RDF_QUAD_POGS on DB.DBA.RDF_QUAD (P,O,G,S);
SQL> create bitmap index RDF_QUAD_PSOG on DB.DBA.RDF_QUAD (P,S,O,G);
```

- For users using Virtuoso 6 or higher, see the new layout here .

You can create other indexes as well. Bitmap indexes are preferable, but if O is the last column, then the index can not be bitmap, so it could be, for e.g.:

```
create index RDF_QUAD_PSGO on DB.DBA.RDF_QUAD (P, S, G, O);
```

but cannot be:

```
create bitmap index RDF_QUAD_PSGO on DB.DBA.RDF_QUAD (P, S, G, O);
```

16.17.16. Fast Approximate RDF Graph Diff and Patch

Two algorithms described below resemble "unified diff" and "patch by unified diff" but they work on RDF graphs, not on plain texts.

They work reasonably for graphs composed from CBDs (concise bounded descriptions) of some subjects, if these subjects are either "named" IRIs or can be identified by values of their inverse functional properties.

Many sorts of commonly used graphs match these restrictions, including all graphs without blank nodes, most of FOAF files, graphs that can be "pretty-printed" in JSON, most of dumps of relational databases etc.

The basic idea is as simple as zipper:

- Place one graph at the left and one to the right,
- Find a retainer box at the right and a matching pin at the left,
- Join them
- Pull the slider as long as possible.
- Repeat this while there are pins and boxes that can be matched and sliders that can be moved.

An IRI in left graph `(say, G1)` matches to same IRI in right graph `(G2)` as pin to box. The same is true for literals too.

Functional and inverse functional properties are teeth that form chains, algorithm "moves sliders" along these chains, incrementally connecting more and more nodes.

If there is a match of this sort `(O1 in G1 matches O2 in G2)` and the matched nodes are values of same inverse functional property `P` (there are `{ S1 P O1 }` in `G1` and `{ S2 P O2 }` in `G2`) then we guess that `S1` matches `S2` .

If `S1` in `G1` matches `S2` in `G2` and the matched nodes are subjects of same functional property `P` (there are `{ S1 P N1 }` in `G1` and `{ S2 P N2 }` in `G2`) then we guess that `N1` matches `N2` , now it's possible to try same interaction on triples where `N1` and `N2` are in subject position, that's how slides move. A typical example of a long zipper is closed list with matched heads.

Make a Diff And Use It

- Using DB.DBA.RDF_GRAPH_DIFF
- Using DB.DBA.RDF_SUO_DIFF_TTL
- Using DB.DBA.RDF_SUO_APPLY_PATCH

Collect Functional And Inverse Functional Properties

Lists of functional properties can be retrieved from an ontology graph by query like:

```
SPARQL define output:valmode "LONG"
SELECT (<LONG::sql:VECTOR_AGG(?s))
FROM <my-ontology-graph>
WHERE
```

```
  {
    ?s a owl:functionalProperty
  }
```

Inverse functional properties could be retrieved by a similar query, but unfortunately the ontology may mention so called NULL values that can be property values for many subjects. Current implementation of diff and patch does not recognize NULL values so they can cause patch with "false alarm" errors. The workaround is to retrieve only properties that have no NULL values declared:

```
SPARQL define output:valmode "LONG"
SELECT (<LONG::sql:VECTOR_AGG(?s))
FROM <my-ontology-graph>
WHERE
  {
    ?s a owl:inverseFunctionalProperty .
    OPTIONAL { ?s owl:nullIFPValue ?v }
    FILTER (!Bound(?v))
  }
```

If no ontology is available then appropriate predicates can be obtained from sample graphs using DB.DBA.RDF_GRAPH_COLLECT_FP_LIST .

Implementation-Specific Extensions of GUO Ontology

Note : This section contains implementation details that are needed only if you want to write your own patch or diff procedure, you don't have to worry about internals if you want to use existing procedures.

Basic GUO ontology is not expressive enough to work with blank nodes, so some custom extensions $ are needed.

In the rest of the description:

```
@prefix guo: <http://webr3.org/owl/guo#>
```

is assumed.

The diff contains one node of `rdf:type guo:diff` .

For debugging purpose it has properties `guo:graph1` and `guo:graph2` that corespond to `gfrom` and `gto` arguments of DB.DBA.RDF_SUO_DIFF_TTL .

The diff also contains zero or more nodes of `rdf:type guo:UpdateInstruction` . These nodes are as described in basic GUO ontology, but `guo:target_graph` is now optional, `guo:target_subject` can be a blank node and objects of predicates "inside" values of `guo:insert` and `guo:delete` can also be blank nodes. These blank nodes are "placeholders" for values, calculated according to the most important GUO extension - rule nodes.

There are eight sorts of rule nodes, four for `gfrom` side of diff and four similar for `gto` side. Out of four sorts related to one side, two are for functional properties and two similar are for inverse functional properties. Thus `rdf:type-s` of these nodes are:

```
guo:from-rule-FP0,
guo:from-rule-FP1,
guo:from-rule-IFP0,
guo:from-rule-IFP1
```

and

```
guo:to-rule-FP0,
guo:to-rule-FP1,
guo:to-rule-IFP ,
guo:to-rule-IFP1 .
```

Each rule node has property `guo:order` that is an non-negative integer.

These integers enumerate all `guo:from-rule-` ... nodes, starting from zero.

When patch procedure works, these rules are used in this order, the result of each rule is a blank node that either exists in the graph or just created.

All results are remembered for use in the rest of the patch procedure.

Similarly, other sequence of these integers enumerate all `guo:to-rule-` ... nodes, also starting from zero.

Consider a sequence of `guo:from-rule-` ... nodes, because `guo:to-rule-` nodes have identical properties.

A rule node can have zero or more values of `guo:dep` property, each value is a bnode that is rule node that should be calculated before the current one.

Every rule has exactly one predicate `guo:path` that is a blank node. Each property of this blank node describes one possible "move of slider": predicate to follow is in predicate position and a node to start from is in object position. An IRI or a literal in object position is used as is, a blank node in object position should be of type `guo:from-rule-` ... and have smaller `guo:order` so it refers to already calculated result bnode of some preceding rule.

Rule of form:

```
R a guo:from-rule-IFP1 ;
  guo:path [ P1 O1 ; P2 O2 ; ... ; Pn On ] .
```

searches for a unique blank node `_:Rres` that is a common subject of triples:

```
 _:Rres P1 O1
 _:Rres P2 O2
  . . .
 _:Rres Pn On
```

in the gfrom graph.

If subjects differ in these triples or some triples are not found or the subject is not a blank node then an appropriate error is logged and rule fails, otherwise `_:Rres` is remembered as the result of the rule.

Similarly, rule of form:

```
R a guo:from-rule-FP1 ;
  guo:path [ P1 O1 ; P2 O2 ; ... ; Pn On ] .
```

searches for a unique blank node `_:Rres` that is a common object of triples:

```
 O1 P1 _:Rres
 O2 P2 _:Rres
  . . .
 On Pn _:Rres
```

in the gfrom graph.

Rule of form:

```
R a guo:from-rule-IFP0 ;
  guo:path [ P1 O1 ; P2 O2 ; ... ; Pn On ] .
```

ensures that the `gfrom` graph does not contain any triple like:

```
 _:Rres P1 O1
 _:Rres P2 O2
```

or

```
_:Rres Pn On
```

It is an error if something exists. If nothing found then the result of the rule is newly created unique blank node. That's how patch procedure creates new blank nodes when it inserts "totally new" data.

Similarly, rule of form:

```
R a guo:from-rule-IFP0 ;
  guo:path [ P1 O1 ; P2 O2 ; ... ; Pn On ] .
```

ensures that the `gfrom` graph does not contain any triple like:

```
O1 P1 _:Rres
O2 P2 _:Rres
```

or

```
 On Pn _:Rres
```

Current version of patch procedure does not use rules `guo:to-rule-` ... , however they can be used by custom procedure of few sorts. First, these rules can be used to produce a "reversed diff". Next, these rules can be used to validate the result of the patch - if the patch can not be reverted then the result is "suspicious".

16.17.17. RDB2RDF Triggers

Linked Data Views have many advantages, if compared to static dumps of the database in RDF triples. However, they does not solve few problems. First, inference is supported only for physically stored triples, so one had to chose between convenience of inference and convenience of Linked Data Views. Next, algorithms that selects triples with non-constant graphs and predicates tend to produce enormous texts of SQL queries if Linked Data Views are complicated enough. Finally, there may be a need in export of big and fresh static RDF dump but preparing this dump would take too much time via both RDF Views and traditional methods.

The solution is set of triggers on source tables of an Linked Data View that edit parts of physical dump on each change of source data. Unlike Linked Data Views that cost nothing while not queried, these triggers add a significant overhead on any data manipulation on sources, continuously. To compensate this, the dump should be in an intensive use and not replaceable by Linked Data Views. In other cases, do not add these triggers.

It is next to impossible to write such triggers by hands so a small API is provided to generate SQL texts from metadata of Linked Data Views.

First of all, views in an RDF storage does not work in full isolation from each other. Some of them may partially disable others due to OPTION(EXCLUSIVE) and some may produce one triple in different ways. As a result, triggers are not made on per-view basis. Instead, a special RDF storage is introduced, namely virtrdf:SyncToQuads , all required triples are added to it and triggers are created for the whole storage. Typically an Linked Data View is created in some other storage, e.g., virtrdf:DefaultQuadStorage and then added to virtrdf:SyncToQuads via:

```
sparql alter quad storage virtrdf:SyncToQuads {
   create <my_rdf_view> using storage virtrdf:DefaultQuadStorage };
```

The following example procedure copies all user-defined Linked Data Views from default quad storage to virtrdf:SyncToQuads:

```
create procedure DB.DBA.RDB2RDF_COPY_ALL_RDF_VIEWS_TO_SYNC ()
{
  for (sparql define input:storage ""
    select (bif:aref(bif:sprintf_inverse (str(?idx), bif:concat (str(rdf:_), "%d"), 0), 0)) ?qm
    from virtrdf:
    where { virtrdf:DefaultQuadStorage-UserMaps ?idx ?qm . ?qm a virtrdf:QuadMap }
    order by asc (bif:sprintf_inverse (bif:concat (str(rdf:_), "%d"), str (?idx), 1)) ) do
    exec (sprintf ('sparql alter quad storage virtrdf:SyncToQuads { create <%s> using storage virtrdf:Def
}
;
```

When the virtrdf:SyncToQuads storage is fully prepared, two API functions can be used:

- DB.DBA.SPARQL_RDB2RDF_LIST_TABLES : The function returns a vector of names of tables that are used as sources for Linked Data Views. Application developer should decide what to do with each of them - create triggers or do some application-specific workarounds.

Note that if some SQL views are used as sources for Linked Data Views and these views does not have INSTEAD triggers then workarounds become mandatory for them, not just a choice, because BEFORE or AFTER triggers on views are not allowed if there is no appropriate INSTEAD trigger. The mode argument should be zero in current version.

- DB.DBA.SPARQL_RDB2RDF_CODEGEN : The function creates an SQL text for a given table and an operation specified by an opcode.

In some cases, Linked Data Views are complicated enough so that BEFORE UPDATE and AFTER DELETE triggers are required in additional to the minimal set. In this case, sparql_rdb2rdf_codegen calls will return a vector of two string sessions, not single string session, and both sessions are sql texts to inspect or execute. In this case, the BEFORE trigger will not delete obsolete quads from RDF_QUAD table, instead it will create records in a special table RDF_QUAD_DELETE_QUEUE as guesses what can be deleted. The AFTER trigger will re-check these guesses, delete related quads if needed and shorten the RDF_QUAD_DELETE_QUEUE.

The extra activity of triggers on RDF_QUAD, RDF_OBJ, RDF_QUAD_DELETE_QUEUE and other tables and indexes of the storage of "physical" triples may cause deadlocks so the application should be carefully checked for proper support of deadlocks if they were very seldom before turning RDB2RDF triggers on. In some cases, the whole processing of RDB2RDF can be moved to a separate server and connected to the main workhorse server via replication.

The following example functions create texts of all triggers, save them to files in for further studying and try to load them. That's probably quite bad scenario for a production database, because it's better to read procedures before loading them, especially if they're triggers, especially if some of them may contain errors.

```
-- This creates one or two files with one or two triggers or other texts and try to load the
generated sql texts.
create procedure DB.DBA.RDB2RDF_EXEC_CODEGEN1_FOR_TABLE
(  in dump_prefix varchar,
   in tbl varchar,
   in dump_id any,
   in txt any )
{
  declare fname varchar;
  declare stat, msg varchar;
  if (isinteger (dump_id))
    dump_id := cast (dump_id as varchar);
  if (__tag of vector = __tag (txt))
    {
      DB.DBA.RDB2RDF_EXEC_CODEGEN1_FOR_TABLE (dump_prefix, tbl, dump_id, txt[0]);
      DB.DBA.RDB2RDF_EXEC_CODEGEN1_FOR_TABLE (dump_prefix, tbl, dump_id || 'p' , txt[1]);
      return;
    }
  if (__tag of varchar <> __tag (txt))
    txt := string_output_string (txt);
  fname := sprintf ('%s_Rdb2Rdf.%s.%s.sql', dump_prefix, tbl, dump_id);
  string_to_file (fname, txt || '\n;\n', -2);
  if ('0' = dump_id)
    return;
  stat := '00000';
  msg := '';
  exec (txt, stat, msg);
  if ('00000' <> stat)
    {
      string_to_file (fname, '\n\n- - - - - 8< - - - - -\n\nError ' || stat || ' ' || msg, -1);
      if (not (subseq (msg, 0, 5) in ('SQ091')))
        signal (stat, msg);
    }
}
;

-- This creates and loads all triggers, init procedure and debug dump related to one table.
create procedure DB.DBA.RDB2RDF_PREPARE_TABLE (in dump_prefix varchar, in tbl varchar)
{
  declare ctr integer;
  for (ctr := 0; ctr <= 4; ctr := ctr+1 )
    DB.DBA.RDB2RDF_EXEC_CODEGEN1_FOR_TABLE (dump_prefix, tbl, ctr, sparql_rdb2rdf_codegen (tbl, ctr));
}
;

-- This creates and loads all triggers, init procedure and debug dump related to all tables used by and L
create procedure DB.DBA.RDB2RDF_PREPARE_ALL_TABLES (in dump_prefix varchar)
```

```
{
  declare tbl_list any;
  tbl_list := sparql_rdb2rdf_list_tables (0);
  foreach (varchar tbl in tbl_list) do
    {
      DB.DBA.RDB2RDF_PREPARE_TABLE (dump_prefix, tbl);
    }
}
;
```

The following combination of calls prepares all triggers for all Linked Data Views of the default storage:

```
DB.DBA.RDB2RDF_COPY_ALL_RDF_VIEWS_TO_SYNC ();
DB.DBA.RDB2RDF_PREPARE_ALL_TABLES (cast (now() as varchar));
```

This does not copy the initial state of RDB2RDF graphs to the physical storage, because this can be dangerous for existing RDF data and even if all procedures will work as expected then they may produce huge amounts of RDF data, run out of transaction log limits and thus require application-specific precautions. It is also possible to make initial loading by a SPARUL statements like:

```
SPARQL
INSERT IN <snapshot-graph> { ?s ?p ?o }
FROM <snapshot-htaph>
WHERE
 { quad map <id-of-rdf-view>
          { ?s ?p ?o }
 };
```

16.18. RDF Data Access Providers (Drivers)

16.18.1. Virtuoso Jena Provider

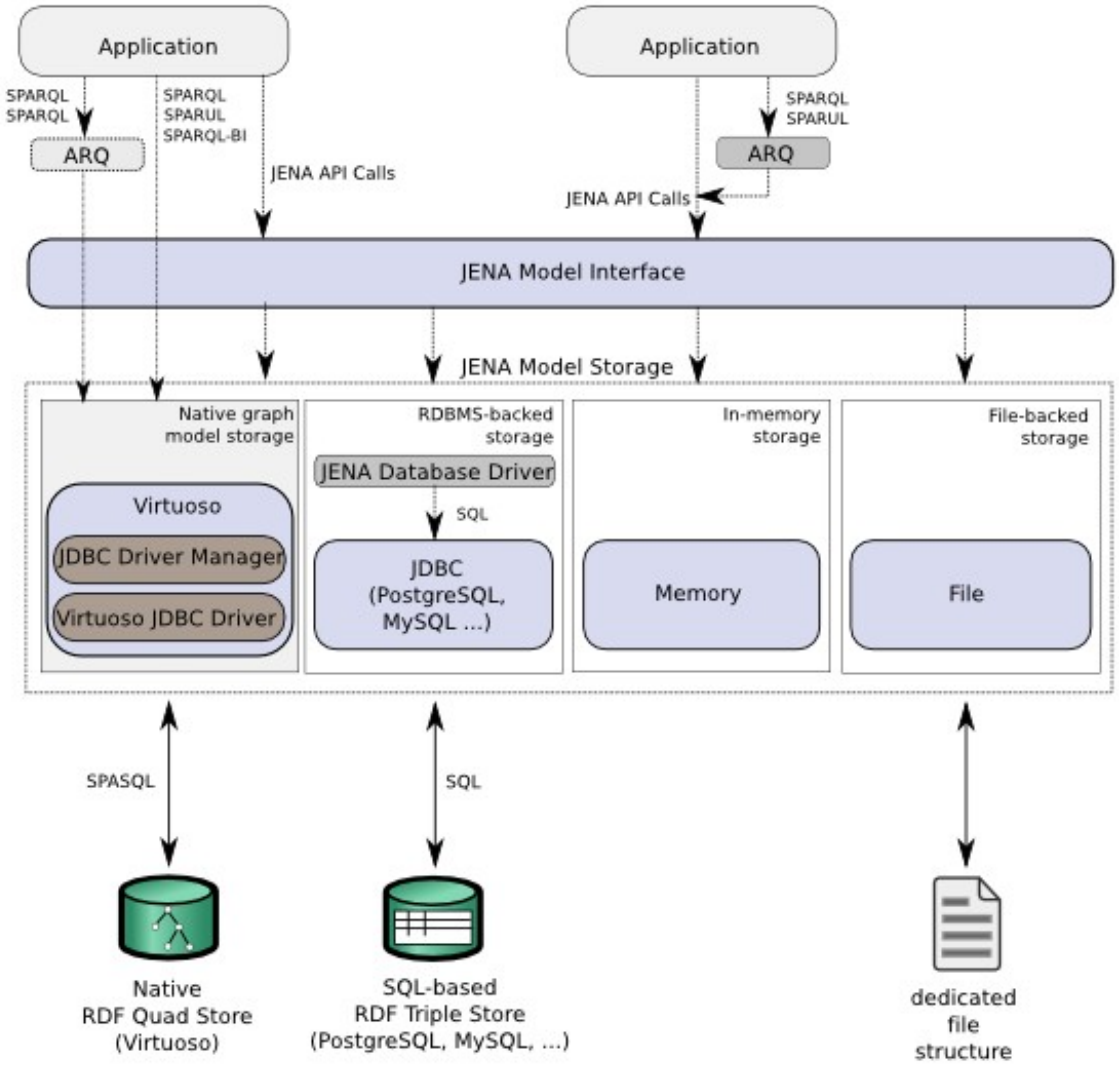
What is Jena

Jena is an open source Semantic Web framework for Java. It provides an API to extract data from and write to RDF graphs. The graphs are represented as an abstract "model". A model can be sourced with data from files, databases, URIs or a combination of these. A Model can also be queried through SPARQL and updated through SPARUL.

What is the Virtuoso Jena Provider

The Virtuoso Jena RDF Data Provider is a fully operational Native Graph Model Storage Provider for the Jena Framework, which enables Semantic Web applications written using the Jena RDF Frameworks to directly query the Virtuoso RDF Quad Store. Providers are available for the latest Jena 2.6.x and 2.10.x versions.

Figure 16.185. Virtuoso Jena RDF Data Provider



Setup

Prerequisites

Download the latest Virtuoso Jena Provider for your Jena framework version, Virtuoso JDBC 3 Driver, Jena Framework, and associated classes and sample programs.

- *Note:*

  The Jena Provider is explicitly bound to the Virtuoso JDBC 3 Driver. You cannot use the Virtuoso JDBC 4 Driver for this purpose at this time.
- The version of the Jena Provider (virt_jena.jar) can be verified with the command:

```
$ java -jar virt_jena.jar
OpenLink Virtuoso(TM) Provider for Jena(TM) Version 2.6.2 [Build 1.2]
```

- Files contained in the zip files are generally older than specifically linked downloads (e.g., the Virtuoso JDBC Driver, virtjdbc3.jar), so don't replace if prompted during extraction. Instead, rename the file extracted from the zip, and compare their versions to be sure you keep only the most recent.

```
$ java -cp virtjdbc3.jar virtuoso.jdbc3.Driver
OpenLink Virtuoso(TM) Driver for JDBC(TM) Version 3.x [Build 3.57]
$ java -cp virtjdbc3.fromzip.jar virtuoso.jdbc3.Driver
OpenLink Virtuoso(TM) Driver for JDBC(TM) Version 3.x [Build 3.11]
```

- Downloads:
  - Virtuoso Jena Provider JAR file, virt_jena.jar
  - Virtuoso JDBC Driver 3 JAR file, virtjdbc3.jar

- Virtuoso JDBC Driver 4 JAR file, virtjdbc4.jar
- Jena Framework and associated classes, jenajars.zip
- Sample programs, virtjenasamples.zip

Compiling Jena Sample Programs

1. Edit the sample programs VirtuosoSPARQLExampleX.java, where X = 1 to 9. Set the JDBC connection strings within to point to a valid Virtuoso Server instance of the form:

   ```
   "jdbc:virtuoso://localhost:1111/charset=UTF-8/log_enable=2"
   ```

   - charset=UTF-8 will be added by Jena provider, if it isn't in connection string. So now you don't need add "charset=UTF-8" to the connection string any more, it is done by Jena provider.
   - log_enable=2: to use row auto commit
   - use these settings to process large rdf data.
2. Ensure that full paths to

   jena.jar, arq.jar,

   and

   virtjdbc3.jar

   are included in the active CLASSPATH setting.
3. Compile the Jena Sample applications using the following command:

   ```
   javac -cp "jena.jar:arq.jar:virtjdbc3.jar:virt_jena.jar:." VirtuosoSPARQLExample1.java
   VirtuosoSPARQLExample2.java VirtuosoSPARQLExample3.java VirtuosoSPARQLExample4.java
   VirtuosoSPARQLExample5.java VirtuosoSPARQLExample6.java VirtuosoSPARQLExample7.java
   VirtuosoSPARQLExample8.java VirtuosoSPARQLExample9.java
   ```

Testing

Once the Provider classes and sample program have been successfully compiled, the Provider can be tested using the sample programs included. Ensure your active CLASSPATH includes full paths to all of the following files, before executing the example commands:

- icu4j_3_4.jar
- iri.jar
- xercesImpl.jar
- axis.jar
- commons-logging-1.1.1.jar
- jena.jar
- arq.jar
- virtjdbc3.jar
- virt_jena.jar

1. VirtuosoSPARQLExample1 returns the contents of the RDF Quad store of the targeted Virtuoso instance, with the following command:

   ```
   java VirtuosoSPARQLExample1
   ```
2. VirtuosoSPARQLExample2 reads in the contents of the following FOAF URIs --

   ```
   http://kidehen.idehen.net/dataspace/person/kidehen#this
   http://www.w3.org/People/Berners-Lee/card#i
   http://demo.openlinksw.com/dataspace/person/demo#this
   ```

   -- and returns the RDF data stored, with the following command:

   ```
   java VirtuosoSPARQLExample2
   ```
3. VirtuosoSPARQLExample3 performs simple addition and deletion operation on the content of the triple store, with the following command:

```
java VirtuosoSPARQLExample3
```

4. VirtuosoSPARQLExample4 demonstrates the use of the *graph.contains* method for searching triples, with the following command:

```
java VirtuosoSPARQLExample4
```

5. VirtuosoSPARQLExample5 demonstrates the use of the *graph.find* method for searching triples, with the following command:

```
java VirtuosoSPARQLExample5
```

6. VirtuosoSPARQLExample6 demonstrates the use of the *graph.getTransactionHandler* method, with the following command:

```
java VirtuosoSPARQLExample6
```

7. VirtuosoSPARQLExample7 demonstrates the use of the graph.getBulkUpdateHandler method, with the following command:

```
java VirtuosoSPARQLExample7
```

8. VirtuosoSPARQLExample8 demonstrates how to insert triples into a graph, with the following command:

```
java VirtuosoSPARQLExample8
```

9. VirtuosoSPARQLExample9 demonstrates the use of the *CONSTRUCT, DESCRIBE,* and *ASK* SPARQL query forms, with the following command:

```
java VirtuosoSPARQLExample9
```

Javadoc API Documentation

Javadocs covers the complete set of classes, interfaces, and methods implemented by the provider:

- Javadoc API Documentation for the Jena 2.6 Provider
- Javadoc API Documentation for the Jena 2.10+ Provider

16.18.2. Virtuoso Sesame Provider

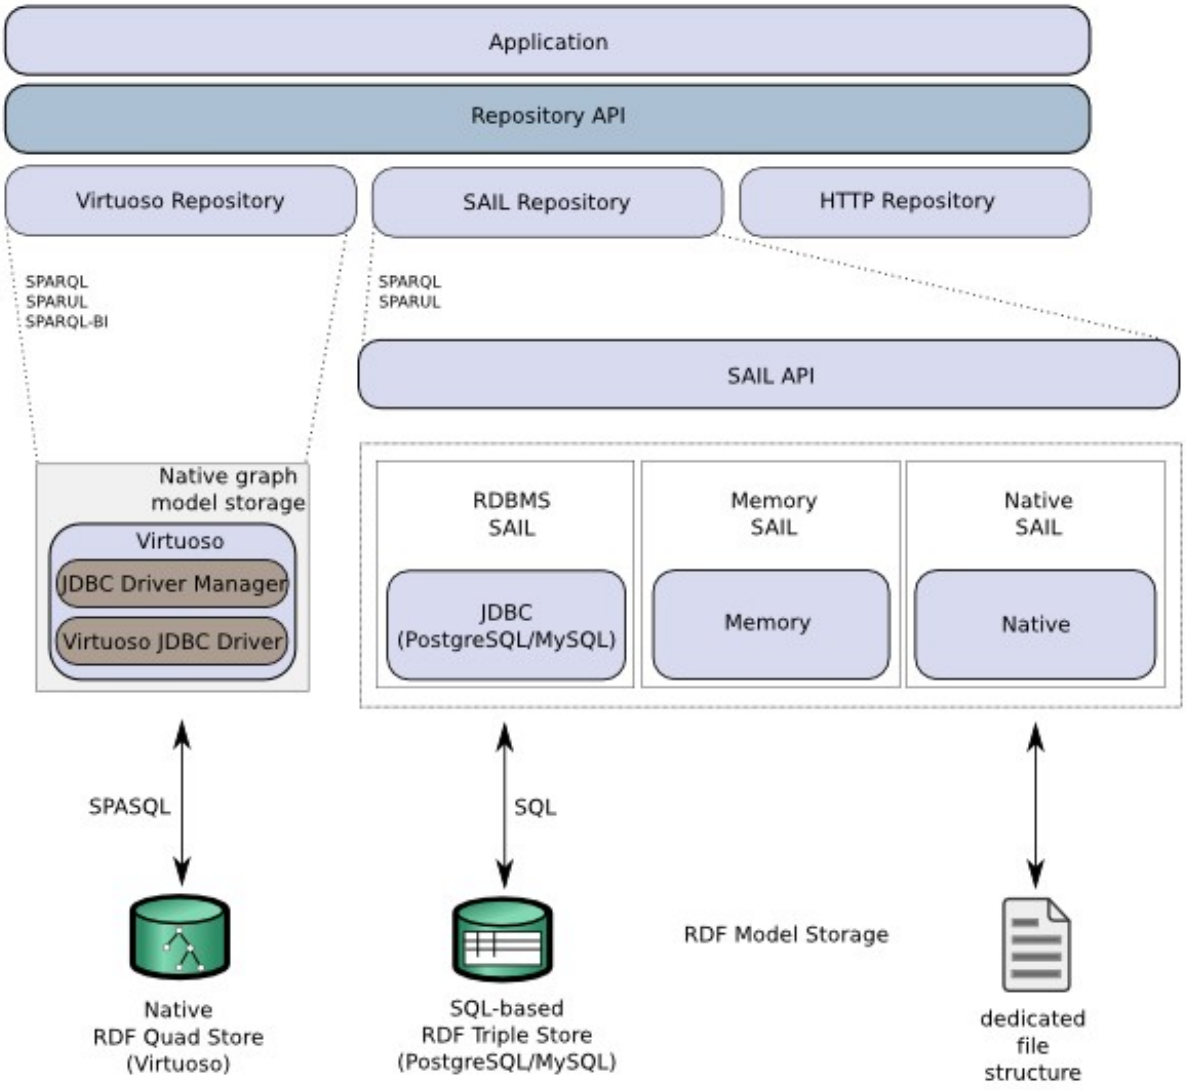
What is Sesame

Sesame is an open source Java framework for storing, querying, and reasoning with RDF and RDF Schema. It can be used as a database for RDF and RDF Schema, or as a Java library for applications that need to work with RDF internally. For example, suppose you need to read a big RDF file, find the relevant information for your application, and use that information. Sesame provides you with the necessary tools to parse, interpret, query, and store all this information, embedded in your own application if you want, or, if you prefer, in a separate database or even on a remote server. More generally: Sesame provides an application developer with a toolbox that contains useful hammers, screwdrivers, etc., for 'Do-It-Yourself' projects with RDF.

What is the Virtuoso Sesame Provider

The Virtuoso Sesame Provider is a fully operational Native Graph Model Storage Provider for the Sesame Framework, allowing users of Virtuoso to leverage the Sesame framework to modify, query, and reason with the Virtuoso quad store using the Java language. The Sesame Repository API offers a central access point for connecting to the Virtuoso quad store. Its purpose is to provides a Java-friendly access point to Virtuoso. It offers various methods for querying and updating the data, while abstracting the details of the underlying machinery. The Provider has been tested against the two latest currently available versions, Sesame 2.6.x, 2.7.x, 2.8.x and the new Sesame 4.x release, for which a new Provider is available.

Figure 16.186. Fig. 1 Sesame Component Stack



If you need more information about how to set up your environment for working with the Sesame APIs, take a look at Chapter 2 of the Sesame User Guide, Setting up to use the Sesame libraries .

Setup

Required Files

This tutorial assumes you have Virtuoso server installed and that the database is accessible at "localhost:1111". In addition, the relevant version of the Virtuoso Sesame Provider, and Sesame java framework need to be installed.

You should download the Virtuoso Sesame Provider JAR archive for the version of Sesame being used, Virtuoso JDBC Driver, Sesame Framework and associated classes and sample programs from our download page . Note the version of the Sesame Provider (virt_sesameX.jar) can be determined with the command:

```
$ java -jar virt_sesame2.jar
OpenLink Virtuoso(TM) Provider for Sesame2(TM) Version 2.6.5 [Build 1.7]
$ java -jar virt_sesame4.jar
OpenLink Virtuoso(TM) Provider for Sesame4(TM) Version 4.0.0 [Build 0.1]
$
```

Sesame 2 Sample Program

Compilation

1. Ensure that full paths to the following files, or equivalents for your version of Sesame, are all included in the active CLASSPATH setting --

- openrdf-sesame-2.1.2-onejar.jar
- slf4j-api-1.5.0.jar
- slf4j-jdk14-1.5.0.jar
- commons-io-2.0.jar
- virtjdbc3.jar
- virt_sesame2.jar

2. Execute the following command:

```
javac VirtuosoTest.java
```

Note: we recommend adding the following to the connect string, to use utf-8 and row-auto-commit:

```
"/charset=UTF-8/log_enable=2"
-- i.e. in VirtuosoTest.java the line:
Repository repository = new VirtuosoRepository("jdbc:virtuoso://" + sa[0] + ":" + sa[1], sa[2], sa
-- should become:
Repository repository = new VirtuosoRepository("jdbc:virtuoso://" + sa[0] + ":" + sa[1]+ "/charset
```

Testing

1. Ensure that full paths to the following files are all included in the active CLASSPATH setting (note the addition of virtuoso_driver, here):

- openrdf-sesame-2.1.2-onejar.jar
- slf4j-api-1.5.0.jar
- slf4j-jdk14-1.5.0.jar
- commons-io-2.0.jar
- virtjdbc3.jar
- virt_sesame2.jar
- virtuoso_driver

2. Run the VirtuosoTest program to test the Sesame 2 Provider with the following command:

```
java VirtuosoTest <hostname> <port> <uid> <pwd>
```

3. The test run should look like this:

```
$ java VirtuosoTest localhost 1111 dba dba

== TEST 1:  : Start
   Loading data from URL: http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com/foaf.r
== TEST 1:  : End
PASSED: TEST 1

== TEST 2:  : Start
   Clearing triple store
== TEST 2:  : End
PASSED: TEST 2

== TEST 3:  : Start
   Loading data from file: virtuoso_driver/data.nt
== TEST 3:  : End
PASSED: TEST 3

== TEST 4:  : Start

Getting Started

This section covers the essentials for connecting to and manipulating data stored in a Virtuoso repository using the Sesame API. More information on the Sesame Framework, including extended examples on how to use the API, can be found in Chapter 8 of the Sesame User's guide, the RepositoryConnection API .

The interfaces for the Repository API can be found in packages virtuoso.sesame2.driver and org.openrdf.repository. Several implementations for these interfaces exist in the Virtuoso Provider download package. The Javadoc reference for the Sesame API is available online and can also be found in the doc directory of the download.

Creating a Virtuoso Repository RDF object

The first step to connecting to Virtuoso through the Sesame API is to create a Repository for it. The Repository object operates on (stacks of) Sail object(s) for storage and retrieval of RDF data.

One of the simplest configurations is a repository that just stores RDF data in main memory, without applying any inference. This is also by far the fastest type of repository that can be used. The following code creates and initialize a non-inferencing main-memory repository:

```
import virtuoso.sesame2.driver.VirtuosoRepository;

Repository myRepository = VirtuosoRepository("jdbc:virtuoso://localhost:1111","dba","dba");

myRepository.initialize();
```

The constructor of the VirtuosoRepository class accepts the JDBC URL of the Virtuoso engine, and the username and password of an authorized user. Following this example, the repository needs to be initialized to prepare the Sail(s) that it operates on, which includes performing operations such as restoring previously stored data, setting up connections to a relational database, etc.

The repository that is created by the above code is volatile: its contents are lost when the object is garbage collected or when the program is shut down. This is fine for cases where, for example, the repository is used as a means for manipulating an RDF model in memory.

Creating a Virtuoso Repository Connection

Now that we have created a VirtuosoRepository object instance, we want to do something with it. This is achieved through the use of the VirtuosoRepositoryConnection class, which can be created by the VirtuosoRepository class.

A VirtuosoRepositoryConnection represents fi as the name suggests fi a connection to the actual Virtuoso quad store. We can issue operations over this connection, and close it when we are done to make sure we are not keeping resources unnecessarily occupied.

In the following sections, we will show some examples of basic operations using the Northwind dataset.

Adding RDF to Virtuoso

The Repository implements the Sesame Repository API, which offers various methods for adding data to a repository. Data can be added programmatically by specifying the location of a file that contains RDF data, and statements can be added individually or in collections.

We perform operations on the repository by requesting a RepositoryConnection from the repository, which returns a VirtuosoRepositoryConnection object. On this VirtuosoRepositoryConnection object we can perform the various operations, such as query evaluation; getting, adding, or removing statements; etc.

The following example code adds two files, one local and one located on the Web, to a repository:

```
import org.openrdf.repository.RepositoryException;

import org.openrdf.repository.Repository;

import org.openrdf.repository.RepositoryConnection;

import org.openrdf.rio.RDFFormat;

import java.io.File;

import java.net.URL;

File file = new File("/path/to/example.rdf");

String baseURI = "http://example.org/example/localRDF";

?
try {

   RepositoryConnection con = myRepository.getConnection();
```

```
        try {
            con.add(file, baseURI, RDFFormat.RDFXML);
            URL url = new URL("http://example.org/example/remoteRDF");
            con.add(url, url.toString(), RDFFormat.RDFXML);
        }
        finally {
            con.close();
        }
    }
    catch (RepositoryException rex) {
        // handle exception
    }
    catch (java.io.IOEXception e) {
        // handle io exception
    }
```

More information on other available methods can be found in the javadoc reference of the RepositoryConnection interface.

Querying Virtuoso

The Repository API has a number of methods for creating and evaluating queries. Three types of queries are distinguished: tuple queries, graph queries, and Boolean queries. The query types differ in the type of results that they produce.

Select Query: The result of a select query is a set of tuples (or variable bindings), where each tuple represents a solution of the query. This type of query is commonly used to get specific values (URIs, blank nodes, literals) from the stored RDF data. The method QueryFactory.executeQuery() returns a Value [ ][ ] for SPARQL "SELECT" queries. The method QueryFactory.executeQuery() also calls the QueryFactory.setResult() which populates a set of tuples for SPARQL "SELECT" queries. The graph can be retrieved using QueryFactory.getBooleanResult().

Graph Query: The result of a graph query is an RDF graph (or set of statements). This type of query is very useful for extracting sub-graphs from the stored RDF data, which can then be queried further, serialized to an RDF document, etc. The method QueryFactory.executeQuery() calls the QueryFactory.setGraphResult() which populates a graph for SPARQL "DESCRIBE" and "CONSTRUCT" queries. The graph can be retrieved using QueryFactory.getGraphResult().

Boolean Query: The result of a Boolean query is a simple Boolean value, i.e., TRUE or FALSE. This type of query can be used to check if a repository contains specific information. The method QueryFactory.executeQuery() calls the QueryFactory.setBooleanResult() which sets a Boolean value for SPARQL "ASK" queries. The value can be retrieved using QueryFactory.getBooleanResult().

Note: Although Sesame 2 currently supports two query languages: SeRQL and SPARQL, the Virtuoso provider only supports the W3C SPARQL specification at this time.

Evaluating a SELECT Query

To evaluate a tuple query we simply do the following:

```
    import java.util.List;
    import org.openrdf.OpenRDFException;
    import org.openrdf.repository.RepositoryConnection;
    import org.openrdf.query.TupleQuery;
```

```
import org.openrdf.query.TupleQueryResult;

import org.openrdf.query.BindingSet;

import org.openrdf.query.QueryLanguage;
?

try {

   RepositoryConnection con = myRepository.getConnection();

   try {

      String queryString = "SELECT x, y FROM  WHERE {x} p {y}";

      TupleQuery tupleQuery = con.prepareTupleQuery(QueryLanguage.SPARQL, queryString);

      TupleQueryResult result = tupleQuery.evaluate();

      try {

         ? // do something with the result

      }

      finally {

         result.close();

      }

   }

   finally {

      con.close();

   }

}

catch (RepositoryException e) {

   // handle exception

}
```

This evaluates a SPARQL query and returns a TupleQueryResult, which consists of a sequence of BindingSet objects. Each BindingSet contains a set of pairs called Binding objects. A Binding object represents a name/value pair for each variable in the query's projection.

We can use the TupleQueryResult to iterate over all results and get each individual result for x and y:

```
while (result.hasNext()) {

   BindingSet bindingSet = result.next();

   Value valueOfX = bindingSet.getValue("x");

   Value valueOfY = bindingSet.getValue("y");

   // do something interesting with the query variable values here?

}
```

As you can see, we retrieve values by name rather than by an index. The names used should be the names of variables as specified in your query. The TupleQueryResult.getBindingNames() method returns a list of binding names, in the order in which they were specified in the query. To process the bindings in each binding set in the order specified by the projection, you can do the following:

```
List bindingNames = result.getBindingNames();

while (result.hasNext()) {

   BindingSet bindingSet = result.next();

   Value firstValue = bindingSet.getValue(bindingNames.get(0));

   Value secondValue = bindingSet.getValue(bindingNames.get(1));

   // do something interesting with the values here?

}
```

It is important to invoke the close() operation on the TupleQueryResult, after we are done with it. A TupleQueryResult evaluates lazily and keeps resources (such as connections to the underlying database) open. Closing the TupleQueryResult frees up these resources. Do not forget that iterating over a result may cause exceptions! The best way to make sure no connections are kept open unnecessarily is to invoke close() in the finally clause.

An alternative to producing a TupleQueryResult is to supply an object that implements the TupleQueryResultHandler interface to the query's evaluate() method. The main difference is that when using a return object, the caller has control over when the next answer is retrieved, whereas with the use of a handler, the connection simply pushes answers to the handler object as soon as it has them available.

As an example we will use SPARQLResultsXMLWriter, which is a TupleQueryResultHandler implementation that writes SPARQL Results XML documents to an output stream or to a writer:

```
import org.openrdf.query.resultio.sparqlxml.SPARQLResultsXMLWriter;

?
FileOutputStream out = new FileOutputStream("/path/to/result.srx");

try {

   SPARQLResultsXMLWriter sparqlWriter = new SPARQLResultsXMLWriter(out);

   RepositoryConnection con = myRepository.getConnection();

   try {

      String queryString = "SELECT * FROM  WHERE {x} p {y}";

      TupleQuery tupleQuery = con.prepareTupleQuery(QueryLanguage.SPARQL, queryString);

      tupleQuery.evaluate(sparqlWriter);

   }

   finally {

      con.close();

   }

}

finally {

   out.close();

}
```

You can just as easily supply your own application-specific implementation of TupleQueryResultHandler, if desired.

Lastly, an important warning: as soon as you are done with the RepositoryConnection object, you should close it. Notice that during processing of the TupleQueryResult object (for example, when iterating over its contents), the RepositoryConnection should still be open. We can invoke con.close() after we have finished with the result.

Evaluating a CONSTRUCT query

The following code evaluates a graph query on a repository:

```
import org.openrdf.query.GraphQueryResult;

GraphQueryResult graphResult = con.prepareGraphQuery(

      QueryLanguage.SPARQL, "CONSTRUCT * FROM {x} p {y}").evaluate();
```

A GraphQueryResult is similar to TupleQueryResult in that it is an object that iterates over the query results. However, for graph queries the query results are RDF statements, so a GraphQueryResult iterates over Statement objects:

```
while (graphResult.hasNext()) {

   Statement st = graphResult.next();

   // ? do something with the resulting statement here.

}
```

The TupleQueryResultHandler equivalent for graph queries is org.openrdf.rio.RDFHandler. Again, this is a generic interface; each object implementing it can process the reported RDF statements in any way it wants.

All writers from Rio (such as the RDFXMLWriter, TurtleWriter, TriXWriter, etc.) implement the RDFHandler interface. This allows them to be used in combination with querying quite easily. In the following example, we use a TurtleWriter to write the result of a SPARQL graph query to standard output in Turtle format:

```
import org.openrdf.rio.turtle.TurtleWriter;

?
RepositoryConnection con = myRepository.getConnection();

try {

   TurtleWriter turtleWriter = new TurtleWriter(System.out);

   con.prepareGraphQuery(QueryLanguage.SPARQL, "CONSTRUCT * FROM  WHERE {x} p {y}").evaluate(turtleWriter

}

finally {

   con.close();

}
```

Again, note that as soon as we are done with the result of the query (either after iterating over the contents of the GraphQueryResult or after invoking the RDFHandler), we invoke con.close() to close the connection and free resources.

Javadoc API Documentation

Javadocs covers the complete set of classes, interfaces, and methods implemented by the provider:

- Javadoc API Documentation for the Sesame 2.6 Provider
- Javadoc API Documentation for the Sesame 2.7+ Provider
- Javadoc API Documentation for the Sesame 4.x Provider

Virtuoso Sesame HTTP Repository Configuration and Usage

What

Sesame is an open source Java framework for storing, querying and reasoning with RDF and RDF Schema. It can be used as a database for RDF and RDF Schema, or as a Java library for applications that need to work with RDF internally. The Sesame HTTP repository serves as a proxy for a RDF store hosted on a remote Sesame server, enabling the querying of the RDF store using the Sesame HTTP protocol.

Why

The Sesame HTTP repository endpoint provides users with the greater flexibility for manipulating the RDF store via a common interface. Sesame provides you with the necessary tools to parse, interpret, query and store all this information, embedded in your own application if you want, or, if you prefer, in a separate database or even on a remote server.

How

To create a new Sesame HTTP repository, the Console needs to create such an RDF document and submit it to the SYSTEM repository. The Console uses so called repository configuration templates to accomplish this. Repository configuration templates are simple Turtle RDF files that describe a repository configuration, where some of the parameters are replaced with variables. The Console parses these templates and asks the user to supply values for the variables. The variables are then substituted with the specified values, which produces the required configuration data.

Setup and Testing

This section details the steps required for configuring and testing a Virtuoso Sesame Repository, both using the HTTP and Console Sesame repositories.

Requirements

- Sesame 2.3.1 or higher
- Virtuoso Sesame 2.x (virt_sesame2.jar) or Virtuoso Sesame 4.x (virt_sesame4.jar) Provider
- Virtuoso JDBC Driver (virtjdbc4.jar)
- Virtuoso System Repository config file for Sesame 2.x or Sesame 4.x (create.xsl)
- Virtuoso Repository config file for Sesame 2.x or Sesame 4.x (create-virtuoso.xsl)
- Configuration Template file for a Virtuoso Repository for Sesame 2.x or Sesame 4.x
- Apache Tomcat version 5 or higher

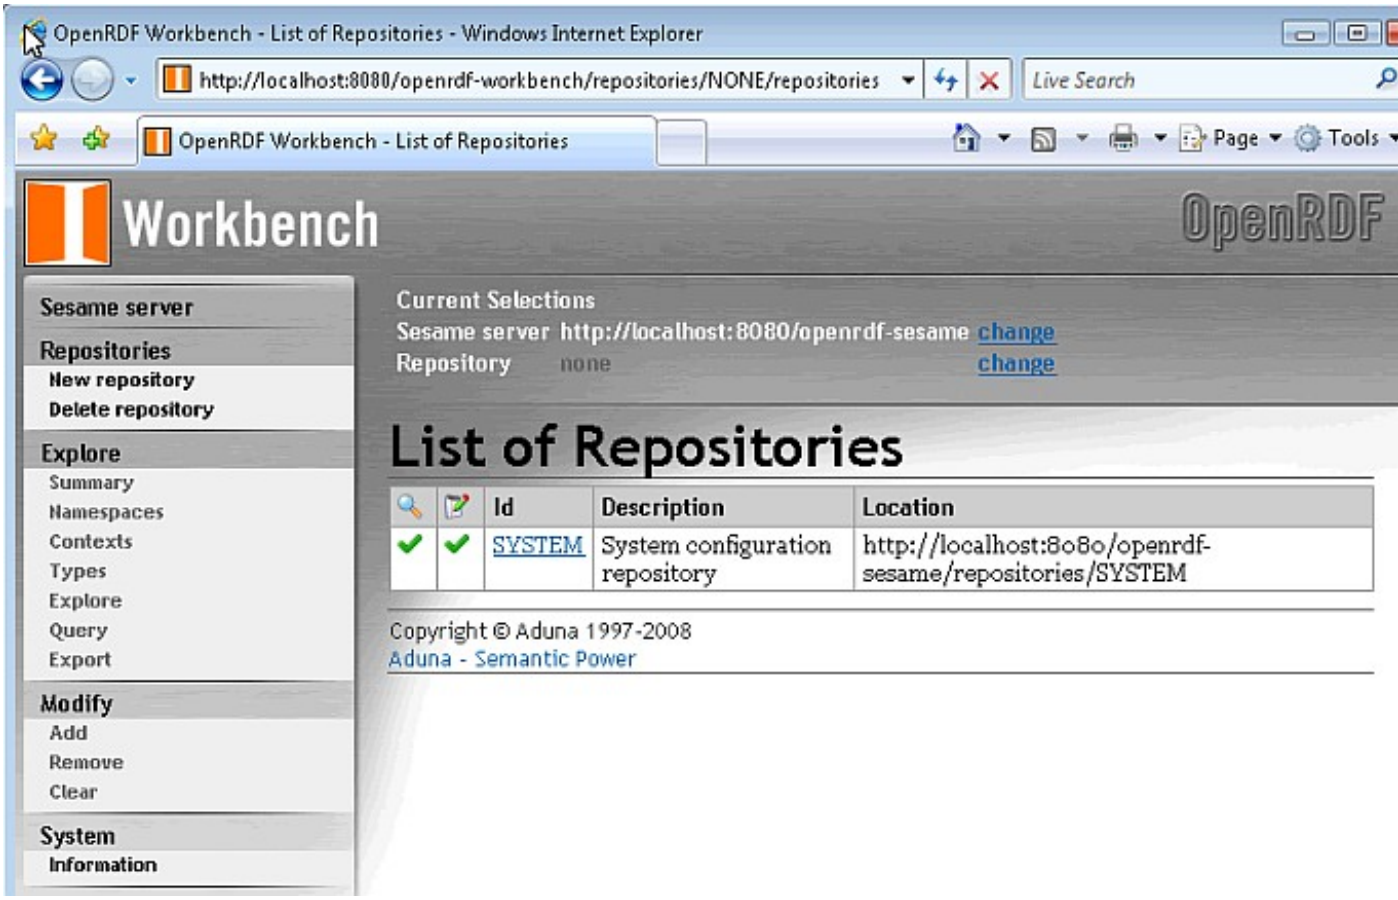
Setup Sesame HTTP Repository

This section details the steps required for configuring and testing a Virtuoso HTTP Sesame Repository.

1. Install Apache Tomcat web server
2. From the Sesame 2.3.1 or higher "lib" directory copy the "openrdf-sesame.war" and "openrdf-worbbench.war" files to the tomcat "webapps" directory where they will automatically be deployed creating two new sub directories "openrdf-sesame" and "openrdf-workbench".
3. Place the corresponding Virtuoso Sesame Provider "virt_sesame2.jar" or "virt_sesame4.jar" and JDBC Driver "virtjdbc4.jar" into the Tomcat ~/webapps/openrdf-sesame/WEB-INF/lib/ and ~/webapps/openrdf-workbench/WEB-INF/lib/ directories for use by the Sesame HTTP Repository for accessing the Virtuoso RDF repository.
4. Place the "create.xsl" and "create-virtuoso.xsl" files in the Tomcat ~/webapps/openrdf-workbench/transformations/ directory. Note "create.xsl" replaces the default provided with Sesame and contains the necessary entries required to reference the new "create-virtuoso.xsl" template file for Virtuoso repository configuration.
5. The Sesame HTTP Repository will now be accessible on the URLs

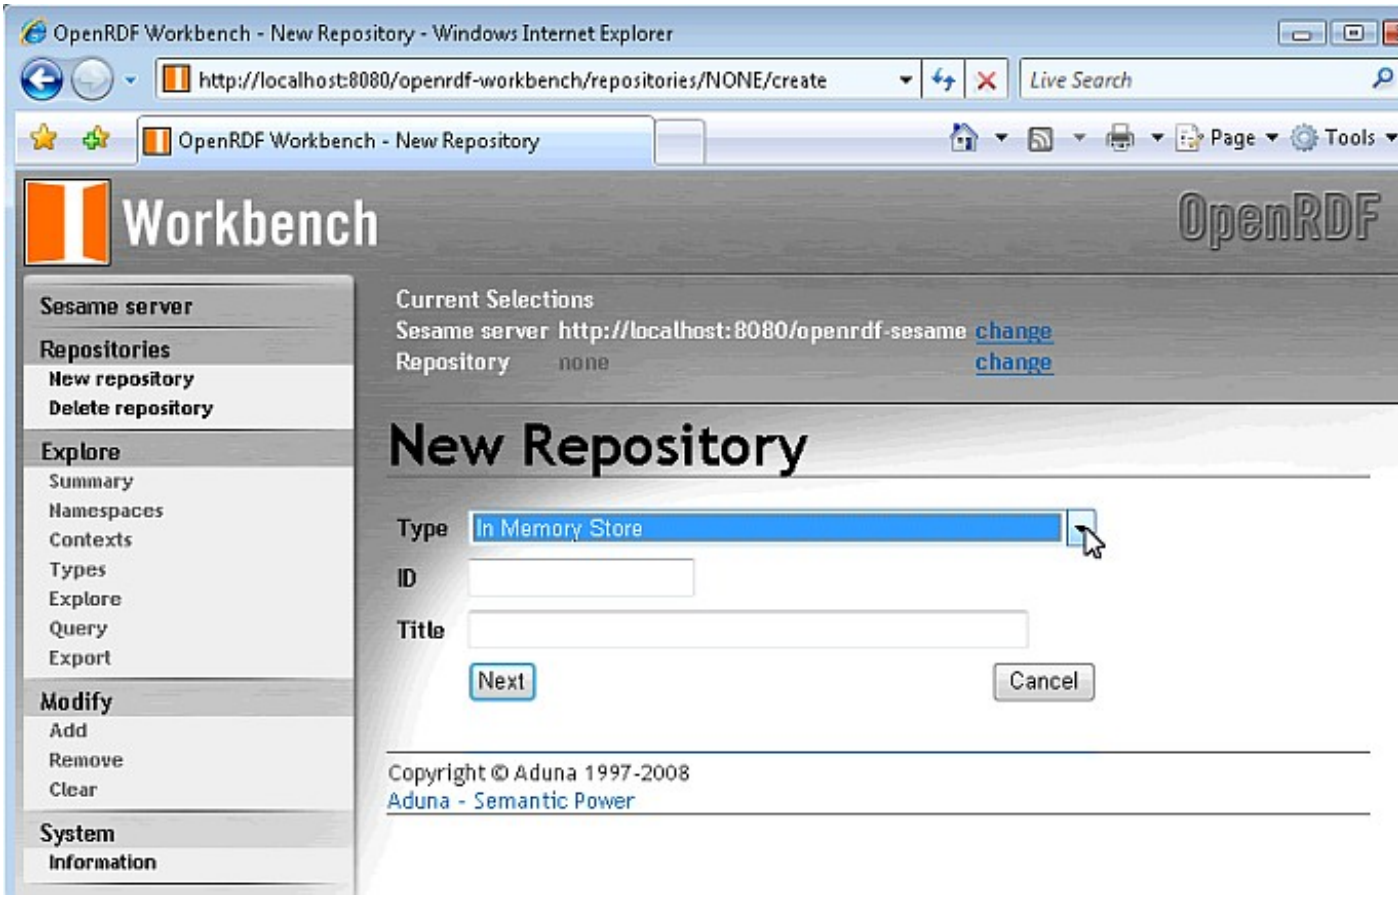
   ```
   http://example.com/openrdf-sesame
   http://example.com/openrdf-workbench
   ```
6. The Sesame OpenRDF Workbench is used for accessing the Sesame HTTP Repositories, loading " http://example.com/openrdf-workbench " will enable the default "SYSTEM" repository to be accessed.

Figure 16.187. Virtuoso Sesame HTTP Repository Configuration and Usage



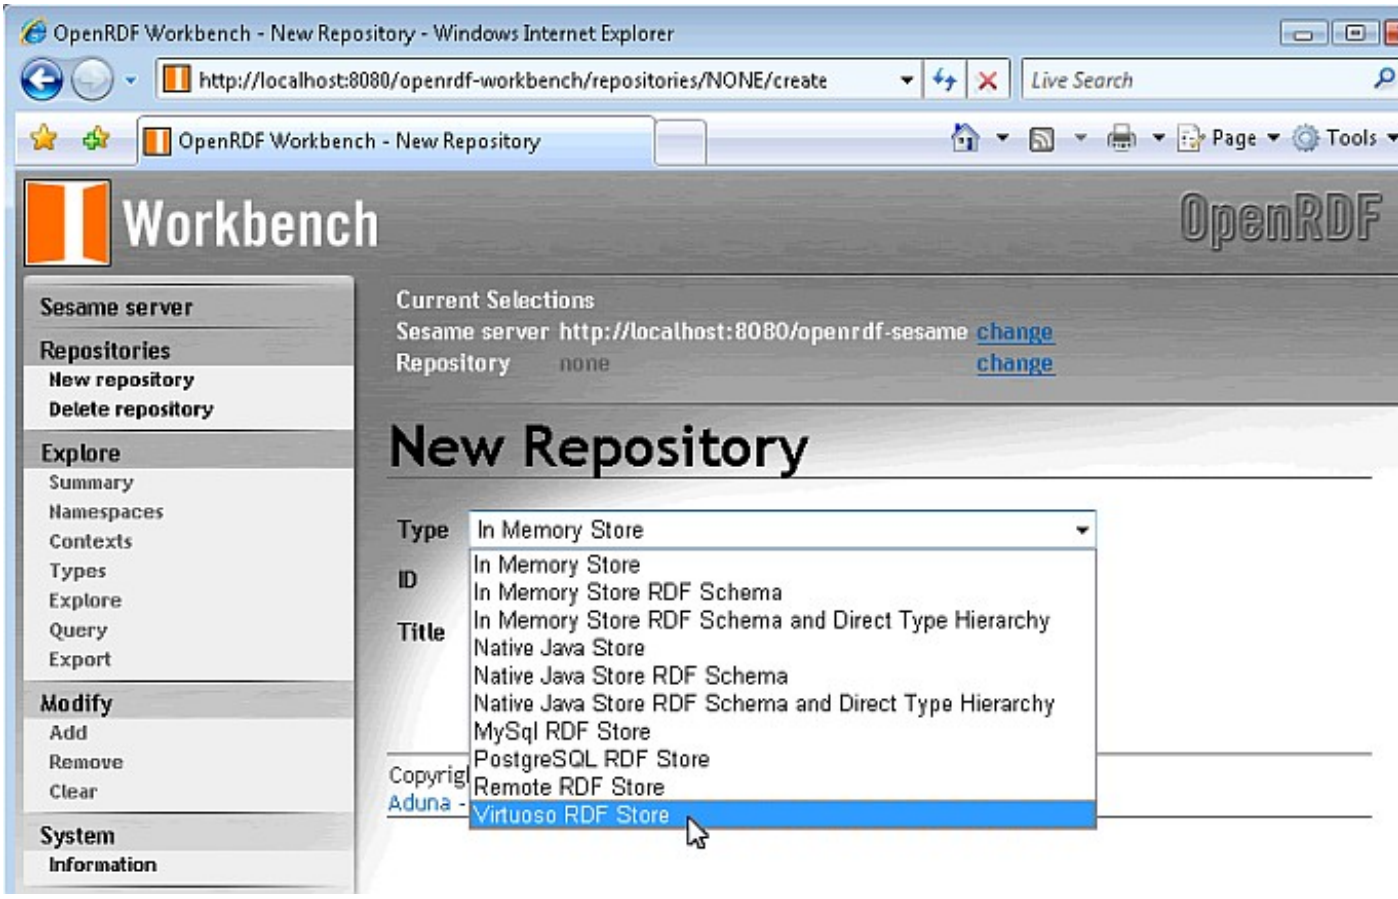
7. Click on the "New Repository" link in the left frame to create a new Sesame Repository.

Figure 16.188. Virtuoso Sesame HTTP Repository Configuration and Usage



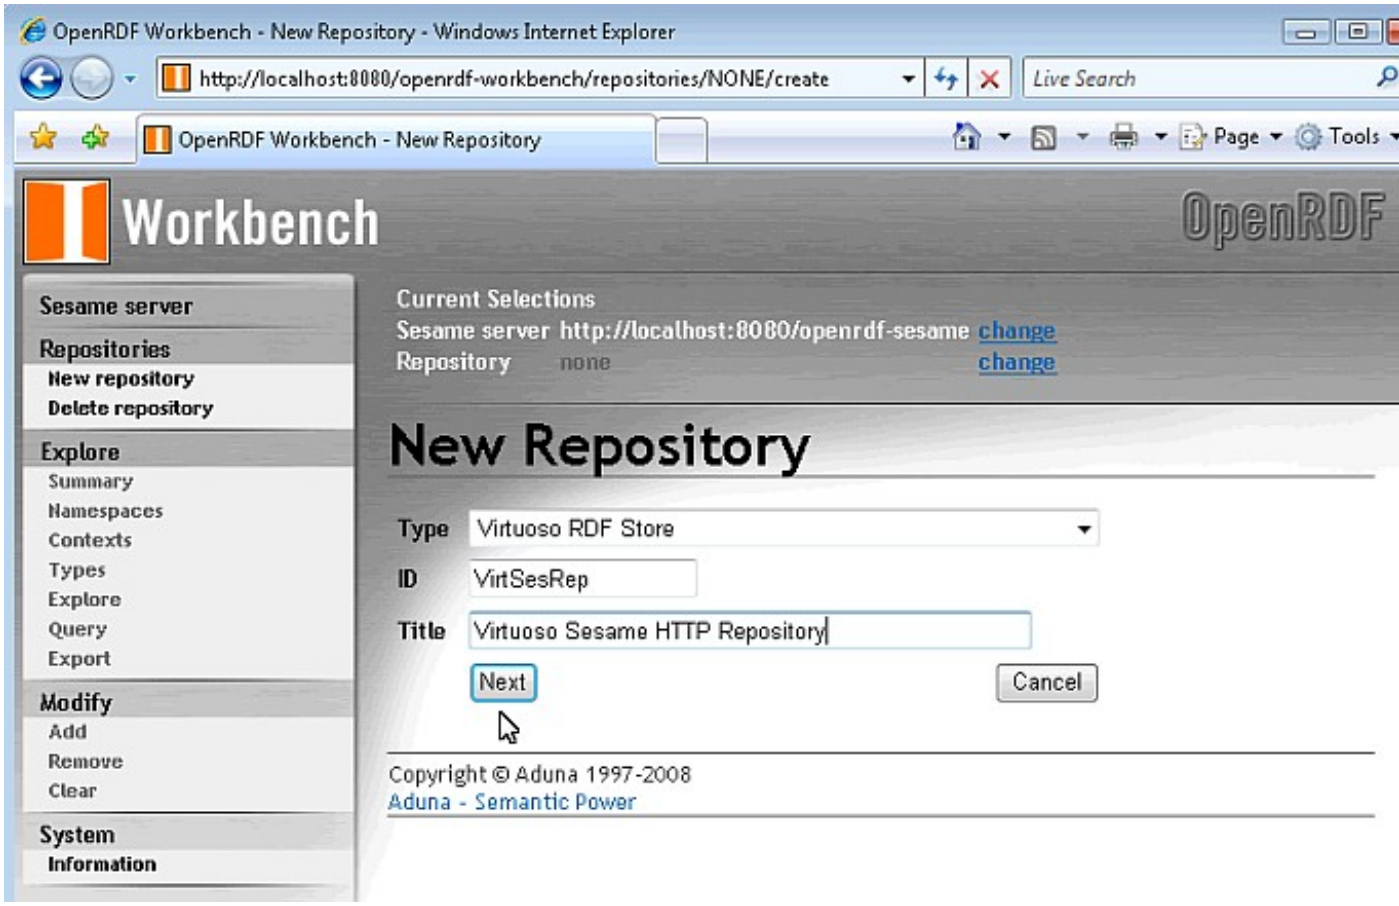
8. Select the "Virtuoso RDF Store" from the "Type" drop down list box presented.

Figure 16.189. Virtuoso Sesame HTTP Repository Configuration and Usage



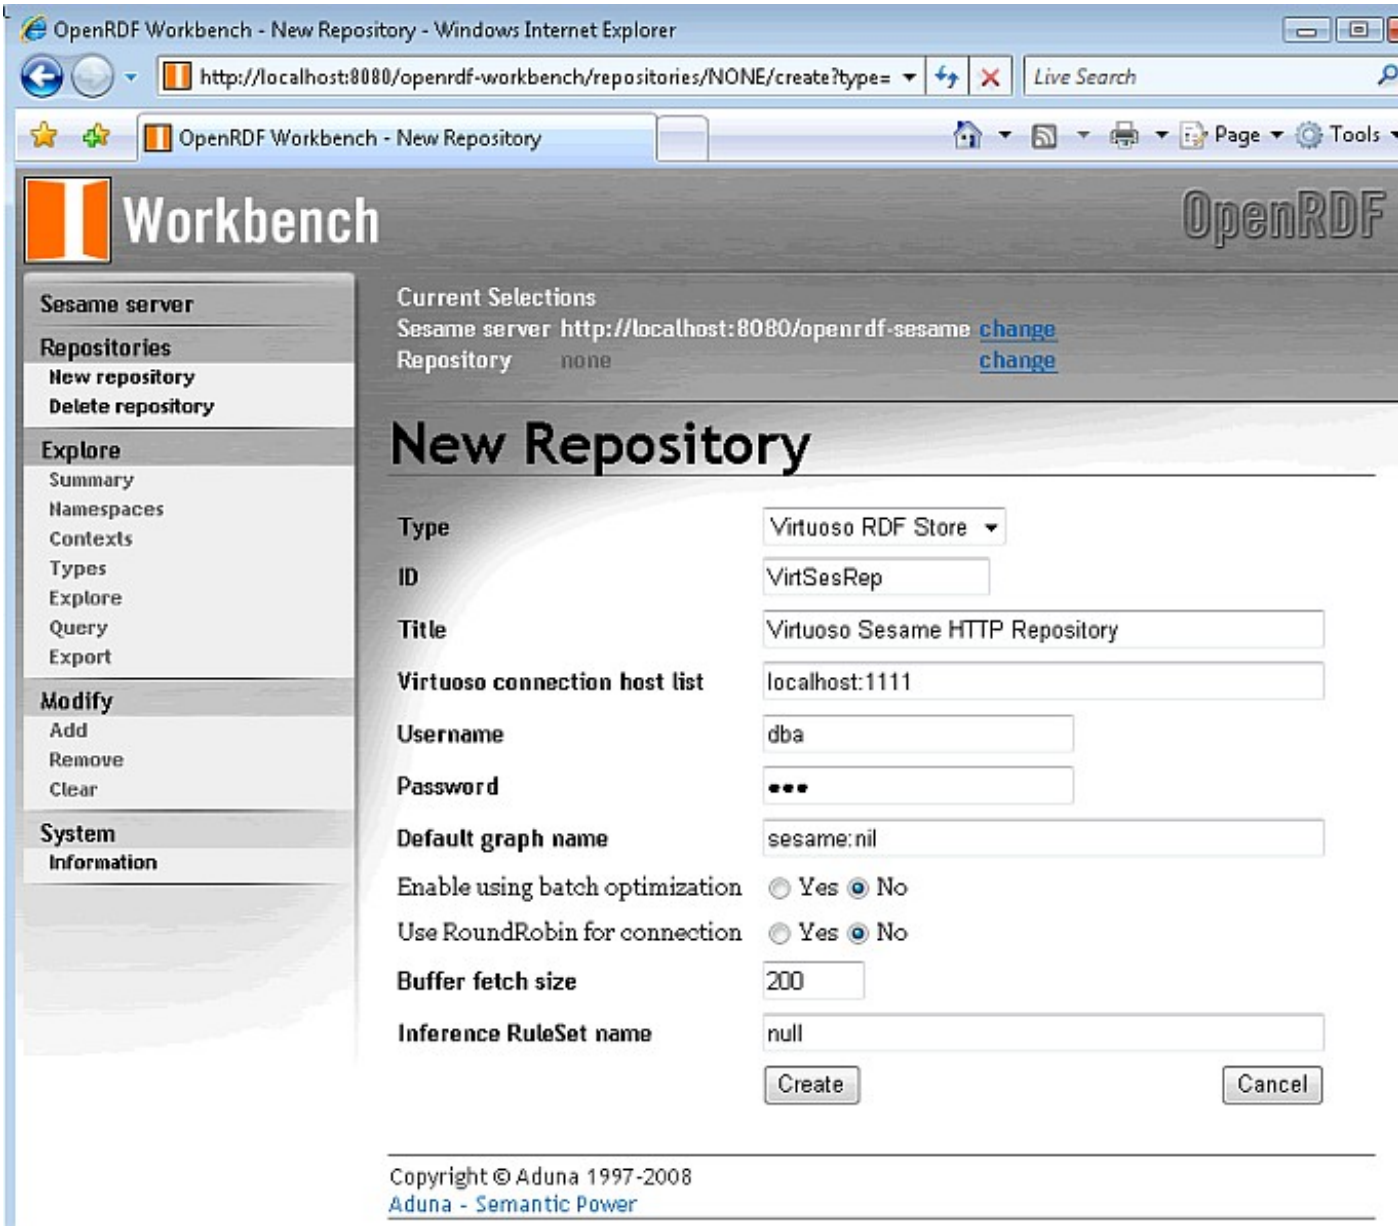
9. Choose suitable repository "ID" and "Title" for the Virtuoso repository to be created and click "Next".

Figure 16.190. Virtuoso Sesame HTTP Repository Configuration and Usage



10. Fill in the connection parameters for the target Virtuoso sever the repository is to be created for and click the "create" button. The minimum required are the hostname, port number, username and password of the Virtuoso Server.

Figure 16.191. Virtuoso Sesame HTTP Repository Configuration and Usage

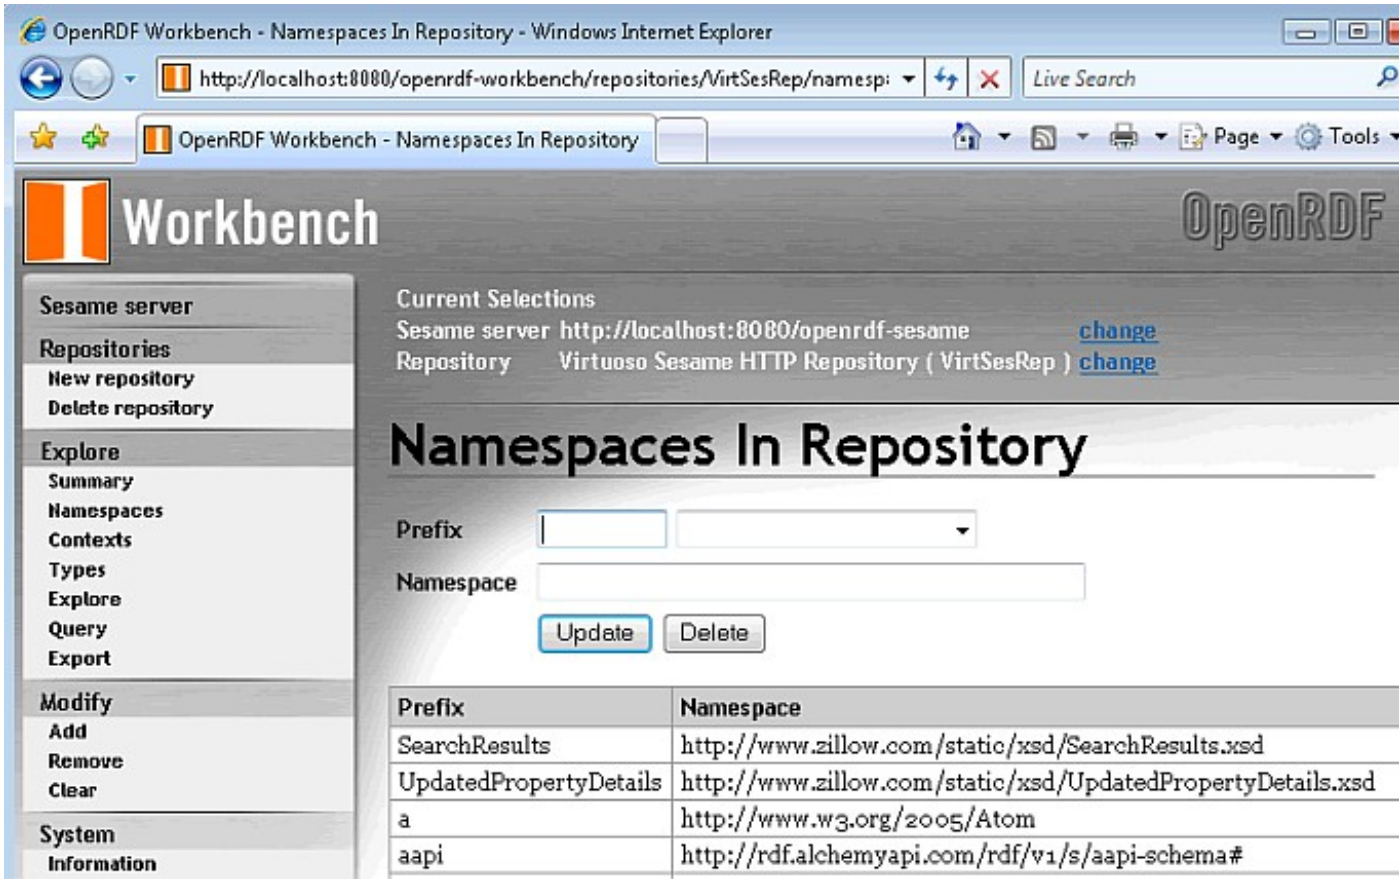


11. The new Virtuoso respository will be created and its summary page displayed.

Figure 16.192. Virtuoso Sesame HTTP Repository Configuration and Usage

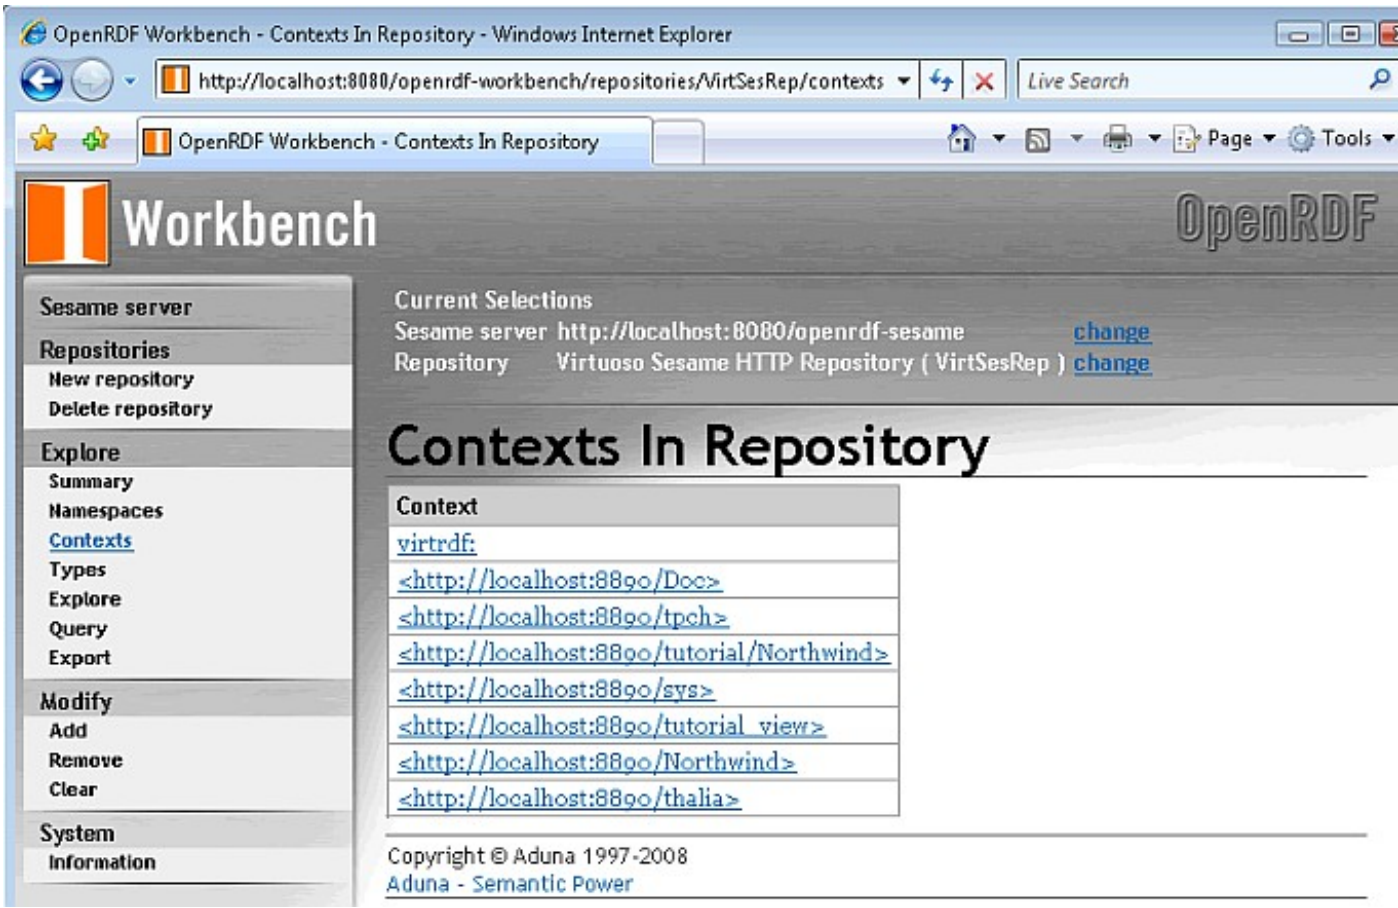
12. Click on the "Namespaces" link in the left frame to obtain a list of the available namespaces in the Virtuoso repository.

Figure 16.193. Virtuoso Sesame HTTP Repository Configuration and Usage



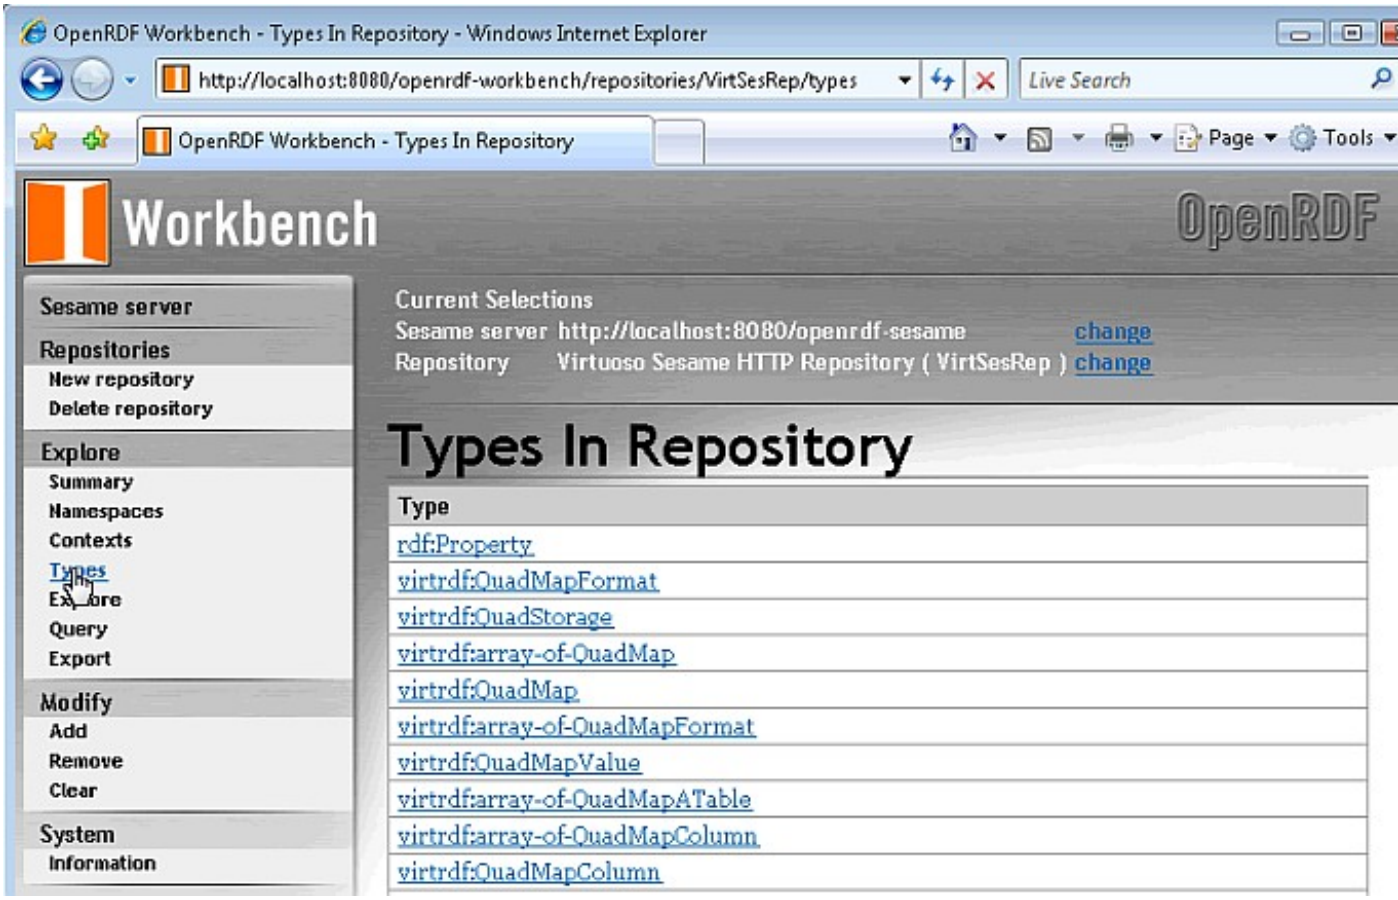
13. Click on the "Context" link in the left frame to obtain a list of the available contexts in the Virtuoso repository.

Figure 16.194. Virtuoso Sesame HTTP Repository Configuration and Usage



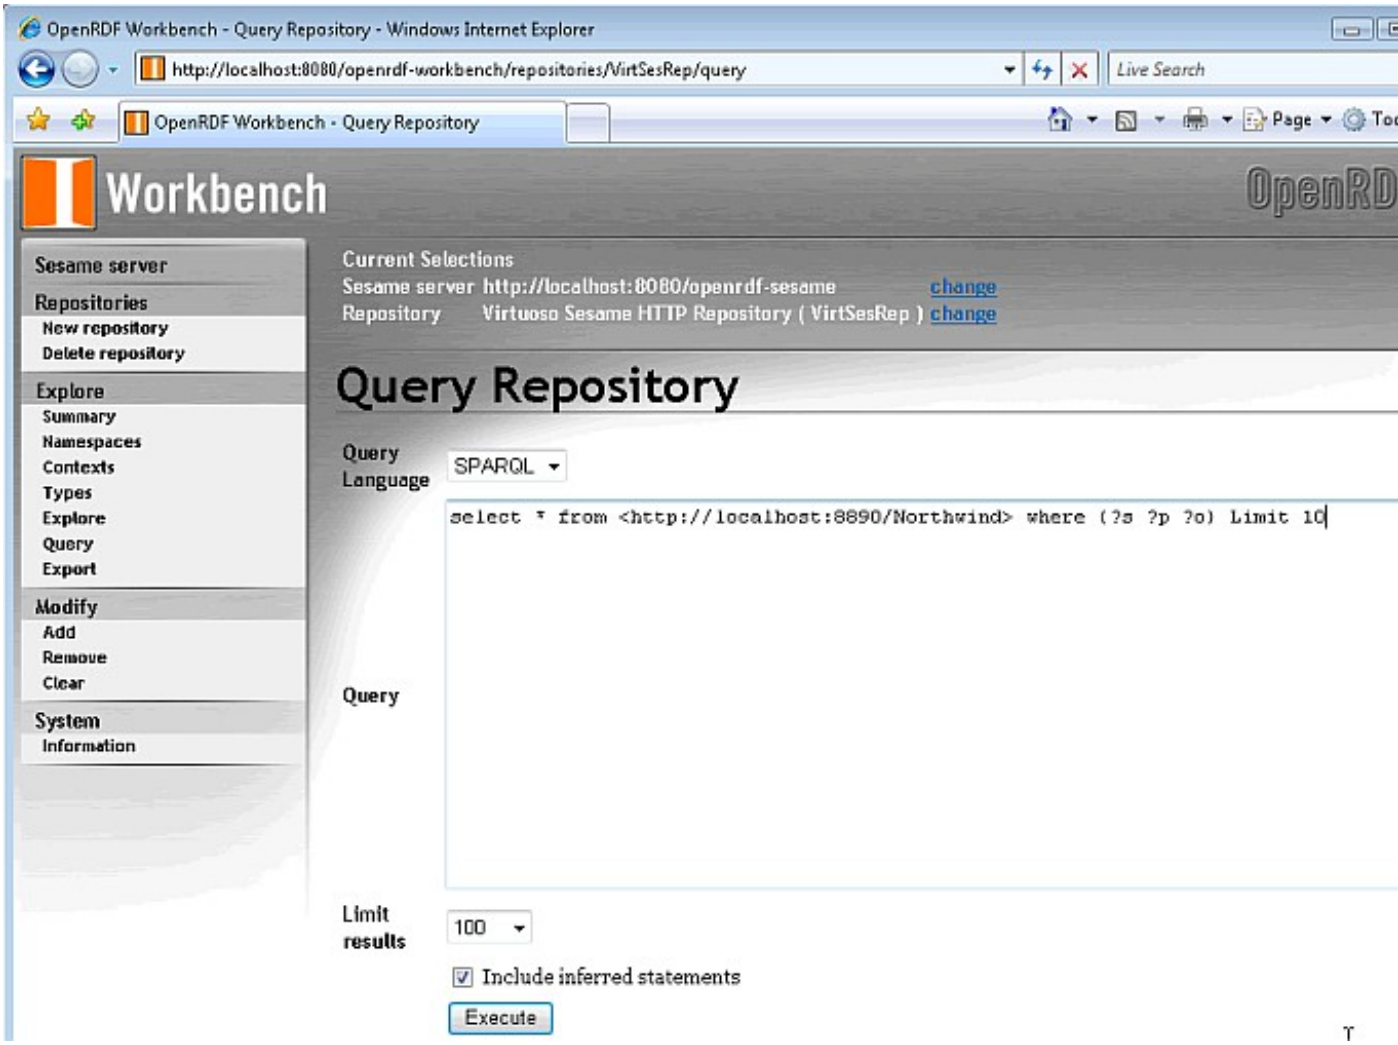
14. Click on the "Types" link in the left frame to obtain a list of the available types in the Virtuoso repository.

Figure 16.195. Virtuoso Sesame HTTP Repository Configuration and Usage



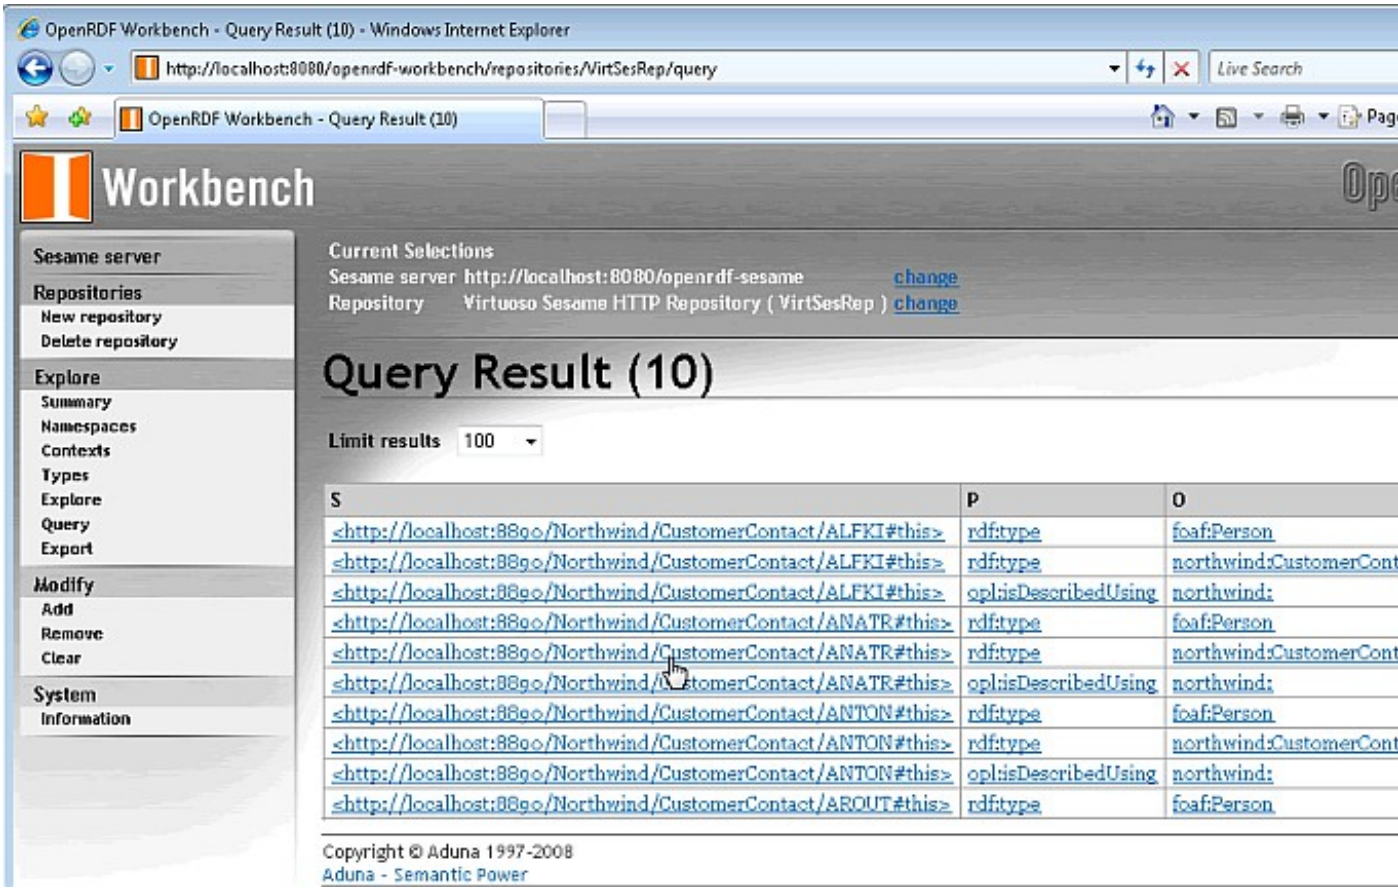
15. Click on the "Query" link in the left frame, enter a suitable SPARQL query to execute against the Virtuoso repository and click the "execute" button.

Figure 16.196. Virtuoso Sesame HTTP Repository Configuration and Usage



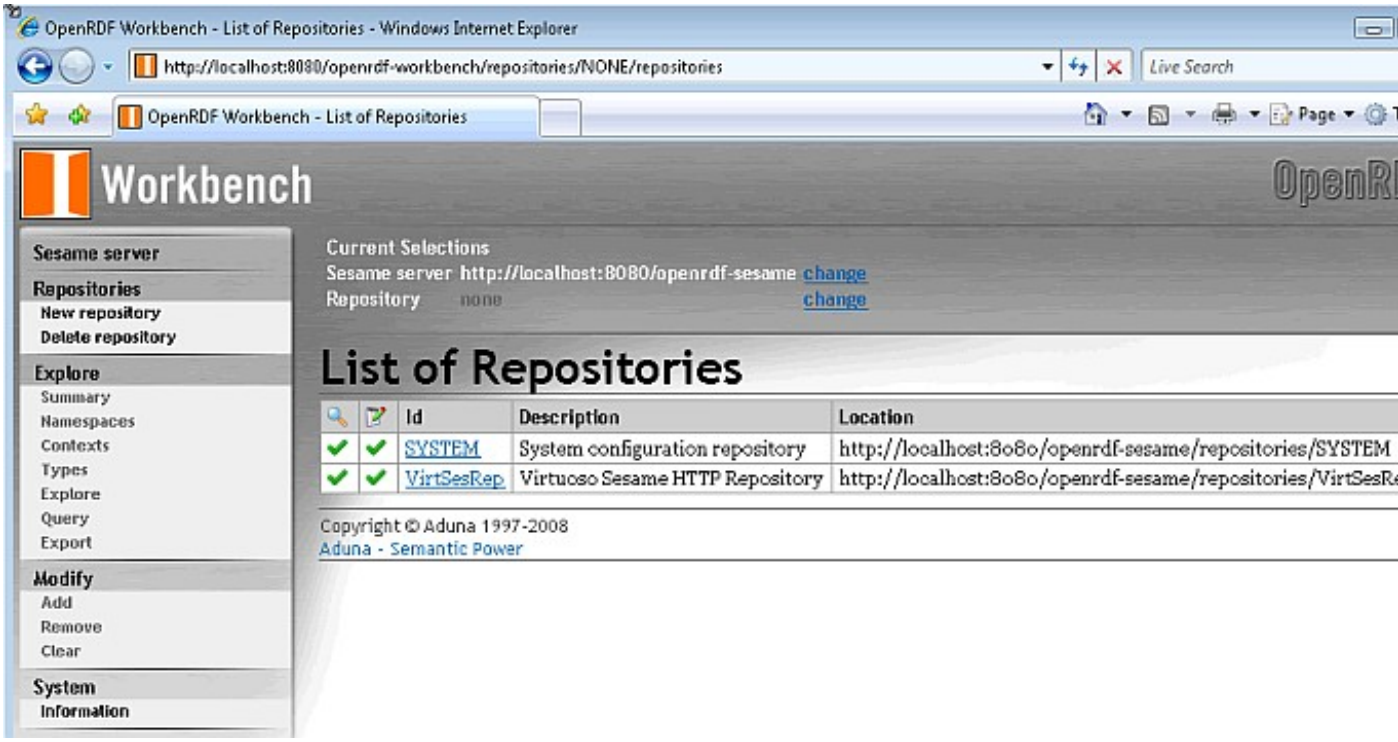
16. The results of the SPARQL query are returned.

Figure 16.197. Virtuoso Sesame HTTP Repository Configuration and Usage



17. Click on the "Repositories" link in the left frame and the newly created Virtuoso repository entry is displayed along side the default SYSTEM repository.

Figure 16.198. Virtuoso Sesame HTTP Repository Configuration and Usage



This section details the steps required for configuring and testing a Virtuoso Sesame Console Repository:

1. Extract Sesame 2.3.1 or higher archive to a location of choice and place the virt_sesame2.jar or virt_sesame4.jar and virtjdbc4.jar files to the sesame "lib" directory
2. Start the sesame console application by running the "console.bat" script in the sesame "bin" directory and then "exit." the program

```
$ sh console.sh
SLF4J: Class path contains multiple SLF4J bindings.
SLF4J: Found binding in [jar:file:/Users/myuser/openrdf-sesame-2.3.1/lib/logback-classic-0.9.18.ja
SLF4J: Found binding in [jar:file:/Users/myuser/openrdf-sesame-2.3.1/lib/slf4j-jdk14-1.5.10.jar!/o
SLF4J: See http://www.slf4j.org/codes.html#multiple_bindings for an explanation.
10:32:38.317 [main] DEBUG info.aduna.platform.PlatformFactory - os.name <http://os.name> <http://o
10:32:38.351 [main] DEBUG info.aduna.platform.PlatformFactory - Detected Mac OS X platform
Connected to default data directory
Commands end with '.' at the end of a line
Type 'help.' for help
exit.
```

3. This will create the necessary sesame application data directories as detailed in the sesame data directory configuration documentation.

```
Windows - C:\Documents and Settings\LocalService\Application Data\Aduna\
Mac OS X - /Users/myuser/Library/Application Support/Aduna/
Linux - $HOME/.aduna/
```

4. If you do not want to use the default sesame data directory location the Sesame console application can be started by specifying a custom data directory location with the "-d" option. Note in this case the directory "OpenRDF Sesame console" always has to be manually appended to the directory as Sesame assumes the data file will reside in a sub directory of this name.

```
$ sh console.sh -d /Users/myuser/OpenRDF Sesame console
```

5. Add the virtuoso.ttl file to the ~/OpenRDF Sesame console/templates folder, to enable the Virtuoso repository default configuration parameters to be located.
6. Start the sesame console application with the required data directory location and create a Virtuoso repository as detailed in the steps below, the key parameters to be specified being the target Virtuoso server hostname, port number, username, password and a unique "Repository ID".

```
$ sh console.sh
SLF4J: Class path contains multiple SLF4J bindings.

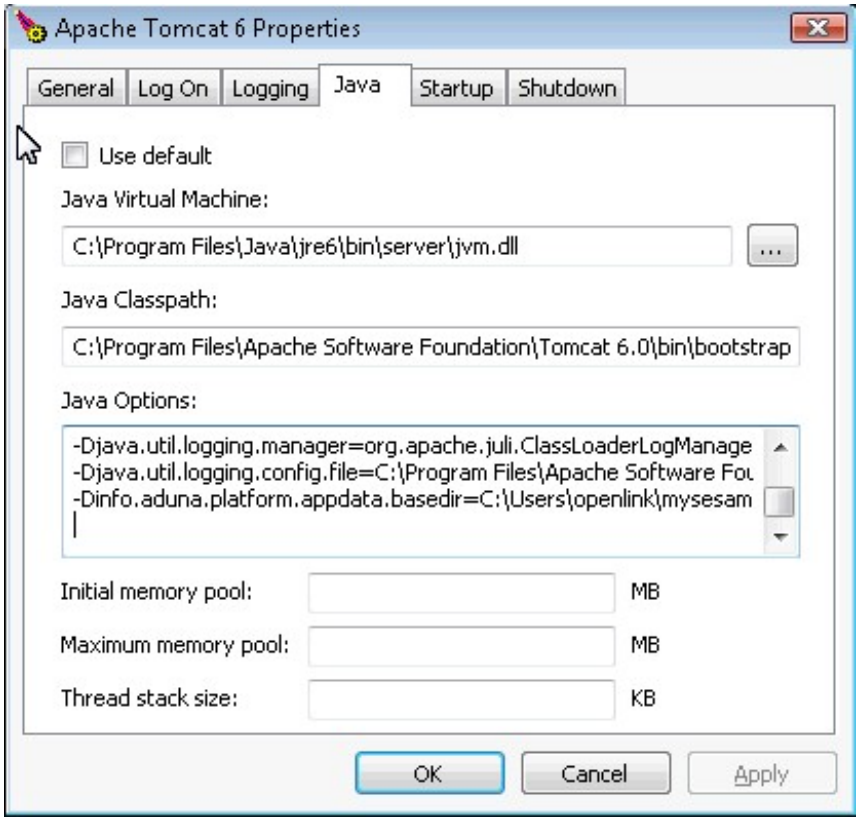
2. Conversely the Sesame HTTP repository can be configured to access the repository created by the Sesame console. To do this the location of the data directory for both needs to be reconfigured using the Java system property info.aduna.platform.appdata.basedir (does not include "OpenRDF Sesame console directory) to point to the same location. When you are using Tomcat as the servlet container then you can set this property using the JAVA_OPTS parameter. Note, if you are using Apache Tomcat as a Windows Service you should use the Windows Services configuration tool to set this property. Other users can either edit the Tomcat startup script or set the property some other way.

```
* set JAVA_OPTS=-Dinfo.aduna.platform.appdata.basedir=\path\to\other\dir\ (on Windows)
* export JAVA_OPTS='-Dinfo.aduna.platform.appdata.basedir=/path/to/other/dir/' (on Linux/UNIX/Ma
```

Figure 16.199. Virtuoso Sesame HTTP Repository Configuration and Usage



Remote Sesame HTTP Repository Connections

There are two methods of making a remote Sesame HTTP connection to a Virtuoso repository:

- *Sesame Remote Repository Manager*

  class - A manager for Repositorys that reside on a remote server, allowing one to access repositories over HTTP similar to how local repositories are accessed using the LocalRepositoryManager?. A connection via this method is made via the Virtuoso Sesame provider which will be faster and provide better support for transactions, than making a direct connection to the SPARQL endpoint using the HTTPRepository class. This is analogous to the ODBC Driver Manager in the ODBC realm for generic access to a data store via a suitable ODBC Driver.
- *Sesame HTTP Repository*

  class - A repository that serves as a proxy for a remote repository on a Sesame server or directly to a SPARQL endpoint. This method does not make use of the Virtuoso Sesame Provider, using instead the HTTP protocol to make requests directly Sesame server or other SPARQL endpoint.

Using the Sesame Remote Repository Manager class

If a Sesame HTTP Repository endpoint, as detailed above already exists, the Remote Repository Manager class can be used to make a remote connection as follows by specify the URL to the remote Sesame HTTP Server and the RepositoryID for the repository the connection is to be made to:

```
//Initialize Remote Repository Manager
RepositoryManager repositoryManager = new RemoteRepositoryManager( "http://hostname:portno/openrdf-sesame
repositoryManager.initialize();

//Set Virtuoso (or any other) repositoryID on http://hostname:portno/openrdf-sesame
Repository repository = repositoryManager.getRepository("RepositoryID");

// Open a connection to this repository
con = repository.getConnection();

// ... do something
```

Using the Sesame HTTP Repository class

A direct connection to the default built-in Virtuoso SPARQL Endpoint can be made using the Sesame HTTP Repository class by simply specifying the URL to the Virtuoso SPARQL Endpoint i.e. http://{hostname}:{port}/sparql as follows:

```
// Initialize Direct SPARQL Endpoint HTTP Repository connection
String endpointURL = "http://hostname:portno/sparql";
HTTPRepository sparqlEndpoint = new HTTPRepository(endpointURL, "");
sparqlEndpoint.initialize();

// Open a connection to this repository
con = sparqlEndpoint.getConnection();

// ... do something
```

Javadoc API Documentation

Sesame Provider Javadoc API Documentation is available enabling the complete set of classes, interfaces and methods implemented for the provider to be viewed.

16.18.3. Virtuoso Redland Provider

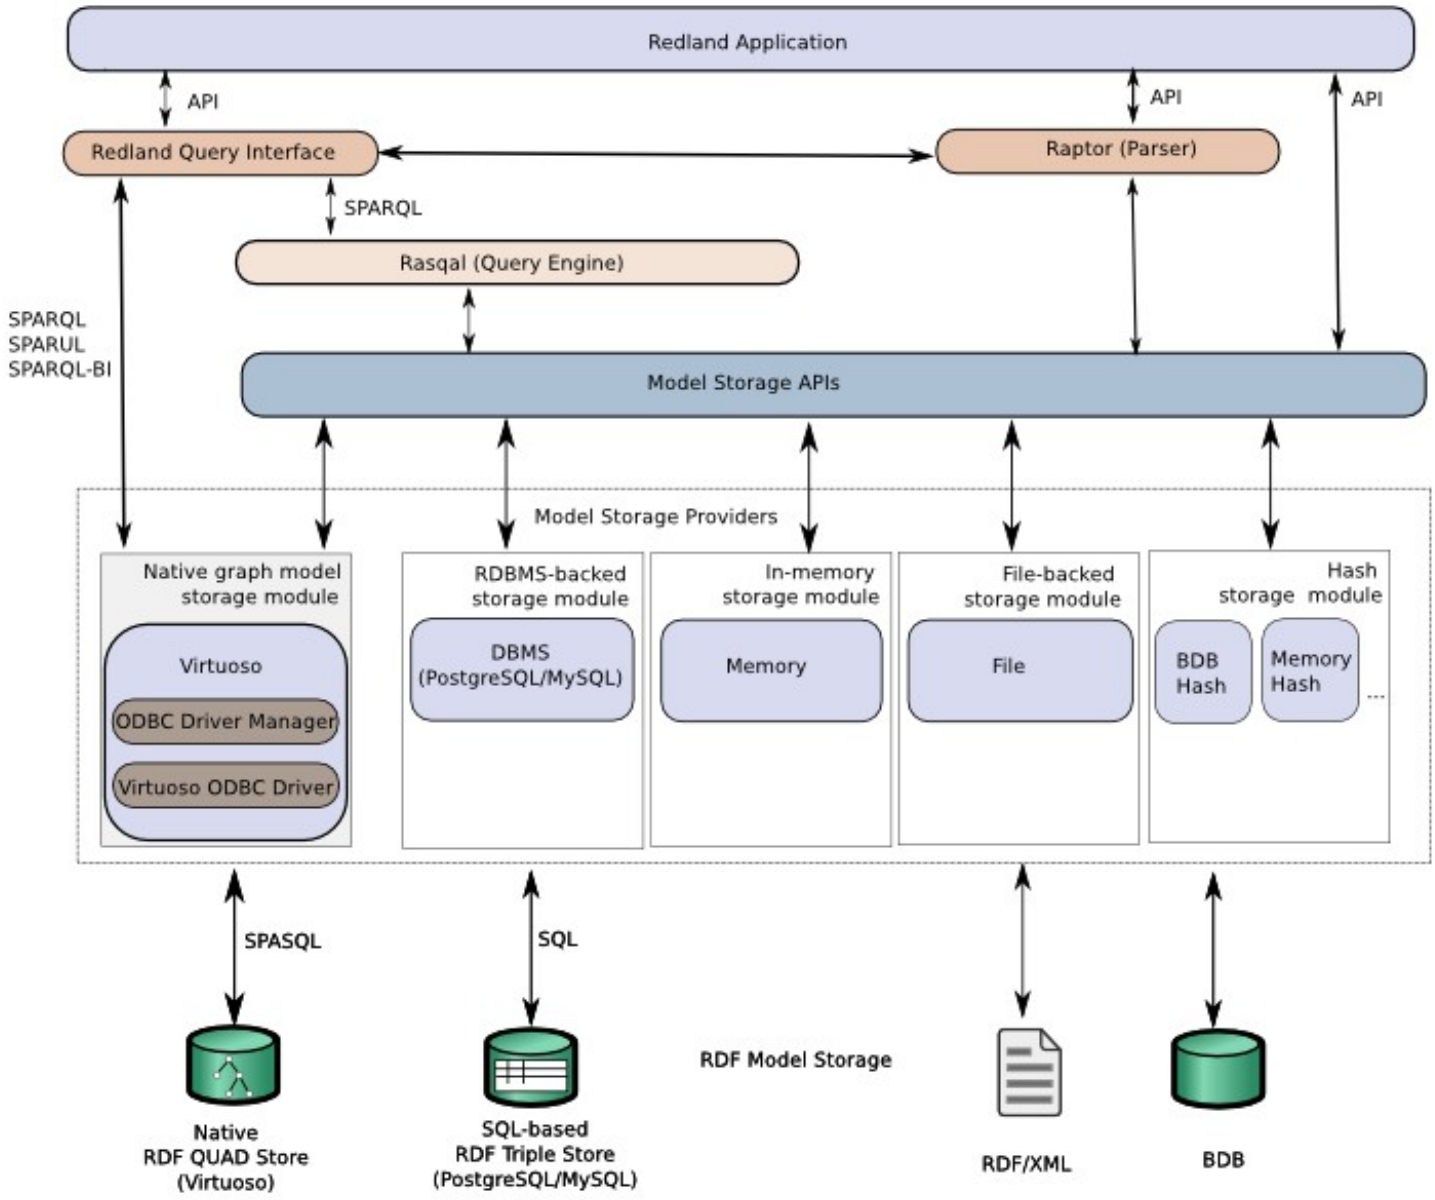
What is Redland

Redland is a set of free software 'C' libraries that provide support for the Resource Description Framework (RDF), providing modular, object based libraries and APIs for manipulating the RDF graph, triples, URIs and Literals. Redland includes several high-level language APIs providing RDF manipulation and storage and requires the Raptor RDF parser and Rasqal RDF syntax and query library for its use.

What is the Virtuoso Redland Provider

The Virtuoso Redland RDF Provider is an implementation of the Storage API, Model and Query interfaces of the Redland framework for RDF. This provider enables the execution of queries via the Redland Rasqal query engine or via Virtuoso query engine directly against the Virtuoso Quad store. The Virtuoso Redland Provider uses ODBC as the data access mechanism for communicating the Virtuoso Quad Store and requires the Virtuoso ODBC Driver be installed on the Redland client and a suitable ODBC DSN be configured for connecting to the target Virtuoso Quad Store instance. The provider has been tested against the Redland 1.0.8 version currently available for download.

Figure 16.200. Redland Component Stack



As indicated in the above diagram the Virtuoso Provider can be used to execute RDF queries either directly against the Virtuoso graph storage module supporting the SPARQL , SPARQL SPARUL, SPARQL-BI query languages or via the Rasqal query engine built into Redland which supports the SPARQL query language. This is done by simply changing the syntax of the query using the "vsparql" rather then default "sparql" construct when executing a query as indicated in the sample queries below:

```
rdfproc -r xml -t "user='dba',password='dba',dsn='Demo'" gr query sparql - "SELECT * WHERE { ?s ?p ?o }"

rdfproc -r xml -t "user='dba',password='dba',dsn='Demo'" gr query vsparql - "SELECT * WHERE { ?s ?p ?o }"
```

The Virtuoso Provider uses the SPASQL query language for querying the remote Virtuoso QUAD store.

Setup

Required Files

The Virtuoso Redland Provider has been integrated into the Redland RDF Framework and submitted to the open source project to become part of the standard distribution available for download . Until this submission has been accepted and committed into the available Redland release a tar ball created by OpenLink Software and a diff for application to a Redland 1.0.8 tree can be obtained from:

- ftp://download.openlinksw.com/support/vos/redland-vos-1.0.8.tar.gz Redland 1.0.8 tar ball with Virtuoso storage support
- Redland 1.0.8 Diff file of changes made for Virtuoso storage support

Compiling Redland with Virtuoso storage support

- Download Redland , extract and apply diff above or download the tar ball above with diff already applied and extract to a location of choice.
- The following additional configure options are available for enabling the Virtuoso storage support:

```
  --with-virtuoso(=yes|no) Enable Virtuoso RDF store (default=auto)
  --with-iodbc(=DIR)        Select iODBC support
                            DIR is the iODBC base install directory
                            (default=/usr/local)
  --with-unixodbc(=DIR)    Select UnixODBC support
                            DIR is the UnixODBC base install directory
                            (default=/usr/local)
  --with-datadirect(=DIR) Select DataDirect support
                            DIR is the DataDirect base install directory
                            (default=/usr/local)
  --with-odbc-inc=DIR      Specify custom ODBC include directory
                            (default=/usr/local/include)
  --with-odbc-lib=DIR      Specify custom ODBC lib directory
                            (default=/usr/local/lib)
```

- The "--with-virtuoso" option default to being auto enable if a valid ODBC Driver Manager (iODBC, UnixODBC? or DataDirect?) or include and lib directories for required ODBC header files and libraries are located with the suitable setting for one or more of the other ODBC related options above. Assuming iODBC is installed the following option can be used to enable Virtuoso storage support to be configured for compilation into your Redland build:

```
./configure --with-iodbc=/usr/local/iODBC
```

- Run "make" to compile the Redland libraries and "sudo make install" to install in the default "/usr/local" location
- Test compilation with test utility utils/rdfproc:

```
rdfproc test parse http://planetrdf.com/guide/rss.rdf
rdfproc test print
rdfproc test serialize ntriples
```

  This test will use the default 'hashes' storage.
- Ensure you have the Virtuoso ODBC Driver installed and a valid ODBC DSN called "Local Virtuoso" configured for your target Virtuoso Server
- Set the following environment variable:

```
export RDFPROC_STORAGE_TYPE=virtuoso                                    ;; Enable Virtuoso Storage
export ODBCINI=<path_to_odbcini_directory>/odbc.ini                       ;; Enable ODBC DSN to be
export LD_LIBRARY_PATH=/usr/local/lib:$LD_LIBRARY_PATH                      ;; May be required to e
```

- Test Virtuoso storage with the provided test program utils/vtest:

```
$ utils/vtest
  1: Remove all triples in <http://red> context
**PASSED**: removed context triples from the graph
  2: Add triples to <http://red> context
**PASSED**: add triple to context
  3: Print all triples in <http://red> context

Connection Parameters

The Virtuoso provider has the following connection parameters available fro use:

- *dsn*

  - ODBC datasource name
- *user*

  - user name of database server
- *password*

  - password of database server
- *host*

  - hostname:portno of the database server
- *charset*

  - database charset to use

NOTE: Take care exposing the password as for example, program arguments or environment variables. The rdfproc utility can help this by reading the password from standard input. Inside programs, one way to prevent storing the password in a string is to construct a Redland hash of the storage options such as via librdf hash_from_string and use librdf_new_storage_with_options to create a storage. The rdfproc utility source code demonstrates this.

The storage name parameter given to the storage constructor librdf new_storage is used inside the virtuoso store to allow multiple stores inside one Virtuoso database instance as parameterized with the above options.

This store always provides contexts; the boolean storage option contexts is not checked.

Examples:

```
/* A new Virtuoso store */
storage=librdf_new_storage(world, "virtuoso", "db1",
    "dsn='Local Virtuoso',user='demo',password='demo'");

/* A different, existing Virtuoso store in the same database as above */
storage=librdf_new_storage(world, "virtuoso", "db2",
    "dsn='Local Virtuoso',user='demo',password='demo'");

/* An existing Virtuoso store on a different database server */
storage=librdf_new_storage(world, "virtuoso", "http://red3",
    "dsn='Remote Virtuoso',user='demo',password='demo'");

/* Opening with an options hash */
options=librdf_new_hash(world, NULL);
librdf_hash_from_string(options,
    "dsn='Local Virtuoso',user='demo'");
librdf_hash_put_strings(options, "password", user_password);
storage=librdf_new_storage_with_options(world, "virtuoso", "http://red3", options);
```

16.19. RDF Graph Replication

The following section demonstrates how to replicate graphs from one Virtuoso instance to (an)other Virtuoso instance(s), using the RDF Replication Feature.

Terms used in this section:

- *Host Virtuoso Instance*

  , aka the publisher: the instance where we will insert RDF data into a Named Graph; then create a publication of this graph.
- *Destination Virtuoso Instance*

  , aka the subscriber: the instance which will subscribe to the publication from the Host Virtuoso Instance.

See Also:

`DB.DBA.RDF_REPL_START()`

`DB.DBA.RDF_REPL_GRAPH_INS()`

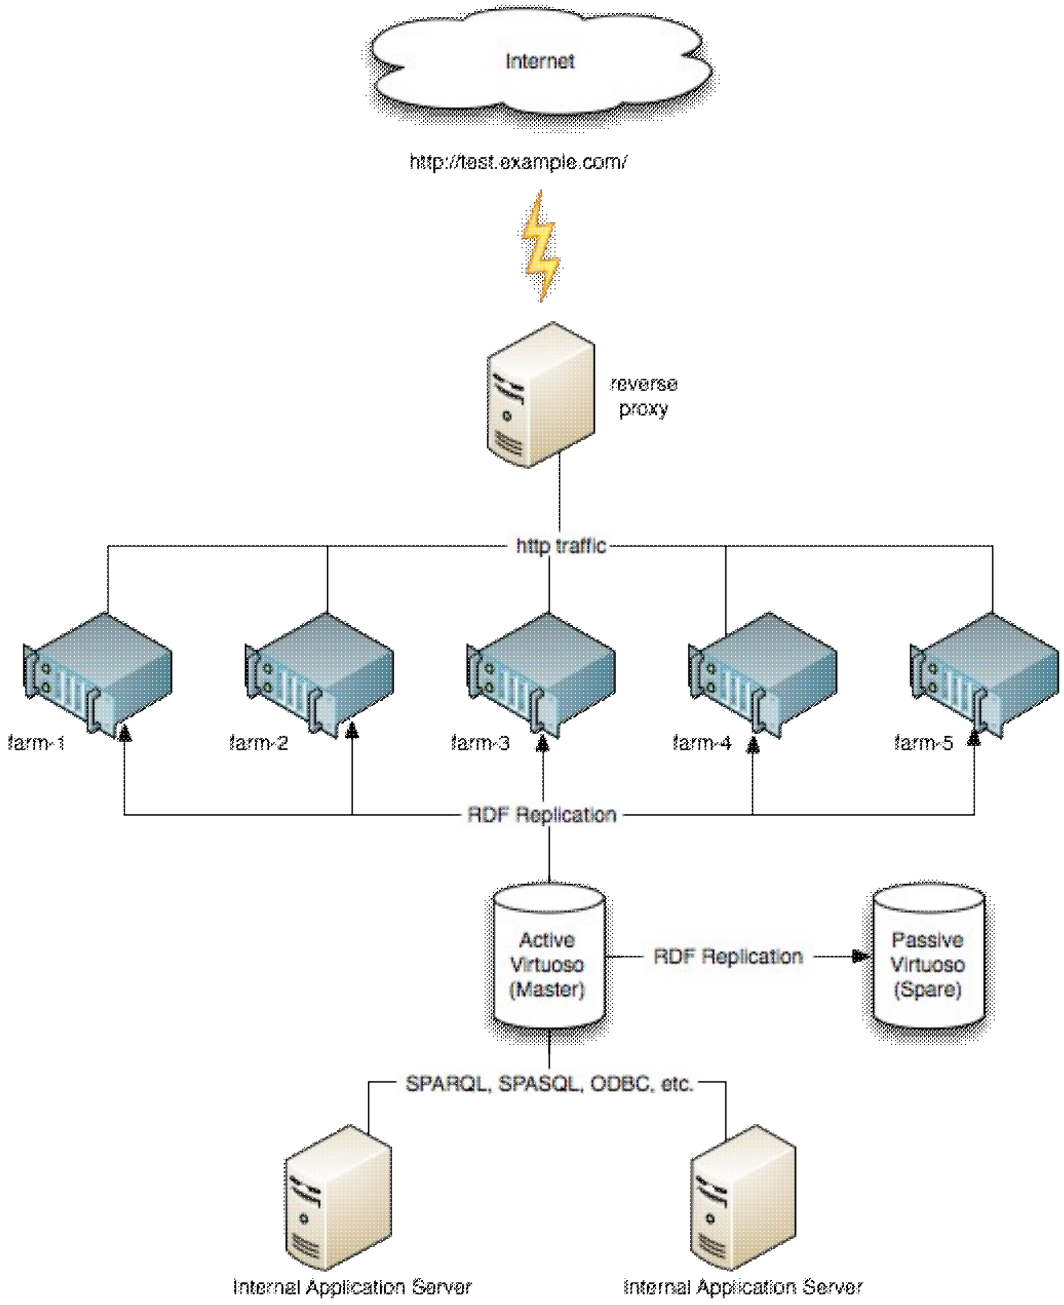
`DB.DBA.RDF_RDF_REPL_GRAPH_DEL()`

The basic outline:

- First, use the Virtuoso Conductor on a Host Virtuoso Instance to publish a named graph.
- Then, use the Virtuoso Conductor on a Destination Virtuoso Instance to subscribe to deltas from the published graph.
- Finally, see how a change in the publisher's graph will appear in the subscriber's graph.

16.19.1. Replication Scenarios

Figure 16.201.



Introduction

In this section we will examine a proposed setup for a back-end server called MASTER which publishes a number of graphs to a set of front-end machines called FARM-1 .. FARM-n and discuss a couple of common scenarios like adding an extra machine to the farm, or replacing a broken instance of MASTER.

In this example we will assume each virtuoso instance running on its own machine, so they can use the same port numbers for both the main server (default 1111) as well as the http port (default 8890) as each machine has an unique IP addresses. In the example we use MASTER-IP and FARM-x-IP which should be replaced by either the real IP address or the DNS name of the machine in question.

Since there will be a reverse-proxy service in front of the farm, all virtuoso instances should have the URIQA Default host set to the outside name for this service. In this example we will use http://test.example.com as the web service we are trying to setup.

Setup

Installing Virtuoso

All machines in this setup should be installed with similar installation paths like:

- /opt/virtuoso
- /dbs/virtuoso
- /virtuoso
- ...

The partition should be big enough to have room for the Virtuoso binaries and libraries, the transaction logs, backups and, if you do not want to use the striping feature of Virtuoso, it will need to have room for the main database files as well.

Here are the quick installation steps:

1. Login as root.
2. Create local user called virtuoso using the chosen installation path as home direcotory.
3. Login as virtuoso.
4. Extract virtuoso-universal-server-6.1.tar in home directory.
5. Run sh install.sh to install Virtuoso.
6. Remove the file install.sh virtuoso-universal-server-6.1.tar virtuoso-server.taz if not otherwise needed.
7. Run bin/virtuoso-stop.sh to shutdown this Virtuoso instance.
8. Install virtuoso.lic for this system in $HOME/bin directory.

As the replication process needs to make an ODBC connection to the MASTER machine, all machines should have the following information in the $HOME/bin/odbc.ini:

```
[ODBC Data Sources]
..
MASTER_DSN = OpenLink Virtuoso

..
[MASTER_DSN]
Driver = OpenLink Virtuoso
Address = MASTER_IP:1111
```

Setting up MASTER

The MASTER machine is the back-end server machine. Various applications feed SPARQL data into this machine it publishes a set of graphs using RDF Replication.

The MASTER machine should ideally be equipped with multiple redundant disks in RAID-1 or RAID-6 mode to minimize the risk that a single bad disk takes down the system. From a Virtuoso point of view we will use a combination of online backups combined with checkpoint audit trail to backup the content of the database in a safe way. The online backups, the checkpoint audit trail as well as the replication logs can also be copied to secondary storage using the rsync command and can be easily scripted as a cron job.

Changes to database/virtuoso.ini:

```
...
[Parameters]
SchedulerInterval    = 1     ; run the internal scheduler every minute
CheckpointAuditTrail = 1     ; enable audit trail on transaction logs
CheckpointInterval   = 60    ; perform an automated checkpoint every 60 minutes
...
[URIQA]
DefaultHost = test.example.com
...
[Replication]
ServerName   = MASTER
ServerEnable = 1
QueueMax     = 5000000
...
```

Once the MASTER is started using the bin/virtuoso-start.sh script we must enable RDF replication before we start add data to the graphs we wish to replicate, so every record is accounted for by the replication process. If there is existing data in the graphs to be

published, then this data would need to be added to a subscriber manually since the replication process creates a delta set of changes since publishing was enabled.

To enable publishing of the graph we use the isql program to connect to the MASTER instance:

```
$ isql MASTER-IP:1111

-- and run the following commands:

-- enable this instance as a publisher
rdf_repl_start();

-- add graphs to replication list
rdf_repl_graph_ins('http://test.example.com');
```

Next we create a backup directory inside the database directory and setup the online backup, again using the isql program:

```
$ cd database
$ mkdir backup
$ isql MASTER_IP:1111

-- and run the following commands:

-- clear any previous context
backup_context_clear();

-- start the backup
backup_online ('bkup-#', 1000000, 0, vector ('backup'));
```

The following files can now be backed up using rsync or similar tool to another machine:

Table 16.22. Files that can be backed up using rsync or similar tool to another machine

Files	Description
database/backup/*.bp	the incremental backup files
database/virtuoso.trx	the main transaction log containing the most recent updates to the database that have not been checkpointed into the database
database/virtuosoTIMESTAMP.trx	all the previous transaction logs which can be used to reconstruct the database
database/__rdf_repl*.log	all the replication logs containing the changes to the published graph

NOTE: Since the database is constantly modified during operation, it is of NO use to backup the virtuoso.db using an rsync script unless the virtuoso instance was shutdown beforehand, or certain extra precautions are taken which we will explain later on.

Setup SPARE master

The SPARE machine is a replica of the MASTER machine. This machine subscribes to the publication of the MASTER to keep an exact match of the RDF graphs, but also publishes this data without any initial subscribers.

The SPARE machine should ideally be equipped similar to the MASTER machine, with multiple redundant disks in RAID-1 or RAID-6 mode to minimize the risk that a single bad disk takes down the system. From a Virtuoso point of view we will use a combination of online backups combined with checkpoint audit trail to backup the content of the database in a safe way. The online backups, the checkpoint audit trail as well as the replication logs can also be copied to secondary storage using the rsync command and can be easily scripted as a cron job.

Changes to database/virtuoso.ini:

```
...
[Parameters]
SchedulerInterval    = 1     ; run the internal scheduler every minute
CheckpointAuditTrail = 1     ; enable audit trail on transaction logs
CheckpointInterval   = 60    ; perform an automated checkpoint every 60 minutes
...
[URIQA]
```

```
DefaultHost = test.example.com
...
[Replication]
ServerName   = SPARE
ServerEnable = 1
QueueMax     = 5000000
...
```

We must enable RDF replication before we start add data to the graphs we wish to replicate, so every record is accounted for by the replication process. If there is existing data in the graphs to be published, then this data would need to be added to a subscriber manually since the replication process creates a delta set of changes since publishing was enabled.

To enable publishing of the graph, as well as subscribing to the MASTER, we first start up this Virtuoso instance with bin/virtuoso-start.sh and then use the isql program to connect to the SPARE instance:

```
$ bin/virtuoso-start.sh
$ isql SPARE-IP:1111

-- and run the following commands:

-- enable this instance as a publisher
rdf_repl_start();

-- add graphs to replication list
rdf_repl_graph_ins('http://test.example.com');

-- connect to master
repl_server ('MASTER', 'MASTER_DSN');

-- start subscribing to __rdf_repl
repl_subscribe ('MASTER', '__rdf_repl', 'dav', 'dav', 'dba', 'dba');

-- start initial replication
repl_sync_all ();

-- add subscription to scheduler
DB.DBA.SUB_SCHEDULE ('MASTER', '__rdf_repl', 1);
```

Next we create a backup directory inside the database directory and setup the online backup, again using the isql program:

```
$ cd database
$ mkdir backup
$ isql SPARE_IP:1111

--and run the following commands:

-- clear any previous context
backup_context_clear();

-- start the backup
backup_online ('bkup-#', 1000000, 0, vector ('backup'));
```

The following files can now be backed up using rsync or similar tool to another machine:

Table 16.23. Files that can be backed up using rsync or similar tool to another machine

Files	Description
database/backup/*.bp	the incremental backup files
database/virtuoso.trx	the main transaction log containing the most recent updates to the database that have not been checkpointed into the database
database/virtuosoTIMESTAMP.trx	all the previous transaction logs which can be used to reconstruct the database
database/__rdf_repl*.log	all the replication logs containing the changes to the published graph

Note: Since the database is constantly modified during operation, it is of NO use to backup the virtuoso.db using an rsync script unless the virtuoso instance was shutdown beforehand, or certain extra precautions are taken which we will explain later on.

Setup FARM-1

The FARM-1 machine is the first front-end server machine. It subscribes to the publication of the MASTER instance to keep up-to-date.

The FARM-1 machine can be run on simpler hardware than the MASTER instance.It does not require the same level of redundancy in terms of hard disks etc, as there are a number of these machines running in parallel each capable of returning results to the proxy. If one FARM machine dies, it can simply be taken from the reverse-proxy list, repaired or replaced with a fresh machine before it is added to the list of servers in the reverse proxy. As such it does not need to be backed up separately, although we could make a backup of this installation to quickly install the rest of the identical FARM boxes.

Change the database/virtuoso.ini file:

```
...
[Parameters]
SchedulerInterval    = 1     ; run the internal scheduler every minute
CheckpointAuditTrail = 0     ; disable audit trail on transaction logs
CheckpointInterval   = 60    ; perform an automated checkpoint every 60 minutes
...
[URIQA]
DefaultHost = test.example.com
...
[Replication]
ServerName   = FARM-1        ; each FARM machine needs to have a unique replication name
ServerEnable = 1
QueueMax     = 5000000
...
```

Next we start up the Virtuoso instance using the bin/virtuoso-start.sh command and use the isql program to subscribe to the MASTER:

```
$ bin/virtuoso-start.sh
$ isql FARM-1-IP:1111

-- connect to master
repl_server ('MASTER', 'MASTER_DSN');

-- start subscribing to __rdf_repl
repl_subscribe ('MASTER', '__rdf_repl', 'dav', 'dav', 'dba', 'dba');

-- start initial replication
repl_sync_all ();

-- add subscription to scheduler
DB.DBA.SUB_SCHEDULE ('MASTER', '__rdf_repl', 1);
```

At this point we can shutdown this Virtuoso instance using the bin/virtuoso-stop.sh command and make a copy of the whole virtuoso installation as a blueprint to copy to another FARM-x machine.

Setup FARM-2 from scratch

We can repeat the same steps we did for the FARM-1 machine, and just make sure we use FARM-2 as the replication name in the database/virtuoso.ini file and use FARM-2-IP:1111 as an argument to the isql program.

Change bin/virtuoso.ini:

```
[Replication]
ServerName = FARM-2
```

Setup FARM-3 using blueprint from FARM-1 installation

Extract the tarred/zipped copy of the installation made at the end of the setup of FARM-1.

Before starting up the instance, we only need to give this instance a unique name for replication:

Change bin/virtuoso.ini:

```
[Replication]
ServerName = FARM-3
```

Next we start up the Virtuoso instance using the bin/virtuoso-start.sh command and since the subscription records and schedule are already performed in the previous step, we just use the isql program to perform a sync against the MASTER:

```
$ bin/virtuoso-start.sh
$ isql FARM-3-IP:1111

-- change replication name
DB.DBA.REPL_SERVER_RENAME ('FARM-1', 'FARM-3')

-- sync against master
repl_sync_all();
```

Setup FARM-4 using clone of FARM-1

If the system has been running for some time, it may not be practical to do a replication from start, so there is an alternative way to setup a new FARM-4 machine.

We can either restore the blue-print backup we make at the end of FARM-1 installation, or we do a fresh installation of virtuoso on the FARM-4 machine.

In both cases we shutdown the virtuoso instance and remove the database, as we are going to replace this.

```
$ bin/virtuoso-stop.sh
$ cd database
$ rm virtuoso.db virtuoso.trx virtuoso.log virtuoso.pxa
```

Change the database/virtuoso.ini file:

```
...
[Parameters]
SchedulerInterval    = 1     ; run the internal scheduler every minute
CheckpointAuditTrail = 0     ; disable audit trail on transaction logs
CheckpointInterval   = 60    ; perform an automated checkpoint every 60 minutes
...
[URIQA]
DefaultHost = test.example.com
...
[Replication]
ServerName   = FARM-4        ; each FARM machine needs to have a unique replication name
ServerEnable = 1
QueueMax     = 5000000
...
```

Next we are going to temporarily disable checkpointing on FARM-1 machine so we can copy its database without risking corruption:

```
$ isql FARM-1-IP:1111

-- disable automatic checkpointing
checkpoint_interval (-1);

-- and do an explicit checkpoint
checkpoint;
```

It is now safe to copy the database across using the rsync command:

```
$ rsync -avz virtuoso@FARM-1-IP:/path/to/virtuoso/database/virtuoso.db database/virtuoso.db
```

Next we re-enable checkpoint interval on FARM-1:

```
$ isql FARM-1-IP:1111

-- re-enable checkpointing
checkpoint_interval(60);
```

The last step is to start the database:

```
$ bin/virtuoso-start.sh
$ isql FARM-4-IP:1111

-- change replication name
DB.DBA.REPL_SERVER_RENAME ('FARM-1', 'FARM-4')

-- sync against master
repl_sync_all();
```

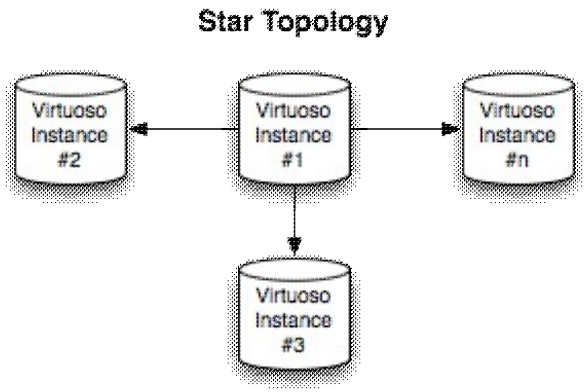
16.19.2. Replication Topologies

Typical replication topologies are Chains, Stars and Bi-directional. They can be achieved with Virtuoso, by repeating the "Publish" and/or "Subscribe" steps on each relevant node.

Star Replication Topology

In a Star, there is one Publisher, and many Subscribers.

Figure 16.202. Star Replication Topology



To set up a Star, follow the scenario:

1. Configure Instance #1 to Publish.
2. Configure Instance #2 to Subscribe to #1.
3. Repeat as necessary.

Star Replication Topology Example

The following How-To walks you through setting up Virtuoso RDF Graph Replication in a Star Topology.

Prerequisites

Database INI Parameters

Suppose there are 3 Virtuoso instances respectively with the following ini parameters values:

1. virtuoso1.ini:

```
...
[Database]
DatabaseFile    = virtuoso1.db
TransactionFile = virtuoso1.trx
ErrorLogFile     = virtuoso1.log
...
[Parameters]
ServerPort              = 1111
SchedulerInterval       = 1
...
```

```
[HTTPServer]
ServerPort                  = 8891
...
[URIQA]
DefaultHost = example.com:8891
...
[Replication]
ServerName   = db1
...
```

2. virtuoso2.ini:

```
...
[Database]
DatabaseFile    = virtuoso2.db
TransactionFile = virtuoso2.trx
ErrorLogFile     = virtuoso2.log
...
[Parameters]
ServerPort               = 1112
SchedulerInterval        = 1
...
[HTTPServer]
ServerPort                  = 8892
...
[URIQA]
DefaultHost = localhost:8892
...
[Replication]
ServerName   = db2
...
```

3. virtuoso3.ini:

```
...
[Database]
DatabaseFile    = virtuoso3.db
TransactionFile = virtuoso3.trx
ErrorLogFile     = virtuoso3.log
...
[Parameters]
ServerPort               = 1113
SchedulerInterval        = 1
...
[HTTPServer]
ServerPort                  = 8893
...
[URIQA]
DefaultHost = example.com:8893
...
[Replication]
ServerName   = db3
...
```

Database DSNs

Use the ODBC Administrator on your Virtuoso host (e.g., on Windows, Start menu -> Control Panel -> Administrative Tools -> Data Sources (ODBC); on Mac OS X, /Applications/Utilities/OpenLink ODBC Administrator.app) to create a System DSN for each of db1, db2, db3, with names db1, db2 and db3, respectively.

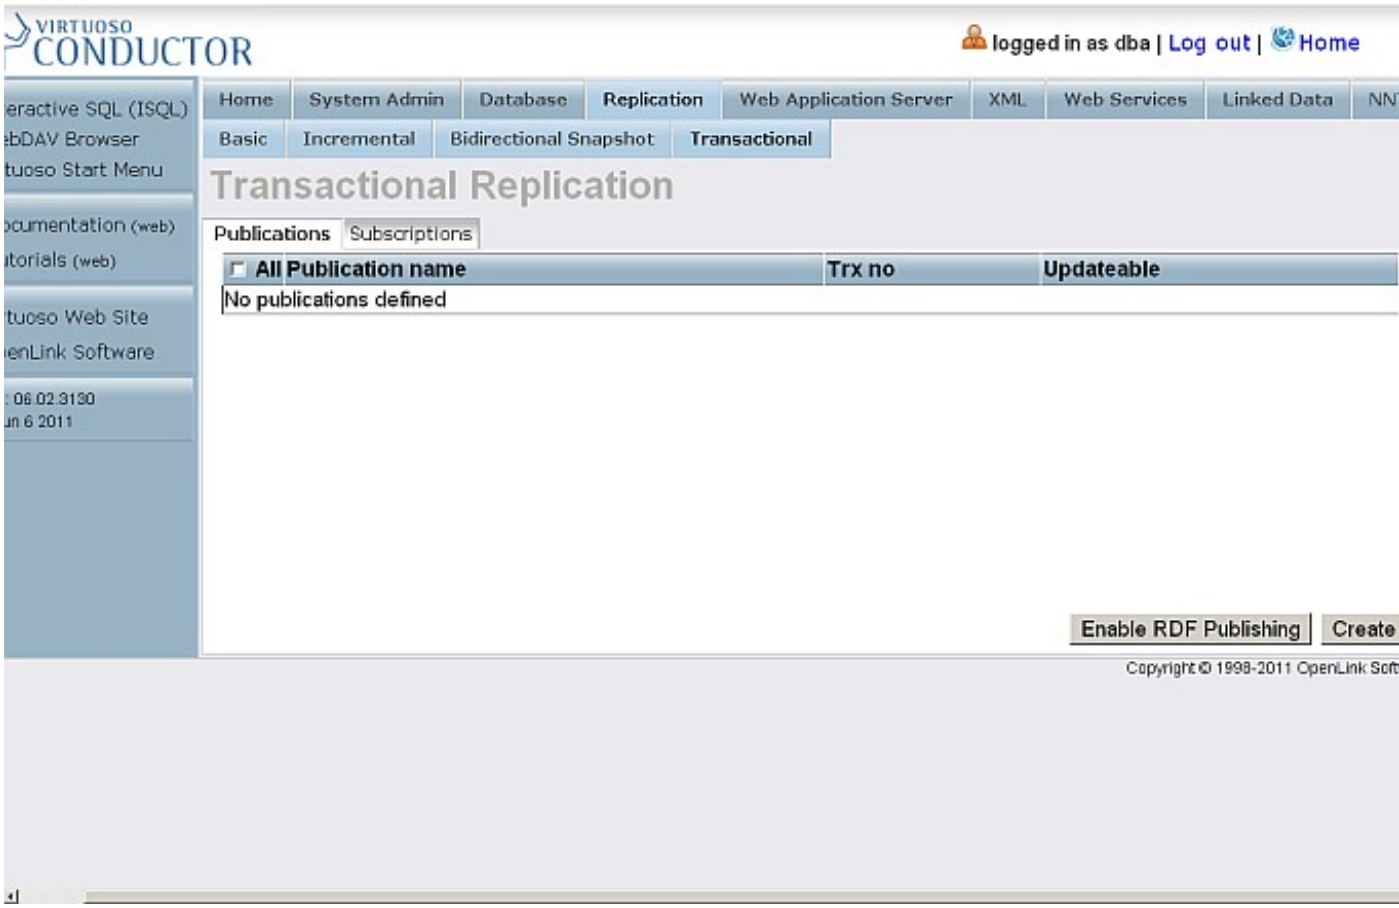
Install Conductor package

On each of the 3 Virtuoso instances install the conductor_dav.vad package.

Create a Publication on the Host Virtuoso Instance db1

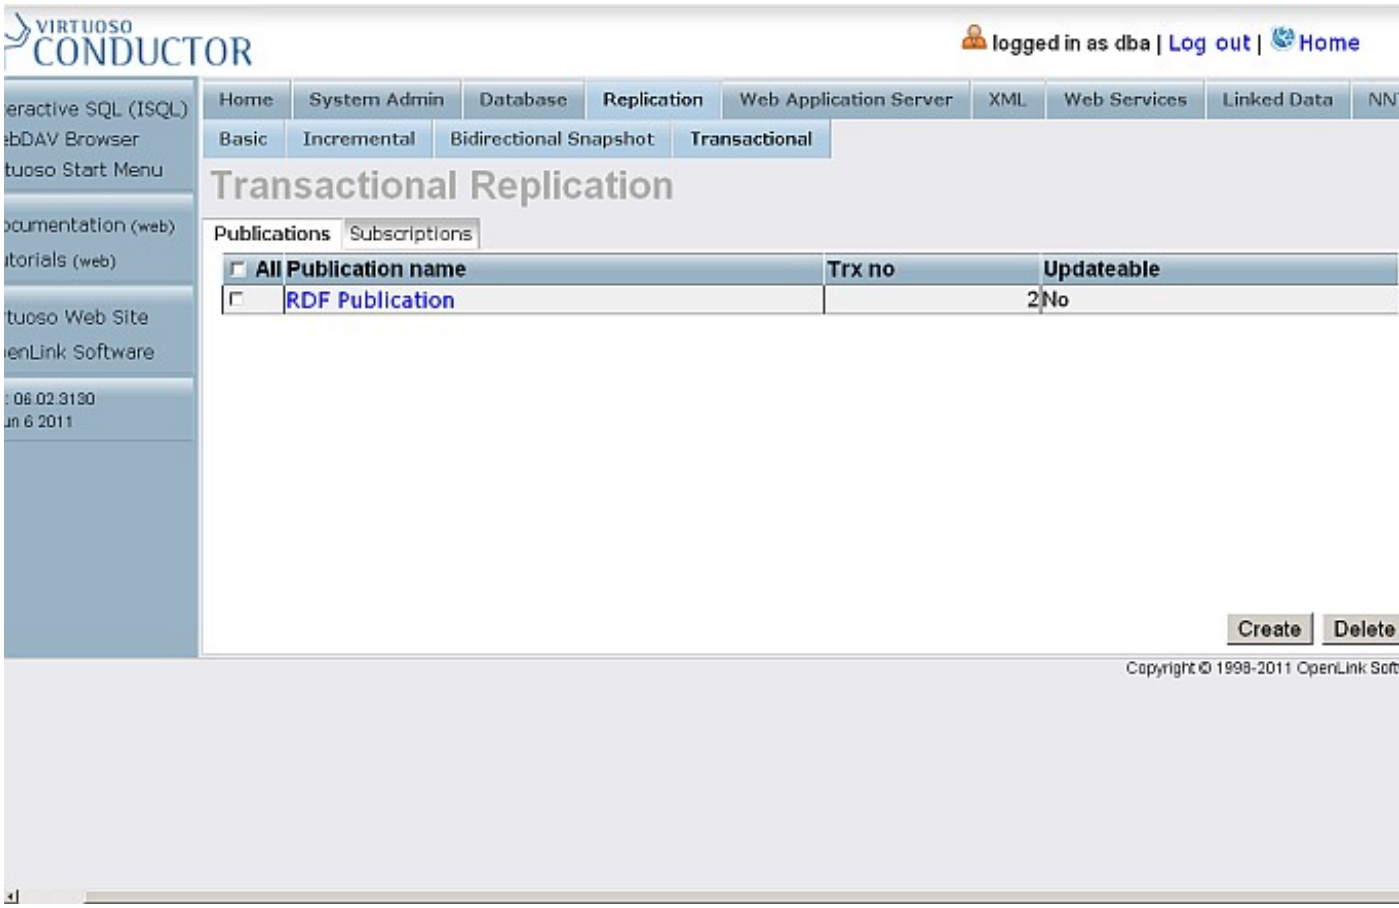
1. Go to Conductor -> Replication -> Transactional -> Publications

Figure 16.203. Star Replication Topology



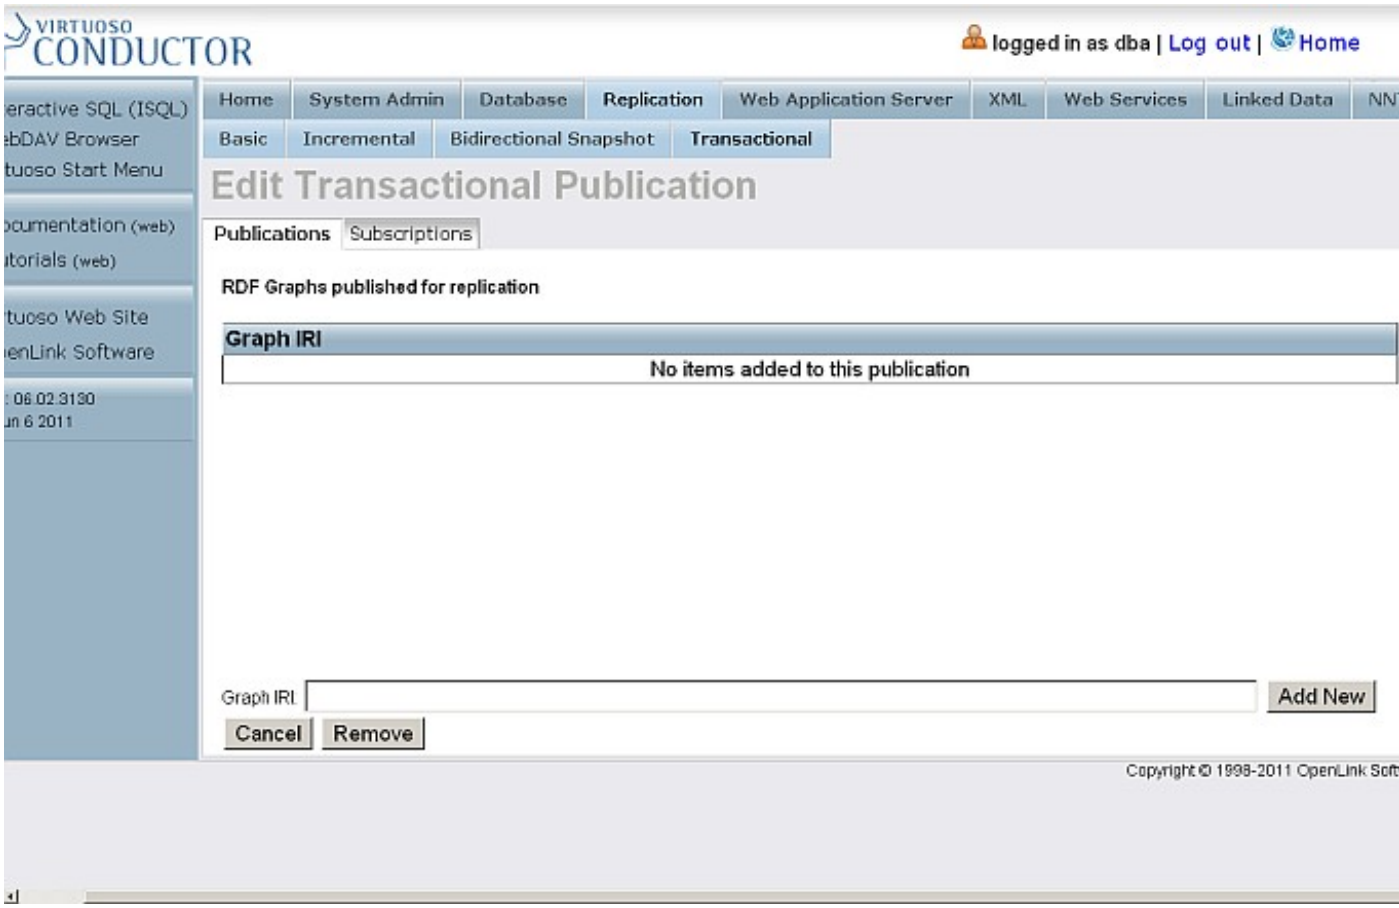
2. Click Enable RDF Publishing
3. A publication with the name RDF Publication should be created:

Figure 16.204. Star Replication Topology



4. Click the link which is the publication name.
5. You will be shown the publication items page:

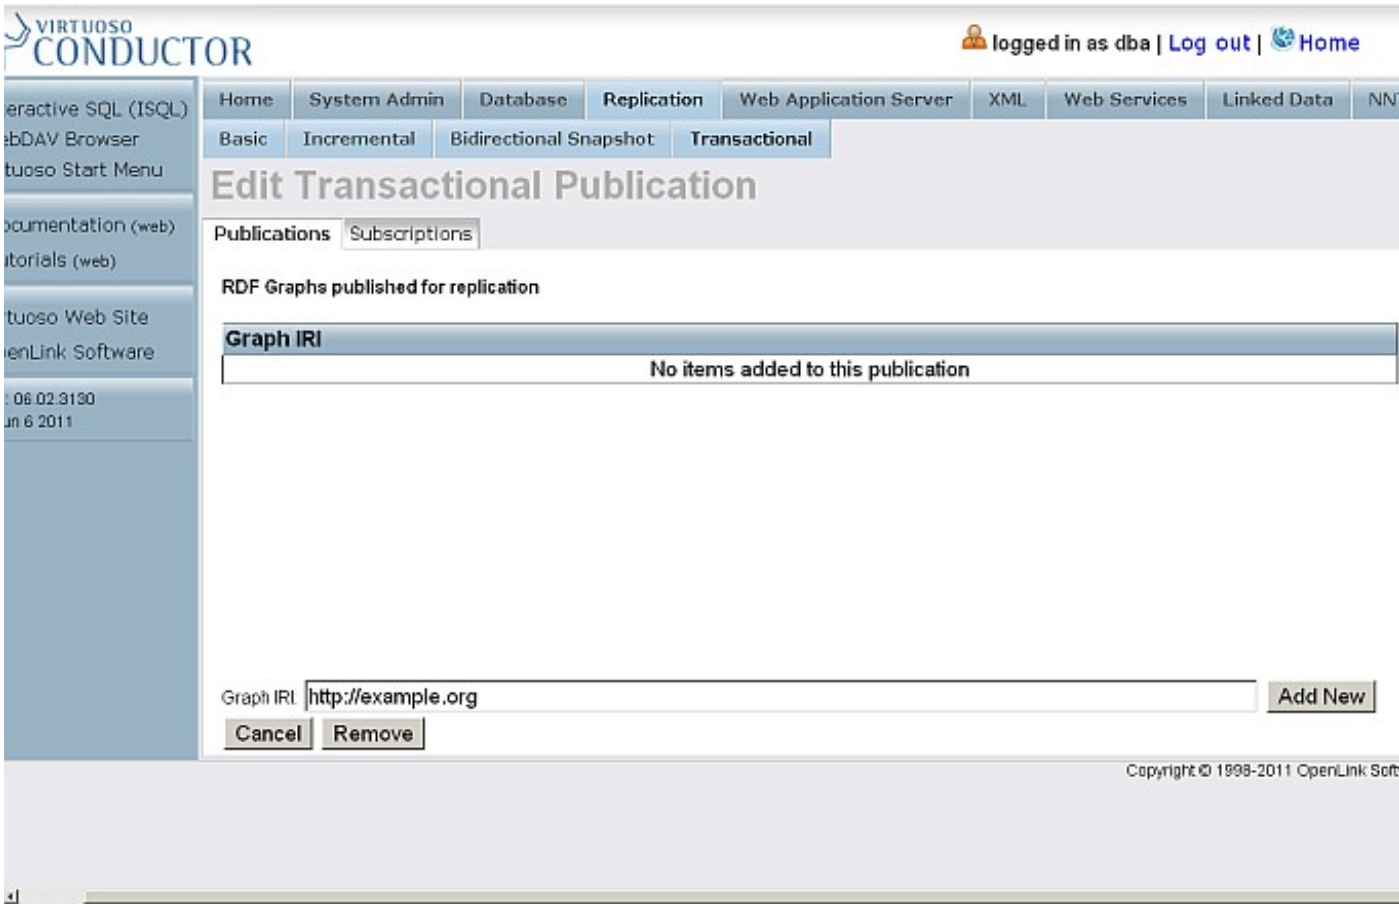
Figure 16.205. Star Replication Topology



6. Enter for Graph IRI:

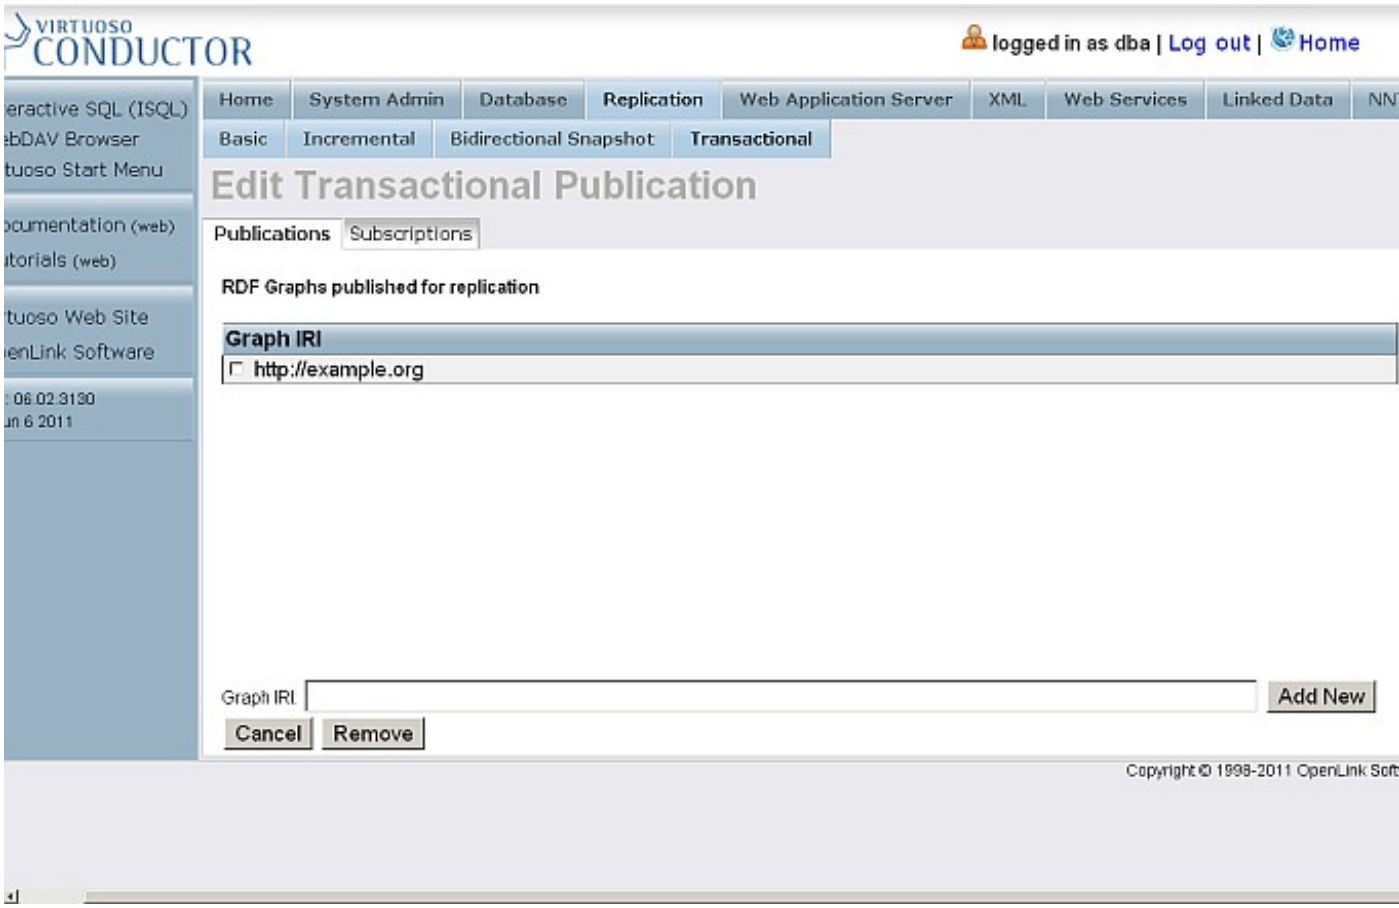
```
http://example.org
```

Figure 16.206. Star Replication Topology



7. Click Add New
8. The item will be created and shown in the list of items for the currently viewed publication.

Figure 16.207. Star Replication Topology

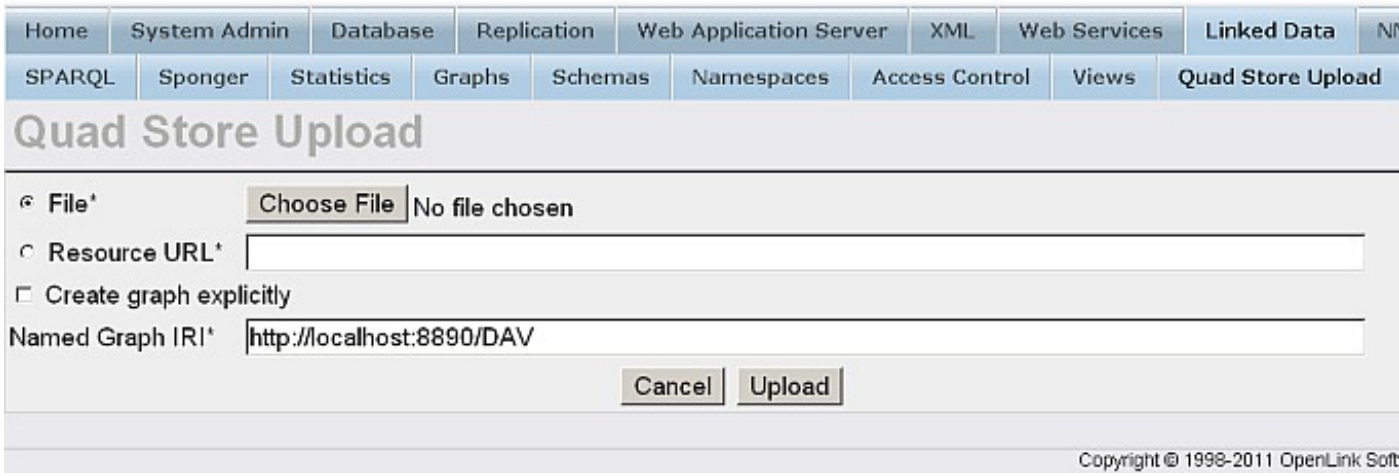


Insert Data into a Named Graph on the Host Virtuoso Instance

There are several ways to insert data into a Virtuoso Named Graph. In this example, we will use the Virtuoso Conductor's Import RDF feature:

1. In the Virtuoso Conductor, go to Linked Data -> Quad Store Upload:

   Figure 16.208. Replication Topology



2. In the form:

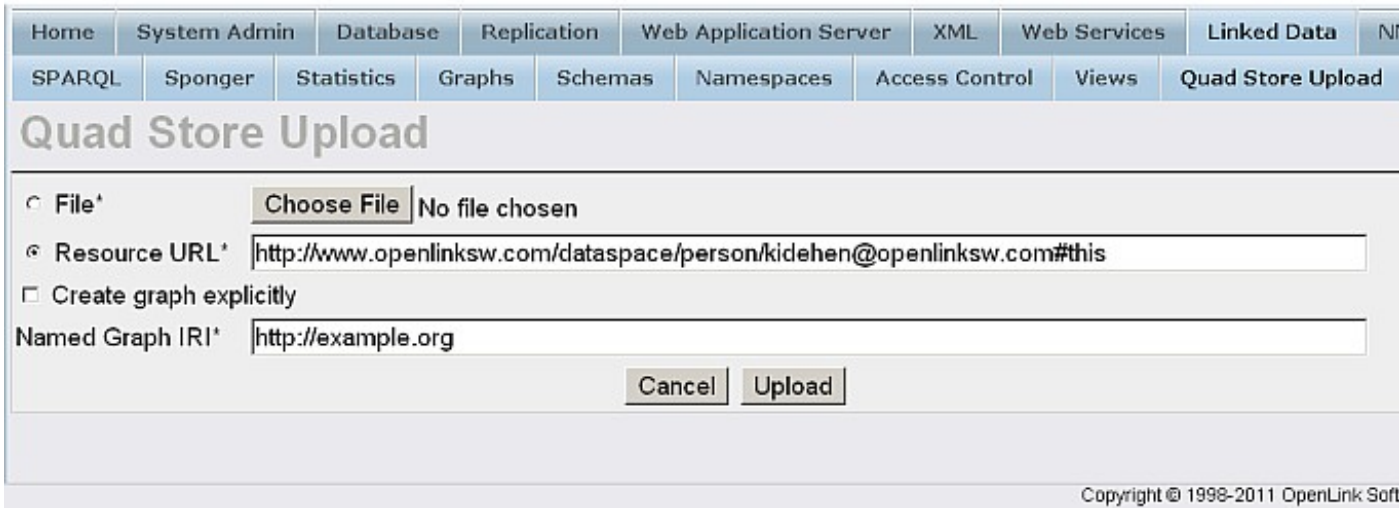
   - Tick the box for Resource URL and enter your resource URL, for e.g.:

     ```
     http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this
     ```

   - Enter for Named Graph IRI:

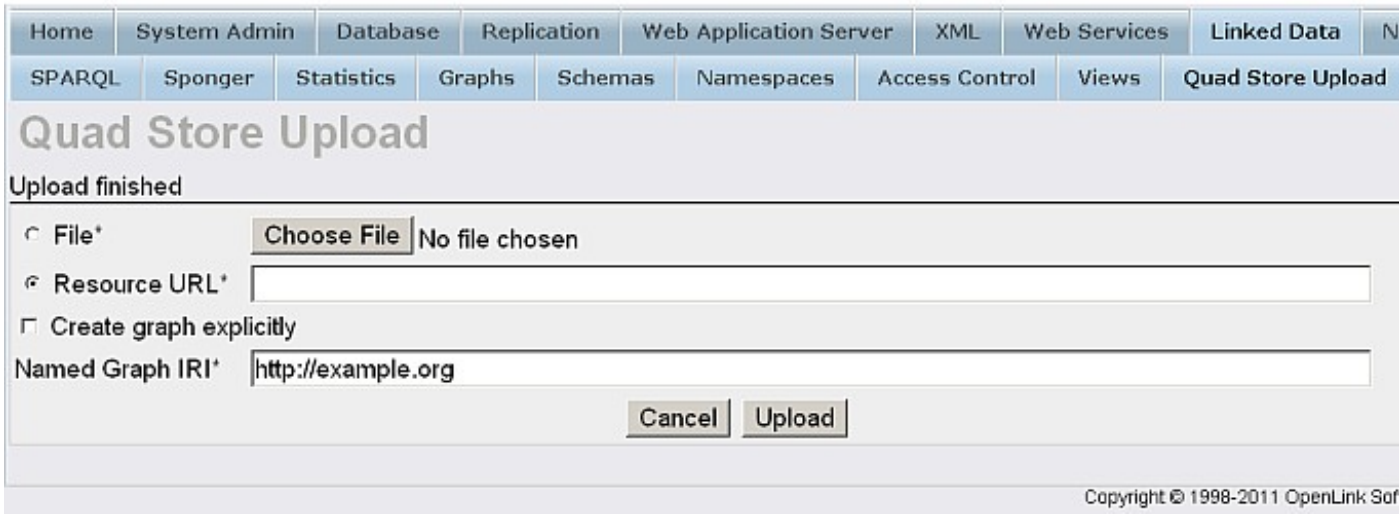
```
http://example.org
```

Figure 16.209. Replication Topology



3. Click Upload
4. A successful upload will result in this message:

Figure 16.210. Star Replication Topology



5. Check the inserted triples by executing a query like the following against the SPARQL endpoint, http://cname:port/sparql:

```
SELECT *
  FROM <http://example.org>
 WHERE { ?s ?p ?o }
```

Figure 16.211. Star Replication Topology

10. See how many triples have been inserted into your graph by executing the following query:

```
SELECT COUNT(*)
  FROM <http://example.org>
 WHERE {?s ?p ?o}
```

Figure 16.221. Star Replication Topology

callret-0
57

These steps may be repeated for any number of Subscriber.

Insert Triples into the Host Virtuoso Instance Graph and check availability at Destination Virtuoso Instance Graph

1. To check the starting count, on the Destination Virtuoso Instance SPARQL Endpoint, execute:

```
SELECT COUNT(*)
  FROM <http://example.org>
 WHERE { ?s ?p ?o }
```

2. On the Host Virtuoso Instance go to Conductor -> Database -> Interactive SQL and execute the following statement:

```
SPARQL INSERT INTO GRAPH <http://example.org>
  {
     <http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this>
     <http://xmlns.com/foaf/0.1/interest>
     <http://dbpedia.org/resource/Web_Services>
  } ;
SPARQL INSERT INTO GRAPH <http://example.org>
  {
    <http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this>
```

```
    <http://xmlns.com/foaf/0.1/interest>
    <http://dbpedia.org/resource/Web_Clients>
  } ;
SPARQL INSERT INTO GRAPH <http://example.org>
  {
    <http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this>
    <http://xmlns.com/foaf/0.1/interest>
    <http://dbpedia.org/resource/SPARQL>
  } ;
```

Figure 16.222. Star Replication Topology

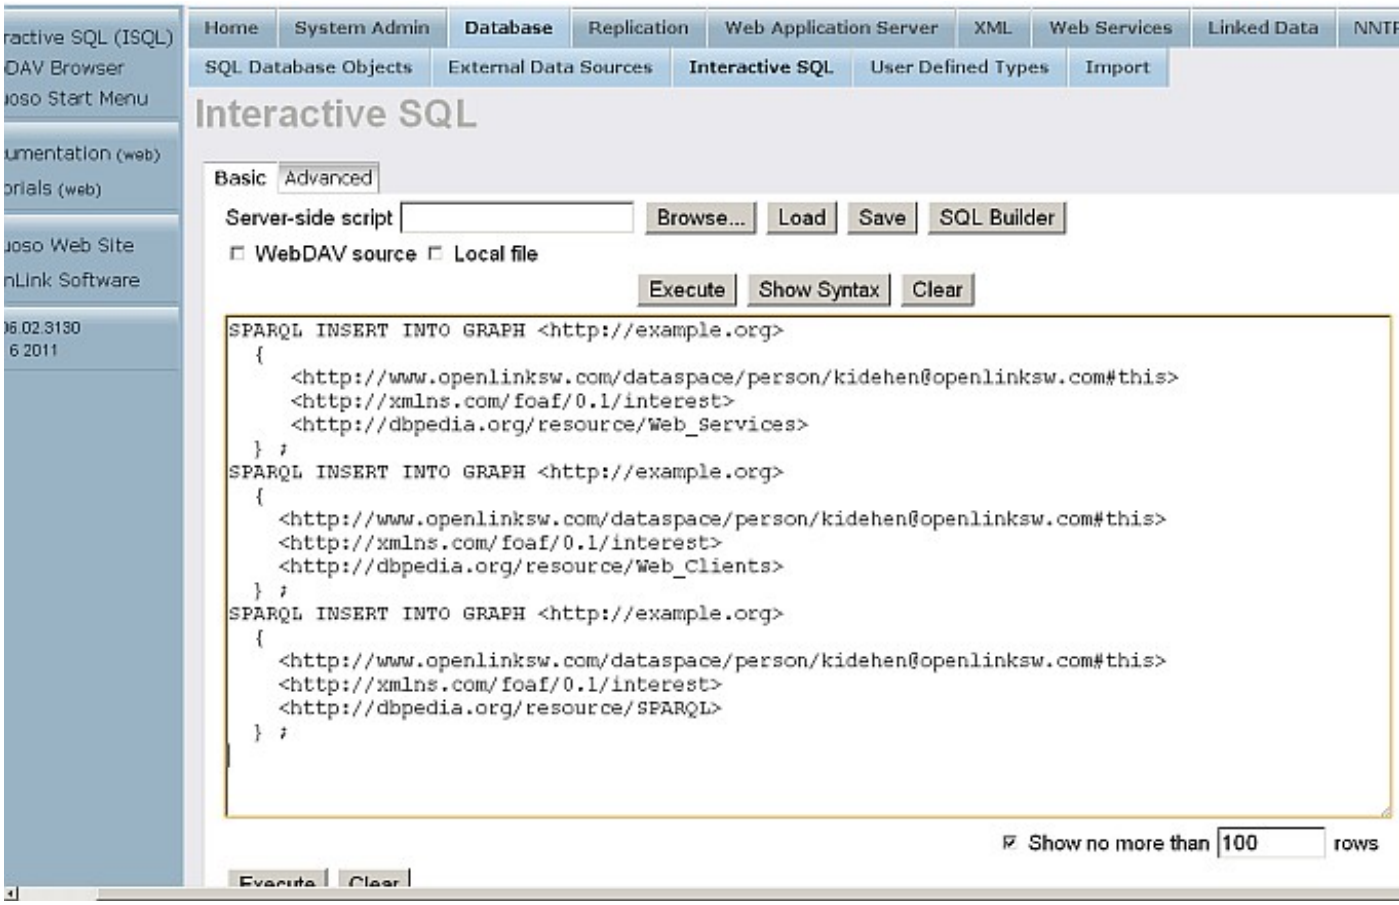

Figure 16.223. Star Replication Topology

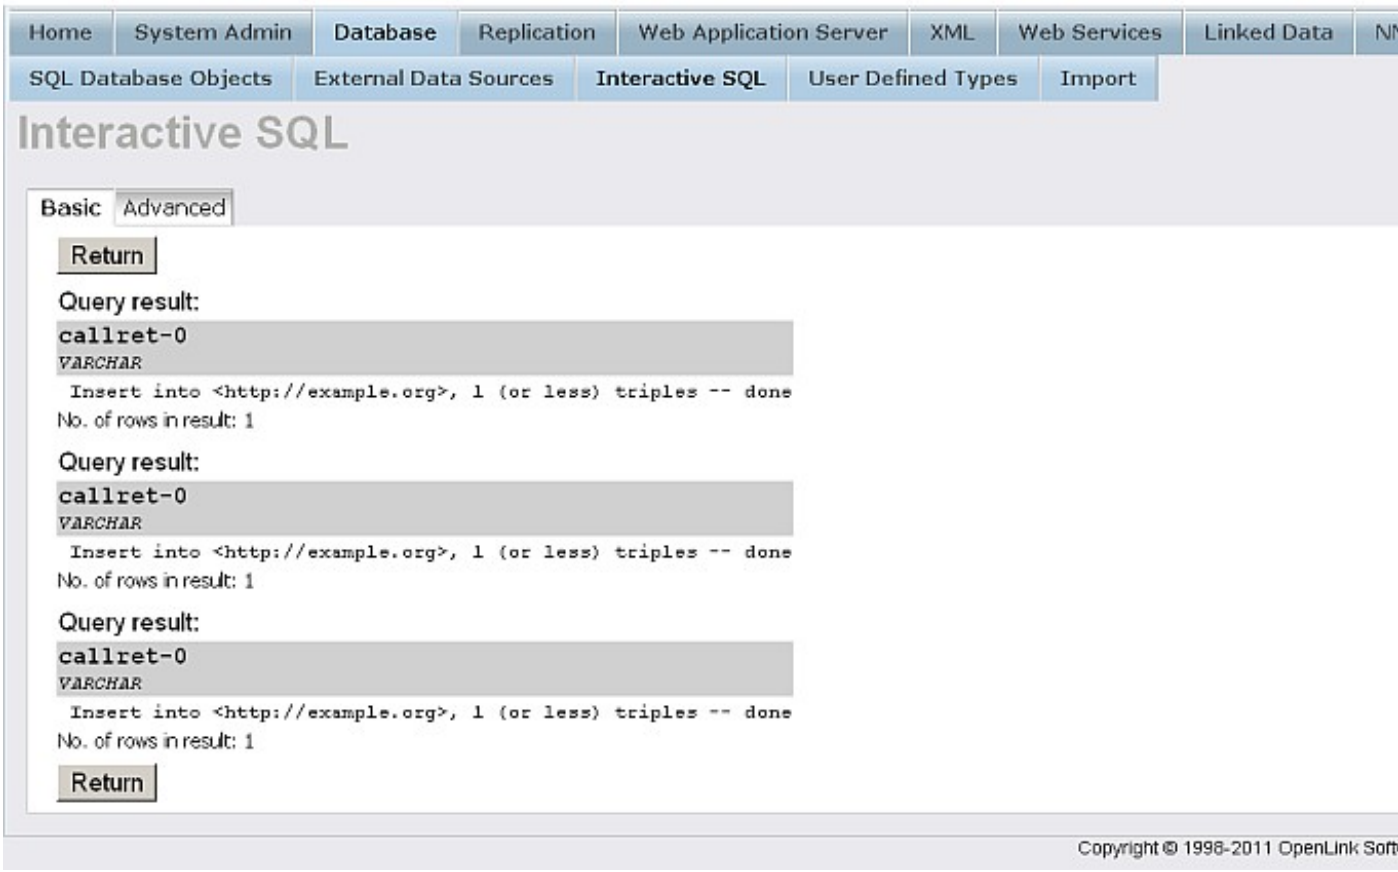

3. To confirm that the triple count has increased by the number of inserted triples, execute the following on the Destination Virtuoso Instance SPARQL Endpoint:

```
SELECT COUNT(*)
  FROM <http://example.org>
 WHERE { ?s ?p ?o }
```

Figure 16.224. Star Replication Topology

callret-0

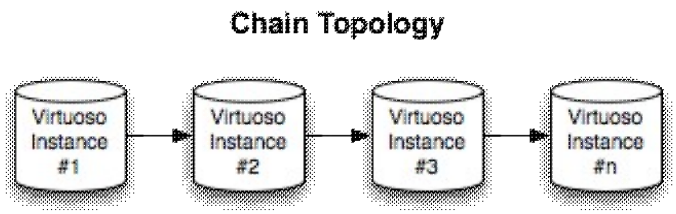
Chain Replication Topology

In a Chain, there is one original Publisher, to which there is only one Subscriber. That Subscriber may also serve as a Publisher, again with only one Subscriber. The chain ends with a Subscriber which does not Publish.

Figure 16.225. Chain Replication Topology



To set up a Chain, follow the scenario:

1. Configure Instance #1 to Publish.
2. Configure Instance #2 to Subscribe to #1.

3. Configure Instance #2 to Publish.
4. Configure Instance #3 to Subscribe to #2.
5. Repeat as necessary.

Chain Replication Topology Example

The following How-To walks you through setting up Virtuoso RDF Graph Replication in a Chain Topology.

Prerequisites

Database INI Parameters

Suppose there are 3 Virtuoso instances respectively with the following ini parameters values:

1. virtuoso1.ini:

```
...
[Database]
DatabaseFile    = virtuoso1.db
TransactionFile = virtuoso1.trx
ErrorLogFile     = virtuoso1.log
...
[Parameters]
ServerPort               = 1111
SchedulerInterval        = 1
...
[HTTPServer]
ServerPort                  = 8891
...
[URIQA]
DefaultHost = example.com:8891
...
[Replication]
ServerName   = db1
...
```

2. virtuoso2.ini:

```
...
[Database]
DatabaseFile    = virtuoso2.db
TransactionFile = virtuoso2.trx
ErrorLogFile     = virtuoso2.log
...
[Parameters]
ServerPort               = 1112
SchedulerInterval        = 1
...
[HTTPServer]
ServerPort                  = 8892
...
[URIQA]
DefaultHost = localhost:8892
...
[Replication]
ServerName   = db2
...
```

3. virtuoso3.ini:

```
...
[Database]
DatabaseFile    = virtuoso3.db
TransactionFile = virtuoso3.trx
ErrorLogFile     = virtuoso3.log
...
[Parameters]
ServerPort               = 1113
SchedulerInterval        = 1
...
[HTTPServer]
```

```
ServerPort                  = 8893
...
[URIQA]
DefaultHost = example.com:8893
...
[Replication]
ServerName   = db3
...
```

Database DSNs

Use the ODBC Administrator on your Virtuoso host (e.g., on Windows, Start menu -> Control Panel -> Administrative Tools -> Data Sources (ODBC); on Mac OS X, /Applications/Utilities/OpenLink ODBC Administrator.app) to create a System DSN for each of db1, db2, db3, with names db1, db2 and db3, respectively.

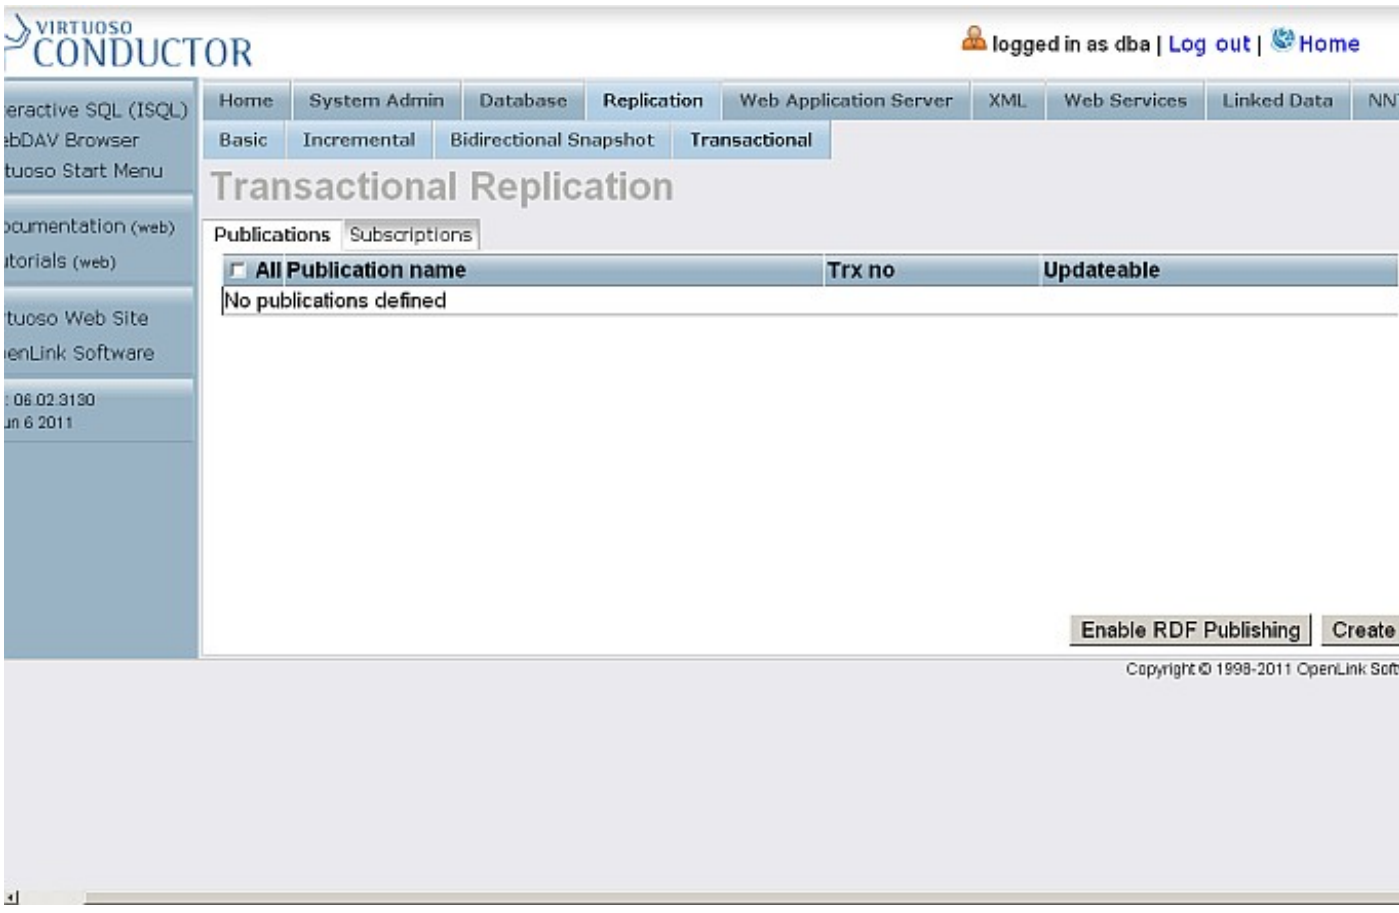
Install Conductor package

On each of the 3 Virtuoso instances install the conductor_dav.vad package.

Create Publication on db1

1. Go to http://example.com:8891/conductor and log in as dba
2. Go to Conductor - > Replication - > Transactional - > Publications

Figure 16.226. Chain Replication Topology



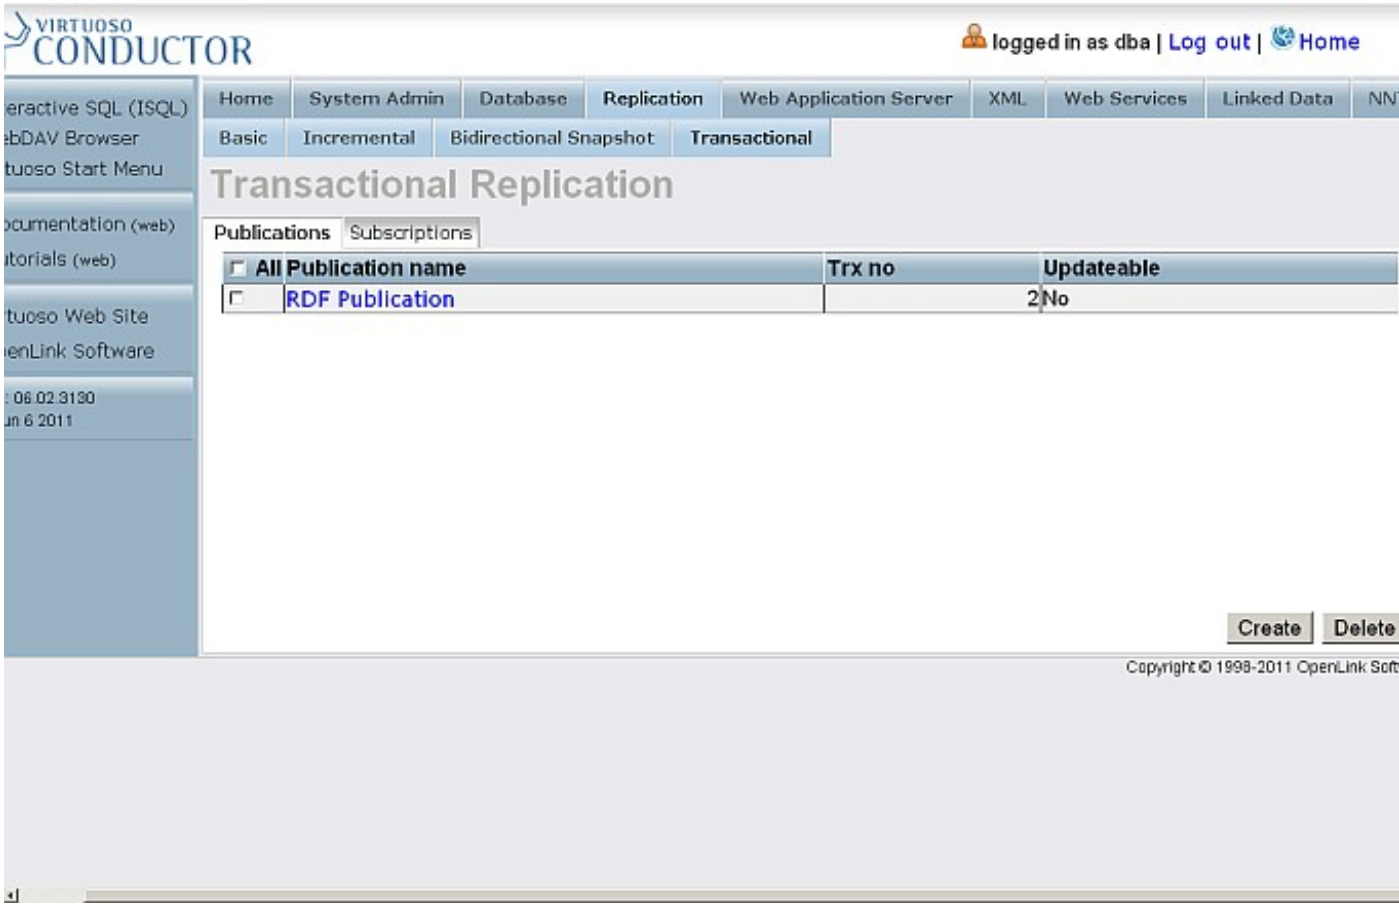
3. Click

   Enable RDF Publishing
4. As result publication with the name

   RDF Publication

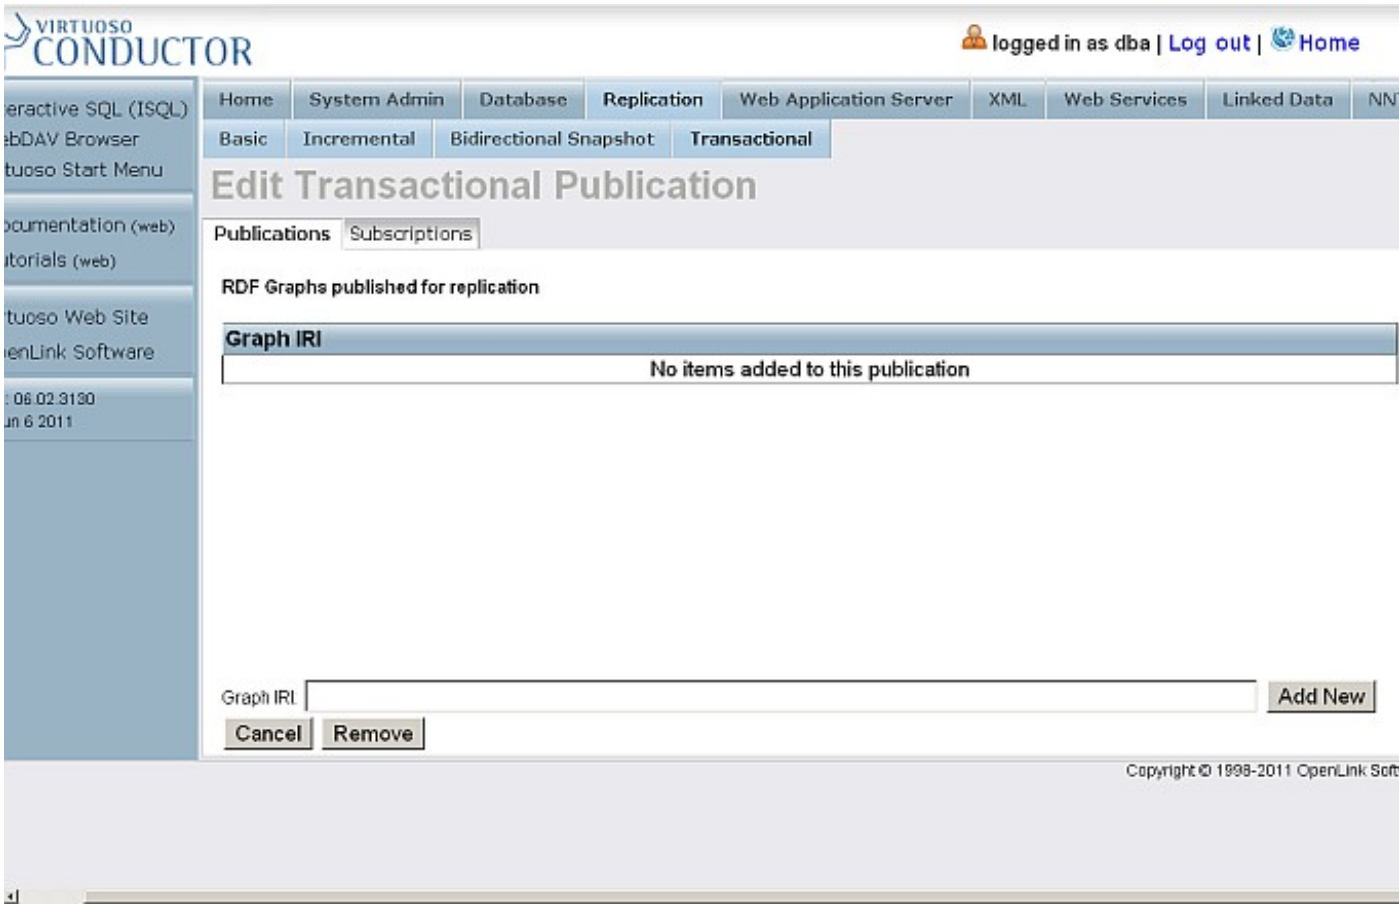
   should be created

Figure 16.227. Chain Replication Topology



5. Click the link which is the publication name.
6. You will be shown the publication items page

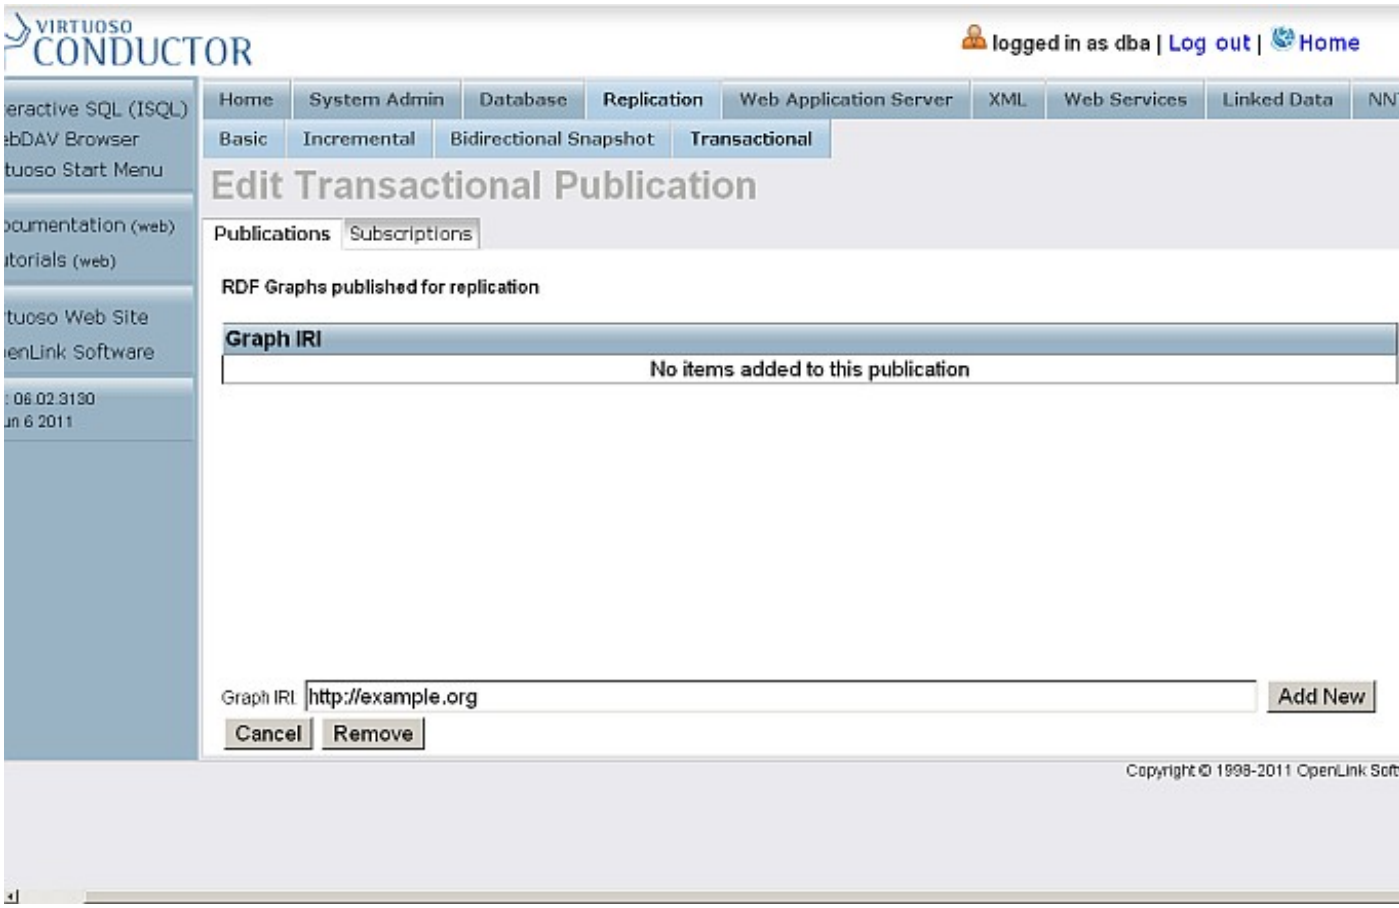
Figure 16.228. Chain Replication Topology



7. Enter for Graph IRI:

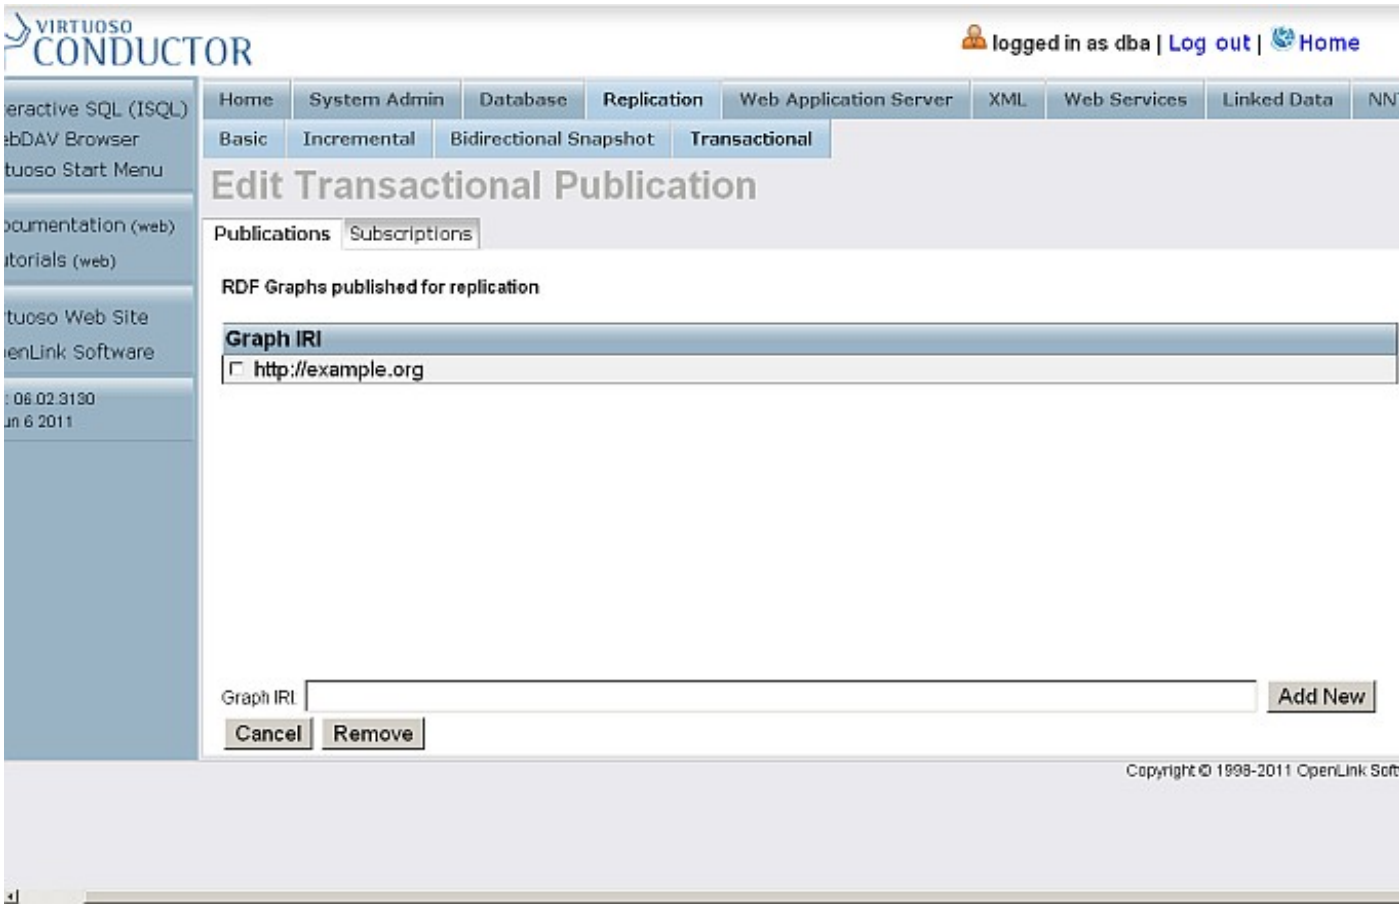
```
http://example.org
```

Figure 16.229. Chain Replication Topology



8. Click Add New
9. The item will be created and shown in the list of items for the currently viewed publication.

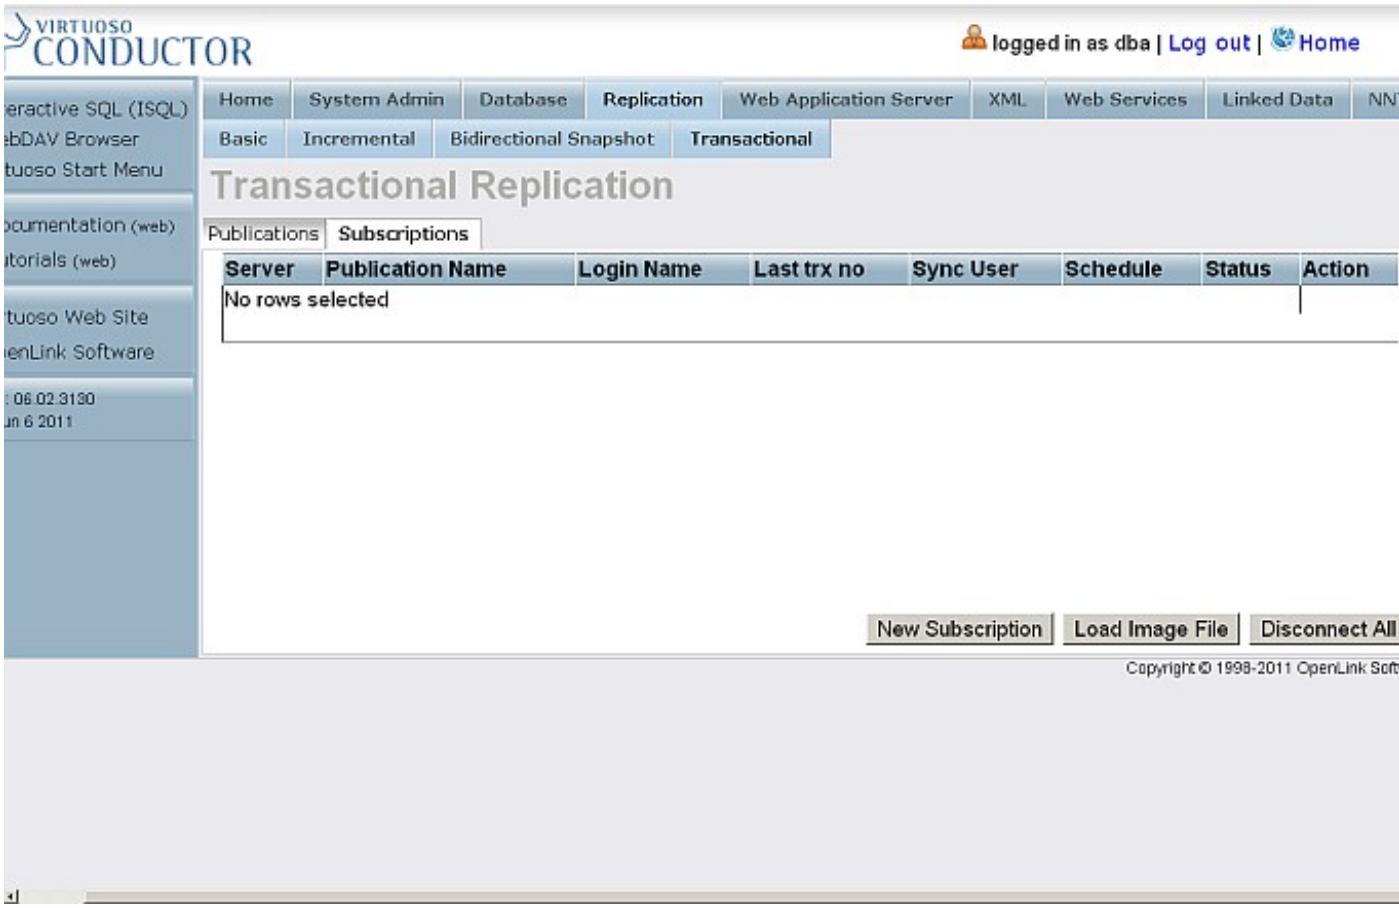
Figure 16.230. Chain Replication Topology



Create subscription from db2 to db1's Publication

1. Log in at http://example.com:8892/conductor
2. Go to Replication - > Transactional - > Subscriptions

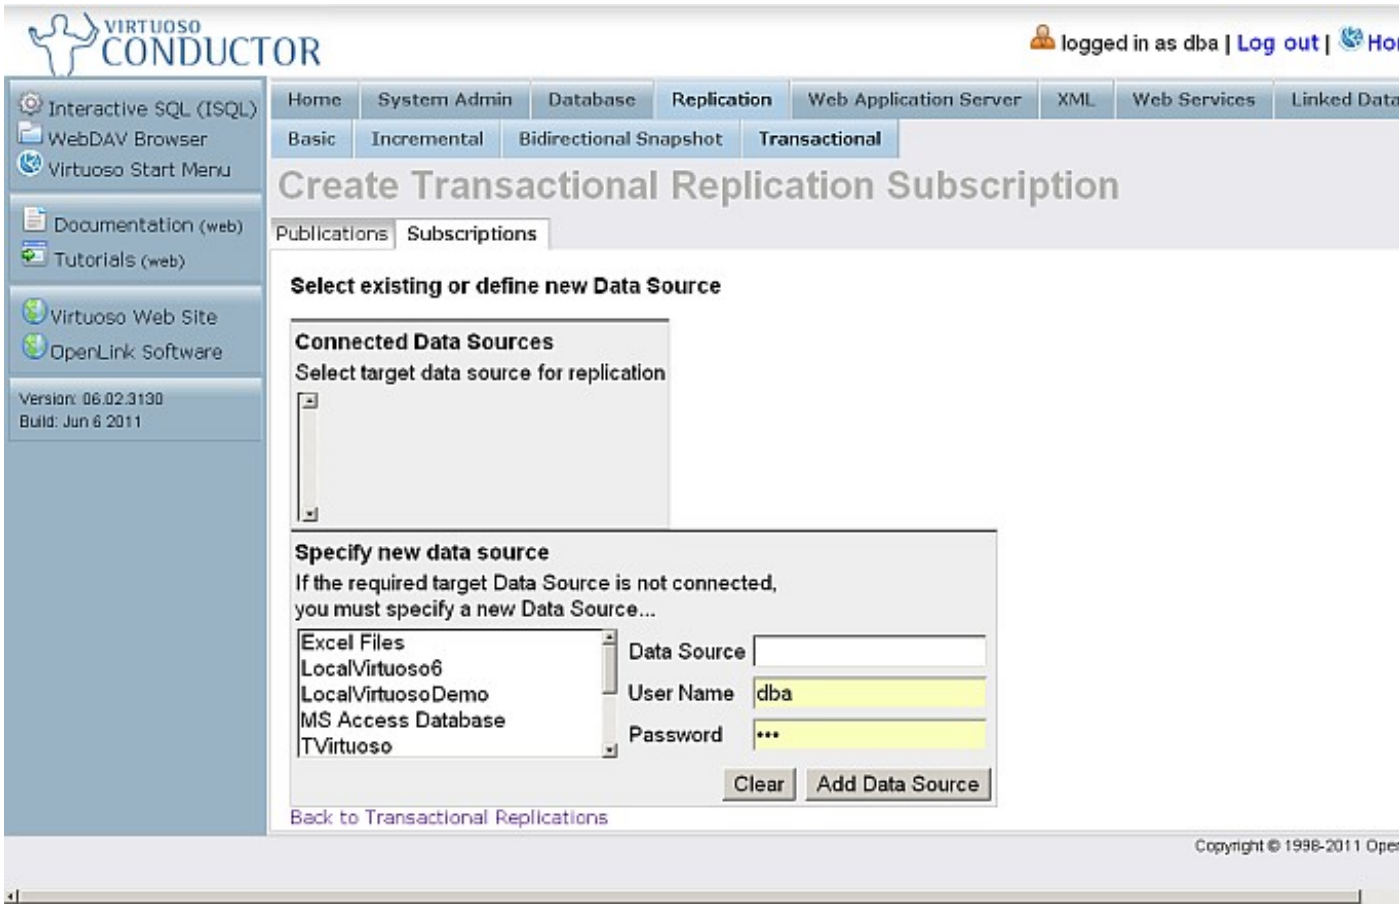
Figure 16.231. Chain Replication Topology



3. Click

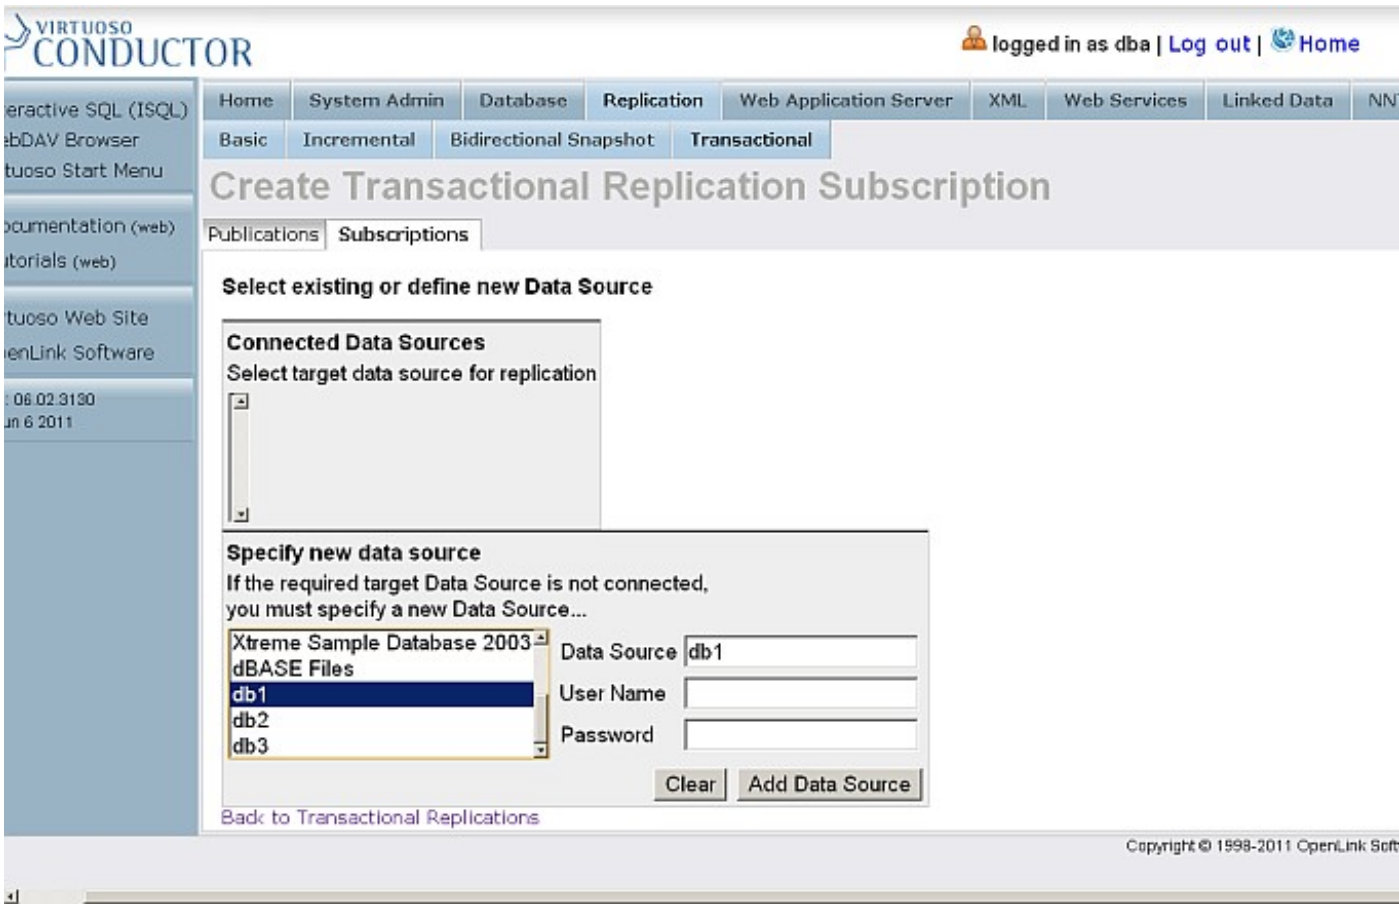
   New Subscription

Figure 16.232. Chain Replication Topology



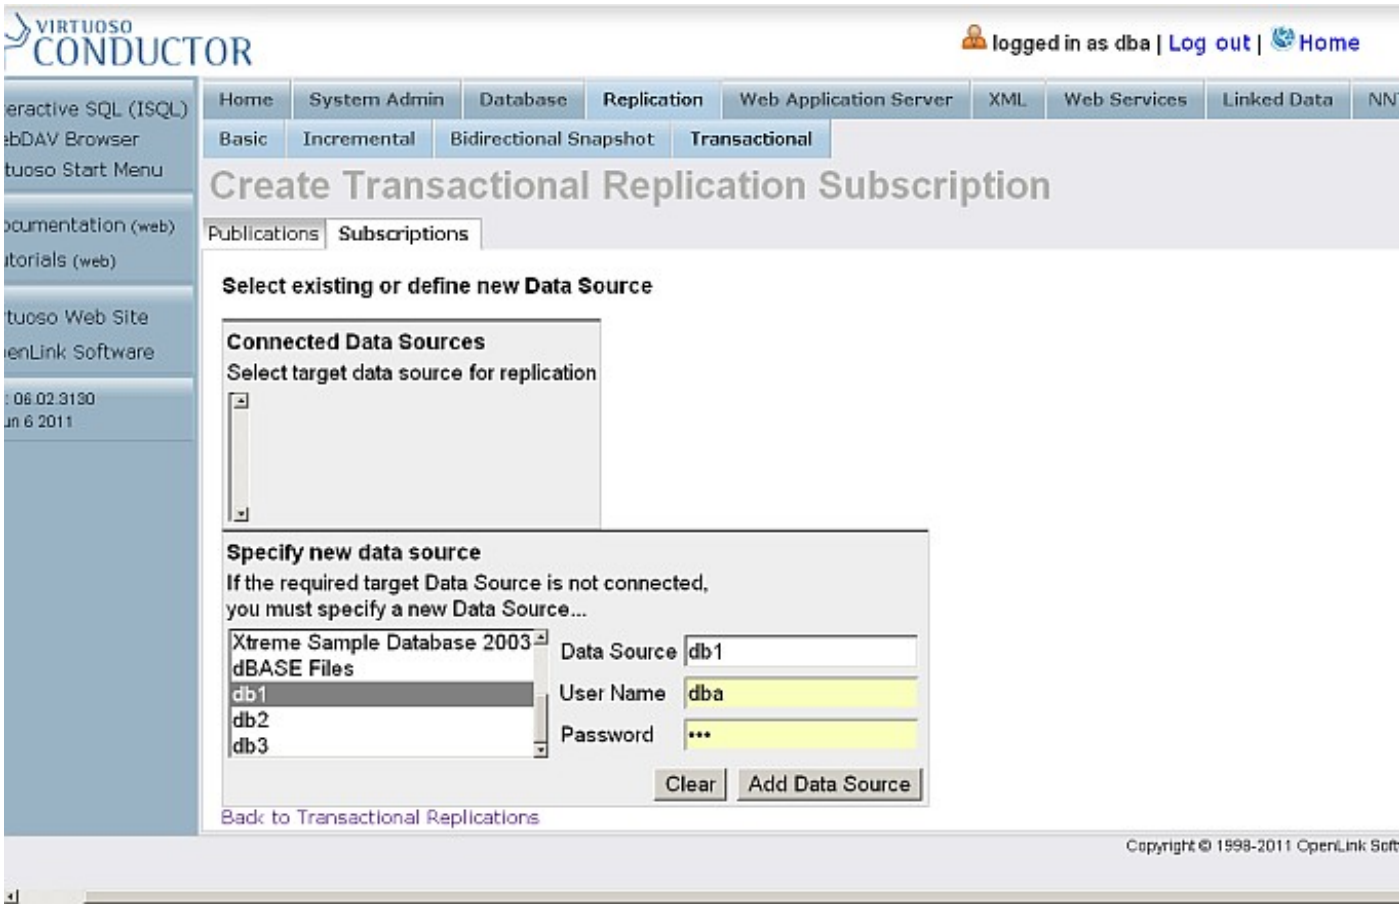
4. From the list of "Specify new data source" select Data Source db1

Figure 16.233. Chain Replication Topology



5. Enter for db1 dba user credentials

Figure 16.234. Chain Replication Topology

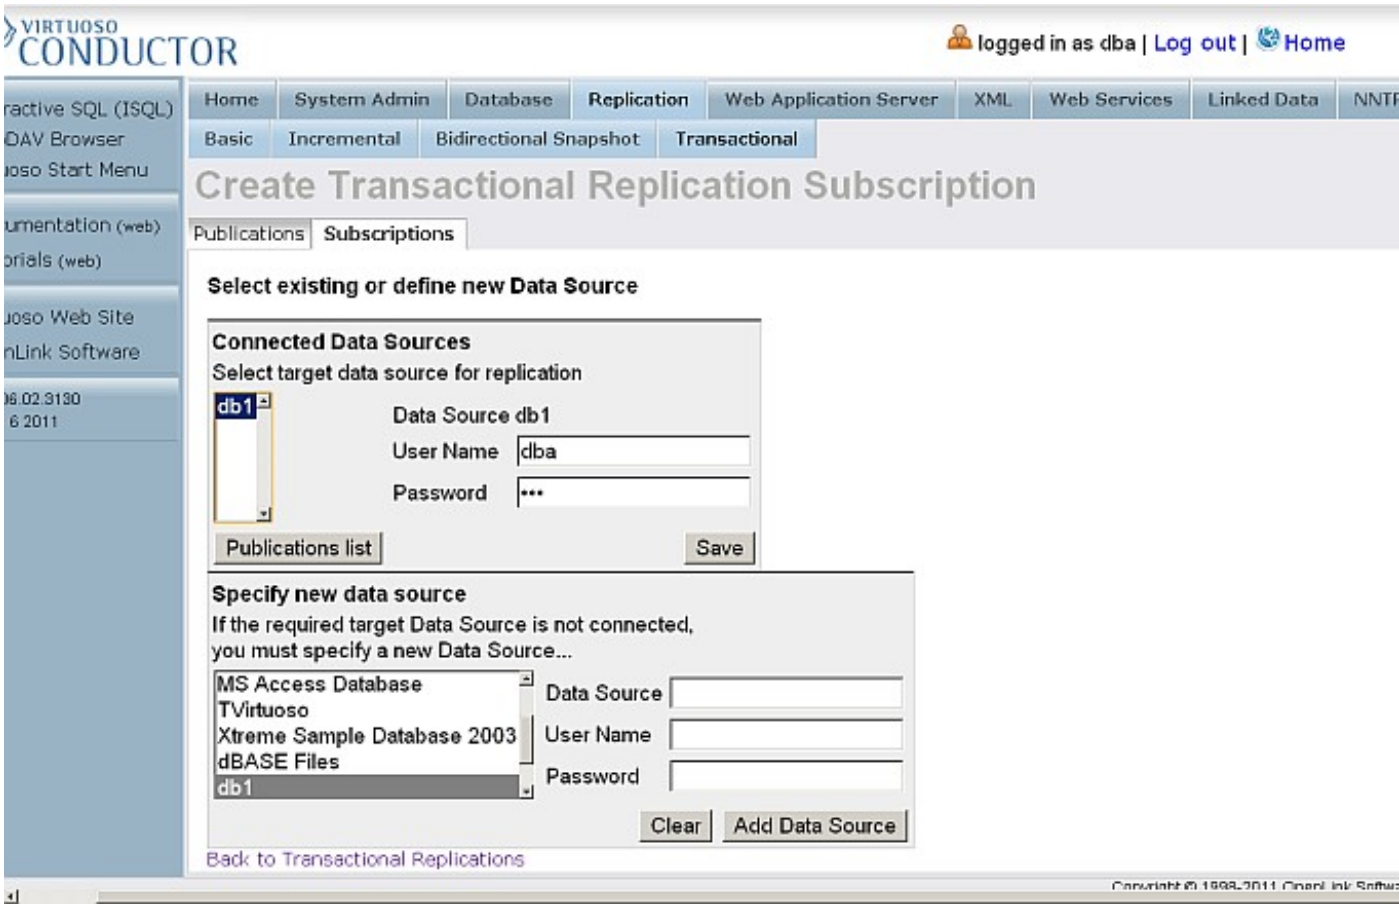


6. Click "Add Data Source"
7. As result

   db1

   will be shown in the "Connected Data Sources" list.

Figure 16.235. Chain Replication Topology

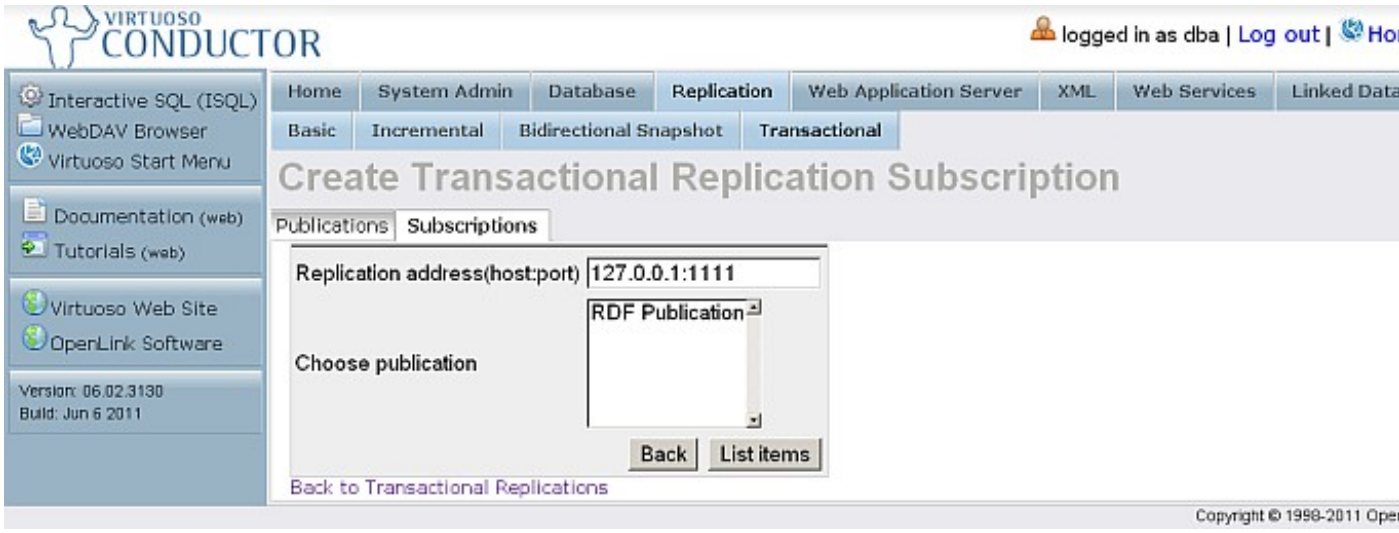


8. Select

   db1

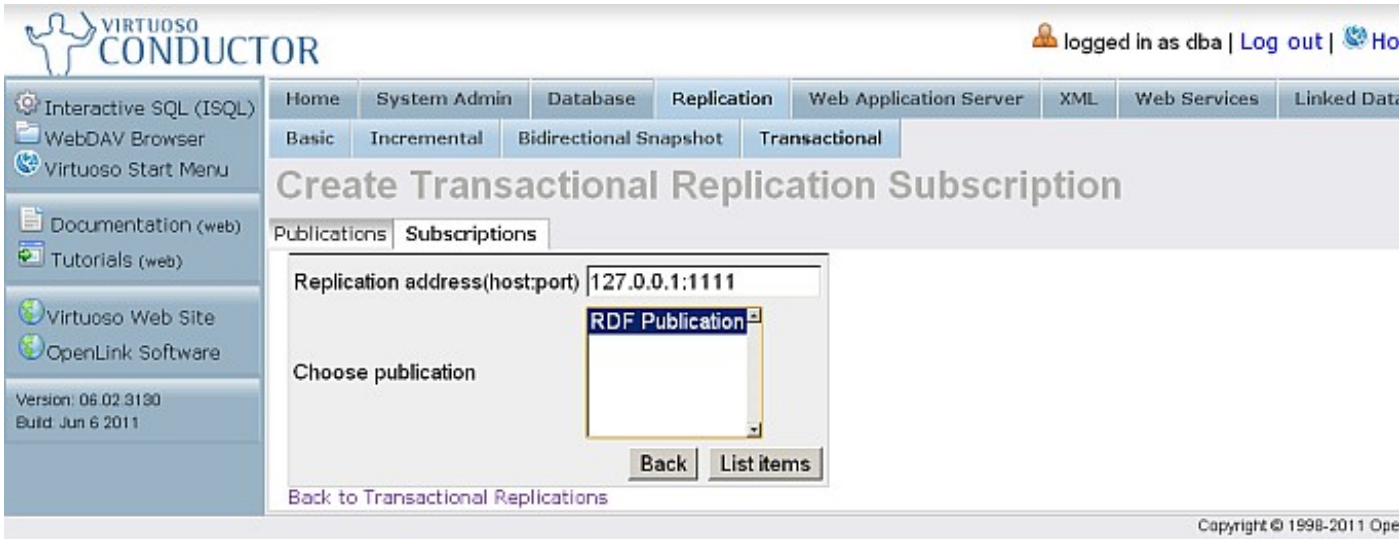
   the "Connected Data Sources" list and click "Publications list"

Figure 16.236. Chain Replication Topology



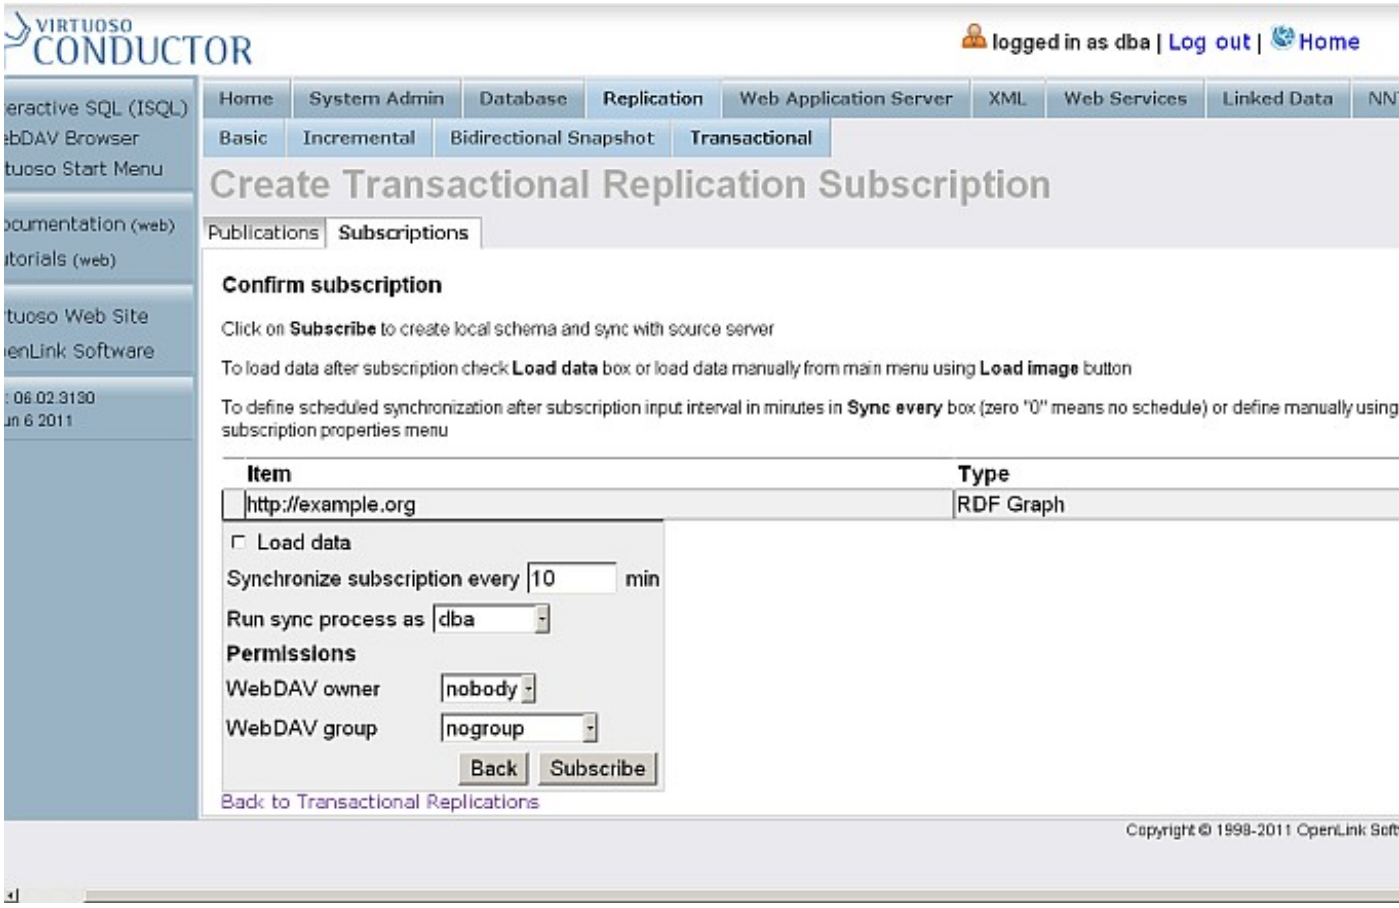
9. As result will be shown the list of available publications for the selected data source. Select the one with name "RDF Publication" and click "List Items".

Figure 16.237. Chain Replication Topology



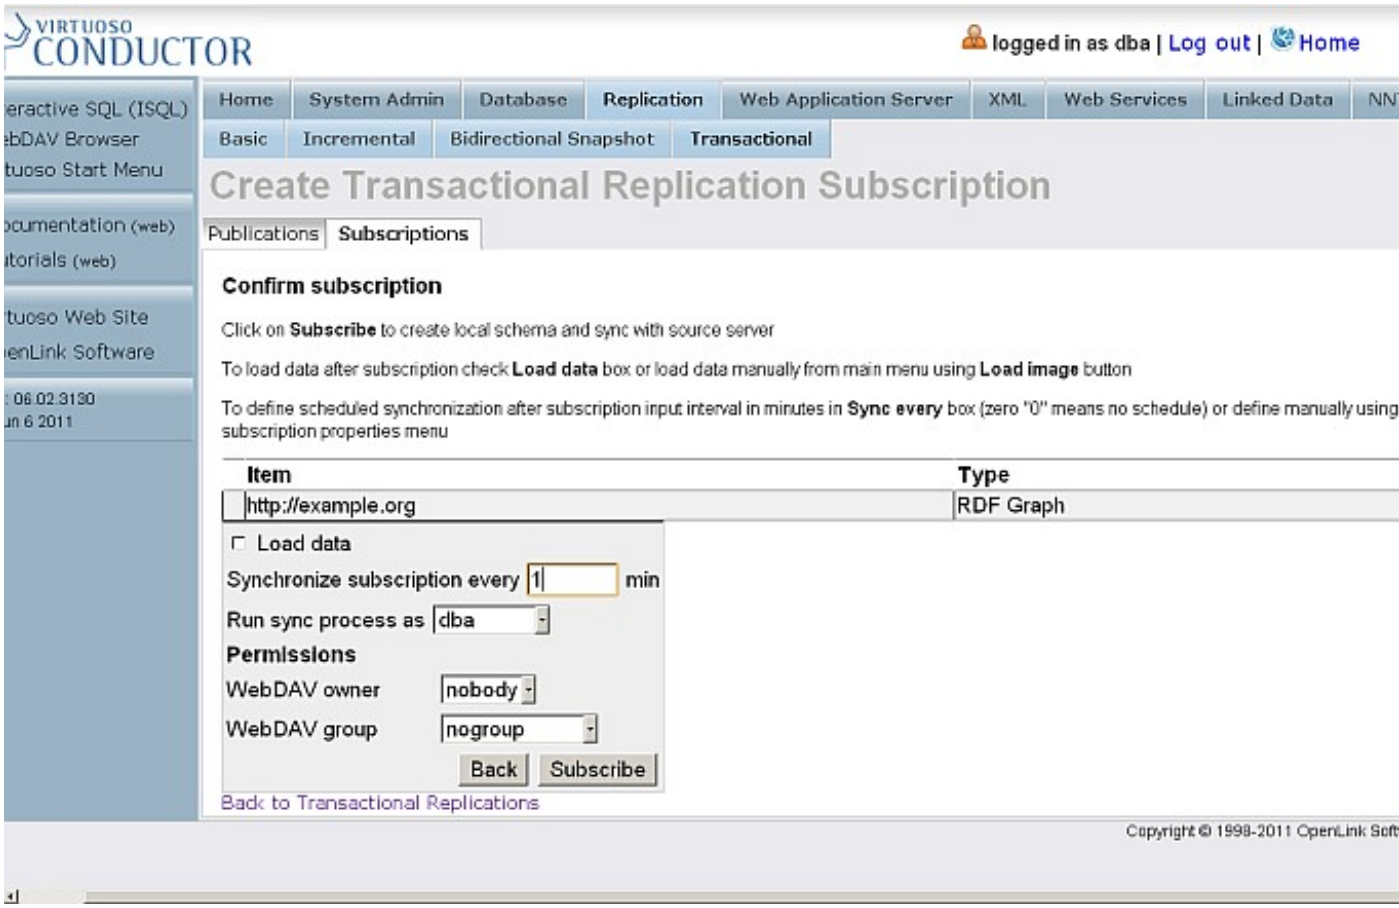
10. As result will be shown the "Confirm subscription" page.

Figure 16.238. Chain Replication Topology



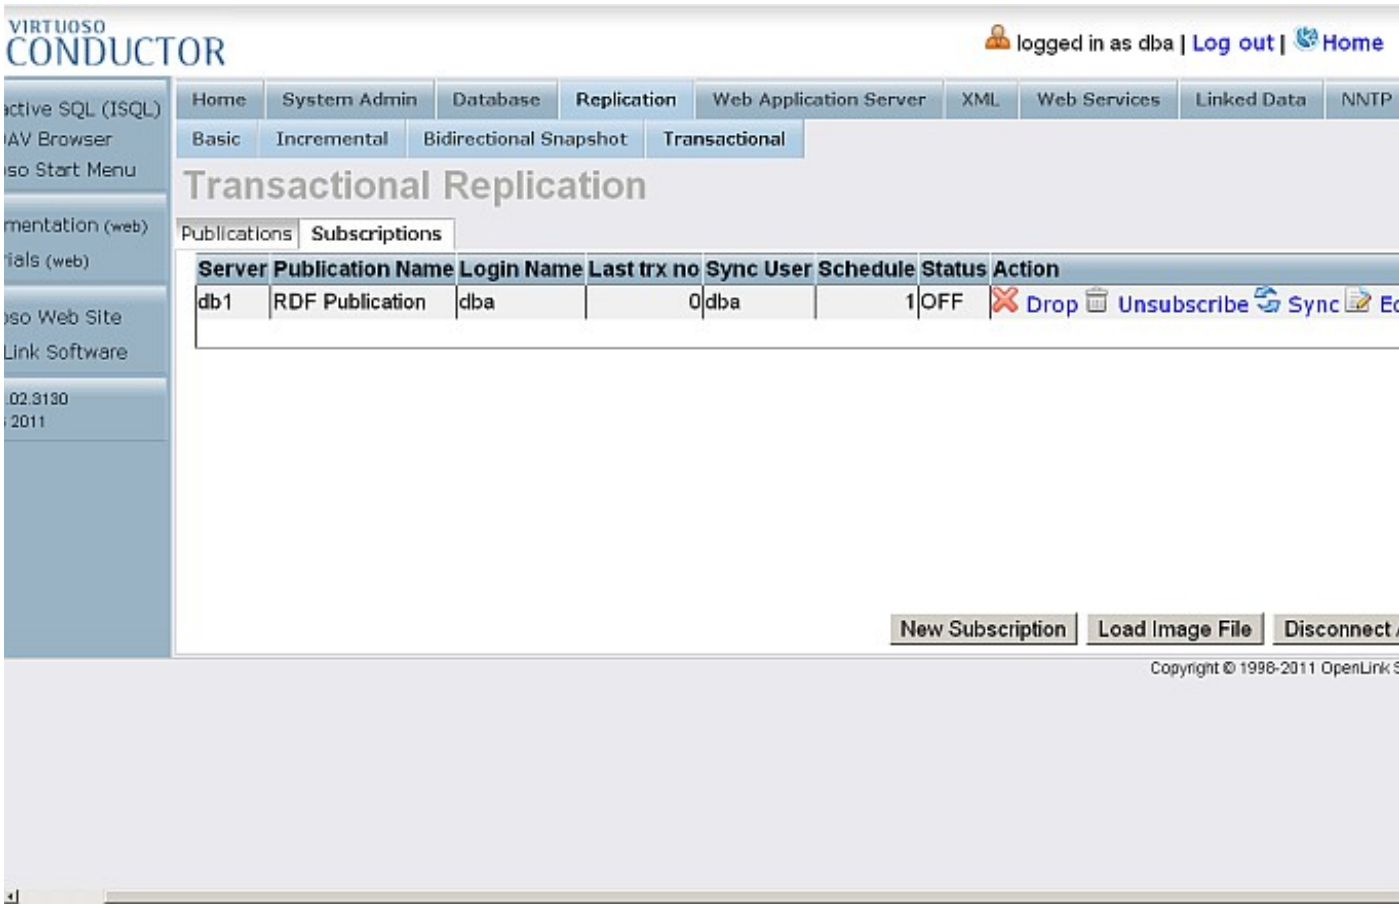
11. The sync interval by default is 10 minutes. For the testing purposes, we will change it to 1 minute.

Figure 16.239. Chain Replication Topology



12. Click "Subscribe"
13. The subscription will be created.

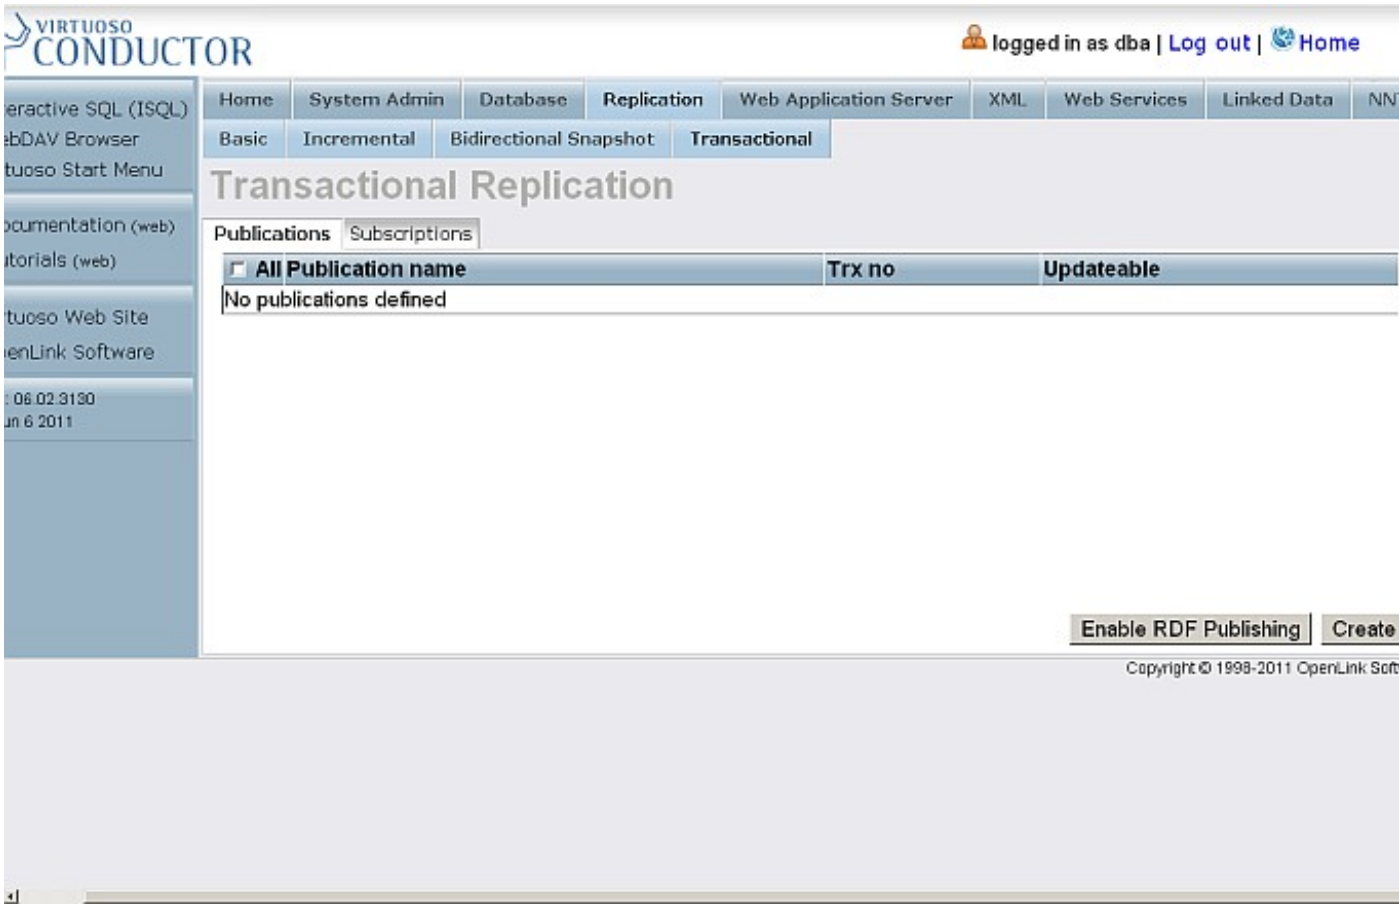
Figure 16.240. Chain Replication Topology



Create Publication on db2

1. Go to http://example.com:8892/conductor and log in as dba
2. Go to Conductor - > Replication - > Transactional - > Publications

Figure 16.241. Chain Replication Topology



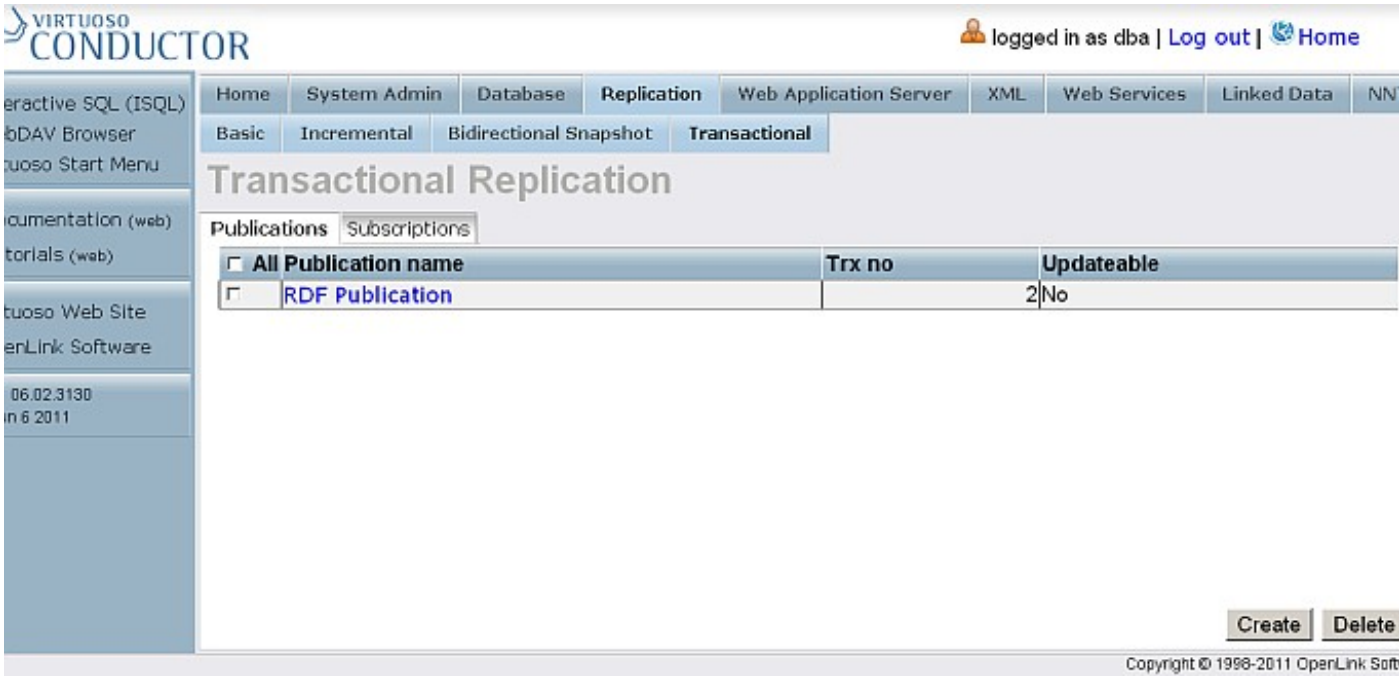
3. Click

   Enable RDF Publishing
4. As result publication with the name

   RDF Publication

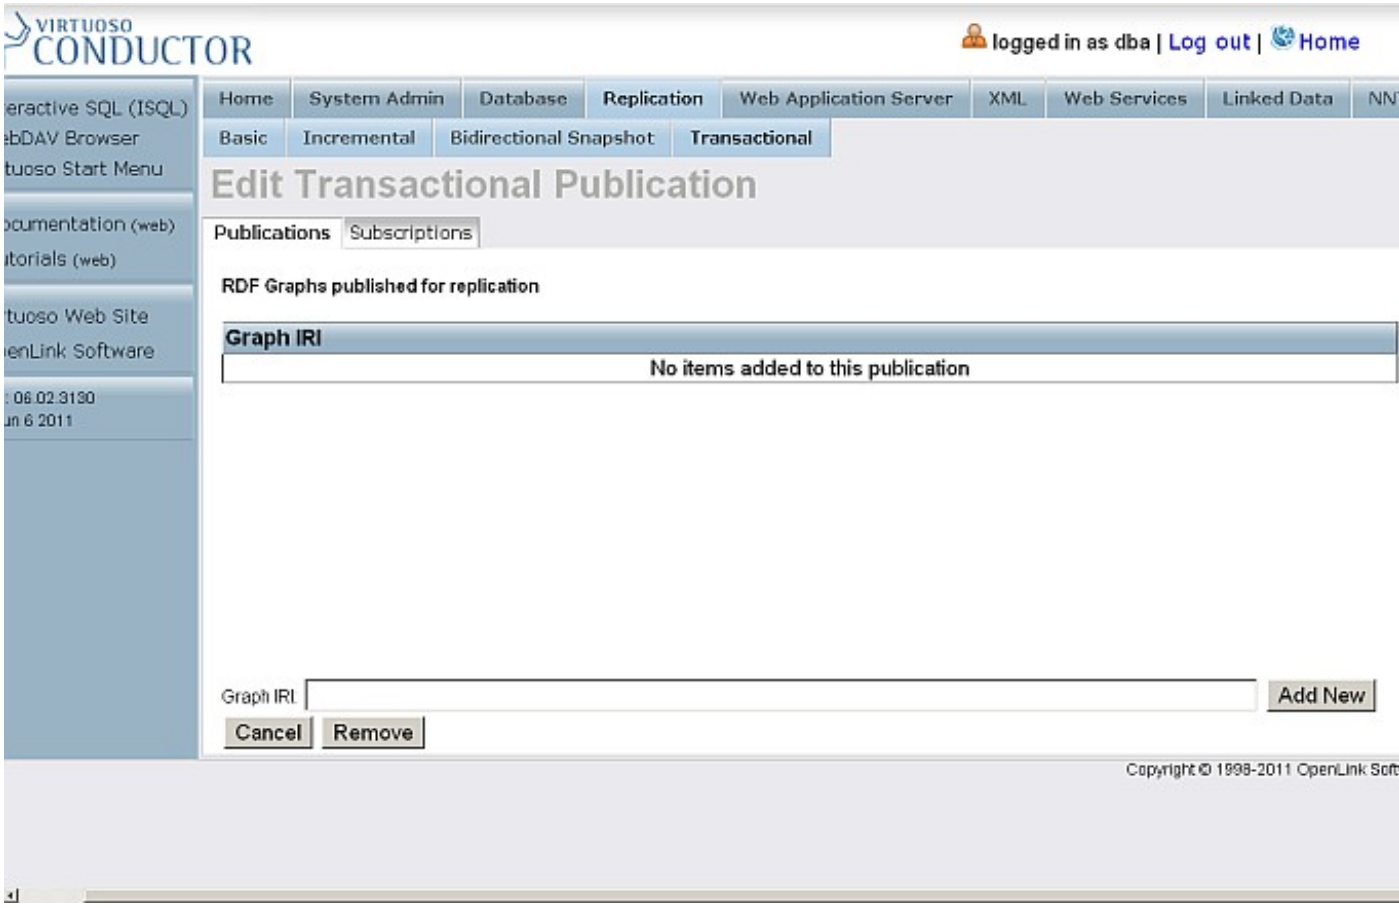
   should be created

Figure 16.242. Chain Replication Topology



5. Click the link which is the publication name.
6. You will be shown the publication items page

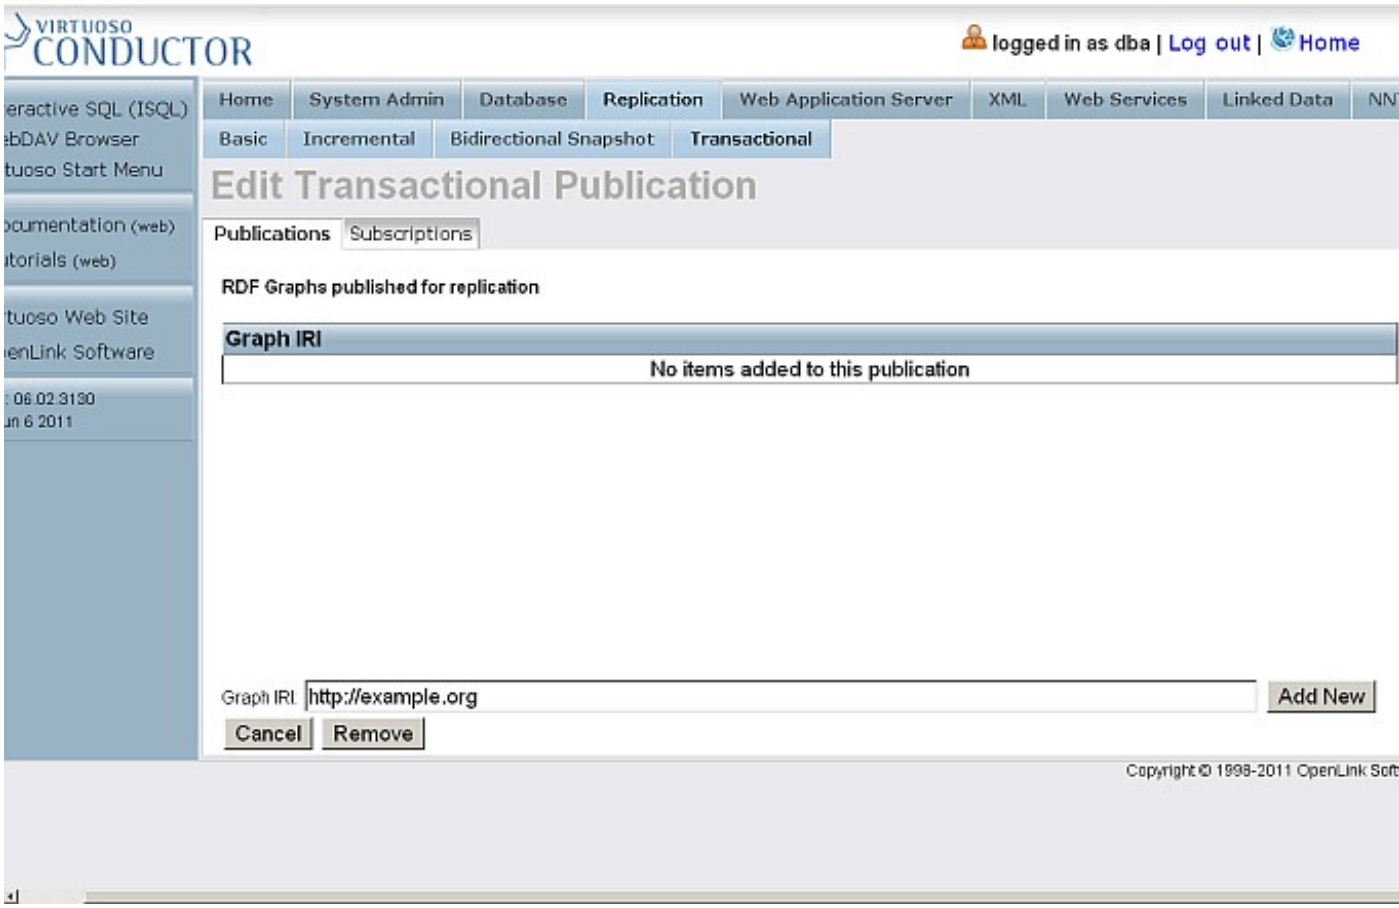
Figure 16.243. Chain Replication Topology



7. Enter for Graph IRI:

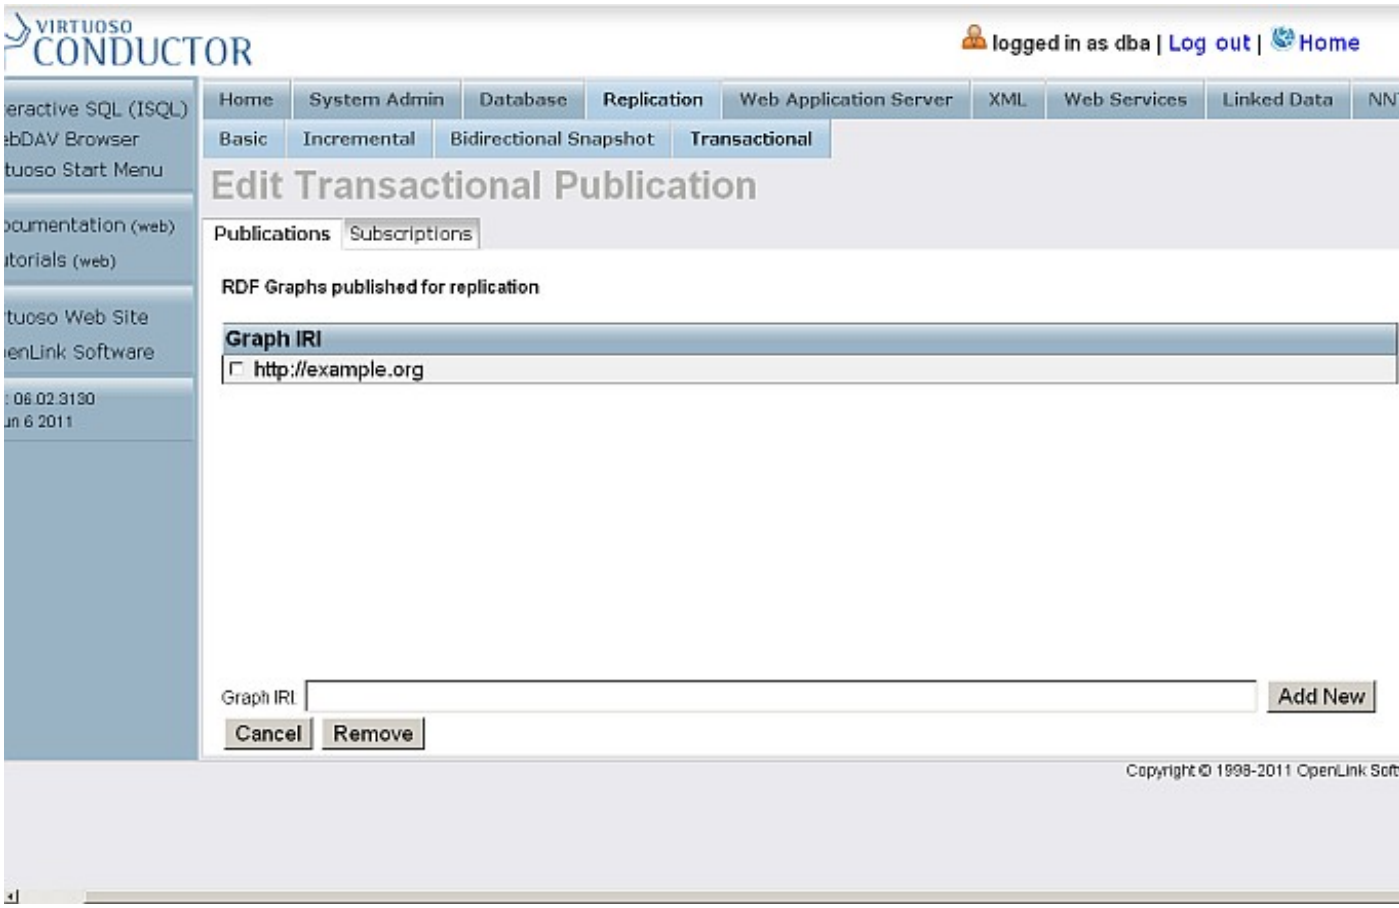
```
http://example.org
```

Figure 16.244. Chain Replication Topology



8. Click Add New
9. The item will be created and shown in the list of items for the currently viewed publication.

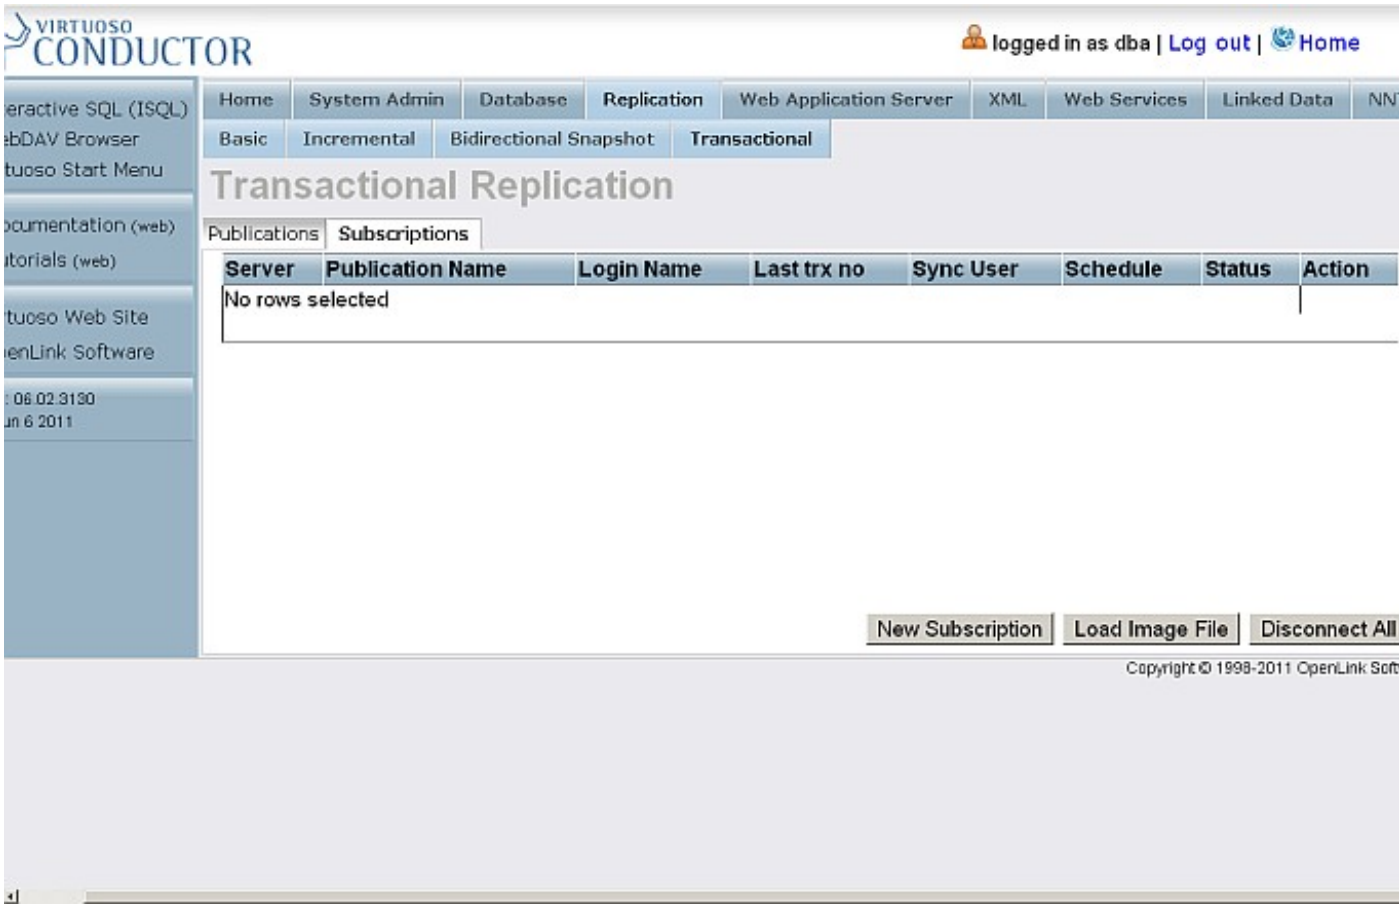
Figure 16.245. Chain Replication Topology



Create subscription from db3 to db2's Publication

1. Log in at http://example.com:8893/conductor
2. Go to Replication - > Transactional - > Subscriptions

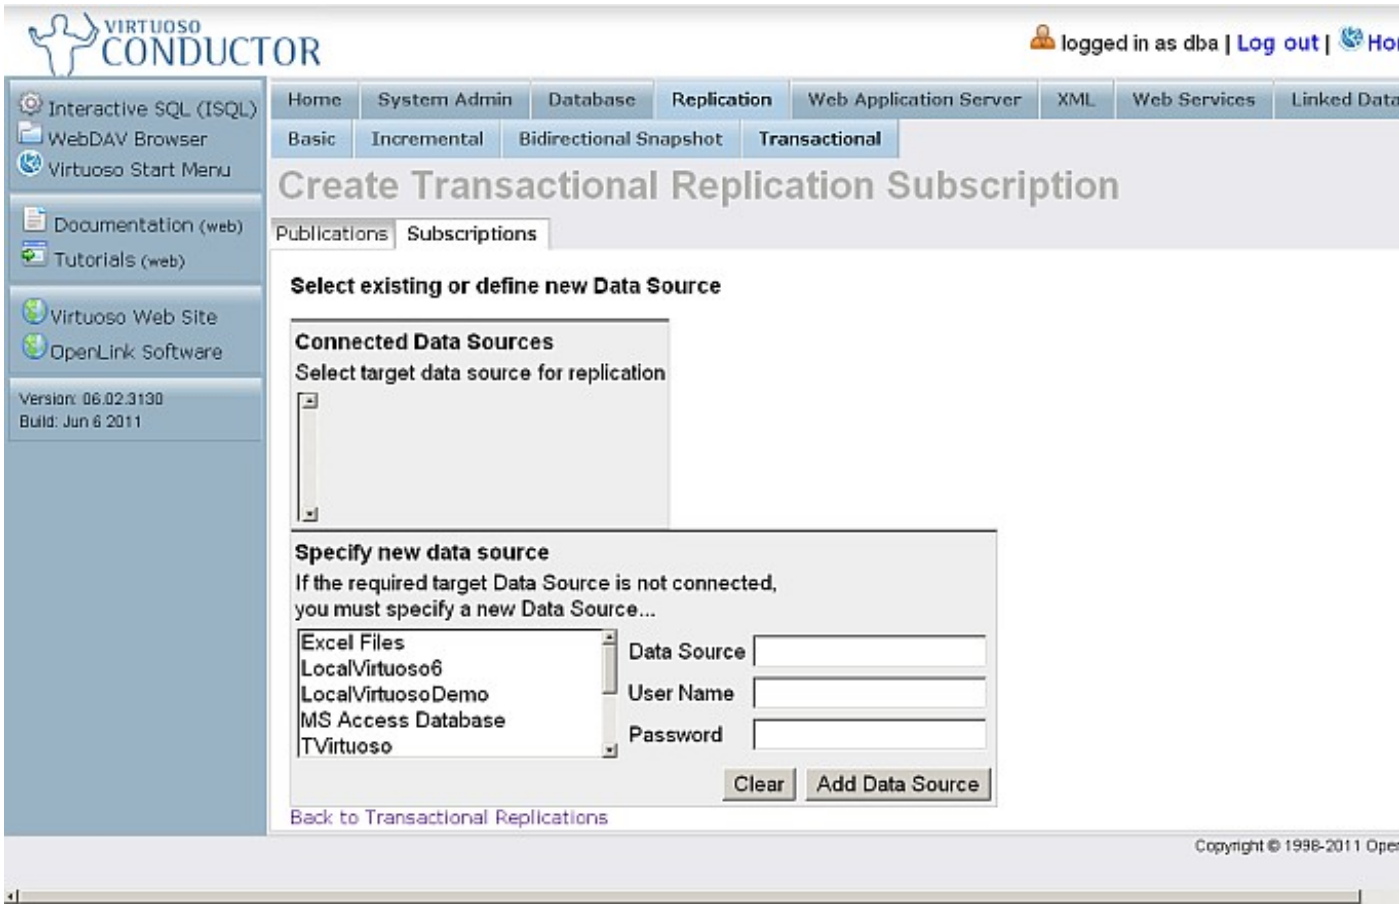
Figure 16.246. Chain Replication Topology



3. Click

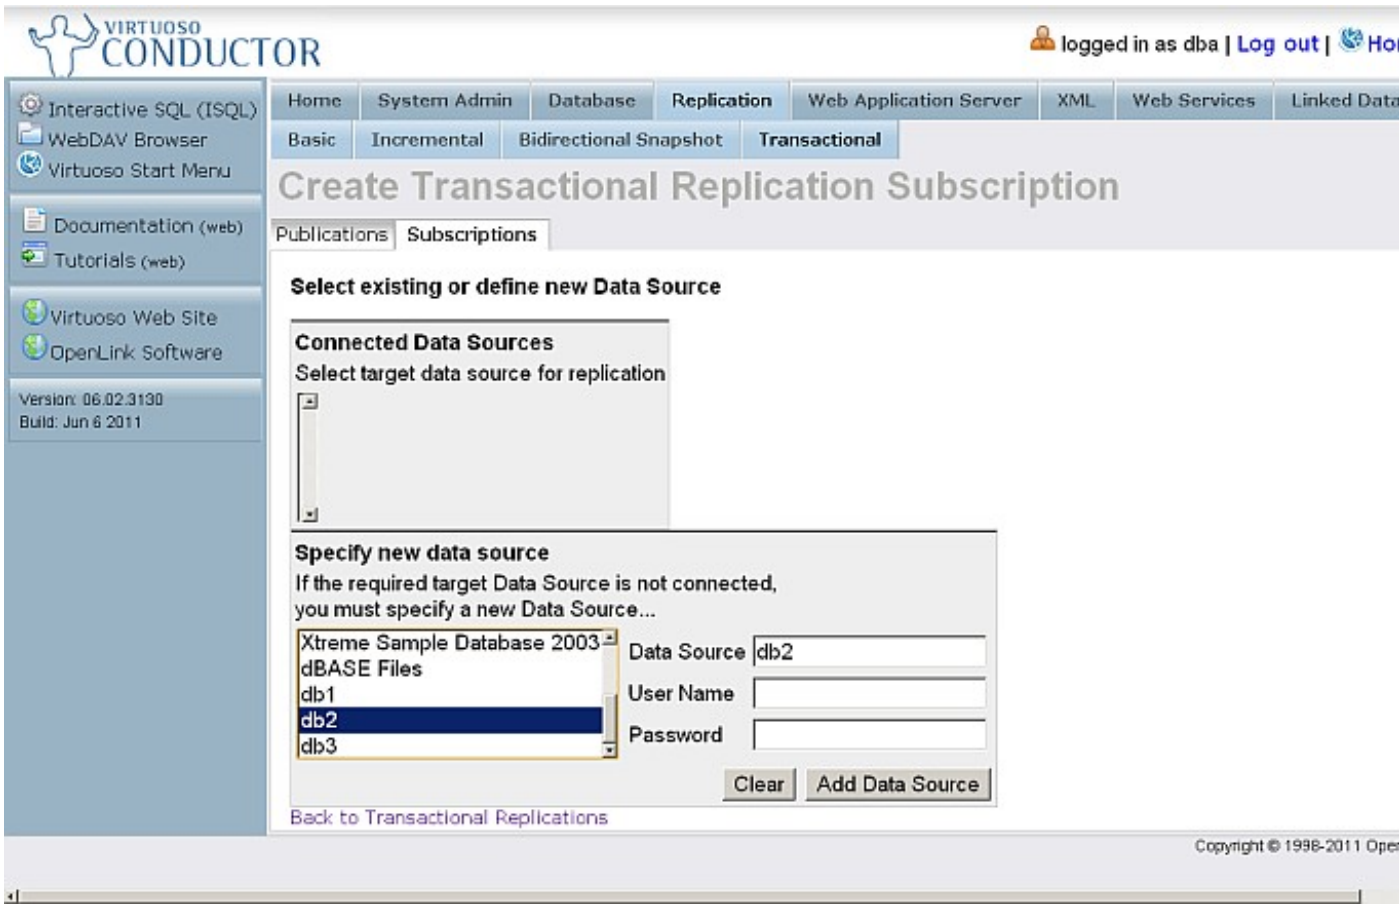
   New Subscription

Figure 16.247. Chain Replication Topology



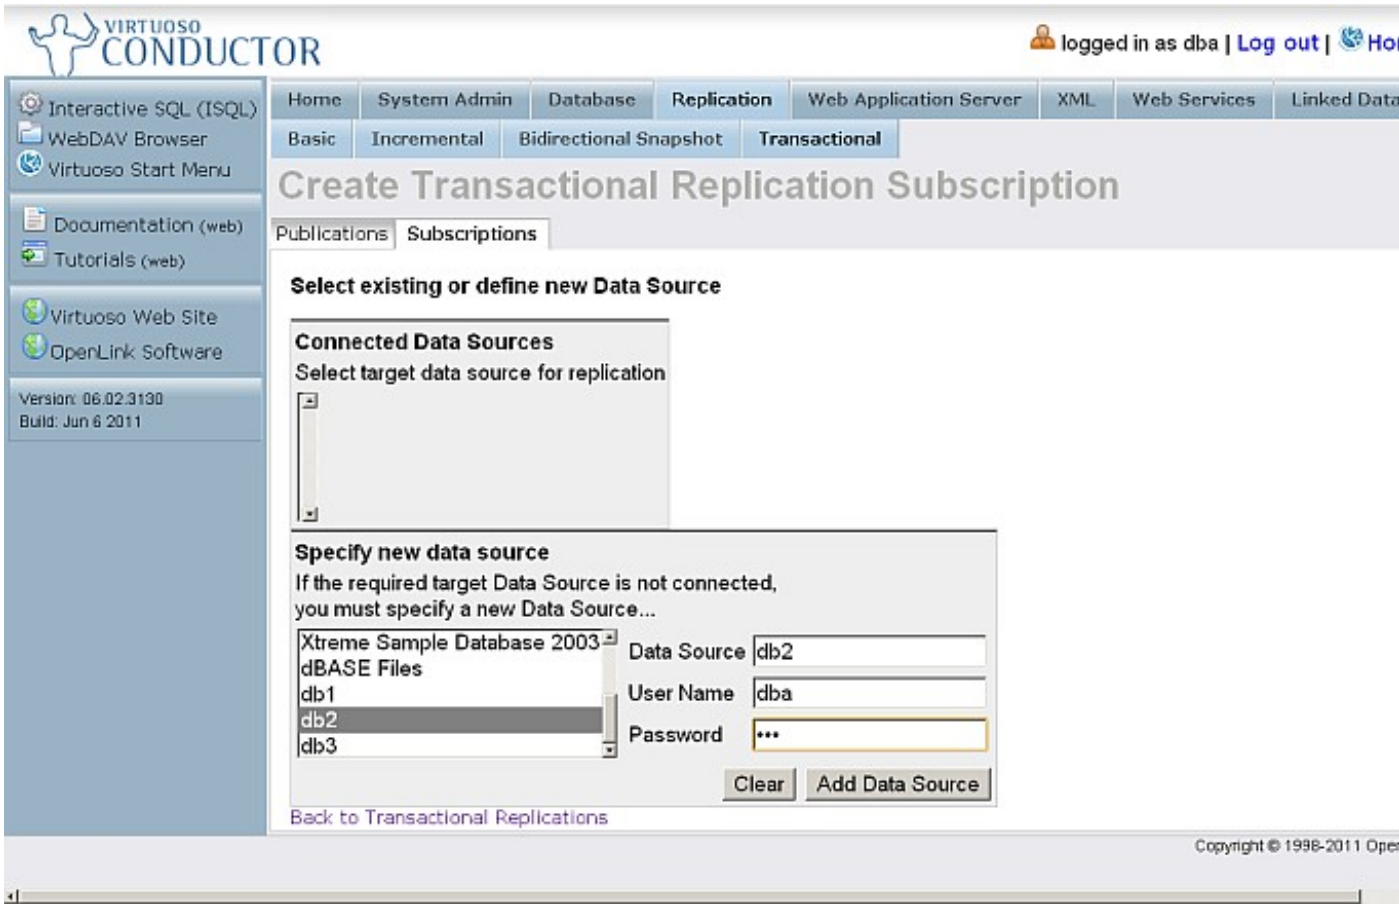
4. From the list of "Specify new data source" select Data Source db2

Figure 16.248. Chain Replication Topology



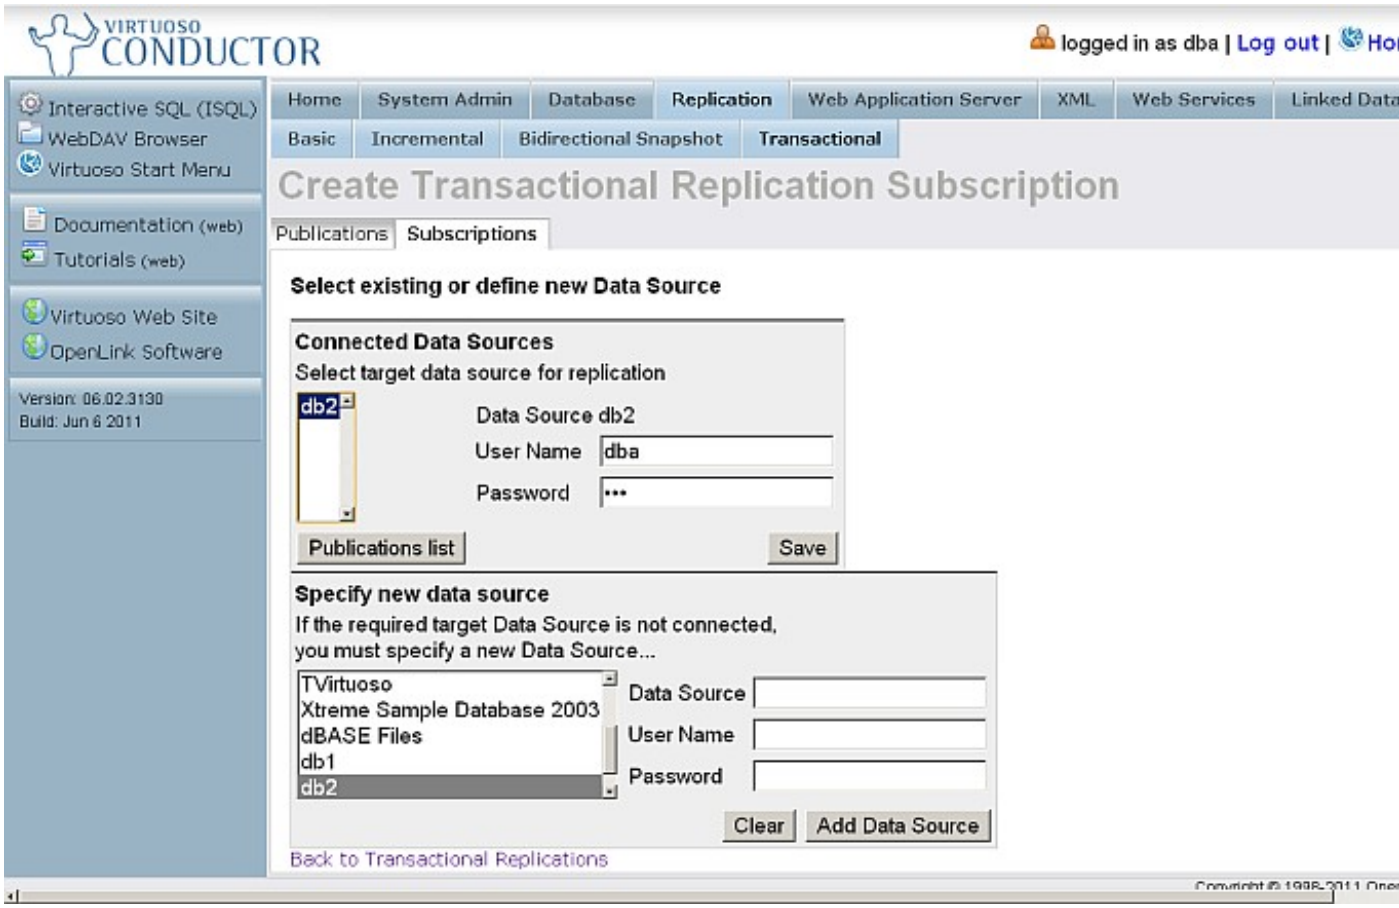
5. Enter for db2 dba user credentials

Figure 16.249. Chain Replication Topology



6. Click "Add Data Source"

Figure 16.250. Chain Replication Topology

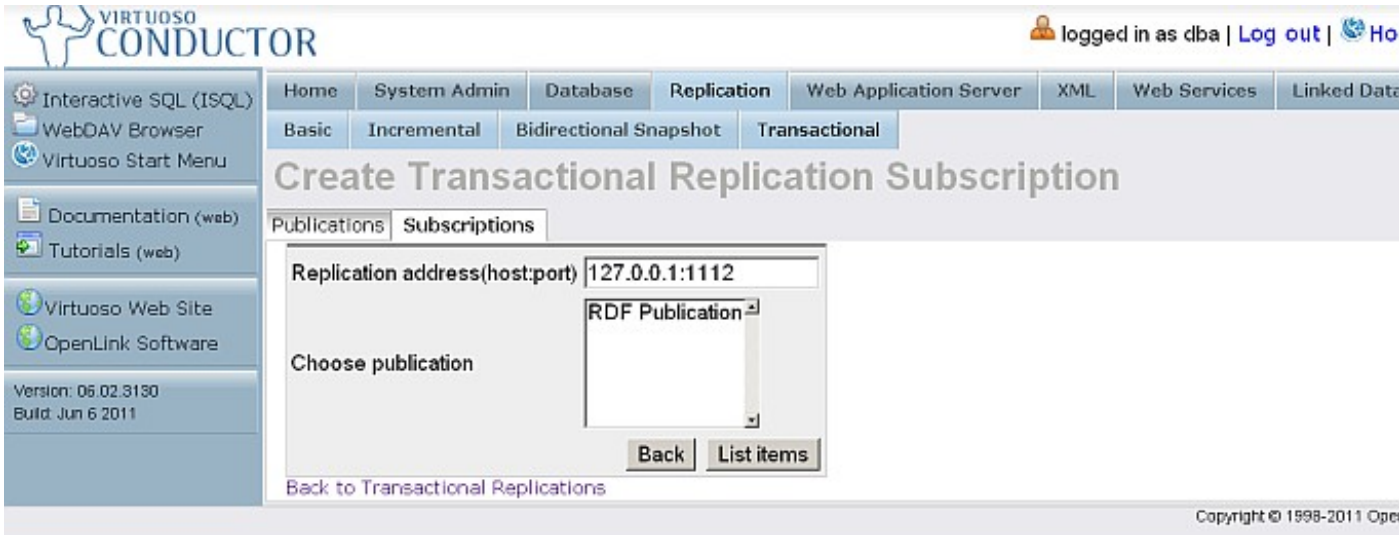


7. As result

   db2

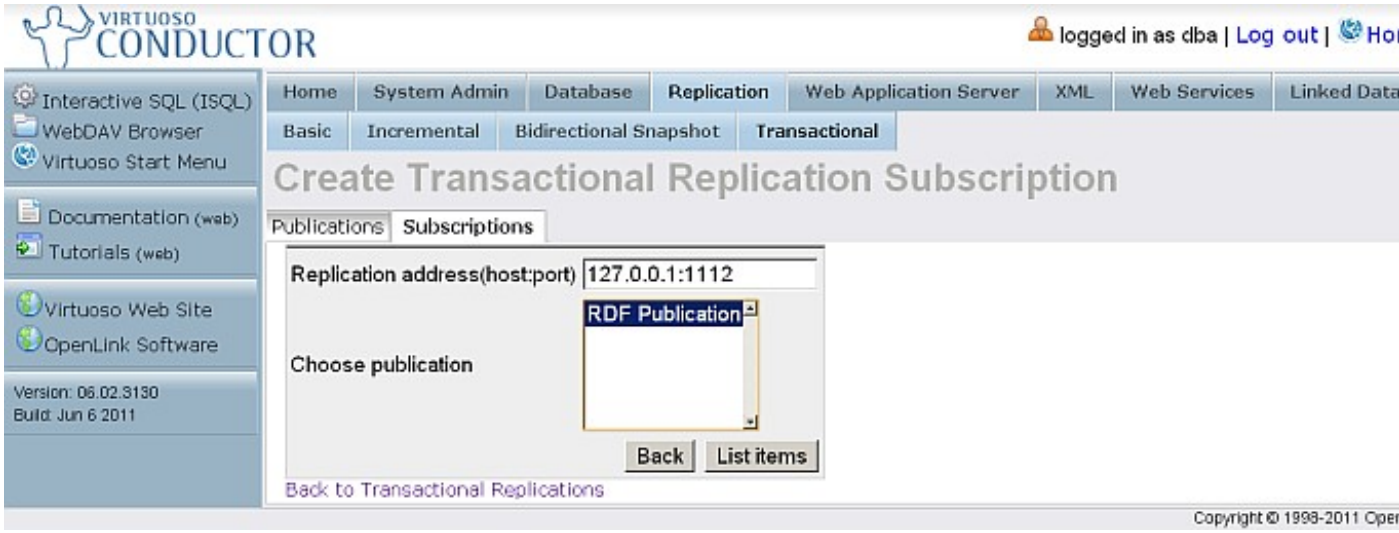
   will be shown in the "Connected Data Sources" list. Select it and click "Publications list"

Figure 16.251. Chain Replication Topology



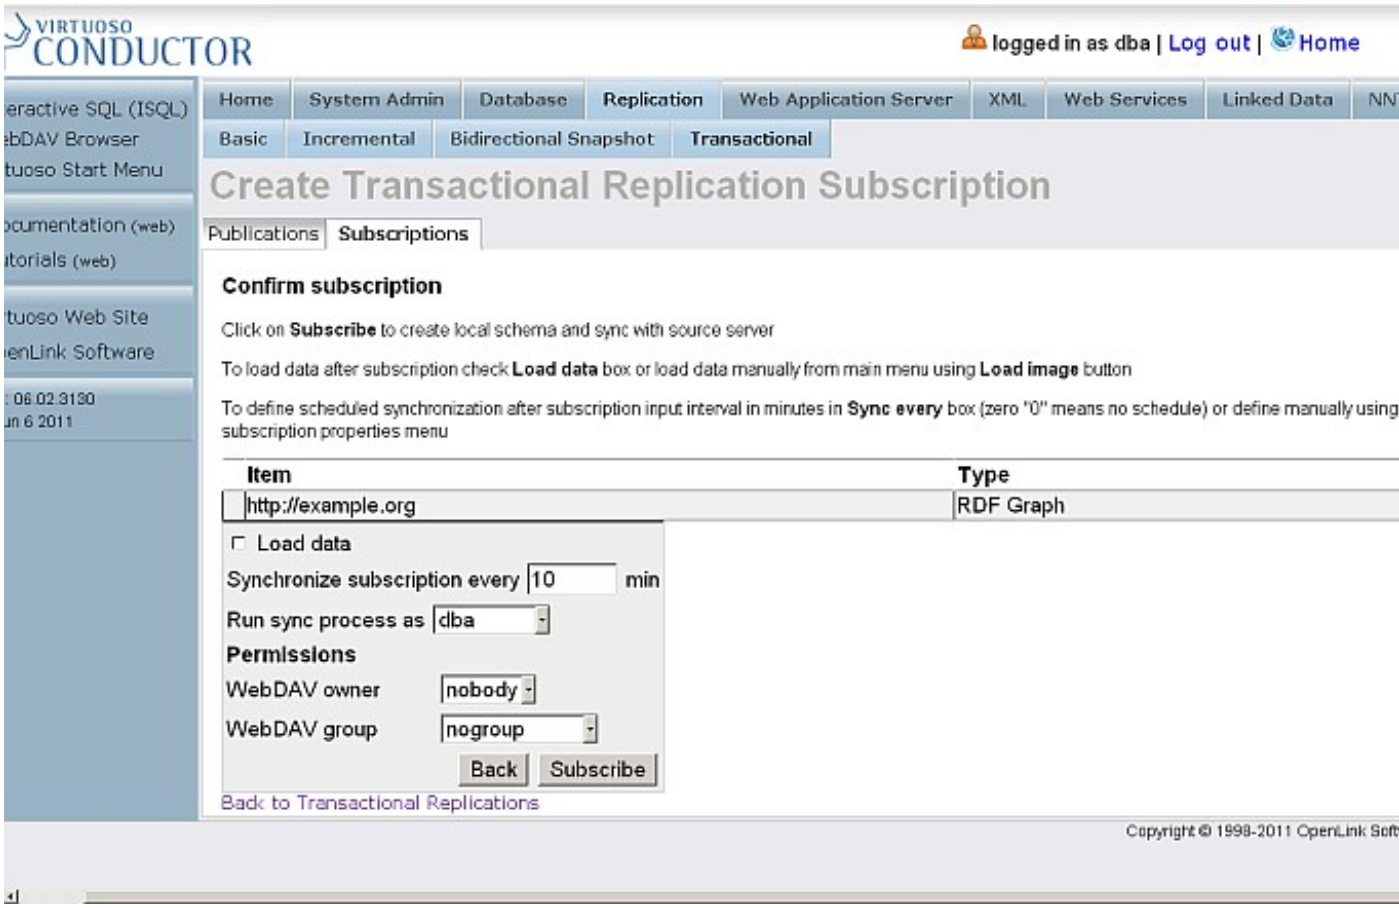
8. As result will be shown the list of available publications for the selected data source. Select the one with name "RDF Publication" and click "List Items".

Figure 16.252. Chain Replication Topology



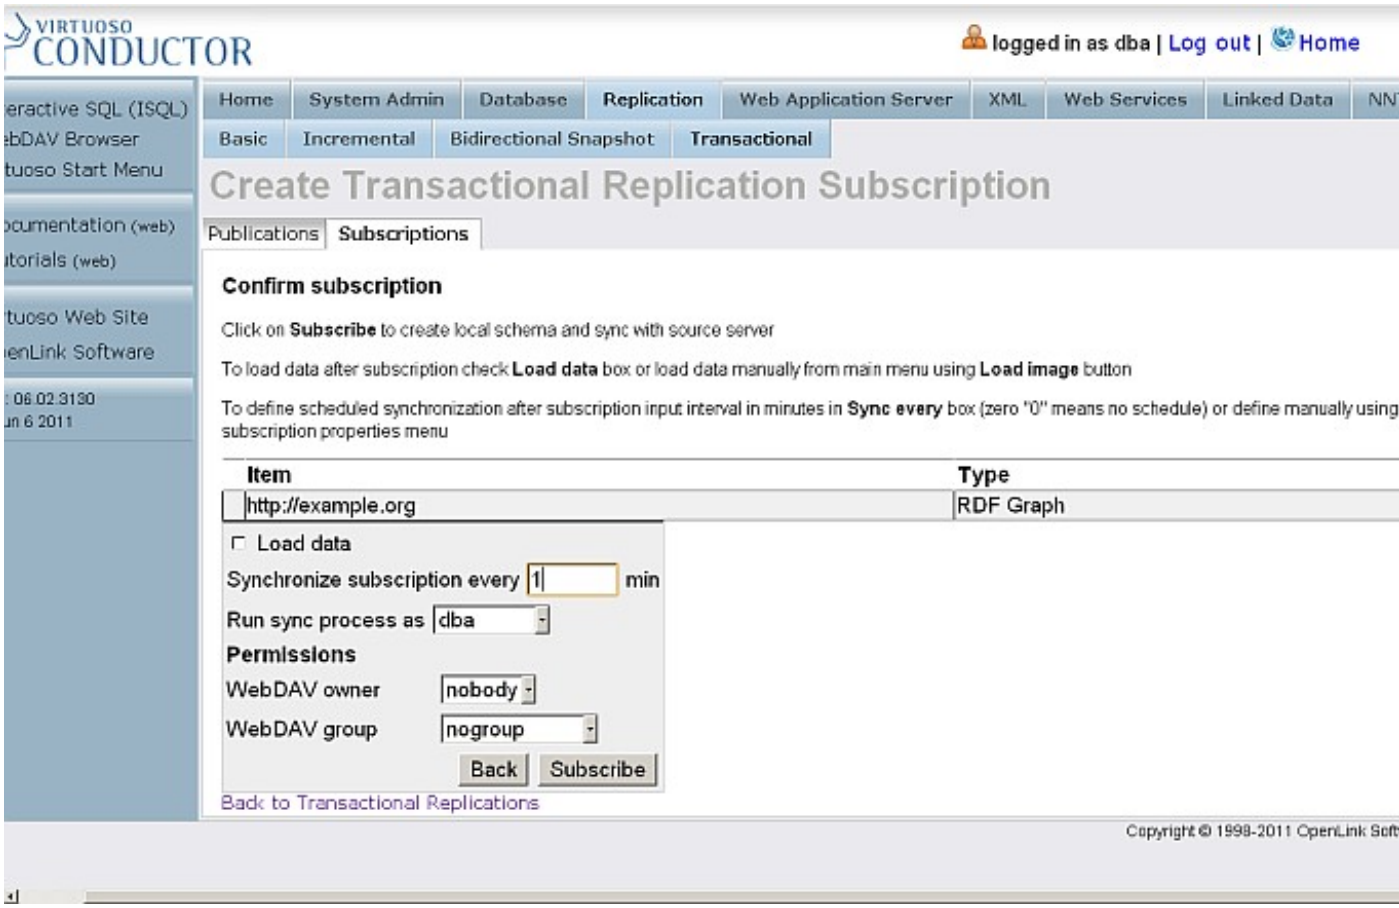
9. As result will be shown the "Confirm subscription" page.

Figure 16.253. Chain Replication Topology



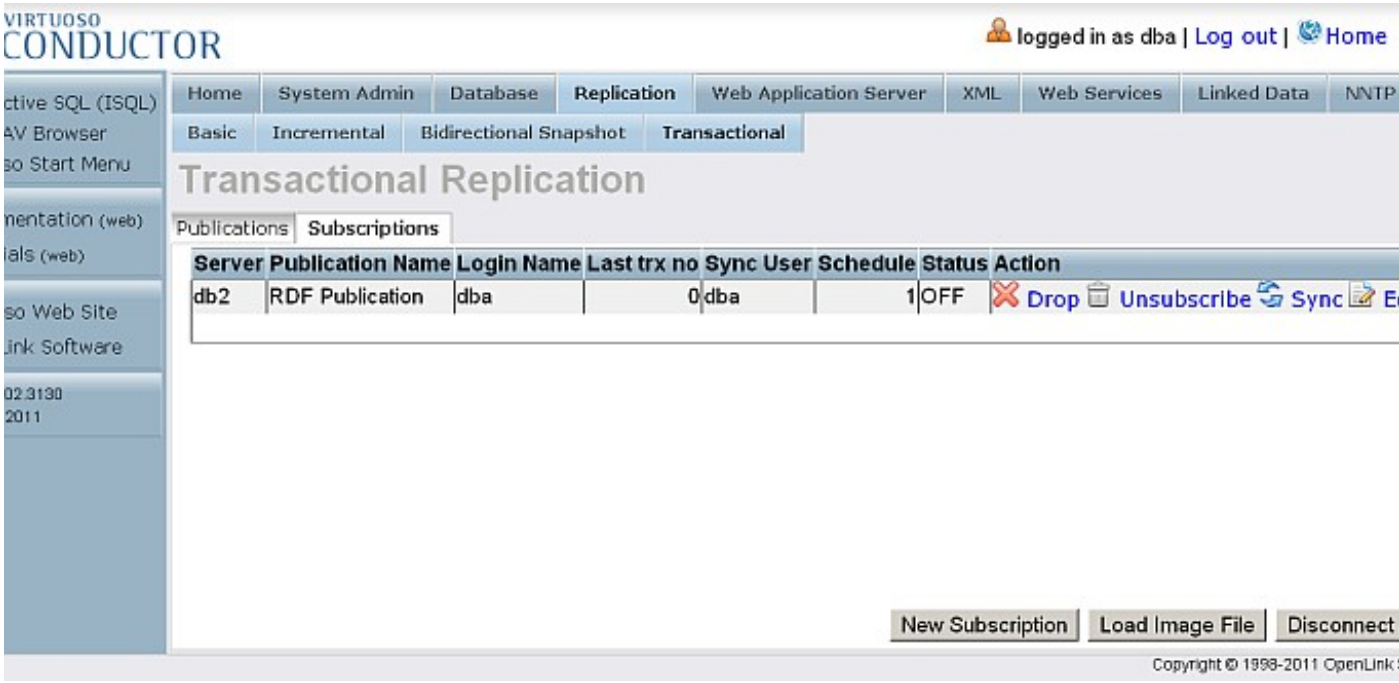
10. The sync interval by default is 10 minutes. For the testing purposes, we will change it to 1 minute.

Figure 16.254. Chain Replication Topology



11. Click "Subscribe"
12. The subscription will be created.

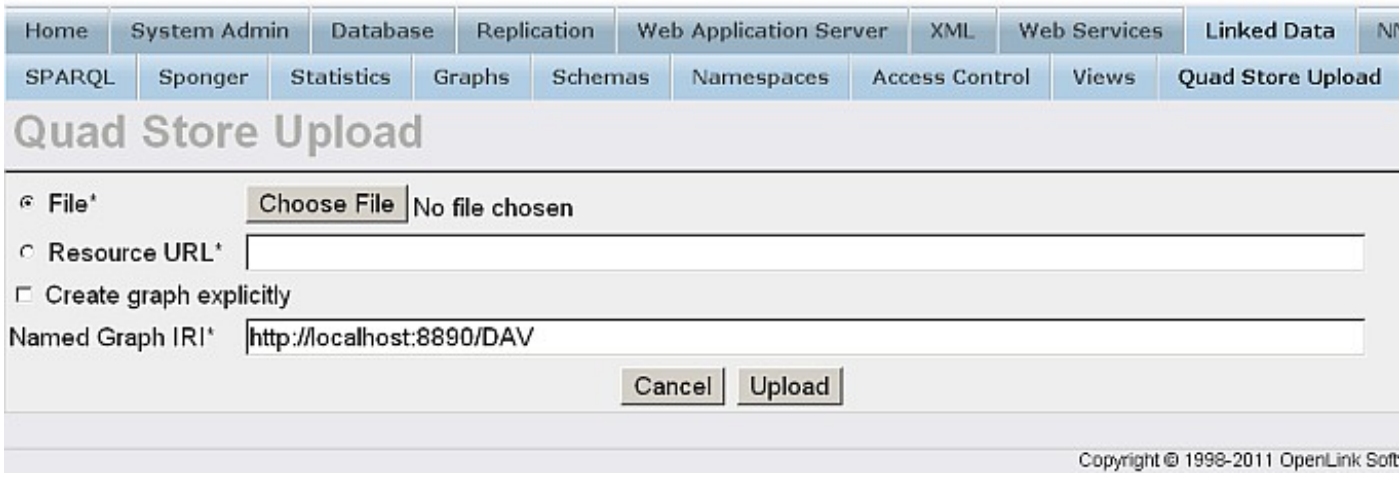
Figure 16.255. Chain Replication Topology



Insert Data into a Named Graph on the db1 Virtuoso Instance

1. Log in at http://example.com:8891/conductor
2. Go to Linked Data -> Quad Store Upload:

Figure 16.256. Chain Replication Topology



3. In the shown form:

   a. Tick the box for

   Resource URL

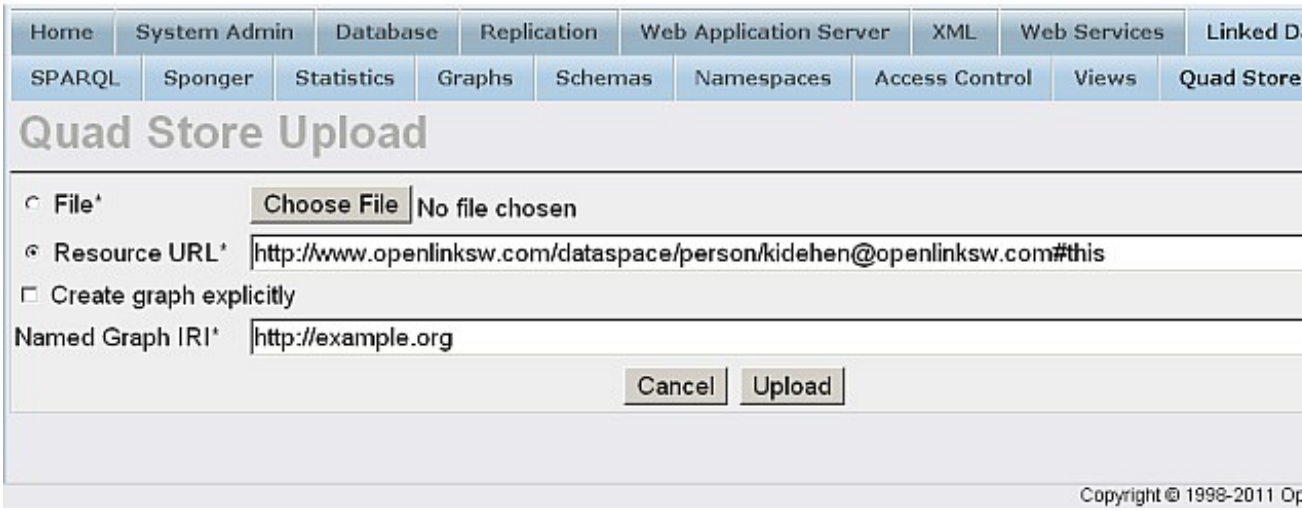
   and enter your resource URL, e.g.:

   ```
   http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this
   ```

   b. Enter for Named Graph IRI:

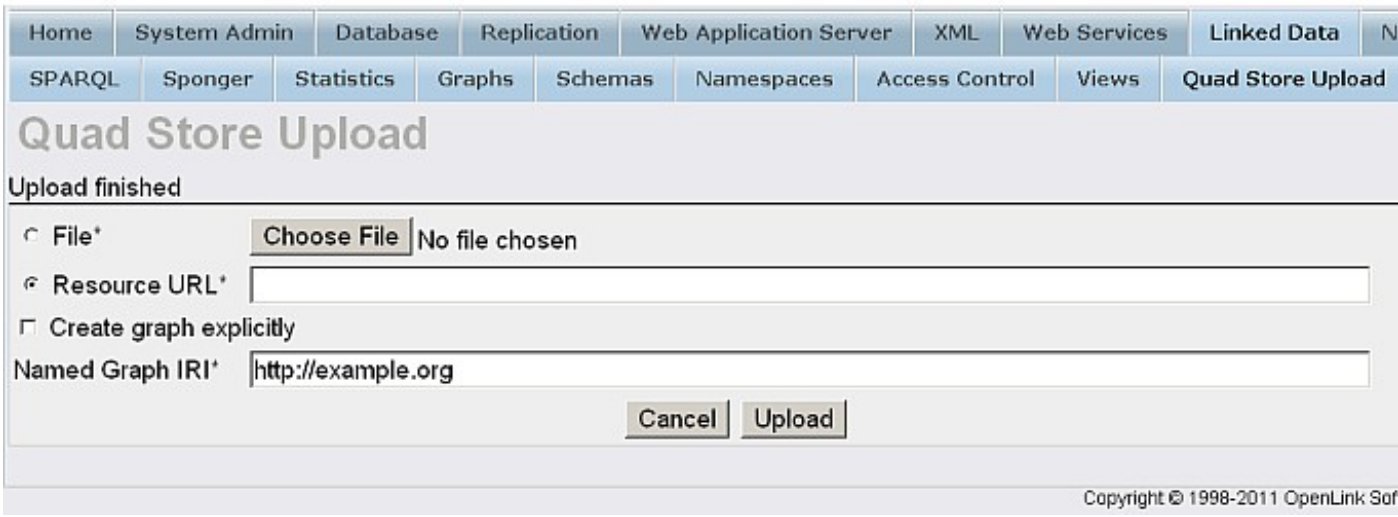
   ```
   http://example.org
   ```

   Figure 16.257. Chain Replication Topology



4. Click Upload
5. A successful upload will result in a shown message.

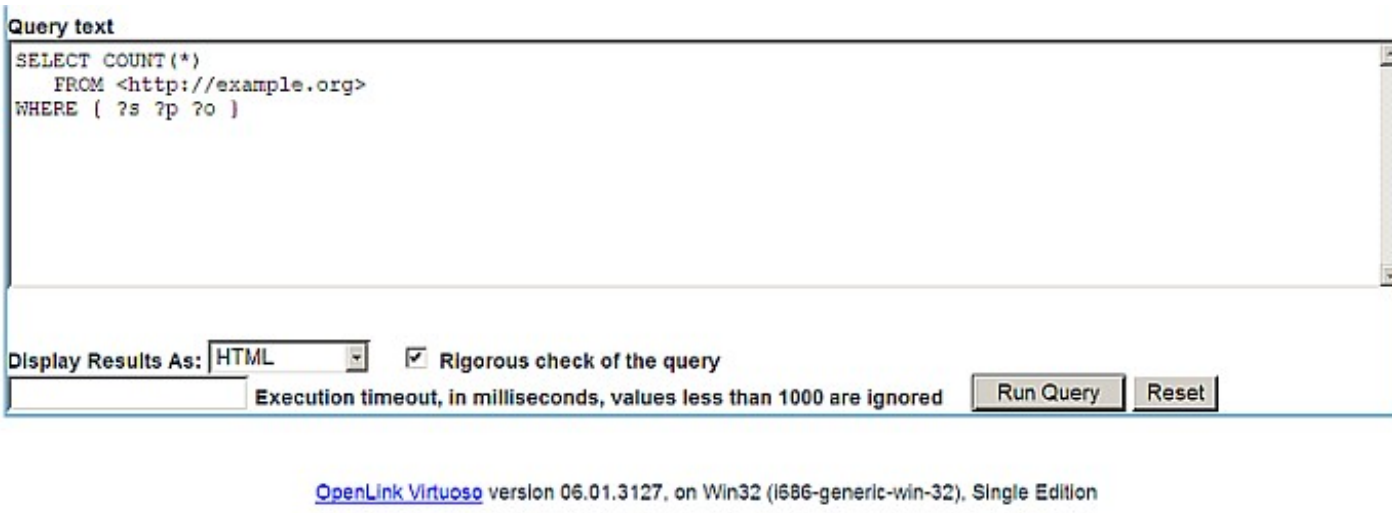
Figure 16.258. Chain Replication Topology



6. Check the count of the inserted triples by executing a query like the following against the SPARQL endpoint, http://example.com:8891/sparql:

```
SELECT COUNT(*)
   FROM <http://example.org>
WHERE { ?s ?p ?o }
```

Figure 16.259. Chain Replication Topology



7. Should return

   57

   as total.

Figure 16.260. Chain Replication Topology

callret-0
57

Check data on the Destination instances db2 and db3

1. To check the starting count, on each of the Destination Virtuoso Instances db2 and db3 from SPARQL Endpoint execute:

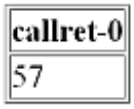
```
SELECT COUNT(*)
   FROM <http://example.org>
WHERE { ?s ?p ?o }
```

2. Should return

   57

   as total.

Figure 16.261. Chain Replication Topology

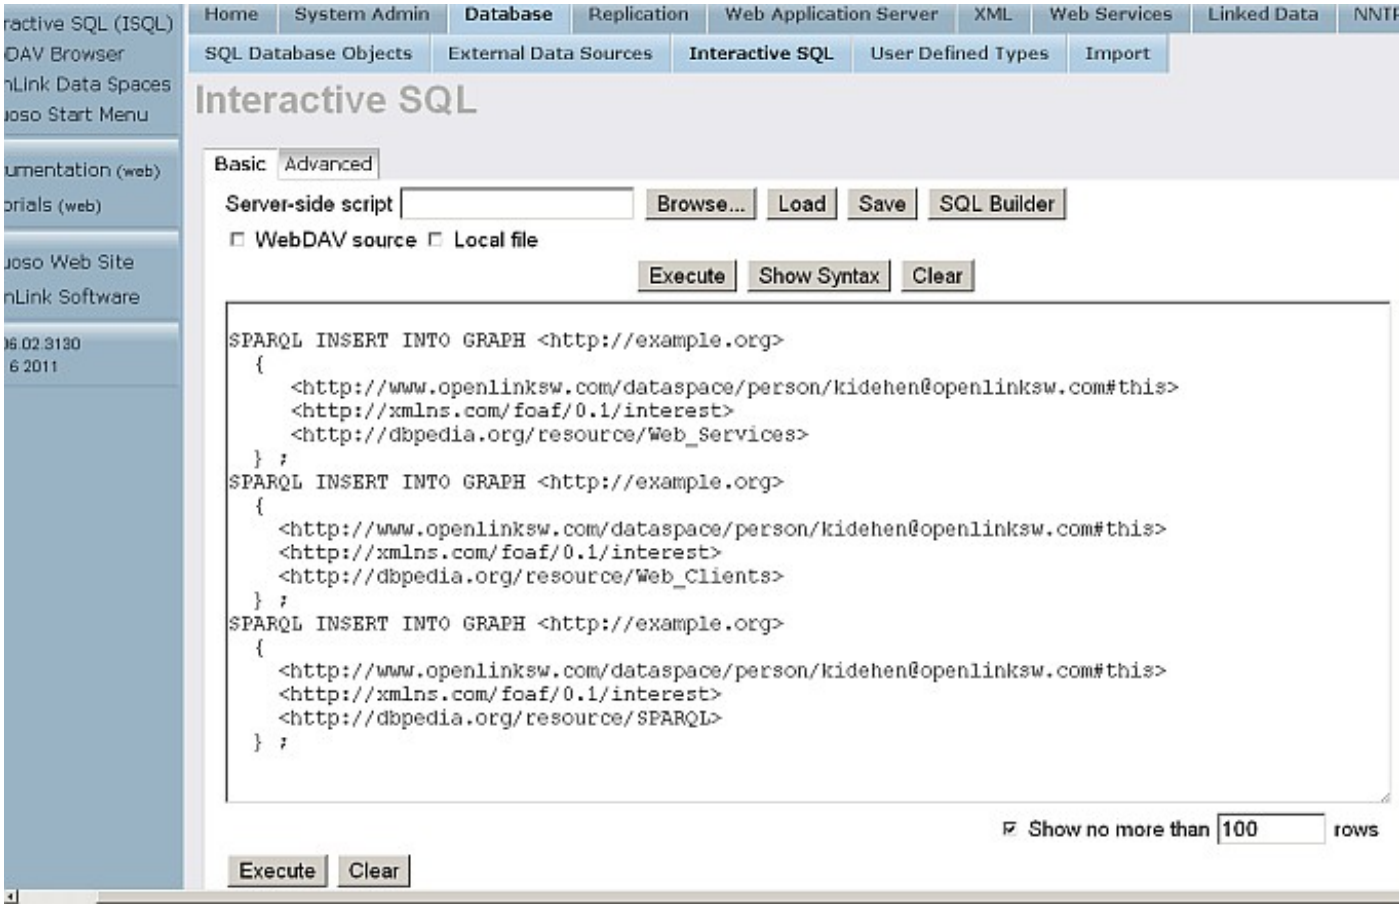


Add new data on db1

1. Disconnect db2 and db3.
2. On the Host Virtuoso Instance db1 go to Conductor - > Database - > Interactive SQL enter the following statement:

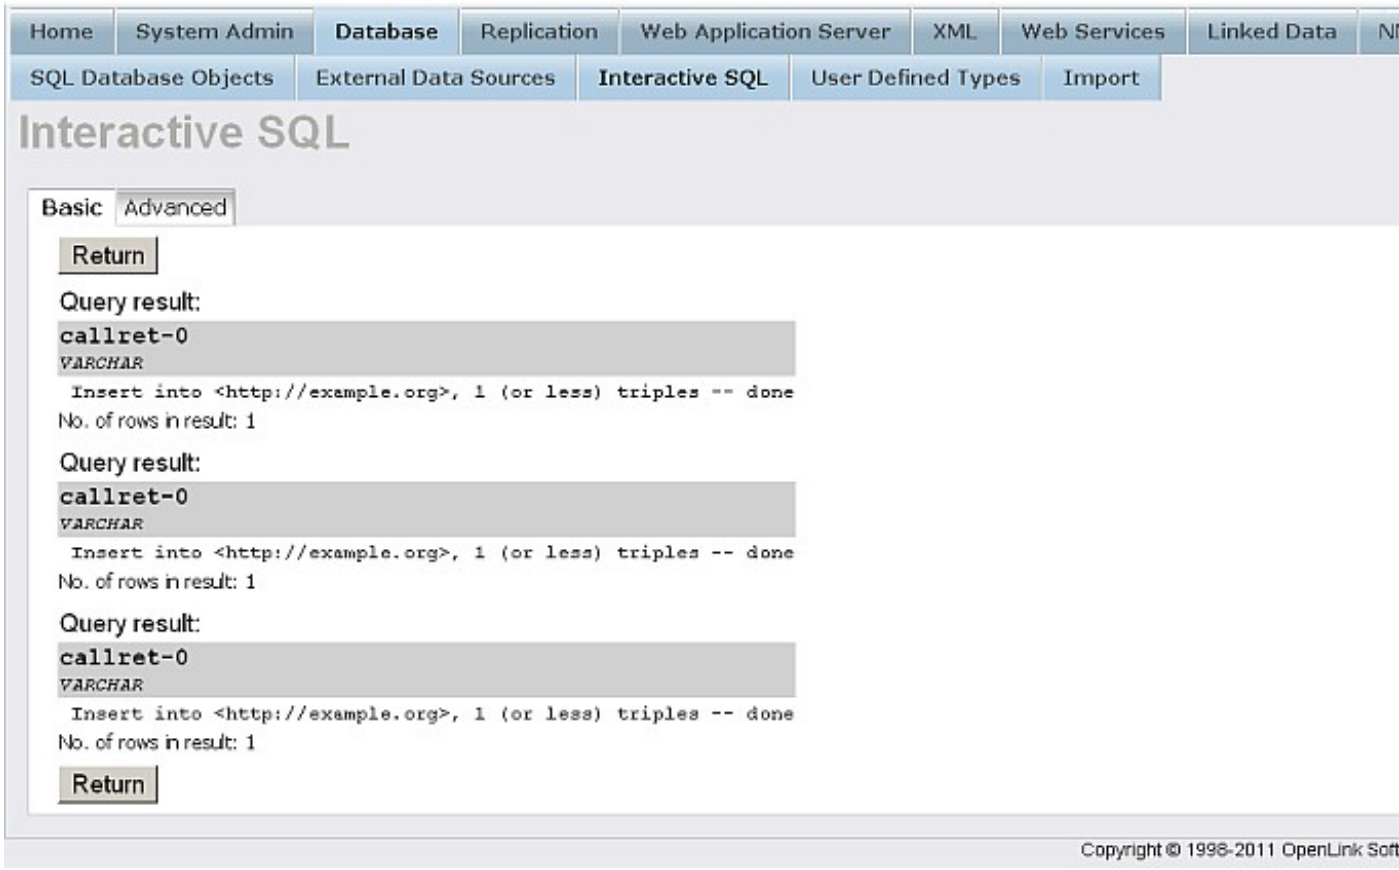
```
SPARQL INSERT INTO GRAPH <http://example.org>
  {
     <http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this>
     <http://xmlns.com/foaf/0.1/interest>
     <http://dbpedia.org/resource/Web_Services>
  } ;
SPARQL INSERT INTO GRAPH <http://example.org>
  {
    <http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this>
    <http://xmlns.com/foaf/0.1/interest>
    <http://dbpedia.org/resource/Web_Clients>
  } ;
SPARQL INSERT INTO GRAPH <http://example.org>
  {
    <http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this>
    <http://xmlns.com/foaf/0.1/interest>
    <http://dbpedia.org/resource/SPARQL>
  } ;
```

Figure 16.262. Chain Replication Topology



3. Click "Execute"
4. As result the triples will be inserted

Figure 16.263. Chain Replication Topology



5. Check the count of the destination instance graph's triples by executing the following query like against the SPARQL endpoint, http://example.com:8891/sparql:

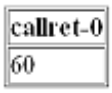
```
SELECT COUNT(*)
   FROM <http://example.org>
WHERE { ?s ?p ?o }
```

6. Should return

   60

   as total.

Figure 16.264. Chain Replication Topology



Check data on the Destination instances db2 and db3

1. Start instances db2 and db3
2. To confirm that the triple count has increased by the number of inserted triples, execute the following on the Destination Virtuoso Instance db2 and db3 SPARQL Endpoint:

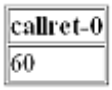
```
SELECT COUNT(*)
   FROM <http://example.org>
WHERE { ?s ?p ?o }
```

3. Should return

   60

   as total.

Figure 16.265. Chain Replication Topology



Bi-directional Replication Topology

Bi-directional Replication Topology Example

The following How-To walks you through setting up Virtuoso RDF Graph Replication in a Bi-directional Topology.

```
db1 <---- db2
db1 ---->

 db2
```

Prerequisites

Database INI Parameters

Suppose there are 2 Virtuoso instances respectively with the following ini parameters values:

1. virtuoso1.ini:

```
...
[Database]
DatabaseFile    = virtuoso1.db
TransactionFile = virtuoso1.trx
```

```
ErrorLogFile     = virtuoso1.log
...
[Parameters]
ServerPort               = 1111
SchedulerInterval        = 1
...
[HTTPServer]
ServerPort                  = 8891
...
[URIQA]
DefaultHost = example.com:8891
...
[Replication]
ServerName   = db1
...
```

2. virtuoso2.ini:

```
...
[Database]
DatabaseFile    = virtuoso2.db
TransactionFile = virtuoso2.trx
ErrorLogFile     = virtuoso2.log
...
[Parameters]
ServerPort               = 1112
SchedulerInterval        = 1
...
[HTTPServer]
ServerPort                  = 8892
...
[URIQA]
DefaultHost = localhost:8892
...
[Replication]
ServerName   = db2
...
```

Database DSNs

Use the ODBC Administrator on your Virtuoso host (e.g., on Windows, Start menu -> Control Panel -> Administrative Tools -> Data Sources (ODBC); on Mac OS X, /Applications/Utilities/OpenLink ODBC Administrator.app) to create a System DSN for db1 and db2 with names db1 and db2 respectively.

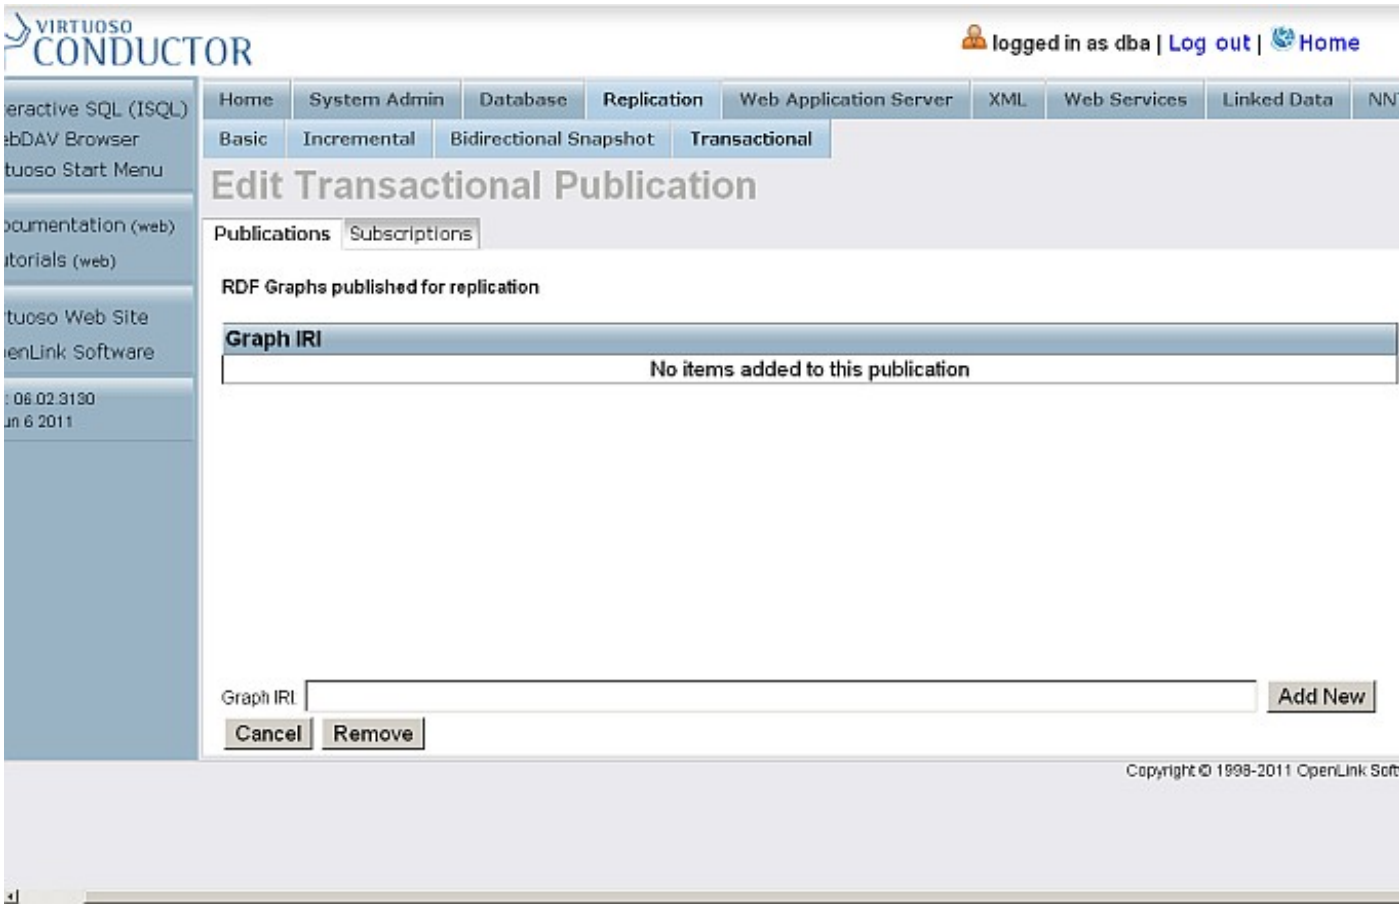
Install Conductor package

On each of the 2 Virtuoso instances install the conductor_dav.vad package.

Create Publication on db2

1. Go to http://example.com:8892/conductor and log in as dba
2. Go to Conductor -> Replication -> Transactional -> Publications

Figure 16.266. Bi-directional Replication Topology



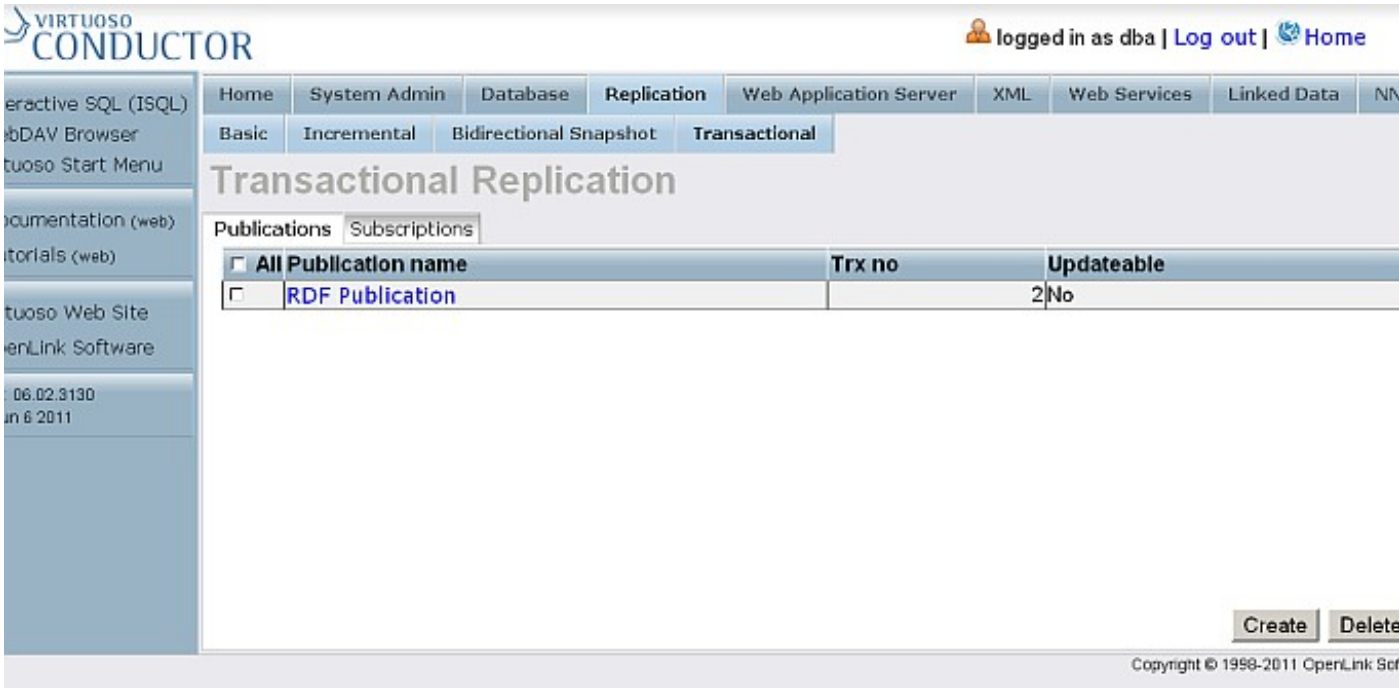
3. Click

   Enable RDF Publishing
4. As result publication with the name

   RDF Publication

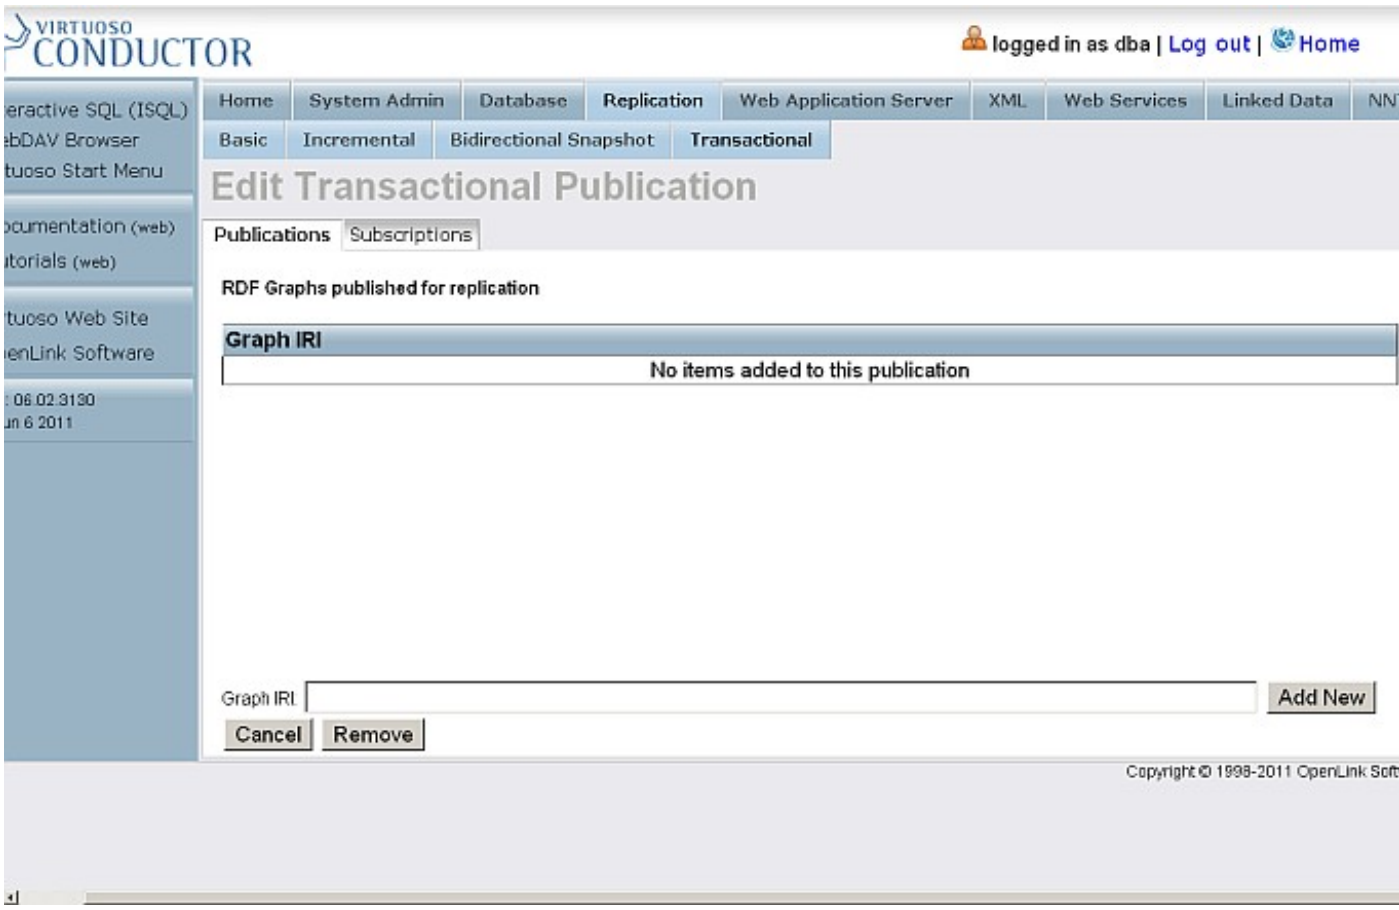
   should be created

Figure 16.267. Bi-directional Replication Topology



5. Click the link which is the publication name.
6. You will be shown the publication items page

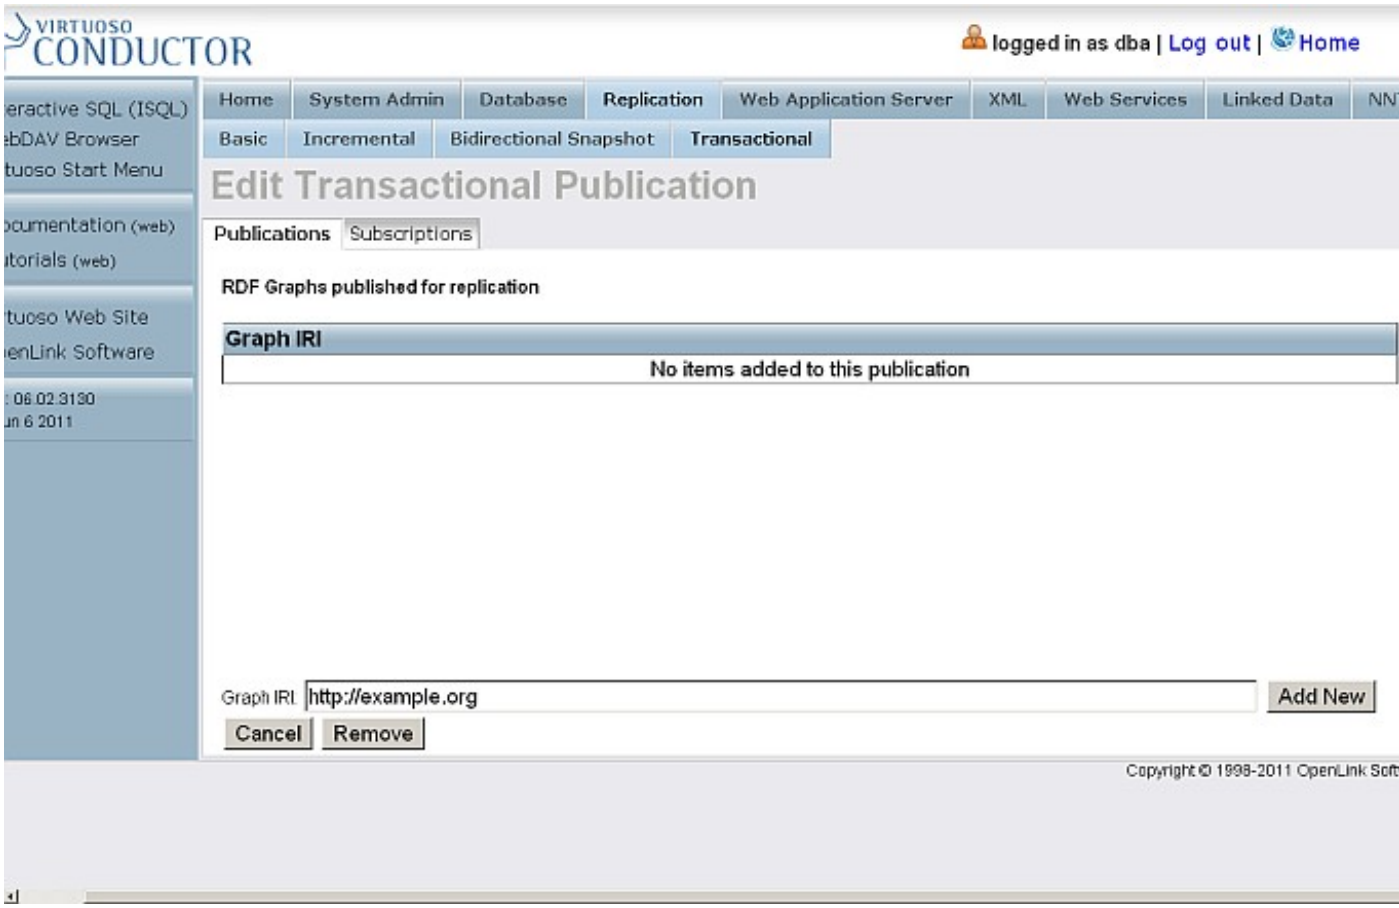
Figure 16.268. Bi-directional Replication Topology



7. Enter for Graph IRI:

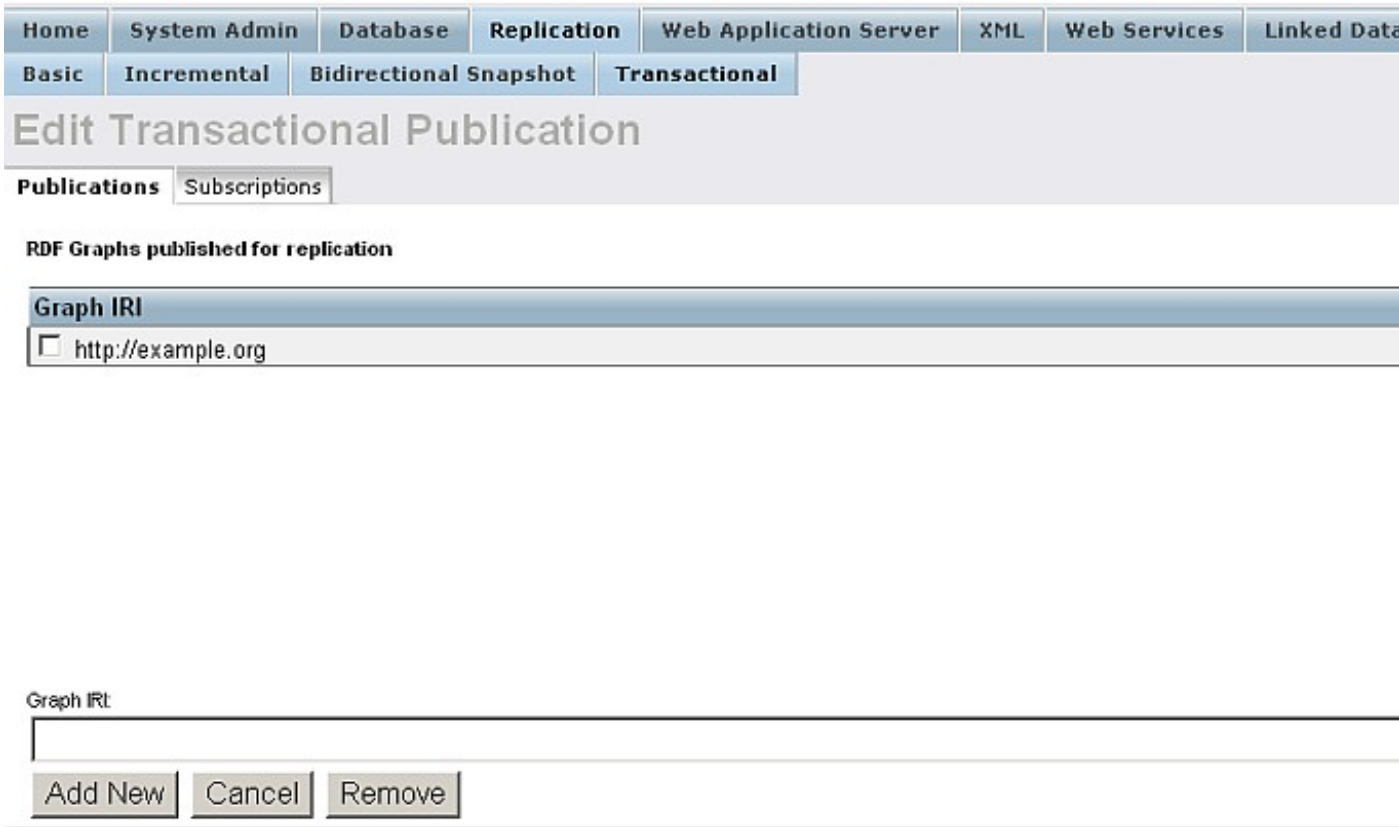
```
http://example.org
```

Figure 16.269. Bi-directional Replication Topology



8. Click Add New
9. The item will be created and shown in the list of items for the currently viewed publication.

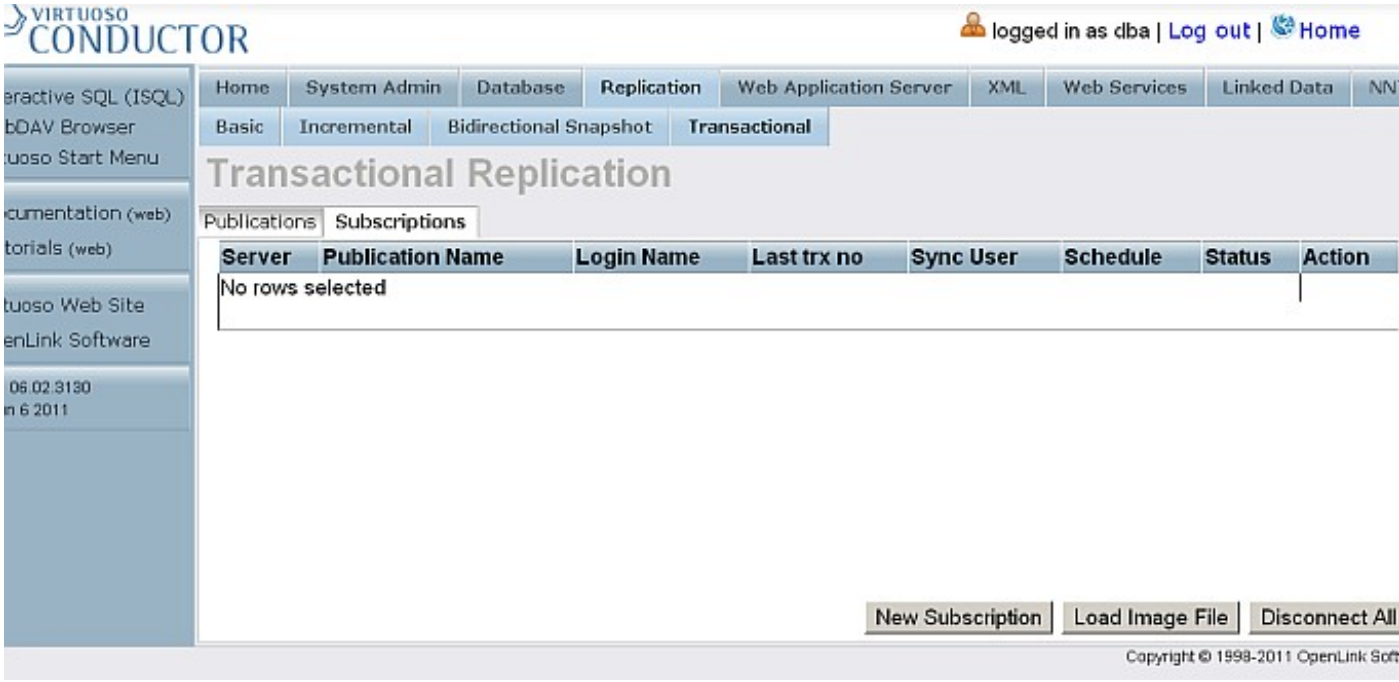
Figure 16.270. Bi-directional Replication Topology



Create subscription from db1 to db2's Publication

1. Log in at http://example.com:8891/conductor
2. Go to Replication -> Transactional -> Subscriptions

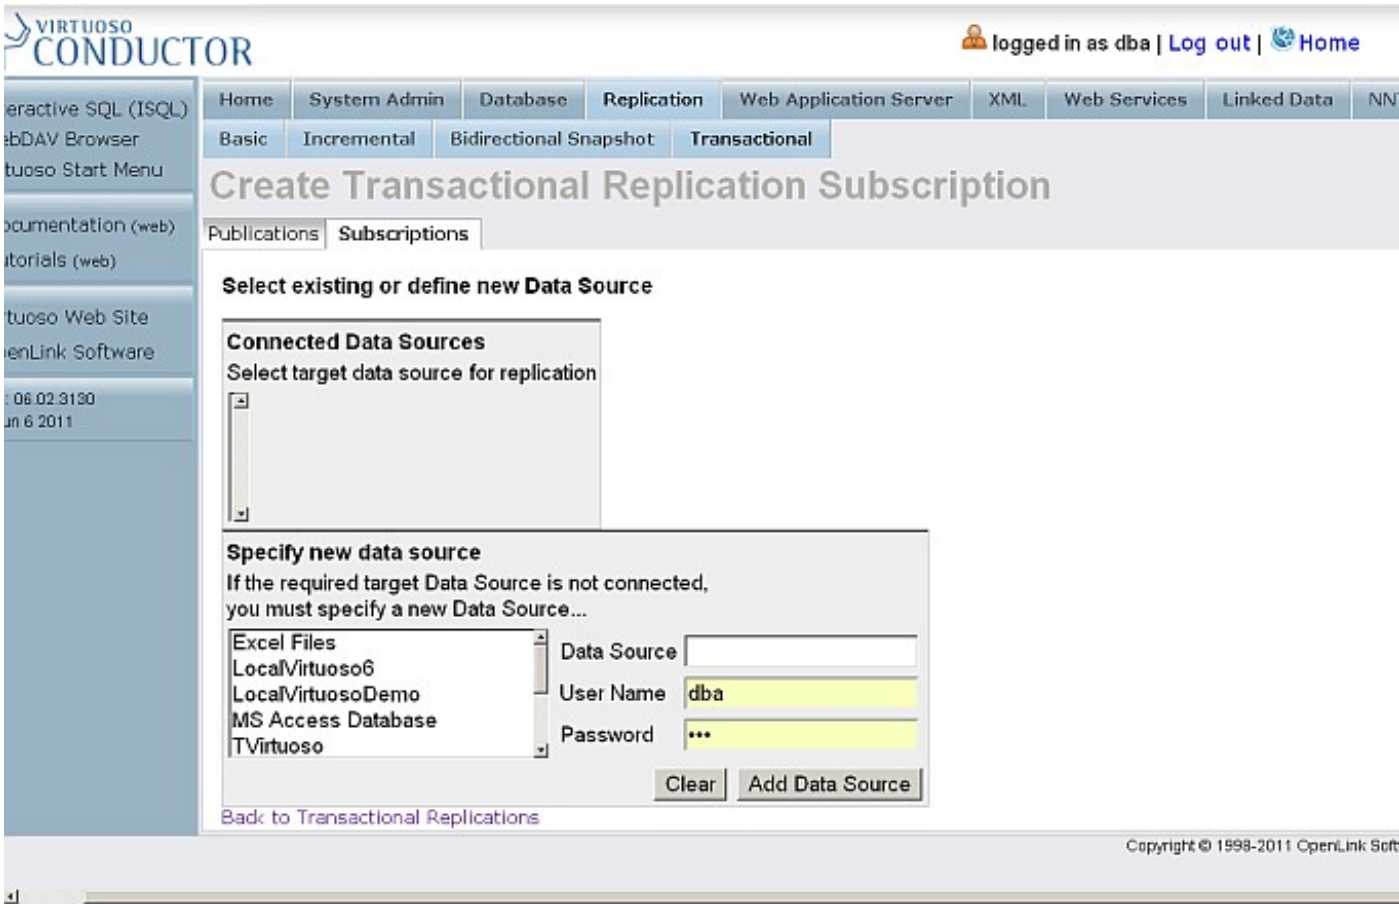
Figure 16.271. Bi-directional Replication Topology



3. Click

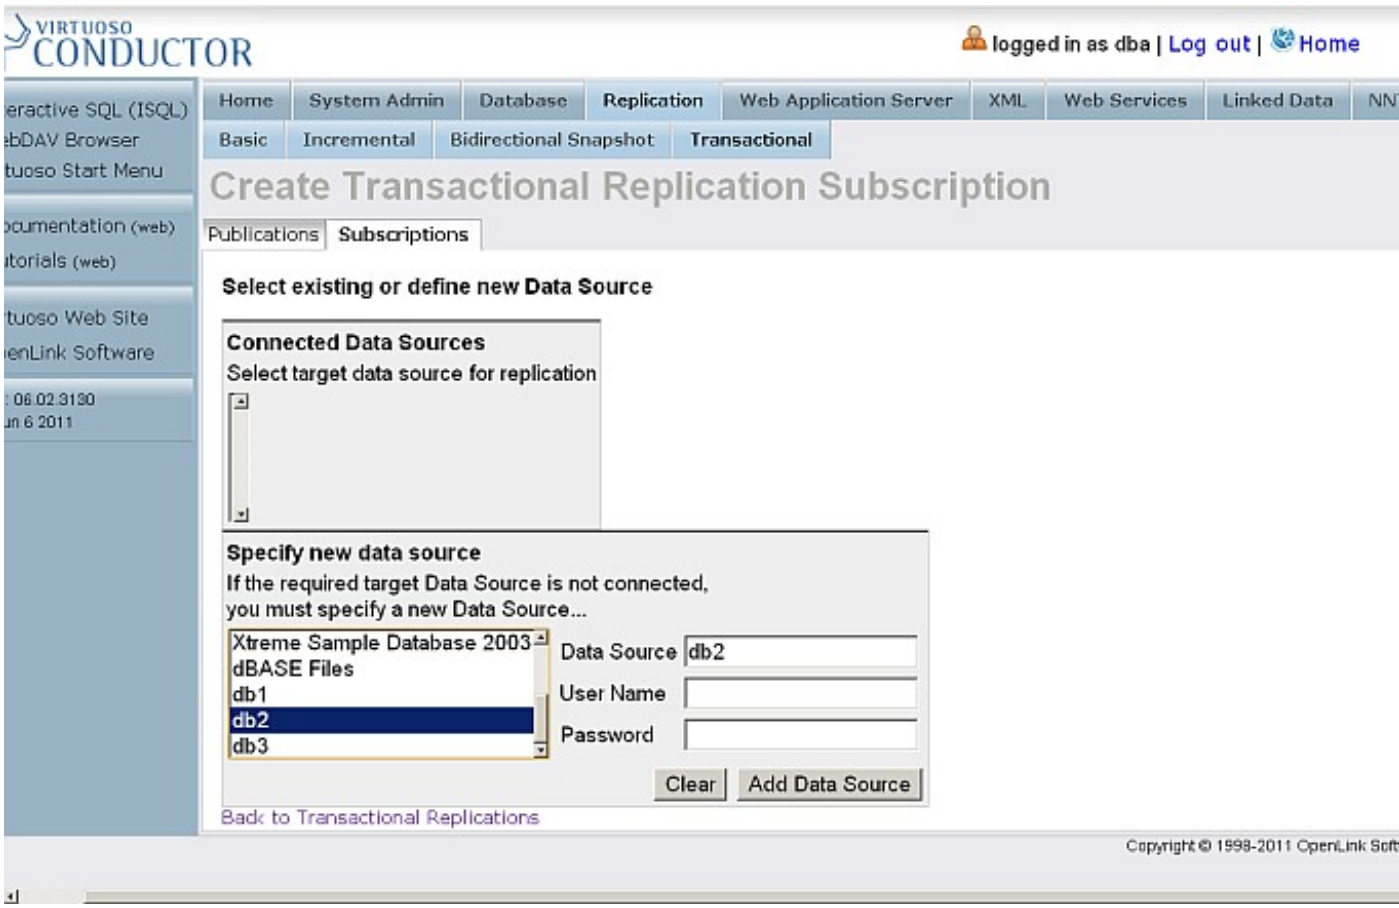
New Subscription

Figure 16.272. Bi-directional Replication Topology



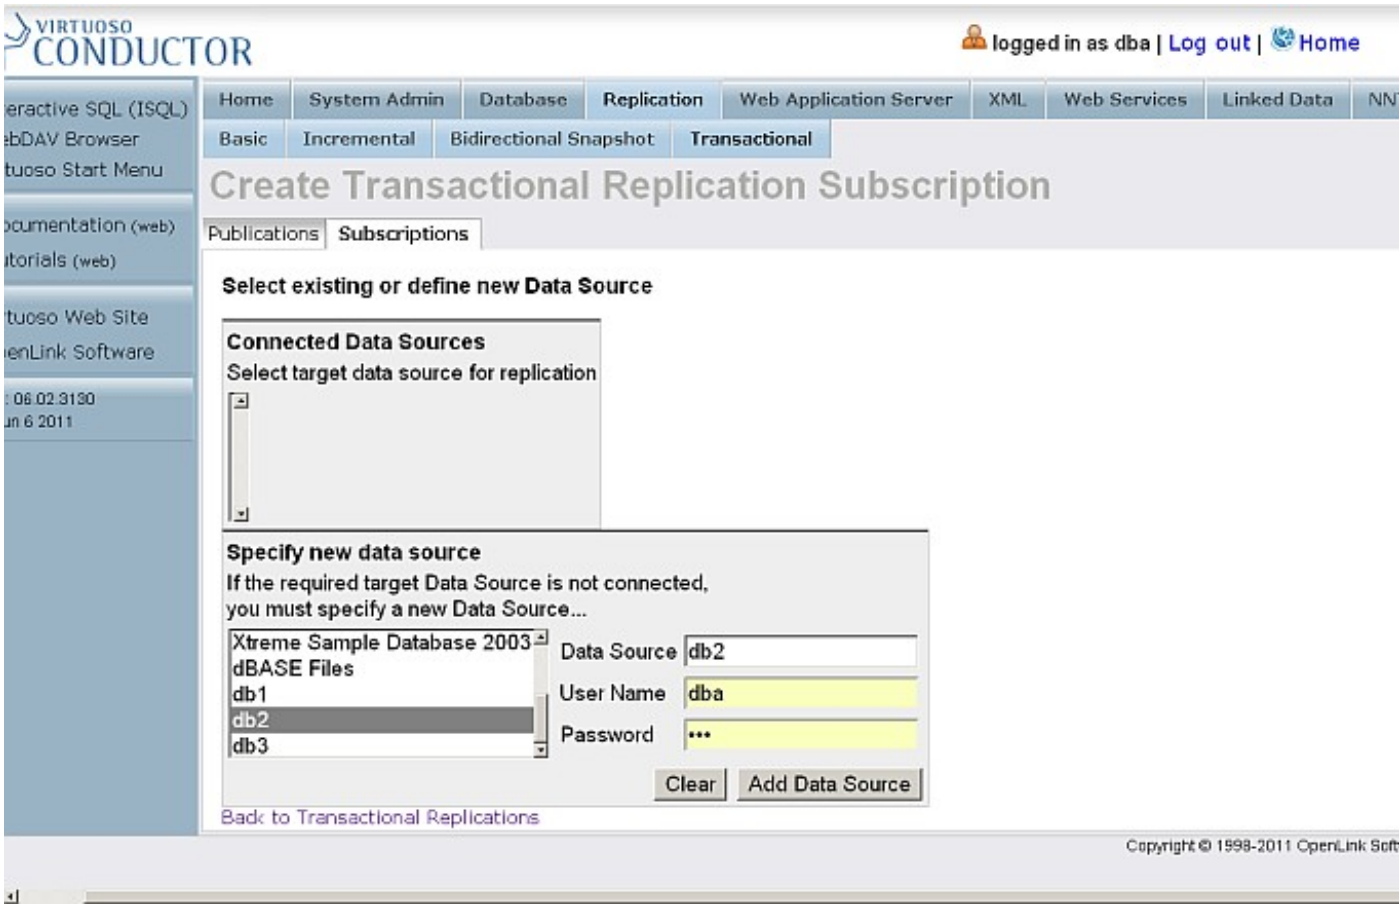
4. From the list of "Specify new data source" select Data Source db2

Figure 16.273. Bi-directional Replication Topology



5. Enter for db2 dba user credentials

Figure 16.274. Bi-directional Replication Topology



6. Click "Add Data Source"
7. As result

   db2

   will be shown in the "Connected Data Sources" list.

   FROM <http://example.org>
WHERE { ?s ?p ?o }
```

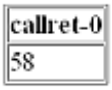
6. Should return

58

as total.

Figure 16.304. Bi-directional Replication Topology



Check data on the Destination instance db1

1. Start instance db1
2. To confirm that the triple count has increased by the number of inserted triples, execute the following statement on db1's SPARQL Endpoint:

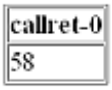
```
SELECT COUNT(*)
   FROM <http://example.org>
WHERE { ?s ?p ?o }
```

3. Should return

58

as total.

Figure 16.305. Bi-directional Replication Topology

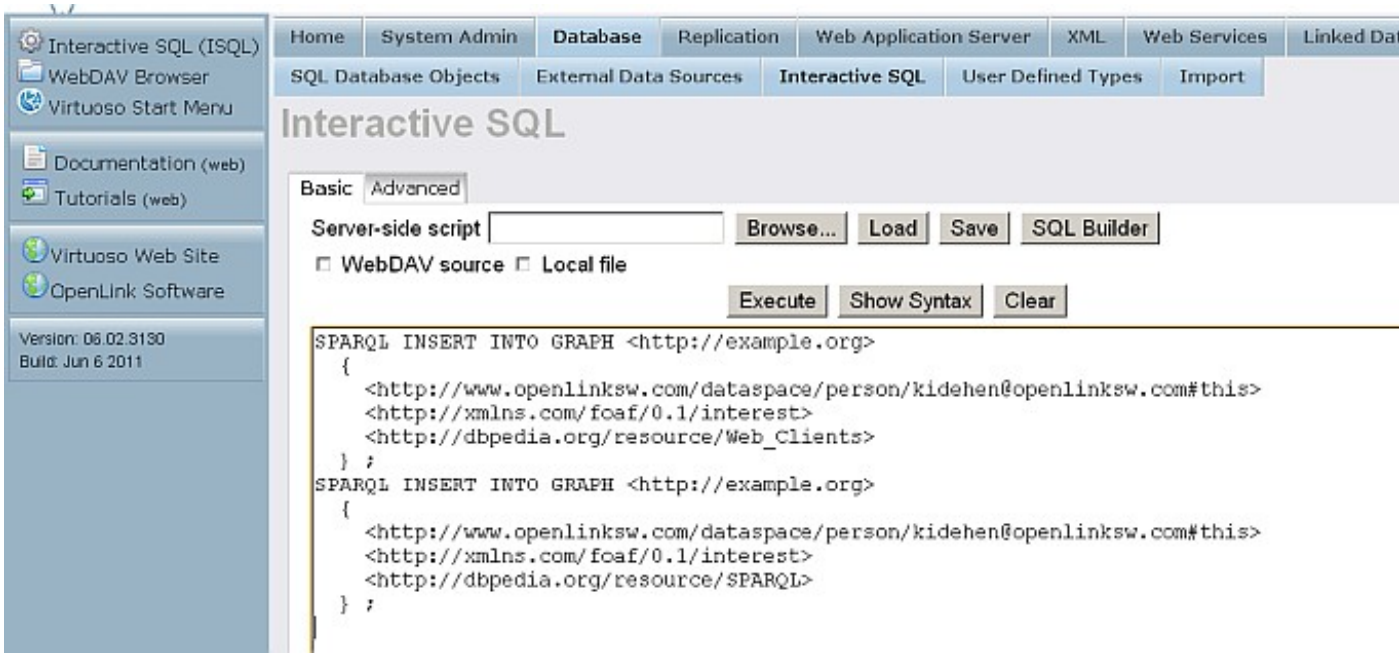


Add new data on db1

1. Disconnect db2.
2. On the Host Virtuoso Instance db1 go to Conductor -> Database -> Interactive SQL enter the following statement:

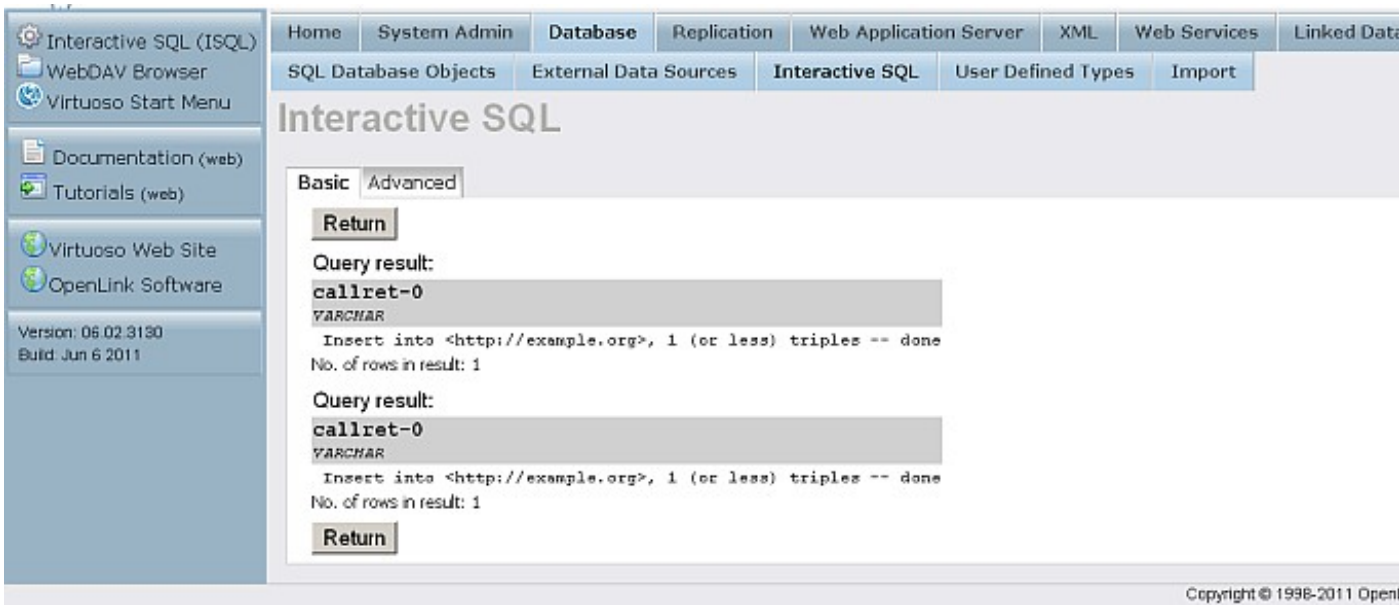
```
SPARQL INSERT INTO GRAPH <http://example.org>
  {
    <http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this>
    <http://xmlns.com/foaf/0.1/interest>
    <http://dbpedia.org/resource/Web_Clients>
  } ;
SPARQL INSERT INTO GRAPH <http://example.org>
  {
    <http://www.openlinksw.com/dataspace/person/kidehen@openlinksw.com#this>
    <http://xmlns.com/foaf/0.1/interest>
    <http://dbpedia.org/resource/SPARQL>
  } ;
```

Figure 16.306. Bi-directional Replication Topology



3. Click "Execute"
4. As result the triples will be inserted

Figure 16.307. Bi-directional Replication Topology



5. Check the count of the destination instance graph's triples by executing the following query like against the SPARQL endpoint, http://example.com:8891/sparql:

```
SELECT COUNT(*)
   FROM <http://example.org>
WHERE { ?s ?p ?o }
```

6. Should return

60

as total.

Figure 16.308. Bi-directional Replication Topology

callret-0
60

Check data on the Destination instance db2

1. Start instance db2
2. To confirm that the triple count has increased by the number of inserted triples, execute the following statement on db2's SPARQL Endpoint:

```
SELECT COUNT(*)
   FROM <http://example.org>
WHERE { ?s ?p ?o }
```

3. Should return

   60

   as total.

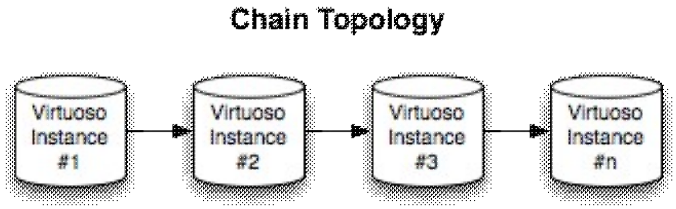
16.19.3. Set up RDF Replication via procedure calls

Example

The following example shows how to use SQL procedures to set up Virtuoso RDF Graph Replication in a Chain Topology.

Figure 16.310. Chain Replication Topology



This can also be done through the HTTP-based Virtuoso Conductor .

Prerequisites

Database INI Parameters

Suppose there are 3 Virtuoso instances on the same machine.

The first instance holds the master copy of the data and publishes its changes to all other instances that subscribe to this master.

The second instance subscribes to the publication of the master copy, but also publishes all of these changes to any instance that subscribes to it.

The third instance only subscribes to the publication of the second instance.

Each of these 3 servers need unique ports and ServerName, DefaultHost for this replication scheme to work properly. Although not needed, this example also sets separate names for the database and related files. This results in the following ini parameters values (only changes are shown, the rest can remain default):

1. repl1/virtuoso.ini:

```
...
[Database]
DatabaseFile    = virtuoso1.db
TransactionFile = virtuoso1.trx
ErrorLogFile     = virtuoso1.log
...
[Parameters]
ServerPort               = 1111
SchedulerInterval        = 1
...
[HTTPServer]
ServerPort                  = 8891
...
[URIQA]
DefaultHost = example.com:8891
...
[Replication]
ServerName   = db1-r
...
```

2. repl2/virtuoso.ini:

```
...
[Database]
DatabaseFile    = virtuoso2.db
TransactionFile = virtuoso2.trx
ErrorLogFile     = virtuoso2.log
...
[Parameters]
ServerPort               = 1112
SchedulerInterval        = 1
...
[HTTPServer]
ServerPort                  = 8892
...
[URIQA]
DefaultHost = localhost:8892
...
[Replication]
ServerName   = db2-r
...
```

3. repl3/virtuoso.ini:

```
...
[Database]
DatabaseFile    = virtuoso3.db
TransactionFile = virtuoso3.trx
ErrorLogFile     = virtuoso3.log
...
[Parameters]
ServerPort               = 1113
SchedulerInterval        = 1
...
[HTTPServer]
ServerPort                  = 8893
...
[URIQA]
DefaultHost = example.com:8893
...
[Replication]
ServerName   = db3-r
...
```

Database DSNs

Use the ODBC Administrator on your Virtuoso host (e.g., on Windows, Start menu -> Control Panel -> Administrative Tools -> Data Sources (ODBC); on Mac OS X, /Applications/Utilities/OpenLink ODBC Administrator.app) to create a System DSN for each of db1, db2, db3, with names db1, db2 and db3, respectively.

Configure Publishers and Subscribers

1. Run the databases by starting start.sh, which has the following content:

```
cd repl1
virtuoso -f &
cd ../repl2
virtuoso -f &
cd ../repl3
virtuoso -f &
cd ..
```

2. Use the

   isql

   command to execute the following rep.sql file:

```
--
--  connect to the first database which is only a publisher
--
set DSN=localhost:1111;
reconnect;

--
-- start publishing the graph http://test.org
---
DB.DBA.RDF_REPL_START();
DB.DBA.RDF_REPL_GRAPH_INS ('http://test.org');

--
--  connect to the second database in the chain, which is both a publisher and a subscriber
--
set DSN=localhost:1112;
reconnect;

--
--  start publishing the graph http://test.org
--
DB.DBA.RDF_REPL_START();
DB.DBA.RDF_REPL_GRAPH_INS ('http://test.org');

--
--  contact the first database
--
repl_server ('db1-r', 'db1', 'localhost:1111');

--
--  subscribe to its RDF publication(s)
--
repl_subscribe ('db1-r', '__rdf_repl', 'dav', 'dav', 'dba', 'dba');

--
--  bring the replication service online
--
repl_sync_all();

--
--  and set scheduler to check every minute
--
DB.DBA.SUB_SCHEDULE ('db1-r', '__rdf_repl', 1);

--
--  connect to the third database in the chain, which is only a subscriber
--
set DSN=localhost:1113;
reconnect;

--
-- uncomment next 2 commands if this database should also be a publisher
--
--DB.DBA.RDF_REPL_START();
--DB.DBA.RDF_REPL_GRAPH_INS ('http://test.org');
```

```
--
--  contact second database
--
repl_server ('db2-r', 'db2', 'localhost:1112');

--
--  subscribe to its RDF publication(s)
--
repl_subscribe ('db2-r', '__rdf_repl', 'dav', 'dav', 'dba', 'dba');

--
--  bring the replication service online
--
repl_sync_all();

--
--  and set schedule to check every minute
--
DB.DBA.SUB_SCHEDULE ('db2-r', '__rdf_repl', 1);
```

Chapter 17. Web Services

Abstract

The term Web Services describes an application of XML for exposing application functionality to disparate clients via the Web. This paradigm provides access to entire applications, modules, objects, functions, and methods via HTTP and other transport protocols. Web Services are inherently platform- and programming-language independent. Services can be developed in one language and consumed in another; this holds true irrespective of client or server host operating system combinations.

A collection of core XML-based specifications and standards work in concert to fulfill the Web services value proposition. These standards include:

SOAP - XML notation that describes how messages are assembled and transmitted over HTTP between services and service consumers.

WSDL - XML notation for describing SOAP services.

UDDI - Application of the SOAP protocol for registering and publishing information about organizations, contacts within organizations, and Web Services that these organizations have chosen to expose to the public.

Virtuoso enables stored procedures to be exposed as Web services that are consumable by any Web services-aware development tool, application, or environment. The stored procedures exposed by Virtuoso may be native stored procedures, or may be hosted in any third-party database that supports stored procedures, and is accessible via an ODBC or JDBC driver. In Virtuoso, exposing stored procedures as Web services does not require any programming effort. You simply identify the stored procedures to be exposed using the Virtuoso Administrative Interface.

This feature is immensely valuable in situations where organizations are seeking to transform time-tested stored procedures into Web Services without having to upgrade or change databases or host operating systems. In modern enterprises, such stored procedures drive mission-critical solutions; Virtuoso's approach to Web services enables you to maximize current investment while minimizing the need for rework.

17.1. SOAP

The Simple Object Access Protocol (SOAP) is a lightweight, extensible, XML-based application layer protocol for information exchange in a decentralized, distributed environment. SOAP defines a framework for message structures and a message processing model. SOAP also defines a set of encoding rules for serializing data and a convention for making remote procedure calls. The SOAP extensibility model provides a foundation for a wide range of composable modules and protocols. Although the most common way to transport SOAP messages is HTTP, it may also be run on top of other protocols.

SOAP includes:

an envelope that defines a framework for describing what is in a message and how to process it

a set of encoding rules for expressing instances of application-defined datatypes

a convention for representing remote procedure calls and responses.

17.1.1. Virtuoso SOAP Support Overview

Virtuoso provides a framework for both consuming SOAP services (acting as a client) and producing them (acting as a server). The Virtuoso web server has a mechanism for handling SOAP messages and passing them to stored procedures for processing. Both SOAP 1.0 and SOAP 1.1 messages and data types are supported. You may use all base SQL data types, as well as heterogeneous arrays, as both arguments and return values of Virtuoso SOAP services. A full-featured set of functions for handling SOAP objects is provided. Services using a transport mechanism other than HTTP can also be constructed using the API. The SOAP framework may be used independently of any of the other web-related services.

Virtuoso/PL can also issue requests to SOAP servers. SOAP can be used to access any application servers, including those running within the Virtuoso server.

The Virtuoso SOAP server extends Virtuoso/PL parameter handling by adding complex data types declared with XML schema as parameter values for stored procedures. The Virtuoso SOAP server provides automatic validation of the parameters in requests, based on schema declarations.

17.1.2. Handling of SOAP HTTP Requests

The Virtuoso web server recognizes SOAP HTTP requests and their version in the POST method handler. When *SOAPMethodName* or *SOAPAction* HTTP header attributes are present with

```
Content-Type: text/xml
```

, the server initiates SOAP call handling. The XML namespace of the SOAP method name is stripped off and Virtuoso searches for a stored procedure with the same name, ignoring case.

The search is done within the default qualifier of the SQL user account assigned for SOAP call execution defined for the virtual host. For example, if the database user assigned in the virtual host's definition for SOAP execution is called SOAPDBUSER and this user has a default qualifier 'SOAPDB' and the request contains an invocation of method called

```
OurSoapMethod
```

, Virtuoso would attempt to find a stored procedure named `SOAPDB.SOAPDBUSER.OurSoapMethod`.

When a matching stored procedure is found, any of its parameters that have names matching parameter entity names in the SOAP call are bound to the call parameter. The parameter name match is also case-insensitive.

Virtuoso maps the procedure parameter datatypes internally by casting from XML data (a string) to the declared parameter datatype of the stored procedure. There is one exception: When an array is being passed, the server creates an array with values of types inferred from the XML Schema of its elements. It is possible to declare that a user defined SQL type be used to represent a

specific XML element in a SOAP request. Thus SQL objects can be constructed and serialized automatically. Note that this also means that the implementation of the user defined type instance may be in a hosted language, thus Java or CLR code may be transparently involved.

Two special parameters - *ws_soap_headers* and *ws_http_headers* - are available to a stored procedure handling a SOAP method invocation. If declared as input parameters for the procedure, *ws_soap_headers* must contain an XML parse tree of the *SOAP:Header* in same format as returned by `xml_tree()`. *ws_http_headers* should hold a one-dimensional array of attribute/value pairs representing the HTTP header fields in the request.

17.1.3. Extending Datatypes for SOAP Objects

Complex datatypes can be defined using XMLSchema and represented by WSDL. Any of the declared types may be used as arguments and return types of Virtuoso/PL procedures. Any procedures can thus be exposed as SOAP methods.

Complex data type definitions are used for values that cannot be contained by simple scalar datatypes. Typical examples are arrays of scalars, structures of scalars, arrays of structures or structures of arrays. A complex datatype may contain scalar and complex datatypes. When a complex type is used in the definition of another complex type, the definition of the contained complex type must exist.

In addition to 'usual' complex types as structures and arrays Virtuoso implements support for 'choice', 'enumeration', anyType and anyElement and extensions to the simple types. Inheritance of complex types is also possible and is discussed further in next chapter.

The 'nillable' and 'minOccurs' attributes in schema definitions have special meaning for PL values returned by PL procedure via SOAP. If this attribute is 'true' then output of NULL values will be serialized in their XML form with XMLSchema instance attribute 'nil' as 'true'. Otherwise if elements have 'minOccurs' equal to 0 (zero), the element will be omitted. If minOccurs is equal to 1 (one) an empty element will be sent to the client. The same algorithm applies to the serialization of PL values passed as parameters to soap_client() function. Therefore it's important to make proper use of these attributes when defining complex structures.

The '__VOID__' string constant has a special meaning in XMLSchema Datatypes. It is used to designate no output for return value. In other words returned value from PL procedure will not be serialized nor exposed in the WSDL file.

You define complex datatypes using `soap_dt_define()`. The function accepts a schema definition excerpt, based on the element *complexType*. The definition must be a valid XML document.

Example 17.1. Declaring and using complex datatypes in SOAP

In this example we define two complex datatypes. The first one, SOAPStruct , consists of scalars; the second one, ArrayOfSOAPStruct , is an array of these structures. These schema excerpts are stored in the filesystem as `struct.xsd` and `array.xsd`.

struct.xsd:

```
<!-- a SOAPStruct type declaration
     file name: struct.xsd -->

<complexType name="SOAPStruct"
   targetNamespace="http://tempuri.tmp/"
   xmlns:enc="http://schemas.xmlsoap.org/soap/encoding/"
   xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
   xmlns="http://www.w3.org/2001/XMLSchema"
   xmlns:tns="services.wsdl">

   <sequence>
     <element name="varString" type="string" nillable="true"/>
     <element name="varInt" type="int" nillable="true"/>
     <element name="varFloat" type="float" nillable="true"/>
   </sequence>
</complexType>
```

array.xsd:

```
<!-- array of SOAPStruct
     file name: array.xsd -->

<complexType name="ArrayOfSOAPStruct"
   targetNamespace="http://tempuri.tmp/"
   xmlns:enc="http://schemas.xmlsoap.org/soap/encoding/"
   xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
   xmlns="http://www.w3.org/2001/XMLSchema"
   xmlns:tns="services.wsdl">

   <complexContent>
   <restriction base="enc:Array">
   <sequence>
   <element name="item" type="tns:SOAPStruct" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
   <attribute ref="enc:arrayType" wsdl:arrayType="tns:SOAPStruct[]"/>
   <attributeGroup ref="enc:commonAttributes"/>
   <attribute ref="enc:offset"/>
   </restriction>
   </complexContent>
</complexType>
```

Next, we issue commands to define a new complex datatype. Correct order is important. (SQL> is the prompt of the Interactive SQL utility included with Virtuoso and should not be typed)

```
SQL> DB..soap_dt_define ('SOAPStruct', file_to_string ('struct.xsd'));
SQL> DB..soap_dt_define ('ArrayOfSOAPStruct', file_to_string ('array.xsd'));
```

Note:

The WSDL specification requires that array names be prefixed with `ArrayOf` .

17.1.4. Inheritance of Datatypes for SOAP Objects

The Virtuoso SOAP server implements handling of inherited XSD types. The simple example of such relation between types can be explained as

```
   Type  A, also know as the 'base' type,
   and type B an extension of A.
   +---+   +---+
   | a |-->

| c |
   | b |   | d |
   +---+   +---+

   which can be defined by two separate types without relation

   A type   B type
   +---+   +---+
   | a |   | a |
   | b |   | b |
   +---+   +- -+
           | c |
           | d |
           +---+
```

But when type A has changed, type B will not be changed in second representation. This is because B is not a relative to A per se.

To work in such situations Virtuoso SOAP server handles extensions to XSD types as follows:

1. each type and base type have defined a User Defined SQL type (UDT).
2. the XSD types defined for SOAP processing are defined with UDT relation (see soap_dt_define)
3. the inheritance is declared with 'extension' element in XSD type declaration

When we have these preliminaries the WSDL will declare in 'schema' part of WSDL all depending types. Furthermore the SOAP processor will handle inherited members of derived types.

Example 17.2. Declaration and usage of depending types

Consider the following XSD and User Defined Type declaration for a base type 'BaseStruct':

```
<!-- XSD type declaration, file base.xsd -->

<complexType name="BaseStruct">
        <sequence>
                <element name="floatMessage" type="xsd:float"/>
                <element name="shortMessage" type="xsd:short"/>
        </sequence>
</complexType>

-- corresponding user defined sql type
create type DB.DBA.BaseStruct as (floatMessage real, shortMessage int __soap_type 'short');
```

Furthermore we are extending the BaseStruct with adding three more elements (members) with declaration of ExtendedStruct:

```
<!-- XSD type declaration, file ext.xsd -->

<complexType name="ExtendedStruct">
        <complexContent>
                <extension base="tns:BaseStruct">
                        <sequence>
                                <element name="stringMessage" type="xsd:string"/>
                                <element name="intMessage" type="xsd:int"/>
                                <element name="anotherIntMessage" type="xsd:int"/>
                        </sequence>
                </extension>
        </complexContent>
</complexType>

 -- corresponding user defined SQL type
create type DB.DBA.ExtendedStruct under DB.DBA.BaseStruct as (
     stringMessage nvarchar __soap_type 'string',
     intMessage int __soap_type 'int',
     anotherIntMessage int __soap_type 'int');
```

Once we are done with declarations as XSD files and user defined SQL types, we must register them as SOAP types for processing:

```
SQL> soap_dt_define ('', file_to_string ('base.xsd'), 'DB.DBA.BaseStruct');
SQL> soap_dt_define ('', file_to_string ('ext.xsd'), 'DB.DBA.ExtendedStruct');
```

Now we are able to create a PL procedure to use as a SOAP method, which simply will accept an ExtendedStruct and echo it back to the client.

```
create procedure
echoExtendedStruct (in param DB.DBA.ExtendedStruct __soap_type 'http://soapinterop.org/types:ExtendedStru
returns DB.DBA.ExtendedStruct __soap_type 'http://soapinterop.org/types:ExtendedStruct'
{
  --  All members  of DB.DBA.ExtendedStruct and DB.DBA.BaseStruct are available in param.
  return param;
}
;

grant execute on echoExtendedStruct to SOAP;
```

The SOAP request to that method will be as follows:

```
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
  xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/"
```

```
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"
  xmlns:m0="http://soapinterop.org/types">
  <SOAP-ENV:Body>
    <m:echoExtendedStruct xmlns:m="http://soapinterop.org/wsdl">
      <param xsi:type="m0:ExtendedStruct">
        <floatMessage xsi:type="xsd:float">3.14159</floatMessage>
        <shortMessage xsi:type="xsd:short">4096</shortMessage>
        <stringMessage xsi:type="xsd:string">String</stringMessage>
        <intMessage xsi:type="xsd:int">0</intMessage>
        <anotherIntMessage xsi:type="xsd:int">0</anotherIntMessage>
      </param>
    </m:echoExtendedStruct>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

The SOAP response to the above request will be as follows:

```
<SOAP:Envelope
SOAP:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:SOAP="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:dt="urn:schemas-microsoft-com:datatypes"
xmlns:ds="http://www.w3.org/2000/09/xmldsig#"
xmlns:xenc="http://www.w3.org/2001/04/xmlenc#"
xmlns:wsse="http://schemas.xmlsoap.org/ws/2002/07/secext"
xmlns:ref="http://schemas.xmlsoap.org/ws/2002/04/reference/"
xmlns:ns0="http://soapinterop.org/types" xmlns:wsdl="services.wsdl">

  <SOAP:Body>
    <cli:echoExtendedStructResponse xmlns:cli="http://soapinterop.org/wsdl">
      <CallReturn xsi:type="ns0:ExtendedStruct">
        <stringMessage xsi:type="xsd:string">String</stringMessage>
        <intMessage xsi:type="xsd:int">0</intMessage>
        <anotherIntMessage xsi:type="xsd:int">0</anotherIntMessage>
        <floatMessage xsi:type="xsd:float">3.14159</floatMessage>
        <shortMessage xsi:type="xsd:short">4096</shortMessage>
      </CallReturn>
    </cli:echoExtendedStructResponse>
  </SOAP:Body>
</SOAP:Envelope>
```

Note:
Although the namespace declarations of XSD types are skipped for better readability, these must be present when declaring (see the Extending Datatypes for SOAP Objects section, discussed earlier)

17.1.5. Complex Types in PL Procedure and UDT Method Definition

Virtuoso/PL allows parameters to be declared as complex objects (structures and arrays) without special XMLSchema datatype defined. To declare a structure as a type of a parameter an UDT must be created and parameter to have it as datatype reference. Also all permitted datatypes (including UDTs) could be declared as elements of an ARRAY of unlimited or limited length.

Important: when a UDT is used in a SOAP context, it MUST be granted to the SQL user for SOAP invocation. In other words the user on whose behalf the SOAP call is processed.

Example 17.3. Procedure definition with a input and output as a structure

The following example defines a UDT 'SOAP_Struct' (containing varchar, integer and float members) and declares the input parameter and return value of a PL procedure to be of the SOAP_Struct type. The input will be verified, UDT will be instantiated with given values for members and it will be echoed back to the client.

```
create type SOAP_Struct as (varString varchar, varInt integer, varFloat real);
```

```
create procedure echoStruct (in s DB.DBA.SOAP_Struct) returns DB.DBA.SOAP_Struct
{
  return s;
};
```

Example 17.4. Procedure definition with a input and output as an integer array

This example declares that input must be an array of integer values with maximum length of 5. If input or output contains more than five integers then a SOAP Fault will be sent back to the client containing an appropriate error message ; otherwise the input array will be echoed back.

```
create procedure echoIntArray (in ia integer array[5]) returns integer array[5]
{
  return ia;
};
```

Example 17.5. Procedure definition with a input and output as a two-dimensional varchar array

This example declares that the input must be an array of integer array values with unlimited length. If the input SOAP message contains a valid array following the current XML encoding rules then an array of integer arrays (vector containing vectors of integers) will be created and passed to the procedure. On success the input array will be echoed back to the client.

```
create procedure echoIntMulArray (in iaa integer array array) returns integer array array
{
  return iaa;
};
```

Example 17.6. Procedure definition with a input and output as an struct array

This example shows how to use an array of structures (UDTs) and also shows usage of the array type as an member of the structure. The UDT 'SOAP_StructA' is similar to the those in first example except 4the member which is an array of integers. This is to demonstrate that arrays are not limited to the Stored Procedure's parameters declaration, they also can be used as a type of UDT member. Upon success the procedure will echo of the input back to the client.

```
create type SOAP_StructA as (varString varchar, varInt integer, varFloat real, varArray integ

create procedure echoStructArray (in sa DB.DBA.SOAP_StructA array) returns DB.DBA.SOAP_Struct
{
  return sa;
};
```

The SOAP request to an endpoint which exposes the echoStructArray as a document/literal encoded SOAP method would be as follows:

```
<?xml version="1.0" ?>
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">
  <SOAP-ENV:Body>
    <ns0:echoStructArray xmlns:ns0="http://temp.uri">
      <sa>
        <item>
          <varString>abcd</varString>
          <varInt>1234</varInt>
          <varFloat>3.14</varFloat>
          <varArray>
            <item>3</item>
            <item>4</item>
```

```
            </varArray>
          </item>
        </sa>
      </ns0:echoStructArray>
    </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

The SOAP server will receive and array of one element containing a structure with string, integer, float and integer array of two elements. Then the response from the SOAP server to the requestor will be:

```
<?xml version="1.0" ?>
<SOAP:Envelope xmlns:SOAP="http://schemas.xmlsoap.org/soap/envelope/">
  <SOAP:Body>
    <cli:echoStructArrayResponse xmlns:cli="http://temp.uri">
      <CallReturn>
        <item>
          <varString>abcd</varString>
          <varInt>1234</varInt>
          <varFloat>3.14</varFloat>
          <varArray>
            <item>3</item>
            <item>4</item>
          </varArray>
        </item>
      </CallReturn>
    </cli:echoStructArrayResponse>
  </SOAP:Body>
</SOAP:Envelope>
```

See also the WSDL file generation section for details how such PL procedures with parameters of complex datatypes are exposed via SOAP enabled virtual HTTP directories.

17.1.6. Complex Types in Procedure Definition using a pre-defined XML Schema datatypes

Declaration of a complex datatype as a parameter is done by adding a special keyword `__soap_type` followed by the name of the defined complex type after normal parameter declaration in the parameter list. The type name is given as a string literal. The same syntax extension also applies to declaration of the return type. This is shown in the following example.

Example 17.7. Procedure Definition with Complex Datatype Parameters

We create a procedure that will accept an array of structures (as defined in the previous example) and return it to the client. It instructs the WSDL generator to assign ArrayOfSOAPStruct as the input parameter and return value types when `WS.SOAP.echoSOAPArray()` is exposed as a SOAP method. The type information is available to SOAP clients that read the WSDL description. Upon receiving an incoming SOAP request, Virtuoso converts the XML representation of the data, after validation, to the form

```
vector(vector([varchar],[integer],[real]), ...)
```

and passed to the `WS.SOAP.echoSOAPArray` . Failed parameter validation is reported to the client.

```
SQL> CREATE PROCEDURE WS.SOAP.echoSOAPArray (in inArray any __soap_type 'ArrayOfSOAPStruct')
             RETURNS any __soap_type 'ArrayOfSOAPStruct'
    {
      return inArray;
    };
```

17.1.7. Default SOAP-SQL Datatype Mappings

When no alternative datatype is assigned, the WSDL generator and SOAP server will use the default mapping described below:

Table 17.1. Default datatype mappings in SOAP

Datatype	Maps to
integer	xsd:int
real	xsd:float
double precision	xsd:double
numeric	xsd:decimal
datetime	xsd:timeInstant
any other type	xsd:string

The REAL SQL type is mapped to the xsd:float SOAP datatype by default and so loss of precision can occur. To improve the precision, the SOAP server will map the xsd:float to the PL double precision datatype instead, but only if the SOAP type is specified. The explicit declaration of __soap_type 'xsd:float' is required to instruct Virtuoso to use the mapping to double precision.

All strings from a SOAP request declared with the SOAP datatype xsd:string will be treated as NVARCHARs on input. All string data such a CHAR, VARCHAR, or NVARCHAR will be encoded as UTF-8 in a SOAP response. This makes processing of wide character sets in SOAP operations possible.

If a User Defined Type (UDT) is used as a type of parameter and no explicit XML Schema datatype given (see special syntax for PL procedures) then in WSDL will be included as a struct definition. Further upon SOAP processing the input struct will be encoded as a UDT instance and passed to the given PL procedure.

The parameters which are declared as an array (see PL procedure syntax) and having no explicit XML Schema datatype given will be exposed as array by means of SOAP encoding rules (see also 'Use' SOAP option to the virtual directory).

Some SOAP applications need a void return as opposed to an empty return, from SOAP operations. To distinguish the empty return from the void return a special SOAP datatype '__VOID__' has been introduced. This will cause the SOAP server to omit the procedure return value when responding to a SOAP request. Also, the return message will be discarded from the WSDL description file.

17.1.8. Exposing Stored Procedures as SOAP Objects

The special physical path `/SOAP/` in the Virtuoso Web server is reserved for SOAP objects. Virtuoso makes available any stored procedure created in the default qualifier of the SOAP user, with execution privileges granted to the SOAP user. You can also use Virtuoso's virtual host mechanism to create new logical paths for accessing SOAP objects. A logical path property `soap_user` determines the db user for SOAP. If a logical path points to the `/SOAP/` special physical path, it will expose any procedures created in the default qualifier of, and with execution privileges to, `soap_user` to the world as SOAP objects.

If the physical path of `/SOAP` exists under the VSP root directory then any non-SOAP specific HTTP requests will be directed there for content. This can be useful for helping to establish the presence and location of a SOAP endpoint - some applications attempt a standard HTTP connection first. You might configure a virtual directory, intended for SOAP, with a default page referencing a description of the SOAP endpoint, a page in the <VSPROOT>/SOAP directory, preventing an `HTTP 404` style error misleading an application into believing the SOAP endpoint is down regardless of whether it tried to talk SOAP to it or not.

Note:
Procedures exposed as SOAP procedures run as any other stored procedure in Virtuoso and can call and get return values from other procedures and functions not exposed through SOAP. The ability to execute procedures attached from remote data sources facilitates SOAP-enabling existing database applications in a heterogeneous environment.

Example 17.8. Creating a new virtual host for SOAP execution

Create new user in the database for SOAP:

```
SQL>CREATE USER SOAPDEMO;
```

Set the default catalogue/qualifier for the new user to WS. This is where procedures to be used as SOAP objects will be created:

```
SQL>USER_SET_QUALIFIER ('SOAPDEMO', 'WS');
```

Create a new virtual host definition, using `vhost_define()` .

```
SQL>VHOST_DEFINE (vhost=>'*ini*',lhost=>'*ini*',lpath=>'/mysoapdomain',ppath=>'/SOAP/',soap_user=>'SOAPDE
```

An existing mapping could be removed using the command:

```
SQL>VHOST_REMOVE (vhost=>'*ini*',lhost=>'*ini*',lpath=>'/mysoapdomain')
```

Note:
`'*ini*'` is a special value that instructs Virtuoso to use the default values from the Virtuoso initialization file.

All procedures that are created with the WS.SOAPDEMO qualifier and then granted execution to SOAPDEMO will be visible to SOAP. Make a simple SOAPTEST procedure and grant the appropriate privileges to the SOAPDEMO user:

```
SQL> create procedure
  WS.SOAPDEMO.SOAPTEST (in par varchar)
{
  return (upper(par));
};

SQL> grant execute on WS.SOAPDEMO.SOAPTEST to SOAPDEMO;
```

The SOAP object may now be tested by using the `soap_client()` function, which returns a vector representation of the SOAP object returned by the call. The example below simply extracts the returned string with `aref()` , as the exact format of the object returned is known:

```
SQL>select aref(aref(
        soap_client (url=>sprintf ('http://example.com:%s/mysoapdomain', server_http_port ()),
        operation=>'SOAPTEST',
        parameters=>vector('par', 'demotext')),
        1), 1);
callret
VARCHAR
_______

DEMOTEXT
```

Printing the output on the console or server log with `dbg_obj_print()` would output something like:

```
(("SOAPTESTResponse" ) (("CallReturn" ) "DEMOTEXT" ) )
```

The automatic service description generation can be verified by retrieving *http://<server:port>/mysoapdomain/services.wsdl* , and preferably tested by pointing a web browser at *http://<server:port>/mysoapdomain/services.vsmx*

```
SQL> select http_get (sprintf ('http://example.com:%s/mysoapdomain/services.wsdl', server_http_port()));
callret
VARCHAR

Testing Web Services using VSMX

17.1.9. Creation of SOAP proxy based on User Defined Types

It is possible to automatically generate PL procedures or UDT classes for invoking a remote SOAP service.

See Also

The `WSDL_IMPORT_UDT()` function for details and examples.

The proxy-creation function `WSDL_IMPORT_UDT()` performs the following purposes:

retrieve and expand the WSDL file published by the end point to be called

compile the result and make SQL script with UDT definition

generate and register XML Schema definition for special types used in the source service

optionally execute the SQL script generated

Once such UDT SOAP proxy is defined it can be used within application code or be re-exposed as a SOAP service on local server instance (see next chapter how to expose UDT as service).

See Also

The Virtuoso Administration Interface provides a web based interface for importing WSDL definitions and creating UDTs and procedures. This can be found in the Virtuoso Server Administration Interface Chapter.

17.1.10. Exposing User Defined Type Methods as SOAP Objects

SQL User Defined Types may define methods. In context of Virtuoso SOAP server they can be exposed as SOAP methods. To do that the UDT must be published at an endpoint. So publishing could be done in two ways: using SQL INSERT statement or using Admin UI: Publishing UI via Virtual directories section.

The published UDTs will then expose all methods to the given virtual directory assigned for SOAP execution. In this case the default constructor will be called for method invocation if the UDT method is non-static.

Note: The method definitions may also contains special SOAP syntax for XML Schema datatypes, using the same options as for PL procedures. (see "PL Procedures and UDT Methods Syntax Affecting WSDL & SOAP Processing" section for details)

The following table specifies which UDTs are published at which end points.

```
create table SYS_SOAP_UDT_PUB
            (SUP_CLASS varchar, -- name of the published UDT, referencing SYS_USER_TYPES.UT_NAME
             SUP_LHOST varchar, -- listen host, referencing HTTP_PATH.HP_LISTEN_HOST
             SUP_HOST varchar,  -- virtual host, referencing HTTP_PATH.HP_HOST
             SUP_END_POINT varchar, -- logical path, referencing HTTP_PATH.HP_LPATH
             primary key (SUP_LHOST, SUP_HOST, SUP_END_POINT, SUP_CLASS))
;
```

Example 17.9. Exposing a UDT Method using SQL statement

The below code creates a UDT containing two methods: static and non-static and exposes them on a virtual directory '/soap-udt'

```
create user SOAP_U2;

VHOST_DEFINE (lpath=>'/soap-udt', ppath=>'/SOAP/', soap_user=>'SOAP_U2',
    soap_opts=>
    vector ('ServiceName', 'UDT',
            'Namespace', 'http://temp.uri',
            'SchemaNS', 'http://temp.uri',
            'MethodInSoapAction', 'yes',
            'elementFormDefault', 'unqualified',
            'Use', 'encoded')
);

create type MyWebSvc
static method echoStatInt (in a int) returns int,
method echoInt (in a int) returns int;

create static method echoStatInt (in a int)
returns int for MyWebSvc
{
  return a;
}
;

create method echoInt (in a int)
returns int for MyWebSvc
{
  return a;
}
;

-- Important: without grant publishing is not final as
-- user for SOAP invocation will not have permissions to instantiate the UDT nor
-- to call its methods
grant execute on MyWebSvc to SOAP_U2;

-- exposing the UDT methods to the /soap-udt endpoint
insert soft SYS_SOAP_UDT_PUB values ('MyWebSvc', '*ini*', '*ini*', '/soap-udt');
```

Exposing the methods of a UDT could be done using Admin UI/Virtual Directories: Create a new or edit an existing SOAP enabled virtual directory and navigate to the SOAP options section, click on the 'Publish' button and from presented list of Database qualifiers select the qualifier containing target UDT, then select it from the User Defined Types list and follow the wizard.

17.1.11. Exposing Remote Third Party SQL Stored Procedures as SOAP Services

Virtuoso can expose any of its available PL resources to the SOAP world. This includes data from remote attached tables and procedures. To do this, one needs to write a wrapper procedure in Virtuoso/PL.

Example 17.10. Exposing a MS SQL Server procedure to SOAP using Virtuoso

Here we have a sample MS SQL Server procedure and an accompanying Virtuoso wrapper function. The MS SQL Server function returns a result set based on a simple join query with a filter input. The Virtuoso procedure calls the remote procedure, iterates through the result set returned and produces XML output. First the MS SQL Server procedure:

```
create procedure ms_remote
        @mask varchar(15)
as
  select c.CustomerID, c.CompanyName, o.OrderDate,
      o.ShippedDate,ol.ProductID, ol.Quantity, ol.Discount
    from Northwind..Customers c
      inner join Northwind..Orders o on c.CustomerID = o.CustomerID
      inner join Northwind.."Order Details" ol on o.OrderID = ol.OrderID
    where c.CustomerID like @mask
;
```

Then the Virtuoso wrapper function:

```
create procedure WS.SOAP.ms_remote_call (
  in dsn varchar, in uid varchar, in pwd varchar, in mask varchar)
{
  declare m, r, ses any;
  vd_remote_data_source (dsn, '', uid, pwd);
  rexecute (dsn, 'ms_remote ?', null, null, vector (mask), 1000, m, r);
  ses := string_output ();
  http ('<?xml version="1.0" ?>\n<remote>\n', ses);
  if (isarray(m) and isarray (r))
    {
      declare i, l, j, k integer;
      declare md, rs any;
      md := m[0];
      i := 0; l := length (md); k := length (r); j := 0;
      while (j < k)
       {
         http ('<record ', ses);
         i:=0;
         while (i < l)
           {
             dbg_obj_print (md[i][0],r[j][i]);
             http (sprintf (' %s="%s"', trim(md[i][0]), trim(cast (r[j][i] as varchar))), ses);
             i := i + 1;
           }
         http (' />\n', ses);
         j := j + 1;
       }
    }
  http ('</remote>', ses);
  return string_output_string (ses);
};
```

Now, as before, we grant execute rights to the SOAP user:

```
grant execute on WS.SOAP.ms_remote_call to SOAP;
```

The remote procedure `ms_remote()` can now be accessed via SOAP.

See Also:
The Virtual Database chapter for information regarding use of remote datasources and their tables.

17.1.12. Virtuoso/PL SOAP Client

Virtuoso has generic SOAP client functionality. This was demonstrated in an example above, where we showed that we had correctly exposed a stored procedure as a SOAP object. The entry point to the SOAP client is `soap_client ()`.

See Also:
Importing A WSDL File

17.1.13. Execution Privileges

Virtual directory mappings allow you to define a specific database user on behalf of which to execute code invoked via SOAP. By default Virtuoso disables SOAP calls unless the database account 'SOAP' exists or a virtual directory mapping is defined for SOAP call execution. If we map a logical HTTP path to `/SOAP` and specify the user 'demo' as the SOAP user then stored procedures or UDT methods will be executed with demo's privileges.

17.1.14. Custom Soap Server Support

Virtuoso allows any VSP page to act as a SOAP endpoint. This permits preprocessing of the SOAP requests to extract additional information - such as one placed for ebXML - and conversion of the SOAP replies to put any additional information in them. SOAP messages with attachments can also be processed this way.

SOAP extensions, such as the ones required for ebXML, can be programmed as VSP services that can handle the additional information contained in the SOAP requests. The `xpath_eval()` function is useful here. The SOAP server could be called after removing extension information; this removal could be done with an XSL transformation. After the SOAP request is processed, additional information can be placed in the result by another XSL transformation.

Having a SOAP server outside the `/SOAP` physical path allows a greater degree of control over what procedures are executed by providing a list of mappings. Having this suite of functions allows SOAP requests to be processed outside an HTTP context (for example after doing `mime_tree()` over an e-mail) and sending the SOAP replies as SMTP messages.

The following built-in functions are relevant in this context:

`soap_server()`

`soap_make_error()`

`soap_box_xml_entity()`

`soap_print_box()`

`http_body_read()`

Example 17.11. Sample SOAP 1.1 server

```
<?vsp
        dbg_obj_print ('vspsoap called');
        declare content_type, soap_method, soap_xml varchar;
        declare payloads any;

        -- get the encoding to find out where the SOAP request should be searched for

        content_type := http_request_header (lines, 'Content-Type');
        if (isstring (content_type))
           content_type := lower (content_type);

        -- get the SOAP method name to execute

        soap_method := http_request_header (lines, 'SOAPAction');
        soap_xml := NULL;
        payloads := NULL;

        -- get the SOAP request
        if (content_type = 'multipart/related')
          {
            -- as in SOAP messages with attachments
            declare attrs any;
            declare inx integer;
            declare start_req varchar;

            -- the SOAP body is in the root part
            -- so get the root part's name
            start_req := http_request_header (lines, 'Content-Type', 'start');

            -- loop over the parts and get the root one.
```

```
    -- Others are placed in the payload array

    inx := 1;
    soap_xml := null;
    attrs := vector (1);
    while (isarray (attrs))
     {
       declare content_id varchar;

       -- get the part's MIME header
       attrs := get_keyword (sprintf ('attr-mime_part%d', inx), params);

       if (isarray (attrs))
         {
           -- extract the Content-ID from it
           content_id := get_keyword ('Content-ID', attrs);
           dbg_obj_print ('cont-id', content_id);

           if (isstring (content_id))
             {
               -- if it is the root part (SOAP request) parse it.
               if (content_id = start_req)
                 soap_xml := xml_tree_doc (xml_tree (
              get_keyword (sprintf ('mime_part%d', inx), params)));
               else
                 {
                   -- otherwise consider it a payload and store a info about the payload
                   -- for later retrieval by get_keyword () VSE based on Content-ID
                   if (payloads is null)
                     payloads := vector (vector (content_id, inx));
                   else
                     payloads := vector_concat (payloads, vector (content_id, inx));
                 }
             }
         }
       inx := inx + 1;
     }
  }
else if (content_type = 'text/xml')
  {
    -- it's a SOAP request without attachments
    -- so get the POST body and parse it.
    soap_xml := xml_tree_doc (xml_tree (http_body_read ()));
  }
else
  signal ('42000', 'unsupported encoding');

-- the things retrieved so far
dbg_obj_print ('vspsoap message', soap_xml);
dbg_obj_print ('vspsoap payloads', payloads);

-- execute the message

-- catch any subsequent SQL error and generate and return SOAP reply XML for it.

declare exit handler for SQLSTATE '*' {
  dbg_obj_print ('vspsoap in error handler for ', __SQL_MESSAGE);
  declare err_msg varchar;
  err_msg := soap_make_error ('300', __SQL_STATE, __SQL_MESSAGE);
  dbg_obj_print ('vspsoap error', err_msg);
  http (err_msg);

  -- note the SOAP SQL state - this is required since based on this value the
  -- HTTP server will not generate any additional reply if the SQL state starts with SOAP
  -- and this way the client will get a properly formatted reply
  resignal 'SOAP';
};

-- now check what is required and act accordingly
if (soap_method = 'ebXML')
  {
    signal ('42000', 'ebXML not implemented yet');
  }
```

```
        else if (soap_method in ('fake#test'))
          {
            declare res any;

            -- note the mapping here : the SOAP call to fake:test will result in a
            -- call to DB.DBA.SOAPTEST PL procedure and it's results returned.

            res := soap_server (soap_xml, soap_method, lines, 11,
                    vector ('fake:test', 'DB.DBA.SOAPTEST'));

            dbg_obj_print ('vspsoap result', res);
            http (res);
          }
        else
          {
            -- simple signal will do as this will be cached by the handler
          -- and formatted as an SOAP error XML
            signal ('42000', concat ('Procedure ', soap_method, ' not defined'));
          }
?>
```

17.1.15. PL Procedures and UDT Methods Syntax Affecting WSDL & SOAP Processing

Special PL syntax can be applied to any of the parameters (including the return value) in a declaration. All of these begins with __SOAP_ prefix and have special meaning. To manipulate more than the XMLSchema type representation and SOAP encoding style, extended syntax is available. With this syntax we can further override the default request/response namespace, name of the output elements, "soapAction" corresponding to the PL procedure and such.

The syntax is as follows:

```
   ...
   CREATE (PROCEDURE|METHOD) ([param_decl [rout_alt_type]] ...) { [BODY] } [RETURNS ....] [rout_alt_type]
   ...

rout_alt_type
        :  /* no SOAP options */
        | soap_kwd STRING opt_soap_enc_mode     /* the basic syntax */
        | __SOAP_OPTIONS '(' soap_kwd EQUALS STRING opt_soap_enc_mode ',' soap_proc_opt_list ')'/* extend
        ;

soap_proc_opt_list
        : soap_proc_opt
        | soap_proc_opt_list ',' soap_proc_opt
        ;

soap_proc_opt /* extension options as PartName:='part2' */
        : NAME EQUALS signed_literal
        ;

soap_kwd
        : __SOAP_TYPE   /* denotes XML datatype, RPC encoding style if applied to the procedure */
        | __SOAP_HEADER /* the parameter is a message in the SOAP Header */
        | __SOAP_FAULT  /* the parameter is a message in SOAP Fault */
        | __SOAP_DOC    /* applies to the procedure, free-form of encoding (literal) */
        | __SOAP_XML_TYPE /*applies to the parameters, the input will be XML tree */
        | __SOAP_DOCW           /* applies to the procedure, literal encoding in style like RPC */
        | __SOAP_HTTP           /* HTTP GET/POST binding will be used */
        ;

opt_soap_enc_mode               /* which part of traffic will be encapsulated and in what way : DIME or M
        : /* no encapsulation */
        | __SOAP_DIME_ENC IN
        | __SOAP_DIME_ENC OUT
        | __SOAP_DIME_ENC INOUT
        | __SOAP_MIME_ENC IN
        | __SOAP_MIME_ENC OUT
        | __SOAP_MIME_ENC INOUT
        ;
```

```
param_decl
        : (IN|OUT|INOUT) param_name data_type_ref [(DEFAULT|:=) literal]
        ;

data_type_ref
        : (data_type_name|udt_name) [ARRAY [intnum] ...]
        ;
```

The above syntax can be applied to the parameter and to the whole procedure, so both places designate different purposes and limitations. When it is applied to the parameter the following keywords can be used: __SOAP_TYPE, __SOAP_HEADER, __SOAP_FAULT and __SOAP_XML_TYPE. The __SOAP_TYPE means that only XSD type will be used to interpret the data, in contrast __SOAP_XML_TYPE designates no deserialization from XML, only parses the parameter XML representation to XML tree and passes it to the procedure. The __SOAP_HEADER and __SOAP_FAULT designate that parameter will be exposed in the SOAP Header or in the SOAP Fault elements. In the second case, that parameter needs to be an 'OUT' parameter (not IN or INOUT). The string after these keywords always denotes the XSD type for SOAP serialization. When it is applied to the PL procedure (after procedure's body), the __SOAP_TYPE, __SOAP_DOC, __SOAP_DOCW, __SOAP_HTTP, __SOAP_DIME_ENC and __SOAP_MIME_ENC can be used. The string after these keywords always denotes the XSD type for SOAP serialization, except __SOAP_DIME_ENC and __SOAP_MIME_ENC which are used for other purposes and can be combined with other keywords. The __SOAP_TYPE denotes RPC style encoding, __SOAP_DOC for document literal (bare parameters) encoding, __SOAP_DOCW for the free-form literal (wrapped) encoding. __SOAP_HTTP is used to denote HTTP style binding instead of SOAP one, in that way procedure can be called via HTTP GET/POST methods without SOAP XML encoding.

The following keywords are supported as extended options:

PartName - changes the name of a OUT parameter to the string as specified, affects WSDL generation and SOAP serialization.

RequestNamespace - designate namespace for the message in the request, affects header, fault and body WSDL declaration, and serialization of SOAP in RPC encoding style.

ResponseNamespace - the same as RequestNamespace, but for SOAP response and output in WSDL declaration.

soapAction - sets the 'soapAction' attribute in WSDL generation, can be applied to the procedure only.

The RequestNamespace and ResponseNamespace can be used only for the procedure and together with the __SOAP_FAULT and __SOAP_HEADER keywords.

The 'ARRAY' modifier to the SQL datatype is allowed when no XML Schema datatype is assigned to the given parameter of the PL procedure or UDT method. In this case the input and output value will be verified to confirm to the rules applicable for an array. Furthermore in this case an XSD definition will be added in the WSDL file at run time.

Example 17.12. SOAP Extension

This example shows both approaches to define parameters and SOAP encoding style. In practice this definition is part of the Interop tests round 4 (group H). The meaning of this is: the SOAP operation is uses RPC encoding style, 'whichFault' is integer, 'param1' and 'param2' are strings. The out parameters 'part2_1' and 'part2_2' will be printed in SOAP:Fault element (see Exposing & Processing SOAP Fault Messages for more details). The interesting fact is that the last two parameters will be serialized as "part2" in different namespaces. And finally no return of the SOAP operation is defined (it's empty).

```
create procedure
"echoMultipleFaults3" (
    in whichFault int __soap_type 'http://www.w3.org/2001/XMLSchema:int',
    in param1 varchar __soap_type 'http://www.w3.org/2001/XMLSchema:string',
    in param2 varchar __soap_type 'http://www.w3.org/2001/XMLSchema:string',
    out part2_1 varchar __soap_options (
        __soap_fault:='http://www.w3.org/2001/XMLSchema:string',
        PartName:='part2',
        ResponseNamespace:='http://soapinterop.org/wsdl/fault1'),
    out part2_2 varchar __soap_options (
        __soap_fault:='http://www.w3.org/2001/XMLSchema:string',
        PartName:='part2',
        ResponseNamespace:='http://soapinterop.org/wsdl/fault2')
    )
   __soap_type '__VOID__'
{

  if (whichFault > 2)
    whichFault := mod (whichFault, 3) + 1;
  declare exit handler for sqlstate 'SF000'
```

```
    {
      http_request_status ('HTTP/1.1 500 Internal Server Error');
      if (whichFault = 1)
        {
          part2_1 := param1;
        }
      else if (whichFault = 2)
        {
          part2_2 := param2;
        }
      connection_set ('SOAPFault', vector ('400', 'echoMultipleFaults3'));
      return;
    };
  signal ('SF000', 'echoEmptyFault');
}
;
```

17.1.16. Exposing & Processing SOAP Header Messages

The Virtuoso SOAP server can be used to process the SOAP Header messages as described in the W3C recommendation (http://www.w3c.org/TR/SOAP , SOAP Header section). They can also be exposed in the WSDL file (services.wsdl) as per W3C WSDL recommendation, using the RPC style encoding.

To bind a message to a SOAP header the special keyword __soap_header is reserved for input and output parameters. The __soap_header followed by the SOAP datatype can be specified for any input or output parameter after normal datatype declarations. This will expose parameters as input or output messages separately. Header binding will also be added to an appropriate section of the WSDL description file for the SOAP message.

Example 17.13. Processing of the SOAP Header element

Consider the following simple SOAP request message with Header element:

```
<?xml version="1.0" encoding="UTF-8"?>
<SOAP-ENV:Envelope
       xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
       xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/"
       xmlns:xsd="http://www.w3.org/2001/XMLSchema"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
    <SOAP-ENV:Header>
      <h:echoMeStringRequest
         xmlns:h="http://soapinterop.org/echoheader/"
         SOAP-ENV:actor="http://schemas.xmlsoap.org/soap/actor/next"
         mustUnderstand="1">hello world</h:echoMeStringRequest>
    </SOAP-ENV:Header>
    <SOAP-ENV:Body>
      <m:echoVoid xmlns:m="http://soapinterop.org/"></m:echoVoid>
    </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

This request will be processed by the Virtuoso SOAP server in the following way:

1. Check whether the echoVoid operation is defined for the given web directory mapping (see: exposing a PL procedure as a SOAP operation)
2. Test whether there is an in-parameter echoMeStringRequest defined for header processing (see below exposing a header parameters)
3. Test the mustUnderstand attribute:
    - If mustUnderstand is 0 or is undefined the request will continue without an error.
    - If mustUnderstand is 1 and the actor attribute is not empty or defined with the http://schemas.xmlsoap.org/soap/actor/next special URI, the request will continue without an error.
    - If the two conditions about fail then the request will be rejected with a SOAP MustUnderstand error.
4. The value of the echoMeStringRequest will be passed as a parameter to the echoVoid procedure.
5. If the call to the echoVoid succeeds, and the corresponding out parameter is supplied for the SOAP response header then it will be sent to the SOAP client.

The following procedure, which represents a part from echoHeaderBindings iterop test (round C), for the demonstration purposes is designed to process the above SOAP message.

```
create procedure
Interop.INTEROP.echoVoid
   (in echoMeStringRequest nvarchar := NULL __soap_header 'http://www.w3.org/2001/XMLSchema:string',
    out echoMeStringResponse nvarchar := NULL __soap_header 'http://www.w3.org/2001/XMLSchema:string')
   __soap_type '__VOID__'
{
  if (echoMeStringRequest is not null)
    echoMeStringResponse := echoMeStringRequest;
};
```

Note:

The __soap_header keyword that instructs the SOAP server to process this parameter via a SOAP Header with datatype string. Also, the condition in the procedure is needed to return the value in SOAP header only if it is supplied. In some other cases it can be returned always, but in this particular example it will be echoed only if the appropriate header is sent.

17.1.17. Exposing & Processing SOAP Fault Messages

The SOAP:Fault message is used to indicate which part of SOAP request fails, so in its general form it may not have a detailed error. But in some cases it is useful to report in detail which element's input(s) are not correct.

Custom soap:fault messages can be generated by application logic as illustrated below:

Have a procedure to generate custom SOAP:Fault messages with at least one OUT parameter denoted by __SOAP_FAULT instead of __SOAP_TYPE keyword following by type to be returned as literal.

Once we have such parameter(s) declared we can set these to some value (of atomic, simple or complex type) as may be appropriate.

And finally we need to set a special connection variable 'SOAPFault', in order to signal custom SOAP:Fault on output. The value of the connection variable needs to be an array of two elements : An integer of 100, 200, 300, 400 which represents the SOAP:VersionMismatch, SOAP:MustUnderstand, SOAP:Client and SOAP:Server errors. And a string which will be printed in textual explanation, human readable format. In real life we will not need to generate 100 or 200 fault messages, but anyway it is possible to do that.

Example 17.14. Signalling a custom SOAP Fault element

Consider we need to indicate to the client that some string is not a valid input, we can use the custom fault message mechanism as.

```
create procedure
echoStringFault (in param nvarchar,
                 out part2 nvarchar __soap_fault 'string')
returns nvarchar
{
  declare exit handler for sqlstate 'SF000'
    {
      http_request_status ('HTTP/1.1 500 Internal Server Error');
      -- we are setting the fault message
      part2 := param;
      -- and instructing the SOAP server to make error 400 with text explanation StringFault
      connection_set ('SOAPFault', vector ('400', 'StringFault'));
      ----------------^^^^^^^^^^
      return;
    };
  -- in real life signalling of the error is under some condition
  -- for example if string is longer that 10 chars
  signal ('SF000', 'echoEmptyFault');
}
;
```

And an wire dump of SOAP request

```
<SOAP-ENV:Envelope SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/" ...>
  <SOAP-ENV:Body>
    <m:echoStringFault xmlns:m="http://soapinterop.org/wsdl">
      <param xsi:type="xsd:string">String</param>
    </m:echoStringFault>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

And SOAP Fault response

```
<?xml version="1.0"?>
<SOAP:Envelope SOAP:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/" ...>
  <SOAP:Body>
    <SOAP:Fault>
      <faultcode>SOAP:Server</faultcode>
      <faultstring>[Virtuoso SOAP server] StringFault</faultstring>
      <detail>
        <h:part2 xmlns:h="http://soapinterop.org/wsdl" xsi:type="xsd:string">String</h:part2>
      </detail>
    </SOAP:Fault>
  </SOAP:Body>
</SOAP:Envelope>
```

Please note that in wire dumps there is no namespace declarations for brevity (places are denoted with '...').

17.1.18. Document Literal Encoding

The Virtuoso SOAP server and client support Document Literal encoding for processing as an alternative to SOAP/RPC. The document/literal encoding allows the transmission of any arbitrary valid XML document instead of a SOAP call following rules from section 5 from SOAP/1.1 specification. This allows us to send and receive SOAP packets that are more free-form ("document" style). If you create a service that can accept more free-form type packets, you can employ constraints within the methods so that they can be independent (bare) or serialized as embedded elements within the method's SOAP structure (wrapped parameters style).

Example 17.15. Comparing SOAP Types

Here are examples of SOAP requests that represent the RPC, Doc/Literal and Doc/Literal with parameters types of SOAP message

-- RPC encoded --

```
<?xml version="1.0"?>
<SOAP-ENV:Envelope
      xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/"
      xmlns:xsd="http://www.w3.org/2001/XMLSchema"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">
   <SOAP-ENV:Body>
     <m:echoString
         SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"
         xmlns:m="http://soapinterop.org/">
           <param0 xsi:type="xsd:string">Enter a message here</param0>
     </m:echoString>
   </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

-- Document Literal --

```
<?xml version="1.0"?>
<SOAP-ENV:Envelope
      xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">
   <SOAP-ENV:Body>
     <ns1:echoStringParam xmlns:ns1="http://soapinterop.org/xsd">Enter a message here</ns1:echoStringPara
```

```
   </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

-- Document Literal with parameters --

```
<?xml version="1.0"?>
<SOAP-ENV:Envelope
      xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">
   <SOAP-ENV:Body>
     <ns1:echoString xmlns:ns1="http://soapinterop.org/xsd">
       <param0>Enter a message here</param0>
     </ns1:echoString>
   </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

SOAP operations can be designated as document/literal or RPC by using the appropriate values in the WSDL description file associated to that SOAP endpoint. As Virtuoso SOAP operations are PL procedures special keywords are used within the procedure to indicate that the document/literal encoding should be used. These special keywords are:

__soap_doc

__soap_docw

These should be placed after the 'returns' keyword in a Virtuoso procedure definition. If 'returns ... __soap_type' is omitted the procedure return type will be equivalent to 'returns varchar __soap_type 'http://www.w3.org/2001/XMLSchema:string'.

Another way to expose a PL procedure or UDT method as a document/literal SOAP methods is to use non-explicit XMLSchema datatypes and to force encoding rules via virtual directory option 'Use' (see also SOAP options section in this chapter and in WSDL chapter section: "Exposing SQL Stored Procedures containing complex datatype definitions" for details and examples).

See Also:

WSDL 1.1 Specification

Example 17.16. SOAP Returns RPC

The following example shows a procedure that will be exposed as an RPC encoded SOAP operation:

```
create procedure
Import1.echoString (in x nvarchar __soap_type 'http://www.w3.org/2001/XMLSchema:string')
returns nvarchar __soap_type 'http://www.w3.org/2001/XMLSchema:string'
{
  return x;
};
```

Example 17.17. SOAP Returns Document Literal

The following example shows a procedure that will be exposed as a document literal encoded operation. Note the __soap_doc keyword after 'returns', also in this case __soap_type for each parameter must be specified since the incoming request must be validated by the given schema element declaration (see below for XMLSchema elements declaration).

```
create procedure
DocLit.echoString (in echoStringParam varchar __soap_type 'http://soapinterop.org/xsd:echoStringParam')
      returns any __soap_doc 'http://soapinterop.org/xsd:echoStringReturn'
{
      return echoStringParam;
};
```

Example 17.18. SOAP Returns Document Literal with Parameters

The following example shows a procedure that will be exposed as document literal encoding operation with parameters style (wrapped). note the __soap_docw keyword after 'returns'.

```
create procedure
DocPars.echoString (in echoString varchar __soap_type 'http://soapinterop.org/xsd:echoString')
      returns any __soap_docw 'http://soapinterop.org/xsd:echoStringResponse'
{
      return echoString;
};
```

In both cases of Document Literal encoding we need to specify the schema element for validation of the incoming SOAP request. Furthermore, this applies to the output elements and return value, as they need to be encoded/validated properly.

Defining WSDL Schema Data Type and Elements

When defining a schema data type (for use within SOAP) the 'targetNamespace' attribute on top level element must be specified in order to describe in which namespace this type is valid. In other words, this type will be used to validate request only within this namespace. Therefore it will be exposed only at this WSDL point where it is used to describe a parameter of an operation associated to it.

Important

All datatypes and elements defined for use in SOAP must have namespace (QName), which means that 'targetNamespace' must be specified in the definition. All non-qualified types will be rejected in SOAP validation and will not be described in the WSDL file.

Example 17.19. Making an array of string data type

Here is an example demonstrating making an array-of-string datatype:

```
select soap_dt_define('','<complexType name="ArrayOfstring"
   targetNamespace="http://soapinterop.org/xsd"
   xmlns:enc="http://schemas.xmlsoap.org/soap/encoding/"
   xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
   xmlns="http://www.w3.org/2001/XMLSchema"
   xmlns:tns="http://soapinterop.org/xsd">
  <complexContent>
     <restriction base="enc:Array">
        <sequence>
           <element name="item" type="string" minOccurs="0" maxOccurs="unbounded" nillable="true"/>
        </sequence>
        <attributeGroup ref="enc:commonAttributes"/>
        <attribute ref="enc:arrayType" wsdl:arrayType="string[]"/>
     </restriction>
  </complexContent>
</complexType>');
```

As document literal encodings work with elements, the elements must be declared as a part of the WSDL file (in the types/schema section). The declared elements can be used to define a doc/literal encoded SOAP operation. This allows for the definition of an element of request and response to enable the server to understand the requests (validate and process) and respond to them (validate the PL data and serialize properly).

Example 17.20. Example of defining elements

Here is an example for the DocLit.echoString SOAP operation using parameters (input parameter and return type):

```
select soap_dt_define('','<element xmlns="http://www.w3.org/2001/XMLSchema"
                                   name="echoStringParam"
                                   targetNamespace="http://soapinterop.org/xsd" type="string" />');

select soap_dt_define('','<element xmlns="http://www.w3.org/2001/XMLSchema"
                                   name="echoStringReturn"
                                   targetNamespace="http://soapinterop.org/xsd" type="string" />');
```

Extensions to Simple Types

The attribute extensions to the simple types (string, float, etc...) can be defined and used in SOAP messages. In that case a PL value is represented as a special structure of 3 elements as follows:

```
vector (<composite>, vector (<attr-name>, <attr-value>, ...), <simple type value>)
```

Example 17.21. An example to define a simple type 'Document'

```
select soap_dt_define('','<complexType name="Document"
             xmlns="http://www.w3.org/2001/XMLSchema"
             xmlns:xsd="http://www.w3.org/2001/XMLSchema"
             targetNamespace="http://soapinterop.org/xsd">
  <simpleContent>
    <extension base="string">
      <xsd:attribute name ="ID" type="string"/>
    </extension>
  </simpleContent>
</complexType>');
```

Note that soap_dt_define() does not need the name to be specified when adding a new type, the name/namespace will be extracted from XSD fragment.

WSDL Generation

As the WSDL file generation is based on granted PL procedures exposed to a given SOAP endpoint, only SOAP datatypes and schema elements used for them will be printed in <types> section. If an undeclared datatype is used for an exposed procedure, the error will be printed in an XML comment where the type definition was expected and not found. If an element or datatype refers to other (dependent) types they will also be automatically included. For example, if we have exposed for a SOAP endpoint only the following procedure:

```
create procedure
INTEROP.echoStructArray (
    in inputStructArray any __soap_type 'http://soapinterop.org/xsd:ArrayOfSOAPStruct')
    __soap_type 'http://soapinterop.org/xsd:ArrayOfSOAPStruct'
{
  return inputStructArray;
};
```

The schema fragment will consist of both SOAPStructure and ArrayOfSOAPStruct data types declaration:

```
<schema targetNamespace="http://soapinterop.org/xsd"
   xmlns="http://www.w3.org/2001/XMLSchema"
   xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/" >
     <complexType name="ArrayOfSOAPStruct" >
       <complexContent>
         <restriction base="soapenc:Array">
           <sequence>
             <element name="item" type="ns0:SOAPStruct" minOccurs="0" maxOccurs="unbounded"/>
           </sequence>
           <attribute ref="soapenc:arrayType" wsdl:arrayType="ns0:SOAPStruct[]"/>
           <attributeGroup ref="soapenc:commonAttributes"/>
           <attribute ref="soapenc:offset"/>
         </restriction>
      </complexContent>
    </complexType>
    <!-- Note this fragment, it's included because ArrayOfSOAPStruct depends from it -->

    <complexType name="SOAPStruct" >
       <all>
          <element name="varString" type="string" nillable="true"/>
          <element name="varInt" type="int" nillable="true"/>
          <element name="varFloat" type="float" nillable="true"/>
       </all>
    </complexType>
</schema>
```

Multiple Namespaces in WSDL and SOAP

When you define a SOAP operation that has parameters from different namespaces or a type referring to a type in another namespace, both will be defined and printed as a separate schema definition in the WSDL file. Hence, we can define a data type in different namespace so they will live together in a single WSDL file. This allows us to make more complex and flexible document-centric style SOAP operations.

Example 17.22. Example from the SOAP Interop 3 Tests

This example is of the echoEmployee operation from interop 3 tests:

```
create procedure
Compound2.echoEmployee (in x any __soap_type 'http://soapinterop.org/employee:x_Employee')
      returns any __soap_doc 'http://soapinterop.org/employee:result_Employee'
{
  return x;
};
```

This will generate the following schema in the WSDL file (only affected parts are shown):

```
<definitions
...
xmlns:ns1="http://soapinterop.org/person"
xmlns:ns0="http://soapinterop.org/employee"
... >

<types>
        <schema targetNamespace="http://soapinterop.org/person"
                xmlns="http://www.w3.org/2001/XMLSchema"
                xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/" elementFormDefault="qualified" >
           <complexType name="Person" >
              <sequence>
                <element minOccurs="1" maxOccurs="1" name="Name" type="string"/>
                <element minOccurs="1" maxOccurs="1" name="Male" type="boolean"/>
              </sequence>
           </complexType>
        </schema>

        <schema targetNamespace="http://soapinterop.org/employee"
                xmlns="http://www.w3.org/2001/XMLSchema"
                xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/" elementFormDefault="qualified" >
                <import namespace='http://soapinterop.org/person' />
            <complexType name="Employee" >
                <sequence>
                   <element minOccurs="1" maxOccurs="1" name="person" type="ns1:Person"/>
                   <element minOccurs="1" maxOccurs="1" name="salary" type="double"/>
                   <element minOccurs="1" maxOccurs="1" name="ID" type="int"/>
                </sequence>
           </complexType>

           <element name="result_Employee" type="ns0:Employee" />
           <element name="x_Employee" type="ns0:Employee" />

        </schema>
</types>
...
```

The PL procedure is defined to use element declaration x_Employee and result_Employee, so this will automatically include the Employee and Person type, upon which they depend. Also, as these types are defined in different namespace, two schema parts will be specified in the WSDL file.

In practice the SOAP developer needs to define elements and types (using soap_dt_define() function), after this, specifying a parameter of PL procedure (or return type) will cause automatic generation of the associated WSDL description in the manner described. Hence, no user intervention is required besides the initial element/type definition.

SOAP Interop round III Endpoints

The following endpoints are pre-defined in the Demo database for SOAP interop III testing (the WSDL files are in the usual services.wsdl for each group of tests):

- *D tests*
  - /r3/EmptySA/ - echoString operation with empty ("") soapAction (PRC encoded)
  - /r3/Import1/ - echoString operation, rpc encoded
  - /r3/Import2/ - echoStruct operation, rpc encoded
  - /r3/Import3/ - echoStruct and adds method echoStructArray, rpc encoded (echoStruct is in different namespace)
  - /r3/Compound1/ - Use of attributes in SOAP payload, including attribute on element of simpleType , doc/literal
  - /r3/Compound2/ - Two schema sections, types in 1st schema references types in the 2nd schema, doc/literal
  - /r3/DocPars/ - Reduced version of SOAPBuilders Interop test wsdl with "parameters" way of describing rpc requests in Document/Literal (Document/Literal - Wrapped). Version has operations echoString, echoArrayOfString and echoStruct
  - /r3/DocLit/ - Reduced version of SOAPBuilders InteropTest test, document/literal mode. Version has operations echoString, echoArrayOfString and echoStruct
  - /r3/RpcEnc/ - Reduced version of SOAPBuilders InteropTest test, rpc/encoded mode. Version has operations echoString, echoArrayOfString and echoStruct
- *E tests*
  - /r3/List/ - echo of list structure (as shown) , RPC encoded

```
struct list {
  int varInt;
  string varString;
  list child; //nullable
}
```

- *F tests*
  - /r3/Hdr/ - Modified version of SOAPBuilders InteropTest test, document/literal mode Version has one operation echoString with 2 headers defined.

17.1.19. DIME encapsulation of SOAP messages

The Direct Message Encapsulation (DiME) format is a message format that can be used to encapsulate one or more payloads of arbitrary type and size. This format can be used in place of MIME, but benefits of DIME are ease of parsing and low memory consumption, as DIME does not require loading the whole message body in order to parse it. This is due to the fact that MIME does not have mechanism for specifying the length of payloads etc. DIME prefixes all data with length and type information.

The structure of a DIME message as per draft-nielsen-dime-02 is:

```
/*
      Legend:

      VERSION = 0x01
      RESRVD  = 0x00
      MB - begin mark
      ME - end mark
      CF - chunked flag
      TYPE_T - type of content type field

      0                   1                   2                   3
      0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
     +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
     |          |M|M|C|       |       |                               |

     +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
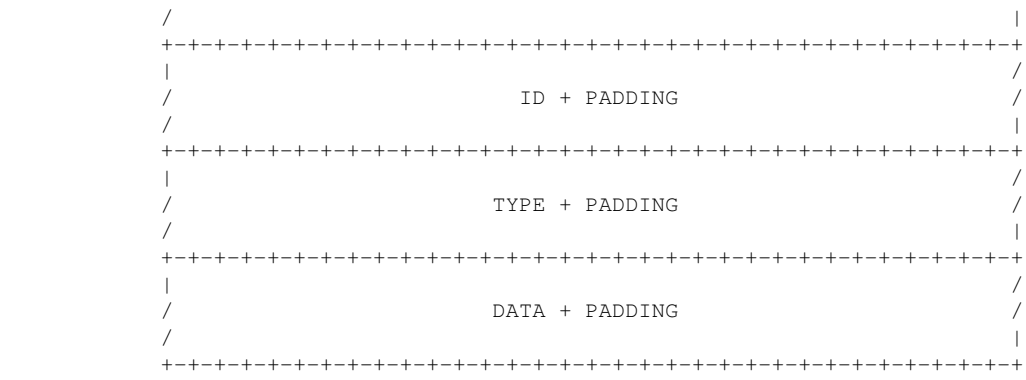
     |                                                               /
     /                     OPTIONS + PADDING                         /
```



The MB,ME,CF flags are used to indicate which part of the DIME message is the current block of data. Also, we notice that there are four length fields of fixed length before any data, id or type payload. This is to make the payload easier to read.

The Virtuoso server implements a DIME parser and composer as functions and filter for DIME in SOAP server. Furthermore the Virtuoso WSDL generator can be instructed to specify a DIME extension to the PL procedure exposed as SOAP method. The implementation is based on draft-nielsen-dime-02 RFC proposal. Please note that in the rest of document we will use 'DIME attachment' term , which is about SOAP message with attachment encapsulated with DIME as per draft-nielsen-dime-soap-01. The special case in these messages is type of first payload, so it's supposed to be a SOAP:Envelope message.

Note: Option fields are not supported.

To setup a SOAP endpoint to recognize DIME encapsulation the "DIME-ENC" option to SOAP in virtual directory must be set to 'yes'. Furthermore the WSDL description of endpoint defined as DIME enabled will contain WSDL extensions to DIME.

As not in all cases input and output of the SOAP server needs to be DIME encoded, the particular PL procedure exposed as SOAP method needs to be defined in special way to indicate which traffic is encoded as DIME. This is done by using special keywords on procedure declaration:

```
CREATE PROCEDURE ([PARAMETERS DECLARATION])
 [RETURNS TYPE] [(__SOAP_TYPE|__SOAP_DOC|_SOAP_DOCW) 'LITERAL'] [__SOAP_DIME_ENC (IN/OUT/INOUT)]
```

The '__SOAP_DIME_ENC IN' indicate that the procedure expects a DIME attachments on input. This can also be used with OUT and INOUT. This will also be indicated in WSDL file (services.wsdl) as DIME extension in appropriate place of 'soap:operation' element.

The format of SOAP attachments passed to PL procedure defined in this way is an array which consists of three string elements: ID, content-type, and attachment data itself. The same format must be used when parameter is an output which needs to be sent as DIME attachment. There is also a special parameter of PL procedure exposed as SOAP method named 'ws_soap_attachments', so when we have such, all attachments received will be passed thru it. In practice we will not need to use 'ws_soap_attachments' , but anyway it's practical use is to handle unreferenced parameters or to debug the request.

Finally we must say that type of parameter needs to have datatype declared as per 'WSDL Extension for SOAP in DIME' proposal, this is needed for indicating in the WSDL what to expect and how to send the attachment. See also the example below.

Example 17.23. Using DIME encapsulation

Suppose we need to accept a binary attachment and echo it back as string encoded in the popular 'base64'.

We first need to enable DIME encapsulation to an endpoint, with virtual directory definition:

```
SQL> VHOST_DEFINE (lpath=>'/r4/groupG/dime/rpc', ppath=>'/SOAP/', soap_user=>'interop4',
    soap_opts => vector ('DIME-ENC', 'yes')) ;
```

The sample PL procedure that takes a binary attachment and transforms it to a base64 encoded string must be declared as:

```
create procedure
```

```
EchoAttachmentAsBase64 (in "In" nvarchar __soap_type 'http://soapinterop.org/attachments/xsd:ReferencedBi
returns nvarchar __soap_type 'base64Binary'
__soap_dime_enc in
{
  -- we are getting the attachment as the 3rd element of input,
  -- do the base64 encoding for it and return it to the requestor
  return encode_base64 (cast ("In"[2] as varchar));
}
;
```

As we have noticed an 'ReferencedBinary' is used to declare 'In' parameter. This has a special purpose for WSDL definition, not for SOAP processing itself. In that case clients are instructed to look at annotation/appinfo of a simple type declared as:

```
<complexType name="ReferencedBinary">
        <simpleContent>
                <restriction base="soap-enc:base64Binary">
                        <annotation>
                                <appinfo>
                                        <content:mediaType value="application/octetstream"/>
                                </appinfo>
                        </annotation>
                        <attributeGroup ref="soap-enc:commonAttributes"/>
                </restriction>
        </simpleContent>
</complexType>
```

This is a little-bit tricky, but this is how to indicate the type of the content and how to resolve the references to the attachments as per the WSDL Extension for SOAP in DIME' proposal.

17.1.20. SOAP Endpoint Options

The virtual directory mechanism provides a special SOAP options for SOAP processing. The SOAP options are name-value pairs contained in a vector: i.e. vector ('name1', 'value1', ...). The SOAP server accepts the following optional parameters settable in the SOAP Options field of the HTTP Virtual Directories Setup interface, or using the `vhost_define()` function:

ServiceName : name of the SOAP service, will be prefixed with 'Virtuoso'. That name is shown in WSDL description.

Namespace : namespace URI of the SOAP:Body request and response.

HeaderNS : namespace URI for SOAP:Header messages.

FaultNS : namespace URI for SOAP:Fault messages.

MethodInSoapAction : enable or disable appending of the method name in the soapAction attribute (WSDL) after namespace URI.

CR-escape : enable or disable escaping of the CRs on wire as &#0xd

elementFormDefault=(unqualified|qualified); Sets the elementFormDefault for schema specification. if qualified is used the elementFormDefault attribute will be set to qualified, in which case elements required to be unqualified can be declared with value of "form" attribute "unqualified".

Use=(encoded|literal) Sets the default SOAP message encoding rules for those PL procedures which have no explicit encoding rule assigned (see SOAP special syntax for PL procedures). The default is 'encoded' which means to follow SOAP RPC encoding as described in SOAP v1.1 specification section 5.1. The 'literal' mode forces the SOAP server to expose PL procedures with the document/literal parameter encoding style.

MethodInSoapAction=(no|yes|empty|only); Controls soapAction attribute manipulation. *no* - only URL for soap requests will be printed. *yes* (default) - the URL and soap method will be printed in form: <url>#<method name>. *empty* - no value will be specified for soapAction. *only* - only the method will be specified in form #<method name>.

DIME-ENC : Controls DIME encapsulation on particular SOAP endpoint, valid values are *no* - (default) not enabled. *yes* - DIME encapsulation is enabled on endpoint

WS-SEC : WS-Security processing is enabled on the endpoint, if it's *yes* , otherwise disabled (default)

WSS-KEY : name of PL procedure, which is supposed to return a key instance, used together with "WS-SEC" option.

WSS-Template : path to the file for making the XML Signature in response message. The "[key reference for signing]" denotes using a default template for signing, see WS Security signing SOAP messages.

WSS-Validate-Signature : This option controls the input behavior, i.e. how to verify the incoming message. Possible values are "0", "1" or "2", where 0 does not verify signatures, 1 expects a signature to exist, 2 will verify signature if one exists.

WS-RP : to enable WS-Routing protocol on particular endpoint, if it's *yes* , otherwise disabled (default).

wsrp-from : Constant for identification of endpoint, an example is 'some@user.network'. This will be included in 'form' element in WS Routing header.

17.2. WSDL

The Web Services Description Language (WSDL) is a standard, structured way of describing SOAP messages and Web services. It is an XML format for describing the network services offered by a service provider. The provider will publish a WSDL file that contains details about the services provided, and the set of operations within each service that the provider supports. For each of the operations, the WSDL file also describes the format that the client must follow in requesting an operation.

Since the WSDL file sets up requirements for both the provider and service requester, this file is like a contract between the two. The provider agrees to provide certain services if the client sends a properly formatted SOAP request. Suppose that we have a WSDL file defining a service called StockQuoteService. This service describes operations such as getTradePrice, getLowestTradePrice, and getHighestTradePrice. You place this WSDL file on the service provider server. A client who wishes to send a SOAP request to this server must first obtain a copy of the WSDL file from the provider, and then use it to format a suitable SOAP request. The client sends this request to the provider. The provider executes the requested operation and sends the results back to the client requester as a SOAP response.

See Also:

The specification of WSDL and its file structures can be found on the W3C site .

17.2.1. Exposing Stored Procedures as WSDL Services

Virtuoso can be both a provider and a client of WSDL. In this section we will explain how to use Virtuoso to expose procedures as SOAP messages, and then publish them as WSDL consumables.

In the descriptions below, lines preceded by

```
SQL>
```

denote that the command is intended to be issued using the ISQL command line interface to Virtuoso.

Virtuoso procedures can easily be published as WSDL consumables. We follow the same steps as we would take to create SOAP objects and then for every SOAP object Virtuoso automatically generates a WSDL file entry. The default Virtuoso has the user SOAP and reserved HTTP path of `/SOAP/` . All procedures that are created in the default qualifier namespace of the SOAP user (WS.SOAP) and have had a 'grant execute to SOAP' permissions established in the database are available to SOAP and thus are automatically available to WSDL. In Virtuoso this is done by requesting the file `services.wsdl` from the server via HTTP from the `/SOAP/` path:

```
http://[host:port]/SOAP/services.wsdl
```

. WSDL files such as this are often referred to as "endpoints" for services.

Virtual directories increase our flexibility by allowing us to map logical HTTP paths to the location `/SOAP/` . This means that we can separate WSDL/SOAP functionality, making groups of services available under different locations. We will now demonstrate this:

1. First, create a new user in the database for creating the stored procedures as SOAP messages:

   ```
   SQL>CREATE USER SOAPDEMO;
   ```
2. Now, set the default catalogue/qualifier for the new user to the WS catalogue where we will create procedures to be used as SOAP objects:

   ```
   SQL>USER_SET_QUALIFIER ('SOAPDEMO', 'WS');
   ```
3. Now create a new virtual host definition, using the `vhost_define()` , so that we can find our SOAP objects later at a desired location.

   ```
   SQL>VHOST_DEFINE (vhost=>'*ini*',lhost=>'*ini*',lpath=>'/services',ppath=>'/SOAP/',soap_user=>'SOA
   ```

   If the mapping already exists, producing an error in the call above, and is not being used, then you can remove it using the command:

```
SQL>VHOST_REMOVE (vhost=>'*ini*',lhost=>'*ini*',lpath=>'/services')
```

Note:
ini is a special indicator telling Virtuoso to take the default values from its initialization file.

4. Now create a simple SOAPTEST procedure and grant the appropriate privileges to the SOAPDEMO user:

```
SQL> create procedure
  WS.SOAPDEMO.SOAPTEST (in par varchar)
{
  return (upper(par));
};

SQL> grant execute on WS.SOAPDEMO.SOAPTEST to SOAPDEMO;
```

5. Now test this new SOAP object's availability by using `soap_client()` . This function would normally return a vector representation of the SOAP object but since we know the dimensions of the object ahead of time we can pin-point the entry using the `aref()` function as follows:

```
SQL> select aref(aref(
        soap_client (url=>sprintf ('http://localhost:%s/services', server_http_port ()),
        operation=>'SOAPTEST', parameters=>vector('par', 'demotext')), 1), 1);
callret
VARCHAR
_______

DEMOTEXT
```

   The actual SOAP object looks more like:

```
(("SOAPTESTResponse" ) (("CallReturn" ) "DEMOTEXT" ) )
```

   which was generated in a Virtuoso server log for debugging purposes using the `dbg_obj_print()` function.

6. Procedures that exist under the WS.SOAPDEMO namespace and have been granted execution to the new SOAPDEMO user are now available as SOAP services and described by WSDL in this example, Virtuoso would publish them from the URL:

```
http://example.com/services/services.wsdl
```

   which will yield the following WSDL description:

```
<?xml version='1.0'?>
<definitions
 targetNamespace='services.wsdl'
 xmlns:xsd='http://www.w3.org/1999/XMLSchema'
 xmlns:soap='http://schemas.xmlsoap.org/wsdl/soap/'
 xmlns:tns ='services.wsdl'
 xmlns ='http://schemas.xmlsoap.org/wsdl/'
 name='VirtuosoSOAP'>
        <message name='SOAPTEST'>
                <part name='par' type='xsd:string'/>
        </message>
        <message name='SOAPTESTResponse'>
                <part name='CallReturn' type='xsd:string'/>
        </message>
        <portType name='SOAPPortType'>
                <operation name='SOAPTEST'>
                        <input message='tns:SOAPTEST' name='SOAPTEST'/>
                        <output message='tns:SOAPTESTResponse' name='SOAPTESTResponse'/>
                </operation>
        </portType>
        <binding name='SOAPBinding' type='tns:SOAPPortType'>
                <soap:binding style='rpc' transport='http://schemas.xmlsoap.org/soap/http'/>
                <operation name='SOAPTEST'>
                        <soap:operation soapAction='urn:openlinksw.com:virtuoso_soap_schema#SOAPTE
                        <input>
                                <soap:body use='encoded' namespace='urn:openlinksw.com:virtuoso_so
                        </input>
                        <output>
                                <soap:body use='encoded' namespace='urn:openlinksw.com:virtuoso_so
```

```
                        </output>
                    </operation>
                </binding>
                <service name='SOAPService'>
                    <port name='SOAPPort' binding='tns:SOAPBinding'>
                        <soap:address location='http://example.com/services'/>
                    </port>
                </service>
            </definitions>
```

See Also:

The Testing Web Services (VSMX) section describes Virtuoso's ability to also automatically generate a test page for your SOAP services, simply by replacing services.wsdl with services.vsmx in the URL.

17.2.2. Exposing SQL Stored Procedures containing complex datatype definitions

When parameters of a PL procedure or UDT (User Defined Type) methods contain parameters declared as UDT or/and as ARRAY then WSDL generation will include XML Schema for them. The schema types in this case will be generated every time WSDL URL is accessed. Also the XMLSchema datatypes will be generated following the default encoding rules forced via 'Use' SOAP option to the given virtual directory.

Example 17.24. Exposing a PL Stored procedures containing complex datatypes

The following example will create a virtual directory '/soap-lit' on default HTTP listener and will expose a single method accepting a array of structures which contains an array of integers, integer, varchar and float members. The SOAP message will use the document/literal encoding rules (option Use=literal).

```
create user SOAP_U1;

VHOST_DEFINE (  lpath=>'/soap-lit',
                ppath=>'/SOAP/', soap_user=>'SOAP_U1',
                soap_opts=>
                vector ('ServiceName', 'Literal',
                    'Namespace', 'http://temp.uri',
                    'SchemaNS', 'http://temp.uri',
                    'MethodInSoapAction', 'yes',
                    'elementFormDefault', 'unqualified',
                    'Use', 'literal'));

create type SOAP_StructA as (varString varchar, varInt integer, varFloat real, varArray integer array);

create procedure echoStructArray (in sa DB.DBA.SOAP_StructA array) returns DB.DBA.SOAP_StructA array
{
  return sa;
};

grant execute on SOAP_StructA to SOAP_U1;
grant execute on echoStructArray to SOAP_U1;
```

This would produce the following WSDL file when accessing the http://[host:port]/soap-lit/services.wsdl URL.

```
<?xml version="1.0"?>
<definitions xmlns:xsd="http://www.w3.org/2001/XMLSchema" xmlns:http="http://schemas.xmlsoap.org/wsdl/htt
  <types>
    <schema xmlns="http://www.w3.org/2001/XMLSchema" xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/" target
      <complexType name="echoStructArray_Response_t">
        <sequence>
          <element name="item" type="ns0:SOAP_StructA" minOccurs="0" maxOccurs="unbounded" nillable="true
        </sequence>
      </complexType>
      <complexType name="echoStructArray_sa_t">
        <sequence>
          <element name="item" type="ns0:SOAP_StructA" minOccurs="0" maxOccurs="unbounded" nillable="true
        </sequence>
      </complexType>
      <complexType name="SOAP_StructA">
        <all>
```

```
            <element name="varString" type="string" nillable="true"/>
            <element name="varInt" type="int" nillable="true"/>
            <element name="varFloat" type="float" nillable="true"/>
            <element name="varArray" type="ns0:SOAP_StructA_varArray_t" nillable="true"/>
          </all>
        </complexType>
        <complexType name="SOAP_StructA_varArray_t">
          <sequence>
            <element name="item" type="int" minOccurs="0" maxOccurs="unbounded" nillable="true"/>
          </sequence>
        </complexType>
        <element name="echoStructArray">
          <complexType>
            <sequence>
              <element minOccurs="1" maxOccurs="1" name="sa" type="ns0:echoStructArray_sa_t"/>
            </sequence>
          </complexType>
        </element>
        <element name="echoStructArrayResponse">
          <complexType>
            <all>
              <element minOccurs="1" maxOccurs="1" name="CallReturn" type="ns0:echoStructArray_Response_t"/
            </all>
          </complexType>
        </element>
      </schema>
    </types>
    <message name="echoStructArrayRequest">
      <part element="dl:echoStructArray" name="parameters"/>
    </message>
    <message name="echoStructArrayResponse">
      <part element="dl:echoStructArrayResponse" name="parameters"/>
    </message>
    <portType name="LiteralDocLiteralPortType">
      <operation name="echoStructArray">
        <input message="tns:echoStructArrayRequest" name="echoStructArrayRequest"/>
        <output message="tns:echoStructArrayResponse" name="echoStructArrayResponse"/>
      </operation>
    </portType>
    <binding name="LiteralDocLiteralBinding" type="tns:LiteralDocLiteralPortType">
      <soap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>
      <operation name="echoStructArray">
        <soap:operation soapAction="http://temp.uri#echoStructArray" style="document"/>
        <input name="echoStructArrayRequest">
          <soap:body use="literal"/>
        </input>
        <output name="echoStructArrayResponse">
          <soap:body use="literal"/>
        </output>
      </operation>
    </binding>
    <service name="VirtuosoLiteral">
      <documentation>Virtuoso SOAP services</documentation>
      <port name="LiteralDocLiteralPort" binding="tns:LiteralDocLiteralBinding">
        <soap:address location="http://example.com/soap-lit"/>
      </port>
    </service>
  </definitions>
```

17.2.3. Exposing Third Party SQL Stored Procedures as WSDL-Compliant Web Services

Virtuoso can expose any of its available PL resource to the SOAP world, and subsequently to the WDSL file. This includes data from remote attached tables and procedures. All you have to do is make sure that the entry point exists as a stored procedure in the correct namespace with the appropriate grants, as before.

See Also

The Virtual Database chapter for information regarding use of remote data sources and their tables.

Because remote procedures may not be directly compatible you are required to write a Virtuoso wrapper function first to handle the remote procedure. Below is a sample MS SQLServer procedure and an accompanying Virtuoso wrapper function. The MS SQLServer function returns a result set based on a simple join query with a filter input. The Virtuoso procedure calls the remote procedure, iterates through the result set returned and produces XML output.

MS SQLServer procedure:

```
create procedure ms_remote
        @mask varchar(15)
as
  select c.CustomerID, c.CompanyName, o.OrderDate,
      o.ShippedDate,ol.ProductID, ol.Quantity, ol.Discount
    from Northwind..Customers c
      inner join Northwind..Orders o on c.CustomerID = o.CustomerID
      inner join Northwind.."Order Details" ol on o.OrderID = ol.OrderID
    where c.CustomerID like @mask
;
```

Virtuoso wrapper function:

```
create procedure WS.SOAP.ms_remote_call (
  in dsn varchar, in uid varchar, in pwd varchar, in mask varchar)
{
  declare m, r, ses any;
  vd_remote_data_source (dsn, '', uid, pwd);
  rexecute (dsn, 'ms_remote ?', null, null, vector (mask), 1000, m, r);
  ses := string_output ();
  http ('<?xml version="1.0" ?>\n<remote>\n', ses);
  if (isarray(m) and isarray (r))
    {
      declare i, l, j, k integer;
      declare md, rs any;
      md := m[0];
      i := 0; l := length (md); k := length (r); j := 0;
      while (j < k)
       {
         http ('<record ', ses);
         i:=0;
         while (i < l)
           {
             dbg_obj_print (md[i][0],r[j][i]);
             http (sprintf (' %s="%s"', trim(md[i][0]), trim(cast (r[j][i] as varchar))), ses);
             i := i + 1;
           }
         http (' />\n', ses);
         j := j + 1;
       }
    }
  http ('</remote>', ses);
  return string_output_string (ses);
};
```

Now, as before, we grant execute rights to the SOAP user:

```
grant execute on WS.SOAP.ms_remote_call to SOAP;
```

The third-party procedures can now be accessed via SOAP and are listed in the WSDL file.

17.2.4. WSDL Descriptions of SOAP Header Messages

The Virtuoso web server automatically generates WSDL descriptions for procedures exposed as SOAP messages, and those exposed to have parameters bound to SOAP Header messages.

Consider the sample of the Interop.INTEROP.echoVoid procedure defined as an example in the SOAP section as:

```
create procedure
Interop.INTEROP.echoVoid
   (in echoMeStringRequest nvarchar := NULL __soap_header 'http://www.w3.org/2001/XMLSchema:string',
    out echoMeStringResponse nvarchar := NULL __soap_header 'http://www.w3.org/2001/XMLSchema:string')
```

```
    __soap_type '__VOID__'
{
  if (echoMeStringRequest is not null)
    echoMeStringResponse := echoMeStringRequest;
};
```

The WSDL description will now contain the header messages also. No extra user intervention is required. The WSDL file that will result will look like:

```
..... WSDL excerpt (consider http://[host:port]/Interop/services.wsdl of an demo DB) ...........
       <message name="echoVoidRequest"></message>
       <message name="echoVoidResponse"></message>
       <message name="echoVoidechoMeStringRequest">
               <part name="echoMeStringRequest" type="xsd:string" />
       </message>
       <message name="echoVoidechoMeStringResponse">
               <part name="echoMeStringResponse" type="xsd:string" />
       </message>
..... in bindings section note the soap:header sections.............
       <operation name="echoVoid">
       <soap:operation soapAction="http://soapinterop.org/" />
       <input>
       <soap:body use="encoded" namespace="http://soapinterop.org/" encodingStyle="http://schemas.xmlsoa
       <soap:header use="encoded" message="tns:echoVoidechoMeStringRequest" part="echoMeStringRequest" n
       </input>
       <output>
       <soap:body use="encoded" namespace="http://soapinterop.org/" encodingStyle="http://schemas.xmlsoa
       <soap:header use="encoded" message="tns:echoVoidechoMeStringResponse" part="echoMeStringResponse"
       </output>
       </operation>
.....more.........
```

17.2.5. Importing A WSDL File & SOAP/WSDL Proxying

Virtuoso can import WSDL files from other locations using the function:

`soap_wsdl_import()`

This function reads the descriptions of SOAP messages available in the WSDL file and automatically creates Virtuoso stored procedure wrappers for executing the SOAP messages directly from Virtuoso in procedures. These generated procedures can then be exposed as SOAP messages in the normal way from the Virtuoso SOAP server, and of course fully described by an automatically generated WSDL file for them, thus creating a proxy service for original messages.

17.2.6. SOAP/WSDL Interoperability

A key feature of the Web services promise is that Web services published with one server can be called from any other client. The ability of each implementation to make use of each others' output is called interoperability. Thus, Web services created with Virtuoso should interoperate smoothly with services created with Microsoft's .NET, Sun's Java, and so on. Interoperable Web services mean that developers and users do not have to think about which programming language or operating system the services are hosted on.

The evolving nature of the SOAP specification, as well as its complexity, leads to differences in SOAP implementations. Unfortunately, these implementation differences decrease interoperability. To counteract this problem, a volunteer group of SOAP application builders has developed a series of interoperability tests.

OpenLink, as a participant in this group, ensures that its SOAP implementation interoperates fully. This means that Virtuoso's SOAP server properly exposes your Web services so they can be used by any client. It also means that Virtuoso can call services published by any compliant provider.

You can view the Round 1 "Interoperability Lab" at www.xmethods.net and the Round 2 at www.whitemesa.com . Please note that OpenLink has no connection with these companies; they are simply places that volunteered to host the testing reference documents on their servers.

The Round 2 tests include base functionality (which duplicates Round 1) as well as more advanced tests labeled "Group B" and "Group C". The WSDL published by OpenLink containing the descriptions of these tests can be found at http://demo.openlinksw.com:8890/Interop/ . This URL will be updated as new interoperability tests are devised.

The SOAP implementation passes all known interoperability tests.

17.3. WebID Protocol Support

WebID Protocol is an authentication and authorization protocol that links a "Web ID" or "Personal URI " to a public key to create a global, decentralized, distributed, and secure authentication system that functions with existing browsers.

WebID Protocol uses PKI standards - usually thought of as hierarchical trust management tools - in a decentralized web-of-trust way . The web of trust is built using semantic web vocabularies (particularly FOAF) published in RESTful manner to form Linked Data.

Based on well known existing standards, WebID Protocol is currently in development, and is being discussed on the FOAF protocols mailing list .

For the most recent description of the protocol, read the one-page "WebID Protocol: Adding Security to Open Distributed Social Networks ". For a more detailed explanation of how the authentication works, see "WebID Protocol: Creating a Web of Trust without Key Signing Parties ".

Automatic discovery of interpersonal trust relationships enables automatic application of appropriate permissions.

In other words, data owners can set fuzzy permissions like "only let my friends see this" or "only let my family edit this." Applications can discover the relationships between the data owner and the data requester/user, and permit (or disallow) any attempted actions, without needing the data owner to explicitly set permissions for each potential user.

One example might be a parent setting permissions on a photo gallery, to permit viewing only by "immediate family". The parent need not list each and every such relative specifically for this application - and need not add new permissions for a new family member (whether by marriage, birth, or otherwise), though they do need to be added to the owner's FOAF. When a new user comes and asks to see the pictures, the gallery application would check the relationships declared by each person (the owner and the visitor), and if they matched up (in other words, the visitor could not get in simply by claiming a family relationship; the relationship must be confirmed by the owner's FOAF data), the pictures would be shown.

17.3.1. x.509 certificate

The WebID Protocol consumer needs an x509 certificate with v3 extension "Subject Alternate Name". This attribute is used for the owner's Web ID. For testing purposes we used OpenSSL demo CA to generate such certificates. If you are not using the OpenSSL demo CA, you must first setup a self-signed CA; read OpenSSL documents on how to do this.

1. Add the following line to the [usr_cert] section of the openssl.cnf file:

   ```
   subjectAltName=$ENV::ALTNAME
   ```
2. Set the environment variable ALTNAME to the owner's Web ID, e.g.,

   ```
   export ALTNAME=URI:http://example.com/dataspace/person/myname#this
   ```
3. Make a self-signed certificate, e.g.,

   ```
   $ CA.pl -newreq (follow the dialog)
   $ CA.pl -sign
   ```
4. When asked to commit the certificate, make sure you see several lines above, like:

   ```
    X509v3 Subject Alternative Name:
                   URI:http://example.com/dataspace/person/myname#this
   ```
5. If your browser wants a PKCS#12 bundle, you must make one:

   ```
   $ openssl pkcs12 -export -in newcert.pem -inkey newkey.pem -out mycert.p12
   ```
6. Rename newcert.pem and newkey.pem, to mycert.pem and mykey.pem for example. The PEM format of the certificate will be needed below.

17.3.2. Setting up Virtuoso HTTPS

To enable the HTTPS listener, you will need another certificate. Existing certificates may not have Subject Alternate Name, so you may want to generate one as in the previous section.

1. The next step is to move newcert.pem, newkey.pem, and cacert.pem into the server's working directory. In our test case, we put the keys in a 'keys' sub-directory, and added the following lines to the [HTTPServer] section of the Virtuoso INI file, virtuoso.ini:

   ```
   SSLPort                     = 4443
   SSLCertificate              = ./keys/localhost.cert.pem
   SSLPrivateKey               = ./keys/localhost.key.pem
   X509ClientVerifyCAFile      = ./keys/localhost.ca.pem
   X509ClientVerify            = 1
   X509ClientVerifyDepth       = 15
   ```
2. Also in the Virtuoso INI file, in the [URIQA] section, DefaultHost (localhost:8890 below) must be edited to correspond to the DNS-resolvable host name ("CNAME") of the Virtuoso host, combined with the ServerPort as set in the [HTTPServer] section of the same INI file.

   ```
   [URIQA]
   DynamicLocal = 1
   DefaultHost  = localhost:8890
   ```

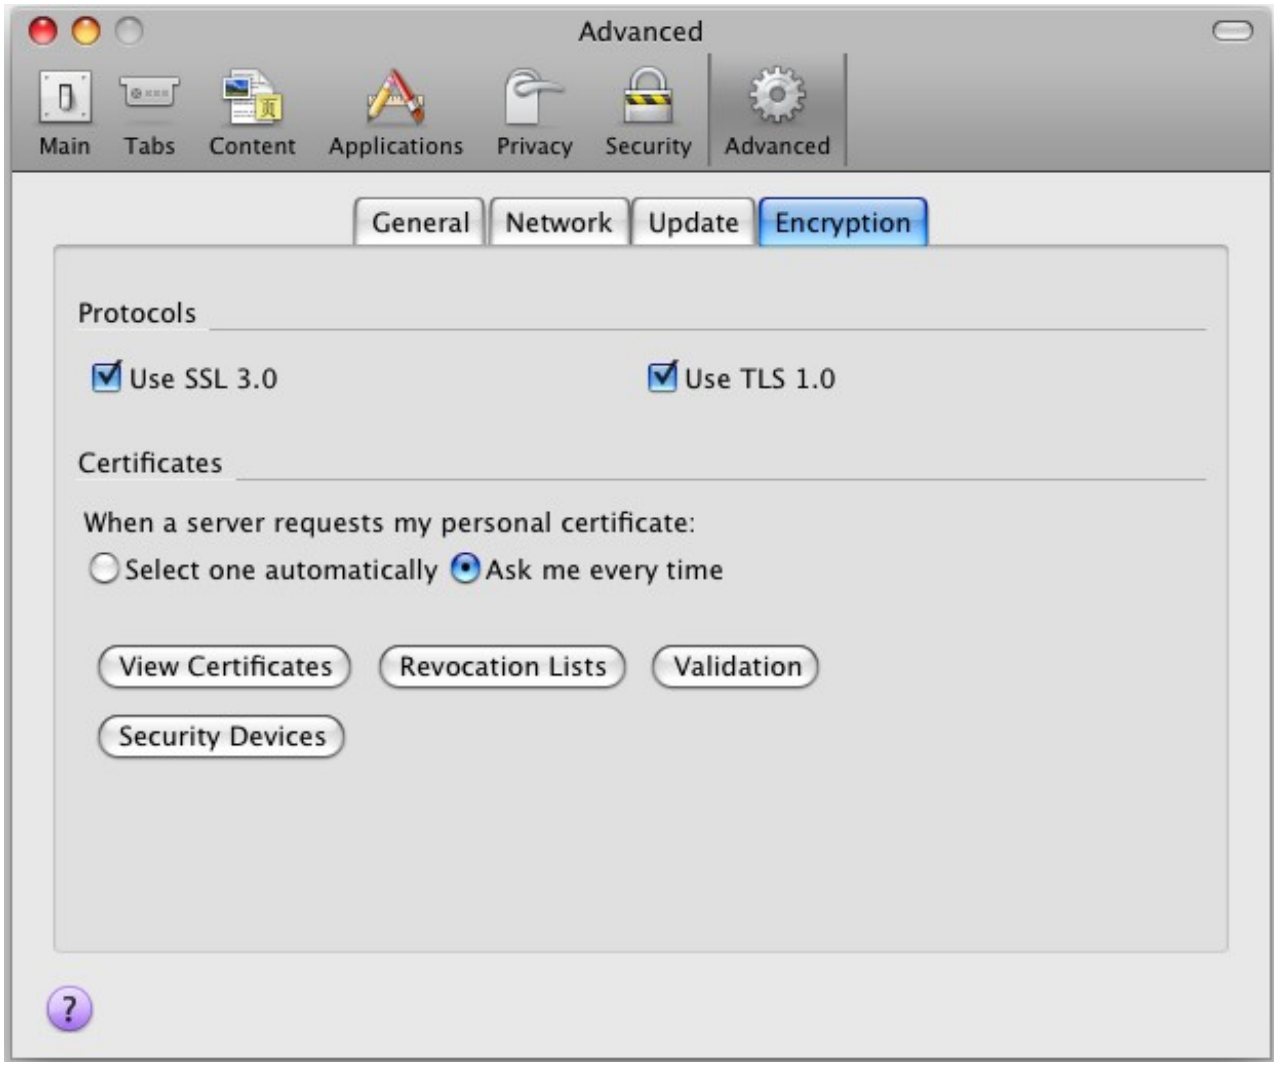
   For instance, if the CNAME of the host is virtuoso.example.com, and the ServerPort is 4321, the DefaultHost should be set to virtuoso.example.com:4321

   ```
   [URIQA]
   DynamicLocal = 1
   DefaultHost  = virtuoso.example.com:4321
   ```
3. Start the Virtuoso server, and look at the log file. Once HTTPS is up, you should see something like:

   ```
   HTTPS Using X509 Client CA ....
   HTTPS/X509 server online at 4443
   ```

17.3.3. Setting Up Firefox

1. **Figure 17.1. Setting Up Firefox**



2. Click the "Add exception" button and enter the address of the HTTPS server you've just configured, i.e., https://virtuoso.example.com:4443/
3. Click OK, and confirm the exception.

Figure 17.2. Setting Up Firefox

4. Click to the "Your Certificates" tab, and import mycert.p12.

17.3.4. Configuring ODS Account to use WebID Protocol

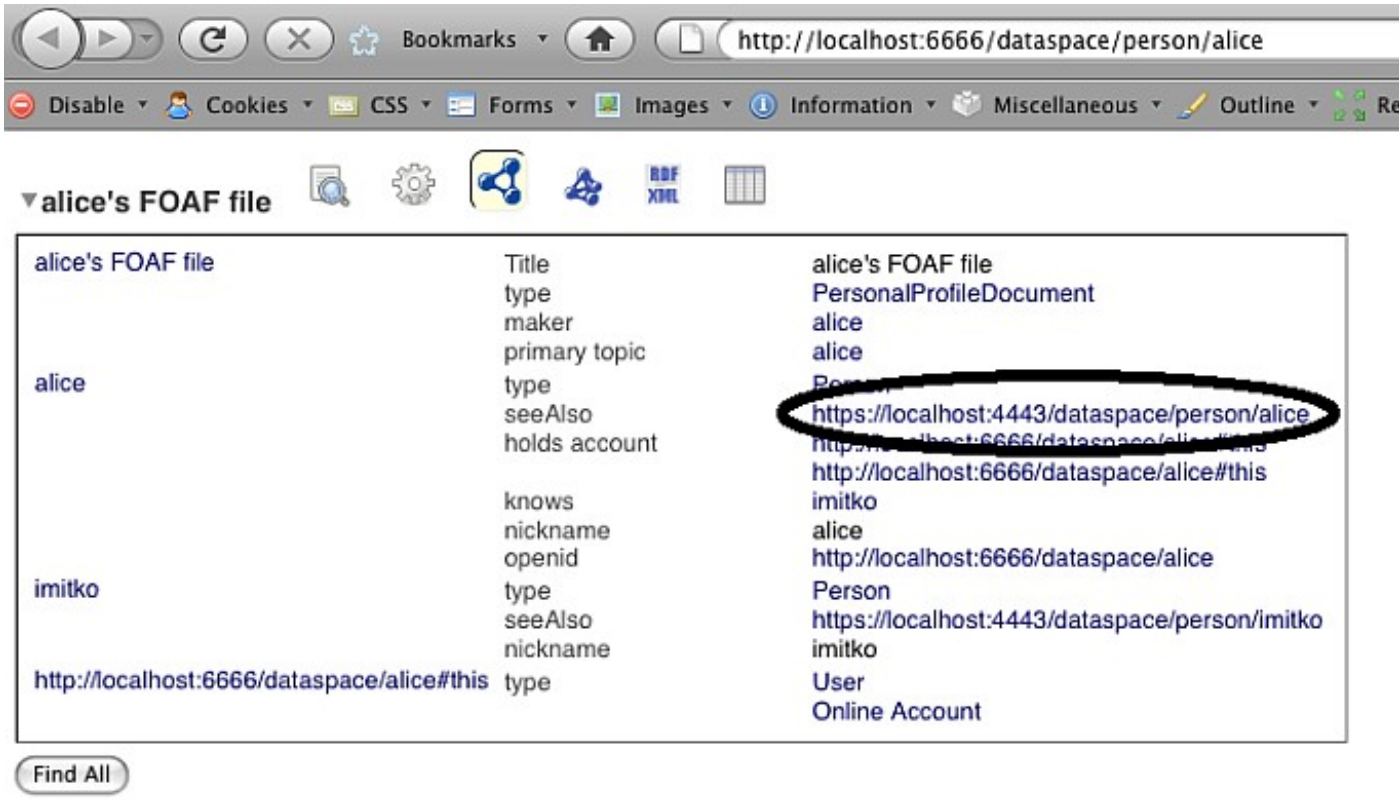
1. Log in to your ODS account, and edit your profile.
2. Click to the Security Tab, and scroll to the bottom, where you will find the X.509 certificate entry area.
3. Copy and paste the PEM format of the certificate (i.e., the content of mykey.pem, from earlier).
4. Press "Save Certificate" button, and you are set.

17.3.5. Testing the setup

To test, we recommend Firefox v3 with the Tabulator extension . Firefox must be set to ask for RDF, as instructed in the Tabulator documentation .

1. Enter an ODS user's URI in the address bar.
2. You should see a protected document's URI. Note that there is no specific "address" data seen:

Figure 17.3. Testing the setup

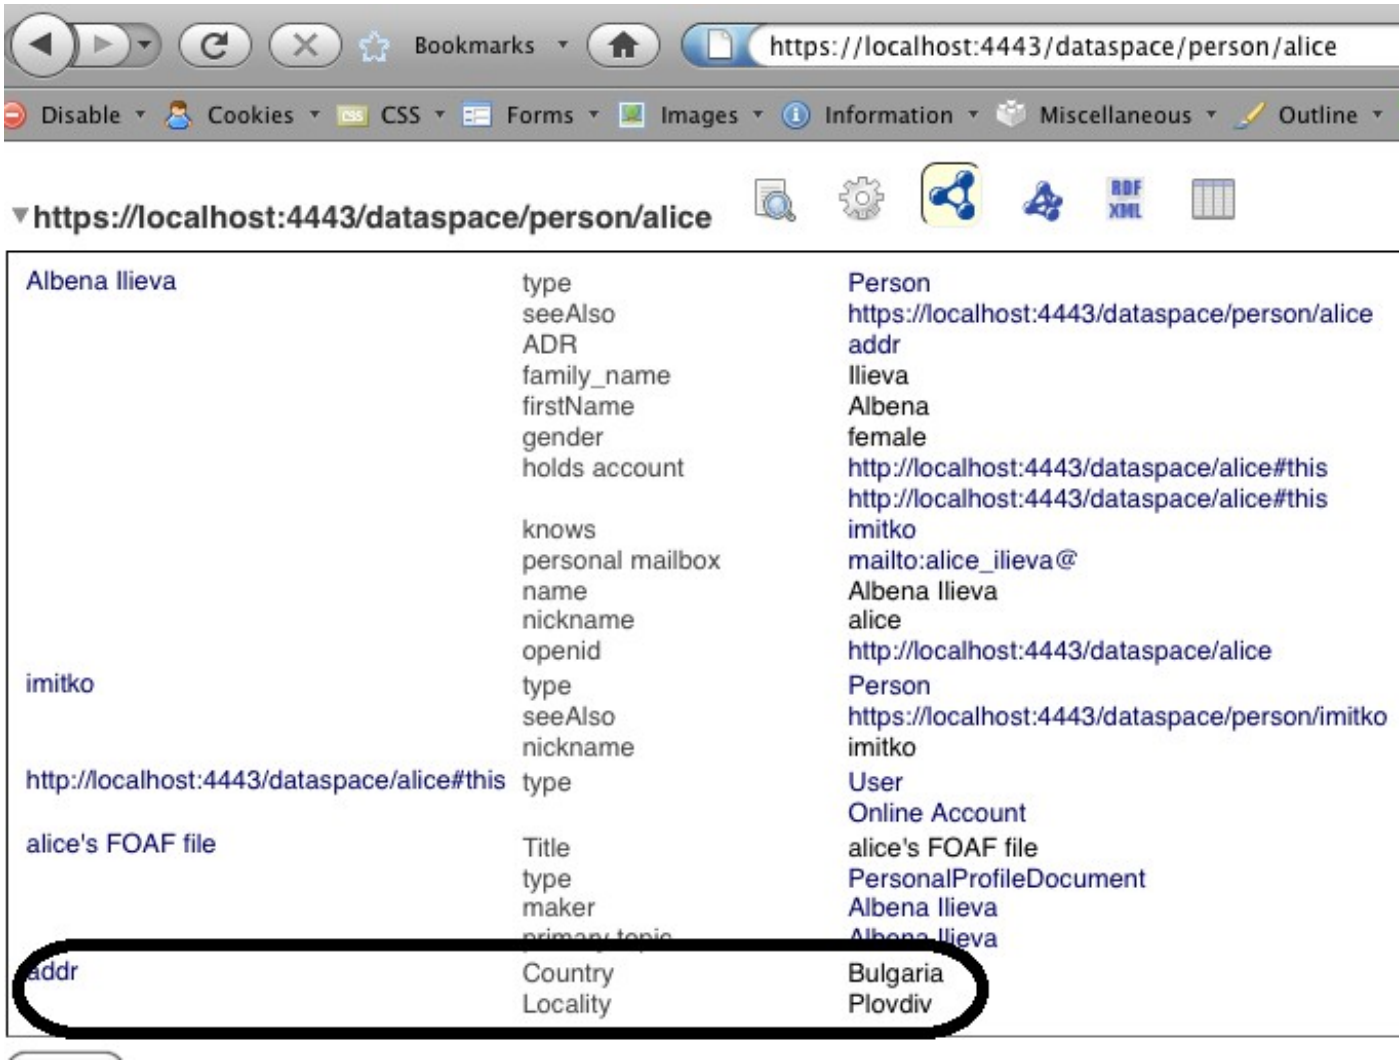


3. When clicked, the browser will ask the user to select a certificate (note: certificate details are erased in the picture below).

Figure 17.4. Testing the setup

4. Now the protected document includes the private address data alongside the previously visible public data!

Figure 17.5. Testing the setup



17.3.6. WebID Protocol ACLs

You can set WebID Protocol ACLs from the Virtuoso Authentication Server UI.

17.3.7. SPARQL-WebID based Endpoint

See details how to create and use a SPARQL-WebID based Endpoint .

17.3.8. CA Keys Import using Conductor

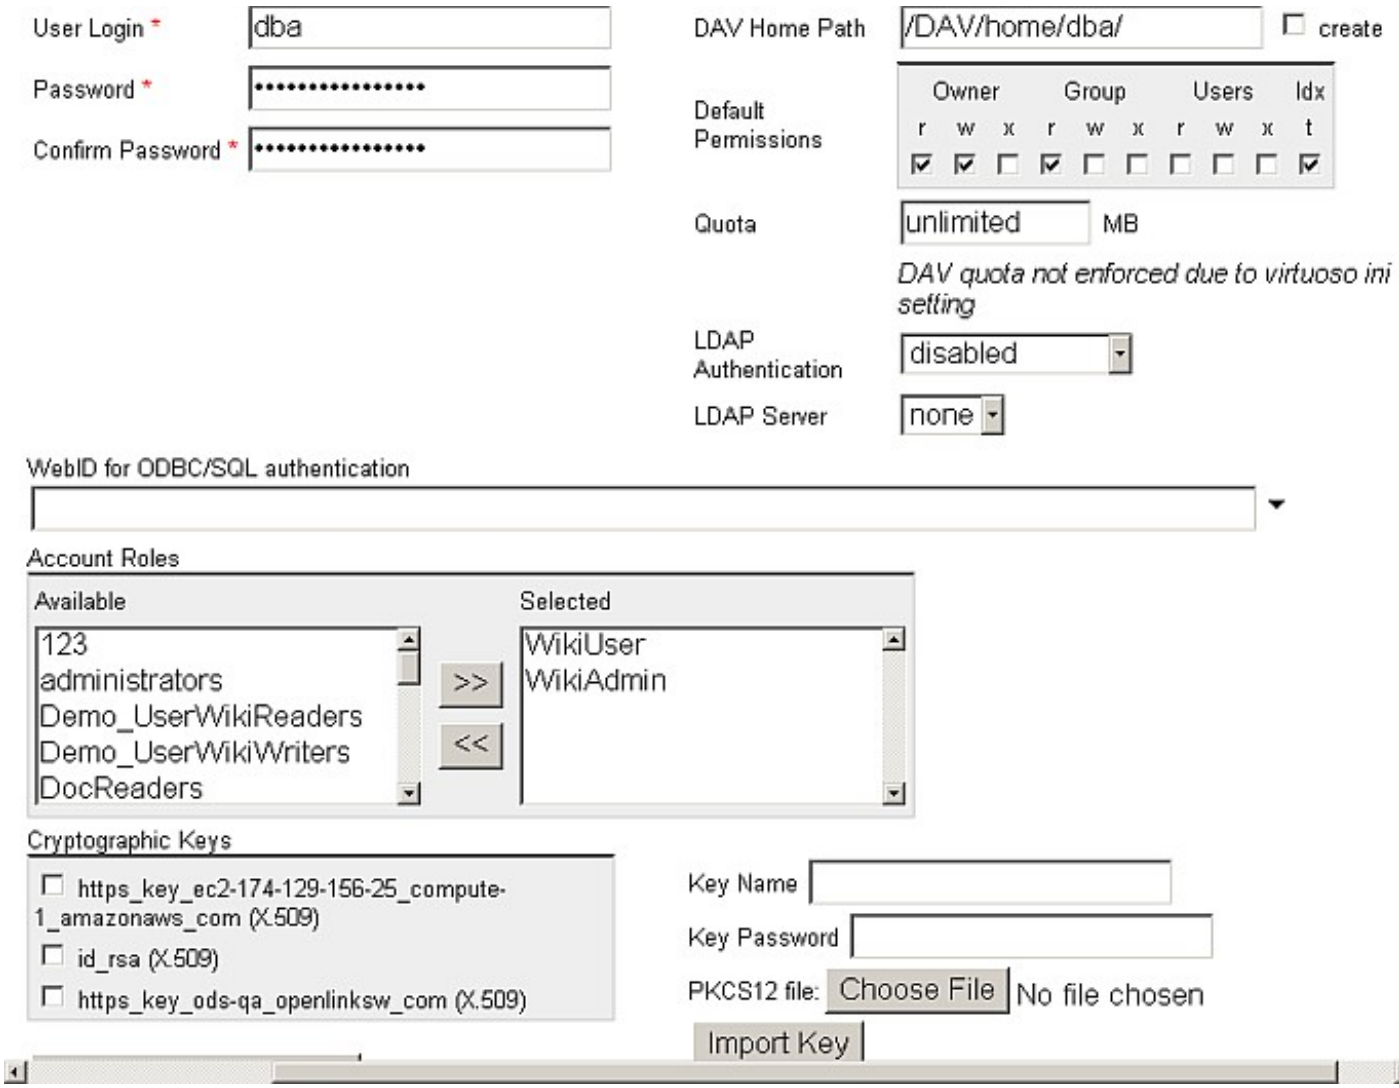
The Virtuoso Conductor allows easy import of user-level CA (Certificate Authority) Keys through System Admin -> User Accounts -> Edit.

The dba user (typically) or other users may need CA keys to execute different services.

For ODS, the dba user must import a certificate with primary key and with name id_rsa. The process takes the following steps:

1. A signing authority (e.g., RSA Labs) generates a site certificate.
2. The site certificate is used to generate certificates for ODS users.
3. The site certificate is imported with name id_rsa for user dba using the Conductor.

Figure 17.6. Conductor CA Keys Import



4. As a result, the ODS user certificates can be authenticated against the site certificate.

If there is a service that requires a different key, the Conductor can be used to import another certificate for the relevant user.

You can use a Key from a global signing authority or produce a self-signed key using the Virtuoso Conductor .

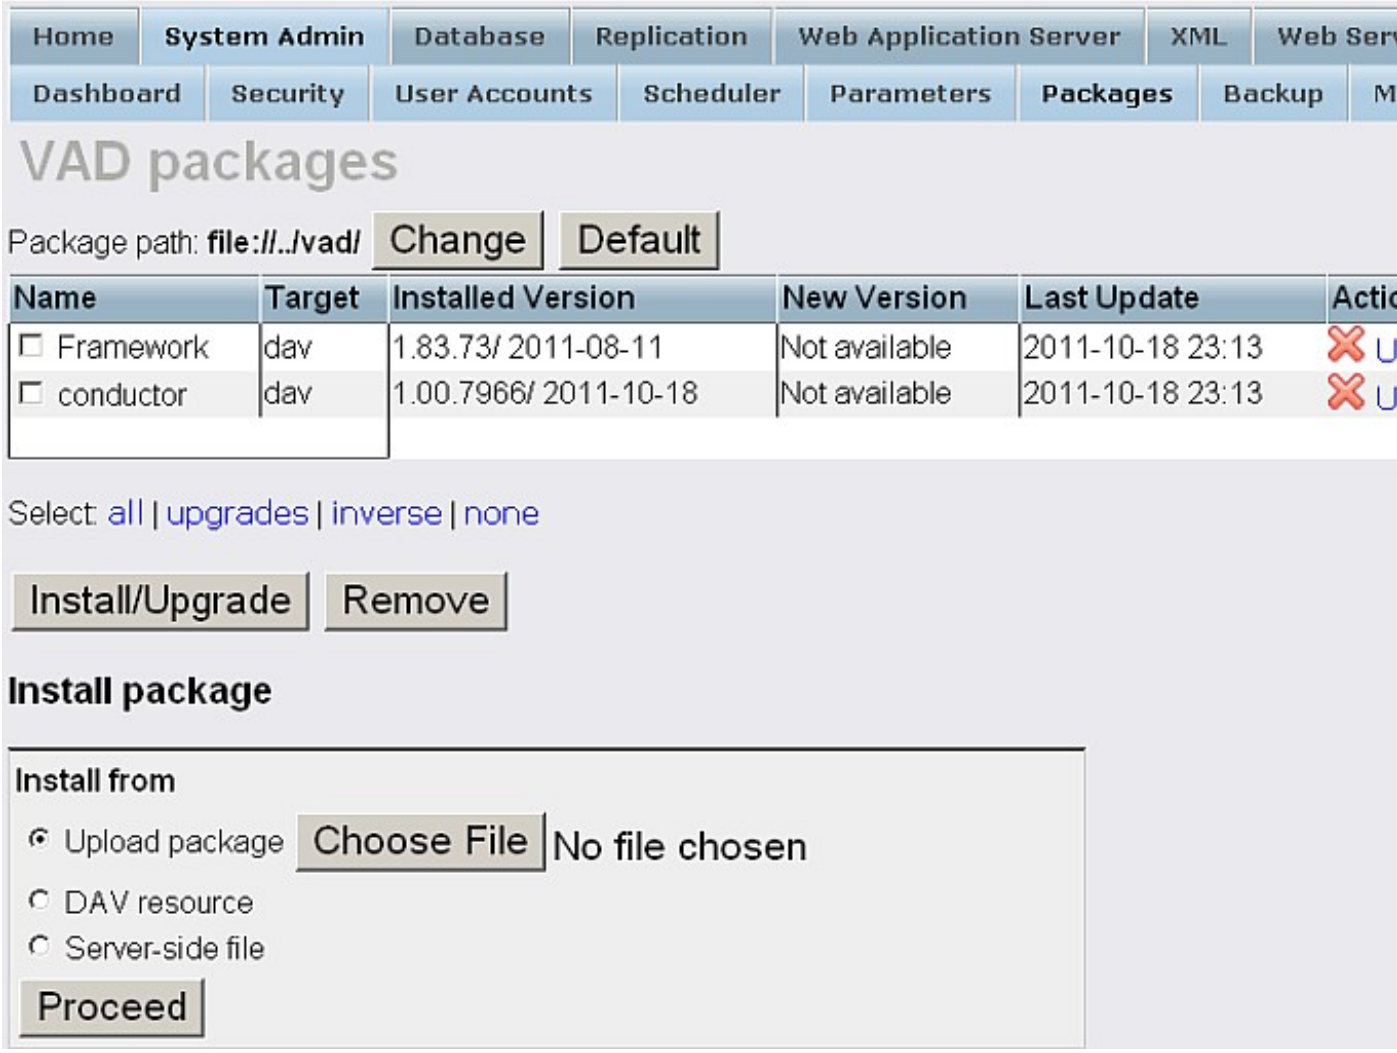
Details and more information how to generate the key see in the next section.

17.3.9. Set Up X.509 certificate issuer, HTTPS listener and generate ODS user's certificates

The following Step-by-Step guide walks you through set up of an X.509 certificate issuer and HTTPS listener, and generation of ODS user certificates.

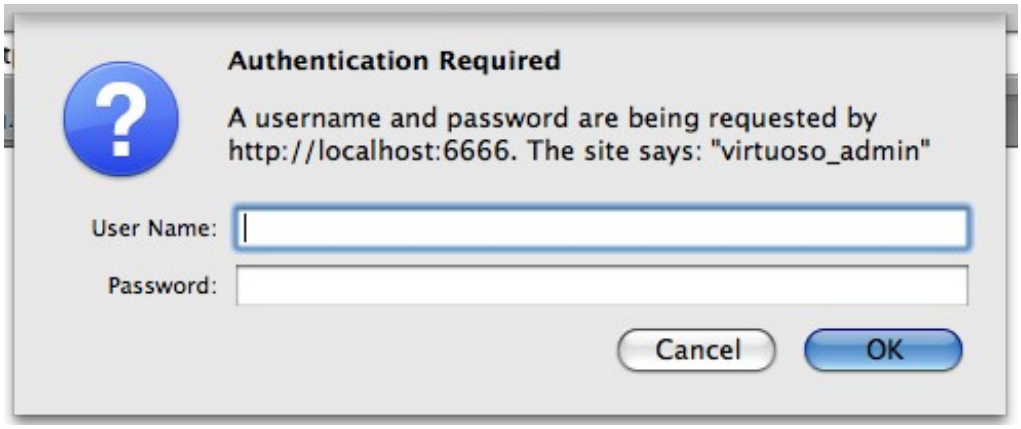
1. Install ODS and Virtuoso Conductor VAD packages.

Figure 17.7. Setting-Up issuer CA



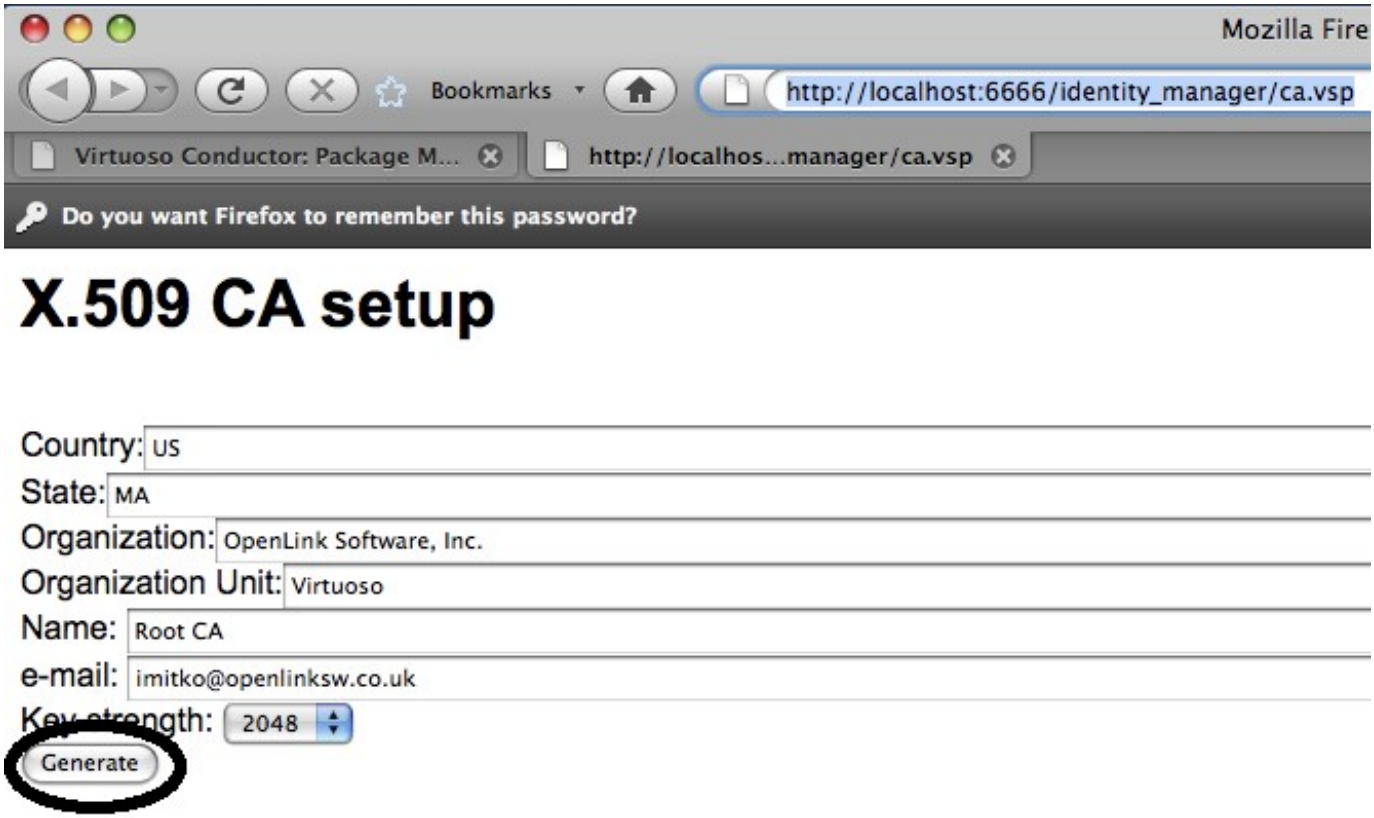
2. Go to the http://cname:port/identity_manager URL, enter the DBA user credentials in the dialog presented.

Figure 17.8. Setting-Up issuer CA



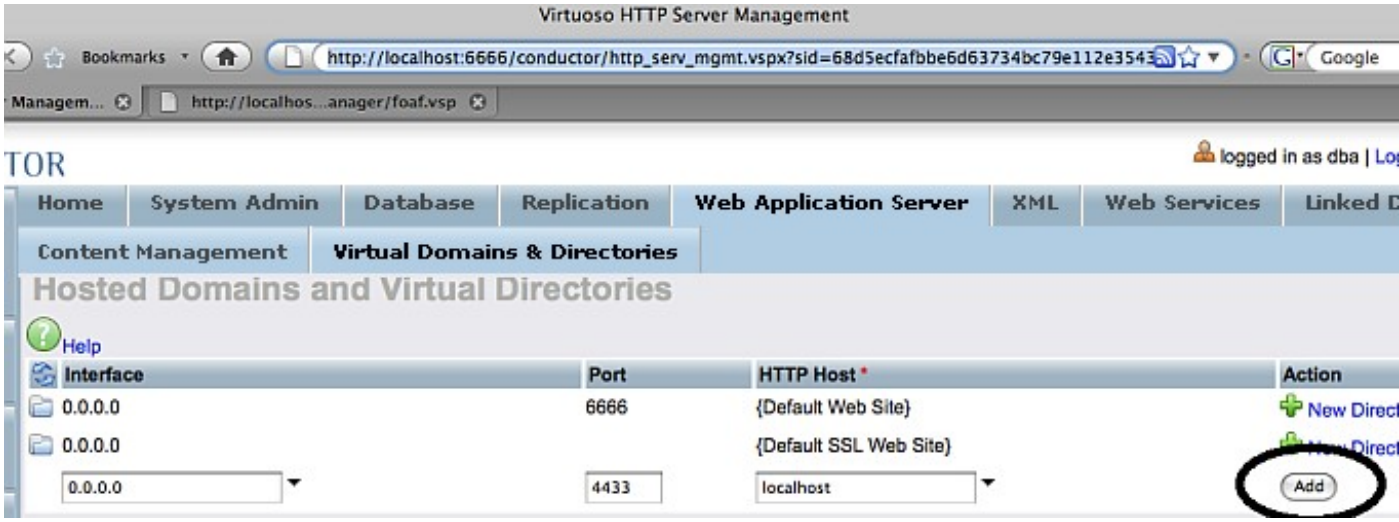
3. Enter the Issuer details and click generate.

Figure 17.9. Setting-Up issuer CA



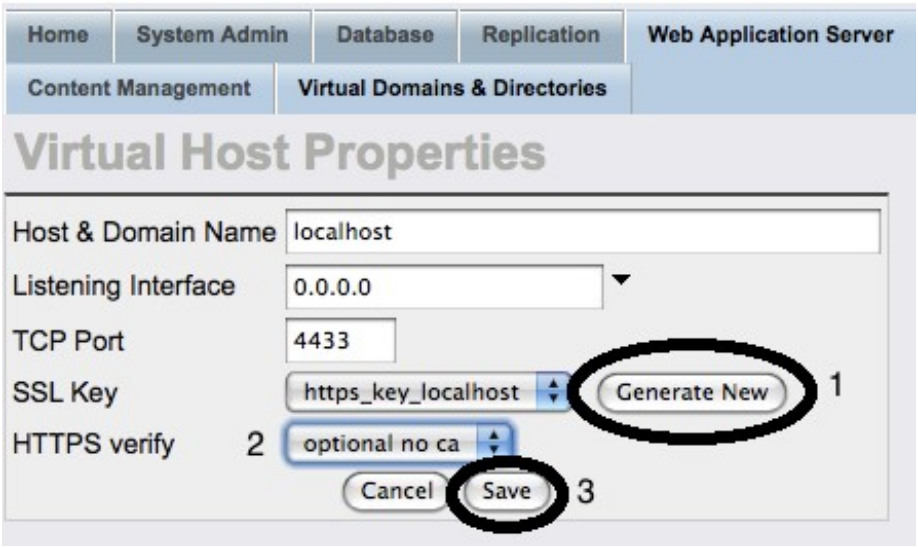
4. Go to Conductor -> Web Application Server -> Virtual Domains & Directories, and add a new listener.

Figure 17.10. Setting-Up issuer CA



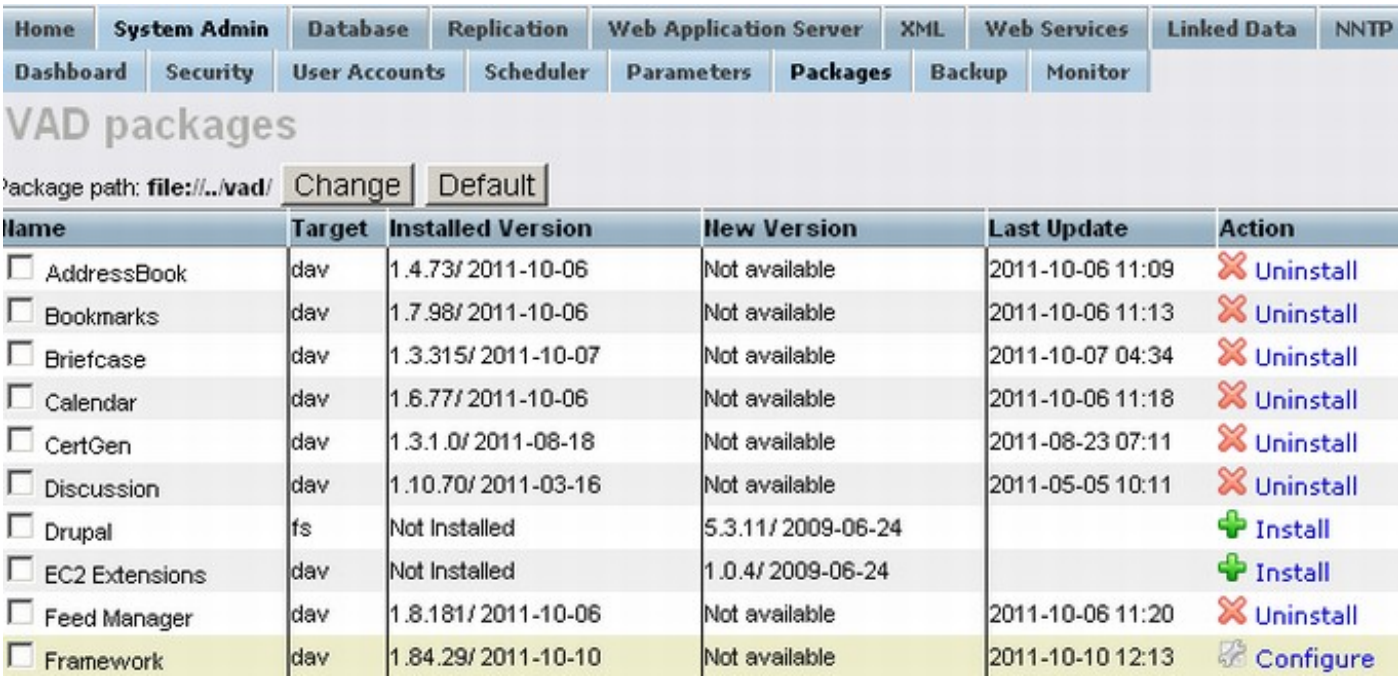
5. Edit the new listener, and generate new key.

Figure 17.11. Setting-Up issuer CA



6. Go to Packages list and select Configure for ODS Framework.

Figure 17.12. Setting-Up issuer CA

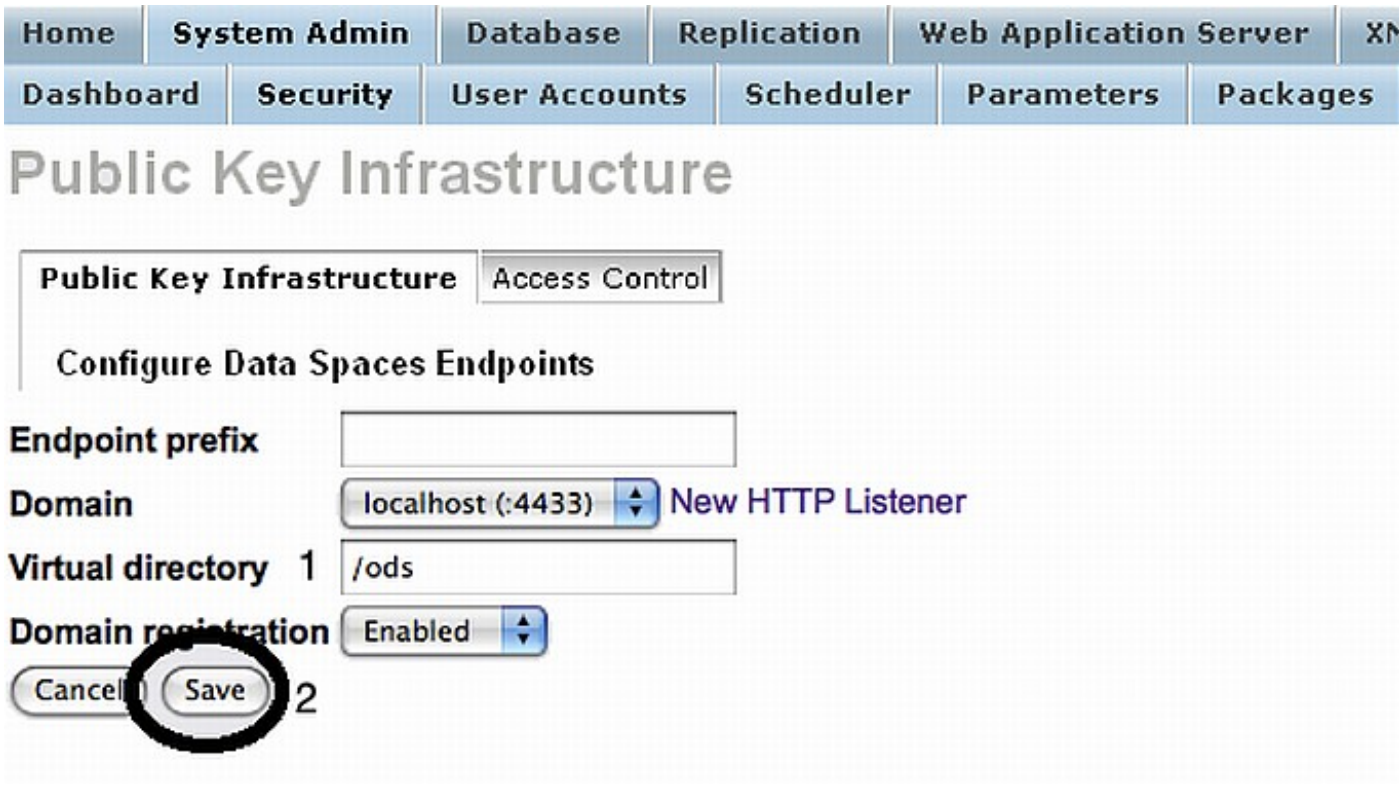


7. Select Create New Endpoint.

Figure 17.13. Setting-Up issuer CA

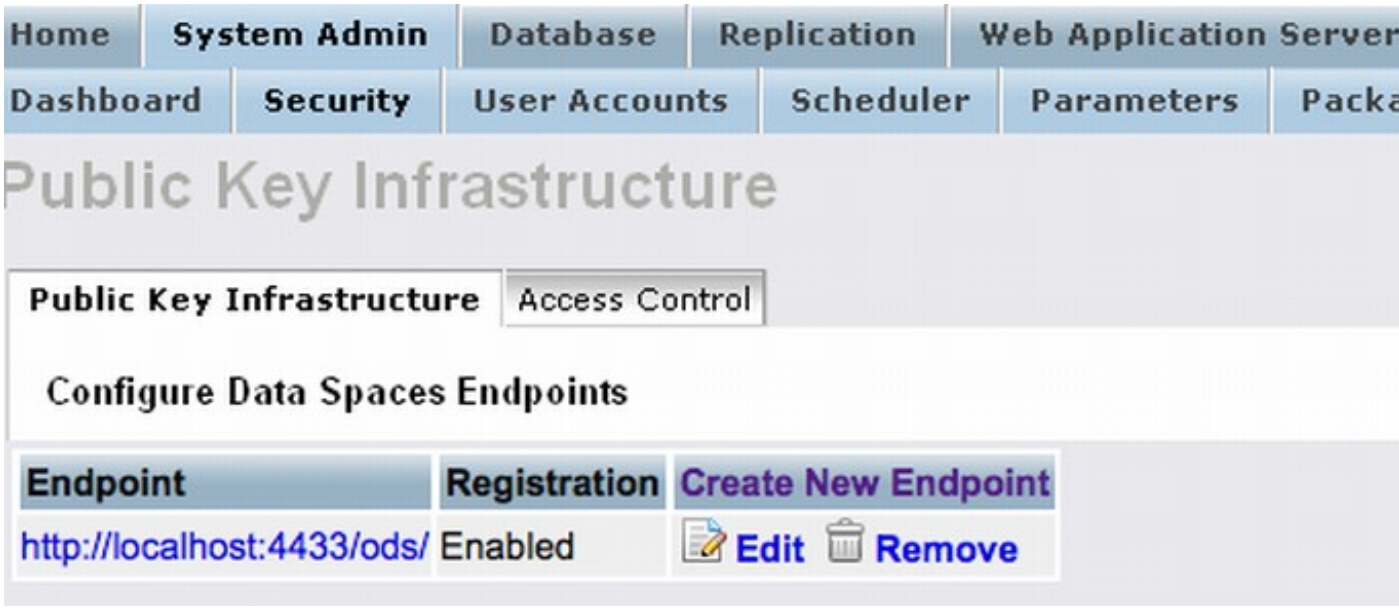
8. Enter the home path for ODS, and save.

Figure 17.14. Setting-Up issuer CA



9. The new endpoint should now appear in the endpoint list.

Figure 17.15. Setting-Up issuer CA

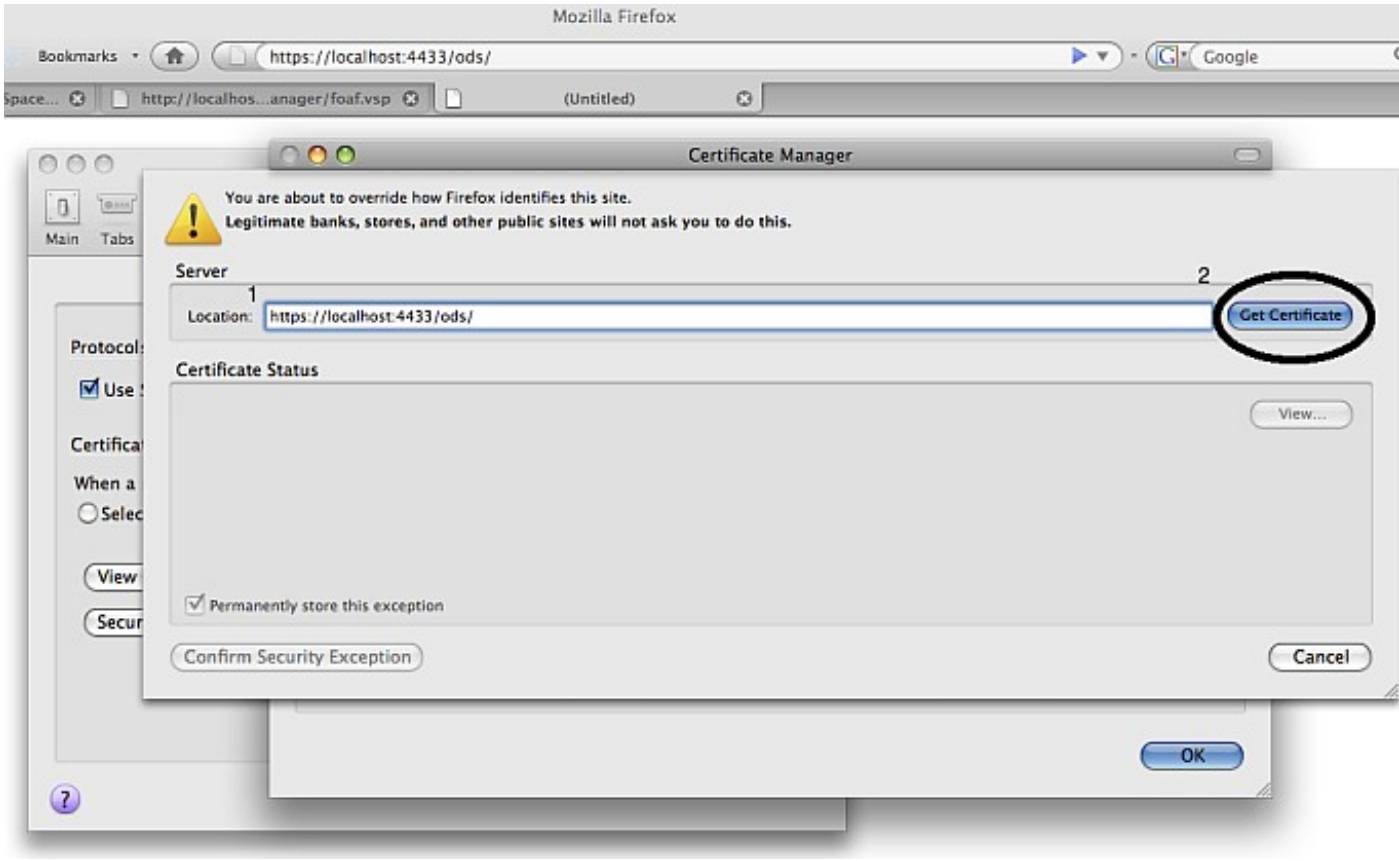


10. Go to the HTTPS site, e.g., https://cname:port/ods; in our example, https://localhost:4433/ods/. If Firefox is used, it will complain that the certificate is not valid, so we must register the site's certificate.

Figure 17.16. Setting-Up issuer CA

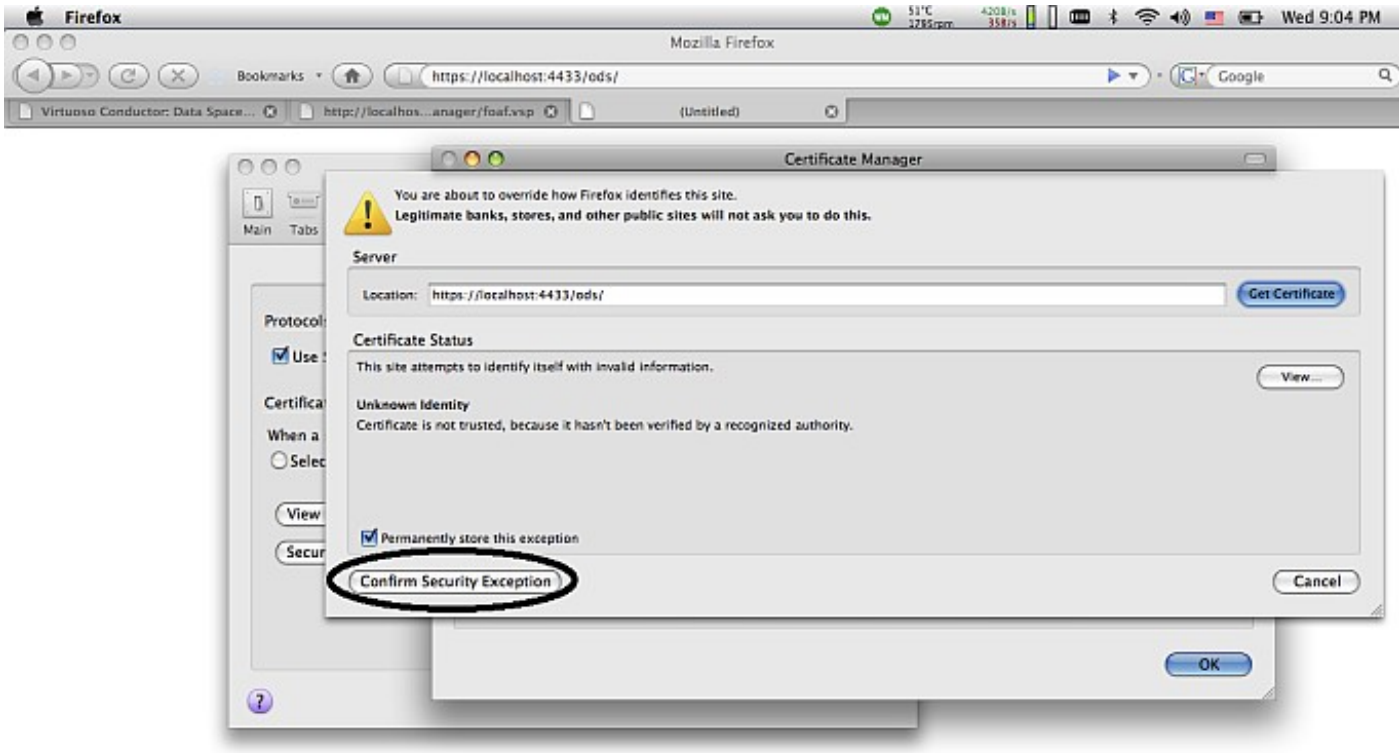
11. In Firefox certificate manager, in Site's certificates, add an exception.

Figure 17.17. Setting-Up issuer CA



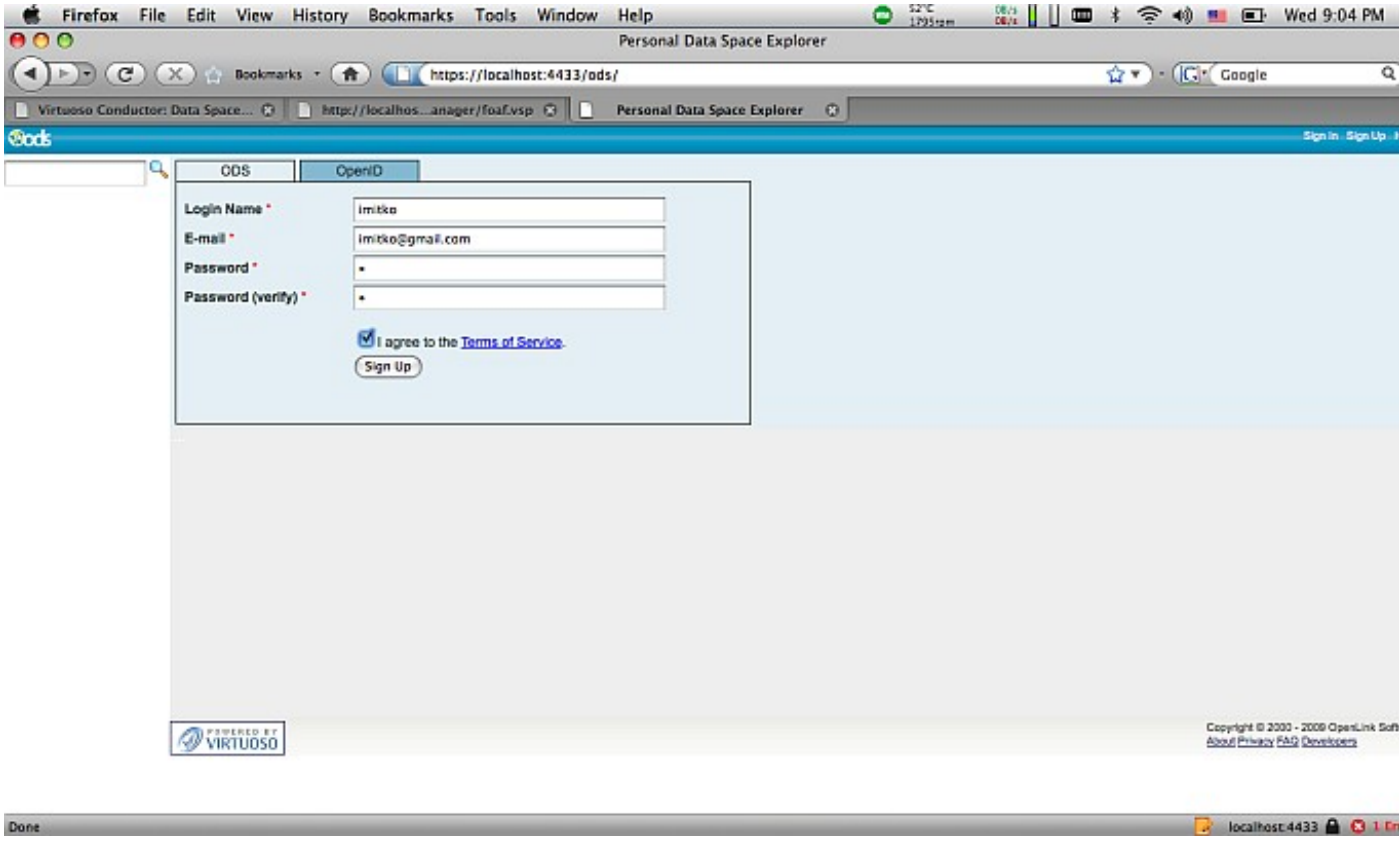
12. Confirm exception.

Figure 17.18. Setting-Up issuer CA



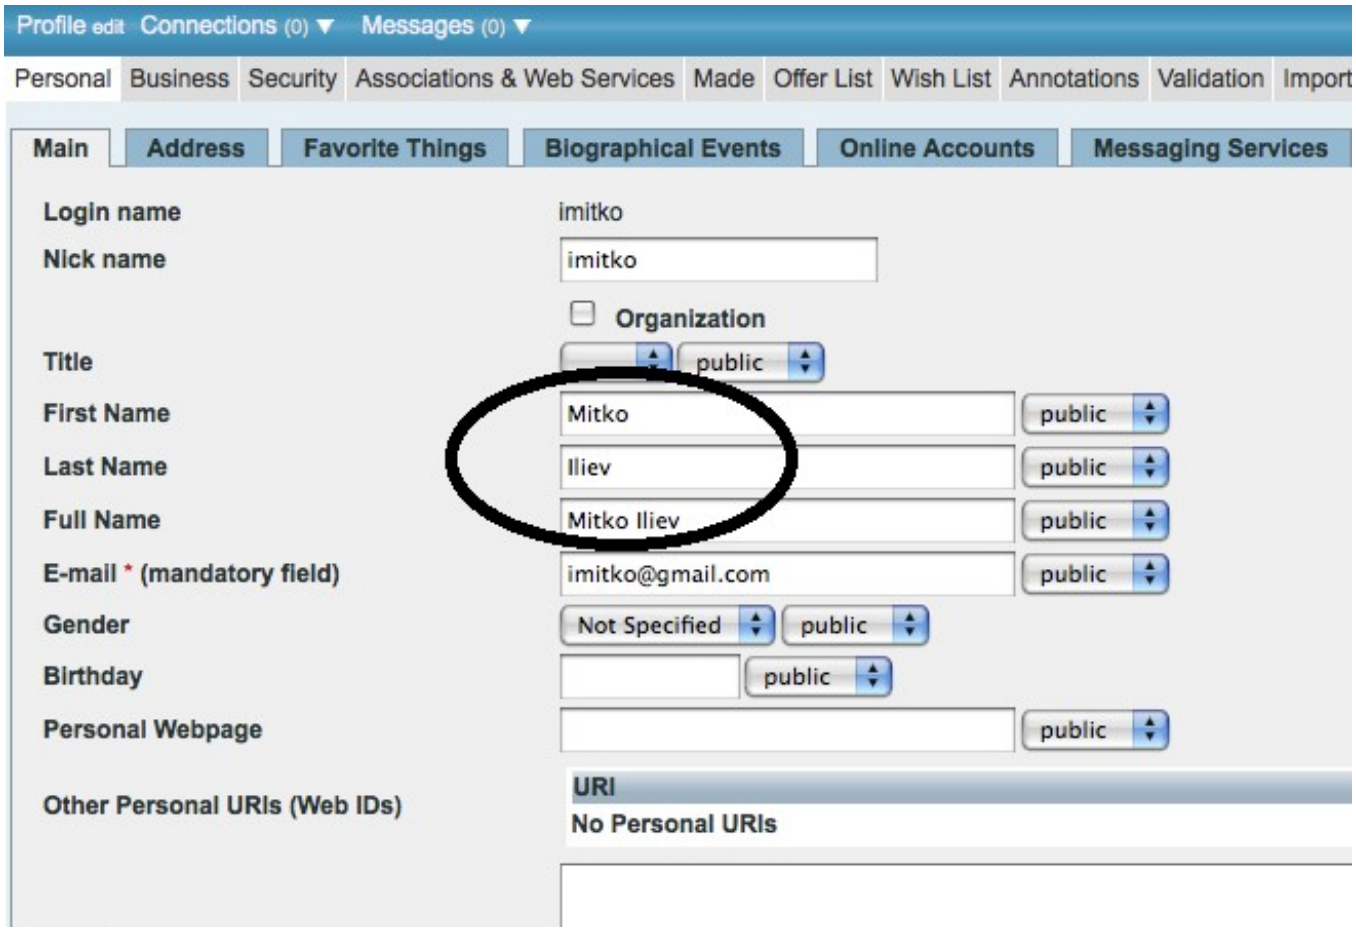
13. Return to ODS site, and register new user.

Figure 17.19. Setting-Up issuer CA



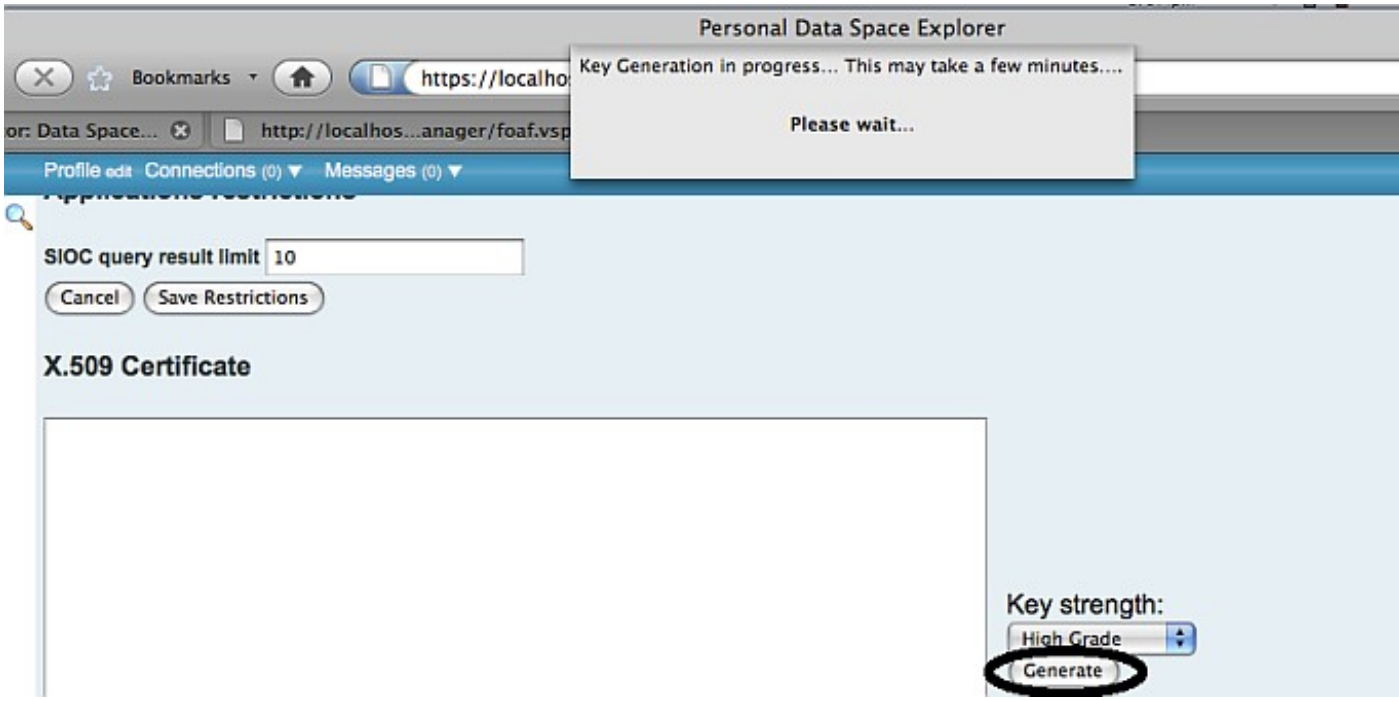
14. Edit the user's profile and enter his/her name(s). If this step is skipped, the certificate will not have a human readable name.

Figure 17.20. Setting-Up issuer CA



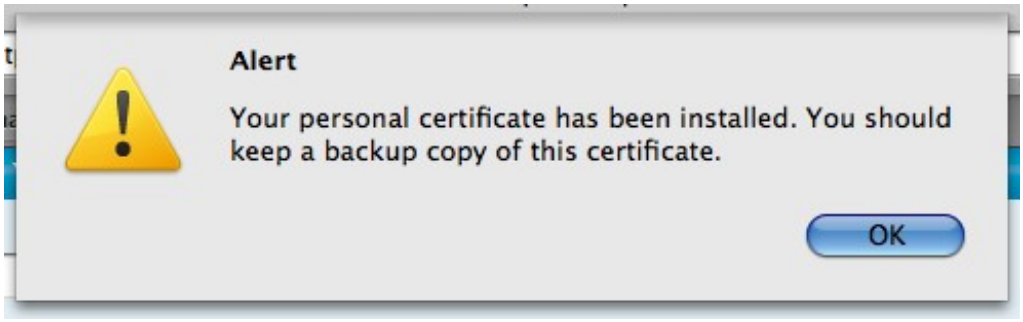
15. Open the Security tab in the Profile Editor, and generate the client key.

Figure 17.21. Setting-Up issuer CA



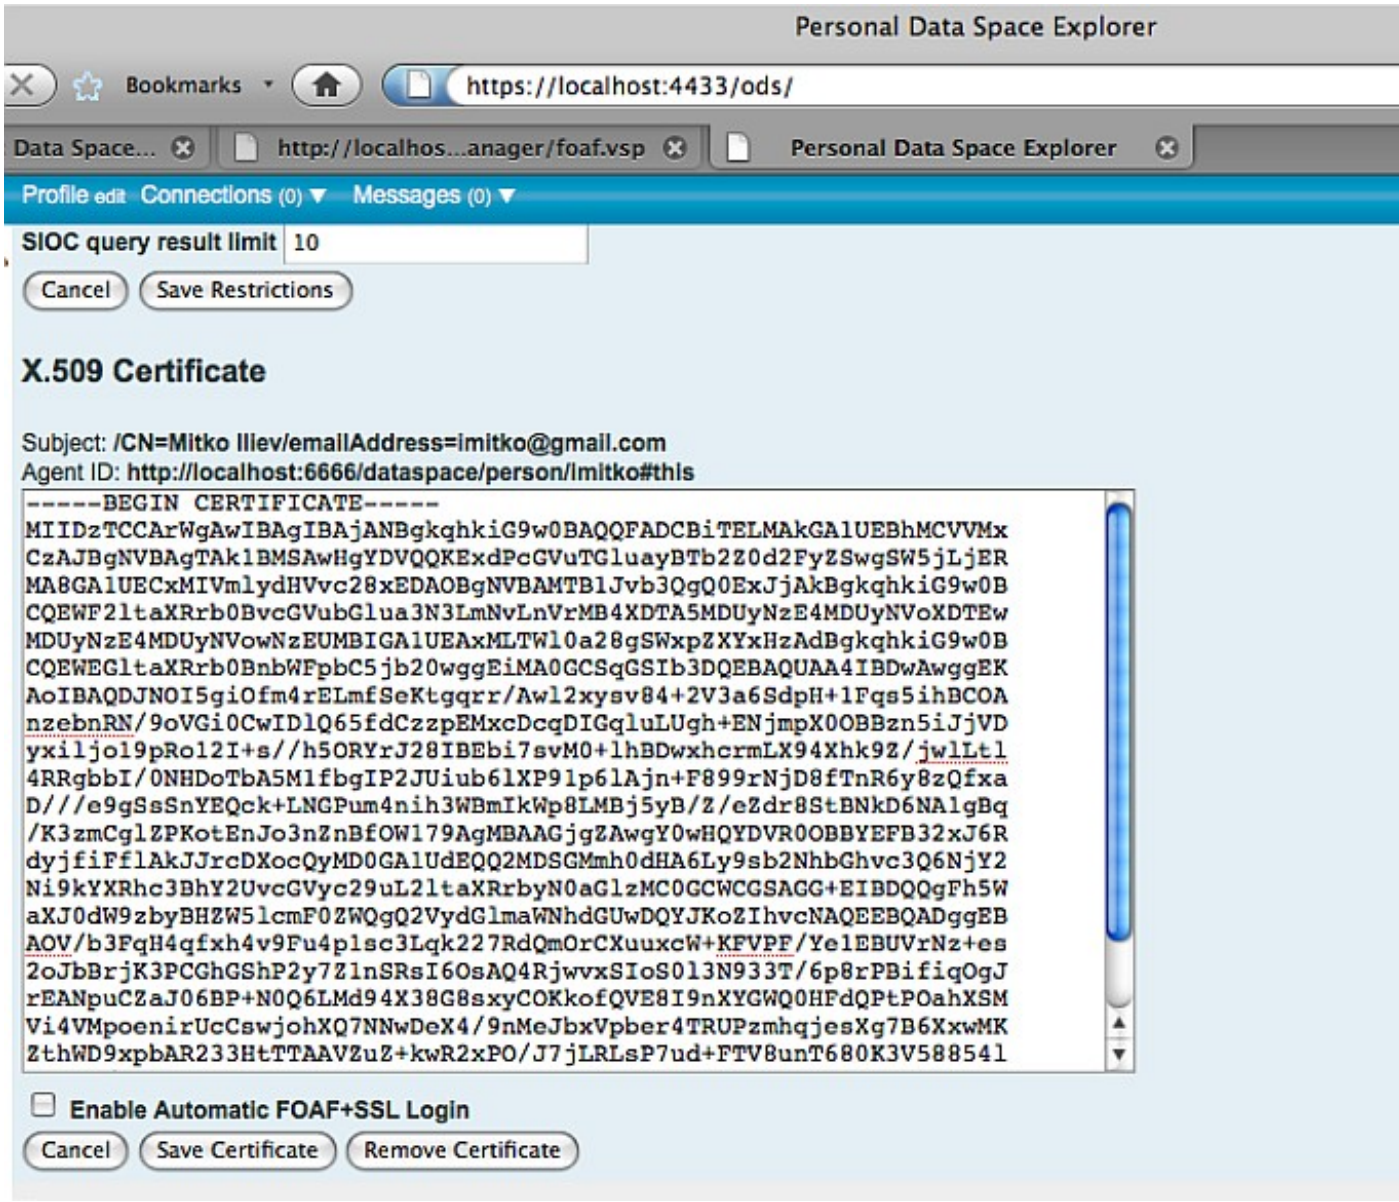
16. If all is set up correctly, you should see this message. It means Firefox has the private key, and has obtained a new certificate from the server.

Figure 17.22. Setting-Up issuer CA



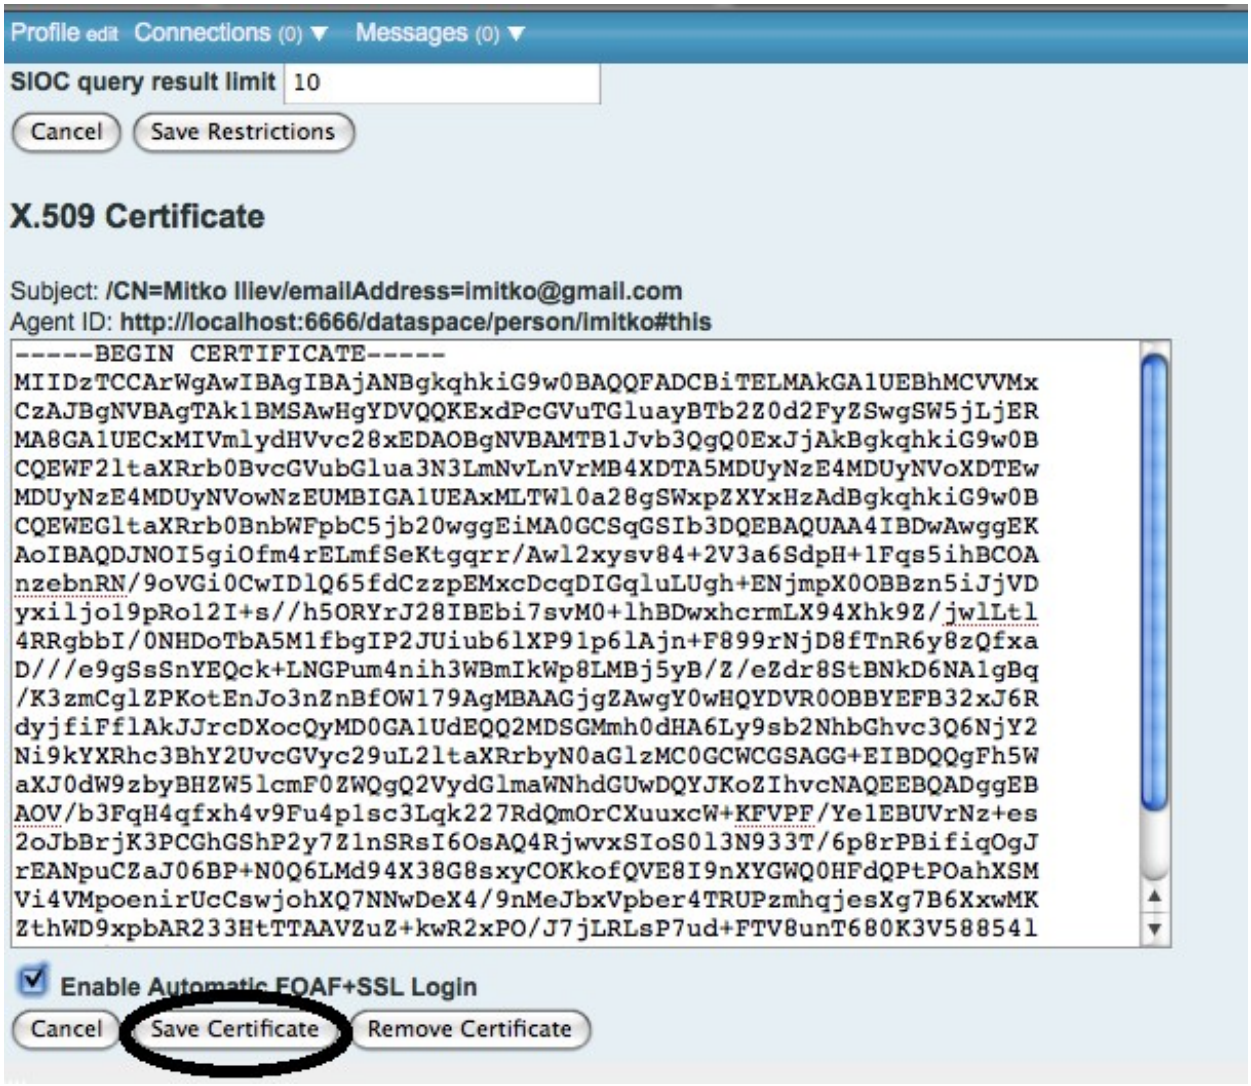
17. Refresh the Security tab by clicking on same tab.

Figure 17.23. Setting-Up issuer CA



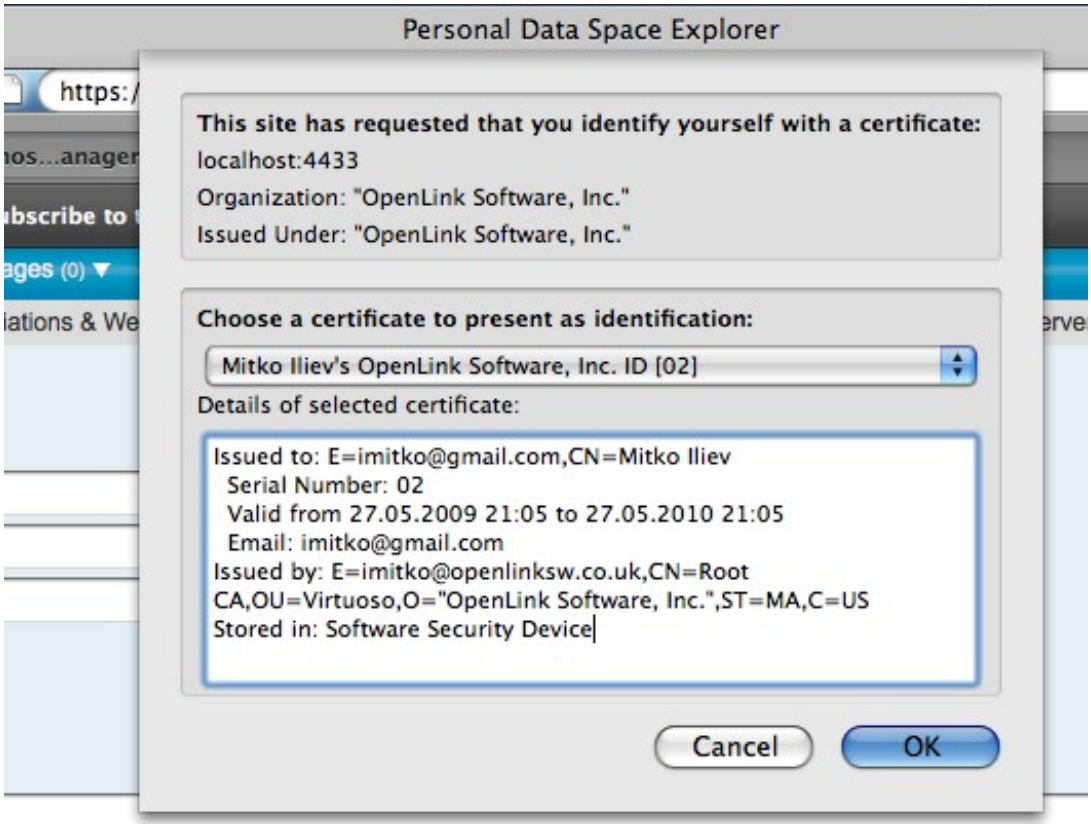
18. Select automatic login option, and save.

Figure 17.24. Setting-Up issuer CA



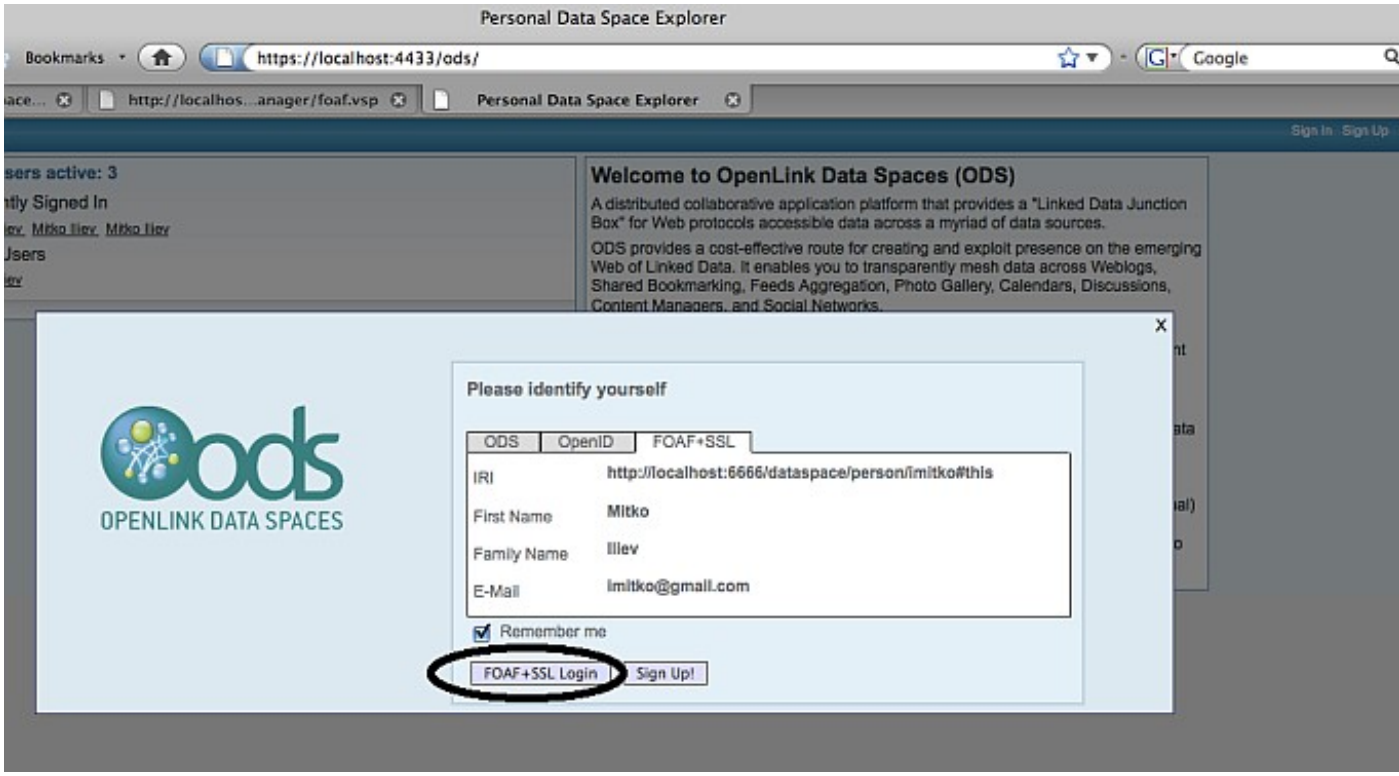
19. Log out from ODS and refresh browser to simulate opening the ODS site. The browser will ask for a certificate; select the one generated in the steps above.

Figure 17.25. Setting-Up issuer CA



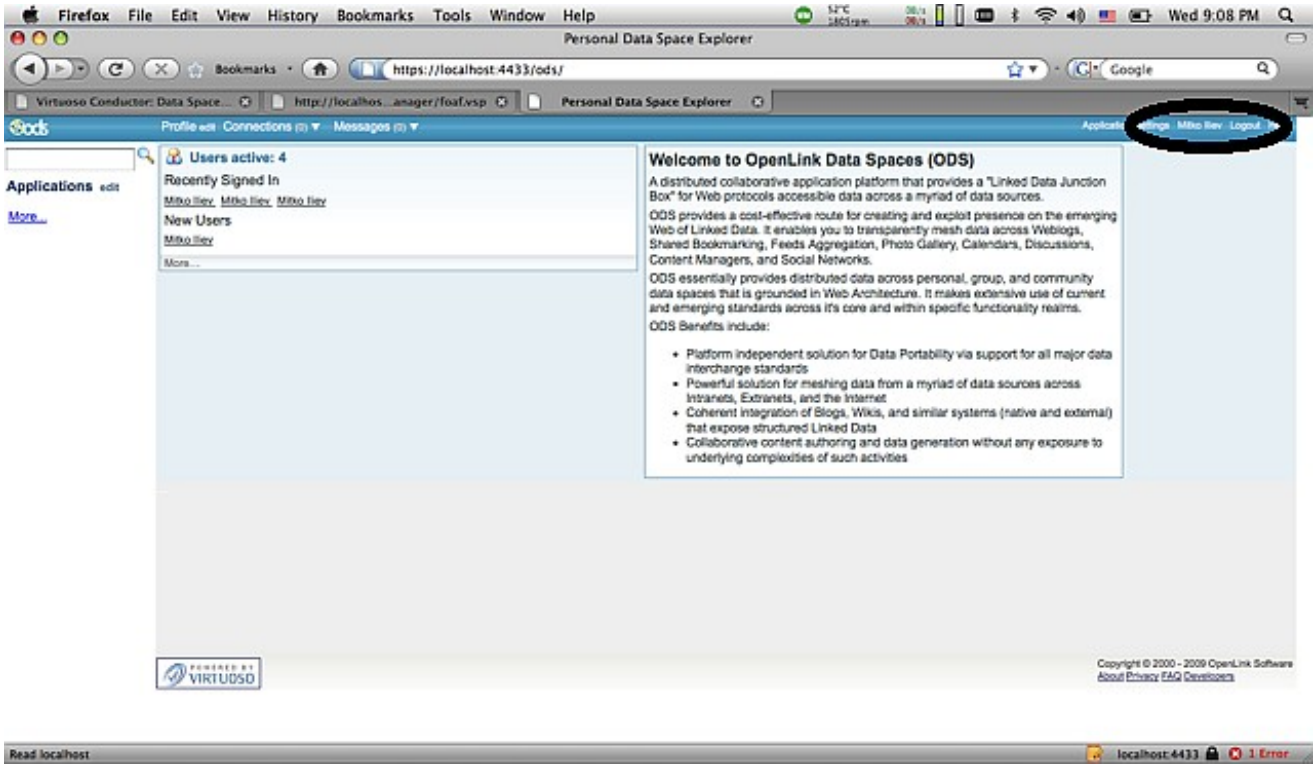
20. ODS presents your card, and asks to login with certificate. Confirm it.

Figure 17.26. Setting-Up issuer CA



21. You should now be logged in to ODS via WebID Protocol.

Figure 17.27. Setting-Up issuer CA



17.3.10. WebID Protocol ODBC Login

See details and examples here .

17.4. OAuth Support

The OAuth protocol enables websites or applications (Consumers) to access Protected Resources from Web services (Service Providers) via an API, without requiring Users to disclose their Service Provider credentials to those Consumers. More generally, OAuth creates a freely-implementable and generic methodology for API-oriented authentication.

For Consumer developers, OAuth is a method to publish and interact with protected data.

For Service Provider developers, OAuth gives users access to their data while protecting their account credentials.

One use case would be allowing a printing service, printer.example.com (the Consumer), to access private photos stored on photos.example.net (the Service Provider), without requiring Users to reveal their photos.example.net credentials to printer.example.com.

OAuth allows the user to selectively grant access to their private resources housed on one site (called the Service Provider), to another site (called the Consumer). In other words, OAuth enables you to grant access to some of your information without sharing all of your identity.

OAuth does not require a specific user interface or interaction pattern, nor does it specify how Service Providers authenticate Users, making the protocol ideally suited for cases where authentication credentials are unavailable to the Consumer, such as with OpenID.

OAuth aims to unify the experience and implementation of delegated web service authentication with a single, community-driven protocol. OAuth builds on existing protocols and best practices that have been independently implemented by various websites. An open standard, supported by large and small providers alike, promotes a consistent and trusted experience for both application developers and the users of those applications.

What is publicly known as "OAuth" is really the "OAuth Core 1.0" specification. The "Core" designation is used to stress that this is the skeleton upon which other extensions and protocols may be built. OAuth Core 1.0 does NOT by itself provide many desired features such as automated discovery of endpoints, language support, support for XML-RPC and SOAP, standard definition of resource access, OpenID integration, a full range of signing algorithms, or any number of other great ideas posted to the OAuth

group.

This was intentional and is viewed by the authors as a benefit. As the name implies, Core deals only with the most fundamental aspects of the protocol:

- Establish a mechanism for exchanging a username and password for a token with defined rights
- Provide tools to protect these tokens

More details can be found here .

17.4.1. OAuth Access Tokens

Credentials bearing tokens enable a user to provide their credentials in tokenized form in cases where HTTP redirection to a browser plus human interaction is unavailable or unsuitable. For example, intermediary intelligent agents, mobile phones, or set-top devices.

Request Authentication

To request an Access Token in this model, the Consumer makes an HTTP request to the Service Provider's Access Token URL. The authentication request contains [nine] parameters contained in the HTTP Authorization header or as URL parameters. Parameter names and values must be "percent-encoded" to handle characters in different character sets. The request should be performed using TLS, and should use HTTP POST.

Receive Authentication

Before granting an access token, the Service Provider must ensure that the request signature has been successfully verified as per OAuth, that a request with the supplied timestamp and nonce has never been received before, and that the supplied username and password match a User's credentials. If successful, the Service Provider generates an Access Token and Token Secret using a 200 Ok response and returns them in the HTTP response body.

Access Protected Resources

After successfully receiving the Access Token and Token Secret, the Consumer is able to access the Protected Resources on behalf of the User as per section 7 of the OAuth core specification. In other words, the Access Token obtained here is no different in capability to the Access Token specified by OAuth. Once authenticated using the above process, the Consumer will sign all subsequent requests for the User's Protected Resources using the returned Token Secret.

17.4.2. Virtuoso OAuth server

Virtuoso implements the OAuth Core 1.0 specification, and exposes the following API endpoints:

Request token

Endpoint:

```
http://server-cname/OAuth/request_token
```

Parameters:

- *oauth_consumer_key* : The Consumer Key.
- *oauth_signature_method* : The signature method the Consumer used to sign the request.
- *oauth_signature* . The signature as defined in Signing Requests (Signing Requests).
- *oauth_timestamp* : As defined in Nonce and Timestamp (Nonce and Timestamp).
- *oauth_nonce* : As defined in Nonce and Timestamp (Nonce and Timestamp).
- *oauth_version* : OPTIONAL. If present, value MUST be 1.0 .

Example

Request:

```
http://example.com/OAuth/request_token?oauth_version=1.0&oauth_nonce
```

```
=dad4cb071e2169cbcaa051d404ac61a3&oauth_timestamp=1201873644&oauth_cons
umer_key=f756023be5ff1f20881cf8fe398069f3976b2304&oauth_signature_metho
d=HMAC-SHA1&oauth_signature=z76k5fQ0msFsQzCmhO%2FJZ329ZUE%3D
```

Note: all long lines in example texts are split, i.e., the GET request is single line.

Response:

```
oauth_token=b4e22daa117b0bebf60ab6ba6e401edc7addd78c&oauth_token_secret
=4de6e3ab17553a0a385ebf6a3b4dd30f
```

Authorization

Endpoint:

```
http://server-cname/OAuth/authorize
```

Parameters:

- *oauth_token* : The Request Token obtained in the previous step. The current implementation of the Service Provider declare this parameter as REQUIRED.
- *oauth_callback* : OPTIONAL. The Consumer MAY specify a URL the Service Provider will use to redirect the User back to the Consumer when Obtaining User Authorization (Obtaining User Authorization) is complete.

Example

Request:

```
http://example.com/OAuth/authorize?oauth_token=b4e22daa117b0bebf60ab
6ba6e401edc7addd78c&oauth_callback=http%3A%2F%2Flocalhost%3A8890%2Foaut
h%2Fexample%2Fclient.php%3Fkey%3Df756023be5ff1f20881cf8fe398069f3976b23
04%26secret%3Dcc249bfb732039d8ecba9e4f94fdead7%26token%3Db4e22daa117b0b
ebf60ab6ba6e401edc7addd78c%26token_secret%3D4de6e3ab17553a0a385ebf6a3b4
dd30f%26endpoint%3Dhttp%253A%252F%252Flocalhost%253A8890%252FOAuth%252F
authorize
```

The User will be asked via web page to accept or decline the token.

Access token

Endpoint:

```
http://server-cname/OAuth/access_token
```

Parameters:

- *oauth_consumer_key* : The Consumer Key.
- *oauth_token* : The Request Token obtained previously.
- *oauth_signature_method* : The signature method the Consumer used to sign the request.
- *oauth_signature* : The signature as defined in Signing Requests (Signing Requests).
- *oauth_timestamp* : As defined in Nonce and Timestamp (Nonce and Timestamp).
- *oauth_nonce* : As defined in Nonce and Timestamp (Nonce and Timestamp).
- *oauth_version* : OPTIONAL. If present, value MUST be 1.0 .

Example

Request:

```
http://example.com/OAuth/access_token?oauth_version=1.0&oauth_nonce=
8ad75091a66bdd741472be42149c828e&oauth_timestamp=1201873800&oauth_consu
mer_key=f756023be5ff1f20881cf8fe398069f3976b2304&oauth_token=b4e22daa11
7b0bebf60ab6ba6e401edc7addd78c&oauth_signature_method=HMAC-SHA1&oauth_s
ignature=tCxy0Lod4%2Bp%2FCBPV7Ph7RrsHXe4%3D
```

Response:

```
oauth_token=8c03b3da93480ca4728cc1194d6d03962f3bb5bb&oauth_token_secret
=854fd29c00adcedff4fbeaeb96584911
```

In addtion to the endpoints it define a API for PL applications to check authentication:

Authentication verification

```
OAUTH.DBA.check_authentication (in params any, in lines any)
```

Parameters:

- *params* : an array of strings representing the HTTP parameters
- *lines* : an array of HTTP request headers

Result:

- on success it returns integer 1,
- on failure it signal an SQL error.

Sample code:

A sample service (oauth.vsp):

```
<html>
<body>
<?vsp
  OAUTH..check_authentication (params, lines);
?>
An OAuth testing page
</body>
</html>
```

Sample request:

```
http://example.com/admin/oauth.vsp?oauth_version=1.0&oauth_nonce=d57
640869b994b2d51bf9800229c4997&oauth_timestamp=1201873935&oauth_consumer
_key=f756023be5ff1f20881cf8fe398069f3976b2304&oauth_token=8c03b3da93480
ca4728cc1194d6d03962f3bb5bb&oauth_signature_method=HMAC-SHA1&oauth_sign
ature=X3K4lr9bJVz5YLnnyJDkykQZivY%3D
```

Sample request:

```
http://example.com/admin/oauth.vsp?oauth_version=1.0&oauth_nonce=d57
640869b994b2d51bf9800229c4997&oauth_timestamp=1201873935&oauth_consumer
_key=f756023be5ff1f20881cf8fe398069f3976b2304&oauth_token=8c03b3da93480
ca4728cc1194d6d03962f3bb5bb&oauth_signature_method=HMAC-SHA1&oauth_sign
ature=X3K4lr9bJVz5YLnnyJDkykQZivY%3D
```

Sample response:

```
<html>
<body>
An OAuth testing page
</body>
</html>
```

17.4.3. OAuth Implementation in OpenLink Data Spaces

OAuth tokens must be generated for each user account, for each ODS application, via ODS -> Settings -> OAuth Keys. This UI provides a list of all applications to which the logged-in user has access, i.e., of which the user is a member or owner. To enable access with OAuth, the user simply selects the desired application instance from the list, and clicks the 'generate keys' button. The generated Consumer Key and Secret will be associated with the given ODS user account & application instance.

Once a consumer token is available, the sequence below must be executed in order to establish an authorized session:

1. client uses request_token to get a token/secret pair for establishing session using consumer token

2. client asks OAuth server to authorize the token from step 1.
3. using authorized token from step 1 client asks OAuth server for authentication token.
4. with authentication token from step 3, clients can access instance data associated with the consumer token from step 1.

Sample OAuth Client

To demonstrate the Virtuoso implementation of OAuth, we have written this sample client, in Virtuoso/PL.

```
<html>
<?vsp
    declare consumer_key, consumer_secret, oauth_token, oauth_secret, signature, timest, nonce varchar;
    declare srv, res, signature_base, ret_url, url, tmp, sid varchar;
    declare meth, pars any;
    consumer_key := {?'key'};
    srv := sprintf ('http://example.com:%s/OAuth/', server_http_port ());
    sid := null;
    res := '';

    sid :=  {?'sid'};
    if (sid = '')
      sid := null;
    else
      {
        -- if selected token is not same as one from the session we need to get new authentication token
        if (consumer_key <> OAUTH..get_consumer_key (sid))
      {
        OAUTH..session_terminate (sid);
            sid := null;
      }
      }

    meth := get_keyword ('meth', params, 'weblog.post.new');;
    pars := get_keyword ('pars', params, 'inst_id=15&title=testing&description=Some test post');;

    if ({?'rt'} is not null and sid is null) -- request new token for the session
      {
    url := srv||'request_token';
    url := OAUTH..sign_request ('GET', url, '', consumer_key, sid);
        res := http_get (url);
    sid := OAUTH..parse_response (sid, consumer_key, res);
    OAUTH..set_session_data (sid, params);
    ret_url := sprintf ('http://example.com:%s/oauth/oauth_client.vsp?ready=%U', server_http_port (), sid
    -- call authorize
        url := sprintf ('%sauthorize?oauth_token=%U&oauth_callback=%U', srv, OAUTH..get_auth_token (sid),
    http_status_set (301);
        http_header (sprintf ('Location: %s\r\n', url));
        return;
      }
    else if ({?'ready'} is not null) -- get access token
      {
    -- we go here when token above is authorized
        sid := {?'ready'};
    url := srv||'access_token';
    consumer_key := OAUTH..get_consumer_key (sid);
    url := OAUTH..sign_request ('GET', url, '', consumer_key, sid);
        res := http_get (url);
    sid := OAUTH..parse_response (sid, consumer_key, res);

      }
    if (sid is not null) -- access token is ready, and we can call API
      {
        -- here we are ready to call service
    if ({?'rt'} is null)
          {
            tmp := OAUTH..get_session_data (sid);
            pars := get_keyword ('pars', tmp, pars);
        meth := get_keyword ('meth', tmp, meth);
      }
    url := sprintf ('http://example.com:%s/ods/api/%s', server_http_port (), meth);
    tmp := split_and_decode (pars);
    params := '';
    for (declare i,l int, l:=length (tmp); i < l; i := i + 2)
```

```
        {
          params := params || sprintf ('%U=%U&', tmp[i], tmp[i+1]);
        }
      --params := sprintf ('inst_id=%d&description=%U&title=%U', 15, 'Some test post', 'testing');
      consumer_key := OAUTH..get_consumer_key (sid);
      url := OAUTH..sign_request ('GET', url, params, consumer_key, sid);
          res := http_get (url);
          --dbg_obj_print (res);
      }
?>
      <head><title>OAuth Client</title></head>
      <body>
      <h1>OAuth client for ODS Controllers</h1>

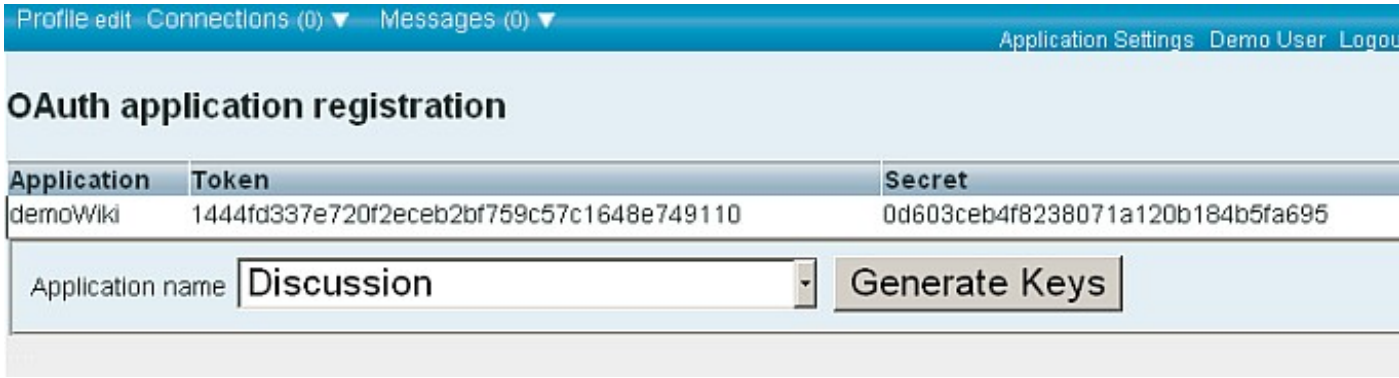
17.4.4. OAuth Generate Keys for ODS Controllers (Web Services)

The following steps describe how to Setup Application OAuth keys in ODS:

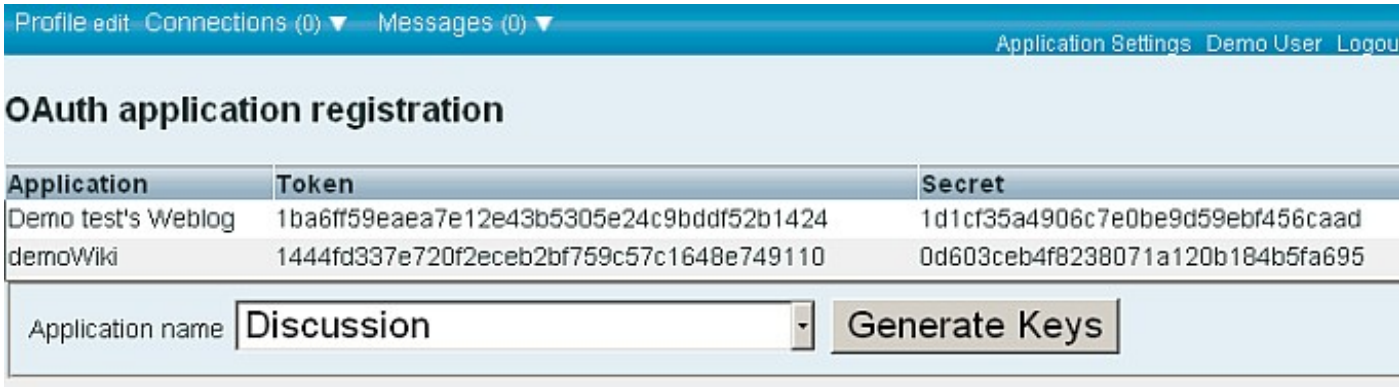
1. Login as user at ODS Data Space.
2. Go to Settings -> OAuth keys

Figure 17.28. OAuth Generate Keys



3. Select Application name from the drop-down list and click the "Generate Keys" button.
4. The generated Token and Secret values for the selected application will be shown as a result.

Figure 17.29. OAuth Generate Keys



17.4.5. ODS Ubiquity Commands

ODS provides Ubiquity commands to manipulate user accounts as well as instances and instance specific data using the ODS Controllers API. This command set is available only for the Firefox browser with the Ubiquity extension installed.

Installation

First, the Ubiquity Firefox extension must be installed. Then, ODS Ubiquity commands can be installed by accessing http://host:port/ods/ods_ubiquity.html page. Ubiquity commands are accessed by the ctrl-space key combination.

Basic Session Setup Commands

ODS OAuth Endpoint Identification

Assuming the OAuth endpoint: http://myopenlink.net/OAuth, in order to change it use the command:

```
Syntax: ods-oauth-host <host_url>
Example: ods-oauth-host http://demo.openlinksw.com/OAuth
```

ODS Command Mode

There are two command modes available to ubiquity commands when working against an ODS instance: oauth or sid.

In OAuth mode, for every ODS application instance, an OAuth key must be obtained and then initialized via the following steps:

- obtain an ODS based OAuth session-key via the ODS example endpoint: http://host:port/ods/oauth_sid.vsp

  ```
  http://myopenlink.net/ods/oauth_sid.vsp
  ```
- bind session key to command session via the command: *ods-set-oauth <oauth-key>* or use *ods-set-[class name]-oauth <oauth-key>* when oauth-key was generated for particular application instance.

If you choose the SID mode of interaction with ODS you have to perform the following steps:

- set mode via command: ods-set-mode sid or ods-set-mode oauth
- set sid via command: ods-set-sid sid

Note: The sid is a session ID applicable to all ODS commands for a given bound instance and user combination. It's obtained from an ODS session.

Example

The following example demonstrates oauth authentication getting the OAuth SID value for ex. for existing Bookmark instance "mybookmarks" with owner user demo at the OpenLink Demo server.

In order to execute correctly the example, you need to have OAuth Generate Key for the Bookmark "mybookmarks" instance at OpenLink Demo server. More information and simple scenario how to be done you can find here.

1. Execute the command:

   ```
   ods-oauth-host <host_url>
   -- for ex.:
   ods-oauth-host http://demo.openlinksw.com/OAuth
   ```

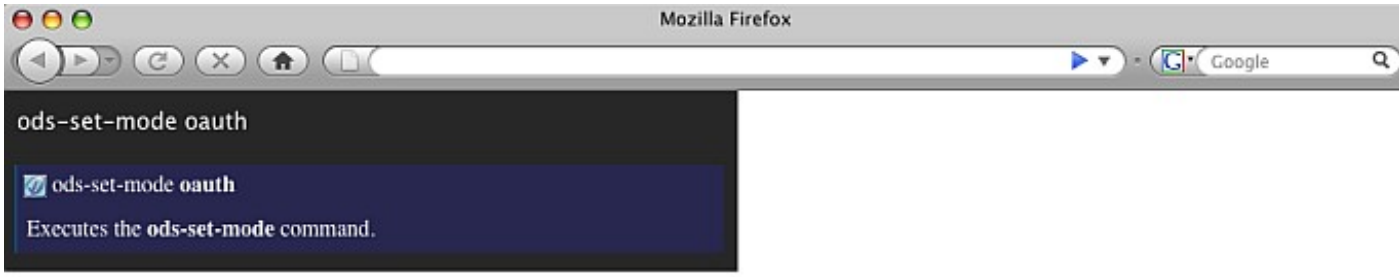
   Figure 17.30. OAuth Authentication

2. Execute the command:

   ```
   ods-set-mode oauth
   ```

   Figure 17.31. OAuth Authentication



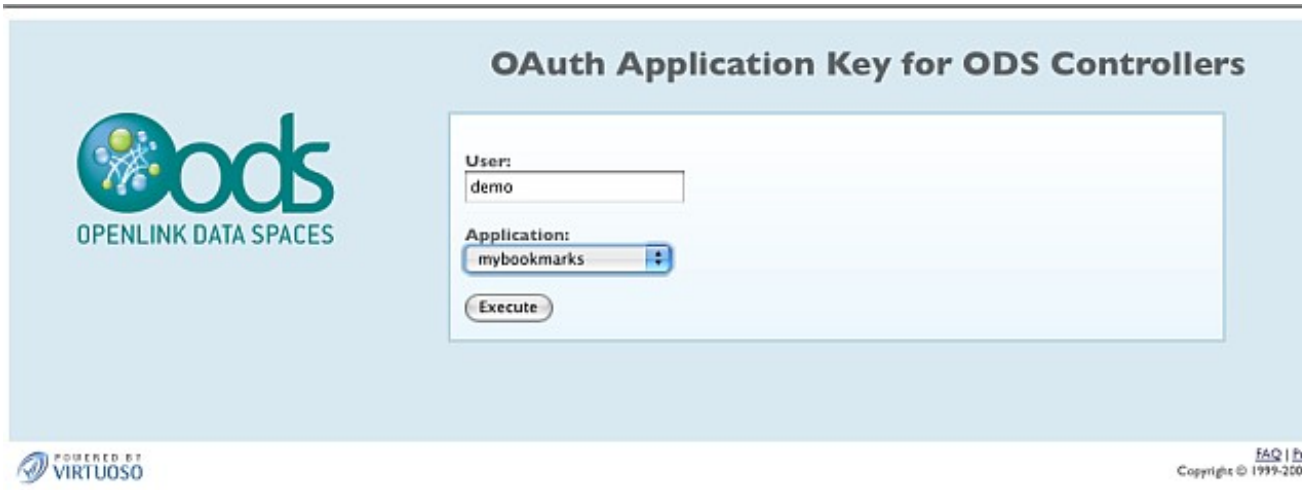
3. Obtain the OAuth Generated Key:

   a. Go to http://cname:port/ods/oauth_sid.vsp . For ex. http://demo.openlinksw.com/ods/oauth_sid.vsp

   Figure 17.32. OAuth Authentication

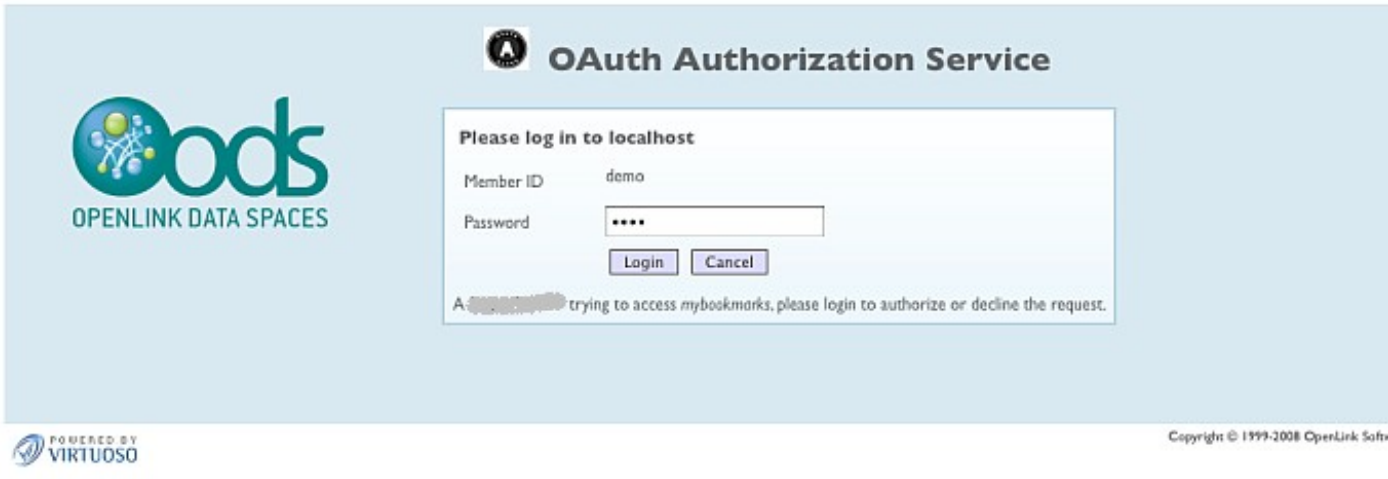
   b. In the shown form enter user demo and choose the application "mybookmarks". Click the "Execute" button.

   Figure 17.33. OAuth Authentication



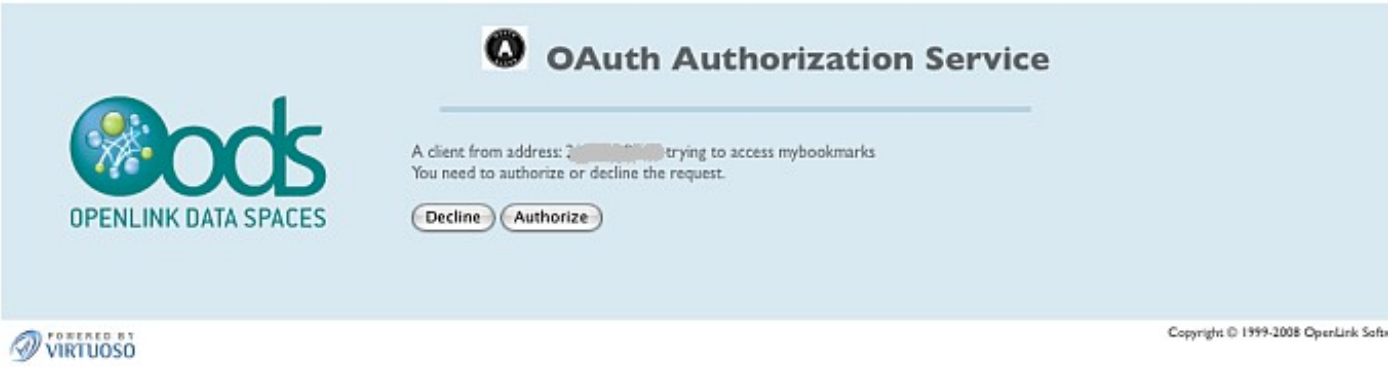
4. As result will be shown a form where you need to enter the user password.
5. Enter for user demo its password and click the "Login" button.

   Figure 17.34. OAuth Authentication



6. Click the "Authorize" button.

Figure 17.35. OAuth Authentication



7. Copy the obtains OAuth SID value for ex.: 7ef4dcf23869488823b771b09b952cc9

Figure 17.36. OAuth Authentication

8. Execute the following command:

```
ods-set-sid 7ef4dcf23869488823b771b09b952cc9
```

```
or

ods-set-addressbook-oauth 7ef4dcf23869488823b771b09b952cc9
```

Figure 17.37. OAuth Authentication

9. You can also execute the command(s) depending on the application type:

```
ods-set-briefcase-oauth <the obtained oauth session-key>
-- or
ods-set-bookmark-oauth <the obtained oauth session-key>
-- or
ods-set-feeds-oauth <the obtained oauth session-key>
-- or
ods-set-calendar-oauth <the obtained oauth session-key>
-- or
ods-set-addressbook-oauth <the obtained oauth session-key>
-- or
ods-set-poll-oauth <the obtained oauth session-key>
-- or
ods-set-weblog-oauth <the obtained oauth session-key>
-- or
ods-set-discussion-oauth <the obtained oauth session-key>
```

17.4.6. OAuth Test Tool for ODS Controllers

The ODS OAuth Test Tool creates examples to show users the correct format for constructing HTTP requests signed according to OAuth specifications. The users use this format in their applications to make successful requests to the ODS REST APIs.

The ODS users generate a Consumer Key and a Consumer Secret for their application instances by ODS application UI (Setings -> OAuth Keys). You can find more information and sample scenario here.

To reach a specific ODS resource via the ODS REST API, a user must also specify a API method and associated API parameters.

ODS OAuth standards validate the credentials of an external user by means of the digital signature. If the user signs the request, and the ODS server validates the digital signature, the developer is granted access to the requested resource.

To tool is accessible via http://host:port/ods/oauth_test.vsp

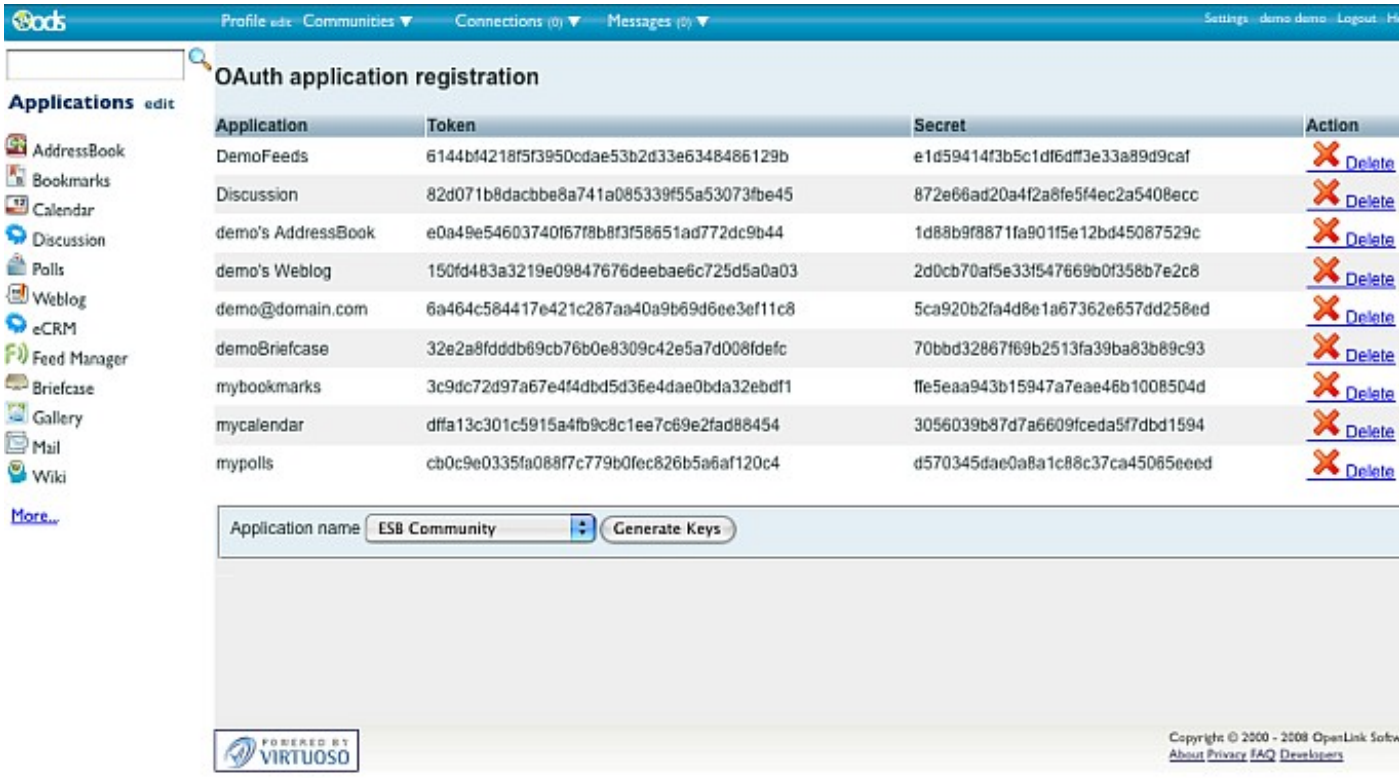
Example

The following example demonstrates creating and getting contact info by the ODS REST APIs weblog.post.new and weblog.post.get using the OAuth Test Tool.

1. Go to http://demo.openlinksw.com/ods
2. Log in as user demo with password demo

3. Go to Settings->OAuth Keys

Figure 17.38. Weblog OAuth



4. Copy the Token value for an Weblog instance or create such in not existing. For ex.:

```
150fd483a3219e09847676deebae6c725d5a0a03
```

5. Go to http://demo.openlinksw.com/ods/oauth_test.vsp
6. In the shown form enter for:

   a. Server: http://demo.openlinksw.com/ods/api
   b. Consumer Key: 150fd483a3219e09847676deebae6c725d5a0a03
   c. API method: weblog.post.new
   d. API parameters:

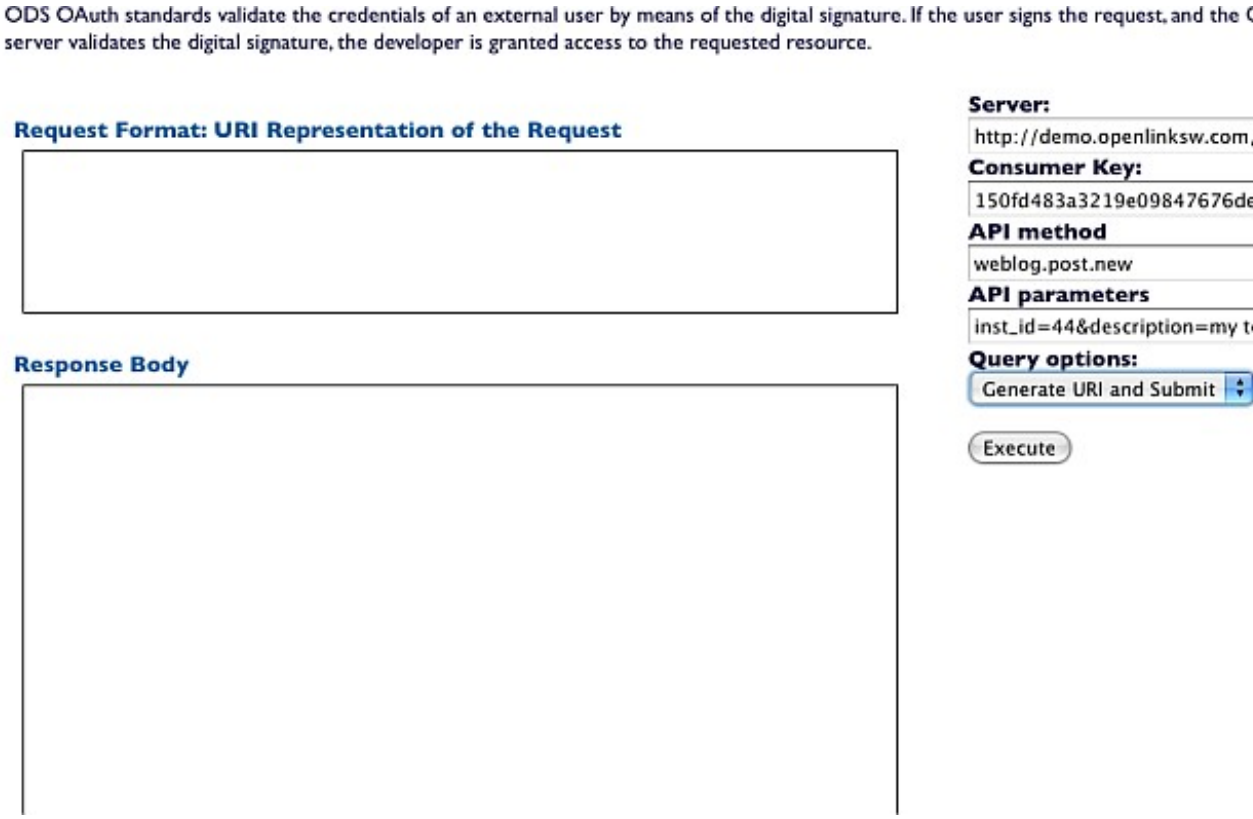
```
inst_id=44&description=my test&title=my first post
```

   - An easy way to get the instance id is using the ODS ubiquity commands sequence:

```
ods-host http://demo.openlinksw.com/ods
ods-set-mode sid
ods-authenticate-user demo password demo
ods-get-instance-id demo's Weblog
```

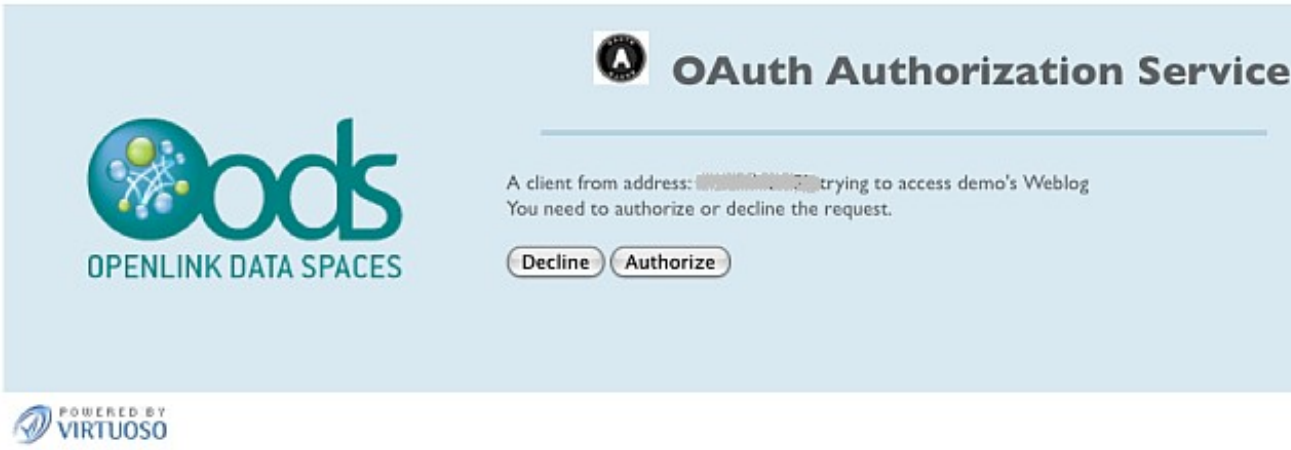
   e. Select for Query options: "Generate URI and Submit".

Figure 17.39. Weblog OAuth



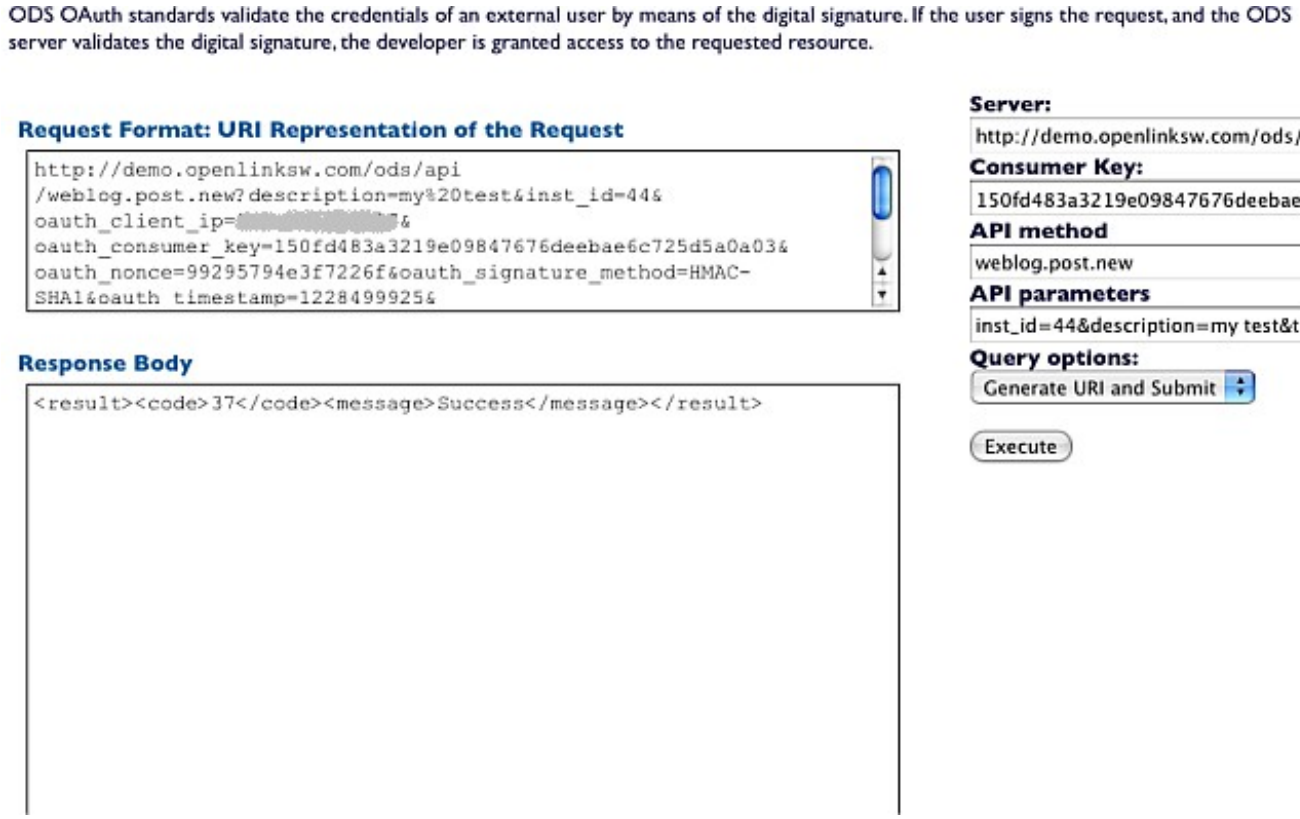
f. Click the "Execute" button.
g. In the shown authorization form click the "Authorize" button.

Figure 17.40. Weblog OAuth



h. As result will be shown the generated URI and the output message of executing the ODS REST API. In our case, the id of the new created post will be: 37

Figure 17.41. Weblog OAuth



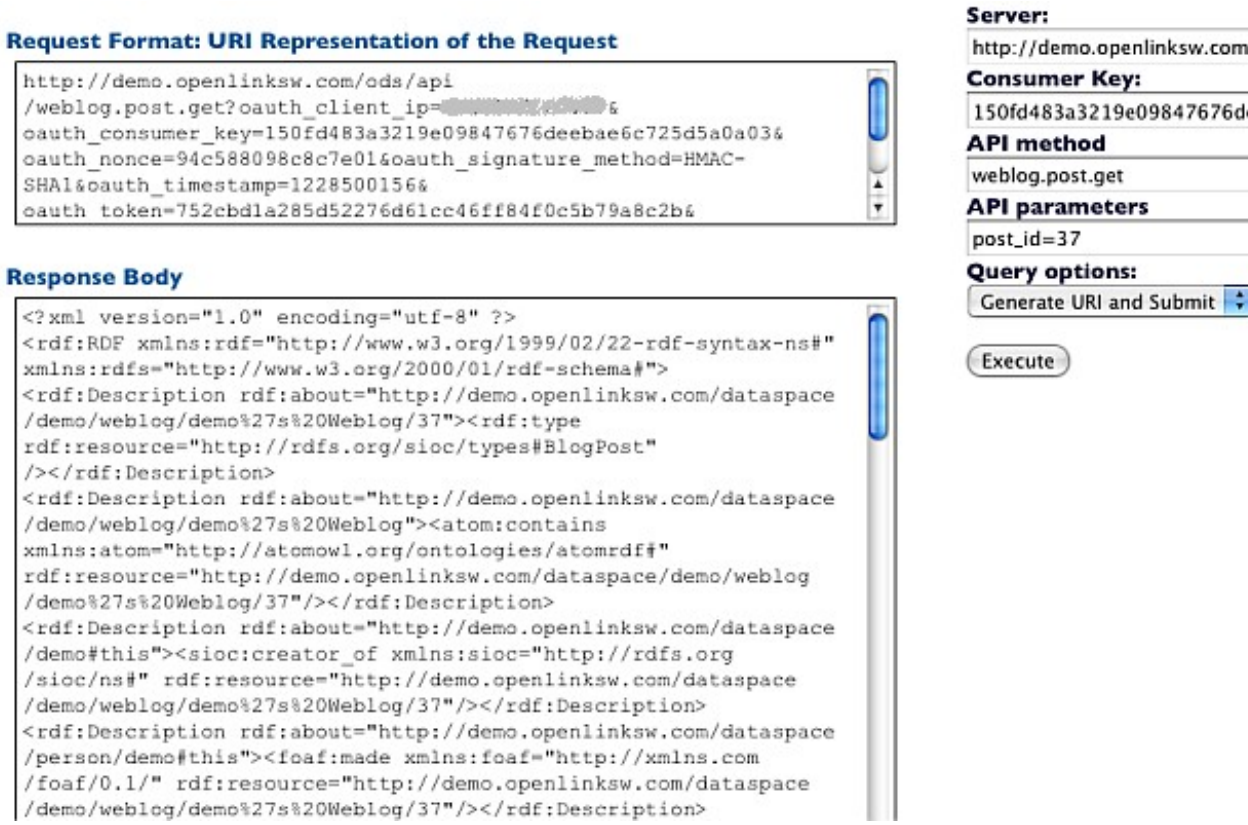
i. Now let's get the data for the created post. In the form enter:

   i. API method: weblog.get
   ii. API parameters: post_id=37
   iii. Select for Query options: "Generate URI and Submit".

j. Click the "Execute" button.

k. As result in the "Response Body" text-area will be shown the retrieved details for the posts with the given above id.

Figure 17.42. Weblog OAuth



17.4.7. OAuth QA

MySpace Tools

In order to use the MySpace OAuth Testing Tool :

1. Need to have registered myspace account.
2. Need to apply to build apps on the MySpace Developer Platform.

Google Tools

Google's OAuth playground tool can be tried here .

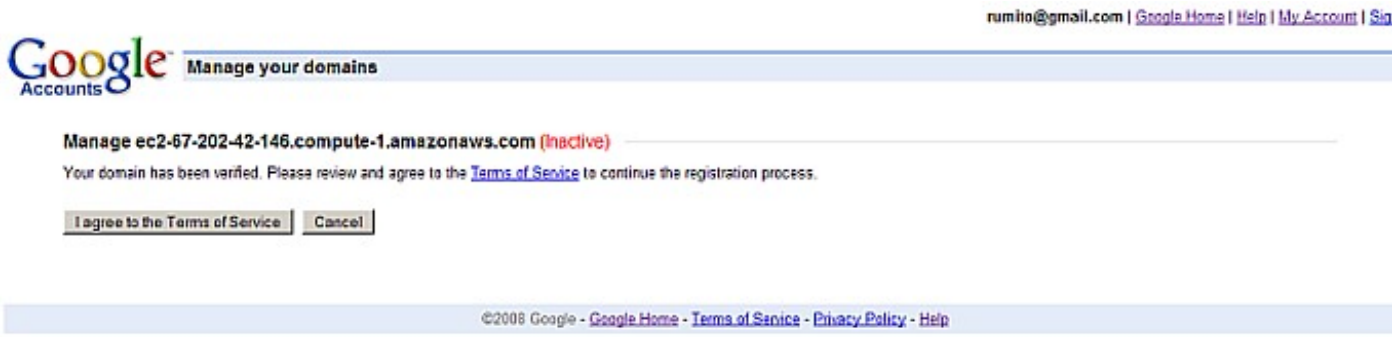
Register your domain in Google

In order to use the tool, you need to register the web application as domain:

1. Login at your gmail account
2. Go to https://www.google.com/accounts/ManageDomains
3. Enter in the field for ex. the QA server ec2-67-202-42-146.compute-1.amazonaws.com and click the "Add Domain" button.

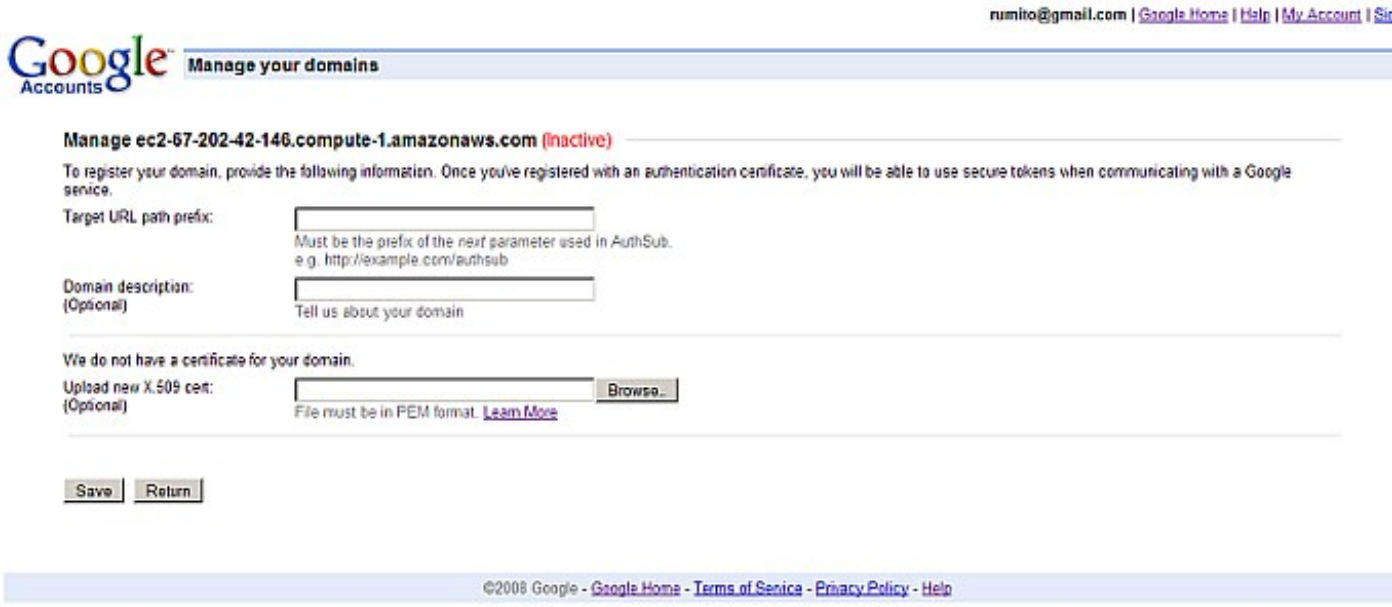
   Note: for now registered domains cannot be deleted (not supported from the Google UI)
4. As result the domain will be created and the manage domain page will be opened. Here you need to verify you have admin privileges by choosing verification method
5. Choose "Upload an HTML file" and follow further the instructions.
6. Once the file is put in the correct server root, you should get the confirmation page:

Figure 17.43. Google OAuth



7. Click the "Agree .." buttons.
8. As result will be additional setting page you need to change. Type in for "Target URL path prefix:": http://ec2-67-202-42-146.compute-1.amazonaws.com/ods

Figure 17.44. Google OAuth

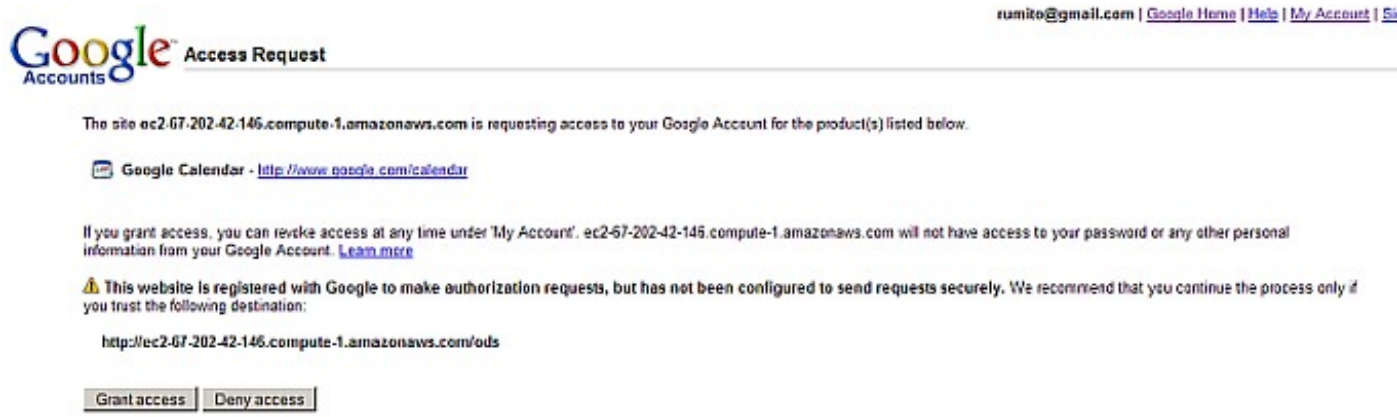


9. Click the "Save" button.
10. As result will be shown the generated OAuth Consumer Secret for the OAuth Consumer Key: ec2-67-202-42-146.compute-1.amazonaws.com:

```
OAuth Consumer Key:      ec2-67-202-42-146.compute-1.amazonaws.com
OAuth Consumer Secret:  uEkfBvpMhTTT/VyFItEnEYt4
```

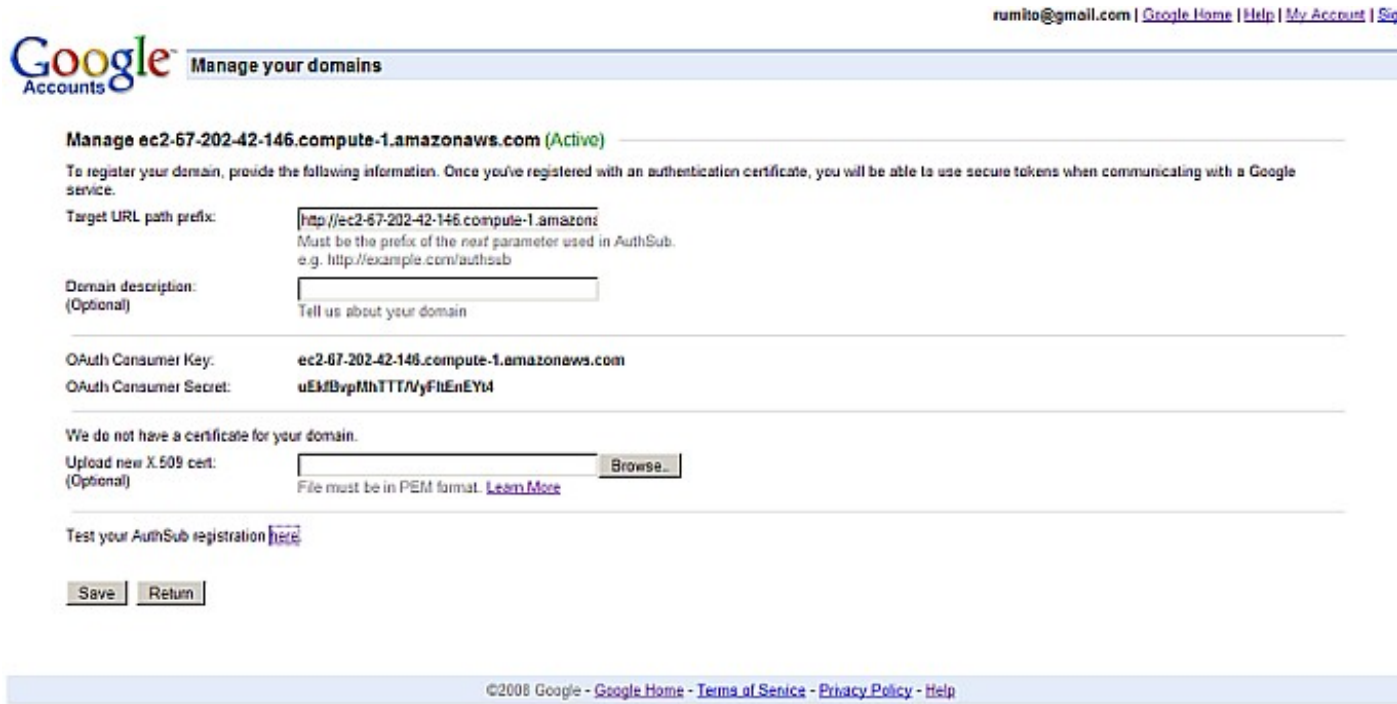
11. Also will be shown "test" link "Test your AuthSub registration here". Click it.
12. As result will be opened new window with OAuth request
13. Click the "Grant Access" button.

Figure 17.45. Google OAuth



14. As result will be redirected to http://ec2-67-202-42-146.compute-1.amazonaws.com/ods/
15. Now lets return to our initial window and click there the button "Save".
16. Note that already is shown for the domain that is "Active":

Figure 17.46. Google OAuth

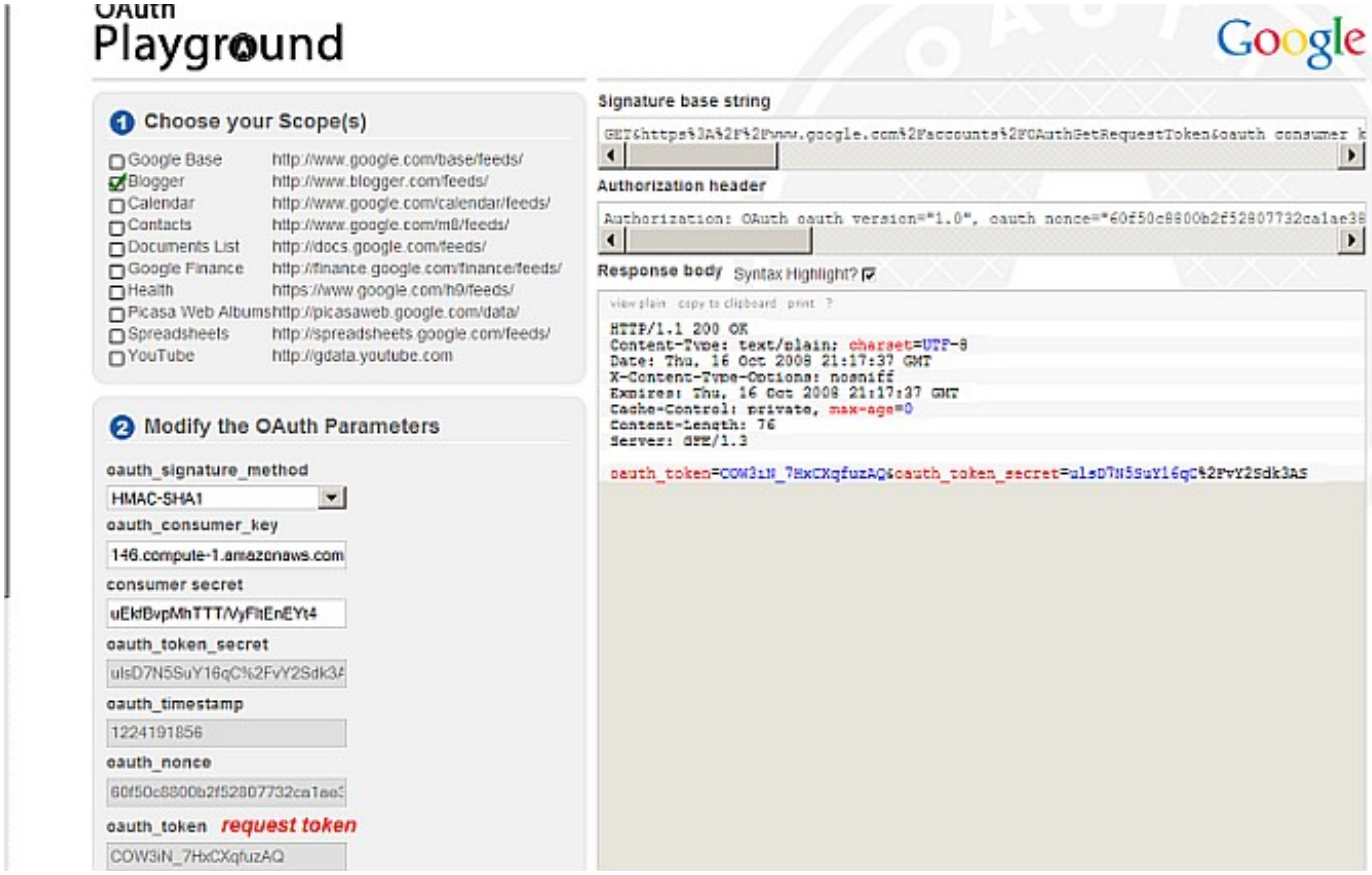


The Playground Tool qa steps

Let's try the playground tool:

1. Go to http://googlecodesamples.com/oauth_playground/
2. Select Scope, for ex. check the check-box for "Blogger".
3. Change oauth signature_method to HMAC-SHA1
4. Enter for "oauth consumer_key": ec2-67-202-42-146.compute-1.amazonaws.com
5. Enter for "consumer secret" the value generated from above.
6. Click the "Request token" button.
7. As result will get Response with Status Ok

Figure 17.47. Google OAuth



- the Signature base string:

```
GET&https%3A%2F%2Fwww.google.com%2Faccounts%2FOAuthGetRequestToken&oauth_consumer_key
%3Dec2-67-202-42-146.compute-.amazonaws.com%26oauth_nonce%3D60f50c8800b2f52807732ca1ae3855e
%26oauth_signature_method%3DHMACSHA1%26oauth_timestamp%3D1224191856%26oauth_version%3D1.0
%26scope%3Dhttp%253A%252F%252Fwww.blogger.com%252Ffeeds%252F
```

- the Authorization header:

```
Authorization: OAuth oauth_version="1.0",
oauth_nonce="60f50c8800b2f52807732ca1ae3855ef",
oauth_timestamp="1224191856",
oauth_consumer_key="ec2-67-202-42-146.compute-1.amazonaws.com",
oauth_signature_method="HMAC-SHA1",
oauth_signature="nohPMCw%2BMrO8%2FwslS4oEm2wfuhg%3D"
```

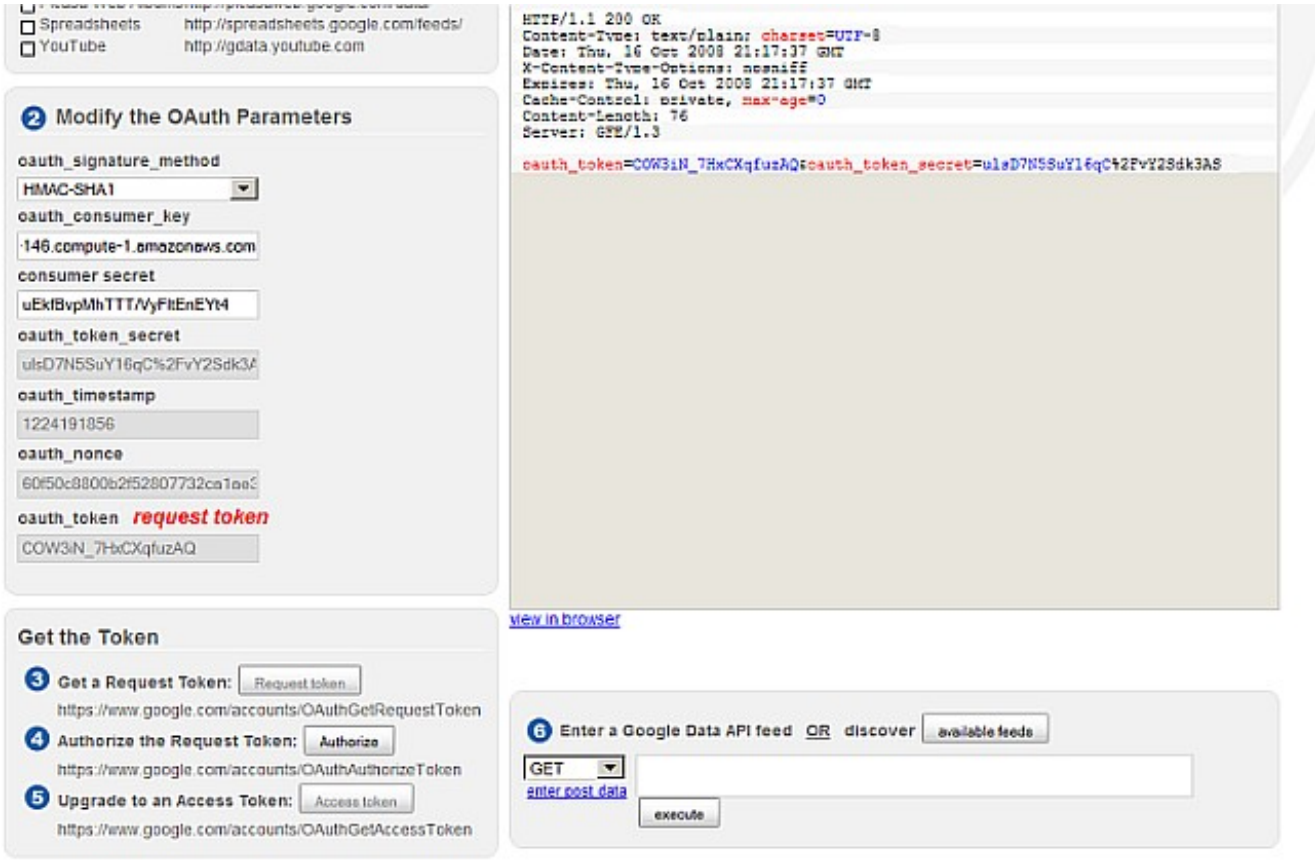
- the Response body:

```
HTTP/1.1 200 OK
Content-Type: text/plain; charset=UTF-8
Date: Thu, 16 Oct 2008 21:17:37 GMT
X-Content-Type-Options: nosniff
Expires: Thu, 16 Oct 2008 21:17:37 GMT
Cache-Control: private, max-age=0
```

```
Content-Length: 76
Server: GFE/1.3
 oauth_token=COW3iN_7HxCXqfuzAQ&oauth_token_secret=ulsD7N5SuY16qC%2FvY2Sdk3AS
```

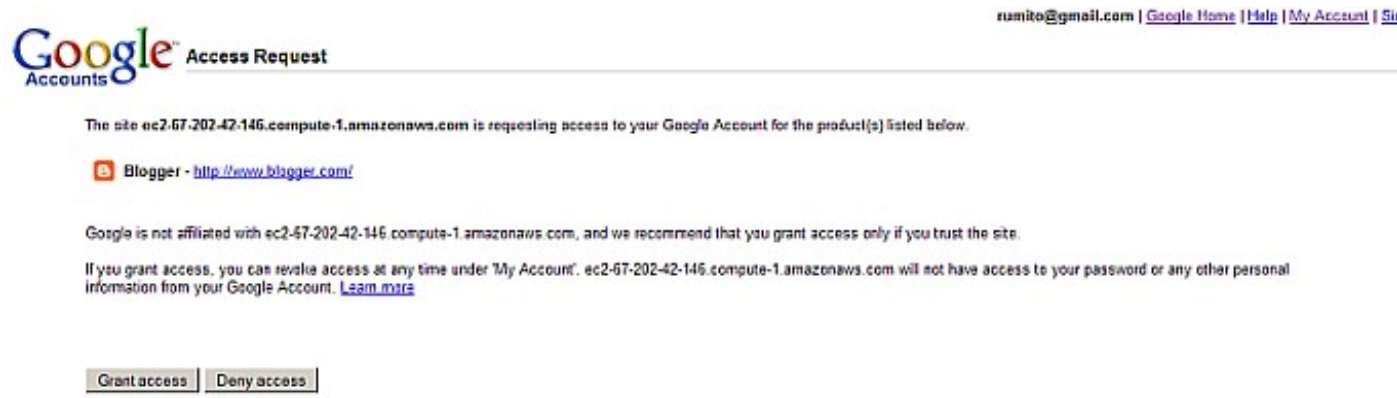
8. And also in the "Get the Token" section now will be active the "Authorize" button. Click it.

Figure 17.48. Google OAuth



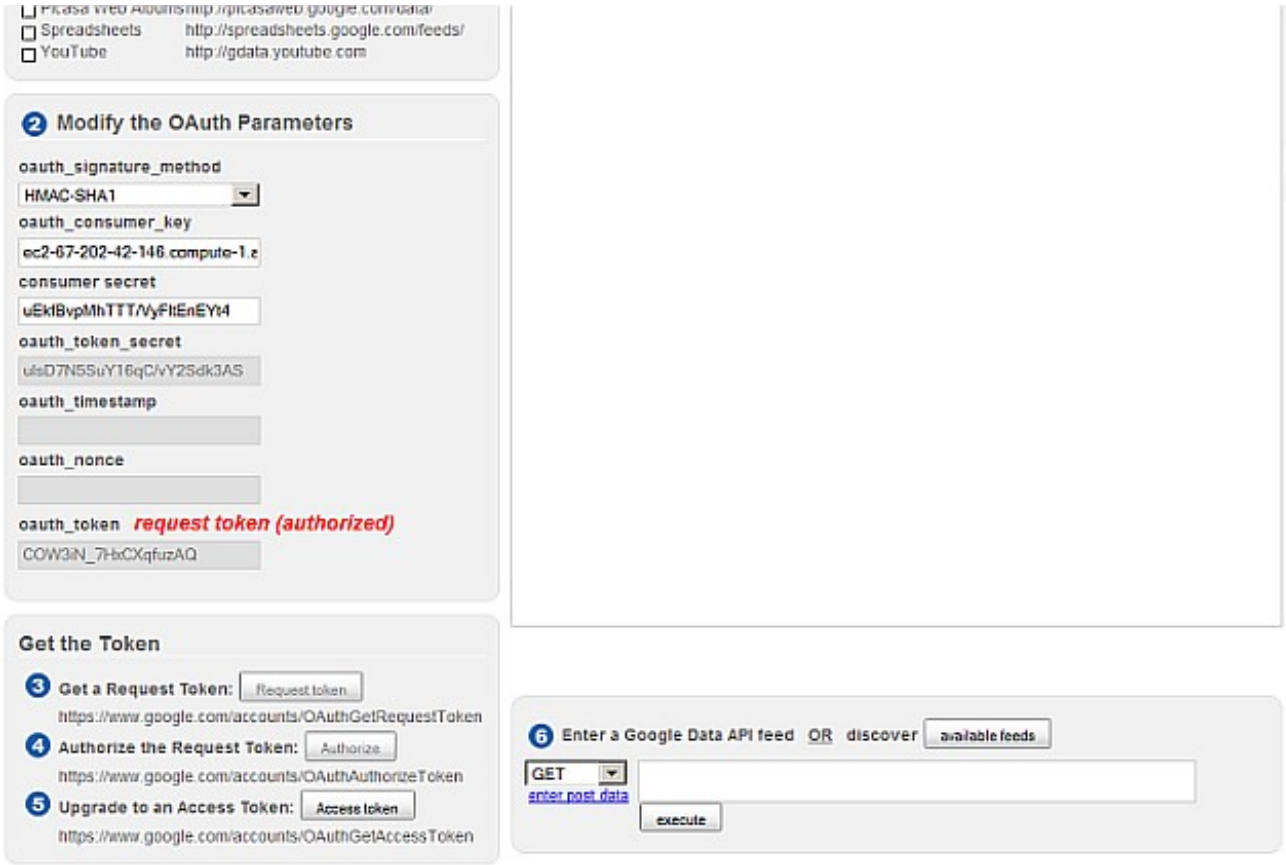
9. As result will be shown the authentication page where you need to click the "Grant Access" button:

Figure 17.49. Google OAuth



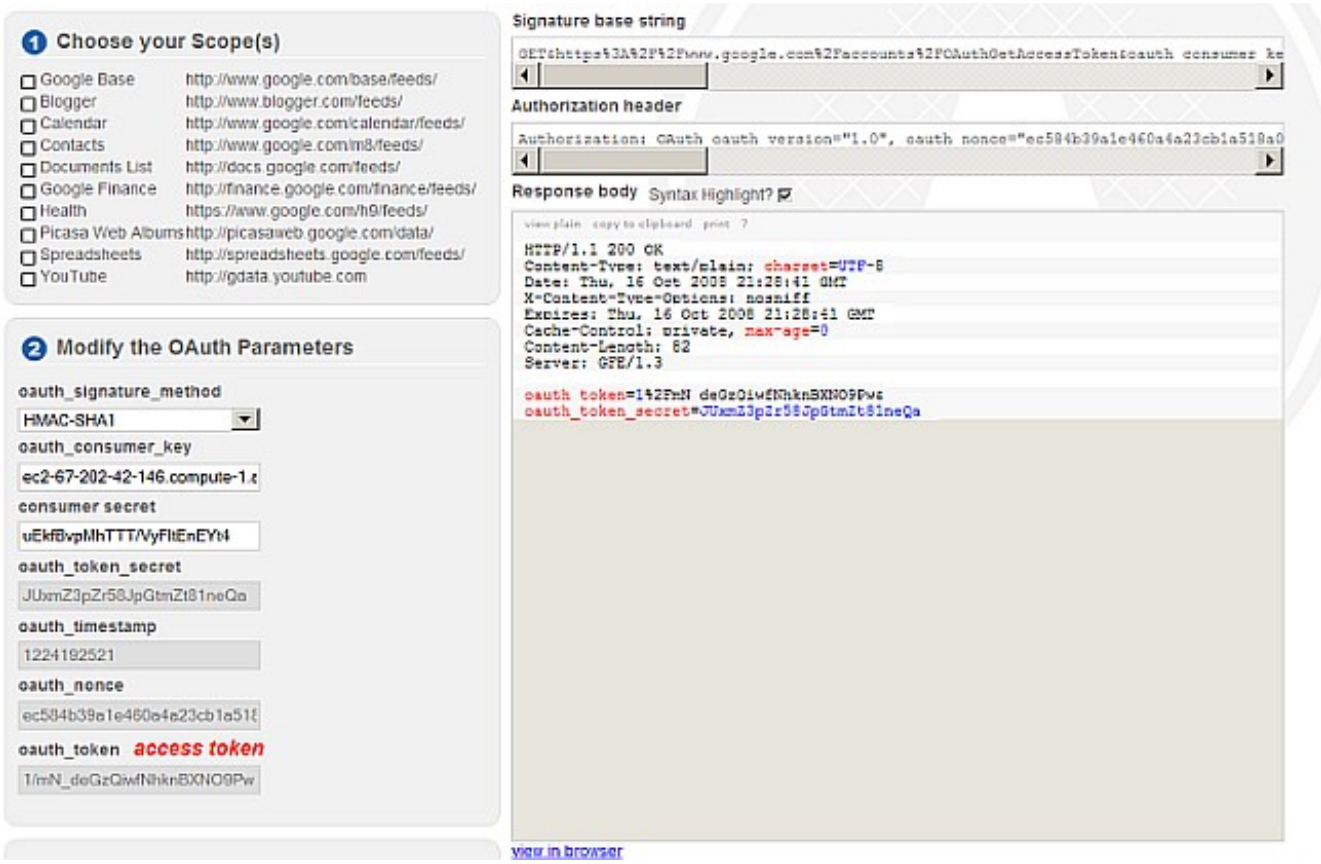
10. As result now in the "Get the Token" section will be active the "Access token" button. Click it.

Figure 17.50. Google OAuth



11. As result the access_token will be obtained:

Figure 17.51. Google OAuth

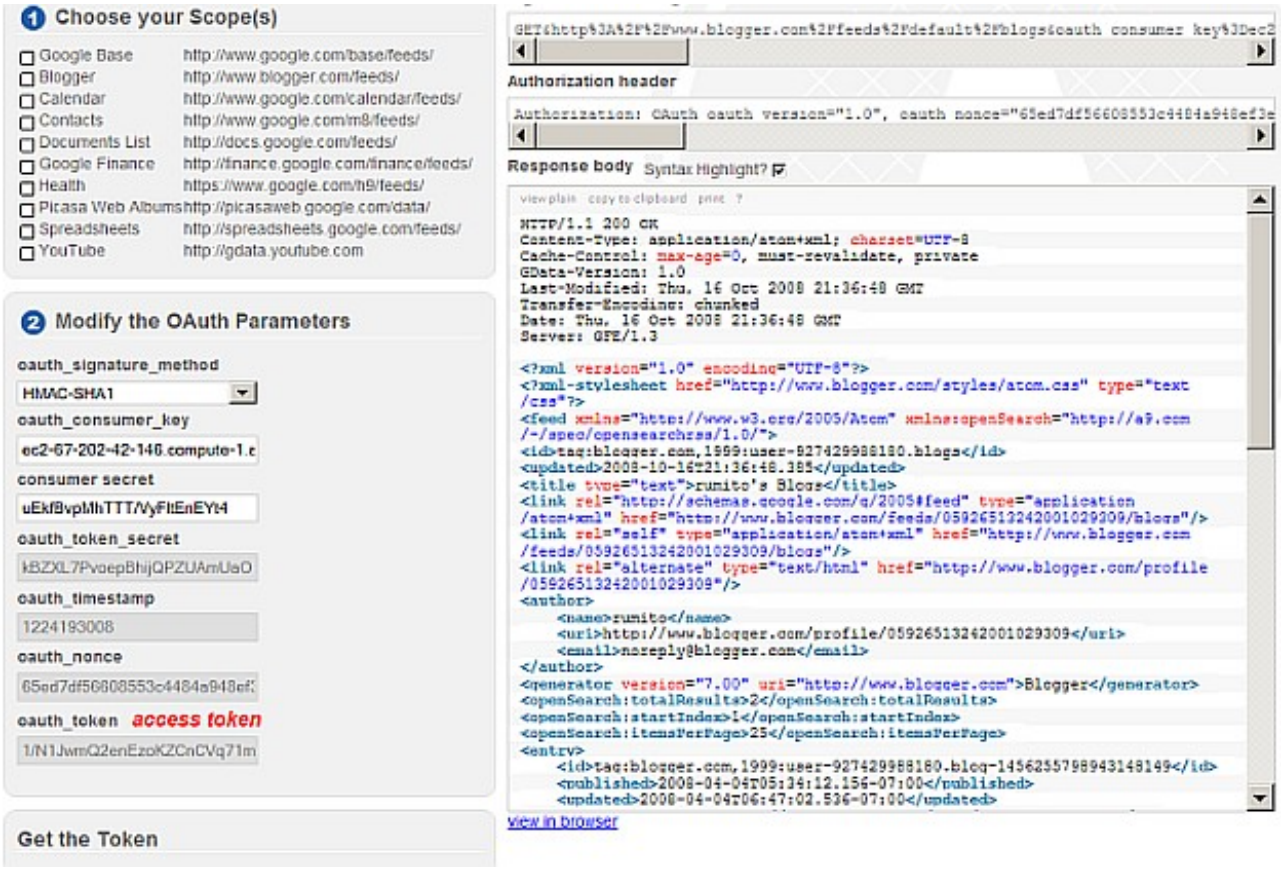


12. Click the "available feeds" button marked as 6.
13. As result in the "Response" body section will be shown:

```
Blogger
http://www.blogger.com/feeds/default/blogs
http://www.blogger.com/feeds/<blogID>/posts/default
http://www.blogger.com/feeds/<blogID>/[<postID>]/comments/default
```

14. Copy the 1st URL and paste in the field after the method GET.
15. Click "execute".
16. As result will find your blogs, post, info at Blogger:

Figure 17.52. Google OAuth



17.5. WS-Security (WSS) Support in Virtuoso SOAP Server

The following terms are used in this section in the following meanings:

- **encryption .** The process of making data unreadable using some secret (see 'key')
- **decryption .** The opposite of encryption
- **signature .** A sequence of binary codes that is calculated based on the original data and a key to secure the content from undetected change.
- **key .** A secret, depending on the type can be symmetric or asymmetric.

  Typical symmetric keys are passwords. Symmetric keys are by their nature more at risk of being compromised if the secret key is stolen. Symmetric keys are usually used to encrypt large amounts of data as they are very fast.

  Asymmetric keys are more secure and their structure is more complicated. Asymmetric keys generally consist of a private and public key pair. The owner of the key can sign data to be verified by recipient with public key. A correspondent can encrypt the data using public key to be decrypted by private key owner. Asymmetric keys are used to sign data, or encrypt small amounts of data as they are slower to process than symmetric ones.
- **certificate .** This is a structure of secure data, which identifies a certificate owner. This is similar to having a user-name and password but more secure. A 'certificate' can be associated with a document as an alias of the X.509 certificate. Certificates are issued by a third-party, not the owner or recipient in the verification path, namely the Certificate Authority (CA). The CA's function is to guarantee that a receiver can trust data accompanied by a particular certificate. Certificates will contain a public key, but never the private key. These must be distinguished from certificates that are exported together with their private key in PKCS#12 format, these are different things.
- **user account space .** This is a data area where a user can store private data. Only ODBC sessions and web page processing code which runs on behalf of a certain SQL user account has access to this area. This is useful for caching private security related information such as keys or certificates.
- **key reference .** A short hand for a key, sometime called a 'key name'. This is a string to uniquely identify a key in a user account space.
- **key instance .** An entity representing a key in PL, this is a not the key per se. The key instance is used in encryption or decryption routines.

The following algorithms are supported:

RSA (http://www.w3.org/2001/04/xmlenc#rsa-1_5)
DSA (http://www.w3.org/2001/04/xmlenc#dsa)
triple DES (http://www.w3.org/2001/04/xmlenc#tripledes-cbc)
AES128 (http://www.w3.org/2001/04/xmlenc#aes128-cbc)
AES192 (http://www.w3.org/2001/04/xmlenc#aes192-cbc)
AES256 (http://www.w3.org/2001/04/xmlenc#aes256-cbc)
Digest algorithms:

SHA1 (http://www.w3.org/2000/09/xmldsig#sha1)
Signing algorithms:

RSA-SHA1 (http://www.w3.org/2000/09/xmldsig#rsa-sha1)
DSA-SHA1 (http://www.w3.org/2000/09/xmldsig#dsa-sha1)
Canonicalization algorithms with comments:

(http://www.w3.org/TR/2001/REC-xml-c14n-20010315)
(http://www.w3.org/TR/2001/REC-xml-c14n)
The keys can be temporary or persistent keys. Temporary keys are loaded only in memory an will be lost when the server is restarted. These are usually used for making symmetric session keys. Persistent keys are kept on the file-system or in the database and will be loaded upon server startup. These are asymmetric keys, certificates that belong to the user.

The location where persistent keys are stored depends on the key reference. If the key reference is a 'file:' URI, then the API's assume file-system storage, otherwise they will be kept in the U_OPT column of the SYS_USERS table as a serialized string. The API functions are described below. Whether keys are stored on the file-system or within the database they will have an in-memory representation which is used in crypto functions. The memory cache of keys is contained in the user account space, hence no user can access or reference another user's keys. Furthermore if a user account is removed all associated keys will also be removed if they were stored in the database. If the keys were on the file-system only the in-memory cache will be deleted.

17.5.1. Client and Server side Certificates & Keys

Since XML encoding routines are executed on server-side, we cannot strictly say that we have client and server certificates (as browser and HTTPS server). To perform the encoding on behalf of a client or user account, the XML encoding functions need to have the keys and certificates loaded in the memory cache of the user. The same applies to server keys and certificates. Therefore we will refer to these as client or server security tokens that are kept on server-side.

Note:
Uploading of keys and certificate must be done under a secure SSL/TLS connection to minimize the risk of vulnerability.

Key Definition & Persistence

```
xenc_key_3DES_rand_create()

USER_KEY_LOAD()
```

Key Encryption

To minimize the risk of non-authorized private key usage, keys are usually kept encrypted with password. If a key or certificate containing a key is loaded using a password, the API will assume it is an encrypted private key and will be kept in that form. In other words encrypted keys are kept in their encrypted form in memory, there will be no raw certificate or key data if the encrypted form is used to import. Virtuoso will ask for passwords to unlock persisted encrypted keys upon server restart. This is only possible when the server is running in foreground mode. If the server is started as background process and the key needs a password to decrypt and load, an error will be logged in the virtuoso log file and that particular key will not be loaded.

Example 17.25. An example of a password prompt and log on success

```
Enter a password for key "wss.pfx":
13:14:04 PL LOG: XENC:   Loaded : wss.pfx
```

Referencing Keys

To make a run-time key instance, used for XML encryption functions, and to perform server or client side the `xenc_key_inst_create (in key_name varchar[, super key inst])` function can be used.

Example 17.26. Example

```
create procedure
DB.DBA.WSDK_GET_KEY ()
{
  -- this returns a instance of shared secret suitable for content encryption
  return xenc_key_inst_create ('WSDK Sample Symmetric Key');
}
;

create procedure
DB.DBA.WS_SOAP_GET_KEY ()
{
  declare superkey, keyinst any;
  superkey := xenc_key_inst_create ('file:dsa.der'); -- already loaded asymmetric key (see above example)
  -- this returns a session key , to be encrypted with a asymmetric one
  keyinst := xenc_key_inst_create (xenc_key_3DES_rand_create (NULL), superkey);
  return keyinst;
}
;
```

Key Removal

To delete a key, persistent or otherwise, the following function is used:

`xenc_key_remove()`

17.5.2. SOAP Server WS-Security Endpoint

The WS-Security processing is performed by filtering incoming and outgoing messages of the Virtuoso SOAP server. These filters are activated when a special SOAP option is set on the current virtual directory that is the SOAP endpoint. The WS-Security filters are invoked on input to verify / decrypt the message. Upon success the message will be processed by the SOAP server, otherwise a `SOAP:Fault` will be returned to the SOAP requester. On outgoing messages, depending of SOAP options, messages produced by the SOAP server can be encoded and signed as well. The administrator configures the WS Security subsystem at the access point level. Different security schemes involving encryption and/or signature can be selected.

The keys and certificates need to be defined in order to get a working secure service. The key/certificate(s) for the SOAP endpoint that is WS-Security enabled are referenced in a special PL hook and/or signature template. If none of these (signature or key instance hook) are defined the response will not be encrypted or signed.

Here are the steps involved in processing a message to a secure end point.

1. SOAP server receives a message on a secure endpoint
2. The message is determined to be for this endpoint, otherwise will be sent to the next SOAP router if routing is enabled.
3. The message (as is) is passed to the decoding routine. At this point keys that are referenced in SOAP message need to be in the user space of the SQL account on whose behalf SOAP accessible procedures of this end point run. If any key does not exist in the user space, the requested processing will fail.

   
   Note:
   Signatures can be verified in the following manners:

   never try signatures
   expect signatures, explicit
   try signature if exists
   This behavior depends on the "WSS-Validate-Signature" option set for the virtual directory.
4. If step 3 completes without problem, security related headers are stripped from the decoded message.
5. The result of point 4 is passed to the usual SOAP server for processing.

6. Once a response is generated by the SOAP method (i.e. corresponding PL procedure, exposed as SOAP method) the result will be encoded and/or signed. This is the last step before the result is sent back to the requestor client. At this point the server behavior is controlled by a few options defined in the virtual directory. See below: "WSS-KEY", "WSS-Template", and "WSS-Type" options.

17.5.3. Virtual Directory SOAP WSS Options

The following SOAP options are available for configuring a virtual directory:

- **WS-SEC .** WS-Security processing is enabled on the endpoint, in practice this enables the input and output message filters for Security Header processing. This MUST be set to enable WS-Security endpoints. All other WS related options will be ignored if this option is disabled. The possible values for this option are "yes" or "no"
- **WSS-KEY .** The name of a PL procedure that is expected to return a key instance. Examples of this can be found in the Referencing Keys section. If this NULL or undefined the SOAP server will not encrypt outgoing messages.
- **WSS-Template .** path and file name to a file containing a template - an instruction for how to make the XML signature for the response message. For more information see the Security Templates section. If this option is NULL or undefined the SOAP server will not sign any outgoing messages from this endpoint. As an example, if the value "sig.xml" was supplied to this option this would imply that the content of template is stored in the file called sig.xml located in the servers working directory. A default template can be used by setting this option to the value `[key reference for signing]` - (note '[]' around name is required). In this case the server will generate a default template based on a key, and produce a default rule for making a signature.
- **WSS-Validate-Signature.** This option controls how the SOAP server responds to incoming messages i.e. how to verify the incoming message.

  possible values are:

  0 do not verify signatures

  1 expects signature to exist

  2 will verify signature if exists

Example 17.27. Configuring WS Secure Endpoints

```
-- definition of /SecureWebServices endpoint
VHOST_DEFINE (
  lpath=>'/SecureWebServices', ppath=>'/SOAP/', soap_user=>'WSS',
  soap_opts=>vector(
    'Namespace','http://temp.uri/',
    'MethodInSoapAction','yes',
    'ServiceName', 'WSSecure',
    'CR-escape', 'no',
    'WS-SEC','yes',
    'WSS-Validate-Signature', 2)
  )
;
```

this will define a WS-Security enabled endpoint that is compatible with .NET WSDK examples. This endpoint will accept encrypted/or signed SOAP messages and will generate an error if security checking fails. Upon success it will return non-encrypted message. Therefore it's a one-way encryption example.

```
-- complex example
VHOST_DEFINE (
  lpath=>'/wss', ppath=>'/SOAP/', soap_user=>'WSS',
  soap_opts=>vector(
    'Namespace','http://soapinterop.org/',
                'MethodInSoapAction','no',
                'ServiceName', 'WSSecure',
                'HeaderNS', 'http://soapinterop.org/echoheader/',
                'CR-escape', 'no',
    'WS-SEC','yes',
                'WSS-KEY','DB.DBA.WS_SOAP_GET_KEY',
                'WSS-Template','wss_tmpl.xml',
    'WSS-Validate-Signature', 1)
  )
;
```

This endpoint will expect signed and encrypted incoming messages and will sign and encrypt outgoing messages too. This is a two-way encryption example, for client to server and reverse.

17.5.4. Accounting & Accounting Hook

If an X.509 certificate is used to sign an incoming message, the following connection variables will be available to the SOAP processing function and accounting hook:

wss-token-owner owner of certificate, an example is "C=US/ST=MA/CN=User Name".

wss-token-issuer issued by , it's like above , but it's name of who is issued the certificate.

wss-token-serial serial number, an integer specific to certificate issuer.

wss-token-start valid from, a string containing a data of validity.

wss-token-end valid to, a string containing data of end of validity.

These can be accessed by invoking connection_get([name-of-info]) when processing the SOAP request, i.e. in the procedure being invoked or from a user defined accounting hook.

A user defined procedure hook named DB.DBA.WS_SOAP_ACCOUNTING can be used for accounting purposes. If it exists it will be invoked after the connection information is set. This PL hook should return 0 when an error occurs or 1 upon success. Hence, a SOAP request may be rejected based on some custom condition.

The procedure prototype is :

```
create procedure DB.DBA.WS_SOAP_ACCOUNTING ()
{
  -- custom logic
  return 1; -- on success
  return 0; -- on failure
}
;
```

Note that the usage of this functionality is global to the Virtuoso server, To get similar functionality for each SOAP method, the developer will need to include account checking within the PL procedures that are exposed as SOAP methods.

17.5.5. Signature Templates

Signature templates are used to define how signatures are generated for SOAP messages. They are XML files containing a structure of Signature elements as per XML Signature standard. The DigestValue and SignatureValue elements are empty, so they will be filled upon output. The most important element is the KeyName element. This must contain a reference to an existing key from the user account space. This key reference does not need to be the same as key for data encryption, it can be a different key. Please note that XML encoding routines will resolve the key automatically, so there is no need to specify how the key instance will be obtained, hence no relation to "WSS-Key" from SOAP options section (above).

Default Template Generation

The default template will create an XML Signature using the following definitions:

a) have a simple template corresponding to a key reference (and it's algorithm) as:

```
TEMP := <?xml version="1.0" encoding="UTF-8"?>
<Signature xmlns="http://www.w3.org/2000/09/xmldsig#" >
  <SignedInfo>
    <CanonicalizationMethod Algorithm="http://www.w3.org/2001/10/xml-exc-c14n#" />
    <SignatureMethod Algorithm="[key algorithm]" />
  </SignedInfo>
  <SignatureValue></SignatureValue>
  <KeyInfo>
    <KeyName>[key reference]</KeyName>
  </KeyInfo>
</Signature>'
```

b) generate references to template a), using the `dsig_template_ext()` function and BODY of the SOAP request.

```
TEMPLATE :=  dsig_template_ext (xtree_doc (SOAP_BODY), TEMP,
      'http://schemas.xmlsoap.org/soap/envelope/', 'Body',
      'http://schemas.xmlsoap.org/rp', 'action',
      'http://schemas.xmlsoap.org/rp', 'to',
      'http://schemas.xmlsoap.org/rp', 'id',
      'http://schemas.xmlsoap.org/ws/2002/07/utility', 'Created',
      'http://schemas.xmlsoap.org/ws/2002/07/utility', 'Expires');
```

In other words, the 'Body' of the SOAP message, part of the routing header elements ('action,'to','id') and, if it exists, Timestamp headers ('Created', 'Expires').

Example 17.28. Using default templates

This example demonstrates the use of the default template mechanism and X.509 certificate with RSA key:

```
--------------- SOAP message
<SOAP:Envelope xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:SOAP="http://schemas.xmlsoap.org/soap/envelope/"
 xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/"
 xmlns:ds="http://www.w3.org/2000/09/xmldsig#"
 xmlns:xenc="http://www.w3.org/2001/04/xmlenc#"
 xmlns:wsse="http://schemas.xmlsoap.org/ws/2002/07/secext"
 xmlns:dt="urn:schemas-microsoft-com:datatypes">
  <SOAP:Header />
  <SOAP:Body
xml:id="id-2e7c29c7-8645-4ad8-af59-06bed179d2fb">
    <AddInt xmlns="http://microsoft.com/wsdk/samples/SumService">
      <a>3</a>
      <b>4</b>
    </AddInt>
  </SOAP:Body>
</SOAP:Envelope>

--------------- Generated signature template
<ds:Signature xmlns:ds="http://www.w3.org/2000/09/xmldsig#"
              xmlns:wsse="http://schemas.xmlsoap.org/ws/2002/07/secext"
              xmlns:wsu="http://schemas.xmlsoap.org/ws/2002/07/utility">
   <ds:SignedInfo>
      <ds:CanonicalizationMethod Algorithm="http://www.w3.org/2001/10/xml-exc-c14n#">
      </ds:CanonicalizationMethod>
      <ds:SignatureMethod Algorithm="http://www.w3.org/2000/09/xmldsig#rsa-sha1"></ds:SignatureMethod>
      <ds:Reference URI="#Id-2e7c29c7-8645-4ad8-af59-06bed179d2fb">
        <ds:Transforms>
          <ds:Transform Algorithm="http://www.w3.org/2001/10/xml-exc-c14n#">
            </ds:Transform>
          </ds:Transforms>
        <ds:DigestMethod Algorithm="http://www.w3.org/2000/09/xmldsig#sha1"></ds:DigestMethod>
        <ds:DigestValue></ds:DigestValue>
      </ds:Reference>
   </ds:SignedInfo>
   <ds:SignatureValue></ds:SignatureValue>
    <ds:KeyInfo>
      <wsse:SecurityTokenReference>
        <wsse:Reference URI="#SecurityToken-24c152e3-26e0-d611-bb59-90b4c67d3be5"></wsse:Reference>
      </wsse:SecurityTokenReference>
    </ds:KeyInfo>
</ds:Signature>
```

Now, an example of a user defined template:

```
<?xml version="1.0" encoding="UTF-8"?>
<Signature xmlns="http://www.w3.org/2000/09/xmldsig#">
    <SignedInfo>
      <CanonicalizationMethod Algorithm="http://www.w3.org/TR/2001/REC-xml-c14n-20010315" />
      <SignatureMethod Algorithm="http://www.w3.org/2000/09/xmldsig#dsa-sha1" />
      <Reference URI="">
        <Transforms>
          <Transform Algorithm="http://www.w3.org/2000/09/xmldsig#enveloped-signature" />
        </Transforms>
        <DigestMethod Algorithm="http://www.w3.org/2000/09/xmldsig#sha1" />
```

```
            <DigestValue></DigestValue>
          </Reference>
        </SignedInfo>
        <SignatureValue></SignatureValue>
        <KeyInfo>
            <KeyName>file:dsa.der</KeyName>
        </KeyInfo>
    </Signature>
```

17.5.6. SOAP Client

The `soap_client()` function is used to make soap requests. Upon success it will return an array containing the XML tree of the result. However, it can return more complex results when the debug parameter is enabled, in which case it can return the request and the response messages as well. Some of the parameters are optional, not all are required and they can be named.

`soap_client()`

17.6. Web Services Routing Protocol (WS-Routing)

The SOAP Routing Protocol (WS-Routing) is a SOAP-based, stateless protocol for exchanging SOAP messages from an initial sender to an ultimate receiver, potentially via a set of intermediaries. The WS-Routing protocol is implemented as a SOAP extension, embedded in a SOAP Header entry.

The WS-Routing implementation consists of SOAP Header processing. The header processing handler for the WS-Routing header determines if the Virtuoso SOAP server can act as an intermediary or a endpoint depending on the rules in message path.

This implementation supports HTTP only. Message Id's generated are UUIDs.

17.6.1. Configuration

Setting-up the WS-Routing for a SOAP service requires you to:

1. make a virtual directory bound to the SOAP endpoint processor (/SOAP)
2. add the following SOAP options:

   WS-RP=yes;
   wsrp-from=[identification for endpoint];

17.6.2. Traversing Message Paths

The initial WS-Routing sender generates a WS-Routing "path" header that indicates the route. The path can indicate a route via one or more intermediaries using the "via" elements as sub-elements of the "fwd" element. The initial sender indicates the ultimate destination by using a "to" element. In the absence of a "to" element the ultimate destination is deduced by the last "via" in the "fwd" element. The second option occurs most commonly when an ultimate destination reverses roles, becomes an initial sender, and uses the reverse path in a received message as a forward path to send a response to the original sender.

In addition, the initial WS-Routing sender inserts a reverse path for indicating where the initial sender can receive reverse path messages. The initial sender sets the ultimate destination in the reverse path using a "via" element as a sub-element of the "rev" element.

A WS-Routing receiver receiving a WS-Routing message inspects the SOAP header and performs the following operations:

- If no "fwd" element is present or if the "fwd" element does not contain any "via" elements then inspect the "to" element and verify that the value identifies itself. If this is the case then THIS receiver is the ultimate destination. If there is no "to" element or if the value of the "to" element does not identify THIS WS-Routing receiver then generate a fault.
- If the "fwd" element is present and contains one or more "via" element(s) then remove the top "via" element listed in the "fwd" element and verify that the value of that "via" element is either empty or identifies THIS WS-Routing receiver. Failing that generate an appropriate WS-Routing fault

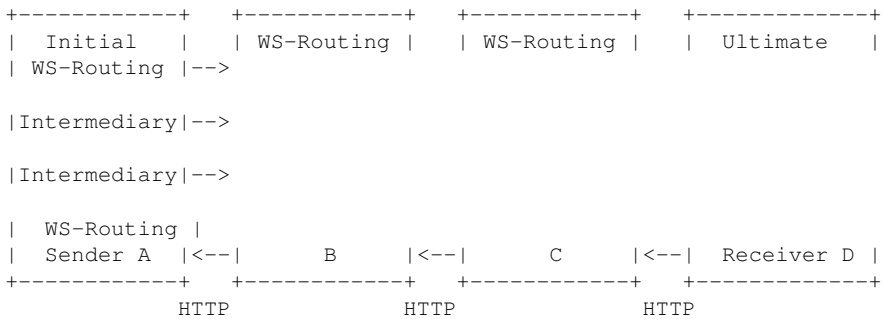
If, after removing the top "via" element there are no remaining "via" element(s) listed in the "fwd" element, and there is no "to" element, then THIS WS-Routing receiver is the ultimate destination.

A WS-Routing intermediary MUST follow these additional rules:

- If a "rev" element is present then add a "via" element as the first "via" element listed in the "rev" element with a value indicating the reverse path endpoint. If a reverse path endpoint cannot be provided then generate a 751 "Reverse Path Unavailable" WS-Routing fault.
- If one or more "via" element(s) remain in the "fwd" element then forward the WS-Routing message to the endpoint identified by the new top "via" element listed in the "fwd" element.
- If there are no remaining "via" element(s) listed in the "fwd" element but there is a "to" element then forward the WS-Routing message to the endpoint identified by the "to" element.
- In the last two cases if the forwarding does not succeed then generate the appropriate WS-Routing fault.

Example 17.29. WS Routing Example

Here is an example SOAP call from a client to an endpoint D.com via intermediaries B.com and C.com:



Request from client to intermediary B

```
<S:Envelope>
<S:Header>
  <m:path
     xmlns:m="http://schemas.xmlsoap.org/rp/"
     S:actor="http://schemas.xmlsoap.org/soap/actor/next"
     S:mustUnderstand="1">
   <m:action>http://soapinterop.org/</m:action>
   <m:to>http://D.com/router</m:to>
   <m:id>uuid:09233523-345b-4351-b623-5dsf35sgs5d6</m:id>
   <m:fwd>
    <m:via>http://B.com/router</m:via>
    <m:via>http://C.com/router</m:via>
   </m:fwd>
   <m:rev />
  </m:path>
</S:Header>
<S:Body>
...
</S:Body>
</S:Envelope>
```

Request from intermediary B to intermediary C

```
<n0:Envelope>
<n0:Header>
  <n2:path
     xmlns:n2="http://schemas.xmlsoap.org/rp/"
     n0:actor="http://schemas.xmlsoap.org/soap/actor/next"
     n0:mustUnderstand="1">
   <n2:action>http://soapinterop.org/</n2:action>
   <n2:to>http://D.com/router</n2:to>
   <n2:id>uuid:09233523-345b-4351-b623-5dsf35sgs5d6</n2:id>
   <n2:fwd>
     <n2:via>http://C.com/router</n2:via>
   </n2:fwd>
```

```
    <n2:rev>
      <n2:via />
    </n2:rev>
  </n2:path>
</n0:Header>
<n0:Body>
...
</n0:Body>
</n0:Envelope>
```

Request from intermediary C to endpoint D

```
<n0:Envelope>
  <n0:Header>
    <n2:path
      xmlns:n2="http://schemas.xmlsoap.org/rp/"
      n0:actor="http://schemas.xmlsoap.org/soap/actor/next"
      n0:mustUnderstand="1">
     <n2:action>http://soapinterop.org/</n2:action>
     <n2:to>http://D.com/router</n2:to>
     <n2:id>uuid:09233523-345b-4351-b623-5dsf35sgs5d6</n2:id>
     <n2:fwd />
     <n2:rev>
      <n2:via />
      <n2:via />
     </n2:rev>
   </n2:path>
</n0:Header>
<n0:Body>
...
</n0:Body>
</n0:Envelope>
```

Response from endpoint to C

```
<n0:Envelope>
<n0:Header>
  <n2:path xmlns:n2="http://schemas.xmlsoap.org/rp/"
          n0:actor="http://schemas.xmlsoap.org/soap/actor/next"
          n0:mustUnderstand="1">
        <n2:action>http://soapinterop.org/</n2:action>
        <n2:id>uuid:2b2d09ec-a93a-11d6-be21-c9f55c969fe7</n2:id>
        <n2:relatesTo>uuid:09233523-345b-4351-b623-5dsf35sgs5d6</n2:relatesTo>
        <n2:fwd>
          <n2:via />
          <n2:via />
        </n2:fwd>
        <n2:rev>
           <n2:via>http://D.com/router</n2:via>
        </n2:rev>
        <n2:from />
  </n2:path>
</n0:Header>
<n0:Body>
...
</n0:Body>
</n0:Envelope>
```

Response from intermediary C to B

```
<n0:Envelope>
 <n0:Header>
    <n2:path xmlns:n2="http://schemas.xmlsoap.org/rp/"
             n0:actor="http://schemas.xmlsoap.org/soap/actor/next"
             n0:mustUnderstand="1">
        <n2:action>http://soapinterop.org/</n2:action>
        <n2:id>uuid:2b2d09ec-a93a-11d6-be21-c9f55c969fe7</n2:id>
        <n2:relatesTo>uuid:09233523-345b-4351-b623-5dsf35sgs5d6</n2:relatesTo>
        <n2:fwd>
          <n2:via />
        </n2:fwd>
        <n2:rev>
```

```
            <n2:via>http://C.com/router</n2:via>
            <n2:via>http://D.com/router</n2:via>
          </n2:rev>
          <n2:from />
       </n2:path>
</n0:Header>
<n0:Body>
...
</n0:Body>
</n0:Envelope>
```

Response from intermediary B to client

```
<n0:Envelope>
<n0:Header>
    <n2:path xmlns:n2="http://schemas.xmlsoap.org/rp/"
             n0:actor="http://schemas.xmlsoap.org/soap/actor/next"
             n0:mustUnderstand="1">
           <n2:action>http://soapinterop.org/</n2:action>
           <n2:id>uuid:2b2d09ec-a93a-11d6-be21-c9f55c969fe7</n2:id>
           <n2:relatesTo>uuid:09233523-345b-4351-b623-5dsf35sgs5d6</n2:relatesTo>
              <n2:fwd />
           <n2:rev>
              <n2:via>http://B.com/router</n2:via>
              <n2:via>http://C.com/router</n2:via>
              <n2:via>http://D.com/router</n2:via>
           </n2:rev>
           <n2:from />
      </n2:path>
</n0:Header>
<n0:Body>
...
</n0:Body>
</n0:Envelope>
```

17.7. Web Services Reliable Messaging Protocol (WS-ReliableMessaging)

The WS-ReliableMessaging protocol is a SOAP-based RPC protocol for guaranteed delivery of messages; possibly in specific order from one sender to one receiver. Such messages are usual SOAP messages - XML documents conforming to the SOAP specification. The Sender is an alias of the transmission initiator, i.e. the originator of the message transfer. The Receiver is a recipient, that which accepts the messages. How accepted messages should be processed is not covered in this document.; What to do with the data and whether to send replies is at the discretion of the application.

See Also:
WS Reliable Messaging

WS Reliable Messaging Exec Summary

Further in this section for brevity WS-RM will be used in place of "Web Services Reliable Messaging Protocol".

Delivery Assurances Types:

AtMostOnce - Delivery at most once without duplication or an error will be raised on at least one endpoint. It is possible that some messages in a sequence may not be delivered.

AtLeastOnce - Every message sent will be delivered or an error will be raised on at least one endpoint. Some messages may be delivered more than once.

ExactlyOnce - Every message sent will be delivered without duplication or an error will be raised on at least one endpoint. This delivery assurance is the logical "and" of the two prior delivery assurances.

InOrder - Messages will be delivered in the order that they were sent. This delivery assurance may be combined with any of the above delivery assurances. It requires that the sequence observed by the ultimate receiver be non-decreasing. It says nothing about duplications or omissions.

WS-RM System Table Definitions in the Appendix section

17.7.1. SOAP CLIENT API Extensions

The SOAP Client API is used for handling, building and accessing complex types required to perform a SOAP request. It allows you to build a structures to access their elements and to build values suitable for passing to the `SOAP_CLIENT()` function. It also allows to de-serialize a SOAP response to a `soap_parameter` and access its members and attributes safely.

Vectors are used to pass or retrieve a complex type using SOAP These vectors contain special content or UDTs. In SOAP, structures are allowed to have multiple members of the same name, or conditional members (choices). Thus it is not possible to cover all variants of XSD types with UDTs (which would be the most elegant way to represent structures). So to cover all variants of structure handling or to express structures containing attributes, we have to use vectors. Since we used a special structure with vectors for expressing such complex types we introduce the following API to deal with them.

The base of API is a UDT 'soap_parameter':

```
create type soap_parameter as
                (
                  s any default null,
                  param_type int default 1,
                  param_xsd varchar default null,
                  ver int default 11
                )
                temporary self as ref
;
```

Its members are:

's' - a vector representing a structure, array or simple type.
'param_type' - designates what is kept in 's' : 1 is struct ; 0 - simple type; 2 - array
'param_xsd' - URL; QName of the type stored in 's'
'ver' - soap version to be used for serialization/deserialization if RPC style is used.
Its Constructors are:

```
constructor method soap_complex_parameter ()
Instantiate an empty structure placeholder;

constructor method soap_simple_parameter (val any),
Instantiate an empty simple type placeholder

constructor method soap_array_parameter (n int),
Instantiate an array placeholder

constructor method soap_single_parameter (elm soap_parameter),
Instantiate an element of containing a type of 'elm'
```

Its Methods are:

```
method get_length () returns any,
Returns the  length of the parameter

method add_member (name varchar, val any) returns any,
Add a new member element to the structure placeholder

method set_member (name varchar, val any) returns any
Sets the value of an existing member by name or will add a new member  if  the member does not exist

method set_member (pos int, val any) returns any,
the same as above but using ordinal position of the member;

method get_member (name varchar) returns any,
Returns a member's value by name

method get_member (pos int) returns any,
Returns member value by ordinal position

method get_value () returns any,
```

```
Returns value for simple types. Only for simple type is applicable

method set_value (val any) returns any,
Sets the value of a simple type

method set_attribute (name varchar, val any) returns any,
Set an attribute value of a structure or simple type

method get_attribute (name varchar) returns any,
Return an attribute value of a structure or simple type

method get_call_param (name varchar) returns any,
```

Serializes the parameter in a form suitable for passing to the SOAP_CLIENT() function. When several parameters needs to be passed to it, then result of those calls must be concatenated (see vector_concat()) Important: set_xsd have to be called with valid ExQName, before doing get_call_param call.

```
method set_xsd (xsd varchar) returns any,
```

Establish a SOAP data-type Expanded QName, referencing the data kept in the soap_parameter. This is a reference to a SOAP complex data-type already defined with soap_dt_define () function (see function reference). This method only sets the relation between data kept in soap_parameter and doesn't check its validity unless serialize is performed. The data-type Expanded QName also will be included into output of the get_call_param method.

Example 17.30. Complex WS Type Example

Consider the following complex type:

```
<xsd:complexType
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    name="SOAPComplexType"
    targetNamespace="http://soapinterop.org/xsd">
 <xsd:sequence>
        <xsd:element minOccurs="1" maxOccurs="1" name="varInt" type="xsd:int" />
        <xsd:element minOccurs="0" maxOccurs="1" name="varString" type="xsd:string" />
        <xsd:element minOccurs="1" maxOccurs="1" name="varFloat" type="xsd:float" />
 </xsd:sequence>
</xsd:complexType>

declare s soap_parameter ;
s := new soap_parameter ();
s.set_xsd ('http://soapinterop.org/xsd:SOAPComplexType');
s.add_member ('varString', 'string');
s.serialize ('mystruct'); -- will generate an error as, varInt and varFloat are
                                    -- missing but they are declared as minOccurs="1"
```

So if we add two more members, and remove varString, to the statements above.

```
s.add_member ('varInt', 123);
s.add_member ('varFloat', 3.14);
s.serialize ('mystruct');
```

Will produce valid output:

```
<mystruct><varInt>123</varInt><varFloat>3.14</varFloat></mystruct>
```

and finally we can make a parameter for the SOAP_CLIENT() function:

```
par := s.get_call_param ('par1');
```

here are the contents of 'par':

```
(
  ("par1", "http://soapinterop.org/xsd:SOAPComplexType" ), -- designates parameter par1, with type SOAPCo
  (<COMPOSITE>, "",     -- this is a marker that it's a struct
        "varInt", 123,  -- the members name/value pairs follows
        "varFloat", 3.14
```

```
    )
)
```

Further methods are:

```
method deserialize (xs any, elem varchar) returns any,
```

Deserializes a element 'elem' from 'xs' (XML tree object) the the soap_parameter.

```
method serialize (tag varchar) returns any,
```

Returns an XML document representing the data kept into the soap_parameter.

```
method set_struct (s any) returns any
```

Explicitly sets the structure/array/simple type kept in the soap_parameter UDT. This can be used to disassemble a nested complex type into its components.

Example 17.31. Example Using WS-RM

echoStruct invocation

```
declare ret any;
declare pa soap_parameter;

pa := new soap_parameter ();
pa.add_member ('varString', 'My String');
pa.add_member ('varInt', 12345);
pa.add_member ('varFloat', 3.1415926);
pa.set_xsd ('http://soapinterop.org/xsd:SOAPStruct');

ret := SOAP_CLIENT (url=>'http://.../interop',
  operation=>'echoStruct', parameters=>pa.get_call_param ('inputStruct'));

pa := new soap_parameter ();
pa.set_xsd ('http://soapinterop.org/xsd:SOAPStruct');
pa.deserialize (ret, 'CallReturn');
return pa.get_member ('varString');
```

echoDocument invocation

```
declare ret any;
declare doc, pa soap_parameter;

doc := new soap_parameter ('The document content');
doc.set_attribute ('ID', uuid());
doc.set_xsd ('http://soapinterop.org/xsd:x_Document');

ret := SOAP_CLIENT (url=>'http://.../r3/Compound1', operation=>'echoDocument',
  parameters=>doc.get_call_param ('x'), style=>1);

pa := new soap_parameter ();
pa.set_xsd ('http://soapinterop.org/xsd:Document');
pa.deserialize (ret, 'result_Document');
dbg_obj_print (pa.s);

return pa.get_attribute ('ID');
```

`SOAP_CLIENT()`

17.7.2. WS-RM Sender API

The WS-RM API allows for:

register/start a conversation
set parameters on both sides (receiver or sender)
check the acknowledgment
retry if needed
to finish or cancel the conversation (can be with cancel)
check for faults
The User Defined Types defined in support of WS-RM are as follows:

- *soap_client () parameters wrapper*

```
create type soap_client_req as
        (
        url varchar,
        operation varchar,
        target_namespace varchar default null,
        parameters any default null,
        headers any default null,
        soap_action varchar default '',
        attachments any default null,
        ticket any default null,
        passwd varchar default null,
        user_name varchar default null,
        user_password varchar default null,
        auth_type varchar default 'none',
        security_type varchar default 'sign',
        debug integer default 0,
        template varchar default null,
        style integer default 0,
        version integer default 11,
        direction integer default 0
        )
;
```

  This UDT is used for passing various parameters to the WS-RM client to send a SOAP messages along with WS-RM specific headers. The members are with same names as for SOAP_CLIENT () function. In other words applications must fill a soap_client_req specific data and pass this to the wsrm_cli methods (see below).
- *client addressing UDT:* To facilitate two-way transport the receiver must know the address of the sender's responder (endpoint for asynchronous Acknowledgment or response). To pass such addresses to the WS-RM client (wsrm_cli) the following UDT is used.

```
create type wsa_cli as
        (
        mid varchar default null,
        "to" varchar default null,
        "from" varchar default null,
        action varchar default null,
        fault_to varchar default null,
        reply_to varchar default null
        )
```

  Whose members are as follows:

  mid - message identifier; unique across space and time
  to - where message traveling to
  from - from where it's sent
  action - WS-Addressing Action headed element
  fault_to - where to return the fault
  reply_to - where to reply; if no such URL given the "to" will be used to reply.

  Important Note:

Important Note:

A special "to" equal to 'http://schemas.xmlsoap.org/ws/2004/08/addressing/role/anonymous ' is used to designate an 'anonymous' sender. Further Acknowledgment can be made as a synchronous reply only. There is no way to return a response in asynchronous manner.

Constructors:

```
constructor method wsa_cli ()
```

Instantiate a new addressing placeholder ; with new message id.

- *WS-RM Client UDT* The following is a core UDT for the sender's activity. It is used to establish a message sequence context, to set various parameters and to send/check/cancel WS-RM encapsulated SOAP messages to the sender.

```
create type wsrm_cli as
        (
        url varchar,
        seq varchar,
        msgno int default -1,
        assurance varchar,
        expiry datetime,
        address wsa_cli,
        i_timeout int,
        resend_intl int,
        ack_intl int,
        dirty int default 0,
        is_last int default 0,
        is_finish int default 0
        )
        temporary self as ref
```

Members:

url - the recipient's URL

seq - identifier; unique Id for batch of messages to be sent together

msgno - unique number/unsigned integer greater than 1, unique identifying a message within a sequence

assurance - policy to be applied on receiver side : AtLeastOne; InOrder; AtMostOne

expiry - message expiration

address - a UDT of type `wsa_cli` ; identifying sender and receiver URLs

i_timeout - inactivity timeout

ack_intl - Acknowledgment interval

dirty - (internal use)

is_last - the current message is a last in sequence

is_finish - transfer is finished; no more messages are pending

Constructors:

```
constructor method wsrm_cli (addr wsa_cli, url varchar),
```

Instantiate a new WS-RM sender object; new message sequence This will generate a new sequence identifier, and will store it into a outgoing sequences table. The default policy will be established.

```
constructor method wsrm_cli (addr wsa_cli, url varchar, seq varchar),
```

Instantiate a WS-RM sender object from a persisted state; The policy and parameters will be read from database and instantiated in WS-RM sender's object.

Methods:

```
method create_sequence () returns any,
```

Start a new sequence with current WS-RM sender's object;

```
method send_message (req soap_client_req, last int) returns any,
```

Send a message to the recipient; depending on 'last' flag this can be designate open or closed message sequence. The 'req' must be fulfilled with appropriate parameters (see above).

```
method send_message (req soap_client_req) returns any,
```

same as send_message (req soap_client_req, 0)

```
method finish (req soap_client_req) returns any,
```

same as send_message (req soap_client_req, 1)

```
method check_state () returns any,
```

retrieves a state for a sequence. If sequence is closed and all is delivered no remote call will be performed. If an message is in pending state a remote call will be issued to check the state of message sequence. The return value is an array containing message numbers (id's within sequence) and their state: 0 or 1 - send or pending

```
method cancel () returns any,
```

cancel the sequence; kill it on WS-RM sender site ; say that to recipient to do that also.

```
method set_parameter (name varchar, val any) returns any,
```

Set a parameter to the current message sequence : like policy; timeout etc. The parameters will be sent together with next WS-RM conversation. Note: Some of parameters may invalidate previous state of message transfer; so in this case the sender will receive a fault and application must handle the situation properly.

Valid 'name's are :

Assurance - 'AtMostOnce','AtLeastOnce','ExactlyOnce','InOrder'
Expiry - date of expiration
Timeout - inactivity timeout in milliseconds
RetryInterval - retry on every n milliseconds if message is not sent
AckInterval - Acknowledgment interval in milliseconds

Sender's responder (endpoint) . To receive an asynchronous Acknowledgment the sender must have an endpoint to handle them. The `WSRMSequenceAcknowledgment()` procedure must be exposed at that endpoint. This accepts and processes asynchronous Acknowledgment. This is used to accept a SequenceAcknowledgment response from a remote party so it will process the response and will set the state of messages that are acknowledged.

17.7.3. WSRM Receiver API

On the receiver side we have PL wrappers that take as arguments all *known* WS-RM headers. This procedure, when granted to a SOAP endpoint will process the incoming requests. It will also answer send the appropriate answers to the sender.

The following is the list of WS-RM receiver wrappers:

1. **WSRMSequence .** accept and store a Sequence requests. This is used to accept Sequence requests from sender and will perform the following actions:

   store the message in incoming message log table

   process and apply the Policy attachment (if supplied); otherwise apply default rule: AtMostOnce

   depending of a addressing headers will reply in synchronous or asynchronous manner. This depends on the value of "From" and "ReplyTo" headers. If these contains non-anonymous URL (see above); an asynchronous Acknowledgment will be sent in a separate TCP connection. Thus in this mode the sender must have defined a listener with WSRMSequenceAcknowledgment exposed to accept such responses. Otherwise synchronous Acknowledgment will be sent in the same TCP connection.

If an error occurred a Fault will be generated

2. **WSRMSequenceTerminate .** accept and process SequenceTerminate requests. This is used to accept cancel request; to kill an existing message sequence. Further actions on such sequence will be rejected.
3. **WSRMAckRequested .** accept and process AckRequested requests. This is used to process AckRequested WS-RM messages and will produce a SequenceAcknowledgment containing info about messages been accepted. Used from sender's side to check the message sequence state.

These PL procedures are built-in to the server, and have to be granted to the user that is assigned as the SOAP execution account for a given virtual directory designated as a WS-RM receiver endpoint.

17.7.4. WS-RM Protocol Endpoint Configuration

The setup is a virtual directory definition and grant of rights to the procedures for sender and receiver endpoints.

This will be demonstrated as an example of setting up both endpoints:

- *Sender*

```
create user WSRMS;
grant execute on WSRMSequenceAcknowledgment to WSRMS;
vhost_define (lpath=>'/replyto', ppath=>'/SOAP/', soap_user=>'WSRMS');
```

- *Reply*

```
create user WSRMR;
grant execute on WSRMSequence to WSRMR;
grant execute on WSRMSequenceTerminate to WSRMR;
grant execute on WSRMAckRequested to WSRMR;
vhost_define (lpath=>'/wsrm', ppath=>'/SOAP/', soap_user=>'WSRMR');
```

Example 17.32. WS-RM Ping Test Example

This is an example client used to perform the interoperability test "Ping" as proposed in "Interop Workshop Scenarios"

```
soap_dt_define ('',
                '<element
                        xmlns="http://www.w3.org/2001/XMLSchema"
                        name="Ping" type="test:Ping_t"
                        targetNamespace = "http://tempuri.org/" xmlns:test="http://tempuri.org/" />');

soap_dt_define ('',
                '<complexType xmlns="http://www.w3.org/2001/XMLSchema"
                              name="Ping_t" targetNamespace = "http://tempuri.org/">
                                <sequence>
                                        <element minOccurs="1" maxOccurs="1" name="Text" type="string"/>
                                </sequence>
                </complexType>');

create procedure WSRMTestPing (in _to varchar, in _from varchar)
  {
    declare addr wsa_cli;
    declare test wsrm_cli;
    declare req soap_client_req;
    declare finish any;
    declare ping soap_parameter;

    ping := new soap_parameter (1);

    ping.set_xsd ('http://tempuri.org/:Ping');
    ping.s := vector ('Hello World');

    addr := new wsa_cli ();
    addr."to" := _to;
    addr."from" := _from;
    addr.action := 'urn:wsrm:Ping';

    req := new soap_client_req ();
    req.url := _to;
    req.operation := 'Ping';
```

```
    req.parameters := ping.get_call_param ('');

    test := new wsrm_cli (addr, _to);

    test.send_message (req);
    test.send_message (req);
    test.finish (req);
    return test.seq;
  }
;
```

17.7.5. Message Examples

Example 17.33. Example: Initial request

```
<SOAP:Envelope>
  <SOAP:Header>
    <wsa:MessageID>uuid:aa8bd508-110b-11d8-8344-8cfad4a25a87</wsa:MessageID>
    <wsa:To>http://host:9999/wsrm</wsa:To>
    <wsa:From>
      <wsa:Address>http://host:9999/replyto</wsa:Address>
    </wsa:From>
    <wsa:Action><!-- depending of application -->

</wsa:Action>
    <wsrm:Sequence>
      <wsu:Identifier>uuid:aa8bfa74-110b-11d8-8344-8cfad4a25a87</wsu:Identifier>
      <wsrm:MessageNumber>1</wsrm:MessageNumber>
    </wsrm:Sequence>
  </SOAP:Header>
  <SOAP:Body>
    <!-- some application data -->

  </SOAP:Body>
</SOAP:Envelope>
```

receiver accepts and return just

```
HTTP/1.1 202 Accepted
Content-Length: 0
```

Last message

```
<SOAP:Envelope>
  <SOAP:Header>
    <wsa:MessageID>uuid:aa8bd508-110b-11d8-8344-8cfad4a25a87</wsa:MessageID>
    <wsa:To>http://host:9999/wsrm</wsa:To>
    <wsa:From>
      <wsa:Address>http://host:9999/replyto</wsa:Address>
    </wsa:From>
    <wsa:Action><!-- depending of application -->

</wsa:Action>
    <wsrm:Sequence>
      <wsu:Identifier>uuid:aa8bfa74-110b-11d8-8344-8cfad4a25a87</wsu:Identifier>
      <wsrm:MessageNumber>2</wsrm:MessageNumber>
      <wsrm:LastMessage/>
    </wsrm:Sequence>
  </SOAP:Header>
  <SOAP:Body>
    <!-- some application data -->

  </SOAP:Body>
</SOAP:Envelope>
```

receiver accepts and returns

```
HTTP/1.1 202 Accepted
Content-Length: 0
```

Sequence Acknowledgment response; sent via another channel

```
<SOAP:Envelope>
  <SOAP:Header>
    <wsa:MessageID>uuid:aadedf64-110b-11d8-8344-8cfad4a25a87</wsa:MessageID>
    <wsa:To>http://schemas.xmlsoap.org/ws/2004/08/addressing/role/anonymous</wsa:To>
    <wsa:From>
      <wsa:Address>http://schemas.xmlsoap.org/ws/2004/08/addressing/role/anonymous</wsa:Address>
    </wsa:From>
    <wsa:Action>http://schemas.xmlsoap.org/ws/2004/08/rm#SequenceAcknowledgment</wsa:Action>
    <wsrm:SequenceAcknowledgment>
      <wsu:Identifier>uuid:aa8bfa74-110b-11d8-8344-8cfad4a25a87</wsu:Identifier>
      <wsrm:AcknowledgmentRange Upper="2" Lower="1"/>
    </wsrm:SequenceAcknowledgment>
  </SOAP:Header>
  <SOAP:Body/>
</SOAP:Envelope>
```

initial sender accepts and returns

```
HTTP/1.1 202 Accepted
Content-Length: 0
```

17.7.6. WS-RM Schema

```
<xsd:schema
    targetNamespace="http://schemas.xmlsoap.org/ws/2003/03/rm"
        xmlns:wsu="http://schemas.xmlsoap.org/ws/2002/07/utility"
        xmlns:wsrm="http://schemas.xmlsoap.org/ws/2003/03/rm"
        xmlns:xsd="http://www.w3.org/2001/XMLSchema"
        elementFormDefault="qualified" attributeFormDefault="unqualified">

        <!-- *** BASE *** -->

    <xsd:complexType name="SequenceType">

    </xsd:schema>
```

17.8. Web Services Trust Protocol (WS-Trust)

In order to secure communication between two parties, the two parties must exchange security credentials (either directly or indirectly). However, each party needs to determine if they can "trust" the asserted credentials of the other party. WS-Security defines the basic mechanisms for providing secure SOAP messaging. WS-Trust is an extension of WS-Security for security token exchange to enable the issuance and dissemination of credentials within different trust domains, and thus manage trust relationships. The goal of WS-Trust is to enable applications to construct trusted SOAP message exchanges.

Using these extensions, applications can engage in secure communication designed to work with the general Web Services framework, including WSDL service descriptions, UDDI businessServices and bindingTemplates, and SOAP messages.

WSS (WS-Security) enabled endpoint can make use of (WST) WS-Trust by exposing the "`RequestSecurityToken` " method. It then will check the WSS headers, decode if appropriate and pass the request parameters to the RequestSecurityToken method.

Virtuoso supports and can generate many session key types. Supported key types are: DSA, 3des and AES. RSA keys can be imported but not generated, likewise x509 certificate generation, however they will be added in the near future.

WSS uses the `UsernameToken` method to bind an issued security token to a particular user.

Each WS enabled SOAP endpoint should have a list of supported encryption methods, keys that may be issued, and authorized users. This can be achieved using a PL (Stored Procedure) hook.

See Also:
Web Services Trust Language (WS-Trust)

The message flow involving WST endpoints will be as follows:

The client (1st instance) must ask the WST endpoint for token (security token, may be a 3des key x509 certificate or whatever security tokens are supported)

WST endpoint may or may not issue a token to the client.

Client sends a message to 2nd instance (the target) to perform the main request.

The 2nd instance (recipient) may accept or reject the request.

The 2nd instance may also ask WST for the token, to encrypt the data for client, which depends on the policy to be applied.

The client has to have a way to know what policy to apply. This can be a UDT that is initialized appropriately and passed to the client routines.

SOAP clients have to have an API to perform:

Request a security token from WST

Invoke the method from recipient with token obtained from WST endpoint.

```
wst_cli(req, policy)
```

The call to `wst_cli` performs the following actions:

For the URL of request determine whether a policy is needed; scan over policy array by URL.

If token has an issuer, then ask issuer with policy conforming to it (obtain via URL from policy array).

Apply the obtained token to the request and pass to the ultimate receiver.

Return response from ultimate receiver.

Server tokens are stored in the `WST_SERVER_ISSUER_TOKENS` system table.

See Also:

WST_SERVER_ISSUER_TOKENS

Tokens can be selected using the system procedure:

```
DB.DBA.WS_TRUST_TOKEN_GEN (
  in "From" any,
  in "MessageID" any,
  in "RequestSecurityToken" any,
  in "Timestamp" any,
  in "To" any).
```

This procedure can be over-ridden for specific cases. The definition of the default procedure is shown below.

```
create procedure  DB.DBA.WS_TRUST_TOKEN_GEN (
  in "From" any,
  in "MessageID" any,
  in "RequestSecurityToken" any,
  in "Timestamp" any, in "To" any )
{
   declare ret any;
   declare t_type, r_type, l_from varchar;

   t_type := cast ("RequestSecurityToken"[3] as varchar);
   r_type := cast ("RequestSecurityToken"[5] as varchar);
   l_from := cast ("From"[3] as varchar);

   select WSK_TOKEN into ret from WST_SERVER_ISSUER_TOKENS
               where WSK_TOKEN_TYPE = t_type and
                 WSK_REQUEST_TYPE = r_type and WSK_FROM = l_from;

   return ret;
}
;
```

Example 17.34. Example

1) client ask for context token token service:

```
<soap:Envelope
  xmlns:wsa="http://schemas.xmlsoap.org/ws/2004/08/addressing"

17.9. XML for Analysis Provider

XML for Analysis (XMLA) is a SOAP based XML API for data access interaction between a client application and a data provider working over the Web. The Virtuoso SOAP server can act as an XMLA data provider, also the Virtuoso SOAP client can be used as a client to talk with an XMLA data provider.

The following terms: result-set and row-set will be used interchangeably to designate repeating content with identical structure. The mention of a result-set and row-set in this document is related to an SQL/ODBC result set which is represented as XML for use in XMLA.

The implementation is based on the "XML for Analysis Specification v 1.0" by Microsoft Corp, found on the MSDN website.

The XMLA protocol consists of two SOAP operations: "Discover" and "Execute" which are described below:

The *Discover* operation is used to retrieve settings and database object information. It accepts the following input parameters:

RequestType - enumerated string.
Restrictions - a structure of restrictions to be applied to the processing of request, the type values may vary, depending on the request.
Properties - properties to the request, such as data source name, initial catalog etc.
Upon success the "Discover" operation will return a specific rowset. The 'specific' means that its structure depends of type of request.

The XMLA data provider supports the following discovery rowsets:

`DISCOVER_DATASOURCES` - to discover available data sources
`DISCOVER_PROPERTIES` - the properties which can be used/set
`DISCOVER_SCHEMA_ROWSETS` - this list itself with allowed restrictions
`DISCOVER_ENUMERATORS` - enumeration values supported by provider
`DISCOVER_KEYWORDS` - reserved words
`DISCOVER_LITERALS` - restrictions on database object names etc.
`DBSCHEMA_CATALOGS` - list of catalogs
`DBSCHEMA_TABLES` - list of tables
`DBSCHEMA_TABLES_INFO` - list of info about tables
`DBSCHEMA_COLUMNS` - list of columns
`DBSCHEMA_PROVIDER_TYPES` - list of datatypes
Here is an example of a response message to the Discover invocation:

```
----
<SOAP:Envelope SOAP:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
  <SOAP:Body>
    <cli:DiscoverResponse xmlns:cli="urn:schemas-microsoft-com:xml-analysis">
      <Result xmlns="">
        <root xmlns="urn:schemas-microsoft-com:xml-analysis:rowset">
          <n0:schema xmlns:n0="http://www.w3.org/2001/XMLSchema"
                     targetNamespace="urn:schemas-microsoft-com:xml-analysis:rowset"
                     elementFormDefault="qualified">
            <n0:element name="root" type="n2:root" xmlns:n2="urn:schemas-microsoft-com:xml-analysis:rowse
            ... more declarations ...
          </n0:schema>
          <row xmlns="urn:schemas-microsoft-com:xml-analysis:rowset">
            ... rowset data ...
          </row>
        </root>
      </Result>
    </cli:DiscoverResponse>
  </SOAP:Body>
</SOAP:Envelope>
  ----
```

The client can use information retrieved with the "Discover" operation for automatically formulating queries etc.

The *Execute* operation is used to process a SQL statement on the server and to return resultset or/and schema description for the resultset. The current implementation supports only SQL statements. It accepts the following input parameters:

Command - a structure with single element - "Statement" , which contains the SQL statement.

Properties - properties to the execution process.
On success the "Execute" operation will return the rowset and/or XSD for the rowset.

```
----
<SOAP:Envelope SOAP:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
  <SOAP:Body>
    <cli:ExecuteResponse xmlns:cli="urn:schemas-microsoft-com:xml-analysis">
      <Result xmlns="">
        <root xmlns="urn:schemas-microsoft-com:xml-analysis:rowset">
          <n0:schema xmlns:n0="http://www.w3.org/2001/XMLSchema"
                     targetNamespace="urn:schemas-microsoft-com:xml-analysis:rowset"
                     elementFormDefault="qualified">
            <n0:element name="root" type="n2:root" xmlns:n2="urn:schemas-microsoft-com:xml-analysis:rowse
            ... more XSD declarations ...
          </n0:schema>
          <row xmlns="urn:schemas-microsoft-com:xml-analysis:rowset">
            ... rowset data ...
          </row>
          more <row> elements
        </root>
      </Result>
    </cli:ExecuteResponse>
  </SOAP:Body>
</SOAP:Envelope>
 ----
```

The XML representation of the result sets can have three forms: Tabular, Multidimensional and Custom. As the Virtuoso server is a tabular data provider itself, hence the current XMLA implementation supports only Tabular representation.

The Tabular representation of the result set consist of two main parts:

schema - XML Schema definition of result

data - sequence of repeating elements, each consisting of elements representing the cells in the rowset

Security . The Execute operation needs the properties Username and Password to be supplied in order to execute the statement on behalf of an SQL user account. If these are not supplied the request will be rejected with SOAP:Fault message. To prevent a network sniffer from catching the password in clear text, it is strongly recommended that sending of these properties be done via HTTPS (SSL/TLS) connection (for HTTPS setup see Web server section, and tutorials).

State Support . The Virtuoso XMLA provider implements statelessness for the settable properties. This means that properties such as UserName and Password can be set in the beginning and they will be restored on server side on the next request ID for which they are not supplied. This mechanism is very similar to URL poisoning state support, which is described in the Web server section of the documentation. In short, the XMLA client asks to begin a session, the XMLA provider returns a session ID and from that point the client sends this ID to the server. If the client wishes, it may cancel the session with an end session request.

The above requests are SOAP messages carried in the SOAP Header element. Please note that these headers can be sent together with Discover or Execute operations.

Here is a a simple session:

```
- client requests a session
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
                   SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<SOAP-ENV:Header>
  <xmla:BeginSession xmlns:xmla="urn:schemas-microsoft-com:xml-analysis" mustUnderstand="1"/>
</SOAP-ENV:Header>
<SOAP-ENV:Body>
   <!-- Discover or Execute call -->

</SOAP-ENV:Body>
</SOAP-ENV:Envelope>

- server returns the SessionID
<SOAP-ENV:Header>
  <xmla:Session xmlns:xmla="urn:schemas-microsoft-com:xml-analysis" mustUnderstand="1" SessionID="NNNNNN"
</SOAP-ENV:Header>

- sequential requests of client contains:
```

```
<SOAP-ENV:Header>
  <xmla:Session xmlns:xmla="urn:schemas-microsoft-com:xml-analysis" mustUnderstand="1" SessionID="NNNNNN"
</SOAP-ENV:Header>

- and finally client cancel the session:
<SOAP-ENV:Header>
  <xmla:EndSession xmlns:xmla="urn:schemas-microsoft-com:xml-analysis" mustUnderstand="1" SessionID="NNNN
</SOAP-ENV:Header>
```

Namespaces

The request and response are in the "urn:schemas-microsoft-com:xml-analysis" namespace. Also SOAPAction header field must be "urn:schemas-microsoft-com:xml-analysis:Discover" and "urn:schemas-microsoft-com:xml-analysis:Execute" for Discover and Execute operations.

Virtuoso extensions

The following settable properties are available to the execute request:

direction - one of forward, backward

skip - integer

n-rows integer

bookmark-from - string

retrieve-row-count - string

The direction indicates in which direction the cursor moves from the bookmark-from. If there is no bookmark-from, the query is always forward from the start of the evaluation.

skip allows skipping a number of rows in the selected direction. n-rows gives the number of rows to return after the skip. Fewer rows will be returned if the evaluation does not extend this far.

The bookmark is an opaque string, acceptable values are values that have been in a bookmark element of a result row.

return-bookmark boolean

If true, a bookmark element is added to each row of the result set.

A simple request / response is added to samples.

The retrieve-row-count element of the query options must be true for rowcount returning to be enabled.

If retrieve-row-count is specified, the response has a row-count element with a text value containing the total result set size of the query, irrespective of the specified window of rows retrieved. Note that for large result sets getting the row count can be prohibitively expensive.

Virtual directory Setup

To make a virtual directory work as an XMLA data provider it is enough to grant execute permissions on Discover and Execute procedures to the SQL account specified for SOAP execution in this virtual directory.

For compliance with XMLA, the virtual directory attribute elementFormDefault must have the value "qualified" in the XMLA SOAP end point.

Here are the steps for setting up a virtual directory for use with XMLA:

```
create user "XMLA";

user_set_qualifier ('XMLA', 'XMLA');
```

```
VHOST_REMOVE (lpath=>'/XMLA');
VHOST_DEFINE (lpath=>'/XMLA', ppath=>'/SOAP/', soap_user => 'XMLA',
              soap_opts => vector ('ServiceName', 'XMLAnalysis', 'elementFormDefault', 'qualified'));

grant execute on DB.."Discover" to "XMLA";
grant execute on DB.."Execute" to "XMLA";
```

Example 17.36. Simple Discovery Request/Response examples

The following example shows a simple request for discovering data sources and response from server.

```
<?xml version="1.0"?>
<SOAP:Envelope SOAP:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
  <SOAP:Body>
    <cli:Discover xmlns:cli="urn:schemas-microsoft-com:xml-analysis">
      <RequestType xsi:type="xsd:string" dt:dt="string">DISCOVER_DATASOURCES</RequestType>
      <Restrictions xsi:nil="1"/>
      <Properties xsi:nil="1" />
      </Properties>
    </cli:Discover>
  </SOAP:Body>
</SOAP:Envelope>

<SOAP:Envelope SOAP:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
  <SOAP:Body>
    <cli:DiscoverResponse xmlns:cli="urn:schemas-microsoft-com:xml-analysis">
      <Result xmlns="">
        <root xmlns="urn:schemas-microsoft-com:xml-analysis:rowset">
          <n0:schema xmlns:n0="http://www.w3.org/2001/XMLSchema"
                     targetNamespace="urn:schemas-microsoft-com:xml-analysis:rowset"
                     elementFormDefault="qualified">
            <n0:element name="root" type="n2:root" xmlns:n2="urn:schemas-microsoft-com:xml-analysis:rowse
            <n0:complexType name="root">
              <n0:sequence minOccurs="0" maxOccurs="unbounded">
                <n0:element name="row" type="n2:row" xmlns:n2="urn:schemas-microsoft-com:xml-analysis:row
              </n0:sequence>
            </n0:complexType>
            <n0:complexType name="row">
              <n0:choice maxOccurs="unbounded" minOccurs="0">

17.10. XML-RPC support

The XML-RPC is a remote procedure calling system via HTTP using XML as the encoding. It is very much like the SOAP protocol, but the data encoding rules are different. XML-RPC supports fewer data types than SOAP. The data is self-describing and position bound.

The Virtuoso SOAP server can process XML-RPC requests using the XML-RPC to SOAP bridge. This is done with two filters : input and output filter. The input filter transforms XML-RPC into a SOAP PRC encoded message. Then the transformed message is passed to the SOAP server for processing. The response from the SOAP server will be re-coded into XML-RPC format in the output filter. The combination of these filters constitutes the bridge.

It is important to remember that XML-RPC defines two complex types : array and structure. These two types are represented by vector () and soap-structure respectively, when passing the data to the PL procedure in question.

Example 17.37. XML-RPC Procedure Definition

An example of a PL procedure representing an XML-RPC method "echoXRtypes" is:

```
create procedure echoXRtypes (
                                in  inInteger   integer,
                                in  inString    varchar,
                                in  inDate      datetime,
                                in  inDouble    double precision,
                                in  inBoolean   smallint,
                                in  inHex       varchar,
                                out outInteger  integer,
                                out outString   varchar,
                                out outDate     datetime,
                                out outDouble   double precision,
                                out outBoolean  smallint,
                                out outHex      varchar __soap_type 'http://www.w3.org/2001/XMLSchema:bas
                            )
{
    outInteger  := inInteger    ;
    outString   := inString     ;
    outDate     := inDate       ;
    outDouble   := inDouble     ;
    outBoolean  := soap_boolean (inBoolean);
    outHex      := inHex        ;
}
;
```

Note that the definition of such procedures does not differ from those of SOAP procedures.

An XML-RPC request may look like:

```
<?xml version="1.0"?>
<methodCall>
<methodName>echoXRtypes</methodName>
<params>
  <param> <value><i4>42</i4></value> </param>
  <param> <value>String</value> </param>
  <param> <value><dateTime.iso8601>1998-07-17T14:08:55</dateTime.iso8601></value> </param>
  <param> <value><double>1234.567</double></value> </param>
  <param> <value><boolean>1</boolean></value> </param>
  <param> <value><base64>eW91IGNhbid0IHJlYWQgdGhpcyE=</base64></value> </param>
</params>
</methodCall>
```

The response for the above message will be :

```
<?xml version="1.0" encoding="ISO-8859-1" ?>
<methodResponse>
<params>
<param> <value> <i4>42</i4> </value> </param>
<param> <value> <string>String</string> </value> </param>
<param> <value> <dateTime.iso8601>1998-07-17T14:08:55.000+03:00</dateTime.iso8601> </value> </param>
<param> <value> <double>1234.567000</double> </value> </param>
<param> <value> <boolean>1</boolean> </value> </param>
<param> <value> <base64>eW91IGNhbid0IHJlYWQgdGhpcyE=</base64> </value> </param>
</params>
</methodResponse>
```

Enabling the XML-RPC -> SOAP bridge is very simple. You make a virtual directory with physical location pointing to /SOAP/ and specify the 'XML-RPC' SOAP option as 'yes'. The following methods are available:

1. **Virtual Directories Visual Administration Interface .** From the main administration menu go to `Web Servers -> Virtual Directories` and add or configure a virtual directory. For the directory definition add a new option in

SOAP options box: " `XML-RPC=yes;` ".

2. **The vhost_define() Function .** Using the ISQL utility one can use the command:

```
SQL> vhost_define (lpath=>'/RPC2', ppath=>'/SOAP/', soap_user=>'dba',
    soap_opts=>vector ('XML-RPC', 'yes'));
```

Note:

Virtual directories configured in this way can only be used for XML-RPC calls. If you need to make SOAP requests, then another virtual directory will be required.

17.11. SyncML

SyncML is a protocol for synchronization of data collections between two devices - a SyncML Client and SyncML Server using an XML data representation. The client is typically some mobile device or mobile PC. The Virtuoso server implements the SyncML server protocol over HTTP.

The SyncML server maintains the data collections within the WebDAV repository. The items (resources) in the collections (folders) represents items found on the client, e.g. VCARD, vcalendar records. As the WebDAV repository does not restrict the type of data that can be stored, likewise there are no restrictions on the type of data that can be synchronized. Also every WebDAV virtual directory can act as a SyncML server endpoint, the SyncML processing is triggered via the `Content-Type` , detected on the POST request (see below).

See Also:

SyncML Schema Tables

The SyncML server detects the following formats from the `Content-Type` header string:

`application/vnd.syncml+wbxml` - WBXML coded XML documents

`application/vnd.syncml+xml` - plain text XML document

These are detected during the POST request to a WebDAV virtual directory thus triggering SyncML processing. When a device makes creates '`application/vnd.syncml+wbxml` ' session, the SyncML server will respond with the WBXML format. Otherwise plain XML will be used to encode SyncML messages.

Basic and MD5 digest SyncML authorization schemes are supported. The WebDAV enabled user accounts are used to perform authentication.

It is possible to query the HTTP authentication type supported by the target device by assigning an authentication hook to a given virtual directory. By default SyncML authentication is digest-md5, so HTTP authentication is off (note that HTTP authentication is different from SyncML authentication).

The following synchronization methods are supported:

Two-way sync

Slow two-way sync

Every item sent from the client device is mapped to a WebDAV resource under a given WebDAV collection. Every device database, such as contacts, calendar, usually requires that a different WebDAV collection be specified because the devices usually can not maintain items of different kinds with a single database. For example, when synchronizing the Contacts of a Nokia 9210 with the server, we can specify `./contacts/` , and likewise for the Calendar database, `./calendar/` . This keeps VCARDS (contacts) and vCalendars in separate collections (folders) on a given virtual directory. It is not possible to keep calendar and contacts (for example) in the same WebDAV collection, unless the device supports such items in a single database.

Important Note:

The target folders (Virtuoso server-side collections) must exists and must be accessible by the WebDAV account used to authenticate against the SyncML server. If credentials or permissions are insufficient then an Error 403 (Forbidden) will be returned to the client.

Example 17.38. Example of a SyncML session

The client begins initial request

```

17.12. UDDI

17.12.1. Concepts

Universal Description, Discovery and Integration (UDDI) is the name of a web-based service that exposes information about a business or other entities and its technical interfaces or APIs. These services are run by UDDI-enabled servers, and can be used by any business that wants to make their information available, as well as anyone who wants to find that information. There is no charge for using the basic services of these sites.

By accessing any of the public sites, anyone can search for information about web services that are made available by or on behalf of a business. This provides a mechanism that allows others to discover what technical programming interfaces are provided for interacting with a business for such purposes as electronic commerce. The benefit to the individual business is increased exposure in an electronic commerce enabled world.

Businesses can register several kinds of simple data to help others answer questions of "who, what, where and how." Simple information about a business - information such as name, business identifiers (D&B D-U-N-S Number(R), etc.), and contact information answers the question "Who." "What" involves classification information including industry codes and product classifications, as well as descriptive information about the services that are available for electronic interchange. Answering the question "Where" involves registering information about the URL or email address (or other address) through which each type of service may be accessed. Finally, the question "How" is answered by registering references to information about specifications that describe how a particular software package or technical interface functions. These references are called '*tModels*' in the documentation.

17.12.2. Dealing with SOAP

UDDI API functions are exposed as SOAP v1.1 messages over the HTTP protocol. In version 1, the `SOAPAction` HTTP Header is required. The value passed in this HTTP Header must be an empty string that is surrounded by double quotes.

Example 17.39. UDDI and Soap

```
POST /UDDI/inquiry HTTP/1.1
Host: www.foo.com
Content-Type: text/xml
Content-Length: nnnn
SOAPAction: ""

.... body follows ....
```

SOAP is used in conjunction with HTTP to provide a simple mechanism for passing XML messages to UDDI-enabled servers using a standard HTTP-POST protocol. Unless specified, all responses will be returned in the normal HTTP response document.

See Also:
For more information about Virtuoso's SOAP Implementation see the SOAP Services section.

17.12.3. Supported API Calls

The UDDI APIs always return a SOAP entity body which contains messages as described in UDDI v1 XML Schema (uddi_1.xsd).

- *Authorization API* - Used to establish authentication mechanism (tokens), dropping already established connections.
  - *discard_authToken:* Used to inform a UDDI enabled server that a previously provided authentication token is no longer valid.
  - *get_authToken:* Used to request an authentication token from a UDDI-enabled server. Authentication tokens are required to use all other APIs defined in the publishers API. This function serves as the program's equivalent of a login request.
  - *get_registeredInfo:* Used to request an abbreviated synopsis of all information currently managed by a given individual.
- *Searching API* The publicly accessible queries are:
  - *find_binding:* Used to locate specific bindings within a registered `businessService`. Returns a `bindingDetail` message.
  - *find_business:* Used to locate information about one or more businesses . Returns a `businessList` message.
  - *find_service:* Used to locate specific services within a registered `businessEntity`. Returns a `serviceList` message.
  - *find_tModel:* Used to locate one or more `tModel` information structures. Returns a `tModelList` structure.
  - *get_bindingDetail:* Used to get full `bindingTemplate` information suitable for making one or more service requests. Returns a `bindingDetail` message.
  - *get_businessDetail:* Used to get full `businessEntity` information for one or more businesses. Returns a `businessDetail` message.
  - *get_businessDetailExt:* Used to get extended `businessEntity` information. Returns a `businessDetailExt` message.
  - *get_serviceDetail:* Used to get full details for a given set of registered `businessService` data. Returns a `serviceDetail` message.
  - *get_tModelDetail:* Used to get full details for a given set of registered `tModel` data. Returns a `tModelDetail` message.
- *Repository Manipulation API*
  - *delete_binding:* Used to remove an existing `bindingTemplate` from the `bindingTemplate`s collection that is part of a specified `businessService` structure.
  - *delete_business:* Used to delete registered `businessEntity` information from the registry.
  - *delete_service:* Used to delete an existing `businessService` from the businessServices collection that is part of a specified `businessEntity`.
  - *delete_tModel:* Used to delete registered information about a `tModel`. If there are any references to a `tModel` when this call is made, the `tModel` will be marked deleted instead of being physically removed.
  - *save_binding:* Used to register new `bindingTemplate` information or update existing `bindingTemplate` information. Use this to control information about technical capabilities exposed by a registered business.
  - *save_business:* Used to register new `businessEntity` information or update existing `businessEntity` information. Use this to control the overall information about the entire business. Of all the save APIs this one has the broadest effect.
  - *save_service:* Used to register or update complete information about a `businessService` exposed by a specified `businessEntity`.
  - *save_tModel:* Used to register or update complete information about a `tModel`.

17.12.4. Authorization Mechanism

The Publishers API describes the messages that are used to control the content contained within a UDDI-enabled server, and can be used by compliant non-operator implementations that adhere to the behaviors described in this programmer's reference specification.

All calls made to UDDI-enabled servers that use the messages defined in the publisher's API will be transported using SSL encryption. UDDI-enabled servers will each provide a service description that exposes a `bindingTemplate` that makes use of HTTPS and SSL to secure the transmission of data.

Authentication

Each of the calls in the publisher's API that change information at a given UDDI-enabled server requires the use of an opaque authentication token. These tokens are generated by or provided by each UDDI-enabled server independently, and are passed from the caller to the UDDI-enabled server in the element named *authInfo*.

These tokens are meaningful only to the UDDI-enabled server that provided them and are to be used according to the published policies of a given UDDI-enabled server.

Each party that has been granted publication access to a given UDDI-enabled server will be provided a token by the site. The methods for obtaining this token are specific to each UDDI-enabled server.

Establishing Credentials

Before any party can publish data within a UDDI-enabled server, credentials and permission to publish must be supplied with the individual operator. Generally, you will only need to interact with one UDDI-enabled server because all data published at any UDDI-enabled server are replicated automatically to all other such servers. Establishing publishing credentials involves providing some verifiable identification information, contact information, and establishing security credentials with the individual server. The specifics of these establishing credentials is server-dependent, and all valid UDDI-enabled servers provide a Web-based user interface through which you can establish an identity and secure permission to publish data.

Every registry implementation that adheres to these specifications establishes its own mechanism for token generation and authentication. The only requirement placed on token generation for use with the publisher's API is that the tokens themselves must be valid string text that can be placed within the *authInfo* XML element. Given that binary-to-string translations are well-understood and in common use, this requirement will not introduce hardships.

Authentication tokens are not required to be valid except at the UDDI-enabled server or implementation from which they originated. These tokens need only have meaning at a single UDDI-enabled server or implementation, and should not be expected to work across sites.

Generating Authentication Tokens

Many implementations are expected to require a login step. The *get_authToken* message is provided to accommodate implementations that desire a login step. Security schemes based on exchanging User ID and password credentials fall into this category. For implementations that desire this kind of security, the *get_authToken* API is provided as a means of generating a temporary authentication token.

Certificate-based authentication and similar security mechanisms do not require this additional step of logging in. Instead, they can pass compatible authentication token information such as a certificate value within the *authInfo* element provided on each of the publisher's API messages. If certificate-based authentication or similar security is employed the use of the *get_authToken* and *discard_authToken* messages is optional.

17.12.5. UDDI API Calls

This section describes the Virtuoso UDDI-related messages. These messages are divided into APIs for authentication, inquiry, and publication.

Authorization API

me_uddi_get_authtoken_dedup

For detailed description and example use of the function, see me_uddi_get_authtoken in the Functions Reference Guide.

me_uddi_get_registeredinfo_dedup

For detailed description and example use of the function, see me_uddi_get_registeredinfo in the Functions Reference Guide.

me_uddi_discard_authtoken_dedup

For detailed description and example use of the function, see me_uddi_discard_authtoken in the Functions Reference Guide.

Inquiry API Functions

The inquiry API messages `find_binding` , `find_business` , `find_service` , and `find_tModel` all accept an optional element named `findQualifiers` . This argument provides a means to allow the caller to override default search behaviors.

The messages in this section represent inquiries that anyone can make of any UDDI-enabled server at any time. These messages all behave synchronously and are required to be exposed via HTTP POST only. Other synchronous or asynchronous mechanisms may be provided at the discretion of the individual UDDI-enabled server or compatible registry.

The publicly accessible queries are:

- *find_binding:* Used to locate specific bindings within a registered `businessService`. Returns a `bindingDetail` message.
- *find_business:* Used to locate information about one or more businesses. Returns a `businessList` message.
- *find_service:* Used to locate specific services within a registered `businessEntity`. Returns a `serviceList` message.
- *find_tModel:* Used to locate one or more `tModel` information structures. Returns a `tModelList` structure.
- *get_bindingDetail:* Used to get full `bindingTemplate` information suitable for making one or more service requests. Returns a `bindingDetail` message.
- *get_businessDetail:* Used to get the full `businessEntity` information for a one or more businesses. Returns a `businessDetail` message.
- *get_businessDetailExt:* Used to get extended `businessEntity` information. Returns a `businessDetailExt` message.
- *get_serviceDetail:* Used to get full details for a given set of registered `businessService` date. Returns a `serviceDetail` message.
- *get_tModelDetail:* Used to get full details for a given set of registered `tModel` data. Returns a `tModelDetail` message.

me_uddi_find_binding_dedup

For detailed description and example use of the function, see me_uddi_find_binding in the Functions Reference Guide.

me_uddi_find_business_dedup

For detailed description and example use of the function, see me_uddi_find_business in the Functions Reference Guide.

me_uddi_find_service_dedup

For detailed description and example use of the function, see me_uddi_find_service in the Functions Reference Guide.

me_uddi_find_tmodel_dedup

For detailed description and example use of the function, see me_uddi_find_tmodel in the Functions Reference Guide.

me_uddi_get_bindingdetail_dedup

For detailed description and example use of the function, see me_uddi_get_bindingdetail in the Functions Reference Guide.

me_uddi_get_businessdetail_dedup

For detailed description and example use of the function, see me_uddi_get_businessdetail in the Functions Reference Guide.

me_uddi_get_businessdetailext_dedup

For detailed description and example use of the function, see me_uddi_get_businessdetailext in the Functions Reference Guide.

me_uddi_get_servicedetail_dedup

For detailed description and example use of the function, see me_uddi_get_servicedetail in the Functions Reference Guide.

me_uddi_get_tmodeldetail_dedup

For detailed description and example use of the function, see me_uddi_get_tmodeldetail in the Functions Reference Guide.

Publishing API Functions

The messages in this section represent inquiries that require authenticated access to an operator site. Each business should initially select one UDDI-enabled server to host their information. Once chosen, information can only be updated at the site originally selected.

The messages defined in this section all behave synchronously and are only callable via HTTP-POST. HTTPS is used exclusively for all the calls defined in this publisher's API.

- *save_binding:* Used to register new `bindingTemplate` information or update existing `bindingTemplate` information. Use this to control information about technical capabilities exposed by a registered business.
- *save_business:* Used to register new `businessEntity` information or update existing `businessEntity` information. Use this to control the overall information about the entire business. Of all the save messages, this one has the broadest effect.
- *save_service:* Used to register or update complete information about a `businessService` exposed by a specified `businessEntity`.
- *save_tModel:* Used to register or update complete information about a `tModel`.
- *delete_binding:* Used to remove an existing `bindingTemplate` from the bindingTemplates collection that is part of a specified `businessService` structure.
- *delete_business:* Used to delete registered `businessEntity` information from the registry.
- *delete_service:* Used to delete an existing `businessService` from the businessServices collection that is part of a specified `businessEntity`.
- *delete_tModel:* Used to delete registered information about a `tModel`. If there are any references to a `tModel` when this call is made, the `tModel` will be marked deleted instead of being physically removed.

me_uddi_save_binding_dedup

For detailed description and example use of the function, see me_uddi_save_binding in the Functions Reference Guide.

me_uddi_save_business_dedup

For detailed description and example use of the function, see me_uddi_save_business in the Functions Reference Guide.

me_uddi_save_service_dedup

For detailed description and example use of the function, see me_uddi_save_service in the Functions Reference Guide.

me_uddi_save_tmodel_dedup

For detailed description and example use of the function, see me_uddi_save_tmodel in the Functions Reference Guide.

me_uddi_delete_binding_dedup

For detailed description and example use of the function, see me_uddi_delete_binding in the Functions Reference Guide.

me_uddi_delete_business_dedup

For detailed description and example use of the function, see me_uddi_delete_business in the Functions Reference Guide.

me_uddi_delete_service_dedup

For detailed description and example use of the function, see me_uddi_delete_service in the Functions Reference Guide.

me_uddi_delete_tmodel_dedup

For detailed description and example use of the function, see me_uddi_delete_tmodel in the Functions Reference Guide.

17.12.6. Examples

Example 17.40. Generic Find

Finds all registry entries for names beginning with 'M':

```
select http_get ('http://example.com/SOAP', null, 'POST',
  'Content-Type: text/xml\r\nSOAPAction: ""',
  '<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
<Body>
<find_business xmlns="urn:uddi-org:api" generic="1.0">
<name>M</name>
</find_business>
</Body>
</Envelope>');
```

Example 17.41. Find By Name 1

Find by name with sort options by name and date, both ascending:

```
select http_get ('http://example.com/SOAP', null, 'POST',
  'Content-Type: text/xml\r\nSOAPAction: ""',
  '<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
<Body>
<find_business xmlns="urn:uddi-org:api" generic="1.0">
<findQualifiers>
<findQualifier>sortByNameAsc</findQualifier>
<findQualifier>sortByDateAsc</findQualifier>
</findQualifiers>
<name></name>
</find_business>
</Body>
</Envelope>');
```

Example 17.42. Find By Name 2

Find by name, sorted by name descending and date ascending:

```
select http_get ('http://example.com/SOAP', null, 'POST',
  'Content-Type: text/xml\r\nSOAPAction: ""',
  '<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
<Body>
<find_business xmlns="urn:uddi-org:api" generic="1.0">
<findQualifiers>
<findQualifier>sortByNameDesc</findQualifier>
<findQualifier>sortByDateAsc</findQualifier>
</findQualifiers>
<name></name>
</find_business>
</Body>
</Envelope>');
```

Example 17.43. Find By Name 3

Find by exact name match, case-sensitive, and sorted by name and date ascending:

```
select http_get ('http://example.com/SOAP', null, 'POST',
  'Content-Type: text/xml\r\nSOAPAction: ""',
  '<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
<Body>
<find_business xmlns="urn:uddi-org:api" generic="1.0">
<findQualifiers>
<findQualifier>exactNameMatch</findQualifier>
<findQualifier>caseSensitiveMatch</findQualifier>
<findQualifier>sortByNameAsc</findQualifier>
<findQualifier>sortByDateAsc</findQualifier>
</findQualifiers>
<name>Microsoft Corporation</name>
</find_business>
</Body>
</Envelope>');
```

Example 17.44. Find By *identifierBag* Element 'DUNS':

```
select http_get ('http://example.com/SOAP', null, 'POST',
  'Content-Type: text/xml\r\nSOAPAction: ""',
  '<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
<Body>
<find_business xmlns="urn:uddi-org:api" generic="1.0">
<findQualifiers>
<findQualifier>exactNameMatch</findQualifier>
<findQualifier>caseSensitiveMatch</findQualifier>
<findQualifier>sortByNameAsc</findQualifier>
<findQualifier>sortByDateAsc</findQualifier>
</findQualifiers>
<identifierBag>
<keyedReference keyName="D-U-N-S" keyValue="08-146-6849"
  tModelKey="UUID:8609C81E-EE1F-4D5A-B202-3EB13AD01823"/>
</identifierBag>
</find_business>
</Body>
</Envelope>');
```

Example 17.45. Find by *tModel*

```
select http_get ('http://example.com/SOAP', null, 'POST',
  'Content-Type: text/xml\r\nSOAPAction: ""',
  '<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
<Body>
<find_business xmlns="urn:uddi-org:api" generic="1.0">
<findQualifiers>
<findQualifier>exactNameMatch</findQualifier>
<findQualifier>caseSensitiveMatch</findQualifier>
<findQualifier>sortByNameAsc</findQualifier>
<findQualifier>sortByDateAsc</findQualifier>
</findQualifiers>
<tModelBag>
<tModelKey>UUID:68DE9E80-AD09-469D-8A37-088422BFBC36</tModelKey>
</tModelBag>
</find_business>
</Body>
</Envelope>');
```

Example 17.46. Find by discovery URL

```
select http_get ('http://example.com/SOAP', null, 'POST',
  'Content-Type: text/xml\r\nSOAPAction: ""',
  '<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
<Body>
<find_business xmlns="urn:uddi-org:api" generic="1.0">
<findQualifiers>
<findQualifier>exactNameMatch</findQualifier>
<findQualifier>caseSensitiveMatch</findQualifier>
<findQualifier>sortByNameAsc</findQualifier>
<findQualifier>sortByDateAsc</findQualifier>
</findQualifiers>
<discoveryURLs>
<discoveryURL>
http://uddi.microsoft.com/discovery?businessKey=D94B25A4-BD6D-4426-AEAC-1087DCC21421
</discoveryURL>
</discoveryURLs>
</find_business>
</Body>
</Envelope>');
```

Example 17.47. Get authentication token

```
select http_get ('http://example.com/SOAP', null, 'POST',
  'Content-Type: text/xml\r\nSOAPAction: ""',
  '<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
<Body>
<get_authToken xmlns="urn:uddi-org:api" generic="1.0">
<userID>dav</userID>
<cred>dav</cred>
</get_authToken>
</Body>
</Envelope>');
```

Example 17.48. Discard Authentication Token

```
select http_get ('http://example.com/SOAP', null, 'POST',
  'Content-Type: text/xml\r\nSOAPAction: ""',
  '<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
<Body>
<discard_authToken xmlns="urn:uddi-org:api" generic="1.0">
<authInfo>71255ffc5b0a22b4699bfcee74cba97f</authInfo>
</discard_authToken>
</Body>
</Envelope>');
```

17.13. Exposing Persistent Stored Modules as Web Services

Virtuoso SQL stored procedures and functions can be exposed as SOAP services very simply from Virtuoso, whether they are native Virtuoso or on remote data sources. This powerful ability means that any database servers already existing within an organization can easily become a component in an eBusiness solution using Virtuoso. All you need is a few simple steps that typically take mere minutes to complete:

- **Choose your stored procedure(s) .** The procedures that you want to expose can either be native Virtuoso stored procedures, or remote stored procedures that can be linked in using the Remote Procedures user interface.

- **Choose a virtual directory .** Because SOAP services need to be exposed and accessed via HTTP a Virtuoso virtual directory must be used. Either use the existing SOAP virtual directory or create a new one.
- **Publish procedures to virtual directory .** The user specified as SOAP account on the virtual directory must have execute privileges on the procedures. Use the Publish options on the virtual directory user interface.
- **Test the VSMX output .** Once procedures have been published as SOAP services they are automatically described by WSDL and testable using Virtuoso's VSMX feature.

XML Query Templates provide a direct way to store SQL in an XML file on the Virtuoso server that when executed, i.e. fetched from a web browser, actually returns the results of the query.

The C Interface chapter describes how users can define custom built-in functions, from C or other programming languages, that can be used from within Virtuoso PL. This also means that VSE's can also be published as a Web Service!

17.13.1. Publishing Stored Procedures as Web Services

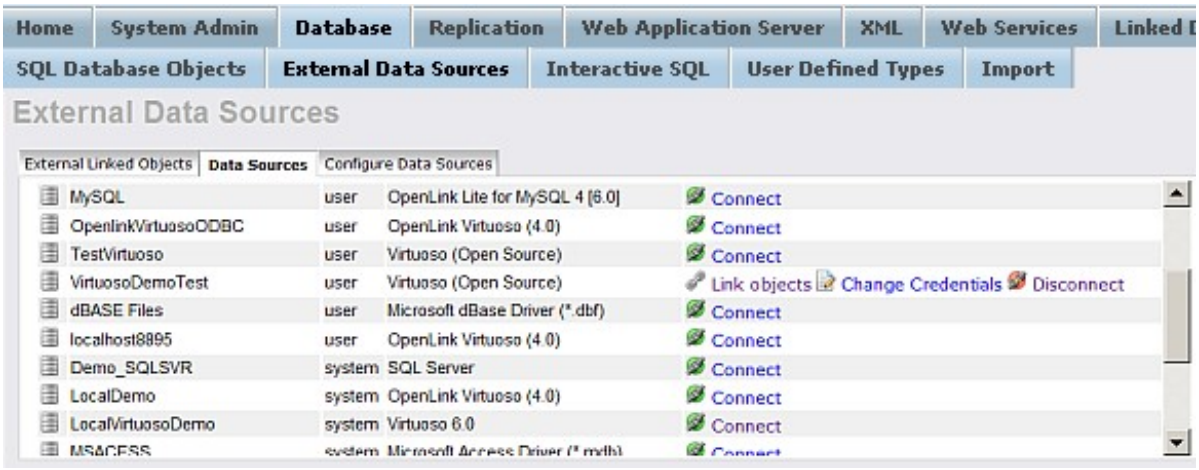
Choosing Stored Procedures to Expose

You can either expose native Virtuoso stored procedures (previously defined or newly created) using the CREATE PROCEDURE statement, or stored procedures from other database types can be linked into Virtuoso using an ODBC datasource.

Virtuoso lists available stored procedures for each catalog in Conductor under: */Database/External Data Sources/External Linked Objects / with checked "Stored Procedures"* .

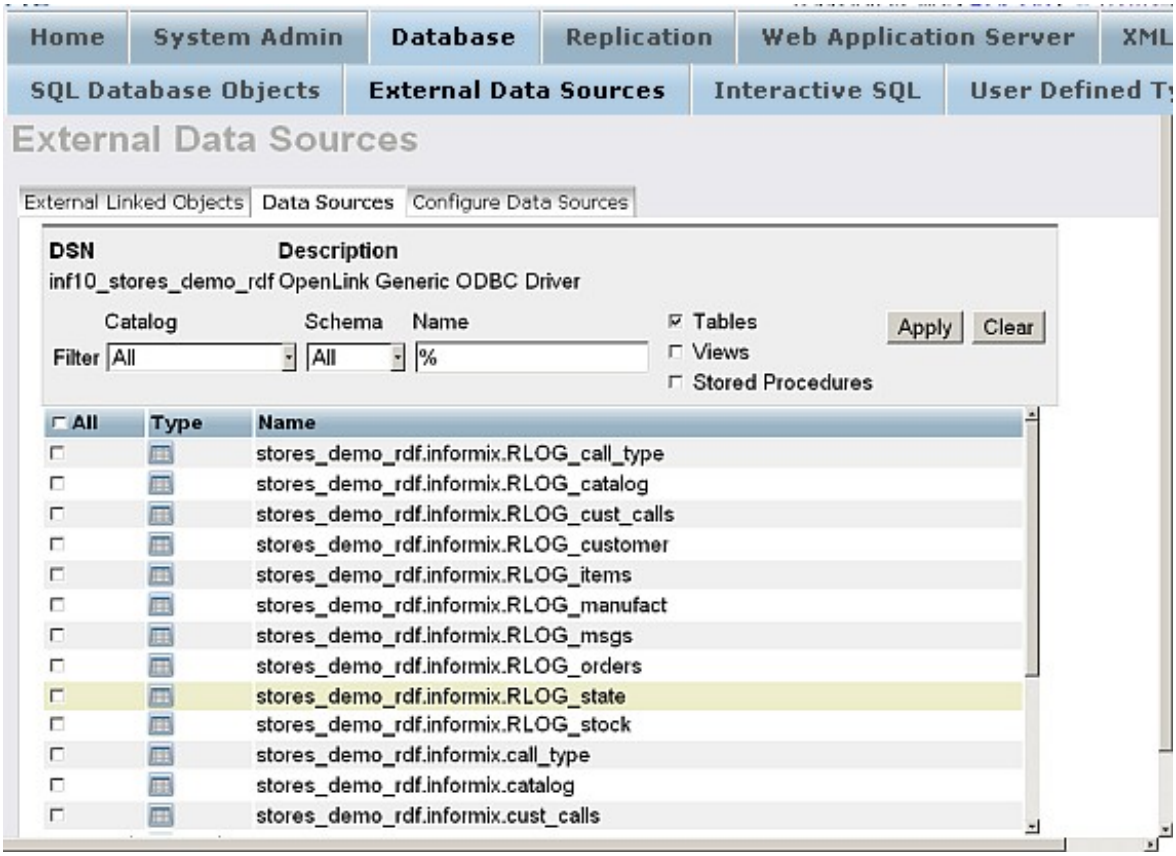
To link a stored procedure from another database system we must first create a valid data source that leads to a connection to that database. Once verified proceed to the Remote Procedures page. Select the "Link objects" link for a data source.

Figure 17.53. Linking Procedures from Remote Data Sources



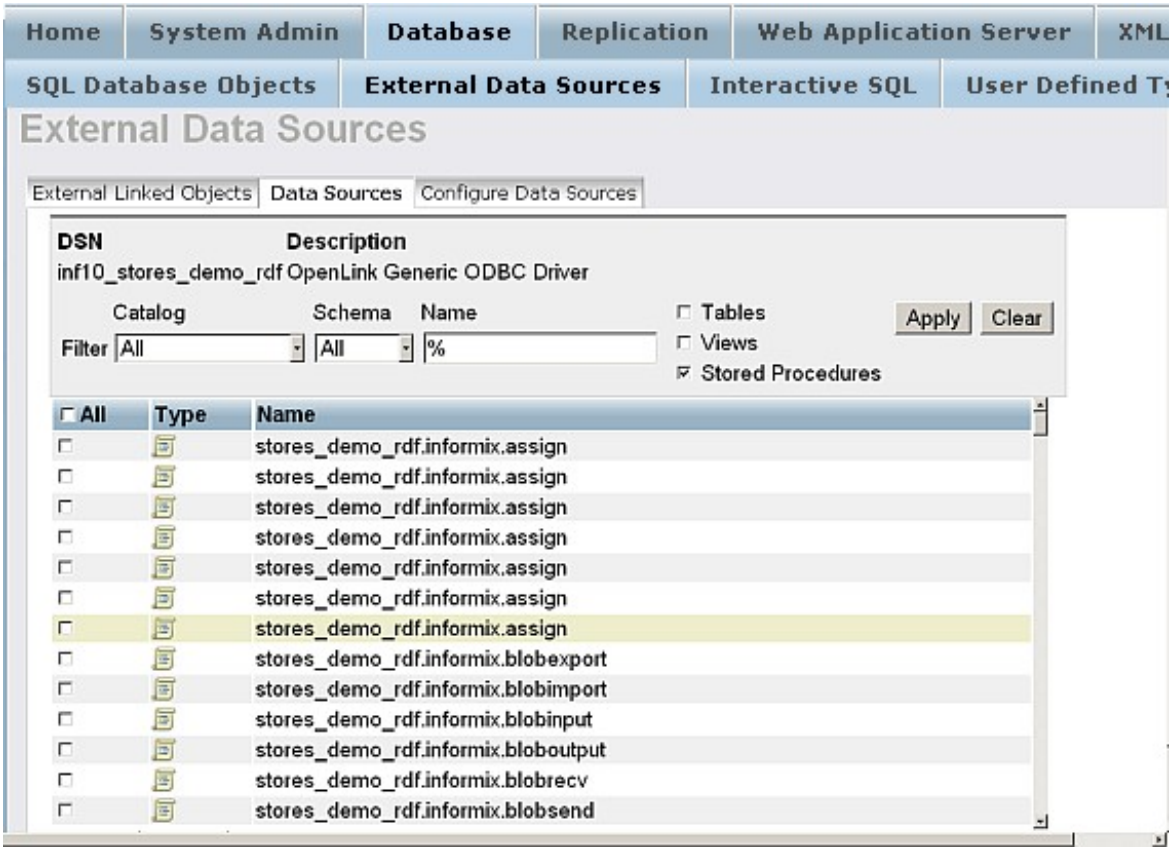
Select the check-box "Store Procedures". Click the "Apply" button. As result will be shown the list of available procedures.

Figure 17.54. Linking Procedures from Remote Datasources



Select the check-boxes for the procedures you want to link and click the "Link" button.

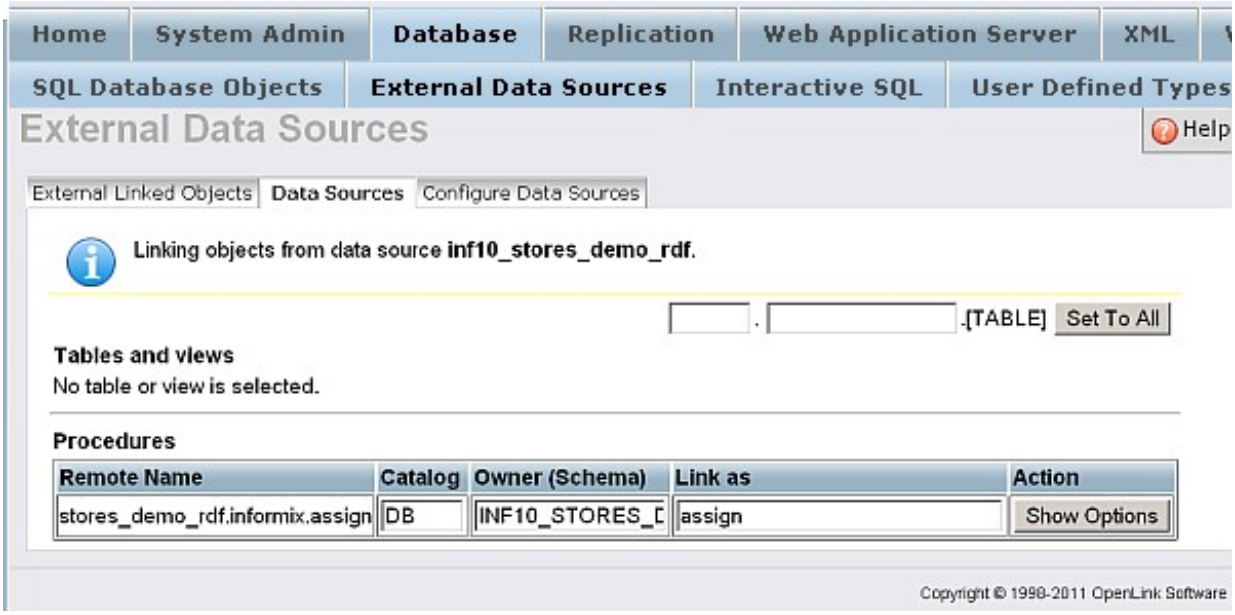
Figure 17.55. Linking Procedures from Remote Datasources



You will be presented with a new page listing the chosen procedures and their data type information. This gives you an opportunity to alter the data type mappings that Virtuoso will use both internally and for any future interactions with the SOAP

server. If you do not want to specify any special type information the details can be left as default.

Figure 17.56. Linking Procedures from Remote Datasources



For each remote procedure you may change how they will be referenced within Virtuoso by making changes to the fields for *Catalog* , *Owner* , *Link as* , and *Description* fields. These fields define how you will find the linked procedure locally to Virtuoso only and do not affect the remote data source.

For each procedure there is an option to *PL Wrapper Requirement* . This option is required if your remote procedure is capable of returning a resultset that you want to process via Virtuoso. Can be *SOAP Execution* , *SQL Execution* or *None* . Also you can specify *Return Type* , *Data Type* , *SOAP Type* .

Once the details are correct press the "Link" button.

See Also:
Linking Remote Procedures

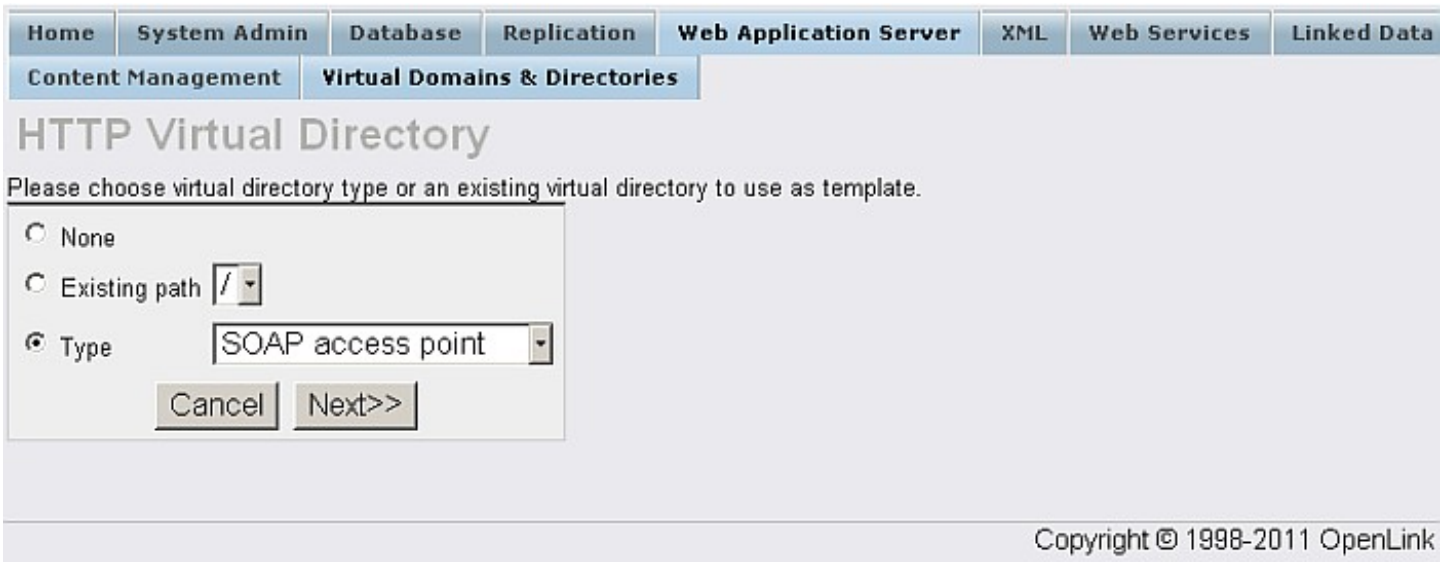
Defining Virtual Directories

Before any procedures native or linked can be exposed as SOAP Services a location in HTTP space must be defined. From Conductor *Web Application Server/Virtual Domains & Directories* you make a new URL Mappings. Click on the *New Directory* link for the {Default Web Site} line to begin defining a new SOAP mapping.

Figure 17.57. Virtual Directories

Select for "Type" from the list the value "SOAP access point" and click the "Next" button.

Figure 17.58. Virtual Directories Mappings

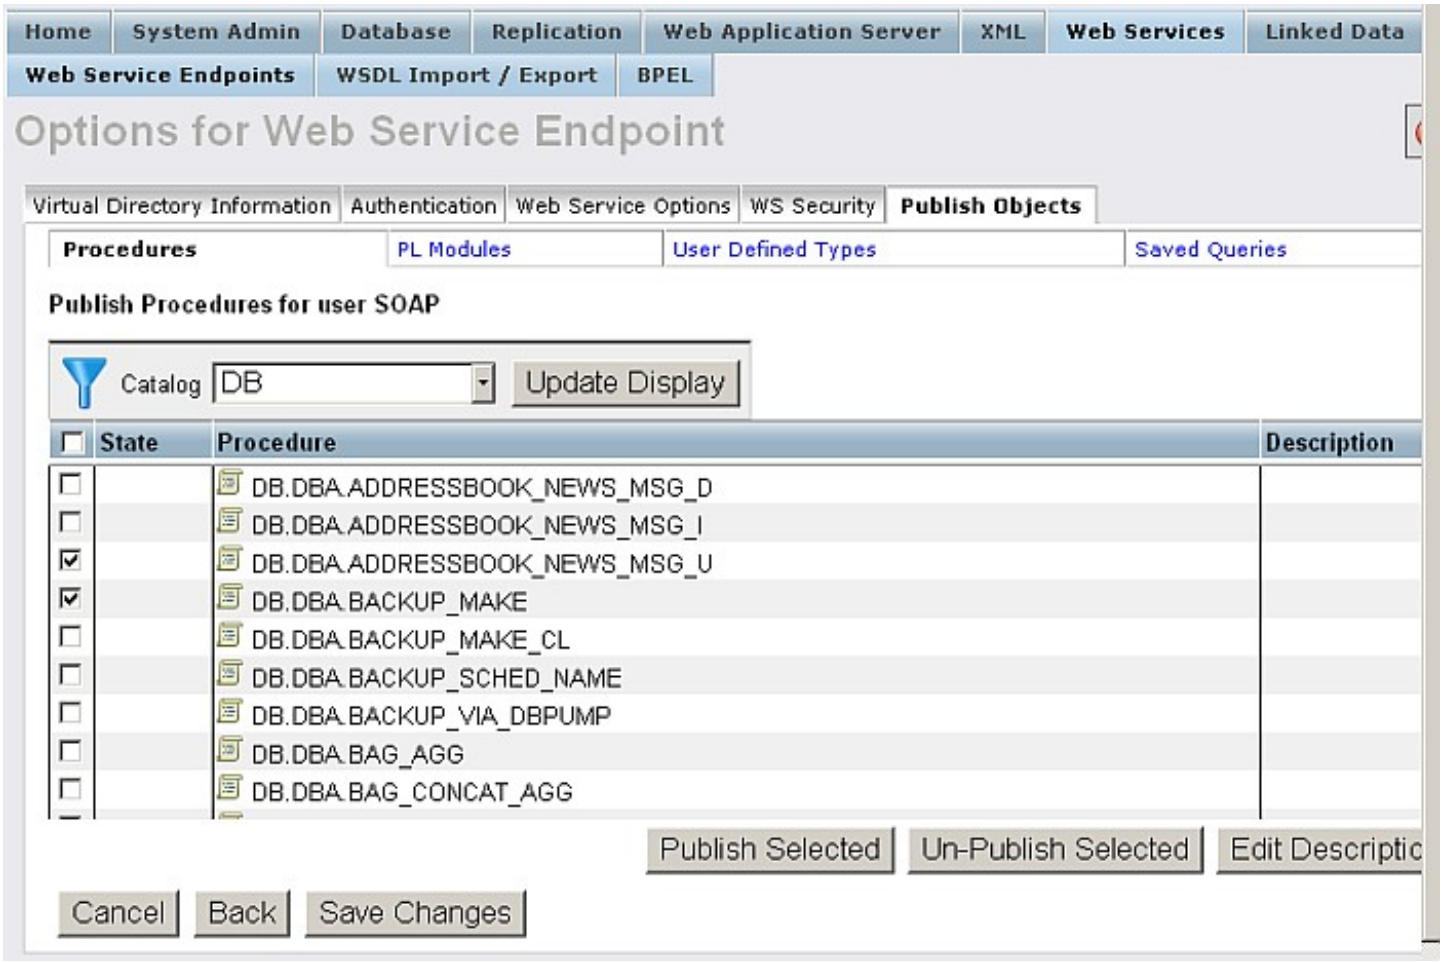


You will then be presented with the following tabs: "Virtual Directory Information", "Authentication", "Web Service Option", "WS Security" and "Publish Objects". Particular options to note are "Virtual Directory Information" and "Publish Objects".

Figure 17.59. Virtual Directories

In *Publish Objects* you can select Virtuoso stored procedures, or remotely linked procedures to be published as SOAP web services. Also you can publish Pl Modules, User Defined Types, or Saved Queries.

Figure 17.60. Publish Objects

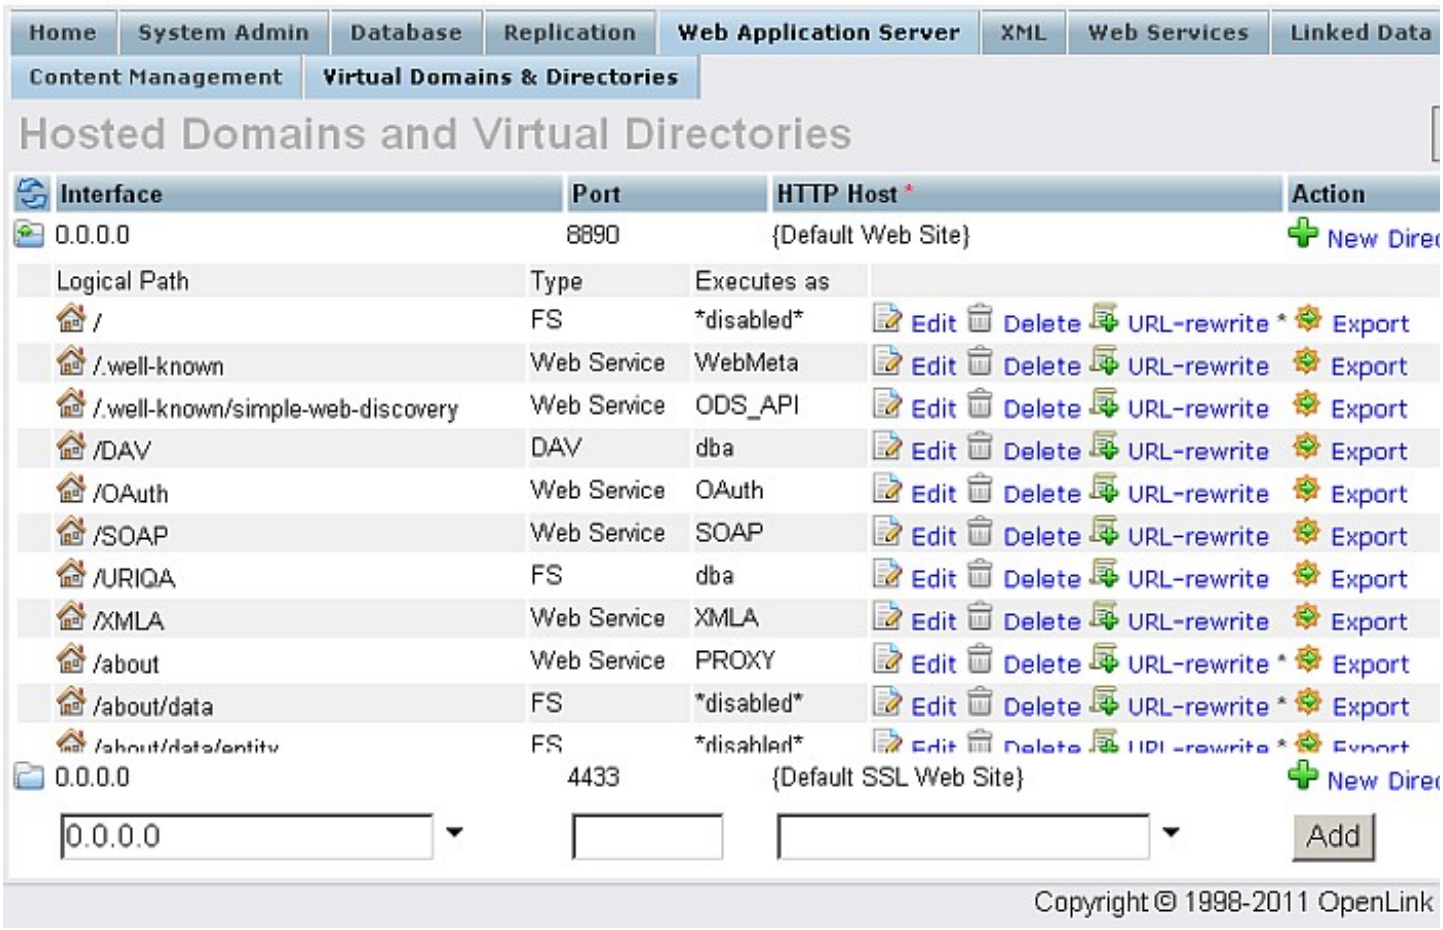


See Also:
Virtual Directories

Publishing Procedures to a Virtual Directory

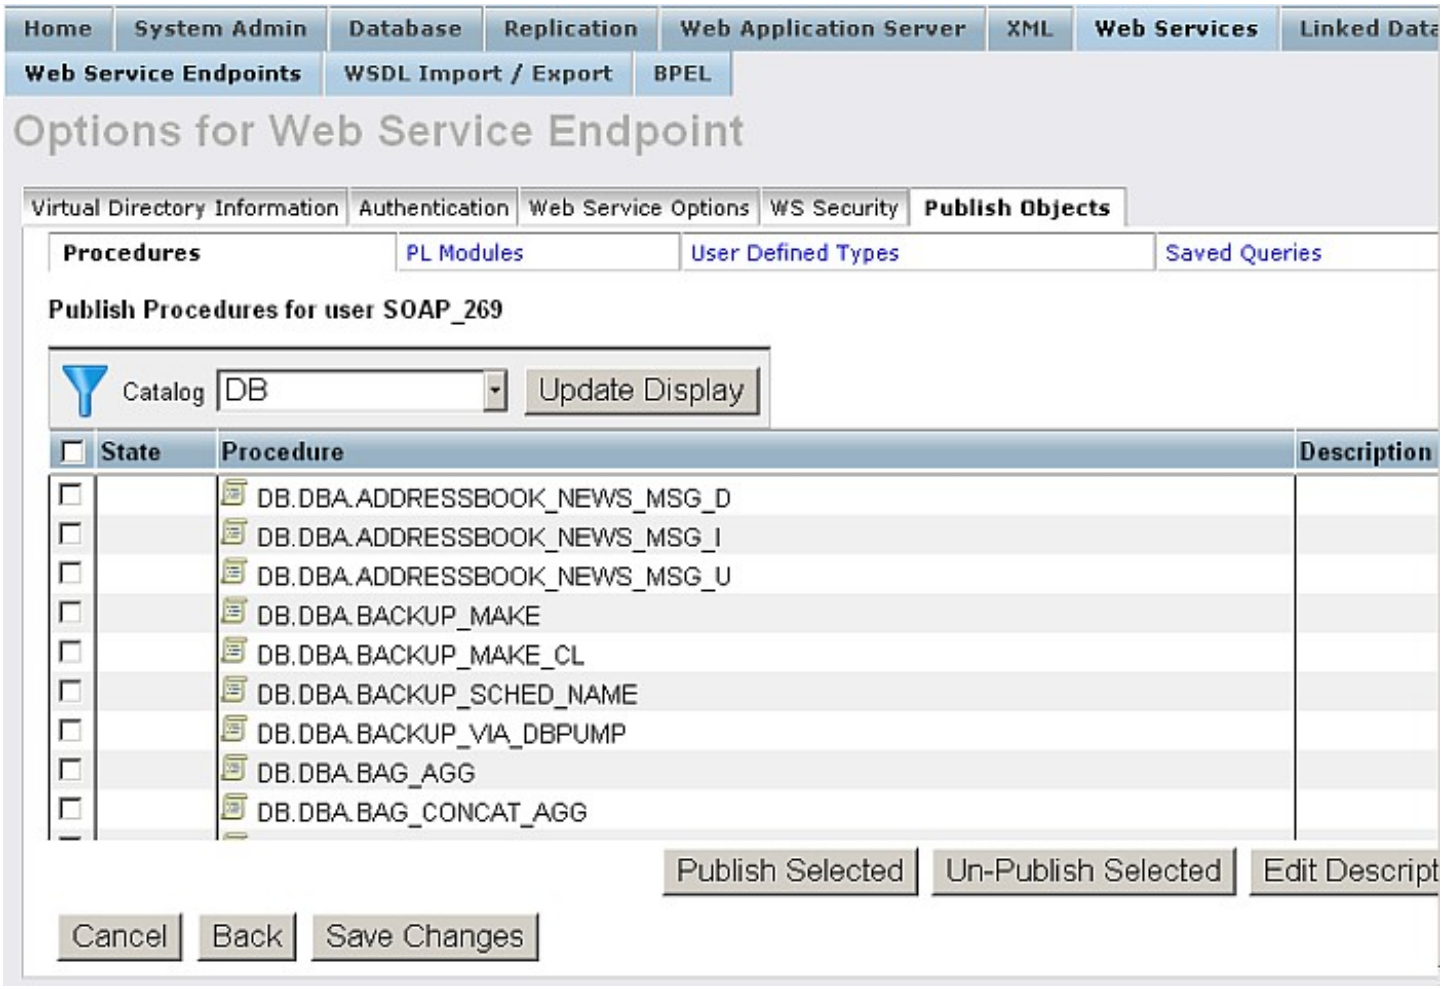
If you already have a virtual directory defined and know what procedures you want to expose as web services you will have to repeat some of the steps in the section above. From Conductor go to *Web Application Server/Virtual Domains & Directories* . Click on the "folder" icon for your {Default Web Site}. You will find the list of previously existing mappings, from which you can select the mapping that you want to edit by pressing on its *Edit* link. Note, the virtual directory should have type "SOAP".

Figure 17.61. Virtual Directories



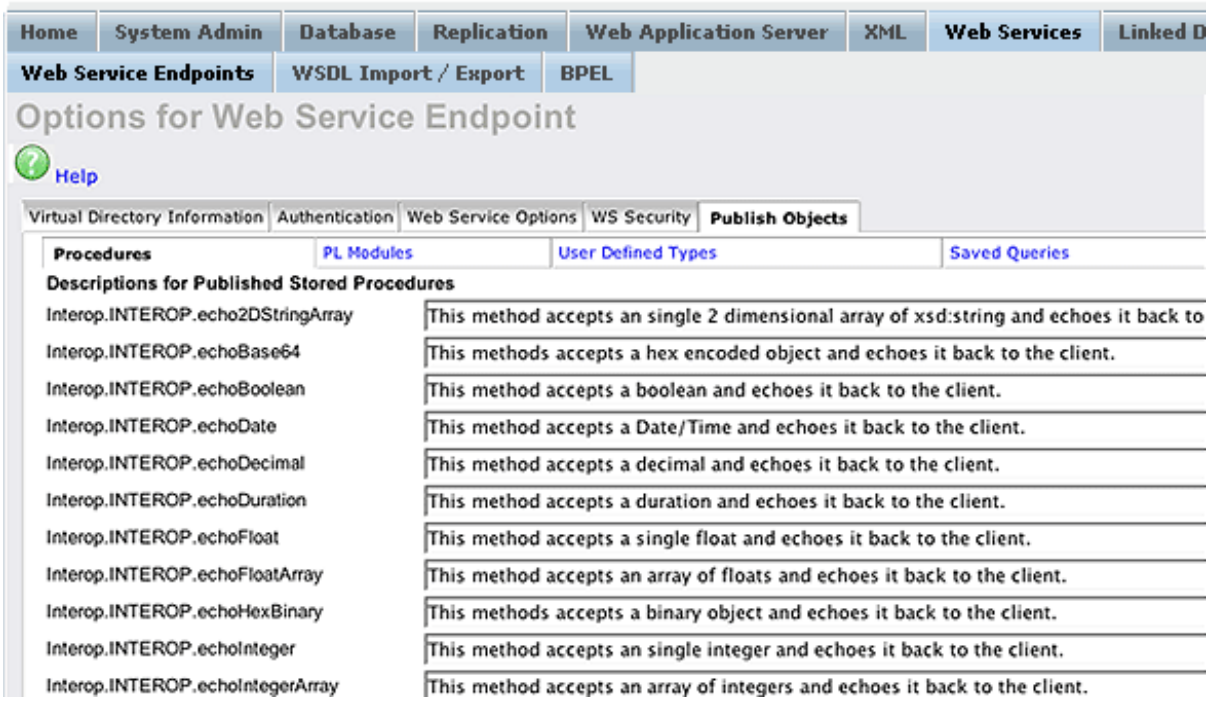
Go to tab "publish Objects" to expose/hide your procedures, Pl Modules, User Defined Types and Saved Queries.

Figure 17.62. Publish Objects



The "Procedures" tab presents the list of available procedures. You can select a catalogue in order to list the procedures you want to publish. When the procedures to be published are selected, you can either click the "Publish Selected" button, or before this to click the "Edit Description" button.

Figure 17.63. Choosing Procedure aPublish



Testing SOAP Services Using VSMX

Virtual directory definitions have a *Logical Path* field, which is reference in URL to find the correct SOAP services. If you connect to Virtuoso on *http://example.com/* , and defined your virtual directory with the logical path of */mysoap* then you will be able to test the following URLs:

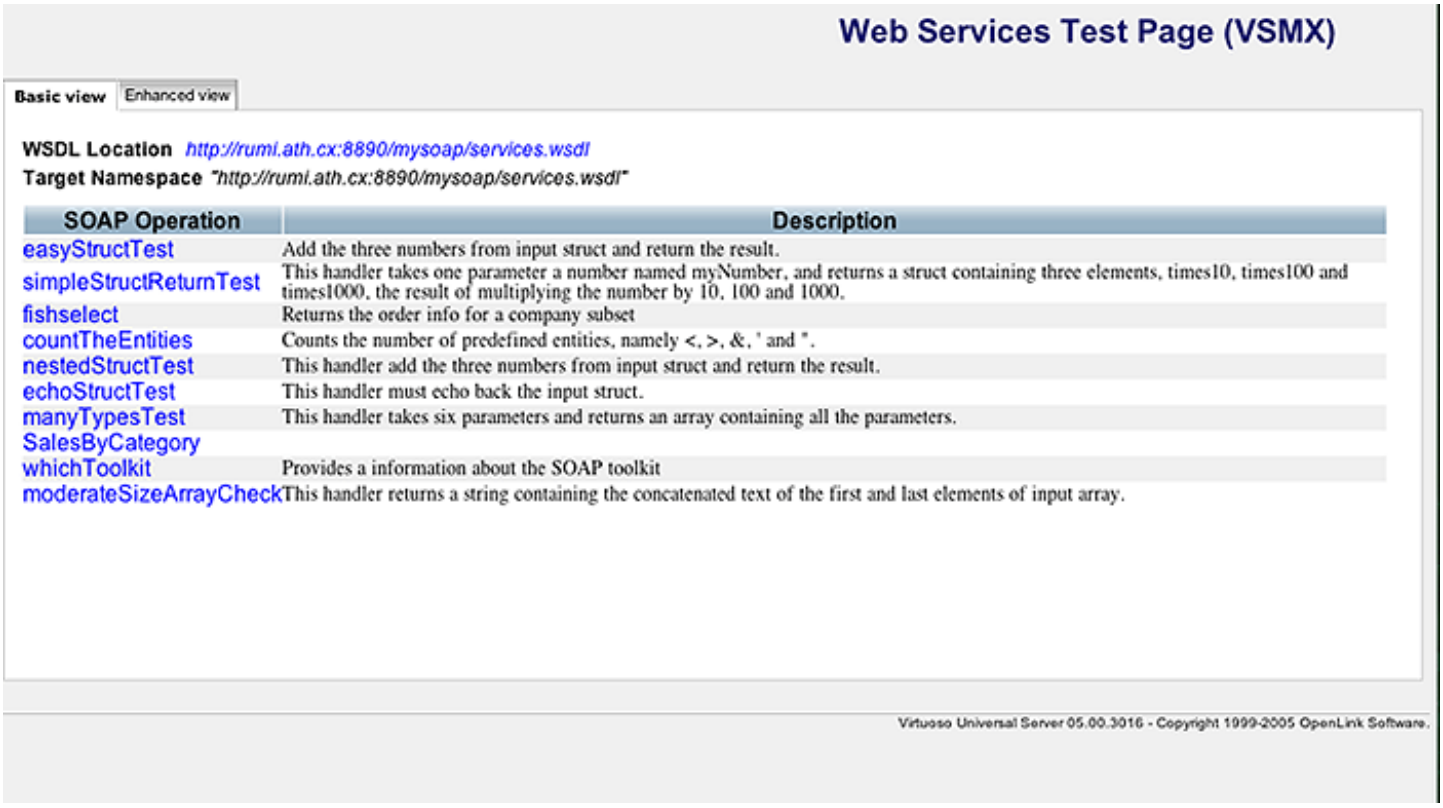
http://example.com/mysoap/services.wsdl

http://example.com/mysoap/services.vsmx

Figure 17.64. Services.wsdl

```
- <definitions targetNamespace="http://rumi.ath.cx:8890/mysoap/services.wsdl" name="SOAP">
  - <types>
    - <schema targetNamespace="http://tempuri.org/">
        <import namespace="http://schemas.xmlsoap.org/soap/encoding/"/>
      - <complexType name="ArrayOfstring">
        - <complexContent>
          - <restriction base="soapenc:Array">
            - <sequence>
                <element name="item" type="string" minOccurs="0" maxOccurs="unbounded" nillable="true"/>
              </sequence>
              <attributeGroup ref="soapenc:commonAttributes"/>
              <attribute ref="soapenc:arrayType" wsdl:arrayType="string[]"/>
            </restriction>
          </complexContent>
        </complexType>
      - <complexType name="toolkit_info">
        - <all>
            <element name="toolkitDocsUrl" type="string"/>
            <element name="toolkitName" type="string"/>
            <element name="toolkitVersion" type="string"/>
            <element name="toolkitOperatingSystem" type="string"/>
          </all>
        </complexType>
      - <complexType name="ctc">
        - <all>
            <element name="ctLeftAngleBrackets" type="int"/>
            <element name="ctRightAngleBrackets" type="int"/>
            <element name="ctAmpersands" type="int"/>
            <element name="ctApostrophes" type="int"/>
            <element name="ctQuotes" type="int"/>
```

Figure 17.65. Services.vsmx



The WSDL description is a standards-based description of the Web Services available from /mysoap. The VSMX page is a Virtuoso generated test page allowing you to test SOAP services. This feature should improve your development time.

See Also:
VSMX ; SOAP ; WSDL .

17.13.2. XML Query Templates

Virtuoso XML templates allow execution of SQL/XML queries over HTTP to obtain an XML document in response and/or perform some operation in the database using updategrams . XML templates can be executed from within Virtuoso procedure language using the `xml_template()` function. XML templates support two types of action: SQL based or updategram based. SQL query based templates must contain the FOR XML clause used in a SELECT statement and hence cannot update the database. Updates to the database can only occur from an updategram. The XML document returned from calling an XML template can be served either raw, or transformed using XSLT.

XML templates provide quick easy access to results from a SQL query as usual, but now this can be saved to a file. The results are not saved, just the query definition. You can use this feature to rapidly produce dynamic reports that can potentially be rendered in different ways by providing an alternate stylesheet. The report can be refined on the fly by providing parameters for the query. The output is reachable via HTTP directly by providing the URL to the template.

See Also:
The XML Templates Section

XML Templates can also be published just like normal store procedures. This is achieved by using a PL wrapper around the XML template. Then the store procedure is published in the normal way.

Stylesheets transformations with be inactive for published XML templates invoked from SOAP.

See Also:
The Publishing Stored Procedures Section above for a further description of publishing XML Templates.

17.13.3. Publishing VSE's as Web Services

The Virtuoso distribution includes the sample VSE, bif_sample.c. It is thus possible to create a function such as:

```
.....
static caddr_t
bif_hello_world (caddr_t * qst, caddr_t * err_ret, state_slot_t ** args)
{
  return box_dv_short_string ("Hello world.");
}
....
```

Then declare it in the init_func() by adding the following code:

```
...
  bif_define_typed ("hello_world", bif_hello_world, &bt_any);
...
```

The next step is creating a stored procedure that calls this function and you are back to publishing a Virtuoso stored procedure again, as in the above section.

```
create procedure BIF_HELLO_WORLD () { return hello_world (); };
```

The C Interface Chapter

17.14. Testing Web Published Web Services

Virtuoso provides a mechanism for testing SOAP messages instantly. This mechanism is the Virtuoso Service Module for XML (VSMX) - an automatically generated test page for published web services. The VSMX file is generated at the same time the WSDL file is generated. A VSMX file is a SOAP operations test page generated based on the descriptions of a WSDL file. The VSMX file has the extension .vsmx, as opposed to the .wsdl extension of the WSDL file, and can be accessed similarly.

VSMX pages give instant access to published SOAP services for testing. Any newly created service will need testing which normally means writing more code to call the service, supply parameters, retrieve the result, display the results in some manor, etc. The VSMX feature of Virtuoso eliminates this otherwise repetitive process by automatically maintaining a test page for SOAP messages: the VSMX file. This greatly speeds up the development and testing cycle. The beauty of this is that this is automated, even Microsoft's ASMX file requires that you code the services descriptions before seeing the results.

Web Service developers would use VSMX to forego the test bed creation step in light of automatic test page generation. Project managers can easily keep track of their developers progress by checking the test page periodically.

Since WSDL descriptions by themselves are not very pleasing to the human eye, the VSMX test page can be used to preview services available on a Virtuoso server, or from a remote source using SOAP/WSDL Proxying . Even experienced developers will find these easier to read than WSDL files.

Each SOAP enabled virtual directory will have a WSDL and VSMX file available. The VSMX file is a test page for the SOAP operations. This test page can be found as simply as the WSDL can be found. From the WSDL chapter we have seen that for every SOAP enabled virtual directory you automatically get the file:

```
http://[host:port]/[SOAP Virtual Directory]/services.wsdl
```

likewise you also get:

```
http://[host:port]/[SOAP Virtual Directory]/services.vsmx
```

You simply point your web browser to this file for the test page. The demo database contains samples that can be found as:

```
http://[host:port]/SOAP/services.vsmx
```

Figure 17.66. VSMX Test Page

The page shows all the operations that are available. Click on the link that corresponds to the operation to test and the services details and test facilities will also appear, allowing you to supply input parameters making the SOAP call.

Once executed the result of SOAP call will be rendered using the Virtuoso XSLT processor and built-in style sheet, and appended to bottom of the services details.

In addition to the simple types: numbers and strings, more complex types such as arrays and structures can be specified as input parameters. For an array, each value must be specified on a separate row in the input text field. For structures the names of structure members will be displayed, following by the equals sign, the values of the structures members can then be input after the equals sign. Arrays of arrays or structures of arrays cannot be used on the test page.

The first comment line of a stored procedure in the format:

```
--## [comment]
```

will be included in the WSDL description of the SOAP message for that procedure when generating the WSDL file.

17.15. BPEL Reference

Introduction. Business Process Execution Language for Web Services (called BPEL4WS or simply BPEL in the rest of this chapter) provides a means of specifying interactions between web services for accomplishing a potentially long running business task.

Used terms .

- **WSDL .** Web Services Description Language as described in the corresponding W3C proposed recommendation. This is a notation for declaring services and the types of data they accept and produce. Also the term may be used to refer to the document containing a WSDL description.
- **partner .** A service or application which interacts with a BPEL process.
- **(BPEL) script .** A document containing BPEL compatible XML constructs.
- **(BPEL process) instance .** An instance of a BPEL process, can be running, suspended, aborted or finished.
- **activity .** An activity is a building block of a BPEL script. Receiving data, invoking other web services, programming language like control structures are all examples of activities.
- **portType .** Container for set of abstract operations see below.
- **operation .** An abstract black-box that have an XML input or/and output. Services potentially supports four types of operations: one-way, request-response, notification and solicit-response; this depends of input and/or output allowed and what is their order. The BPEL4WS uses one-way and request-response operations. Operations are grouped in 'ports' which define what operations a particular service supports.
- **message .** An abstract XML fragment that is used for operation input and output. In particular this is used inside SOAP Envelope and for value of the BPEL variables. Also the WSDL specification specifies how abstract messages will be used as concrete messages using the SOAP protocol and which encoding will be used.

17.15.1. Activities

Common attributes and elements

Every BPEL activity accepts the following standard attributes: 'name', 'joinCondition' and 'suppressJoinFailure'. The 'name' attribute is an optional unique within the script NCName (as defined in the XMLSchema) identifying the activity. The 'joinCondition' is a boolean expression which determine how incoming links' state will be tested, by default this is 'true()' which means the logical OR of the states of incoming links. The 'suppressJoinFailure' is a flag to raise or not exception if join condition fails, by default this is 'no'.

The common elements for every activity are 'target' and 'source'. These elements are used together with links and used to designate which link the current activity depends on or for which one it is a prerequisite. See also section for 'flow' activity below.

receive

This allows the business process to do a blocking wait for a particular message to arrive.

A BPEL process instance is created by a receive activity with the createInstance attribute set to true.

partnerLink
: name of a partner declared in the script from which the process is to receive a message.

portType
: name of the 'port' as declared in corresponding WSDL file.

operation
: name of the operation

variable
: name of the variable to which the received message will be assigned.

createInstance
: used to make instance of the BPEL process and start its execution.

```
<receive partnerLink="ncname" portType="qname" operation="ncname"
    variable="ncname"? createInstance="yes|no"?
    standard-attributes>
    standard-elements
    <correlations>?
        <correlation set="ncname" initiate="yes|no"?/>+
    </correlations>
</receive>
```

reply

allows the business process to send a message in reply to a message that was received through a <receive>

partnerLink
: name of a partner declared in the script to which to send a message.

portType
: name of the 'port' as declared in corresponding WSDL file.

operation
: name of the operation

variable
: name of the variable whose value will be used as output message.

faultName

```
<reply partnerLink="ncname" portType="qname" operation="ncname"
    variable="ncname"? faultName="qname"?
    standard-attributes>
    standard-elements
    <correlations>?
        <correlation set="ncname" initiate="yes|no"?/>+
    </correlations>
</reply>
```

invoke

This allows the business process to invoke a one-way or request-response operation on a portType offered by a partner. When both 'inputVariable' and 'outputVariable' are specified this means request-response operation will be performed. Please note that the operation is defined primarily in the partner's WSDL.

partnerLink
: name of a partner declared in the script to who send a message and optionally receive a response.

portType
: name of the 'port' as declared in corresponding WSDL file.

operation
: name of the operation to invoke

inputVariable
: name of the variable whose value will be used as the message to the partner.

outputVariable
: name of the variable to which the response will be assigned.

```
<invoke partnerLink="ncname" portType="qname" operation="ncname"
    inputVariable="ncname"? outputVariable="ncname"?
    standard-attributes>
    standard-elements
    <correlations>?
        <correlation set="ncname" initiate="yes|no"?
            pattern="in|out|out-in"/>+
    </correlations>
    <catch faultName="qname" faultVariable="ncname"?>*
        activity
```

```
        </catch>
        <catchAll>?
            activity
        </catchAll>
        <compensationHandler>?
            activity
        </compensationHandler>
    </invoke>
```

assign

can be used to update the values of variables with new data. An <assign> construct can contain any number of elementary assignments (copy sub-elements).

```
    <assign standard-attributes>
        standard-elements
        <copy>+
            from-spec
            to-spec
        </copy>
    </assign>
```

from-spec

This represents in <copy> the right part of the assignment.

```
    <from variable="ncname" part="ncname"? query="xpath-expression"?/>
    <from partnerLink="ncname" endpointReference="myRole|partnerRole"/>
    <from variable="ncname" property="qname"/>
    <from expression="general-expr"/>
    <from>literal value</from>
```

to-spec

This represents in <copy> the l-value of the assignment.

```
    <from variable="ncname" part="ncname"? query="xpath-expression"?/>
    <from partnerLink="ncname" endpointReference="myRole|partnerRole"/>
    <from variable="ncname" property="qname"/>
```

throw

generates a fault from inside the business process

faultName
: the fault code to be thrown.

faultVariable

```
    <throw faultName="qname" faultVariable="ncname"? standard-attributes>
        standard-elements
    </throw>
```

terminate

Used to immediately terminate the execution of a business process instance.

```
    <terminate standard-attributes>
        standard-elements
    </terminate>
```

wait

Wait until a given point in time or for a specified duration.

for
: an duration expression as defined in XMLSchema (for example PT10S)

until
: an date time expression as defined in XMLSchema

```
<wait (for="duration-expr" | until="deadline-expr") standard-attributes>
    standard-elements
</wait>
```

empty

insert a "no-op" instruction into a business process

```
<empty standard-attributes>
    standard-elements
</empty>
```

sequence

define a collection of activities to be performed sequentially in lexical order

```
<sequence standard-attributes>
    standard-elementsactivity+
</sequence>
```

switch

Select exactly one branch of activity from a set of choices

case
: the branch which will be executed if 'condition' attribute returns true.

otherwise
: will be executed if all 'case' conditions are evaluated to false.

```
<switch standard-attributes>
    standard-elements
    <case condition="bool-expr">+
        activity
    </case>
    <otherwise>?
        activity
    </otherwise>
</switch>
```

while

Repeat activity while a condition is true.

condition
: an XPath expression which will be evaluated every time before contained activities. If this evaluates to false the loop finishes.

```
<while condition="bool-expr" standard-attributes>
    standard-elementsactivity
</while>
```

pick

This blocks and waits for a suitable message to arrive or for a time-out expire. When one of the events specified in the body of the pick occurs the pick completes. Only one of the activities in the body of the pick will actually take place.

createInstance

This is an alternative of the 'receive' to make a new process instance. And can be expressed as: 'pick' plus 'onMessage' equals to 'receive' activity.

```
<pick createInstance="yes|no"? standard-attributes>
    standard-elements
    <onMessage partnerLink="ncname" portType="qname"
        operation="ncname" variable="ncname"?>+
        <correlations>?
            <correlation set="ncname" initiate="yes|no"?/>+
        </correlations>
        activity
    </onMessage>
    <onAlarm (for="duration-expr" | until="deadline-expr")>*
        activity
    </onAlarm>
</pick>
```

onMessage

This is to wait for an incoming message from given partner.

The attributes are the same as for receive activity

onAlarm

This will register a time-wait object whose expiration will trigger the pick. Obviously no more than one can be specified in a given 'pick'

The attributes are the same as for the wait activity

scope

defines a nested activity with its own associated variables, fault handlers, and compensation handler

variableAccessSerializable

```
<scope variableAccessSerializable="yes|no" standard-attributes>
    standard-elements
    <variables/>?
    <correlationSets/>?
    <faultHandlers/>?
    <compensationHandler/>?
    <eventHandlers/>?
    activity
</scope>
```

flow

Specifies one or more activities to be performed concurrently.

```
<flow standard-attributes>
    standard-elements
    <links>?
        <link name="ncname"/>+
    </links>
    activity+
</flow>
```

compensate

This is used to invoke compensation on an inner scope that has already completed normally. This construct can be invoked only from within a fault handler or another compensation handler

```
<compensate scope="ncname"? standard-attributes>
```

```
    standard-elements
</compensate>
```

compensationHandler

```
<compensationHandler>?
    activity
</compensationHandler>
```

faultHandlers

```
<faultHandlers>?
    <catch faultName="qname"? faultVariable="ncname"?>*
        activity
    </catch>
    <catchAll>?
        activity
    </catchAll>
</faultHandlers>
```

catch

This container will be executed whose 'faultName' attribute value matches the thrown fault.

catchAll

This container will be executed if non of the 'catch' containers are matched, so if no 'catchAll' is specified, the contained scopes will be compensated and the fault will be re-thrown to the outer scope.

eventHandlers

This is a container for events, thus it can contain onMessage or/and onAlarm events. Semantic of the onMessage and onAlarm is same as defined in pick activity, the difference is that here these can be executed asynchronously while the events of the defining scope are running. The events in an event handler section may thus interrupt the execution of the body of the scope. This feature can be used for supporting asynchronous cancel messages or timeouts imposed on a whole sequence of operations..

```
<eventHandlers>?
    <onMessage partnerLink="ncname" portType="qname"
        operation="ncname"
        variable="ncname"?>*

        <correlations>?
            <correlation set="ncname" initiate="yes|no"/>+
        </correlations>
        activity
    </onMessage>
    <onAlarm for="duration-expr"? until="deadline-expr"?>*
        activity
    </onAlarm>
</eventHandlers>
```

exec

This is a specific extension of the Virtuoso BPEL implementation. The exec activity allows executing SQL code from inside a BPEL process without having to define a distinct SOAP service for this.

binding
: only "SQL", "JAVA" and "CLR" are currently permitted.

```
<bpelv:exec binding="SQL">
    insert into dummy values ('hello world');
</bpelv:exec>
```

SQL execution

The additional procedures BPEL.BPEL.setVariableData and BPEL.BPEL.getVariableData allow manipulating BPEL variables. See SQL API for details.

All errors occurring during the SQL execution are translated into BPEL errors.

Java execution

Configuration

First of all, the java support in BPEL4WS is available only for java enabled virtuoso servers. In order to enable java support the following administration steps need to be taken:

- 1. Make java compiler (javac) available for virtuoso server
- 2. Enable "system" call by setting the AllowOSCalls? parameter in virtuoso.ini to 1.
- 3. Add "classlib" directory to CLASSPATH

After the BPEL4WS package has been installed, the server needs to be restarted.

The BPEL4WS package creates the classlib directory in the server's root with BpelVarsAdaptor?.class. This directory and this file are necessary for the proper operation of the Java interface.

Using java code in BPEL4WS

There are two elements which support java execution in BPEL4WS scripts: <bpelv:exec binding="JAVA" import?> (namespace is "http://www.openlinksw.com/virtuoso/bpel") and the Oracle compatible form <bpelx:exec import?> (namespace is "http://schemas.oracle.com/bpel/extension"). These tags are equal.

If the tag contains the "import" attribute the appropriate package will be imported. Example:

```
<bpelx:exec import="java.util.*"/>
```

Otherwise, the included code will be executed. It is suggested to use <![CDATA[statement for representing the java code. Example:

```
<bpelx:exec>
   System.out.println("getVariableData returned: " + getVariableData ("request", "req_payload", "/v:destR

   setVariableData ("res",
         "repl_payload",
         "/v:destResponse/v:country",
         "KZ");
</bpelx:exec>
```

The two "functions" are available for accessing script variables: setVariableData and getVariableData (analogs of the xpath functions with same names).

```
void setVariableData (String var_name, String part, String query_path, Object value);
```

sets the variable. The value to be set is restricted to be string or integer in this version.

```
getVariableData
```

is a full analog of xpath function getVariableData. See details below.

Note, the activity does not commit changes to the database until it finishes successfully, so if in a case of exception the variables are kept untouched. This also means that deadlocks can occur.

The communication errors must be handled and processed in the java code itself.

If some unhandled exception occurs in java code, it will be translated to a BPEL error. See details in the next section.

Errors

Two types of errors can be signalled:

- 1. upload time exceptions
- 2. runtime exceptions

The first type exceptions are related to configuration and java syntax errors. These are as follows:

- 1. [BPELX] The "system" call is disabled, it is needed for use java code in BPEL4WS scripts. * This error is signalled when the "AllowOSCalls" is set to 0. So the engine can not call java compiler. It One must set this parameter in ini file to 1 and restart the server to resolve this issue.
- 2. [BPELX] Compilation of java code for NAME failed. Try to call "javac NAME.java" for details. * The compilation of generated class for the activity has failed. Try to call the suggested operation from command prompt with the same PATH and CLASSPATH global variables to see the javac output.

Runtime errors not handled by java method itself are translated to the BPEL fault in the following form:

```
<bpws:javaFault sqlState="SQLSTATE">
 error message
</bpws:javaFault>
```

this error can be handled by BPEL fault handler. Here is an example:

```
...
    <receive partnerLink="caller" portType="v:dest" operation="check_dest" variable="request" createInsta
    <scope>
      <faultHandlers>
        <catch faultName="bpws:javaFault" faultVariable="error">
          <assign>
            <copy>
              <from variable="error" query="/javaFault"/>
              <to variable="res" part="repl_payload" query="/destResponse/country"/>
            </copy>
          </assign>
        </catch>
      </faultHandlers>
      <bpelv:exec binding="JAVA" name="invokeSomething"><![CDATA[
   System.out.println("Executing Java exec in BPEL");
   System.out.println("getVariableData returned: " + getVariableData ("request", "req_payload", "/v:destR

   setVariableData ("res",
         "repl_payload",
         "/destResponse/country",
         "UK");
   if (true)
     throw (new Exception("test"));
   ]] >
       </bpelv:exec>
     </scope>
    <reply partnerLink="caller" portType="v:dest" operation="check_dest" variable="res"/>
...
```

In this code the handler for java exception is set:

```
...
        <catch faultName="bpws:javaFault" faultVariable="error">
          <assign>
            <copy>
              <from variable="error" query="/javaFault"/>
              <to variable="res" part="repl_payload" query="/destResponse/country"/>
            </copy>
          </assign>
        </catch>
...
```

The handler takes the error message from the variable which holds it ("error") and puts it into the response variable.

BPEL variables accessors

```
void setVariableData (String var_name, String part, String query_path,
            Object value)
```

- changes BPEL variable named var_name. The "part" is a part of the message stored in the variable. "query_path" selects the data in the variable to be changed. The "value" can be only string or integer, so if several subdata need to be changed the setVariableData must be called several times. If the "part" and "query_path" must be ignored their can be passed as empty strings ("").

```
String getVariableData (String var_name, String part, String query)
```

- returns selected data from the part named by "part" argument of variable named by "var_name" argument. If the selection failed the NULL is returned.

Special variables

There are two special variables: "variables" and "xmlnss_pre". They can be changed in the java code, in this case the behaviour of the engine is unpredictable. So, it is strongly recommended do not use these variables.

JavaMail usage example

```
<?xml version="1.0"?>
<process xmlns:jsm="urn:java:sendMail"
        xmlns="http://schemas.xmlsoap.org/ws/2003/03/business-process/"
        name="javaSendMail"
        targetNamespace="urn:java:sendMail"
        xmlns:bpelx="http://schemas.oracle.com/bpel/extension"
        xmlns:bpelv="http://www.openlinksw.com/virtuoso/bpel">

  <bpelv:exec binding="JAVA" import="java.io.*"/>
  <bpelv:exec binding="JAVA" import="java.net.InetAddress"/>
  <bpelv:exec binding="JAVA" import="java.util.Properties"/>
  <bpelv:exec binding="JAVA" import="java.util.Date"/>
  <bpelv:exec binding="JAVA" import="javax.mail.*"/>
  <bpelv:exec binding="JAVA" import="javax.mail.internet.*"/>
  <bpelv:exec binding="JAVA" import="com.sun.mail.smtp.*"/>

  <partnerLinks>
    <partnerLink name="caller" partnerLinkType="jsm:dest"/>
  </partnerLinks>

  <variables>
    <variable name="request" messageType="jsm:destRequestMessage"/>
    <variable name="res" messageType="jsm:destResponseMessage"/>
  </variables>
  <sequence>
    <receive partnerLink="caller" portType="jsm:dest" operation="send" variable="request" createInstance=
    <bpelv:exec binding="JAVA" name="sendMail"><![CDATA[
        String  to, subject = null, from = null;
        String mailhost = (String) getVariableData ("request", "req_payload", "/jsm:destRequest/jsm:mailh
        String mailer = "OpenLink Virtuoso[BPEL script]";
        try {
                to = (String) getVariableData ("request", "req_payload", "/jsm:destRequest/jsm:to");
                subject = (String) getVariableData ("request", "req_payload", "/jsm:destRequest/jsm:subje

                Properties props = System.getProperties();
                props.put("mail.smtp.host", mailhost);
                Session session = Session.getInstance(props, null);

                Message msg = new MimeMessage(session);
                if (from != null)
                        msg.setFrom(new InternetAddress(from));
                else
```

```
                msg.setFrom();
            msg.setRecipients(Message.RecipientType.TO,
                                InternetAddress.parse(to, false));
            msg.setSubject(subject);
            msg.setText ((String)getVariableData ("request", "req_payload", "/jsm:destRequest/jsm:tex

            msg.setHeader("X-Mailer", mailer);
            msg.setSentDate(new Date());
            SMTPTransport t = (SMTPTransport)session.getTransport("smtp");
            try {
                t.connect();
                t.sendMessage(msg, msg.getAllRecipients());
            } finally {
                System.out.println("Response: " +
                                        t.getLastServerResponse());
                t.close();
            }

            System.out.println("\nMail was sent successfully.");
            setVariableData ("res",
                    "repl_payload",
                    "/jsm:destResponse/jsm:status",
                    "OK");

        } catch (Exception e) {
            String err_str = "Failed: " + e.toString();
            e.printStackTrace();
            if (e instanceof SendFailedException) {
                MessagingException sfe = (MessagingException)e;
                if (sfe instanceof SMTPSendFailedException) {
                    SMTPSendFailedException ssfe =
                                (SMTPSendFailedException)sfe;
                    System.out.println("SMTP SEND FAILED:");
                    System.out.println(ssfe.toString());
                    System.out.println("  Command: " + ssfe.getCommand());
                    System.out.println("  RetCode: " + ssfe.getReturnCode());
                    System.out.println("  Response: " + ssfe.getMessage());
                } else {
                        System.out.println("Send failed: " + sfe.toString());
                }
                Exception ne;
                while ((ne = sfe.getNextException()) != null &&
                        ne instanceof MessagingException) {
                    sfe = (MessagingException)ne;
                    if (sfe instanceof SMTPAddressFailedException) {
                        SMTPAddressFailedException ssfe =
                                        (SMTPAddressFailedException)sfe;
                        System.out.println("ADDRESS FAILED:");
                        System.out.println(ssfe.toString());
                        System.out.println("  Address: " + ssfe.getAddress());
                        System.out.println("  Command: " + ssfe.getCommand());
                        System.out.println("  RetCode: " + ssfe.getReturnCode());
                        System.out.println("  Response: " + ssfe.getMessage());
                    } else if (sfe instanceof SMTPAddressSucceededException) {
                        System.out.println("ADDRESS SUCCEEDED:");
                        SMTPAddressSucceededException ssfe =
                                        (SMTPAddressSucceededException)sfe;
                        System.out.println(ssfe.toString());
                        System.out.println("  Address: " + ssfe.getAddress());
                        System.out.println("  Command: " + ssfe.getCommand());
                        System.out.println("  RetCode: " + ssfe.getReturnCode());
                        System.out.println("  Response: " + ssfe.getMessage());
                    }
                }
            }
            setVariableData ("res",
                        "repl_payload",
                        "/jsm:destResponse/jsm:status",
                        err_str);
        }

        ]] ></bpelv:exec>
    <reply partnerLink="caller" portType="jsm:dest" operation="send" variable="res"/>
```

```
  </sequence>
</process>
```

and support WSDL file:

```
<?xml version="1.0"?>
<definitions name="javaSendMail"
  targetNamespace="urn:java:sendMail"
  xmlns:jsm="urn:java:sendMail"
  xmlns:plnk="http://schemas.xmlsoap.org/ws/2003/05/partner-link/"
  xmlns="http://schemas.xmlsoap.org/wsdl/">
  <types>
    <schema attributeFormDefault="qualified" elementFormDefault="qualified"
      targetNamespace="urn:java:sendMail"
      xmlns="http://www.w3.org/2001/XMLSchema">
      <element name="destRequest">
        <complexType>
          <sequence>
            <element name="mailhost" type="string"/>
            <element name="to" type="string"/>
            <element name="subject" type="string"/>
            <element name="text" type="string"/>
          </sequence>
        </complexType>
      </element>
      <element name="destResponse">
        <complexType>

     <plnk:role name="destProvider">
       <plnk:portType name="jsm:dest"/>
     </plnk:role>
   </plnk:partnerLinkType>
</definitions>
```

.NET CLR execution

Configuration

The CLR is available only for CLR enabled Virtuoso servers. In order to configure the server for CLR support in BPEL4WS engine the following administration steps need to be taken:

- 1. Initiate "CLRAssembliesDir" configuration entry ("Directory where .NET CLR assemblies must be stored") by the path where "virt_bpel4ws.dll", "virtclr.dll" etc are stored.

Using the C# code in BPEL4WS

The tag for supporting CLR is <exec binding="CLR" [using | ref]>.

<exec> with "using" attribute relates to "using" directive in C# code.

```
<bpelv:exec binding="CLR" using="System"/>
```

in BPEL file is a substitution of

```
using System;
```

statement in the C# code.

To import assemblies (with a manifest) the <exec> element with "ref" attribute must be used:

```
<bpelv:exec binding="CLR" ref="metad1.dll"/>
<bpelv:exec binding="CLR" ref="d:\\myassemblies\\sms_service.dll"/>
```

If the tag does not contain these attributes then the content of the tag is treated as C# code. It is suggested to use CDATA sections for the code. Example:

```
<bpelv:exec binding="CLR" name="invokeSomething"><![CDATA[

        Console.WriteLine("Executing CLR assembly in BPEL");
        Console.WriteLine("getVariableData returned: " + getVariableData ("request", "req_payload", "/tns

        setVariableData ("res",
                         "repl_payload",
                         "/destResponse/country",
                         "UK");
]] ></bpelv:exec>
```

Two "functions" are available for accessing script variables: setVariableData and getVariableData (analogs of the xpath functions with same names).

```
void setVariableData (String var_name, String part, String query_path, Object value);
```

sets the variable. The value to be set is restricted to be string or integer in this version.

```
Object getVariableData (String var_name, String part, String query)
```

is a full analog of xpath function getVariableData. See details below.

Note, the activity does not commit changes to the database until it finishes successfully, so in a case of exception the variables are kept untouched. This also means that deadlocks can not occur during C# code execution (naturally, this statement is not true if the code contains direct invocation of SQL through the "in-process" .NET provider).

If the some unhandled exception occurred in C# code, it will be translated to a BPEL error. See details in the next section.

Runtime Errors

Runtime errors not handled by CLR itself are translated to the BPEL fault in the following form:

```
<bpws:clrFault sqlState="SQLSTATE">
 error message

</bpws:javaFault>
```

this error can be handled by BPEL fault handler. Here is an example:

```
...
    <scope>
      <faultHandlers>
        <catch faultName="bpws:clrFault" faultVariable="error">
          <assign>
            <copy>
```

```
              <from variable="error" query="/clrFault/text()"/>
              <to variable="res" part="repl_payload" query="/clr:destResponse/clr:status"/>
            </copy>
          </assign>
        </catch>
      </faultHandlers>
      <bpelv:exec binding="CLR" name="Hotmail"><![CDATA[
            String login, passwd;
               login = (String) getVariableData ("request", "req_payload", "/clr:destRequest/clr:login")
               passwd = (String) getVariableData ("request", "req_payload", "/clr:destRequest/clr:passwo
               Console.WriteLine ("user:" + login + " password:" + passwd);

               HotmailUsage usage = new HotmailUsage();
               Console.WriteLine ("Result: " + usage.Call_Hotmail (login, passwd));

               setVariableData ("res",
                       "repl_payload",
                       "/clr:destResponse/clr:status",
                       "OK");
        ]] ></bpelv:exec>
        </scope>
    <reply partnerLink="caller" portType="clr:dest" operation="send" variable="res"/>
...
```

In this code the handler for CLR exception is set:

```
...
        <catch faultName="bpws:clrFault" faultVariable="error">
          <assign>
            <copy>
              <from variable="error" query="/clrFault/text()"/>
              <to variable="res" part="repl_payload" query="/clr:destResponse/clr:status"/>
            </copy>
          </assign>
        </catch>
...
```

The handler takes the error message from the variable which holds it ("error") and puts it into the response variable.

BPEL variable accessors

The name and the signature of BPEL accessors for CLR are fully equal to the java accessors. See java section for details.

Special variables

The special variables for CLR are the same as for Java. See java section for details.

CLR Sample

```
<?xml version="1.0"?>
<process xmlns:clr="urn:clr:Hotmail"
        xmlns="http://schemas.xmlsoap.org/ws/2003/03/business-process/"
        name="clrHotmail"
        targetNamespace="urn:clr:Hotmail"
        xmlns:bpelx="http://schemas.oracle.com/bpel/extension"
        xmlns:bpelv="http://www.openlinksw.com/virtuoso/bpel">

  <bpelv:exec binding="CLR" using="HotmailUsageChecker"/>
  <bpelv:exec binding="CLR" ref="l:\\distrib_3_0\\bin\\Hotmail.dll"/>
  <bpelv:exec binding="CLR" using="System"/>

  <partnerLinks>
    <partnerLink name="caller" partnerLinkType="clr:dest"/>
  </partnerLinks>

  <variables>
    <variable name="request" messageType="clr:destRequestMessage"/>
    <variable name="res" messageType="clr:destResponseMessage"/>
  </variables>
```

```
  <sequence>
    <receive partnerLink="caller" portType="clr:dest" operation="send" variable="request" createInstance=
    <scope>
      <faultHandlers>
        <catch faultName="bpws:clrFault" faultVariable="error">
          <assign>
            <copy>
              <from variable="error" query="/clrFault/text()"/>
              <to variable="res" part="repl_payload" query="/clr:destResponse/clr:status"/>
            </copy>
          </assign>
        </catch>
      </faultHandlers>
      <bpelv:exec binding="CLR" name="Hotmail"><![CDATA[
             String login, passwd;
                login = (String) getVariableData ("request", "req_payload", "/clr:destRequest/clr:login")
                passwd = (String) getVariableData ("request", "req_payload", "/clr:destRequest/clr:passwo
                Console.WriteLine ("user:" + login + " password:" + passwd);

                HotmailUsage usage = new HotmailUsage();
                Console.WriteLine ("Result: " + usage.Call_Hotmail (login, passwd));

                setVariableData ("res",
                        "repl_payload",
                        "/clr:destResponse/clr:status",
                        "OK");
        ]]></bpelv:exec>
        </scope>
    <reply partnerLink="caller" portType="clr:dest" operation="send" variable="res"/>
  </sequence>
</process>
```

17.15.2. Protocol Support

The Virtuoso BPEL implementation supports WS Security and WS Reliable Messaging. These protocols may be enabled and configured for individual partner links. The WS-Addressing protocol is automatically used when the partner has such capabilities.

The Partner link options are stored in XML format in the 'BPEL.BPEL.partner_link_init' table in 'bpl_opts' column. See the document format and table description below in this chapter.

WS-Addressing (WSA)

WS-Addressing is transparently handled via WSDL description and request of the partner(s). If the partner has WSA headers exposed then the corresponding operation will be invoked with WSA headers. If the partner uses WSA to call the BPEL service then the service will respond to the partner with WSA headers included.

The benefit of using WSA consists in transparently handled message correlation via "MessageID" and "RelatesTo" headers. Thus no explicit message correlation needs to be specified when the partner is WSA capable (see LoanFlow demo in tutorials to see how this works). Also when the reply is asynchronous the return path can be handled via the "ReplyTo" WSA headers.

As WSA has different revisions that are supported by different implementations (partners), the version of the protocol is configurable via wsOptions/addressing element (see below).

The 'wsa' partner link option can be used in API functions to set or retrieve the value of the wsOptions/addressing.

WS-Security (WSS)

There are several cases where privacy and confidentiality must be observed , this is especially true when business processes involve payment systems, personal information etc. In those cases a partner may, depending on Web Service policy, require secure messages (signed, encrypted or both). Such partners usually do not expose (for many reasons) in WSDL the WSS headers, hence this must be configured by the BPEL administrator per partner.

In order for the BPEL server to be able to sign and encrypt messages keys have to be uploaded into the BPEL user repository. This can be done with the USER_KEY_LOAD() function or using the BPEL GUI (Partner Link properties).

It is important to know the following basics:

- The private key is needed in order to decrypt or sign messages.
- The partner public key is needed to encrypt messages or verify signatures.

These keys have to be described in wsOptions/security/key and wsOptions/security/pubkey in the 'Partner link options' XML document. Note that in the options document are stored only the names of the keys, as the keys themselves are registered in the BPEL user key repository.

Note: Use the 'wss-priv-key' and 'wss-pub-key' partner link option in API functions to set or change the value of them.

The encryption and signing is independently configurable for outbound or inbound messages. This is settable via the following options:

- wsOptions/security/in/encrypt - 'Optional': inbound message MAY be encrypted, 'Mandatory': inbound message MUST be encrypted ('wss-in-encrypt' option in API)
- wsOptions/security/in/signature - same as encryption but for XML signature ('wss-in-signature' option in API)
- wsOptions/security/in/keys - this is a list of keys (key names) that are trusted; only SOAP messages signed with one of these keys will be accepted. If this list is empty, all parties will be accepted unless signature is invalid or message can not be decrypted. ('wss-in-signers' option in API)
- wsOptions/security/out/encrypt - type of the session key for encryption 3DES, AES128, AES192 or AES256. ('wss-out-encrypt-key' option in API)
- wsOptions/security/out/signature - 'Default': the WSS default template (see WS-Security chapter for details), 'Custom': in this case 'function' attribute must refer to a PL procedure returning XML Signature template. ('wss-out-signature-type' and 'wss-out-signature-function' options in API)

WS-Reliable Messaging (WSRM)

The WSRM is applicable for those partners which can be invoked asynchronously. For both inbound or outbound (from the point of view of the process) WSRM can be enabled. The options are settable in wsOptions/delivery/in or wsOptions/delivery/out ('wsrm-in-type' and 'wsrm-out-type' options in API) respectively.

- ExactlyOnce - message will be delivered only once to the destination.
- InOrder - messages will be delivered in the same order as they are sent from the script.

HTTP security

Some partner services may require HTTPS or/and HTTP authentication instead of using WS-Security protocol to ensure SOAP message privacy.

When a partner's endpoint URL contains HTTPS scheme (like https://) the request and response operations will be made with HTTP over SSL (HTTPS protocol). In this case no additional options to the partner links are needed.

In case when a partner service needs a HTTP authentication, the user name and password (for that service) needs to be configured for the given partner link. These are settable via wsOptions/security/http-auth ('http-auth-uid' and 'http-auth-pwd' options in API) element in partner link options. Note that only basic HTTP authentication is supported.

Partner link options format

```
<wsOptions>
    <!-- WSA revision namespace -->

    <addressing version="http://schemas.xmlsoap.org/ws/2003/03/addressing|http://schemas.xmlsoap.org/ws/2
  <!-- WSS options -->

  <security>
      <!-- basic HTTP Authentication -->

      <http-auth username="" password=""/>
      <!-- WSS keys -->

      <key name="[Private Key]"/>
      <pubkey name="[Partner public key]"/>
    <in>
```

```
      <encrypt type="NONE|Optional|Mandatory"/>
      <signature type="NONE|Optional|Mandatory" />
      <keys>
          <!-- trusties -->

          <key name="[Trusted Public Key]"/>
          ...
      </keys>
    </in>
    <out>
        <encrypt type="NONE|3DES|AES128|AES192|AES256"/>
        <signature type="NONE|Default|Custom" function="[PL procedure name]"/>
    </out>
  </security>
  <!-- WSRM options -->

  <delivery>
    <in  type="NONE|ExactlyOnce|InOrder"/>
    <out type="NONE|ExactlyOnce|InOrder" />
  </delivery>
</wsOptions>
```

Configuring the Partner link options

The partner link options can be configured vi BPEL UI (http://host:port/BPELGUI) or programmatically using `plink_get_option()` and `plink_set_option()` functions. It is possible to update the partner link options with SQL update statement using the configuration (described above), but use of the BPEL UI or API functions is recommended.

Dynamic Partner Links

The 'assign' activity allows partner links to be assigned values at run time. This means that partner links can be dynamic and that a process may call partners that were not known at the time of defining the process. Partner links can be defined at run time using the 'EndpointReference' element from the WS-Addressing specification :

```
<xs:element name="EndpointReference" type="wsa:EndpointReferenceType"/>
<xs:complexType name="EndpointReferenceType">
  <xs:sequence>
    <xs:element name="Address" type="wsa:AttributedURI"/>
    <xs:element name="ReferenceProperties" type="wsa:ReferencePropertiesType" minOccurs="0"/>
    <xs:element name="PortType" type="wsa:AttributedQName" minOccurs="0"/>
    <xs:element name="ServiceName" type="wsa:ServiceNameType" minOccurs="0"/>
    <xs:any namespace="##other" processContents="lax" minOccurs="0" maxOccurs="unbounded" />
  </xs:sequence>
  <xs:anyAttribute namespace="##other" processContents="lax"/>
</xs:complexType>
```

Thus it may keep endpoint URL, Port type, Service name and any number of implementation specific options under 'ReferenceProperties'. Also it may keep any other extensible elements and attributes.

The Virtuoso BPEL implementation extends the EndpointReferenceType with element 'wsOptions' under WSA element 'ReferenceProperties' (see previous section for 'wsOptions' element description). Thus it is possible to decide at run time to send a secure reply (WSS) or to use reliable messaging (WSRM). The following excerpt shows BPEL source that assigns WS Security options to a partner link:

```
    ...
    <assign>
        <copy>
            <from>
                <EndpointReference xmlns="http://schemas.xmlsoap.org/ws/2003/03/addressing">
                    <Address>http://securehost/myService</Address>
                    <ReferenceProperties>
                        <wsOptions xmlns="">
                            <addressing version="http://schemas.xmlsoap.org/ws/2003/03/addressing"/>
                            <security>
                                <http-auth username="" password=""/>
                                <key name="myKey"/>
                                <pubkey name="serverKey"/>
```

```
                                <in>
                                    <encrypt type="Optional"/>
                                    <signature type="Optional" />
                                    <keys/>
                                </in>
                                <out>
                                    <encrypt type="AES128"/>
                                    <signature type="Default"/>
                                </out>
                            </security>
                        </wsOptions>
                    </ReferenceProperties>
                </EndpointReference>
            </from>
            <to partnerLink="service"/>
        </copy>
    </assign>
    ...
```

To manipulate the partner link options and endpoint URL we can also use variables declared as element EndpointReference from WS-Addressing schema.

17.15.3. Process lifecycle

A BPEL process may have more than one version during development or maintenance in production environment. This means the process may have a more than one copy on the server where one of these copies is current all others are either obsolete or in the process of being defined . We will call these states further in this section as 'current', 'obsolete' or 'edit' (versions). The link between these versions is the process name which remains the same during process life-cycle.

When a process is compiled for the first time it becomes 'current'. The current version of a process is the one that was most recently compiled without errors. Only a current version of a process can make new instances in response to receiving messages. For a single process name only one version can be current at any one time. The other compiled versions of the process are always obsolete, meaning that new instances cannot be created but that old instances may proceed and complete.

The 'obsolete' version can not crate new process instances, it may only receive messages for its instances which are still running or suspended. In other words the old process instances will continue and any new instances will be instances of the current version.

The 'edit' state means that a new copy of the process is created but it is still not compiled. After successful compilation, a process in the edit state is set into the current state and the formerly current process is set to the the obsolete state.

All process versions may have only one endpoint corresponding to the process. The BPEL administrator MUST take care about endpoints to make sure that clients using the process are compatible with different process versions. This means that if changes in new versions are for example in the logic but not in the process' WSDL then new endpoint is not needed in most cases; furthermore in this case clients will be compatible with new input and output message structure; except in the case where the same messages are used with logically different meaning. So when a new process version involves significant change to messages then the new process should have a new endpoint and WSDL description.

17.15.4. Using virtual directories

To allow a process to make new instances or to receive messages from remote services in asynchronous way it needs an endpoint. Endpoint means an URL that allows to accept and process known SOAP messages.

Every process has a default endpoint which is accessible via the 'http://[host:port]/BPELGUI/bpel.vsp?script=[process_name]' URL. Also it has a default WSDL document describing the process at URL http://[host:port]/BPELGUI/bpel.vsp?script=[process_name]&wsdl. Upon compilation a different virtual directory can be specified for the process. For example if '/Service' is specified the 'http://[host:port]/Service' would be the endpoint URL also in this case the WSDL will be available on 'http://[host:port]/Service?wsdl'.

It is important to note that changing the virtual directory when a process is redefined will force all clients to update their configuration. This is the case when a major changes are made to the process and clients need to be re-linked against new WSDL. So when changes are small there will be no need of a new virtual directory. (See section 'Process life-cycle' above for process versions).

17.15.5. Process archiving

When an instance of a BPEL process is completed it will be archived and purged from system after a configurable time interval. The interval is settable via 'InstanceExpiryDelay' configuration option (see below how to change). The default interval for archiving is one day.

The archive file contains status of the instance which is archived, execution path of the activities when execution is completed, value of the variables and partner links.

The format of the archive file is as follows:

```
<instances>
  <instance
xml:id="[instance id]">
    <status code="[2 - success |3 - error]" error="[error description]"/>
    <execution>
        <node
xml:id="[activity id]" type="[activity type]"/>
        ... more nodes may follow ...
    </execution>
    <variables>
        <variable name="[name of the variable]">... variable value ...</variable>
        ... more variables may follow ...
    </variables>
    <partnerLinks>
      <partnerLink name="[name of the partner link]">
        <EndpointReference>
            <Address>... partner link endpoint ...</Address>
        </EndpointReference>
      </partnerLink>
      ... more partner links may follow ...
    </partnerLinks>
  </instance>
</instances>
```

17.15.6. Configuration parameters

The BPEL engine has global configuration parameters settable via the configuration settings page of its web user interface. These are global and are kept in the BPEL..configuration table as name/value pairs.

- EngineMailAddress - e-mail address to whom will be sent error alerts and reports.
- ErrorAlertSkeleton - e-mail template for error alerts
- ErrorReportSkeleton - e-mail template for error reports
- AlertSubject - Subject for error alert e-mail
- CommonEmailHeader - Header for all BPEL e-mail notifications
- ErrorSubject - Subject for error report e-mail
- InstanceExpiryDelay - how long (hours a completed instance will be kept in the database before purging.
- MailServer - if specified this will be used to send the error alerts and reports. If this is not specified the default (from INI file) mail server will be used.
- Statistics - process statistics flag, if 0 (default) the statistics collection is disabled. When this is 1 the engine will start collecting statistics for new process instances .

17.15.7. Process Statistics

The BPEL process can be set to collect statistics, this can be enabled by turning on the statistics flag (see Configuration section). If the statistics flag is on the following data is available:

- count of instance creations per instance creating partner link
- count/duration/data volume of invokes per invoked synchronous partner link
- count/data volume per asynchronous partner link
- waiting time/count/data volume at non-instance creating receives
- average time to complete for process
- Errors per partner link

- count of created instances
- count of completed instances
- count of instances that could not terminate successfully

17.15.8. Deployment file suitcase format

The relation between a BPEL process and different partner links can be stored in a deployment file. This file contains a description for every partner link mention in the process. The descriptor file simplifies deployment. Entering the URL of this file through the web administration interface will download and register all sources needed for the process compilation.

The format of the deployment file is as follows:

```
    <BPELSuitcase>
        <BPELProcess
xml:id="[process id]" src="[URI of the file containing BPEL script]">
                <partnerLinkBindings>
                        <partnerLinkBinding name="[name of the partner]">
                            <property name="wsdlLocation">[URI of the WSDL for the partner]</property>
                        </partnerLinkBinding>
                        ... more partnerLinkBinding may follow ...
                </partnerLinkBindings>
        </BPELProcess>
    </BPELSuitcase>
```

17.15.9. SQL API

The following API functions are available:

bpel_compile_script_dedup

For detailed description and example use of the function, see bpel_compile_script in the Functions Reference Guide.

bpel_copy_script_dedup

For detailed description and example use of the function, see bpel_copy_script in the Functions Reference Guide.

bpel_get_partner_links_dedup

For detailed description and example use of the function, see bpel_get_partner_links in the Functions Reference Guide.

bpel_instance_delete_dedup

For detailed description and example use of the function, see bpel_instance_delete in the Functions Reference Guide.

bpel_purge_dedup

For detailed description and example use of the function, see bpel_purge in the Functions Reference Guide.

bpel_script_delete_dedup

For detailed description and example use of the function, see bpel_script_delete in the Functions Reference Guide.

bpel_script_obsolete_dedup

For detailed description and example use of the function, see bpel_script_obsolete in the Functions Reference Guide.

bpel_script_source_update_dedup

For detailed description and example use of the function, see bpel_script_source_update in the Functions Reference Guide.

bpel_script_upload_dedup

For detailed description and example use of the function, see bpel_script_upload in the Functions Reference Guide.

bpel_wsdl_upload_dedup

For detailed description and example use of the function, see bpel_wsdl_upload in the Functions Reference Guide.

plink_get_option_dedup

For detailed description and example use of the function, see plink_get_option in the Functions Reference Guide.

plink_set_option_dedup

For detailed description and example use of the function, see plink_set_option in the Functions Reference Guide.

bpel_import_script_dedup

For detailed description and example use of the function, see bpel_import_script in the Functions Reference Guide.

17.15.10. BPEL XPath Functions

bpel_get_var_dedup

For detailed description and example use of the function, see bpel_get_var in the Functions Reference Guide.

bpel_set_var_dedup

For detailed description and example use of the function, see bpel_set_var in the Functions Reference Guide.

xpf_processxquery_dedup

For detailed description and example use of the function, see xpf_processxquery in the Functions Reference Guide.

xpf_processxslt_dedup

For detailed description and example use of the function, see xpf_processxslt in the Functions Reference Guide.

xpf_processxsql_dedup

For detailed description and example use of the function, see xpf_processxsql in the Functions Reference Guide.

17.15.11. Tables

BPEL Engine Tables

```
-- Scripts table, keeps one record per version
create table BPEL.BPEL.script (
        bs_id integer identity,         -- unique id identifying the process
        bs_uri varchar,                 -- obsoleted: script source URI
        bs_name varchar,                -- process name, all versions have same name
        bs_state int,                   -- 0 on, current version, 1 obsolete, 2 edit mode
        bs_date datetime,               -- date of registration
        bs_audit int default 0,         -- audit flag : 1 on, 0 off
        bs_debug int default 0,         -- debug flag
        bs_version int default 0,       -- process version
        bs_parent_id int default null,  -- fk to bs_id of previous process version
        bs_first_node_id int,           -- the first node id in the graph
        bs_pickup_bf varbinary default '\x0',   -- bitmask for resume nodes
        bs_act_num      int,            -- stores the total number of activities
        bs_lpath        varchar default null, -- virtual directory

        -- process statistics
        bs_n_completed int default 0,
```

```
        bs_n_errors int default 0,
        bs_n_create int default 0,
        bs_cum_wait int default 0,
        primary key (bs_id));

-- BPEL and WSDL sources
create table BPEL..script_source
        (
         bsrc_script_id int, -- script id, fk to bs_id of scripts table.
         bsrc_role varchar,  -- one of bpel, bpel-ext, wsdl, deploy, partner-1... partner-n
         bsrc_text long xml, -- source text
         bsrc_url varchar,   -- if this comes from an uri
         bsrc_temp varchar,  -- contains the namespaces info
         primary key (bsrc_script_id, bsrc_role)
)
;

-- Process instances
create table BPEL.BPEL.instance (
        bi_id int identity,             -- global immutable id of instance
        bi_script int,                  -- fk to bs_id from BPEL.BPEL.script
        bi_scope_no int default 0,      -- sequence counter for scope numbers in instance
        bi_state int default 0,
                -- 0, started
                -- 1, suspended (wait for signal)
                -- 2, finished
                -- 3, aborted
        bi_error any,                   -- error
        bi_lerror_handled int,
        bi_last_act     datetime,       -- last activity execution
        bi_started      datetime,       -- start time
        bi_init_oper    varchar,        -- operation that made the instance
        bi_wsa          long xml,       -- WS-Addressing headers
        bi_activities_bf varbinary default '\x0\x0', -- bitmask for each activity is completed or not
        bi_link_status_bf varbinary default '\x0\x0', -- bitmask for link status
        bi_prefix_info varchar default '', -- xpath prefix string
        primary key (bi_id));

-- Initial values (URL etc.) for partner links
create table BPEL.BPEL.partner_link_init (
        bpl_script int,         -- script instance id

         primary key (hc_script, hc_type,  hc_name)
)
;
```

17.15.12. Errors

During the BPEL process execution we may consider following types of errors:

- Server failure - This means that the server as a whole has stopped operations and requires manual intervention. This is the case for: out of disk or database corruption.
- Network - This category applies to possibly transient conditions of not being able to contact partners. The server remains in operation for unaffected partners.
- Process Instance - This category applies to process instances getting an unhandled error condition. The process instance is out of service until the condition is resolved. This may indicate a bug in the process itself or a component used by it.

These errors will be logged in the file system (bpel_audit/server_log.txt) . If logging fails, an email is sent to the operator. The errors are also logged in the 'BPEL.BPEL.error_log' table so as to avoid repeatedly sending the same message.

During uploading the BPEL process we may consider following types of errors:

- bpel.xml file contains non-absolute paths and must be changed to absolute in order the uploading to be successful. This is in case user uses import_script api.
- wsdl file contains non-absolute paths at importing other wsdl file or xsd and must be changed to absolute in order the uploading to be successful. This is in case user uses upload process by choosing url/file for bpel and wsdl.
- process name already exists. This means there is already uploaded a process with the given name.
- at least one activity "receive" or "pick" must be declared at script source. Otherwise will be reported error this condition to be accomplished.

Connection Errors

The communication error can be caught by explicit fault handler in the script. In this case the <catch> handler must catch the fault "bpws:communicationFault":

```
<catch faultName="bpws:communicationFault" faultVariable="error">
 ...
</catch>
```

The error variable "error" will contain the following fault structure:

```
<comFault sqlState="xxxxx" message="text-of-message"
  partnerLink="plinkname" activity="name of activity" partnerURI="uri of
partner">
   <message>-- copy of the message being sent when fault occurred -- </message>
</comFault>
```

which can be used for reporting, recovery etc... The "sqlState" attribute contains SQL error state and the "message" stores the first line of SQL error message.

If the script does not handle this fault, the script will be frozen until explicit or implicit restart.

Here is an example of explicit communication handling:

```
<process xmlns:tns="urn:echo:echoService" xmlns="http://schemas.xmlsoap.org/ws/2003/03/business-process/"
  <partnerLinks>
    <partnerLink name="caller" partnerLinkType="tns:echoSLT"/>
    <partnerLink name="test" partnerLinkType="tns:testSLT" partnerRole="service"/>
  </partnerLinks>
  <variables>
    <variable name="request" messageType="tns:StringMessageType"/>
    <variable name="res" messageType="tns:StringMessageType"/>
    <variable name="n_tries" messageType="tns:IntMessageType"/>
  </variables>
  <sequence name="EchoSequence">
    <assign>
      <copy>
        <from expression="3"/>
        <to variable="n_tries" part="value" query="/value"/>
      </copy>
    </assign>
    <receive partnerLink="caller" portType="tns:echoPT" operation="echo" variable="request" createInstanc
    <while condition="getVariableData ('n_tries', 'value', '/value')
          &gt; 0">
      <sequence>
        <scope>
          <faultHandlers>
            <catch faultName="bpws:communicationFault" faultVariable="error">
              <sequence>
                <bpelv:exec binding="SQL">
                  dbg_obj_print (BPEL.BPEL.getVariableData ('error'));
                  dbg_obj_print (BPEL.BPEL.getVariableData ('n_tries'));
                </bpelv:exec>
```

```
                <assign>
                  <copy>
                    <from variable="error" query="/comFault/@sqlState"/>
                    <to variable="res" part="echoString" query="/echoString"/>
                  </copy>
                  <copy>
                    <from expression="getVariableData ('n_tries',
                          'value', '/value') - 1"/>
                    <to variable="n_tries" part="value" query="/value"/>
                  </copy>
                </assign>
                <wait for="PT10S"/>
              </sequence>
            </catch>
            <catchAll>
              <empty/>
            </catchAll>
          </faultHandlers>
          <sequence>
            <invoke partnerLink="test" portType="tns:SOAPPortType" operation="test" inputVariable="reques
            <assign>
              <copy>
                <from expression="0"/>
                <to variable="n_tries" part="value" query="/value"/>
              </copy>
            </assign>
          </sequence>
        </scope>
      </sequence>
    </while>
    <reply partnerLink="caller" portType="tns:echoPT" operation="echo" variable="res" name="EchoReply"/>
  </sequence>
</process>
```

In this example the process in a case of communication exception makes 3 reconnection retries to the remote service. Each reconnection is made after waiting 10 seconds.

Deadlock Errors

During concurrent execution of several BPEL scripts deadlock conditions can be signalled. That is why Virtuoso BPEL engine contains implicit deadlock detection and retry capability. When the deadlock is detected, the engine tries to wait some time, and retry the transaction. If the number of retries exceeds some maximum number the script execution will be aborted and mail will be sent to the operator with an appropriate message.

The time to wait before retry and the maximum number of retries can be configured on the configuration page of the administration UI.

17.15.13. Samples

Simple echo script

```
<process name="echo" targetNamespace="http://temp.uri" xmlns:tns="http://temp.uri"
    xmlns="http://schemas.xmlsoap.org/ws/2003/03/business-process/">

    <partnerLinks>
        <partnerLink name="caller" partnerLinkType="tns:echoService"/>
    </partnerLinks>

    <variables>
        <variable name="request" messageType="tns:StringMessageType"/>
    </variables>

    <sequence name="EchoSequence">
        <receive partnerLink="caller" portType="tns:echoPort"
            operation="echo" variable="request"
            createInstance="yes" name="EchoReceive"/>
        <reply partnerLink="caller" portType="tns:echoPort"
            operation="echo" variable="request" name="EchoReply"/>
    </sequence>
```

```
</process>
```

... and corresponding WSDL

```
<definitions targetNamespace="http://temp.uri" xmlns:tns="http://temp.uri"
             xmlns:pl="http://schemas.xmlsoap.org/ws/2003/05/partner-link/"
             xmlns:xsd="http://www.w3.org/2001/XMLSchema"
             xmlns="http://schemas.xmlsoap.org/wsdl/">

   <message name="StringMessageType">
      <part name="echoString" type="xsd:string"/>
   </message>

   <portType name="echoPort">
      <operation name="echo">
         <input message="tns:StringMessageType"/>
         <output message="tns:StringMessageType"/>
      </operation>
   </portType>

17.15.15. BPEL4WS VAD Package installation

Using Conductor

- Step 1. Download BPEL4WS VAD and copy it to a local directory.
- Step 2. Go to Conductor UI: http://host:port/conductor/
- Step 3. Login into the Virtuoso Conductor using the admin account.
- Step 4. Select Systems Admin->Packages Tab.
- Step 5. Under the Install Packaged, section of the UI is a list of VAD packages. If this is the first time you have installed a VAD package you will only see the Virtuoso Conductor. Directly under this list is the option Install a Package. You can either enter or browse to the location of the directory of the BPEL4WS package or enter a DAV location.
- Step 6. Once you have provided the location, select Proceed to upload the package.

Using ISQL

```
SQL>VAD_INSTALL('bpel4ws.vad',0);
 SQL_STATE  SQL_MESSAGE
 VARCHAR  VARCHAR
 _____________________________________________________________________________

 00000    GUI is accessible via http://host:port/BPELGUI
 00000    Quick Start is available from http://host:port/BPELGUI/start.vsp
 00000    No errors detected, installation complete.
 00000    Now making a final checkpoint.
 00000    Final checkpoint is made.
 00000    SUCCESS

 7 Rows. -- 5438 msec.
```

17.16. XSQL

XSQL is an XML-based format for describing simple stored procedures that can parse XML data, query or update database tables and compose XML output. Both input and output XMLs of such procedures are usually standard three-level documents: a top-level `ROWSET` element contains some number of `ROW` elements and every `ROW` contains one element per database field. XSQL lets the application developer avoid writing routine code for parsing and composing such documents: the server translates a short and self-evident XSQL description into a relatively long Virtuoso/PL procedure.

XSQL pages are usually executed from XSLT stylesheets by calling `processXSQL()` XPATH function. When the page is executed, it can access an XML entity that is context entity of the `processXSQL()` call. This entity is used inside the page as an implicit parameter called "context XML".

An XSQL document that describes one procedure is called "XSQL page". A page consists of small directives. Every directive is written as a single XML element from namespace "urn:oracle-xsql" (the typical namespace prefix is "xsql"). Every directive describes one standard operation. The resulting Virtuoso/PL procedure will execute all directives in turn. Directives are of four sorts:

Parameter assignments create and initialize local variables ("page parameters") that can be used in the rest of page.

Data modification requests can insert, delete or update data in database tables.

XML generators can query database or page parameters and produce XML fragments. These fragments form the resulting XML that is returned by the procedure.

DML directives let the author to put arbitrary Virtuoso/PL code in the procedure.

All directives are children of one op-level element called 'xsql:page'. This element can have any number of attributes but no one attribute is used by Virtuoso. These attributes may be used by specialized XSQL editors and standalone XSQL processors that should establish a database connection to read and write data so store connection details as attributes of 'xsql:page'.

The XSQL development cycle consists of editing '.xsql' resources in the file system or Virtuoso DAV. The editing can take place using a regular text editor or a supporting XML editor or some specialized third-party XSQL tool.

17.16.1. XSQL Syntax

Properties of each XSQL directives are specified by XML attributes. These attributes are of different types, mostly SQL expressions, calculateable strings, SQL names and lists of names (e.g., name of a database table or a list of columns of a table).

In some cases, SQL expressions are long and it is not convenient to place them into attribute values. Such expressions are written as text content of the XSQL directive element.

SQL expressions. XSQL allows slightly extended syntax of SQL expressions. If X is a name of page parameter made by xsql:set-page-param then special notation "{@X}" stands for the reference to the parameter value. This notation can be used in any place where a variable name is acceptable. In addition, this notation can be used inside string literals, such a literal is translated into a string concatenation expression; e.g., `'text-head{@X}text-middle{@Y}text-tail'` is converted into `concat ('text-head', cast ({@X} as varchar), 'text-middle', cast ({@Y} as varchar), 'text-tail')`.

Calculateable strings . Some attribute values are strings like resource URIs or XML names to be used in the output generated by a page. They are usually written 'as is' but they can use "{@X}" notation to insert the value of page parameter into the resulting string. The actual value of a calculateable string is compiled only once even if it appears many times in the XML output of the page.

Names of SQL columns . Some attributes are not arbitrary SQL expressions but only SQL column names. These names are written 'as is'. Only unqualified names are allowed, not in form 'table.column'. No "{@X}" is allowed for obvious reasons. If SQL name is case-sensitive or contains nonalphabetical characters then the name should be enclosed in double quotes. For readability, use single quotes to surround attribute value to not mix them with possible double quotes used in SQL name. Whitespace characters are not allowed in these names because these will not make proper names of XML elements.

Names of SQL tables . SQL table names are also written 'as is', with the same rules for double quotes around case-sensitive parts of the name. Both qualified and unqualified names are allowed.

Lists of names of SQL columns . When the value of attribute lists one or more column names, white space characters or commas delimit column names. The list should be space-delimited like 'COL1 COL2 COL3' or comma-delimited like 'COL1, COL2, COL3' but not a mix of them like 'COL1, COL2 COL3'.

17.16.2. XSQL Directives

xsql:delete-request

Deletes the rows listed in the context XML.

```
<xsql:delete-request
  table="table_name"
  key-columns="column_list"
  [ transform="calculateable_URI_string" ]
/>
```

If 'transform' URI is specified then it is used as a name of XSLT stylesheet that is applied to the context XML before the rest of processing. The result of that stylesheet should be in standard ROWSET/ROW form. The result may also contain elements with other names but they will be silently ignored.

After this optional XSLT transformation, the XSQL procedure gets all ROW elements in all top-level ROWSET elements of the source XML. For each such element it parses all subelements whose names match column names listed in the 'key-columns' attribute. It is legal to have a ROW element that does not contain an element that matches a particular column; the missing element is treated as a database NULL. If a subelement of ROW has attribute 'NULL' equal to 'Y' then it is also treated as database NULL.

When required subelements of ROW are parsed, the procedure deletes all rows from the specified table that have all specified column values equal to values specified by ROW subelements. When the delete operation is complete, the procedure parses all subelements of the next ROW element in queue and so on.

```
<xsql:delete-request table='"Demo"."demo"."Customers"' key-columns='"CustomerID"'/>
```

xsql:dml

Executes an arbitrary fragment of Virtuoso/PL code.

```
<xsql:dml>
One or more Virtuoso/PL statements, {@X} syntax is allowed.
</xsql:dml>
```

The XSQL procedure will contain the text of the directive 'as is'; the only change is that `{@X}` notation is replaced with appropriate Virtuoso/PL variables. Note that the use of `<![CDATA[...]]>` XML syntax is very convenient here.

```
<xsql:set-page-param name="X" value="2"/>
<xsql:set-page-param name="Y" value="2"/>
<xsql:dml><![CDATA[
-- This will simply print the string on server's console:
dbg_obj_print ('Hello World\n');
-- This will compose a string '2 * 2 =' and print on console:
dbg_obj_print ('{@X} * {@Y} = ');
-- This will calculate and print a well-known product.
-- Note that attempt to write {@X * @Y} or {@X * Y} results in a syntax error.
dbg_obj_print ({@X} * {@Y}, '\n');
]]>
</xsql:dml>
```

xsql:include-owa

This Oracle-specific directive is not implemented.

xsql:include-param

Puts the value of the specified page parameter into the resulting XML of the page.

```
<xsql:include-param name="page_param_name"/>
```

This writes the value of the specified page parameter as an element whose name is made from the name of parameter. NULL value results in an empty element that has attribute named 'NULL' with value 'Y'.

Note that XML elements ROWSET and ROW have special use in XSQL pages. The use of parameter names ROWSET and ROW is legal but may cause undesired effects.

```
<xsql:set-page-param name="an-int" value="2"/>
<xsql:set-page-param name="an-xml" value="xtree_doc('<sample>text</sample>')"/>
<xsql:set-page-param name="a-null" value="NULL"/>
```

```
<!-- This will form an element <an-int>2</an-int> -->

<xsql:include-param name="an-int"/>

<!-- This will form an element <an-xml><sample>text</sample></an-xml> -->

<xsql:include-param name="an-xml"/>

<!-- This will form an element <a-null NULL="Y"/> -->

<xsql:include-param name="a-null"/>
```

xsql:include-request-params

This directive is not implemented in this version.

xsql:include-xml

This directive is not implemented in this version.

xsql:include-xsql

This directive is not implemented in this version.

xsql:insert-param

Inserts rows listed in XML that is stored in page parameter.

```
<xsql:insert-param
  name="parameter_XML_name"
  table="table_name"
  [ mode="enum" (could be "into", "soft" or "replacing", default is "into") ]
  [ columns="column_list" ]
  [ date-format="string" (allowed but ignored) ]
  [ transform="calculateable_URI_string" ]
/>
```

The directive inserts into a table all data rows listed in the value of a page parameter that is named by 'name' attribute. The destination table is specified by 'table' attribute.

If 'transform' URI is specified then it is used as a name of XSLT stylesheet that is applied to the source data before the rest of processing. The result of that stylesheet should be in standard ROWSET/ROW form. The result may also contain redundant elements but they will be silently ignored.

After this optional XSLT transformation, the XSQL procedure gets all ROW elements in all top-level ROWSET elements of the source. For each such element it parses all subelements whose names match column names listed in the 'columns' attribute; if the 'columns' attribute is not specified then all column names from the destination table are used. It is legal to have a ROW element that does not contain an element that matches a particular column; the missing element is treated as a database NULL. If a subelement of ROW has attribute 'NULL' equal to 'Y' then it is also treated as database NULL.

When required subelements of ROW are parsed, the procedure adds a row to the table. It executes INSERT INTO, INSERT SOFT or INSERT REPLACING statement depending on the value of 'mode' attribute. When the insert operation is complete, the procedure parses all subelements of the next ROW element in queue and so on.

```
<xsql:insert-param name="customer-details" table='"Demo"."demo"."Customers"' />
```

xsql:insert-request

Inserts the rows listed in context XML.

```
<xsql:insert-request
  table="table_name"
  [ mode="enum" (could be "into", "soft" or "replacing", default is "into") ]
  [ columns="column_list" ]
```

```
  [ date-format="string" (allowed but ignored) ]
  [ transform="calculateable_URI_string" ]
/>
```

The directive inserts into a table all data rows listed in context XML. The destination table is specified by 'table' attribute.

If 'transform' URI is specified then it is used as a name of XSLT stylesheet that is applied to the context XML before the rest of processing. The result of that stylesheet should be in standard ROWSET/ROW form. The result may also contain redundant elements but they will be silently ignored.

After this optional XSLT transformation, the XSQL procedure gets all ROW elements in all top-level ROWSET elements of the source. For each such element it parses all subelements whose names match column names listed in the 'columns' attribute; if the 'columns' attribute is not specified then all column names from the destination table are used. It is legal to have a ROW element that does not contain an element that matches a particular column; the missing element is treated as a database NULL. If a subelement of ROW has attribute 'NULL' equal to 'Y' then it is also treated as database NULL.

When required subelements of ROW are parsed, the procedure adds a row to the table. It executes INSERT INTO, INSERT SOFT or INSERT REPLACING statement depending on the value of 'mode' attribute. When the insert operation is complete, the procedure parses all subelements of the next ROW element in queue and so on.

```
<xsql:insert-request table='"Demo"."demo"."Customers"' columns='"CustomerID", "Phone", "Fax"'/>
```

xsql:query

This executes an SELECT statement and writes its result set into the resulting XML in some sort of ROWSET/ROW format.

```
<xsql:query
  [ fetch-size="integer" (allowed but ignored) ]
  [ id-attribute="calculateable_XML_NAME_string" ]
  [ id-attribute-column="SQL_column_name" ]
  [ max-rows="integer_SQL_expn" (default is no limit) ]
  [ null-indicator="boolean" (default value is "no") ]
  [ row-element="calculateable_XML_NAME_string" (default value is "ROW") ]
  [ rowset-element="string" (default value is "ROWSET") ]
  [ skip-rows="integer_SQL_expn" (default is no skip) ]
  [ tag-case="enum" (could be "lower" or "upper", default is "lower") ]
>
Text of SELECT statement, {@X} syntax is allowed.
</xsql:query>
```

When no attributes is specified, the directive executes the SELECT statement and composes an XML fragment that consists of ROWSET element that have one ROW child element per row of the result set of the executed statement. Every ROW has one child element per result set column. The name of each element is made by converting column name to lowercase and element values are serializations of result set fields. The procedure does not create elements for fields with NULL values so an element with no text inside means empty string value but the totally missing element means NULL. In addition, ROW element have so-called "id attribute" whose name is 'num' and value is a number of the row in the result set.

If attribute 'null-indicator' is equal to '1' or 'yes' then elements are created for both non-NULL and NULL field values. Unlike elements that represent empty strings, element that represent NULL will have an attribute with name 'NULL' and value 'Y'.

Attributes 'id-attribute' and 'id-attribute-column' configures the composing of "id attribute". 'id-attribute-column' instructs to use the value specified SQL column as a value of attribute, 'id-attribute' can specify an attribute name other than default 'num'.

Attribute 'tag-case' specifies the character case of elements for columns. This does not affect names for ROW and ROWSET elements.

Element names ROW and ROWSET can be changed to whatever else by specifying attributes 'row-element' and 'rowset-element'. Either or both of these elements can be omitted at all by specifying empty string value for appropriate attributes; this will prevent the result set from proper parsing by some standard tools but may be convenient for special purposes. Note that If 'row-element' is empty string and ROW should not be created then attributes 'id-attribute' and 'id-attribute-column' should not be used.

Attributes 'max-rows' and 'skip-rows' adds TOP N and SKIP N clauses to the specified SELECT statement. They are supported mostly for compatibility. Attribute 'fetch-size' is ignored at all.

Note that Oracle allows the xsql:query to contain any code that produces a result set whereas Virtuoso allows only SELECT statement.

```
<xsql:set-page-param name="usermask" value="'%DAV%'"/>
<xsql:query>
-- This will produce the following XML fragment:
-- <ROWSET>
--   <ROW num="1"><u_id>3</u_id><u_name>administrators</u_name>
--      <u_full_name>WebDAV Administrators</u_full_name><ROW>
--   <ROW num="2"><u_id>3</u_id><u_name>dav</u_name>
--      <u_full_name>WebDAV System Administrator</u_full_name><ROW>
-- </ROWSET>
SELECT U_ID, U_NAME, U_FULL_NAME from SYS_USERS where U_FULL_NAME like {@usermask}
</xsql:query>
```

xsql:ref-cursor-function

This directive is not implemented in this version of Virtuoso Server.

xsql:set-cookie

This Oracle-specific directive is not implemented.

xsql:set-page-param

Declares a page parameter and assigns a value to it.

```
<xsql:set-page-param
  name="XML_name"
  [ ignore-empty-value="boolean" ]
  [ value="SQL_expression" ]
  [ xpath="XPATH_expression" ]
>
SQL expression, {@X} syntax is allowed, but only
for names that were declared above the current one.
</xsql:set-page-param>
```

The declaration should contain either 'value' attribute or 'xpath' attribute or a SQL expression as a text inside element, but not two or three of them simultaneously. The specified expression is calculated and the result is saved as a page variable with name specified by 'name' attribute. The resulting page variable can be used in other SQL expressions and calculateable strings of the page via '{@X}' notation described in XSQL Syntax subsection above.

If the directive uses 'xpath' attribute, the XPATH expression is applied to the context XML of the page. To apply an XPATH expression to some other XML entity, use `xpath_eval()` function in SQL expression specified by 'value' attribute or text inside the element.

If attribute 'ignore-empty-value' is set to 'yes' or '1' and the value of the calculated expression is an empty string then the page parameter is set to NULL. This may be convenient for handling default values that are passed to the page from HTML forms.

It is recommended to have names of parameters compatible with "XML 1.1 unqualified name" syntax. Hence, it is better to use minus sign instead of underscore and avoid using unusual characters like spaces. This become important when you use xsql:include-param because the name of create XML element will be equal to the name of parameter.

```
<!-- string constant '%DAV%' is an SQL expression -->

<xsql:set-page-param name="user-mask" value="'%DAV%'"/>

<!-- SELECT statement is an expression too, but only when enclosed in parenthesis.
  Without parenthesis, it is an SQL operator but not an SQL expression. -->

<xsql:set-page-param name="user-id">
(select U_ID from SYS_USERS where U_FULL_NAME like {@user-mask})
</xsql:set-page-param>

<!-- This copies implicit page argument 'context XML'
  into plain page parameter 'my-context' -->
```

```
<xsql:set-page-param name="my-context" xpath="." />
```

xsql:set-session-param

This Oracle-specific directive is not implemented.

xsql:set-stylesheet-param

This directive is not implemented.

xsql:insert-request

Updates the rows listed in context XML.

```
<xsql:update-request
  key-columns="column_list"
  table="table_name"
  [ columns="column_list" ]
  [ date-format="string" (allowed but ignored) ]
  [ transform="calculateable_URI_string" ]
/>
```

The directive updates a table by changing rows listed in the context XML. The destination table is specified by 'table' attribute.

If 'transform' URI is specified then it is used as a name of XSLT stylesheet that is applied to the context XML before the rest of processing. The result of that stylesheet should be in standard ROWSET/ROW form. The result may also contain redundant elements but they will be silently ignored.

After this optional XSLT transformation, the XSQL procedure gets all ROW elements in all top-level ROWSET elements of the source. For each such element it parses all subelements whose names match column names listed in the 'key-columns' attribute or in the 'columns' attribute; if the 'columns' attribute is not specified then it works as if all column names from the destination table are listed in 'columns'. It is legal to have a ROW element that does not contain an element that matches a particular column; the missing element is treated as a database NULL. If a subelement of ROW has attribute 'NULL' equal to 'Y' then it is also treated as database NULL.

When required subelements of ROW are parsed, the procedure updates all rows in the table that have all values of key columns equal to values listed in ROW. All these rows are updated by values from subelements of ROW. If 'columns' is specified then only named fields are updated; otherwise, the update operation changes all fields of a table.

When the update operation is complete, the procedure parses all subelements of the next ROW element in queue and so on.

```
<xsql:insert-request table='"Demo"."demo"."Customers"' columns='"CustomerID", "Phone", "Fax"'/>
```

Chapter 18. Runtime Hosting

Abstract

Virtuoso can be extended by in-process hosting of a number of different run time environments. This includes: Microsoft's .NET CLR (CLR), the Mono ECMA-CLI (Mono), and the Java Virtual Machine (JVM). Thus, you can create persistent stored modules, SQL functions, and user defined data types using any Microsoft .NET or Mono bound language, Java, and traditional languages such as 'C'/C++.

Objects provided by hosted run times, such as Java and CLR can be directly and transparently accessed from SQL. This also means that application logic in any hosted language can be exposed as a web service. By offering a choice of hosted run times in a cross platform setting, Virtuoso adds a new degree of freedom for the application designer. Applications can now be developed and deployed on either Windows, Linux or Unix, can be written in Java or any .net CLR bound language and can talk to any database via Virtuoso's virtual databasing capabilities.

The Virtuoso Server Extension Interface (VSEI) provides C interfaces and hooks that enable developers to write external functionality that can be bolted on the side of Virtuoso and called as SQL functions.

18.1. Runtime Environments

The Virtuoso server in its standard build is a single executable. To allow for external customizations based on VSEs the Virtuoso server engine becomes a callable library, the main function is re-written to incorporate other libraries and a new executable is created. For example, a Virtuoso server that contains PHP support under Windows consists of:

```
 65K virtuoso-odbc-php-t.exe
5.2M libvirtuoso-odbc-t.dll
1.2M php4ts.dll
```

which replaces the usual `7M virtuoso-odbc-t.exe`. `virtuoso.odbc-php-t.exe` is then executed in the usual way.

The Linux counterpart would be an `8M virtuoso-odbc-php-t` binary.

The Virtuoso executable files provided in the installer are appropriately named to indicate which customizations are supported. e.g. one that contains "php" and "clr" in the file name has been built with PHP and CLR support.

The location of the support libraries (.DLL's) for the various customizations of Virtuoso on Windows must either be in the %PATH%; environment variable or be the same directory as the virtuoso .EXE file. Virtuoso will not be able to start otherwise.

Note:

If Virtuoso is starting as a system service then the SYSTEM PATH must be altered as opposed to the USER PATH. The USER PATH is appropriate to alter if Virtuoso is being started as that user, usually when in debug/foreground mode. This is applicable to any required environment variables, not just PATH.

Hosted environments that require SQL access back to the database can make use of the in-process client mechanism. Hosted Runtimes such as PHP and ASP .Net would ordinarily use an RPC based (ODBC) connection. To improve the efficiency of the system, keeping it all in-process, a special connection can be made with no alteration to the API used in the code for communication.

See Also:

The In-Process Client keeps connections within Virtuoso avoiding unnecessary RPCs.

18.2. CLR, .Net & ASPX Host

The Common Language Runtime (CLR) is the foundation upon which the Microsoft® .NET strategy is built. The CLR provides an execution environment that manages running code and provides services that make software development easier. These services include automatic memory management, cross-language integration, interoperability with existing code and systems, simplified deployment, and a fine grained security system. The .NET platform also brings with it a new programming language called C#. It is very similar to Java and allows developers to make full use of all features available on the .NET runtime.

The CLR can run a variety of different types of applications, such as: console applications, Web server scripts, traditional Win32-based applications, and more.

The CLR provides a language specification for compilers to generate classes and code that can interoperate with other programming languages (The Common Language Specification: CLS) . Any API that is written using a CLS provider language can be used by any language that is a CLS consumer. Compilers generate code in a format called Common Intermediate Language (CIL) which is an intermediate representation of a compiled program and is easy to compile to native code or be compiled using Just-in-Time (JIT) engines. The restrictions placed by the runtime on the CIL byte codes ensures good potential for code optimization by the JIT compiler. The runtime environment provides garbage collection, threading and a comprehensive class library. All these things make code development easier and more appealing by allowing a mixture of languages to be collaborating to produce results, all contained within a managed sandbox to prevent bugs from breaking other running programs.

Windows has compilers that target the virtual machine from a number of languages: Managed C++, JavaScript, Eiffel, Component Pascal, APL, Cobol, Perl, Python, Ruby, Scheme, Smalltalk, Standard ML, Haskell, Mercury and Oberon.

Virtuoso is a CLR host. It is responsible for initializing the runtime, defining the application domain (its runtime boundaries, security settings, etc), and executing user code within such domains. Windows can be used as the development platform, a very developer friendly environment with a rich set of tools, but you will not be restricted to Windows, .NET and IIS to run the assemblies produced. Where .NET is not readily available or desired Virtuoso contains Mono, an open source re-implementation of Microsoft .NET, a vehicle making .NET cross-platform.

The CLR run time is a part of the Virtuoso process. The Mono run time may be run either as in-process or as out-of-process. Hosted applications can make use of the regular Virtuoso .net data provider to access Virtuoso SQL data and procedures. Microsoft ASPX files can also be run directly from Virtuoso either from the filesystem or WebDAV. Each of these capabilities releases you from the Microsoft platforms without compromising your development platform.

18.2.1. Environment Setup

Follow the steps below to configure the CLR runtime environment with Virtuoso:

1. **Install .Net Framework SDK.** The .Net Framework can be downloaded from the Microsoft web site.
2. **Install virtclr.dll into the GAC.** The `virtclr.dll` library supplied with Virtuoso must be installed into the .Net 'Global Assembly Cache (GAC)'.

.Net library components can be installed into the GAC using the command: `gacutil /i <DLL>`. The gacutil utility is supplied with the .Net framework. In this case we would use the command:

```
gacutil /i virtclr.dll
```

3. **Register virtclr with COM.** The virtclr.dll library must be registered as COM object using the 'regasm' utility as follows:

```
regasm virtclr.dll
```

4. **Install virt_http.dll into the GAC.** The `virt_http.dll` library supplied with Virtuoso must be installed into the .Net 'Global Assembly Cache (GAC)'.

```
gacutil /i virt_http.dll
```

Note:

The utilities gacutil and regasm are typically found in `%WINDIR%\Microsoft.NET\Framework\<version>` e.g. `C:\WINDOWS\Microsoft.NET\Framework\v1.0.3705.288`.

Failure to register the components successfully as described will generate "Virtuoso failed to initialize" messages. The Virtuoso installer, however, should automatically register the components for you.

Private assemblies must be deployed within the directory of the containing application and are found during runtime through a process called probing - a mapping from an assembly's identity to a file on disk that contains the manifest.

By default, probing for private assemblies is done from the root directory (application base) of the calling application (Virtuoso in this case) and the subdirectories that follow naming conventions based on assembly name and culture. You can customize this behavior by specifying a privatePath in your application's configuration file. The privatePath is a semi-colon delimited list of directories that the common language runtime will search for private assemblies. These directory names are relative to the application base - they cannot point outside the application base. The directories in the privatePath will be searched after the application base itself. The following configuration file adds a bin directory to the assembly search path:

```
<configuration>
    <runtime>
        <assemblyBinding xmlns="urn:schemas-microsoft-com:asm.v1">
            <probing privatePath="bin"/>
        </assemblyBinding>
    </runtime>
</configuration>
```

Configuration files are called: `<application name>.config`.

18.2.2. Testing the Virtuoso .NET Runtime Environment

To test that you have successfully started the Virtuoso server with .NET CLR runtime support make a simple library, import the contained class into Virtuoso and call it.

Using an text editor create a C# source file in the server root directory called sanity.cs, with the following contents:

```
using System;

public class sanity
{
    public static string test(string  name) {
       return "Hello "+ name + ", from Virtuoso";
    }
}
```

This sample needs to be compiled into bytecode assembly before it can be used. Use a command prompt that is suitable set up to find .NET utilities in its path, the .NET Framework SDK installation provides a shortcut in the Start menu to a command prompt that is preconfigured. From the command prompt change directory to the Virtuoso server root containing the C# source file.

```
C:\Program Files\OpenLink\Virtuoso 3.0\bin>csc /target:library sanity.cs
Microsoft (R) Visual C# .NET Compiler version 7.00.9466
for Microsoft (R) .NET Framework version 1.0.3705
Copyright (C) Microsoft Corporation 2001. All rights reserved.
```

Now this library must be introduce to the Virtuoso Server. Using ISQL use the following commands to test the CLR:

```
C:\Program Files\OpenLink\Virtuoso 3.0\bin>isql 1112
Connected to OpenLink Virtuoso
Driver: 03.00.2315 OpenLink Virtuoso ODBC Driver
OpenLink Interactive SQL (Virtuoso), version 0.9849b.
Type HELP; for help and EXIT; to exit.
SQL> DB..import_clr (vector ('sanity'), vector ('sanity'));

Done. -- 300 msec.
SQL> select sanity::test('Rob');
callret
VARCHAR
_______________________________________________

Hello Rob, from Virtuoso

1 Rows. -- 60 msec.
```

Congratulations, you have proven that your Virtuoso server can run .NET classes.

18.3. CLR & Mono

The Mono Project is an open development initiative sponsored by Ximian that is working to develop an open source, Unix version of the Microsoft .NET development and run time platform. Its objective is to enable Unix developers to build and deploy cross-platform .NET Applications. Likewise, this expands the capabilities of Windows programmers, this project opens .NET to non Windows platforms. Mono will implement various Microsoft technologies that have now been submitted to the ECMA for standardization.

The Goal is similar to that of Java, implementing a common virtual machine on multiple operating systems, however you are not restricted to one language.

Like .NET, Mono contains a Common Language Infrastructure (CLI) virtual, machine that contains a class loader, Just-in-time compiler, and a garbage collecting runtime; a class library that can work with any language which works on the CLR; a compiler for the C# language.

Windows has compilers that target the virtual machine from a number of languages: Managed C++, JavaScript, Eiffel, Component Pascal, APL, Cobol, Perl, Python, Ruby, Scheme, Smalltalk, Standard ML, Haskell, Mercury and Oberon. A single object system, threading system, class libraries, and garbage collection system can be shared across all these languages, the CLR.

The CLR and the Common Type System (CTS) enables applications and libraries to be written in a collection of different languages that target the CLR byte code. This means that you could define a class to do algebraic manipulation written in C#, that class can be reused from any other language that supports the CLI. You could create a class in C#, subclass it in C++ and instantiate it in an Eiffel program.

The External Hosted Create PROCEDURE Syntax

18.3.1. Environment Setup

Ximian announced the launch of the Mono project, an effort to create an open source implementation of the .NET Development Framework.

Follow the steps below to configure the CLR runtime environment with Virtuoso:

1. **Install Mono.** The Mono package is available from the Mono project home page in the form of an RPM for Linux. The source is also available.
2. **Make mscorlib.dll available to /usr/local/lib.** The mscorlib.dll is installed by Mono and needs to be symlinked from its default location to `/usr/local/lib` .

18.3.2. Testing the Virtuoso Mono Runtime Environment

To test that you have successfully started the Virtuoso server with Mono CLR runtime support make a simple library, import the contained class into Virtuoso and call it.

Using an text editor create a C# source file in the server root directory called sanity.cs, with the following contents:

```
using System;

public class sanity
{
    public static string test(string  name) {
       return "Hello "+ name + ", from Virtuoso";
    }
}
```

This sample needs to be compiled into bytecode assembly before it can be used. Make sure you environment is configured to use Mono, change directory to the Virtuoso server root containing the C# source file. Run:

```
bash$ mcs /target:library sanity.cs
Compilation succeeded
```

Now this library must be introduce to the Virtuoso Server. Using ISQL use the following commands to test the CLR:

```
C:\Program Files\OpenLink\Virtuoso 3.0\bin>isql 1112
Connected to OpenLink Virtuoso
Driver: 03.00.2315 OpenLink Virtuoso ODBC Driver
OpenLink Interactive SQL (Virtuoso), version 0.9849b.
Type HELP; for help and EXIT; to exit.
SQL> DB..import_clr (vector ('sanity'), vector ('sanity'));

Done. -- 300 msec.
SQL> select sanity::test('Rob');
callret
VARCHAR
_______________________________________________

Hello Rob, from Virtuoso

1 Rows. -- 60 msec.
```

Congratulations, you have proven that your Virtuoso server can run .NET classes via Mono Runtime.

18.4. Embedded Java VM API

The Java VM is an embedded system within Virtuoso that allows the calling of class Java methods and getting class properties. It uses the JAVA JNI API to interact with the JAVA VM.

18.4.1. Correspondence Between Virtuoso & Java VM Threads

At maximum one Java VM will be started on demand. If a function from the Java VM API is called and no JVM is running, one will be started, as required. Since Virtuoso is multithreaded it requires JDK version 1.3 or above in order to make better use of it's multithreading support. If the Java VM is already running the API VSEs attaches the current Virtuoso working thread, if not already attached, as a Java VM thread to the running VM. The Virtuoso worker thread does not automatically detached itself from the Java VM after use, therefore, in order to prevent leaving redundant Virtuoso worker threads being left attached to the Java VM the `java_vm_detach()` VSE should be used.

The following require access to the Java VM:

all Virtuoso JAVA PL API (JVM VSEs)

allocating/deallocating/copying of the Virtuoso/PL Java VM class reference values.

If no subsequent JVM VSEs are called after calling `java_vm_detach()` , the worker thread can still attach to the VM in order to deallocate or copy Java VM class reference values. In order to ensure that the worker thread is properly detached it is advisable to set all the variables that may hold Java VM class reference values to NULL, which deallocates their current value, before calling the `java_vm_detach()` JVM VSE.

Attaching and detaching Virtuoso worker threads is marked as a debug level message in the Virtuoso Event log, so that these messages can be used to debug the process.

18.4.2. Virtuoso/PL <-> Java VM Type Mapping Schema

Since the Java language uses a different set of data types than Virtuoso a type mapping system has been established to allow the passage of data to and from Java. All Java simple types are mapped to a corresponding Virtuoso type as follows:

Table 18.1. Java - Virtuoso Data Type Mapping

Java Type/Class	Virtuoso Internal Type
boolean	smallint
char	smallint
double	double precision
float	real
int	integer
short	integer
long	integer
boolean	smallint
java.lang.String	NVARCHAR
java.util.Date	DATETIME

All other Java objects are represented as a special Virtuoso value, which contains a reference to the Java object in the VM memory space. When such a value is returned as a Virtuoso/PL return value or as a result set column, it calls the `java.lang.Object.toString()` method for the Java VM object it refers to and that result is returned to the calling client.

Arrays are mapped to a Virtuoso vector of their elements. The array handling routines are recursive, so each element may be a Java array or a scalar type.

The above mappings are applied when converting Virtuoso/PL data to Java data as follows:

method parameter values in java_call_method VSE

method parameter values in java_new_object VSE

property values in java_set_property VSE

the instance parameters in java_call_method/java_get_property/java_set_property VSEs

The above mappings are applied in the opposite direction (Java Data -> Virtuoso/PL data) as follows:

method return values in java_call_method VSE

return value of the java_new_object VSE

property values returned from java_get_property VSE

18.4.3. References to Java VM Class Instances in Virtuoso/PL

Java Class instances are represented as a Virtuoso/PL variable values using a Java VM Global Reference. Each time such a Virtuoso/PL variable value is created or copied, it adds a Java VM Global Reference. When it is freed, it removes the Java VM global reference, allowing the Java Garbage collector (GC) to free it. Each of the API VSEs create a Java VM local frame upon it's start, and frees it upon exit. This allows for fast deallocation of the local objects created by mapping Virtuoso/PL native values to Java objects.

18.4.4. Specifying the Correct Java Type When Passing Values from Virtuoso/PL

Each method parameter in the `java_new_object()` /`java_call_method()` can be either the value itself or a two-element vector. When it is a two-element vector it's first element is the JNI type signature string, e.g.: for integer - I, for array of integers - [I], for java.lang.String - Ljava/lang/String. The signature is important because the Java VM JNI API needs it in order to find the appropriate constructor/method/property.

18.4.5. Virtuoso Java PL API VSEs

The API consists of the following VSEs:

`java_call_method()`

`java_set_property()`

`java_get_property()`

`java_load_class()`

`java_new_object()`

`java_vm_attach()`

`java_vm_detach()`

18.4.6. Java Security

Java classes are hosted in one of two modes:

Restricted

Unrestricted

Java class Permissions are managed by security classes that fall into categories as follows listed with it managing class:

File - java.io.FilePermission

Socket - java.net.SocketPermission

Net - java.net.NetPermission

Security - java.security.SecurityPermission

Runtime - java.lang.RuntimePermission

Property - java.util.PropertyPermission

AWT - java.awt.AWTPermission

Reflect - java.lang.reflect.ReflectPermission

Serializable - java.io.SerializablePermission

Restricted classes are not allowed any of the above privileges. Virtuoso returns errors that are returned by the security manager if breaches in security are attempted by a hosted Java class.

By default all Java classes are imported/created/hosted in restricted mode. To create Java class based user defined types that are unrestricted you need to use create type syntax with UNRESTRICTED keyword. The `import_jar()` function can also be used to import classes, its third optional parameter can be used to define the security mode.

 **Note:**

Note:

New behavior since Virtuoso 3.2 provides these two security modes defaulting to restricted. Prior to this Java classes were hosted in unrestricted mode.

Example 18.1. Java Security

The class Write_file, shown below, will attempt to write to a file on the file system. This class will be used to create a user defined type first in unrestricted mode and then in restricted mode to demonstrate how security exceptions are returned.

Source of Write_file.java:

```
import java.io.*;

public class Write_file
{
  public String write ()
    {
      String myFile = "foo";
      File f = new File(myFile);
      DataOutputStream dos;

      try
        {
          dos = new DataOutputStream (new BufferedOutputStream(new FileOutputStream (myFile),128));
          dos.writeBytes("ABC\n");
          dos.flush();
          dos.close();
        }

      catch (IOException ioe)
        {
          System.out.println("writeFile: caught i/o exception");
        }

      return "OK";
    }
}
```

Create the unrestricted type:

```
create type "Write_file" language JAVA external name 'Write_file'
  unrestricted METHOD "write" ()
  returns nvarchar external type 'Ljava/lang/String;' external name 'write';
```

Test calling the method:

```
SQL> select new Write_file().write();
callret
NVARCHAR
_______________________________________

OK
```

Now we want to recreate the type in restricted mode, remembering to drop it first:

```
drop type DB.DBA.write_file;

create type "Write_file" language JAVA external name 'Write_file'
  METHOD "write" ()
  returns nvarchar external type 'Ljava/lang/String;' external name 'write';
```

Test calling the method:

```
SQL> select new Write_file().write();

*** Error 42000: [Virtuoso Driver][Virtuoso Server]JV001: Java exception
occurred : java.security.AccessControlException : access denied
(java.io.FilePermission foo write)
in  __udt_method_call:(BIF),
```

```
<Top Level>
at line 1 of Top-Level:
select new Write_file().write()
```

Another way to import the above class is by use the `import_jar()` such as:

```
import_jar (NULL, 'Write_file', 1) - will import java classes in unrestricted mode.
import_jar (NULL, 'Write_file') - will import java classes in restricted mode.
```

18.5. Virtuoso Server Extension Interface (VSEI) (C Interface)

18.5.1. Virtuoso Server Extension Interface (VSEI)

The Virtuoso Server Extension Interface allows Virtuoso functionality to be extended by including new functions written in other languages such as C. These new functions are SQL callable.

These functions share the same C prototype and use Virtuoso internal APIs to do the following:

Retrieve arguments.

Assign values to output parameters.

Compile and execute SQL/PL statements and fetch results.

Signal SQL errors.

Return values.

A SQL-callable C function is called a Virtuoso Server Extension (VSE). These are external functions integrated into Virtuoso by linking their executable produced with a Virtuoso server in library format, rather than executable. VSEs were formally known as BIFs, which stood for Built-In Functions. Such functions must be exported using the `bif_define()` or `bif_define_typed()` C-functions when initializing the extended Virtuoso server.

These functions will thereafter be invoked on server threads. The functions should be re-entrant and comply to some simple memory management conventions outlined below.

These functions may execute arbitrary C code and call arbitrary APIs, to the extent these are compatible with the host operating system's threading model.

Virtuoso VSEs can be debugged within the normal C debugger by either starting Virtuoso under the debugger in foreground mode or by attaching the debugger to a running process.

Stack consumption should not be excessive: threads normally have 100K of stack on 32 bit platforms. The stack size may however be increased by settings in the virtuoso.ini file.

18.5.2. SQL Run Time Objects

The Virtuoso Server Extension API introduces the following data types:

box
: This is a run-time-typed block of memory which represents any SQL data type, e.g. number, string, array etc. Boxes have a type and length that are retrievable at run time and can be allocated, freed and otherwise manipulated by functions appropriate to each type of box. Boxes may form trees through use of heterogeneous arrays but should not form graphs.

query_t
: This is a compiled query, corresponding to a SQL statement or procedure compilation. The *`query_t`* is made from a SQL string and can thereafter be executed multiple times. This is a read-only object, not affected by execution on any number of threads, analogously to machine code not being affected by being executed.

query_instance_t
: This is a structure representing a query execution state. These are created when executing a *`query_t`* . This is analogous to a stack frame of a C function. It holds all relevant query state, such as cursor positions, intermediate results, column values etc. This is passed to all VSEs so they can have access to environment information such as current transaction, current client etc. The query instance references the *`query_t`* . As a rule, the query instance is specific to a thread. A query instance can be relatively long lived in the case of a cursor, which may live across multiple client-server message exchanges.

state_slot_t
: This is a part of *query_t* that specifies or describes a query time variable, column, parameter, intermediate result etc. This is analogous to an offset in a stack frame, it actually indexes a position inside a query instance. Given the state slot and the instance, it is possible to read or to set a value in the query state. Arguments of VSEs are passed as an array of state. Slots combined with the running query instance give the arguments values, and can be used to set output parameters.

local_cursor_t
: When executing a select statement, the local cursor structure is returned for accessing the result set rows. This is always a forward-only cursor. This can be advanced, column values may be accessed and the cursor may be closed.

18.5.3. Memory Management Rules

All state slots in a query have distinct values. With the exception of a reference parameter, no value is referenced twice. All state slot values can therefore be recursively freed independently of each other.

If a VSE returns data, this data must always be new, i.e. allocated inside the VSE and may not be a copy of or include any of the arguments as a substructure. All return values and arguments must be legitimate boxes and may not share a structure.

18.5.4. Server Main Function

The server main function for a customized Virtuoso server has the following format:

```
static void (*old_ddl_hook) (client_connection_t *cli) = NULL;

static void
ddl_hook (client_connection_t *cli)
{
  if (old_ddl_hook)
    old_ddl_hook (cli);

  /* DDL code (depending on the server being fully initialized
    (ex: create table) ) goes here */
}

static void
init_func (void)
{
  old_ddl_hook = set_ddl_init_hook (ddl_hook);
  /* initialization code (prerequisite for server initialization
     (bif_define, unrelated init code) goes here */
}

int
main (int argc, char *argv[])
{
  VirtuosoServerSetInitHook (init_func);
  return VirtuosoServerMain (argc, argv);
}
```

There are three phases to custom code initialization:

execution of the `main()` function

execution of the `init_func()` function

execution of the `ddl_hook()` function

The `init_func()` function is called before any server initialization functions are called. This is typically a place for defining new VSEs, allocation of synchronization objects (since the server does not have any threads yet), and/or custom code initialization not related to Virtuoso. Here, the `set_ddl_init_hook()` should be called also, if it exists, to register the `ddl_hook()` callback function.

Note:

The `old_ddl_hook()` mechanism - this allows queuing of the ddl_hooks.

The `ddl_hook()` function is called during normal startup just before the roll forward, but after the server's internal structure has been initialized. This is typically a place to execute SQL statements to initialize the extension. The variable *client_connection_t ** is passed to the function to provide the client connection that should be used for SQL execution.

The `main()` function can call `VirtuosoServerSetInitHook()` if there is any Virtuoso-related initialization to be performed, and should then call the `VirtuosoServerMain()` function to start the Virtuoso server. The `VirtuosoServerMain()` function will return control after the server has been shut down.

18.5.5. Compiling & Linking

The files should be compiled for the multi-threaded environment appropriate to the operating system and should be linked accordingly e.g. `-lm` , `-ldl` .

The Virtuoso distribution contains the following libraries/object files:

- **libvirtuoso-* libraries/object files.** The Virtuoso engine. The suffix denotes the kind of remote and threading support : -iodbc for iODBC, -udbc for UDBC, -t for native threads, -f for fiber threads.
- **c_javavm object file.** the Virtuoso Java VM Integration file (no main function). This is the file to be linked in if the custom code executable needs to have Java VM support. To initialize the Java VM integration the C function `void bif_init_func_javavm (void)` should be called from the `VirtuosoServerSetInitHook` hook. This file references the `libjvm` library from the Java JRE, hence, should also be appended to your linker options.
- **c_bif_server_php object file.** The Virtuoso PHP integration support library. This is the file to be linked in if the custom code executable needs to have the PHP support built in. To initialize the PHP engine integration the C++ function `void init_func_php (void)` should be called from the `VirtuosoServerSetInitHook` hook. Note that this file is a C++ object file and needs to be linked in accordingly. This file references the libphp4 library.
- **basec object file.** The Virtuoso .NET CLR Integration file. This is the file to be linked in if the custom code executable needs to have the .NET CLR integration built in. This is a C file.
- **c_dotnet object file.** The Virtuoso .NET CLR Integration file. This is the file to be linked in if the custom code executable needs to have the .NET CLR integration (and nothing but) built in. This is a C++ file. Binaries using this file should initialize the .NET CLR support by calling the C++ function `void bif_init_func_clr (void)` (defined in the basec object file) from the `VirtuosoServerSetInitHook` hook. In order for the .NET CLR support to work correctly the `::CoInitialize` Win32 COM API should also be called before the `VirtuosoServerMain` call.
- **sql_code_javavm object file.** This contains the DDL definitions for the Java VM support. Executables using that binary should call the `sqls_define_javavm` function in their DDL init hook.
- **sql_code_xslt object file.** This contains the DDL definitions of the XSLT stylesheets used in the Java VM & CLI support. Executables using that binary should call the `sqls_define_xslt` function in their DDL init hook.
- **sql_code_clr object file.** This contains the DDL definitions for the .NET CLR integration support. Executables using that binary should call the `sqls_define_clr` function in their DDL init hook.

18.5.6. Functions by Category

General Box Functions

The box, usually marked with the caddr_t data type is the basic representation of any SQL data in Virtuoso. All boxes have a run time data type, with a name beginning with `DV_` . All boxes have a 3 byte run time length which allows for up to 16 MB of contiguous array size in SQL data.

The further interpretation of the content of the box is determined by the type tag. The length is always an exact byte length, although the actual length is rounded up to the next suitably aligned value. The length and tag of a box must never be changed while the box is allocated but the content is freely writable. The tag and length reside immediately under the pointer of the box, so that a box, with the appropriate type cast will pass as a C array or string.

Numbers are generally represented as boxes. There is an exception for small integers, which are always distinguishable from pointers. Thus the range from -10000 to 10000 are not allocated as boxes holding the value but can be passed directly. This is hidden however and the programmer need not be concerned about this except sometimes when debugging.

The byte order in boxes depends on the platform.

The most important types are:

DV_SHORT_STRING - The box contains a null terminated string of char. The box length is 1 + the count of characters, including the final 0 in the count.

DV_LONG_STRING - same as DV_SHORT_STRING.

DV_LONG_INT, TAG_BOX - The box is sizeof (long) long, with the long as element 0, in the appropriate byte order.

DV_SINGLE_FLOAT - sizeof (float) bytes, containing the float.

DV_DOUBLE_FLOAT - sizeof (double) bytes, contains the double.

DV_NUMERIC - opaque, contains a decimal floating point. The `numeric_t` functions can be used, see appropriate documentation.

DV_BIN - Binary string, no terminating 0 counted in the length.

DV_DATETIME - datetime, opaque, dt_ functions can be used, see appropriate documentation.

DV_BLOB_HANDLE - Blob handle, opaque but convertible to string if short enough.

DV_ARRAY_OF_POINTER - Heterogeneous array, sizeof (caddr_t) * n_elements, first all elements are box pointers. The length is in bytes, so divide by sizeof (caddr_t).

DV_DB_NULL - a box of 0 bytes (header only), represents the SQL NULL value.

Box Functions

```
box_t dk_alloc_box ( uint32 bytes ,
                     int tag );
```

`dk_alloc_box()` allocates a box of the given size and type. The initial contents are undefined.

```
int dk_free_box ( box_t box );
```

`dk_free_box()` frees a box allocated by `dk_alloc_box()` . The argument may not be any other pointer.

```
int dk_free_tree ( box_t box );
```

`dk_free_tree()` is like `dk_free_box()` but will free recursively, following through DV_ARRAY_OF_POINTER boxes.

```
uint32 box_length ( box_t box2 );
```

```
#define box_tag(box) \
        (*((dtp_t *) &(((unsigned char *)(box))[-1])))
```

These return the length and the tag of a box.

```
long unbox ( box_t n );
```

```
box_t box_num ( long n );
```

```
box_t box_dv_short_string ( char *string
                            );
```

```
box_t box_double ( double d );
```

```
box_t box_float ( float f );
```

```
#define unbox_num(n) unbox(n)
#define unbox_float(f) (*((float *)f))
#define unbox_double(f) (*((double *)f))
#define unbox_string(s) ((char *)s)
```

The above functions and macros convert between C data types and boxes. `box_dv_short_string()` takes a `char *` to any null terminated string and allocates a string box of appropriate size. This itself looks like a null terminated string but has the box header with the run time length and type under the pointer.

```
box_t box_copy ( box_t box );
```

box_copy() returns an identical size box with the same type and contents.

box_t **box_copy_tree** (box_t *box*);

box_copy_tree() performs a recursive copy, traversing DV_ARRAY_OF_POINTER references.

int **box_equal** (box_t *b1* ,
box_t *b2*);

Given two arbitrary boxes, returns true if they are recursively equal.

Example 18.2. Box Examples

Below is the code for box_copy_tree:

```
box_t
box_copy (box_t box)
{
  dtp_t tag;
  uint32 len;
  box_t copy;

  if (!IS_BOX_POINTER (box))
    return box;

  tag = box_tag (box);
  if (box_copier[tag])
    return (box_copier[tag] (box));
  len = box_length (box);
  copy = dk_alloc_box (len, tag);
  memcpy (copy, box, (uint32) len);
  return copy;
}

box_t
box_copy_tree (box_t box)
{
  box_t *copy;
  dtp_t tag;

  if (!IS_BOX_POINTER (box))
    return box;

  tag = box_tag (box);
  copy = (box_t *) box_copy (box);
  if (tag == DV_ARRAY_OF_POINTER || tag == DV_LIST_OF_POINTER)
    {
      uint32 inx, len = BOX_ELEMENTS (box);
      for (inx = 0; inx < len; inx++)
        copy[inx] = box_copy_tree (((box_t *) box)[inx]);
    }

  return (box_t) copy;
}
```

Note:

The IS_BOX_POINTER check at the start will detect the unboxed, 'bare' small integers which are actually not allocated and can be returned by value. Only then can box_tag be used to find the type.

The DV_TYPE_OF macro should be used instead of box_tag when the type is unknown to avoid de-referencing a small integer.

Also note BOX_ELEMENTS , which is box_length () / sizeof (caddr_t). This is practical for iterating over arrays.

See Also

See Also

The VSEI Functions .

18.5.7. VSEI Definition

```
typedef caddr_t (*bif_t) (caddr_t *qst, caddr_t *error_return, state_slot_t ** arguments);
void bif_define (char *name, bif_t bif);
void bif_define_typed (char * name, bif_t bif, bif_type_t *bt);
```

These functions associate a function pointer to a VSE name. The typed variant allows associating a value type used when inferring SQL meta-data if the result is returned to a client. The type can be one of the following externs:

extern *bif_type_t* bt_varchar;
extern *bif_type_t* bt_any;
extern *bif_type_t* bt_integer;
extern *bif_type_t* bt_double;
extern *bif_type_t* bt_float;
extern *bif_type_t* bt_numeric;
extern *bif_type_t* bt_convert;
extern *bif_type_t* bt_timestamp;
extern *bif_type_t* bt_time;
extern *bif_type_t* bt_date;
extern *bif_type_t* bt_datetime;
extern *bif_type_t* bt_bin;

If a VSE accesses indexes either by its own internal code or by executing Virtuoso/PL statements, there becomes a potential for deadlocks. To prevent deadlocks, the Virtuoso/PL compiler must be informed of potential index usage inside the VSE. Special deadlock-safe code can be created for its needs. The `bif_set_uses_index()` function should be used after `bif_define()` or `bif_define_typed()` in such cases.

The potential for deadlocking is always present if the VSE executes Virtuoso/PL code or uses XPath/XSLT functions. Other functions of Virtuoso's C interface are deadlock-safe since they perform no database access.

18.5.8. SQL Exceptions

```
caddr_t srv_make_error (char *code, char *msg);
void sqlr_error (char *code, char *msg,...);
void sqlr_resignal (caddr_t err);
```

An error object is a three element array of type `DV_ARRAY_OF_POINTER` , consisting of the number 3, the SQL state and the message. The control flow in case of errors signalled inside VSEs is a longjmp to an outer context, typically that of the calling stored procedure or top level query. The condition is there handled or sent to the next level up, ultimately to the ODBC, JDBC or Web client. Executing a SQL statement inside a VSE always returns and never exits the VSE by longjmp. Thus the VSE gets a first look at all SQL errors caused by statements executed by it.

sqlr_error is the normal function for signaling a SQL state. It takes a 5 character SQL state, a printf format string and optional arguments, a la printf.

sqlr_resignal is used to throw a condition to the next level handler. This is typically done when executing a query which returns an error and the error is sent up to the caller of the VSE.

srv_make_error makes the error structure. The expression

sqlr_resignal (srv_make_error ("12345", "message")); is equivalent to sqlr_error ("12345", "message");

Note

srv_make_error does not take the printf-type arguments.

By convention a NULL pointer indicates no error. sqlr_resignal (NULL) is an error.

The macros:

```
#define ERR_STATE(err)  (((caddr_t*) err)[1])
#define ERR_MESSAGE(err)  (((caddr_t*) err)[2])
```

can be used to read an error returned by a statement.

18.5.9. Executing SQL

```
query_t * sql_compile (char *string2, client_connection_t * cli,
                                caddr_t * err, int store_procs);
void qr_free (query_t * qr);

client_connection_t * qi_client (caddr_t * qi);
```

These functions allow executing SQL from VSEs. First the SQL statement needs to be compiled with sql_compile. The statement may take value parameters and may be a DDL or DML statement, including select, update, procedure call, table creation etc.

The query_t returned can be used multiple times on any number of simultaneous threads. if an application repeatedly performs the same queries the text can be compiled once and reused at infinitum.

qr_free will free a query returned by sql_compile.

Example 18.3. Example

```
{
  caddr_t err = NULL;
  query_t * qr  = sql_compile ("select * from SYS_USERS", qi_client (qst), &err, 0);
  ...
  if (err)
  exit (-1);
  qr_free (qr);
}
```

```
caddr_t qr_rec_exec (query_t * qr, client_connection_t * cli,
    local_cursor_t ** lc_ret, query_instance_t * caller, stmt_options_t * opts,
    long n_pars, ...);
```

Once a query is compiled it can be executed and fetched. This function executes a query in the context of a VSE. The execution is on behalf of the same user and in the same transaction as the VSE. This is only possible in the context of a VSE, not at top level in the main program, for example.

The first argument is the compiled query to execute. The second is the client connection, obtained by qi_client from the qst argument of the VSE. The lc_ret, if non NULL will get a be set to a newly allocated local_cursor_t * that allows fetching rows from the result set. This only applies to a select statement. The caller is the qst argument of the VSE, The opts can be NULL. The n_args is the count of query parameters, 0 if no parameters are passed.

The return value is an error, suitable for sqlr_resignal. A NULL value means success.

It should be double-checked if the query access or potentially may access any tables or indexes. If it may do this, the VSE must be described as deadlock-unsafe by calling bif_set_uses_index() after bif_define() or bif_define_typed(). If qr_rec_exec access any tables or views, and the call of VSE from Virtuoso/PL code is compiled as deadlock-safe, the whole server may be halted.

If parameters are passed, a group of 3 actual parameters follows for each ? in the query being executed. In each such group the first is the name of the parameter, of the form ":n", where n is the position of the parameter, starting at 0, so ":0" corresponds to the 1st ? and ":11" to the 12th. The second in the group of 3 is the value, usually a box pointer. The third is the type, one of QRP_INT, QRP_STRING or QRP_RAW.

QRP_INT means that the value will be converted to a box as by box_num. QRP_STRING means that the value will be converted to a string as by box_dv_short_string. In either case the value is allocated and freed as part of the execution. QRP_RAW means that an arbitrary box is passed as is. If so, this box will be freed in the process and MUST NOT BE REFERENCED AGAIN in the VSE. if the statement is a select, lc_ret should be specified and should be the address of a local_cursor_t * variable, where the

cursor can be returned.

```
long lc_next (local_cursor_t * lc);
caddr_t lc_nth_col (local_cursor_t * lc, int n);
void lc_free (local_cursor_t * lc);
```

These functions allow reading through a result set. The local_cursor_t * must have come from qr_rec_exec.

lc_next will move the cursor one row forward. The first call after the exec places the cursor on the first row. A 0 return value indicates that the cursor is at end. if 0 is returned at the first call, the result set had zero rows. The data member lc_error may be set and should be checked after calls to this function. See examples. The value will be suitable for sqlr_resignal if copied (box_copy_tree).

The lc_nth_col returns the value of the nth column of the current row. The index is 0 based. The value is an arbitrary box pointer and is READ ONLY, to be copied (box_copy_tree) if the application needs to keep it around. The value will stay readable until the next lc_next or lc_free. Use DV_TYPE_OF et al to determine the type of the value.

lc_free frees the cursor and any resources associated to it. This has no effect on the transaction.

The bif_my_select function returns an array with one element for each row of the SYS_KEYS table. The rows are themselves arrays containing the column values.

18.5.10. Adding New Languages And Encodings Into Virtuoso

There are too many languages to be able to support them all by default so Virtuoso is user extensible in this respect. The built-in 'x-any' language supports most languages to a degree, but it is not the optimum solution for some specific languages or if you want to perform a words' normalization to make text search more effective. To make Virtuoso extensible, language-specific functions are organized into *language handlers* , and handlers are organized in hierarchical trees. Every handler contains pointers to such functions as "count words in given string", "call given callback once for every word in the string" etc.

XML documents and SQL procedures may identify languages by their names, for example by value of *xml:lang* attribute, `content_language` argument of built-in functions, or by `__lang` option etc... Every language handler defines up to two names of the language it supports, one matching ISO 639 regulations (e.g. 'en'), and one matching RFC 1766 (e.g. 'en-UK'). When Virtuoso finds a match to the language name specified, it searches through the an internal hash-table. If the name is unknown, the 'x-any' handler will be returned as a default.

Custom language handlers should contain a pointer to a more generic handler, e.g. to the handler, Handler may have NULLs stored instead of pointers to required functions, these NULLs will be replaced with pointers to generic handler's functions automatically when the custom handler will be activated.

See Also:

lh_get_handler

lh_load_handler

There are two trees of language handlers in current version of Virtuoso. "Main" tree starts from 'x-any' root and contains handlers of languages used in documents, another tree starts from 'x-ftq-x-any' root contains handlers of Free Text query ('ftq') languages. The difference is in handling of wildcard characters: query string 'hello, wo*ld' consists of two "words", 'hello' and 'wo*ld', and 'x-ftq-x-any' will properly locate them, but 'x-any' handler will report three words -- 'hello', 'wo' and 'ld', because it knows nothing about special meaning of '*' in query strings. That is why every handler may contain a pointer to a handler of its own query language.

In addition to plain language handlers, it's possible to add handlers of "encoded language" They are useful if you have large number of documents in some particular encoding and speed of free text indexing is critical for your applications. While usual handlers deal with Unicode data, and it requires data to be decoded before processing, functions of "encoded language" handler may accept buffers of encoded text, eliminating decoding.

See Also:

elh_get_handler

elh_load_handler

The OpenLink Virtuoso Server distribution contains sources of sample language handler for 'en-UK' language. The difference between 'x-any' handler and this one is in handling of abbreviations and numbers. 'en-UK' handler will read phrase '$3.54 per sq.inch.' as the sequence of words '3.54', 'per' and 'sq.inch', instead of sequence '54', 'per', 'sq' and 'inch' that 'x-any' will read. The generic 'x-any' handler has no specific rules for dealing with the "decimal point" because in many scripts "decimal comma" is used, thus '3.54' will be processed as pair of words '3' and '54', but '3' will be ignored in many cases as noise word due to its 1-character length.

In addition to the language extension interface, Virtuoso provides an *eh_load_handler* function to add new encodings, but it should be used solely for multi-character encodings which cannot be supported through the usual Virtuoso International Character Support . If an encoding was created by the CHARSET_DEFINE function, Virtuoso can build special lookup tables for very fast text translation from Unicode to the encoding, thus you are not likely to gain in performance by writing your own C code, but some applications will know nothing about your encoding because they will check only the SYS_CHARSETS system table.

18.6. VSEI Plugins

Virtuoso functionality can be enhanced through external libraries by loading shared objects or DLLs. The new functions are written in a language of the developer's choice and compiled to produce a shared library appropriate to the operating system. The path to the shared library must be declared in the Virtuoso INI file and the server restarted before it can be used.

The Virtuoso INI file uses a [Plugins] configuration section for listing shared libraries for the server to load upon startup. The layout is as follows:

```
[Plugins]
LoadPath = <module path> (example : /home/virtuoso/hosting)
Load1 = <module type>, <module name> (example : hosting_perl.so)
Load2 = <module type 2>, <module name 2>
..
LoadN = <module type N>, <module name N>
```

Virtuoso reads the Load1, Load2, ... LoadN lines from the [Plugins] section and attaches them according to their type.

`<module path>` is the directory containing shared modules for use with Virtuoso. (e.g. `/home/virtuoso/hosting`)

`<module type>` specifies the type of module that is to be loaded, and hence how Virtuoso is to use it. So far only the "Hosting" type exists.

`<module name>` is the file name of the modules shared library or object. (e.g. `hosting_perl.so`)

The "Hosting" type defines entry points for initialization of the runtime hosting environment, destruction of the user environment and execution of a file or string containing commands in the hosted language. It also returns a list of file extensions that it is capable of processing. Virtuoso dynamically defines memory-resident (no disk image) HTTP server handlers for each specified type. For example, the Perl hosting plugin supports 'pl' extension. Hence, upon initialization of the hosting plugin, Virtuoso defines the `__http_handler_pl(..)` function according to the API for file type handlers in the Virtuoso HTTP server. With this handler in place, each hit on a .pl file (file system or WebDAV) with appropriate execute permissions will cause the HTTP server to execute the code within it and return the result instead of simple the file contents.

The handler will call the __hosting_http_handler VSE with a special set of parameters to represent the HTTP environment correctly.

There's a VSE to call each of the hosting modules:

`__hosting_http_handler ( in` *`extension`* `varchar, in` *`content`* `varchar, [in` *`params`* `varchar, ] [in` *`lines`* `any, ] [inout` *`filename_head_ret`* `varchar, ] [in` *`options`* `any, ] [out` *`diag_ret`* `varchar]) returns varchar`

such that:

extension
: Selects plugin by supported extension handler. e.g. pass 'pl' for the perl plugin.

content
: If <filename_head_ret> is NULL or unspecified this will be the name of the file containing the code to execute in the hosted environment, otherwise this will be program code to execute as a string.

params
: (optional) A string containing the HTTP parameters as encoded in the HTTP request body.

lines
: (optional) A vector (array) containing the HTTP request headers, in the same format as those passed to VSPs.

filename_head_ret
: (optional) On input this is the "name" to put on the command text passed in <content>. If this is NULL it means that <content> holds the path and filename containing the commands. On output this contains the HTTP headers of the HTTP response generated by the plugin, if any and in HTTP mode.

options
: (optional) A vector holding name/value pairs of strings passed as options to the plugin. The Perl plugin sets the other options as environment variables before calling the perl code.

  There is a "`__VIRT_CGI `" = "`0` "/"`1` " option to control whether the plugin operates in HTTP mode (`__VIRT_CGI=1`) i.e. implements the CGI interface and treats the output as an HTTP response.

diag_ret
: (optional) Returns various diagnostics messages returned while the code is running if any. The perl plugin sets this to the collected STDERR messages.

The function will return a varchar containing the HTTP body if in HTTP mode (`__VIRT_CGI = 1`) or the messages printed to STDOUT.

Virtuoso will normally call to memory each plugin as required, and expel it when finished. This behavior can be controlled by the INI file parameter:

```
[HTTPServer]
PersistentHostingModules = 1/0 default 0
```

Setting `PersistentHostingModules` to "1" prevents Virtuoso from removing the interpreters from the HTTP threads after each request.

Example 18.4. Using the Perl Plugin

Executing Perl code directly:

```
select __hosting_http_handler ('pl', 'print "hello world"; ', '', vector (), 'helloworld.pl');

returns : hello world
```

Executing a perl script file (perl/test_print.pl in the Virtuoso working directory):

```
/perl/test_print.pl
-------------------
#!/usr/bin/perl
print "hello world file";

select __hosting_http_handler ('pl', 'perl/test_print.pl');

returns : hello world file
```

Note:
The hosting_perl hosting module uses the perl `tie()` function to "tie" up the STDIN, STDOUT, STDERR, exit() and %ENV perl objects. Untying any of these may lead to unpredictable results.

Chapter 19. Internet Services

Abstract

This section discusses Virtuoso's support for DAV, email, usenet news, mime and other internet standards.

The WebDAV repository lets Virtuoso store and index content within the database. This can then be accessible directly via the HTTP protocol.

This chapter describes the MIME extensions that have been implemented in Virtuoso.

This covers examples of use of MIME for composition of MIME messages and content for mail transit of HTTP output.

19.1. WebDAV Server

Virtuoso supports the WebDAV protocol, which is an extension of HTTP for cooperative work on the Internet. DAV resources can be of any mime type, including binary types. The DAV resources are stored in the Virtuoso database as large objects, they are not in the file system and can only be accessed through the DAV protocol. Direct SQL access to the DAV tables is also possible, so there's a set of Virtuoso/PL procedures that acts as DAV API to let server-side applications access DAV. Virtuoso DAV can be

extended by virtual collections. Instead of accessing DAV tables, DAV server can retrieve data from applications, thus an application can generate documents on demand and these documents will be available via DAV as well as plain DAV resources. Moreover, resources can be submitted directly to the application via DAV. Virtuoso DAV provides settable access rights and ownership of resources. Access rights as such are not covered by the DAV specification but Virtuoso implements both ACLs (access control lists) and a Unix file system like scheme for ownership and permissions. SQL accounts enabled for DAV are valid owners of DAV resources. A resource has both a user owner and a group owner, plus an optional access control list that can grant privileges to users and roles alike. A user can have DAV-only access, SQL/ODBC-only access, both of them or neither. User account information is stored in relational tables and can be manipulated from SQL or through a Web UI.

Virtuoso DAV can store metadata about resources. These metadata are extracted from resources automatically, and can be edited by users. In addition, users can place public and personal 'tags' on resources to categorize data according for personal needs without interference between users. Virtuoso DAV has a powerful and scalable search engine that let application locate resources that match given list of criteria. The search can process both plain DAV resources and data published by applications in virtual collections. Search criteria can check for resource properties, content, metadata and tags.

Certain special processing is provided for the following types of DAV resources:

Any textual content types are automatically indexed in a free text index.

Any XML content types are indexed in the same free text index as other text plus can be queried with the *xcontains* SQL predicate.

Some well-known types of documents are parsed in order to extract metadata, such as author of MS Office document or musical genre of MP3 audio file or resolution of an image.

VSP/VSPX pages - DAV resources can be dynamic web pages written in VSP or VSPX. Requesting such a page with GET or POST will execute the logic on the page. This is very convenient way of building web applications.

DAV resources are stored in an ordinary relational table. The text and XML query features used with DAV are separately usable from SQL on any table with the appropriate indexes and are thus not intrinsically related to DAV.

WebDAV (Web Distributed Authoring and Versioning) is a communication protocol for the Internet implemented as an extension to HTTP 1.1. The WebDAV specification was published by the Internet Engineering Task Force (IETF) in February 1999.

Most operating systems have support for accessing data hosted on DAV servers.

DAV was designed to provide more methods for handling server resources. In addition to the usual HTTP methods such as GET, POST, HEAD, PUT, DELETE, OPTIONS are methods for making directories (or collections), a lock mechanism, copying of resources and collections, predefined and userd-defined properties of resources and collections.

DAV consists of HTTP extensions, often with a message body containing XML. DAV also provides a basic schema for resource metadata by allowing arbitrary XML properties to be attached to resources.

Virtuoso supports the following HTTP methods:

Table 19.1. Features List - Virtuoso Web DAV HTTP Method Support

HTTP Method	Description
HEAD	Meta method for examining server properties or network behavior.
GET	Retrieves documents from the server
POST, PUT	Posts or puts documents on the server
MKCOL	Creates a collection
MOVE	For moving resources and/or collections within the server
DELETE	Removes resources or collections of resources from the server
LOCK, UNLOCK	Locks or unlocks a resource or collection to protect from modification by others
PROPFIND, PROPPATCH	Retrieves and sets properties for collections and/or resources. In addition to arbitrary user-defined properties, Virtuoso supports two sets of predefined properties: standard DAV properties (type, creation time, modification time, size etc.) and Virtuoso-specific DAV properties (access control, tags, extensions for virtual collections.)
MGET (experimental)	Retrieves RDF metadata of a document according to URIQA rules
	Updates RDF metadata of a document according to URIQA rules and appropriate RDF Schemas

HTTP Method	Description
MPUT/MDELETE (experimental)

IETF RFC 2518 regarding WebDAV Specification

19.1.1. DAV User Accounts

Any non-disabled SQL account with the U_DAV_ENABLE column set to non-zero is a valid DAV account. The administration user interface provides a check box for enabling DAV access and will make a default home collection etc. Alternately, regular SQL can be used for setting the DAV flag on. The DAV API or protocol requests can be used for creating collections and resources for the user.

Any non-disabled SQL account with the U_DAV_ENABLE column set to non-zero is a valid DAV account. The administration user interface provides a check box for enabling DAV access and will make a default home collection etc. Alternately, regular SQL can be used for setting the DAV flag on. The DAV API or protocol requests can be used for creating collections and resources for the user.

There is an automatically created initial DAV enabled account called "dav". This has general administration privileges over all DAV.

There are four predefined DAV accounts.

User "dav" is the most powerful DAV account.

DAV group "administrators" usually consists of "dav" only; membership in this group does not give any special privileges but this group is assigned by default to resources that are owned by "dav". Thus group access rights to resources owned by "dav" can be used solely by users that are added to "administrators".

User "nobody" is a special account that acts as owner of all resources that have no real owner person or owner application. It is impossible to log on as "nobody" so it's impossible to use owner permissions of the resource.

Group account "nogroup" always consists of only one user "nobody"; User "nobody" can not become a member of any other group. It is impossible to add other users to "nogroup" or add "nogroup" to some role.

Note:

The WebDAV admin user "dav" can be deleted. However, after a server restart the initial setting of this account will be added again.

Important

It is strongly recommended that the Virtuoso administrator change the default account password of the DAV administrative user after installation.

Example 19.1. Manipulating WebDAV Users By Hand

```
USER_CREATE ('user', 'userpassword',
  vector ('SQL_ENABLE', 0, 'DAV_ENABLE', 1, 'PERMISSIONS', '110100000RR', 'DISABLED', 0));
```

This will create a new account named 'user' with password 'upwd', default permissions for new resources and collections created by the account will be '110100000RR' (equivalent of UNIX 'rw-r----' permissions, recursive free-text indexing and metadata extraction) and the account is enabled and ready to use.

```
DAV_ADD_USER ('user', 'userpassword', '110100000RR', 0, '/DAV/home/user/',
  'Full User Name', 'user@example.com', 'dav', 'davpassword');
```

this will do almost the same but it will describe the user in more details and require no DBA privileges -- only DAV password. In addition, DAV_ADD_USER () can both create a new user and grant DAV permissions to an already existing SQL user.

The following statement is used to grant role 'administrators' to the 'user' account.

```
GRANT ADMINISTRATORS TO "user";
```

or

```
USER_GRANT_ROLE ('user', 'administrators');
```

The following will disable the account 'user' until 'DISABLED' option is returned to zero.

```
USER_SET_OPTION ('user', 'DISABLED', 1);
```

DAV access permissions can be revoked permanently:

```
DAV_DELETE_USER ('user' , 'dav', 'davpassword');
```

WS & DAV System Tables

19.1.2. WebDAV Authentication

Virtuoso WebDAV offers two types of authentication dependent on the connecting clients abilities. These are:

Basic (Clear Text) Authentication - sends passwords over the connection in clear text. Clear text passwords can be intercepted and read so should be avoided or used only if you encrypt passwords through SSL.

Digest Authentication - passwords are always transmitted in an MD5 hash.

Basic Authentication

Basic Authentication is a widely used, industry-standard method for collecting user name and password information. The following steps outline how a client is authenticated using Basic authentication:

1. The client browser displays a dialog box for a user to enter a user name and password (his/her credentials).
2. The client browser then attempts to establish a connection to the server using the user's credentials. The clear text password is Base64-encoded before it is sent over the network.
3. If a user's credentials are rejected, the client may re-display the authentication dialog box to re-enter the user's credentials. Failing to supply correct details will terminate the connection, reporting an error to the user.
4. When Virtuoso verifies that the user name and password are valid, a connection is established.

The advantage of Basic authentication is that most clients support it. The disadvantage is that it transmits passwords in an unencrypted form. Simple network monitoring can easily reveal your password. Basic authentication is not recommended unless you are confident that the connection between the user and Virtuoso is secure.

Note:
Base64 encoding is not encryption. A Base64-encoded password can be easily intercepted by a network sniffer and easily decoded.

Digest Authentication

Digest authentication provides a security improvement over Basic authentication in how a user's credentials are sent across the network. Digest authentication transmits credentials across the network as an MD5 hash, or message digest, where the original username and password cannot be deciphered from the hash. Digest authentication relies on the HTTP 1.1 protocol as defined in RFC 2617, which not all browsers support.

The following steps outline how a client is authenticated using Digest authentication:

Figure 19.1. Digest Authentication

1. The client requests a file or connection from Virtuoso.
2. Virtuoso challenges the request, informing that client: Digest is in use, what the realm name is.
3. The client prompts the user for credentials. The client creates an MD5 hash of the credentials and the realm name and resubmits the request, this time supplying the MD5 hash.
4. If Virtuoso approves the credentials then the resource or connection is granted to the client, and the data is returned.

19.1.3. WebDAV Symbolic Links

Virtuoso supports a special type of WebDAV resources, a redirect reference resource, named WebDAV links. This is to extend the WebDAV service to allow multiple access paths to existing resources.

As with conventional HTTP, the redirect reference simply responds to the client with an HTTP/1.1 302 (Found) status code, redirecting the client to a different resource, the target specified in the redirect resource, using the `Location:` header. This behavior is equivalent to UNIX symbolic links. A redirect reference makes it possible to access the target resource indirectly through any URI mapped to the redirect reference resource. The integrity is not guaranteed for associated redirect reference resources.

WebDAV links do not provide a way to circumvent WebDAV security or virtual directories. The target resource must be directly available to the client being redirected.

WebDAV links are achieved by adding a special WebDAV property, '`redirectref`', whose value must contain the reference target URL.

WebDAV link targets are not limited to the WebDAV repository, and may target any HTTP accessible resource.

The WebDAV links can be made with DAV API function `DAV_PROP_SET()` , or can be done via the Content Management interface of the Admin UI. In the admin UI select WebDAV/WebDAV Services/Content Management and press on the *Create Link* button to create a link. In the form choose the target, permissions, owner and enter the name of the link. Pressing the *Add* button will create the new link in the current WebDAV folder.

Example 19.2. WebDAV Links Programmatically

Assuming that we are creating the link as the administrator using the default WebDAV administrator username and password, creating a link from `/a/b.html` to `/c/d/f.html` could be as follows:

```
SQL> select DAV_RES_UPLOAD ('/DAV/a/b.html','','','110100000NN', 'dav', 'nobody', 'dav', 'dav');

SQL> DAV_PROP_SET ('/DAV/a/b.html', 'redirectref', '/c/d/f.html', 'dav', 'dav');
```

The target, '`/c/d/f.html`' could be any HTTP URL. In this case it will be a resource on the same HTTP server.

See Also:

DAV Add and Update functions and DAV Manipulation functions .

WebDAV links behaviour in resource manipulation requests. When some link is moved the target will have the same properties as source, ie. it will be a link. When a copy operation is made the target will have content of the reference i.e. it will be

a resource, not a link. Delete operation on link will remove only the redirect reference resource, not the referenced target itself. Content upload requests will change the content of the referenced target.

19.1.4. Access Right Permissions of Web Resources

The WebDAV resources have two sorts of access right permissions. 'Classical' UNIX filesystem style permissions let assign different permissions for owner user, owner group and public access. Access Control Lists (ACLs) let assign permissions in more flexible Windows style but they are less convenient for simple tasks. Both set of permissions can be applied to the same resource or collection. In any case, each resource or collection (directory/folder) can have defined Read, Write and Execute permissions. The write permission applies to operations which perform content or property change or locking as PUT, PROPPATCH, MOVE, destination URI in COPY, LOCK, UNLOCK, DELETE, MPUT and MUPDATE. The read permission applies to read operations as GET, POST, PROPFIND, HEAD, source URI in COPY and MGET; read permission is also required for any write operation.

See Also

RFC2518 for more details of methods/operations

The execute permission applies only to the active content stored in the WebDAV domain. If a VSP or VSPX page stored in a WebDAV domain has execute permissions then retrieval of that page will perform execution of active content. Note also a special flag to the virtual directory which can override the execution flags for active pages. (for the details how this flag can be set see 'options' in VHOST_DEFINE() function). If such a flag is set to the virtual directory, then all active pages under that directory (direct and indirect children) will be treated as execution flag of the resource is set. In almost any case, user should have both read and execute permissions to access active content.

Resources with the following extensions are treated as executable content: .vsp, .vspx, .xml if this has the XML template properties set. Any other extension is also considered executable if there is a corresponding WS.WS."__http_handler_<extension>" PL procedure.

The UNIX style permissions can be set for user, group or public access. ACL consists of records called Access Control Entries (ACEs). Every ACE allow or deny some sorts of access to an individual user or to a group. Resource owner or administrator can add an "explicit" ACE to the ACL of particular resource or "recursively" add "implicit" ACEs to every resource and subcollection of some collection. The server checks permissions in the following order:

1. match the user part of UNIX-style permissions to the specific operation, if user is the owner of the resource.
2. match the user group part of UNIX-style permissions to the specific operation, if user belongs to a group which owns the resource.
3. match the public part of UNIX-style permissions to the specific operation.
4. If Access Control List is not empty, scan ACEs from the beginning of the list to the end. The loop stops at the first ACE that mentions either the user in question or one of the roles granted to it. Depending on the type of the ACE, the access is either granted or denied and the rest of list has no effect.
5. If ACL contains no appropriate ACE then the access is denied.

According to these rules, the order of records in ACL is important. ACEs are ordered following two rules: "deny" ACEs has higher priority than "allow" ACEs; "local" rules has higher priority that "global":

1. All explicit ACEs are placed in a group before any inherited ACEs.
2. Within the group of explicit ACEs, access-denied ACEs are placed before access-allowed ACEs.
3. Inherited ACEs are placed in the order in which they are inherited. ACEs inherited from the child object's parent come first, then ACEs inherited from the grandparent, and so on up the tree of objects.
4. For each level of inherited ACEs, access-denied ACEs are placed before access-allowed ACEs.

New resources and collections take their initial permissions from the user default permissions mask, U_DEFAULT_PERMS of SYS_USERS. (see: WebDAV Users Administration). In the case of a resource created as public or a collection mask of '110110110' (equivalent of UNIX 'rw-rw-rw'), then everybody can read and write it.

Example 19.3. WebDAV Permissions

Consider a resource with the following permissions:

```
'111110100'
```

This permission string is equivalent to UNIX 'rwxrw-r--'. The resource can be executed, read and written to by the owner, group

members can read and write to it, and non authenticated (public) users or users not belonging to the group group can only read it.

Every resource or collection has two additional flags in permissions, that instruct the server whether resources should be indexed for free-text search and whether resources should be parsed to extract metadata:

Free-text indexing flag can take one of three values: "N", "R" and "T". If a resource has this flag set to R or T then the resource will be free-text indexed. If a collection has this flag set to T then resources directly contained within the collection will be free-text indexed. If a collection has this flag set to R then resources contained within the collection will be free-text indexed, and the setting will be applied to all members and collections underneath recursively. New resources and collections acquire this setting from their parent collection.

Similarly, metadata extraction flag can take one of three values: "N", "R" and "M". If a resource has this flag set to R or M then its metadata are extracted. If a collection has this flag set to T then metadata are extracted from resources directly contained within the collection. If a collection has this flag set to R then metadata are extracted from resources contained within the collection, and the setting will be applied to all members and collections underneath recursively. New resources and collections acquire this setting from its parent collection.

19.1.5. DAV and RDF Metadata

When a Virtuoso server has a URIQA default host setting, it will make metadata extracted from DAV resources available for querying via SPARQL. All metadata for public readable DAV resources are stored in a system graph. The graph IRI is composed from the DAV path of the resource and the URIQA default host name.

see DefaultHost in the URIQA section of the virtuoso.ini file, described in the URIQA section of the documentation for details on configuration.

The automatic maintenance of the SPARQL queryable metadata can be disabled and enable using the function DB.DBA.DAV_REPLICATE_ALL_TO_RDF_QUAD. An argument of 1 enables this and a 0 disables this. The setting stays in effect until it is changed with the same function. For new database, the feature is on by default. Old databases are by default upgraded to have a SPARQL queryable DAV metadata graph upon startup if the URIQA default host name is defined.

If the URIQA default host name changes, the RDF graph can be updated by simply re-enabling the feature. This will adjust the graph and resource IRI's.

If the URIQA default name of the host is example.com, then, the graph will be http://example.com/DAV .

The IRI's of DAV resources will be like http://example.com/DAV/docsrc/XMLDOM.xml , meaning that these are directly usable from a user agent for accessing the resource.

```
SQL> sparql select ?s ?o from <http://example.com/DAV> where {?s <http://www.openlinksw.com/schemas/DAV#o
s                                                                                o
VARCHAR                                                                          VARCHAR
_______________________________________________________________________________

http://example.com/DAV/docsrc/2pc.xml                                        mailto:somebody@example.do
http://example.com/DAV/docsrc/Virtdocs.spp                                   mailto:somebody@example.do

SQL> sparql select ?p ?o from <http://example.com/DAV> where {<http://example.com/DAV/docsrc/2pc.xml> ?p
p                                                                                o
VARCHAR                                                                          VARCHAR
_______________________________________________________________________________

http://purl.org/dc/terms/created                                                 2006-05-23 15:10:32
http://purl.org/dc/terms/modified                                                2006-05-23 15:10:32
http://www.openlinksw.com/schemas/DAV#ownerUser                                  mailto:somebody@example
http://purl.org/dc/terms/extent                                                  7850
```

The examples above show how simple SPARQL queries can be used to retrieve information about DAV resources.

The properties supported for all public readable resources are:

http://purl.org/dc/terms/created - The creation date as SQL datetime.

http://purl.org/dc/terms/modified - Modification time as SQL datetime.

http://www.openlinksw.com/schemas/DAV#ownerUser - The contents of u_e_mail in sys_users for the SQL account owning the resource. This has the protocol prefix mailto:, as in mailto:somebody@example.com.

http://purl.org/dc/terms/extent The size of the resource in bytes as a SQL integer.

http://www.openlinksw.com/schemas/DAV#tag - There is one triple for each public tag of the DAV resource. The value is the string of the tag as a SQL string.

http://www.w3.org/1999/02/22-rdf-syntax-ns#type - The RDF schema for MIME-type of of the DAV resource. If the resource is not recognized as one of the below, this predicate will be omitted.

Table 19.2. RDF Schema by MIME-type

MIME- ype	RDF Schema
application/bpel+xml	http://www.openlinksw.com/schemas/WSDL#
application/doap+rdf	http://www.openlinksw.com/schemas/doap#

text/wiki	http://www.openlinksw.com/schemas/Wiki#

Additional predicates may exist as a result of resource type specific metadata extraction.

19.1.6. Special Attributes of Web Resources

The Virtuoso WebDAV implementation provides a set of special attributes (properties) for the resources to manipulate the retrieval of XML documents. Properties can be set generate dynamic content based on XML/SQL queries. Special properties can

also be applied to WebDAV folders for storing XML data in a special pre-parsed persistent XML format.

The following special properties are supported:

- **xml-stylesheet.** must contain a valid URL to an XSLT style sheet. Upon request of an XML document with this property set, the WebDAV server will automatically perform the transformation of the XML document and will send the result of transformation to the user-agent instead of the original XML source. This property is only settable for documents having MIME type text/xml.
- **xml-sql.** must contain a valid XML/SQL query (see also: FOR XML statements). When this property is set the server will execute the query and the XML result will be sent to the client. Note that if xml-stylesheet is also supplied for this resource the result will be transformed and then sent to the client.
- **xml-sql-root.** specifies the root element name of automatically generated XML resources when xml-sql is specified. Otherwise it has no effect.
- **xml-sql-dtd.** can be specified as a string value 'on' or valid URL. When the value is 'on' the DTD declaration will be implied in the automatically generated XML resource. Otherwise when the URL is supplied this URL will be included in the DTD declaration of the automatically generated XML resource. If xml-sql is not specified this property has no effect.
- **xml-sql-schema.** specifies the URI for the XML Schema. This schema URI will be included in the XML header, to allow client-side schema validation. If xml-sql is not specified this property has no effect.
- **xper.** can be specified for a collection (folder). When this property is set on a WebDAV collection, the direct resource members will be stored and updated as persistent XML. Note that existing resources will not be changed until they are updated. The reversal of this property for collections will not change the resources at the same time, they will be reverted to the text/xml storage on first update operation. Resources already stored as XML persistent documents also have the xper property set, but manipulation of this property must not be used to revert the storage.

19.2. URIQA Semantic Web Enabler

Virtuoso supports the URIQA (URI Query Agent) extension of HTTP WebDAV protocol. URIQA adds three new methods to HTTP in order to retrieve, add and remove RDF metadata about a given subject. The subject is identified by its URI. If the subject is a DAV resource then URIQA will usually reuse the DAV URI of the resource. If the subject is not a resource but something else (physical entity, imaginary thing or vocabulary item) then URIQA can be used to process metadata about the subject even if the subject itself can not be accessed via HTTP.

URIQA-specific HTTP methods are called MGET (to retrieve existing metadata), MPUT (to add or update RDF triples) and MDELETE (to remove some or all triples). A single URIQA request usually deals with a single subject that is specified by request URI. The MGET response, however, can return metadata about more than one RDF subject, e.g., the request about a book can return both data about the book itself plus some data about persons who are known as authors of the book.

In addition to URIQA-specific HTTP methods, Virtuoso implements a semantic web service interface that allows plain HTTP clients to access metadata using traditional GET or POST HTTP methods.

The Virtuoso URIQA implementation allows flexible configuration using an ordered list of request handlers. Every handler has a pattern for URIs; if the URI in the request does not match the pattern then the handler is ignored, otherwise a callback function of the handler is called to process the request. The default configuration of Virtuoso server will try three sorts of actions.

If the URI points to a resource located at the server then the first handler returns DAV metadata of the resource.

If the URI points to a resource that is outside the server, and URI is of sort 'http://...' then Virtuoso will send a URIQA web service request to the remote server specified in URI in hope that it will return at least something, the response is passed to the client unchange.

Any other URI results in an error.

Note:

URIQA is not yet a stable standard. Virtuoso implements draft of URIQA proposal from Nokia, dated 2004. As URIQA will evolve, future versions of Virtuoso will implement updated versions of the specification. There is no warranty that future implementations will be compatible with the current one.

The Nokia URI Query Agent Model

19.2.1. URIQA HTTP Methods

All three methods have a set of HTTP header parameters to specify the precise URI of the subject. HTTP does not require that every resource is accessible via a single valid URI, so many equivalent URLs can point to same resource and the result of typical HTTP request does not change if one of equivalent URLs is replaces with some other. Unlike HTTP GET, HTTP PUT etc., metadata methods may return different results for different URLs even if these URLs are equivalent for other methods. URIQA rules are very simple.

If the URIQA request header contains 'URIQA-uri' parameter line then the value of this parameter is used and any other URI data are ignored.

If the URIQA request header contains 'Host' parameter line then the URL from the first line of the request is patched to contain host name specified by 'Host' parameter, no matter whether the original URL contains host or what host name or network interface or port is user by client to connect to the server.

If the URIQA request header does not contain 'URIQA-uri' or 'Host' line then the URL from the first line of the request is used 'as is', extended by host name from 'DefaultHost' URIQA configuration parameter if needed.

Example 19.4. Examples of MGET Requests

The following requests are all equivalent:

Request 1. 'URIQA-uri' is used, the rest does not matter.

```
MGET /foo HTTP/1.1
Host: example.com
URIQA-uri: http://example.com/foo
```

Request 2. 'URIQA-uri' is missing, 'Host' is used, the host name www.example.com is ignored.

```
MGET http://www.example.com/foo HTTP/1.1
Host: example.com
```

Request 3. The URI from the first line is used verbatim. This is unsafe, because proxy servers can alter the URI, e.g. by adding port number.

```
MGET http://example.com/foo HTTP/1.1
```

Request 4. The URI from the first line is used, but host name is retrieved from 'DefaultHost' URIQA configuration parameter. If the parameter is set to example.com then the request is equivalent to previous.

```
MGET /foo HTTP/1.1
```

MGET Method

MGET request contains a subject URI and the response consists of RDF/XML representation of an RDF graph with metadata about the subject. In many cases, the returned graph is a Concise Bounded Description of the resource or something similar, but it can be of any sort.

There are no integrity rules. E.g., if a response for request about subject A contains some data about B then the request about B may return same or different data, or even report that B does not exists. If URI refers to non-existing resource or even to a non-existing server or protocol then the response can be an 'not found' error or an empty graph or even a non-empty graph, depending on the handler that processed the request.

Usually MGET request consists of only subject URI specification, but it can contain any other parameters such as an authentication or even the HTTP request body with extra data for some particular handler. For Virtuoso DAV resources, MGET will need read permission on the subject resource, because the resulting RDF is retrieved from 'http://local.virt/DAV-RDF' property of the resource.

MPUT Method

MPUT request contains an HTTP header that describe a subject URI and contains Content-Length, and the body must be an RDF/XML that consist of triples that should be added. The server will try to add new RDF triples from the body to the description of the subject. In some cases, the server will replace obsolete triples with triples from the body, e.g., if some RDF Schema is in use that states for a predicate that it can not have more than one value for any given subject.

There are no integrity rules. If MPUT request with subject A submits data about resource B then the updated data may become visible via MGET request with subject A and stay unchanged if retrieved directly by MGET with subject B. For instance, the default request handler for DAV will update only 'http://local.virt/DAV-RDF' DAV property of the subject resource not touching any DAV properties of resources named in the request.

A client application can not use MPUT with subject URI that refers to a non-DAV Virtuoso resource, because disk-resident resources do not have DAV properties, including DAV metadata properties. MPUT can refer to nonexisting Virtuoso DAV resource only if the name of this resource has been already locked for uploading of the resource. The most reliable way, however, is to upload the resource first and update metadata only after the uploading. There are two reasons to do operations in this sequence. First of all, Virtuoso can automatically extract some metadata from the content of uploaded resource and if MPUT happens after the upload then MPUT data can properly overwrite automatically extracted values. An additional reason is that resource uploading will set the MIME-type of the resource and may associate some RDF Schemas with the resource; hence MPUT can properly update some triples instead of storing multiple values for some predicate that should have only one value according to RDF Schema.

For Virtuoso DAV resources, MPUT will need both read and write permissions on the subject resource, because 'http://local.virt/DAV-RDF' property of the resource is first retrieved and then updated.

MDELETE Method

MDELETE request contains an HTTP header that describe a subject URI and may contain the body. If present then the body must be an RDF/XML that consist of triples that should be deleted. If the body is totally missing then MDELETE removes all metadata associated with the subject URI.

There are no integrity rules. If MDELETE request with subject A removes triples about resource B then these triples may stay visible if retrieved directly by MGET with subject B. For instance, the default request handler for DAV will update only 'http://local.virt/DAV-RDF' DAV property of the subject resource not touching any DAV properties of resources named in the request.

For Virtuoso DAV resources, MPUT will need both read and write permissions on the subject resource, because 'http://local.virt/DAV-RDF' property of the resource is first retrieved and then updated.

19.2.2. URIQA Web Service

Virtuoso provides the '/uriqa/' web service for clients that do not support URIQA-specific methods. Instead of passing URI and method name in HTTP parameter lines, web service calls pass them as part of web service URI. The beginning of the path can be any, starting from '/uriqa/' or '/URIQA/'. The following two requests are to retrieve metadata about 'http://example.com/foo'.

```
GET /uriqa?uri=http%3a%2f%2fexample%2ecom%2ffoo HTTP/1.1

GET /uriqa?uri=http%3a%2f%2fexample%2ecom%2ffoo&method=MGET HTTP/1.1
```

The following request header is for MPUT

```
GET /uriqa?uri=http%3a%2f%2fexample%2ecom%2ffoo&method=MPUT HTTP/1.1
```

The URIQA web service does not need complicated rules for URI passing because the request can not be significantly changed by any proxy. The value of the 'uri' parameter should be an absolute URI.

19.2.3. URIQA Section in Virtuoso Configuration File

By default,the Virtuoso server acts only as URIQA proxy, i.e. it redirects incoming requests to other servers without trying to return metadata about DAV resources or other data stored on the server itself. To let URIQA retrieve local metadata, the Virtuoso server should know names that can be used by clients to access it. Virtuoso configuration file, e.g., virtuoso.ini, can contain these

names as parameters in "[URIQA]" section

"DefaultHost" is the "canonical" server name that is used to identify the service. It should be either server name including domain name, or an IP address in standard notation, if the server does not have any name. If Virtuoso default HTTP port is not equal to 80 then the port should be mentioned, e.g. "www.example.com:8088".

"LocalHostNames" lists all names that can be used to access the server, such as server names with and without domain name, IP addresses in Internet and intranets etc. The list is comma-delimited string of names. If an URIQA client can reside on server's box, e.g. for debugging purposes, then it may be worth to add names "localhost, localhost.localdomain, 127.0.0.1" to this list.

"LocalHostMasks" is similar to "LocalHostNames" but it lists patterns for names in SQL "like" operator style. If Virtuoso listens at multiple ports and it is the only URIQA enabled service on the machine then it can be convenient to specify "LocalHostMasks = www.example.com:%" instead of "LocalHostNames = www.example.com:8088, www.example.com:8089, www.example.com:8090 ...".

"Fingerprint" is a string that identifies a group of servers that shares same metadata, such as servers that replicate each other. It is an error if two servers have the same fingerprint string and one of them tries to redirect a URIQA request to another instead of prepare an response locally. Such behavior indicates configuration error, and the use of fingerprints help administrator to get a meaningful diagnostics, because suspicious URIQA requests become signed by all intermediate Virtuoso proxies. If this parameter is not specified then a random unique string is created and stored in the database, so you don't have to specify this parameter for typical installations.

"DynamicLocal" is a flag (1 or 0), when it is on and the host part of the IRI matches the Host header of the HTTP request in context or the DefaultHost if outside of HTTP context, then this is replaced with local: before looking up the IRI ID. Even if DynamicLocal is not on and the `local:` prefix occurs in the IRI string being translated to IRI_ID, the translating the IRI_ID back to the IRI name will depend on the context as described as follows: When returning IRI's from id's, this prefix is replaced by the Host header of the HTTP request and if not running with HTTP, with the DefaultHost from this section. The effects of DynamicLocal = 1 can be very confusing since many names can refer to the exact same thing. For example, if the DefaultHost is http://dbpedia.org, `iri_to_id ('http://dbpedia.org/resource/Paris') = iri_to_id ('local:///resource/Paris)` is true and so is `'http://dbpedia.org/resource/Paris' = id_to_iri (iri_to_id ('local:///resource/Paris'))` These hold in a SQL client context, i.e. also when connected through RDF frameworks like Jena or Sesame. When running a SPARQL protocol request, the Host: header influences the behavior, likewise when using web interactive SQL in Conductor.

These configuration parameters are "sticky". If they're found in configuration file then they are preserved in the database registry. If configuration file has changed then new values will be used after server restart. If database dump is replayed on a server whose configuration file does not contain these parameters then values from dump will stay in the registry. If database dump is replayed on a server whose configuration file contains other values then values from dump will stay in the registry till server restart.

19.2.4. URI Matching Rules

A simple installation does not require any special configuration of URIQA except specifying server names in the [URIQA] section of configuration file (virtuoso.ini). However complex applications may need from URIQA more than simple retrieval of metadata of DAV resources. Like HTTP virtual hosts, URIQA may require different processing for different URIs, so Virtuoso offers appropriate tools.

When the URIQA server gets an URI to process, it reads the system table WS.WS.URIQA_HANDLER to find out the procedure that can access metadata about some range of URIs. This table is defined as follows:

```
create table WS.WS.URIQA_HANDLER
(
  UH_ID integer not null primary key,
  UH_ORDER integer not null,
  UH_NAME varchar not null unique,
  UH_MATCH_COND varchar not null,
  UH_MATCH_ENV any,
  UH_HANDLER varchar not null,
  UH_HANDLER_ENV any
)
create index URIQA_HANDLER_ORDER_NAME on WS.WS.URIQA_HANDLER (UH_ORDER, UH_NAME)
;
```

The server scans the table in order of ascending values in UH_ORDER column, and checks whether the request URI matches the condition specified by UH_MATCH_COND and UH_MATCH_ENV. As soon as an appropriate row is found, a function with name specified by UH_HANDLER is called with parameters that describe the request plus any extra application-specific data as stored in UH_HANDLER_ENV. The function should either compose a response and set a flag to 1 or do nothing and set a flag to 0. If 1 is set then the processing of the request is complete, otherwise the server resumes table scan.

At server startup, up to three records are automatically added into WS.WS.URIQA_HANDLER.

First record has UH_ORDER equal to 100. It tells the server that if an URI has server name equal to one of names listed in "LocalHostNames" configuration parameter then metadata should be retrieved from local DAV of the server.

Second record is very similar, it also has UH_ORDER equal to 100, but uses SQL 'like' operator instead of '='. It tells the server that if an URI has server name like one of masks listed in "LocalHostMasks" configuration parameter then metadata should be retrieved from local DAV of the server.

The third record has UH_ORDER equal to 999, and tells the server to act as URIQA proxy if the requested URI starts with "http" protocol name.

Applications can add more lines to the table to handle different sorts of URIs via different application specific functions. The name of function should begin with "WS.WS.URIQA_HANDLER_", the rest is as specified by UH_HANDLER of the row. The signature of function should be

```
function WS.WS.URIQA_HANDLER_myexample (
  inout op varchar,   -- operation name, 'MGET', 'MPUT' or 'MDELETE';
  inout uri varchar,  -- request URI;
  inout split any,    -- request URI split by WS.WS.PARSE_URI into parts;
  inout body any,     -- the body of the request;
  inout params any,   -- get_keyword style vector of parameters of the request;
  inout lines any,    -- vector of lines of HTTP request header;
  inout app_env any,  -- any application-specific data from UH_HANDLER_ENV;
  inout is_final integer -- status flag. Function sets the flag to 1 to report that the request response
  ) re0turns any              -- returns a status vector, see below.
```

Status vector describes either the reason why the request has failed, or the success status. It consists of four elements:

SQL_STATE as five-char string, "00000" if success;

DAV error code as an integer, if the operation has failed due to DAV error, 0 if success or an error other than DAV;

HTTP status as three-digit string, such as "200" for "OK" or "404" for "not found";

Brief description of an error, such as HTTP response status ("OK", "not found" etc.) or SQL_MESSAGE, "OK" if success;

In case of DAV error, elements 3 and 4 can be set to NULL to generate proper values automatically.

Examples are:

```
vector ('00000', 0, '200', 'OK');
vector ('URIQA', 0, '500', 'The remote URIQA server returned an invalid header');
vector ('URIQA', -1, '404', 'Invalid URI; Ill formed or missing path to the resource');
vector ('URIQA', -12, null, null);
```

The current version of Virtuoso supports the following names of matching operations for use in UH_MATCH_COND:

"schema =" -- URI schema name should be equal to UH_MATCH_ENV;

"server =" -- URI server name (including port, if specified) should be equal to UH_MATCH_ENV;

"server like" -- URI server name (including port, if specified) should be "like" to UH_MATCH_ENV;

"server in" -- URI server name (including port, if specified) should be member of UH_MATCH_ENV vector of strings;

"server like in" -- URI server name (including port, if specified) should be "like" to one of members of UH_MATCH_ENV vector of strings;

"default" -- Any URI will match so any request is passed to the handler if not handled before.

19.3. Mail Delivery & Storage

19.3.1. The SMTP Client

smtp_send_dedup

For detailed description and example use of the function, see smtp_send in the Functions Reference Guide.

19.3.2. POP3 Server

The Virtuoso POP3 Server implementation supports the following commands as defined in RFC - 1939:

DELE
LIST
NOOP
PASS
QUIT
RETR
RSET
STAT
TOP
UIDL
USER

The POP3 Server listening port is configured in the HTTP section of the virtuoso.ini.

POP3Port = xxx, in HTTP section.

If the port is not defined in the configuration file then the POP3 server subsystem will be disabled.

Users and passwords of the POP3 Server are described in the system view WS.WS.SYS_DAV_USER over SYS_USERS. These users can be administered from the users section of the Virtuoso Administration User Interface.

The system table DB.DBA.MAIL_MESSAGE is used to stored the messages.

19.3.3. Storing Email in Virtuoso

A generic mail delivery driver enables SMTP servers to deliver email to be stored in either Virtuoso or non Virtuoso SQL database.

Mail storage can occur in a number of ways:

1. Replacing the default generic SMTP mail handler (the program "procmail")
2. Replacing the mail storage settings for individual users Replacing Default SMTP Mail Handler Sendmail

Replacing procmail As Default Mail Handler In Sendmail Configurations

When this configuration is in use, the mails for all of your "sendmail" mail recipients are written to a SQL Database table.

1. Copy the file "odbc_mail.default.ini" to "/etc/odbc_mail.ini"

   
   Important
   Make sure that /etc/odbc_mail.ini is NOT GROUP/WORLD writable. virt_mail will fail to run if it is.
2. Copy or symbolically link the file "virt_mail" to "/usr/bin/virt_mail"
3. Edit /etc/odbc_mail.ini and change the login settings to match your current database installation.

   Note: If you don't have or want to use procmail, comment out the "Fallback" setting in the "[Deliver]" section.
4. Edit the file "/etc/sendmail.cf" as described below:

   Change

   ```
   Mlocal, P=/usr/bin/procmail, F=lsDFMAw5:/|@qSPfhn9, S=10/30,
     R=20/40,T=DNS/RFC822/X-Unix, A=procmail -Y -a $h -d $u
   ```

   To:

   ```
   Mlocal, P=/usr/bin/virt_mail, F=lsDFMA5:/|@qSPhn9, S=10/30,
   ```

```
R=20/40, T=DNS/RFC822/X-Unix, A=virt_mail -c /etc/odbc_mail.ini -l $u -s $g
```

NOTE: The changes to the F= setting involves removing both the 'w' and 'f' flags.

The removal of the 'w' flag affects lookups in /etc/passwd, which are no longer required if all mail delivery goes into a SQL Database. The default ini file is set up to maildrop via procmail, which will perform the check correctly.

Replacing The Mail Storage Settings For Individual Users

Using Sendmail

1. Copy odbc_mail.default.ini to ~the_user_name/odbc_mail.ini

   Important
   Make sure that /etc/odbc_mail.ini is NOT GROUP/WORLD writable. virt_mail will fail to run if it is.
2. At the end of the file ~the_user_name/.procmailrc put something like:

   ```
   :0:
   | /usr/bin/virt_mail -c .odbc_mail.ini -l the_user_name
   ```

   replacing the_user_name with the user you are setting up.

   Note: the '-l ..' parameter is used to relate the local recipient to the database user for which the maildrop is done. See the remarks in the odbc_mail.default.ini file.
3. Adjust the parameters in .odbc_mail.ini to match your configuration

   Important
   disable Fallback delivery in the .odbc_mail.ini file.
   Comment out the "Fallback =" entry in the .odbc_mail.ini or set it to something that does not involve procmail. This may lead to drop loops, otherwise.

Using Qmail

1. Copy odbc_mail.default.ini to ~the_user_name/.odbc_mail.ini

   Important
   Make sure that the .odbc_mail.ini file is NOT GROUP/WORLD writable. virt_mail will fail to run if it is.
2. If you are setting up a .qmail, you can simply do the following:

   ```
   | /usr/bin/virt_mail -m qmail -c .odbc_mail.ini
   ```

   If you are setting up .qmail-default or .qmail-<some_alias_name>, make sure you adjust the RemovePrefix accordingly in the odbc_mail.ini.

   This also works if a single user is receiving mail for an entire (virtual) domain.

   If you want to configure qmail so that user 'db' gets all mail for example.com, do the following:

   a. create a new user db in /etc/passwd etc.
   b. remove example.com from /var/qmail/control/locals
   c. add to /var/qmail/controls/virtualdomains:

      ```
      example.com:db
      ```

   d. adjust /var/qmail/users/assign accordingly:

      ```
      =db:db:<uid>:<gid>:<home>:::

      +db-:db:<uid>:<gid>:<home>:-::
      ```

      or run qmail-pw2u < /etc/passwd > /var/qmail/users/assign then run qmail-newu and restart qmail
   e. in ~db/.qmail-default, put:

```
| /usr/bin/virt_mail -m qmail -c .odbc_mail.ini
```

f. in .odbc_mail.ini, set:

```
RemovePrefix=db-
```

Now, mail to info@example.com will be delivered to the qmail alias db-info@example.com and is stored into the database for user 'info'.

3. Adjust the parameters in .odbc_mail.ini to match your configuration

Using Courier

1. Copy odbc_mail.default.ini to ~the_user_name/.odbc_mail.ini

Important

Make sure that the .odbc_mail.ini file is NOT GROUP/WORLD writable. virt_mail will fail to run if it is.

2. If you are setting up a .courier, you can simply do the following:

```
| /usr/bin/virt_mail -mcourier -c .odbc_mail.ini
```

If you are setting up .courier-default or .courier-<some_alias_name>, make sure you adjust the RemovePrefix accordingly in the .odbc_mail.ini.

Note: although courier is very similar to qmail in this respect, it is different from qmail in how it handles exit codes. If you use -mqmail while running under courier, you'll get the wrong exit codes, so mail is bounced instead of retried.

Note also that if delivering to multiple recipients in a .courier file, make sure the virt_mail is specified first. This is because if the virt_mail fails with a temporary error, the other recipients will get another drop when courier re-attempts to deliver the mail.

Right:

\w

```
| /usr/bin/virt_mail -mcourier -c .odbc_mail.ini
./Maildir
```

Wrong:

```
./Maildir
| /usr/bin/virt_mail -mcourier -c .odbc_mail.ini
```

3. Adjust the parameters in .odbc_mail.ini to match your configuration

Using EXIM

Here are code snippets for Exim that perform maildrops into the odbc database.

```
## IN TRANSPORT SECTION

# Delivers into the database
odbc:
  driver = pipe
  command = /usr/bin/virt_mail \
        -c /etc/odbc_mail.ini \
        -s "${if def:return_path{$return_path}{MAILER-DAEMON}}" \
        -l "$local_part"
  user = USERNAME
  return_path_add
  delivery_date_add
  prefix =
  suffix =
  temp_errors = 73 : 74 : 75
  return_fail_output

# NOTE: Make sure the USERNAME in the 'user = USERNAME' setting matches
# the owner of /etc/odbc_mail.ini, because this file must have mode 0600.
```

```
# Consider creating a new user account for this delivery only.
# You should specify 'user = root' here only if Fallback delivery is
# configured in /etc/odbc_mail.ini (for procmail fallback delivery
# for instance)

## IN DIRECTORS SECTION

# Attempts delivery of all mail into the database
to_db:
  driver = smartuser
  transport = odbc
  require_files = /etc/odbc_mail.ini
  #
  # uncomment line below to deliver all mail to db-XXX into the database, for any
  # value of XXX. For this to work, set "RemovePrefix = db-" in
  # the [Translate] section in /etc/odbc_mail.ini
  #prefix = db-
```

Mail System Tables

The electronic mail accounts are regular SQL accounts.

Id (MM_ID) of the message is unique per account/folder (folder can be 'Inbox' etc.)

See Also:
Mail system tables

Pop3 Client

The Virtuoso POP3 Client implementation can retrieve messages from any POP3 server.

pop3_get_dedup

For detailed description and example use of the function, see pop3_get in the Functions Reference Guide.

Commands

UIDL - get only UIDL's of messages.

DELETE - delete messages after downloading.

Example 19.5. Examples

1. To get 10 KB. messages from the server 'openlinksw.com' POP3 port 110, user name 'user_1', password 'pass_1'

```
Pop3_get ('openlinksw.com:110', 'user_1', 'pass_1', 10000);
```

2. To get and delete 5 KB. messages from the server 'openlinksw.com' POP3 port 110, user name 'user_1', password 'pass_1'

```
Pop3_get ('openlinksw.com:110', 'user_1', 'pass_1', 5000, 'DELETE');
```

3. To get UIDL's of 100 kb. messages from the server 'openlinksw.com' POP3 port 110, user name 'user_1', password 'pass_1'

```
Pop3_get ('openlinksw.com:110', 'user_1', 'pass_1', 100000, 'UIDL');
```

19.3.4. The Virtuoso Mail Sink

The Virtuoso Sink is used to store messages received by Windows 2000 IIS SMTP Service into the MAIL_MESSAGES table in Virtuoso. It consists of an executable, run as a service, and a VBscript for registering a COM object with the IIS, interfacing it with the Virtuoso Sink

The User ID(s) in MAIL_MESSAGES to whom the message belongs to is determined by parsing the **To:** field in the mail message into a list of recipients. For each entry in the list, if an @-sign is found, the user ID will consist of the characters to the left of it, otherwise the whole entry is used.

Registry Entries for the Virtuoso Sink.

```
<<<<<<<< VirtuosoSink.reg
REGEDIT4

[HKEY_LOCAL_MACHINE\SOFTWARE\OpenLink Software\VirtuosoSink]
"User"="dba"
"Password"="dba"
"DSN"="Virtuoso"
"ConnectionCount"=dword:00000001
>>>>>>>> VirtuosoSink.reg
```

These are the registry entries used by the Sink service. ConnectionCount is the number of connections to Virtuoso to be pooled.

Installation

Use these commands to install the Virtuoso Sink:

VirtuosoSink /RegServer Registers the COM Object VirtuosoSink.SMTP into the registry

VirtuosoSink /Service Creates the Service in Manual start mode

cscript smtpreg.vbs /add 1 OnArrival Virtuoso_SMTP_Sink VirtuosoSink.SMTP "mail from=*" - Registers the COM Object as a mail sink with the IIS SMTP service.

See Also:

The MSDN page for more information about registering sinks.

Sink Operation

When the service starts it opens a pool of connections to Virtuoso and waits for a COM event. When the COM callback gets called, the service invokes a stored procedure and passes the message text to it. The procedure then stores the message into the database. In event of lost connection to the database, the service would try once to re-establish it and re-execute the stored procedure call. Errors and successful message routings are entered into the Windows 2000 Application Log.

19.4. NNTP Newsgroups

19.4.1. NNTP Client

nntp_get_dedup

For detailed description and example use of the function, see nntp_get in the Functions Reference Guide.

19.4.2. Commands and Examples

If the requested messages don't exist, `nttp_get()` returns NULL.

Get a list of all groups from the server 'news.openlinksw.com', port 119:

Example 19.6. nntp_get()

```
nntp_get ('news.openlinksw.com:119', 'list');
```

This call returns an array of the form Array ((<group 1> varchar, <last message> integer, <first message> integer, <posting allowed> varchar) (<group 2> . . . .) . . .)

ARTICLE, HEAD, BODY, STAT To get the bodies of all messages in the group 'openlink.public.virtuoso':

```
nntp_get ('news.openlinksw.com:119', 'body', 'openlink.public.virtuoso');
```

This call returns an array of the form Array ((<message number> integer, <body of message> blob) . . .)

To get the article (head + body) of messages numbered from 5 to 10 in the group 'openlink.public.virtuoso':

```
nntp_get ('news.openlinksw.com:119', 'article', 'openlink.public.virtuoso', 5, 10);
```

This call returns an array of the form Array ((<message number> integer, <body of message> blob) . . .)

To get the headers of messages numbered from 7 to the end of the 'openlink.public.virtuoso' group:

```
nntp_get ('news.openlinksw.com:119', 'head', 'openlink.public.virtuoso', 7);
```

To get the status of all messages in the group 'openlink.public.virtuoso':

```
nntp_get ('news.openlinksw.com:119', 'stat', 'openlink.public.virtuoso',);
```

This call returns an array of the form Array ((<message number> integer, <message ID> varchar) . . .)

To get the status of the 'openlink.public.virtuoso' group:

```
nntp_get ('news.openlinksw.com:119', 'group', 'openlink.public.virtuoso');
```

This call returns an array of the form Array (<number of messages> integer, <first message> integer, <last message> integer)

19.5. NNTP Server

19.5.1. Enabling the NNTP Server

The Virtuoso News Server listening port is configured in the HTTP section of the virtuoso.ini file.

```
[HTTPServer]
NewsServerPort   = 119
```

If the port is not defined Virtuoso will disable the News Server subsystem.

19.5.2. NNTP Server Commands

The server supports the following commands:

article [MessageID|Number]
body [Number]
group newsgroup
head [Number]
help
last
list
mode reader
newgroups yymmdd hhmmss
next
post
xover [range]
stat [MessageID|Number]

See Also:

News System Tables

19.5.3. Add Groups to NNTP Server

To add a new newsgroup you must insert a row into the table DB.DBA.NEWS_GROUPS. Below is an example of an insert statement that you could use to do this:

```
insert into DB.DBA.NEWS_GROUPS (NG_NAME, NG_DESC, NG_UP_INT, NG_CLEAR_INT,
        NG_POST, NG_UP_TIME, NG_OUT_GROUP, NG_NUM, NG_FIRST, NG_LAST,
        NG_SERVER, NG_SERV_PORT, NG_CREAT, NG_UP_MESS, NG_PASS)
values ('openlink.public.virtuoso', 'virtuoso news group' ,
```

```
update interval, clear interval, 1, now(), 'openlink.public.virtuoso',
0, 0, 0, 'news.openlinksw.com', 110, now(), 0, 0);
```

If the group you want to add is local, change

```
news.openlinksw.com
```

to

```
localhost
```

, change the port to 0, and the

```
external name
```

to

```
''
```

(that is, two single quotes).

See also the Newsgroups Administration section of the Visual Server Administration Interface.

19.6. MIME & Internet Messages

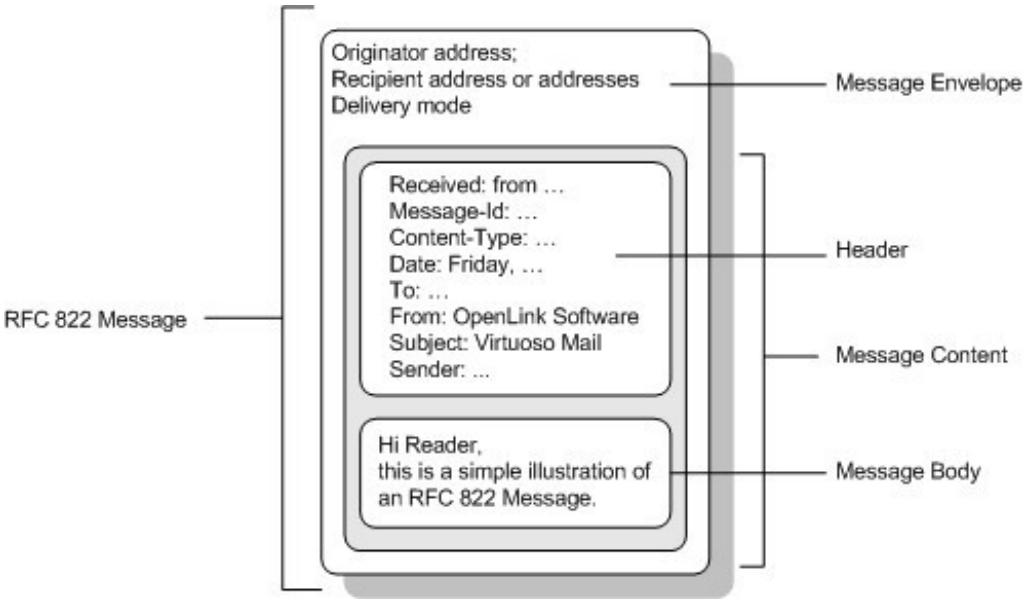
19.6.1. About Simple Internet (RFC 822) Messages

RFC 822 messages have two major parts:

- **Message envelope.** The message envelope contains all the information needed to accomplish transmission and delivery of the message. This information includes the e-mail address of the message's creator fi also known as the originator. This string matches the information in the Sender: header, if this header is present. The envelope is created by a user agent (such as MS Outlook) and is meaningful only to the message transfer agents (MTAs) that move the message on the path to its destination.
- **Message contents.** The contents make up the object to be delivered to the recipient. Message contents consist of lines of ASCII text. This text is arranged in the classic "memo" format, in which the message contains one or more introductory headers and a body.

This structure can be seen in the following illustration:

Figure 19.2. The structure of an Internet mail



Example 19.7. Simple Internet Mail Message

As you can see in the following sample of a message's contents, the format described in RFC 822 produces messages readable with little difficulty by humans.

The first few lines, from the first instance of "Received" to "Precedence", are headers. These lines define the recipients, the sender, the date, and other information involved with message transmission.

Following the headers is a blank line. This is marked by the consecutive occurrence of the four characters: CR, LF, CR, LF. After this blank line starts the body of the message. In the following example, only the final few lines make up the message body.

```

19.6.2. MIME Messages - Extension to Simple Internet Messages

MIME (Multipurpose Internet Mail Extensions) grew out of a need to encapsulate messages within messages. It includes multipart messages comprising a variety of file types such as images, audio, and video. MIME does all this while following all the standard SMTP and RFC 822 mail rules. MIME messages can be constructed to transport mail over any mail transport system that is compliant with SMTP. MIME is able to transmit objects with varying ranges of complexity in a way that allows any MIME-compliant user agent (UA) to faithfully process them and hand them off to an appropriate application. The multiple parts are arranged so that the parts requiring the least sophisticated UA are at the beginning of the message. In fact, most MIME UAs include courtesy text when constructing messages to give users of non-MIME UAs an indication of the message content. This courtesy text is inserted ahead of any MIME parts.

MIME is consistent with Internet mail protocols using headers and bodies. It allows for transmission of 7-bit printable US-ASCII characters and maximum 1000-character lines in message bodies over all Internet mail transports. It has become the most widely used extension to the simple e-mail standard. It is also used as a transport mechanism in Web pages.

Each content body part is made up of header fields and content. The headers convey specific information about the content for the message recipient. The content can be essentially any serialized stream of bytes, such as binary data or HTML. When necessary, the content is encoded so that the entire body complies with RFC 822. If the content is encoded, MIME defines the header Content-Transfer-Encoding to specify the mechanism. Other details are sometimes included, such as the Content-Disposition, which indicates to the recipient whether the content is to be treated simply as an attachment, or whether it is to be rendered inline with other content in other body parts.

Example 19.8. A simple MIME message sample

Mime message including a picture stored as a file GIF format. Because .gif files use 8-bit bytes, and the RFC 822 format requires messages to contain only US-ASCII text, the picture data must be encoded. For the recipient to correctly decode and display the picture, it needs information about which encoding mechanism was used. The following example shows part of a MIME header that identifies that the content is a .gif file, that it is encoded using the standard base64 algorithm, and that it is to be treated by the e-mail client as an attachment.

```
Content-Type: image/gif;
     name="picture.gif"
Content-Transfer-Encoding: base64
Content-Disposition: attachment;
     filename="picture.gif"
```

```
[encoded content here]
...
```

MIME accomplishes this simplifying and rebuilding of complex files by encoding a file and transporting it as a message body, or a series of messages with component parts of the file. A MIME-compliant user agent (UA) on the receiving end can decode the message, presenting it to the reader or providing it to another application as a file. A UA that is not MIME-compliant will be able to process a MIME-encoded mail message, but may not be able to decode the message.

MIME defines a message format that allows for:

- Textual message bodies in character sets other than US-ASCII.
- Non-textual message bodies.
- Multipart message bodies.
- Textual header information in character sets other than US-ASCII.

Example 19.9. Sample MIME Message

MIME uses headers and separators to tell a UA what processing is required to re-create the message. An example with no encoded body parts is:

```
From: OpenLink Support <techsupp@openlinksw.co.uk>
MIME-Version: 1.0
Content-Type: multipart/mixed;
        boundary="XXXXboundary text"

This is a multipart message in MIME format.

--XXXXboundary text
Content-Type: text/plain

here is the body text

--XXXXboundary text
Content-Type: text/plain;
Content-Disposition: attachment;
        filename="test.txt"

this is the attachment text

--XXXXboundary text--
```

This example shows the use of a MIME message to send a text message and an attached text file. Both are body parts of this message.

The "MIME-Version:" header tells the receiving UA to treat this as a MIME message.

The "Content-Type:" header specifies "multipart/mixed". This tells the receiving UA that this message has parts separated by the string argument defined in "boundary=". A MIME-compliant UA will only display or otherwise process content following the specified "boundary=" text strings. The actual boundaries are constructed using the "boundary=" string, prepended by "--". The final body part is followed by the "boundary=" string with the "--" both prepended and appended.

In the preceding example, the courtesy message "This is a multipart message in MIME format." will not be displayed or otherwise processed by the MIME UA since it does not follow a "boundary=" string. A UA that does not support MIME will display it, and at least this part of the message will be readable no matter what features the reader supports. If our example had encoded parts, they would make no sense to the human reader using a non-MIME-compliant UA, but at least the courtesy message would give the user a hint as to why.

There are two message body parts in our example. Each body part has headers of its own, in addition to the overall message headers. Each body-part begins with the boundary string. If there were no headers in the body parts, then the blank line that must follow headers in RFC 822 messages would follow the boundary string. The first body part is a plain text message. It is the message the sender might have typed into a UA. Its single "Content-Type:" header identifies it as "text/plain", meaning US-ASCII characters are used exclusively and any UA should be able to display this body part. Text/plain is the default content type.

The second body part in this example contains the file attachment. Since the file attachment is an ASCII text file, it is sent with no encoding and its content-type is given as text/plain. The "Content-Disposition: attachment" header has an attribute, "filename=", which specifies a suggested name for the file. This header specifies that this body part is to be treated as a file rather than being displayed to the user and is to be saved on local storage under the suggested file name.

MIME Headers

MIME headers appear at the beginning of a MIME message as well as within the separate body parts. Some MIME headers can be used both as message headers and in MIME body parts. Some additional headers are defined for use only in body parts.

The following headers are defined in MIME:

- **MIME-Version.** Required header indicating that this message is to use the rules of MIME. "MIME-Version: 1.0" is the only currently defined MIME-Version header allowed. The MIME-Version header is a top-level header only and does not appear in body parts unless the body part is an encapsulated, fully formed message of content-type message/rfc822, which might have its own MIME-Version header.
- **Content-Type.** Content-Type headers are used to specify the media type and subtype of data in the body of a message and to fully specify the native representation of such data. This header embodies much of the power of MIME. The IETF can add new official content types. Additionally, private content-type values can be defined by anyone. Such private content types have values of "x-something" or "X-something", where "something" can take on any value.
- **Content-Transfer-Encoding.** Content-Transfer-Encoding headers can have two different meanings. If the value is "base64" or "quoted-printable", then the header indicates the encoding used for this body part. If the value is "7bit", "8bit", or "binary", then the header indicates that there is no encoding and that this value indicates only the type of content this body part contains. The default is "7bit". It should be noted that "8bit" and "binary" are not guaranteed to be properly handled by all Internet (SMTP) MTAs valid in Internet mail. Eight bit content is not valid in Internet mail headers. Provision is made for private Content-Transfer-Encoding headers. These have values that begin with "x-" or "X-". These are for specialized cases where the users have the tools to decode or otherwise process a specific "x-" encoding.
- **Content-ID.** Content-ID headers are world-unique values that identify body parts, individually or as groups. They are necessary at times to distinguish body parts and allow cross-referencing between body parts.
- **Content-Description.** Content-Description headers are optional and are often used to add descriptive text to non-textual body parts.
- **Content-Disposition.** Content-Disposition headers provide information about how to present a message or a body part. When a body part is to be treated as an attached file, the Content-Disposition header will include a file name attribute.

There are additional headers that are applied in specialized situations, such as Content-Base and Content-Location. All of the "Content-xxx" headers have defined sub-headers, fields, and/or attributes. Headers that begin with "Content-" are the only headers that have defined meaning in body parts. All other body part headers can be ignored and might actually be removed by message transfer agents (MTAs).

MIME_TREE - MIME parser

mime_tree_dedup

For detailed description and example use of the function, see mime_tree in the Functions Reference Guide.

Processing HTTP PUT of type "multipart/form-data"

When the Virtuoso server receives a PUT request of type "multipart/form-data" from the client agent, then it passes the HTTP text to the MIME_TREE function internally and adds any MIME subpart as an element pair ("name", "value") of the "params" parameter of the vsp page being specified in the URI. It also adds an additional "params" pair for each HTTP request MIME part named "attr-name" and whose value is an array of all MIME header fields of that part.

Example 19.10. Example:

Consider the following HTTP request:

```
PUT handler.vsp
Content-Type: "multipart/form-data"; boundary="--end_part"
```

```
----end_part
Content-Type: image/gif
Content-Disposition: form-data; name=upload_control; filename="some image.gif"

GIF...
----end_part
Content-Type: text/plain
Content-Disposition: form-data; name=textarea

The description
----end_part--
```

Virtuoso parses that and produces the following params content when calling handler.vsp:

```
( "upload_control", "GIF....",
  "attr-upload_control", ( "Content-Type", "image/gif",
                "Content-Disposition", "form-data", "name",
                "upload_control", "filename", "some image.gif"),
  "textarea", "The description",
  "attr-textarea", ("Content-Type", "text/plain",
                "Content-Disposition", "form-data", "name",
                "textarea")
)
```

This allows for vsp's to handle uniformly "x-www-form/url-encoded" and "multipart/form-data" PUTS and to have full access to the MIME headers if needed.

19.6.3. S/MIME Support

S/MIME is a specification for secure electronic mail. S/MIME stands for Secure/Multipurpose Internet Mail Extensions and was designed to add security to e-mail messages in MIME format. The security services offered are authentication (using digital signatures) and privacy (using encryption).

The S/MIME specification consists of two documents: S/MIME Message Specification (RFC 2311) and S/MIME Certificate Handling (RFC 2312) . Both of these are Internet Drafts. The S/MIME community has submitted these to the IETF. The goal is to form a working group and produce an Internet standard.

All certificates and private keys are read and stored as PEM encoded strings. If the server is compiled without SSL support then dummy versions of smime_sign, smime_verify, pem_certificates_to_array and get_certificate_info are available so that existing SQL code would not be broken. Currently the Virtuoso server supports S/MIME signing and S/MIME signature verification. These are done through the following 2 functions:

`smime_verify()`

`smime_sign()`

A useful utility function for S/MIME support is:

`pem_certificates_to_array()`

19.7. FTP Services

Virtuoso provides both FTP client and server functionality. The Virtuoso FTP client functions allow for programmatic access to ftp servers from Virtuoso/ PL to list, submit and retrieve files from an FTP server. The Virtuoso FTP server provides FTP access to the Virtuoso WebDAV repository using the same authentication and permissions system as WebDAV, and an configurable anonymous user access.

19.7.1. FTP Client

Virtuoso provides three functions that mimic their FTP command counterparts. These are:

`ftp_get()` - to retrieve a file from an FTP server.

`ftp_put()` - to submit a file to an FTP server.

`ftp_ls()` - list the contents of a directory on an FTP server.

The Virtuoso client uses free ports within the range 20000 - 30000 for active mode connections. This is configurable using the parameters: `FTPServerMinFreePort` and `FTPServerMaxFreePort` in the `HTTPServer` section of the Virtuoso INI file.

19.7.2. FTP Server

Virtuoso can provide FTP access to its WebDAV repository. This FTP server functionality relies on the same credentials and permissions that WebDAV uses. The server is enabled by listing the `FTPServerPort` parameter in the `HTTPServer` section of the Virtuoso INI file. This parameter must be accompanied by a port number to listen at.

```
[HTTPServer]
FTPServerPort = 21
```

Will instruct Virtuoso to listen for FTP requests on the default FTP port of 21.

```
[HTTPServer]
...
FTPServerTimeout = 600
...
```

To control timeout of connections use "FTPServerTimeout" ini parameter. The default time out is 600 sec. This is only for command connection.

The Virtuoso FTP server can be instructed to create a session log file using the parameter:

```
[HTTPServer]
...
FTPServerLogFile = ftpserver
...
```

If specified Virtuoso will produce an FTP server log file with the date appended to the name given in the parameter and the files extension as ".log". The log file is rotated daily. It will contain the following information:

`ftpserverDDMMYYYY.log`:-

Client Host Name

Authorized User

Time

User Command

Server Response Code

Bytes Transferred

An example of which is:

```
hostname anonymous [22/Oct/2003:15:21:43 +0300] "PASS user@domain.com" 230 0
hostname anonymous [22/Oct/2003:15:23:11 +0300] "LIST" 226 162
hostname dav [22/Oct/2003:15:25:00 +0300] "PASS <hidden>" 230 0
```

Virtuoso can allow special "anonymous" user access to the FTP Server by supplying the following Virtuoso INI file parameter:

```
[HTTPServer]
...
FTPServerAnonymousLogin = 0
...
```

The anonymous user is not a real user, it has no SQL or DAV login ability. The anonymous user can only access collections or resources that are set to public. The password of the anonymous user is trivially checked to contain the "@" symbol and is shown in plain-text for the "PASS" command detailed in the log file. Valid DAV users passwords are never revealed in the FTP log file. By default anonymous login is denied.

```
[HTTPServer]
...
FTPServerAnonymousHome = /DAV/dir_name/
...
```

You can control the anonymous user home dir by "FTPServerAnonymousHome" parameter in the ini fail. By default home dir for anonymous user is DAV root dir.

The Virtuoso server supports the usual variety of commands such as:

```
USER    PASS    CWD     CDUP    HELP
QUIT    PORT    PASV    TYPE    NOOP
STOR    RNFR    RNTO    MODE    RETR
DELE    RMD     MKD     PWD     SYST
SIZE    LIST    NLST    ABOR
```

By default the server uses free ports within the range 20000 - 30000 for passive mode connections. This is configurable using the parameters: `FTPServerMinFreePort` and `FTPServerMaxFreePort` in the `HTTPServer` section of the Virtuoso INI file.

The FTP server root directory is the home directory of the authenticated DAV user.

19.8. VSP Guide

19.8.1. Introduction

Virtuoso Server Pages are the equivalent of a stored procedure in a Web page that is compiled when it is first read by the Virtuoso server. Virtuoso detects when the '.vsp' file is modified and recompiles the procedure. Since VSP is essentially Virtuoso PL in a Web page you can do anything that PL can, either directly or from interaction with the user. VSP gives you the advantage of not having to worry about making connections to the database. You also avoid the overhead of RPCs because the HTTP server is built into Virtuoso. When you write a VSP page the connection is automatic since you are already in Virtuoso.

VSP is server script and is therefore executed in the server as it is encountered on the page. For this reason client (JavaScript) and server script cannot directly interact but can supplement each other. You can call JavaScript inside a VSP loop, for example, to manipulate something that already exists on the page but you cannot pass variables by reference from VSP directly to JavaScript or vice versa.

Page flow control can be managed using FORMs. The state of the page is defined in form fields such as INPUT boxes and TEXTAREA boxes and then passed to the next form or page using POST.

19.8.2. Simple HTML FORM usage

We start with a small example that shows the source of a page including a FORM with data from the user being sent when a submit button is pressed. We then examine the elements and attributes of this simple form that are important to us at this stage.

Basic Forms

Example 19.11. Simple Forms

```
<HTML>
  <HEAD>
    <TITLE>Simple FORM demo</TITLE>
  </HEAD>
  <BODY>
  <FORM METHOD="POST" ACTION="formdemo_receiver.vsp">
    <P>Test form, type some info and click Submit</P>
    <INPUT TYPE="TEXT" NAME="myInput" />
    <INPUT TYPE="SUBMIT" NAME="submit" VALUE="Submit" />
  </FORM>
```

```
  </BODY>
</HTML>
```

The METHOD attribute of a FORM TAG in a VSP page can be either GET or POST. The GET method allows the form submission to be contained completely in a URL; this can be advantageous because it permits bookmarking in browsers, but it also prevents form data from containing non ASCII characters such as accented letters and special symbols and restricts the amount of form data that can be handled. The GET method is l mited by the maximum length of the URL that the server and browser can process. To be safe, any form whose input might contain non-ASCII characters or more than 100 characters should use METHOD="POST".

With the POST method, the form input is submitted as an HTTP POST request with the form data sent in the body of the request. Most current browsers are unable to bookmark POST requests, but POST does not entail the character encoding and length restrictions imposed by GET.

The ACTION attribute of FORM specifies the URI of the form handler. This will usually be another web page that performs some action based on the data that is sent from the originating form. The URI could point to the same page as the data originated and for pages that perform a well-defined small set of functions it usually does. When a page needs to manage multiple states there needs to be some flow control that can determine how the page was reached; for example, to differentiate whether it arrived at as a result of someone clicking on the submit button or it is the first time the page has been visited.

Exchanging Values in Forms

Now we add some VSP to check the values of the parameters in the form. VSP markup is typically contained in <?vsp ... ?> blocks.

Example 19.12. Forms and Values

```
<HTML>
  <HEAD>
    <TITLE>Simple FORM demo</TITLE>
  </HEAD>
  <BODY>
  <P>Last value sent:

  <?vsp
    http(get_keyword('myInput', params, 'no value'));
   ?>

</P>

  <FORM METHOD="POST" ACTION="formdemo.vsp">
    <P>Test form, type some info and click Submit</P>
    <INPUT TYPE="TEXT" NAME="myInput" />
    <INPUT TYPE="SUBMIT" NAME="submit" VALUE="Submit" />
  </FORM>
  </BODY>
</HTML>
```

This is the same example as above but now it uses the same page for the form handler and displays the parameters each time. Clicking the Submit button takes you to the same page and displays whatever you typed in the field last time.

The VSP block uses two nested functions. The `http()` function allows you to send data to the HTTP client, the browser. What we send to the browser is the result of the `get_keyword()` function, which has three parameters: *`search_for`*, *`source_array`*, and *`default_val`*. It searches for the keyword-value pair (keyword=value) where the keyword matches the *`search_for`* parameter (in this case 'myInput') in the array passed in the *`source_array`* parameter. It returns the value if one is found; otherwise returns the *`default_val`* parameter in the function, in this case 'no value'. The *`params`* argument is a special array that contains all page parameters from the previous FORM state.

Conditional Processing

Now we extend this further to add some conditional control so that if a value was entered we can respond directly to it. We will also use a variable this time, which must be declared first.

Example 19.13. Conditional Processing Using IF

```
<HTML>
  <HEAD>
    <TITLE>Simple FORM demo</TITLE>
  </HEAD>
  <BODY>

  <?vsp
        declare _myInput varchar;

        _myInput := get_keyword('myInput', params, '');

    if (_myInput <> '')
        {       http('<P>Hello, ');
                http(_myInput);
                http('</P>');
        }
        else
        {       http('<P>Please enter your name</P>');
        }
   ?>

  <FORM METHOD="POST" ACTION="formdemo.vsp">
    <INPUT TYPE="TEXT" NAME="myInput" VALUE="" />
    <INPUT TYPE="SUBMIT" NAME="submit" VALUE="Submit" />
  </FORM>
  </BODY>
</HTML>
```

Further Page Control

We now extend this to control the whole content of the page. In this example we see that VSP and HTML can be interleaved.

Example 19.14. Page Control

```
<HTML>
  <HEAD>
    <TITLE>Simple FORM demo</TITLE>
  </HEAD>
  <BODY>

  <?vsp
        declare _myInput varchar;
        declare Mode varchar;

        _myInput := get_keyword('myInput', params, '');
        Mode := get_keyword('submit', params, '');

    if (Mode = 'Submit')
        {
   ?>
    <P>Hello, <?vsp http(_myInput); ?>
        </P>

<FORM METHOD="POST" ACTION="demo4.vsp">
<INPUT TYPE="HIDDEN" NAME="myInput" VALUE="" />
<INPUT TYPE="SUBMIT" NAME="submit" VALUE="Again" />
</FORM>

  <?vsp
        }
          else
        {
```

```
    ?>

  <P>Please enter you name</P>
  <FORM METHOD="POST" ACTION="demo4.vsp">
    <INPUT TYPE="TEXT" NAME="myInput" />
    <INPUT TYPE="SUBMIT" NAME="submit" VALUE="Submit" />
  </FORM>

  <?vsp
    }
  ?>
  </BODY>
</HTML>
```

We start by setting the mode based on whether the Submit button has been pressed. When the mode has changed a different version of the page is sent to the browser. In the new version, the Again button the appears, to return you to the previous state when pressed.

Communicating Parameters Between Pages

Now we will use two pages to do the same job as in the demo above.

Example 19.15. Using more than one page

Page 1

```
<HTML>
  <HEAD>
    <TITLE>Multi Page Demo</TITLE>
  </HEAD>
  <BODY>
  <P>Please enter you name</P>
  <FORM METHOD="POST" ACTION="demo5_2.vsp">
    <INPUT TYPE="TEXT" NAME="myInput" />
    <INPUT TYPE="SUBMIT" NAME="submit" VALUE="Submit" />
  </FORM>
  </BODY>
</HTML>
```

Page 2

```
<HTML>
  <HEAD>
    <TITLE>Multi Page Demo</TITLE>
  </HEAD>
  <BODY>
  <P>The value you entered was:
  <?vsp
    http(get_keyword('submit', params, 'no data'));
  ?>
  </P>
  <FORM METHOD="POST" ACTION="demo5_1.vsp">
    <INPUT TYPE="SUBMIT" NAME="submit" VALUE="Back" />
  </FORM>
  </BODY>
</HTML>
```

Using JavaScript to Control Forms

JavaScript is a programming language that can be used in the browser and is useful for client-side programming. It is useful to be able to do some work on the client machine before making another round trip to the server for more processing. JavaScript is also useful for making things more appealing to the Web page viewer.

JavaScript can be made to respond to events within the browser such as when the mouse is moved over a link, a graphic or a button or when the mouse is clicked on some part of the page. This can be achieved by using event handlers within the HTML

tags and placing JavaScript code in their content. Common event handlers are *onMouseOver* , *onMouseClick* , *onMouseOut* , *onChange* , and the like.

A simple but useful example of this would be to simplify one of the previous examples by placing a handler on the text box so that you do not have to press the submit button to send the form to the server:

```
<FORM METHOD="POST" ACTION="demo5_2.vsp" NAME="demo5_2">
  <INPUT TYPE="TEXT" NAME="myInput" onChange="document.demo5_2.submit()" />
  <INPUT TYPE="SUBMIT" NAME="submit" VALUE="Submit" />
</FORM>
```

19.8.3. Interacting with the Database

This section describes manipulating data within Virtuoso from VSP. Unless the required tables already exist, new ones will need to be created. This example will involve a simple table of people and a series of pages for adding, editing, viewing, and deleting its entries.

Creating a Table

Tables should be created so that their entries can be uniquely identified. This is very important so that if we need to edit or delete one particular entry we can distinguish it from other entries. A *primary key* is how a database enforces unique rows, by refusing to allow duplicate data to be inserted. It is up to the user to choose a column in the table to act as a primary key. Sometimes one or more of the columns of data are naturally unique either singularly or in composite; other times it is necessary to add a column to contain unique codes for each row.

See Also:

Primary Keys

Here is the definition of the simple table that will be used:

```
CREATE TABLE DB.DBA.DEMO_PEOPLE (
  EMAIL VARCHAR(255) PRIMARY KEY,
  FORENAME VARCHAR(100),
  SURNAME VARCHAR(100)
);
```

The email address has been selected as a primary key.

Basic Form Input Page

After the table has been created; for example via Virtuoso's iSQL utility; it will need some data. For this we create a "New Person" page. This page uses form inputs and some VSP code to determine whether an insert button was pressed. If the insert button is pressed then the page takes submitted values from the POST and uses them to construct an SQL statement that inserts a new row into the table. This is demonstrated below:

```
<HTML>
  <HEAD>
    <TITLE>New Person Page</TITLE>
  </HEAD>
  <BODY>
  <?vsp

    declare _email, _forename, _surname varchar;

    _email := get_keyword('email', params, '');
    _forename := get_keyword('forename', params, '');
    _surname := get_keyword('surname', params, '');

    -- insert new person if we came from the insert button
    if ('' <> get_keyword('ins_button', params, ''))
    {
      INSERT INTO DB.DBA.DEMO_PEOPLE(EMAIL, FORENAME, SURNAME)
        VALUES(_email, _forename, _surname);
    }
  ?>
  <P>Please enter the details of new person:</P>
```

```
  <FORM METHOD="POST" ACTION="demo_people_add.vsp">
  <TABLE>
    <TR><TH>Email:</TH><TD><INPUT TYPE="TEXT" NAME="email" /></TD></TR>
    <TR><TH>Forename:</TH><TD><INPUT TYPE="TEXT" NAME="forename" /></TD></TR>
    <TR><TH>Surname:</TH><TD><INPUT TYPE="TEXT" NAME="surname" /></TD></TR>
  </TABLE>

  <INPUT TYPE="SUBMIT" NAME="ins_button" VALUE="Insert" />
  </FORM>

  </BODY>
</HTML>
```

The underscores were added to this example to keep the param variables and page variables visibly distinguishable.

Displaying Table Data in a VSP Page

Now that some data exists in the table we need a way to display it. The FOR ... DO construct is used to construct the insides of an HTML table:

```
<HTML>
  <HEAD>
    <TITLE>The People Page</TITLE>
  </HEAD>
  <BODY>
  <P>The Peoples' Details</P>

  <TABLE>
    <TR><TH>Email</TH><TH>Forename</TH><TH>Surname</TH></TR>
  <?vsp
    FOR (SELECT EMAIL, FORENAME, SURNAME FROM DB.DBA.DEMO_PEOPLE) DO
    {
  ?>
    <TR><TD><?=EMAIL?></TD><TD><?=FORENAME?></TD><TD><?=SURNAME?></TD></TR>
  <?vsp
    }
  ?>
  </TABLE>
  </BODY>
</HTML>
```

Simple Form Delete Page

The page above can easily be extended to allow deletion. For each row an 'action' link is added. The action Remove link hardwires a form GET on the URL. This is then intercepted by the IF condition looking for the *remove* parameter.

```
<HTML>
  <HEAD>
    <TITLE>The People Page With Deletion</TITLE>
  </HEAD>
  <BODY>
  <?vsp
    declare deleteme varchar;

    deleteme := get_keyword('remove', params, '');
    if ('' <> deleteme)
      DELETE FROM DB.DBA.DEMO_PEOPLE WHERE EMAIL = deleteme;
  ?>

  <FORM METHOD="POST" ACTION="demo_people_view2.vsp">
  <P>The Peoples' Details</P>

  <TABLE>
    <TR><TH>Email</TH><TH>Forename</TH><TH>Surname</TH>
      <TH>Action</TH></TR>
  <?vsp
    FOR (SELECT EMAIL, FORENAME, SURNAME FROM DB.DBA.DEMO_PEOPLE) DO
    {
  ?>
    <TR><TD><?=EMAIL?></TD><TD><?=FORENAME?></TD><TD><?=SURNAME?></TD>
      <TD><A HREF="?remove=<?=EMAIL?>">Remove</A></TD></TR>
```

```
  <?vsp
    }
  ?>
  </TABLE>
  </FORM>
  </BODY>
</HTML>
```

Simple Form Edit Page

The last step is to have a way to edit rows of the table. To do this, we combine everything that we have so far and use the SQL UPDATE statement to update the row. The EMAIL column is not made updateable since this is the primary key.

```
<HTML>
  <HEAD>
    <TITLE>The People Page With Deletion</TITLE>
  </HEAD>
  <BODY>
  <FORM METHOD="POST" ACTION="demo_people_view3.vsp">
  <?vsp
    declare deleteme, editme, edt_email, edt_forename, edt_surname,
            save_email, save_forename, save_surname varchar;

    deleteme := get_keyword('remove', params, '');
    if ('' <> deleteme)
      DELETE FROM DB.DBA.DEMO_PEOPLE WHERE EMAIL = deleteme;

    if ('' <> get_keyword('save_button', params, ''))
    {
      save_email := get_keyword('email', params, '');
      save_forename := get_keyword('forename', params, '');
      save_surname := get_keyword('surname', params, '');

      update DB.DBA.DEMO_PEOPLE
        SET FORENAME = save_forename, SURNAME=save_surname
        WHERE EMAIL = save_email ;
    }

    editme := get_keyword('edit', params, '');
    if ('' <> editme)
    {
      SELECT EMAIL, FORENAME, SURNAME
        INTO edt_email, edt_forename, edt_surname
        FROM DB.DBA.DEMO_PEOPLE WHERE EMAIL = editme;
  ?>
  <TABLE>
    <TR><TH>Email:</TH><TD><INPUT DISABLED TYPE="TEXT" NAME="email" VALUE="<?=edt_email?>" /></TD></TR>
    <TR><TH>Forename:</TH><TD><INPUT TYPE="TEXT" NAME="forename" VALUE="<?=edt_forename?>" /></TD></TR>
    <TR><TH>Surname:</TH><TD><INPUT TYPE="TEXT" NAME="surname" VALUE="<?=edt_surname?>" /></TD></TR>
  </TABLE>
  <INPUT TYPE="SUBMIT" NAME="save_button" VALUE="Save" />
  <?vsp
    }
  ?>

  <P>The Peoples' Details</P>

  <TABLE>
    <TR><TH>Email</TH><TH>Forename</TH><TH>Surname</TH>
      <TH>Action</TH></TR>
  <?vsp
    FOR (SELECT EMAIL, FORENAME, SURNAME FROM DB.DBA.DEMO_PEOPLE) DO
    {
  ?>
    <TR><TD><?=EMAIL?></TD><TD><?=FORENAME?></TD><TD><?=SURNAME?></TD>
      <TD><A HREF="?remove=<?=EMAIL?>">Remove</A> <A HREF="?edit=<?=EMAIL?>">Edit</A></TD></TR>
  <?vsp
    }
  ?>
  </TABLE>
  </FORM>
  </BODY>
```

```
</HTML>
```

19.8.4. The Forums Application

The "Forums" Application is a World Wide Web Application for posting, reading and searching of messages developed under the Virtuoso VDBMS with a wide usage of Virtuoso Server Pages (VSP) and server-side XSL-T transformation.

Messages in the forums are classified to forums and sub-forums by interest. Posting is only allowed for registered users. Registration is performed via a registration form. Every registered user can create new a theme, post new messages to an existing theme or reply to an existing message. Unregistered users can only search, browse, and read existing themes and messages.

Principles

The application is based on VSPs, XML and XSLT transformations. The VSPs are used to produce XML documents that are transformed to HTML using server side XSLT. The design and appearance of the application depends solely on XSLT style sheets. This allows us to divide the development into two distinct parts: layout and design, and functionality of the application.

Session management is based on URL manipulation and persistent HTTP session variables. The messages are stored in Database as XML documents with a free-text index applied over them.

Navigation

The application consists of four main pages:

1. *home.vsp* - the main page introduces the forums with the following information:

   Forums: name of each forum with link to the relevant sub-forums.
   Total: total number of messages for this forum.
   New: new messages for this forum within the last day.
   Last: number of the last message inserted in the forum.
   Total users: count of registered users.
   Options: login if the user is already registered in the forums.
   Registration: add a new user.
   Search: search in the messages.
2. *subforums.vsp* - sub-forums of the current forum with the following information:

   Subforum: name of each sub-forum with links to relevant themes.
   Total: total number of messages for this forum.
   New: new messages for this forum within the last day.
   Last: number of the last message inserted in the forum.
   Options: login if the user is already registered in the forums.
   Registration: add a new user
   Search: search in the messages.
   Forums path: links to the home page and to the forum to which the current sub-forums belong.
3. *forum.vsp* - themes of the current sub-forum with the following information:

   Theme: name of each theme with links to its messages.
   Total: total number of messages for this theme.
   New: new messages for this theme within the last day.
   Last: number of the last message inserted in the theme.
   Options: login if the user is already registered in the forums.
   Registration: add a new user.
   Search: search in the messages.
   Forums path: links to the home page, to the forum and to the sub-forum to which the current themes belong.
4. *thread.vsp* - messages of the current theme with the following information:

Message: name of each message with a link to its properties. When the link is activated the same page is presented, but with the tree of messages for which the current message is the parent.

Author: the name of the author of the current message.

Date: posting date of the message.

Options: login if the user is already registered in the forums.

Registration: add a new user.

Search: search in the messages.

Forums path: links to the home page, to the forum and to the sub-forum to which the current message belongs. Also for the current message, the parent message's name is presented. As users move lower in the tree, they can go back using this path.

Remarks

The basic principles of the application's implementation are:

The result of a VSP execution is a well-formed XML document.

Use the Virtuoso server to do server-side XSLT transformations with appropriate style sheets whenever needed.

Use URL manipulations for session management.

Use post-processing functions to provide commonly used parameters (such as user ID) as session variables.

If users are not logged in they can access all pages of the site, but if they want to insert a new theme or create a new message, they have to log in. When users attempt to create or insert, they will be prompted with the login page. When they log in, the forums application will take them directly to the form for inserting messages or themes. If users are not logged in, the name 'anonymous' is displayed, instead of the e-mail address that would be displayed if they were logged in.

The Search Page

Users can search in three ways:

Theme title: titles of message that are titles of themes.

Message title: titles of message that have the current theme as parent.

Message body: bodies of messages that have different themes as parents.

Search results contain information about how many hits were found, and for each hit the following:

Message title: the title of the current message. When you search in message bodies, the message titles are displayed.

Time: date the message or theme was inserted.

Author: author of the message or theme.

The search page provides the interface for searching contents of forums including messages and titles.

```
<?vsp
  declare id, acount, aresults integer;
  declare aquery, awhat, askiped, search_res, sid, uid, url, usr varchar;

  -- > at this point we instruct server to do server-side XSLT transformation
        -- >    over resultant document
  -- > The transformation will be done before sending the document to the user-agent
  -- >    and after page execution is done.
        -- > To provide flexible file location we use a registry setting for XSLT
        -- >    style sheets
  http_xslt(sprintf ('file:%s/search.xsl', registry_get ('app_forums_xslt_location')));

  -- > because the application does URL poisoning for session management
  -- > we must retrieve the request parameters:

  -- > the session ID
  sid      := get_keyword('sid', params, '0');
  -- > the query text
  aquery   := get_keyword('q',params,'');
  -- > the query locator (for what we searching)
  awhat    := get_keyword('wh',params,'t');
  -- > how many records to skip
  askiped  := atoi (get_keyword('sk',params,'0'));
```

```
  -- > how many results to return
  aresults := atoi (get_keyword('rs',params,'10'));
  -- > hits count
  acount   := atoi (get_keyword('c',params,'0'));

  url := 'thread.vsp';

  -- > also we get the user ID from the session variables
  uid := connection_get ('pid');
  usr := connection_get ('usr');

  -- > now we are ready and call the stored procedure that returns the result from search
  search_res := FORI_SEARCH_RES (aquery, awhat, askiped, aresults, acount);
?>

<!-- now we produce the result as well-formed XML document -->

<?xml version="1.0"?>
<page>
<sid><?=sid?></sid>
<usr><?=usr?></usr>
<url><?=url?></url>
<nav_2><?vsp http(FORI_SEARCH_FORM (sid, aquery, awhat, askiped, aresults, acount)); ?></nav_2>
<css_1/>
<squery><?=aquery?></squery>
<swhat><?=awhat?></swhat>
<sskiped><?=askiped?></sskiped>
<sresults><?=aresults?></sresults>
<scount><?=acount?></scount>
<?vsp http (search_res); ?>
<?vsp http (FORI_SEARCH_NAVIGATION (
  sprintf('search.vsp?q=%s&wh=%s&rs=%d&c=%d&sid=%s&', aquery, awhat, aresults, acount, sid),
         acount, askiped, aresults)); ?>
</page>
```

Search Page Analysis

First we declare the variables used inside the page. In VSP, variables can be defined at any time, but it is generally good practice is to declare them near the top.

We call `http_xslt()` with a file URL parameter. This instructs the Virtuoso server to do XSLT transformation on the server side before sending output to the client, and after execution of the page. Hence we will produce an XML document.

After this we need to get the input parameters session_id, query text, how many records to skip, and how many records to display. We do this by calling `get_keyword()` and passing it the 'params' array. Every VSP page has *`params`* , *`path`* , and *`lines`* as input parameters. For each call we supply a default value in case the variable has not been used. For some of the parameters we need an integer, but varchars are always returned, so we use `atoi()` on the result to convert it to an integer.

Next we retrieve the persistent variables *`user id`* and *`user name`* . We do this by calling `connection_get()` with the session variable name.

After this preparation, we are ready to perform the searching by calling the PL stored procedure `FORI_SEARCH_RES()` . This procedure returns the XML entities that contain the results from the search.

Once we have results, we want to produce the XML document that will be used in the XSLT transformation. We do this part of the work using the shortcuts to the `http_value()` function: '<?= ?>' pairs, and also in some places '<?vsp ?>' to call the `FORI_SEARCH_FORM()` and `FORI_SEARCH_NAVIGATION()` procedures and output their results.

The main benefits to this approach are:

design independency of VSP content: if we need a different design we only need to change the XSLT style sheet;

different style sheets can represent different themes. If we pass an additional 'theme' parameter, for example, we can associate a new theme with a different style sheet. This way we have a fast approach to customizing the look of the page;

browser independence: because we do server-side XSLT transformation we do not need the browser to support XSLT or XML at all.

If we comment out the line that instructs Virtuoso to perform the XSLT transformation (`http_xslt()`) we will get the following document:

```
<?xml version="1.0"?>
<page>
<sid>0</sid>
<usr>anonymous</usr>
<url>thread.vsp</url>
<nav_2><search_form>
<hidden>
<hidden_input type="hidden" name="sid" value="0" />
<hidden_input type="hidden" name="sk" value="0" />
<hidden_input type="hidden" name="rs" value="10" />
<hidden_input type="hidden" name="c" value="0" />
</hidden>
<select name="wh">
<option value="t" selected="1">theme title</option>
<option value="mt">message title</option>
<option value="mb">message body</option>
</select>
</search_form>
</nav_2>
<css_1/>
<squery></squery>
<swhat>t</swhat>
<sskiped>0</sskiped>
<sresults>10</sresults>
<scount>0</scount>
<search_result>
<no_hits/>
</search_result>
<navigation pages="0">
</navigation>
</page>
```

If we re-enable the XSLT transformation the user agent will receive the following HTML content:

```
<html><head>
<style type="text/css">
a:hover{color:#a2a2a2}
.id{font-size:12px;font-family:arial,sans-serif;font-weight:bold;color:#004C87}
.ie{font-size:12px;font-family:verdana,sans-serif;color:#FFFFFF}
.ir{font-size:14px;font-weight:bold;font-family:verdana,sans-serif;color:#FFFFFF}
.if{font-size:12px;text-decoration:none;font-family:verdana,sans-serif;
   font-weight:bold;color:#E1F2FE}
.iname{font-size:12px;font-weight:bold;font-family:verdana,sans-serif;color:#FFFFFF}
.ipath{font-size:12px;text-decoration:none;font-weight:bold;
   font-family:verdana,sans-serif;color:#004C87}
.inew {font-size:12px;text-decoration:none;font-weight:bold;
   font-family:verdana,sans-serif;color:#FFC600}
.text {font-size:12px;text-decoration:none;font-family:Arial,sans-serif;color:#004C87}
</style>
</head>
  <body>

19.8.5. Setting up server-side Cross-Origin Resource Sharing (CORS) with Virtuoso

User agents (e.g., Web browsers) have traditionally restricted scripts within web pages by a Same Origin Policy, which allowed scripts to make requests only to resources within the same domain from which the scripts themselves originated. This restriction is meant to protect the user and their computer from "Trojan horse websites" which may appear to be safe, but which then make unsafe HTTP requests to other, invisible sites. This restriction also protects the second website from potential "Denial of Service" and other attacks, whether accidental or intentional.

This policy has the unfortunate side-effect of also preventing client-side Web applications served from one website ("Origin") from retrieving data from another website ("Origin").

Cross-Origin Resource Sharing (CORS) is a mechanism intended to enable safer client-side cross-origin requests, primarily focused on data.

How does CORS work?

Authentication and session-management information methods are extended in several ways:

- Enforcement by User Agent
  - A server providing a resource can include an

    Access-Control-Allow-Origin

    HTTP response header, with a value of the request's triggering script's site of origin (that is, the site which provided the script which made the request for the resource), to indicate whether access to the resource's contents may be allowed. The user agent validates that the value in this header matches the actual origin of the script which made the request.
  - User agents can use a "pre-flight request" to discover whether a cross-origin resource is prepared to accept requests from a given script origin, using a complex method (which we will not detail here). Again, the response is validated by the user agent.
- Enforcement by Server-side Application
  - Server-side applications can refer to the

    Origin

    HTTP request header to discover whether the user agent deemed it a cross-origin request. Here, the server-side application enforces limitations (e.g., returning nothing, partial results, or full results) on the cross-origin requests that they are willing to service at all.

CORS Setup for Virtuoso servers

With Virtuoso 6 and later (specific earliest versions as noted below), CORS support may be configured at the server-level or enabled through application logic (scripting, PL, etc.).

When working with older versions of Virtuoso, CORS support cannot be configured at the server-level, but it may be enabled within application logic (scripting, PL, etc.).

Application-level CORS Setup

Any Virtuoso PL (VSP)-based application can implement CORS checking through well-known HTTP functions `http_request_header()` and `http_header()` . This method will work with any version of Virtuoso. For instance:

```
<?vsp
    IF (http_request_header (lines, 'Origin', NULL) = 'http://host.org')
      {
          http_header ('Access-Control-Allow-Origin: http://host.org\r\n');
      }
   ELSE
      {
         RETURN;
      }
-- Additional code here ---

?>
```

Applications running in other hosted environments (Perl, Python, PHP, ASP.NET, etc.) may also use their specific scripting options to add and/or check relevent headers.

Server-level CORS Setup

Note: These instance/server-level configuration instructions require Virtuoso Open Source (VOS) 6.1.3 or later , or Virtuoso Commercial Edition 6.2.3129 or later .

1. In the Virtuoso Conductor, go to

   Web Application Server -> Virtual Directories & Directories

   .

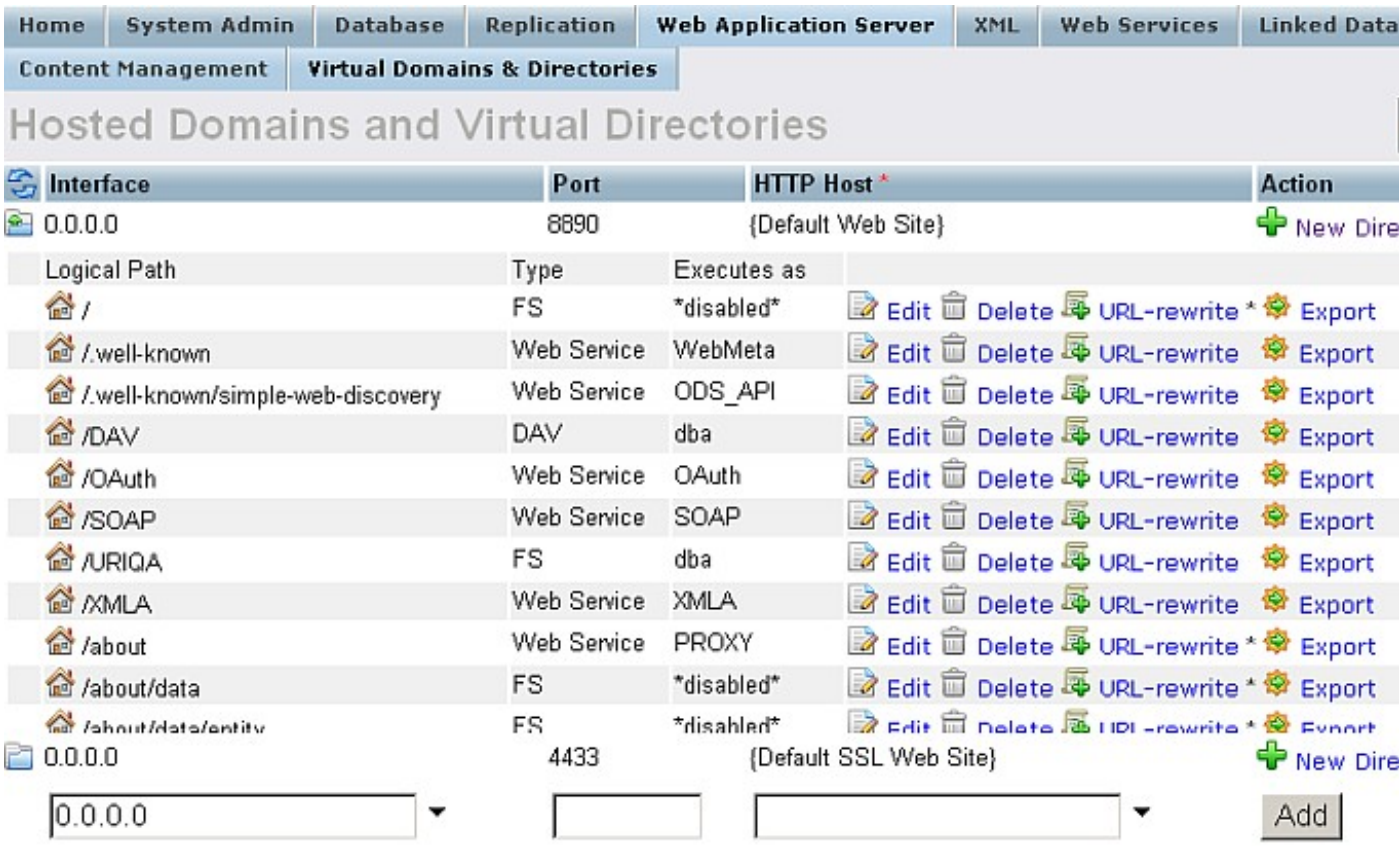
Figure 19.3. Server-side Cross-Origin Resource Sharing (CORS) Example Setup

2. Expand the

   Interface

   store.

Figure 19.4. Server-side Cross-Origin Resource Sharing (CORS) Example Setup



3. Click

   New Directory

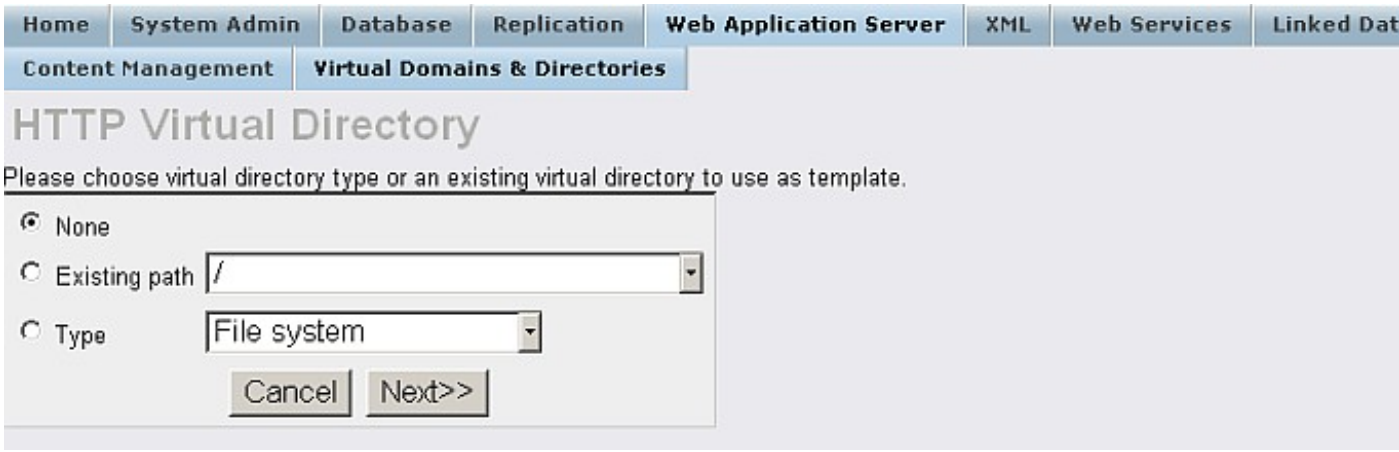
.

4. Specify the desired

   Virtual Directory Type

   , or choose an existing virtual directory to use as a template.

   Figure 19.5. Server-side Cross-Origin Resource Sharing (CORS) Example Setup



5. Click

   Next

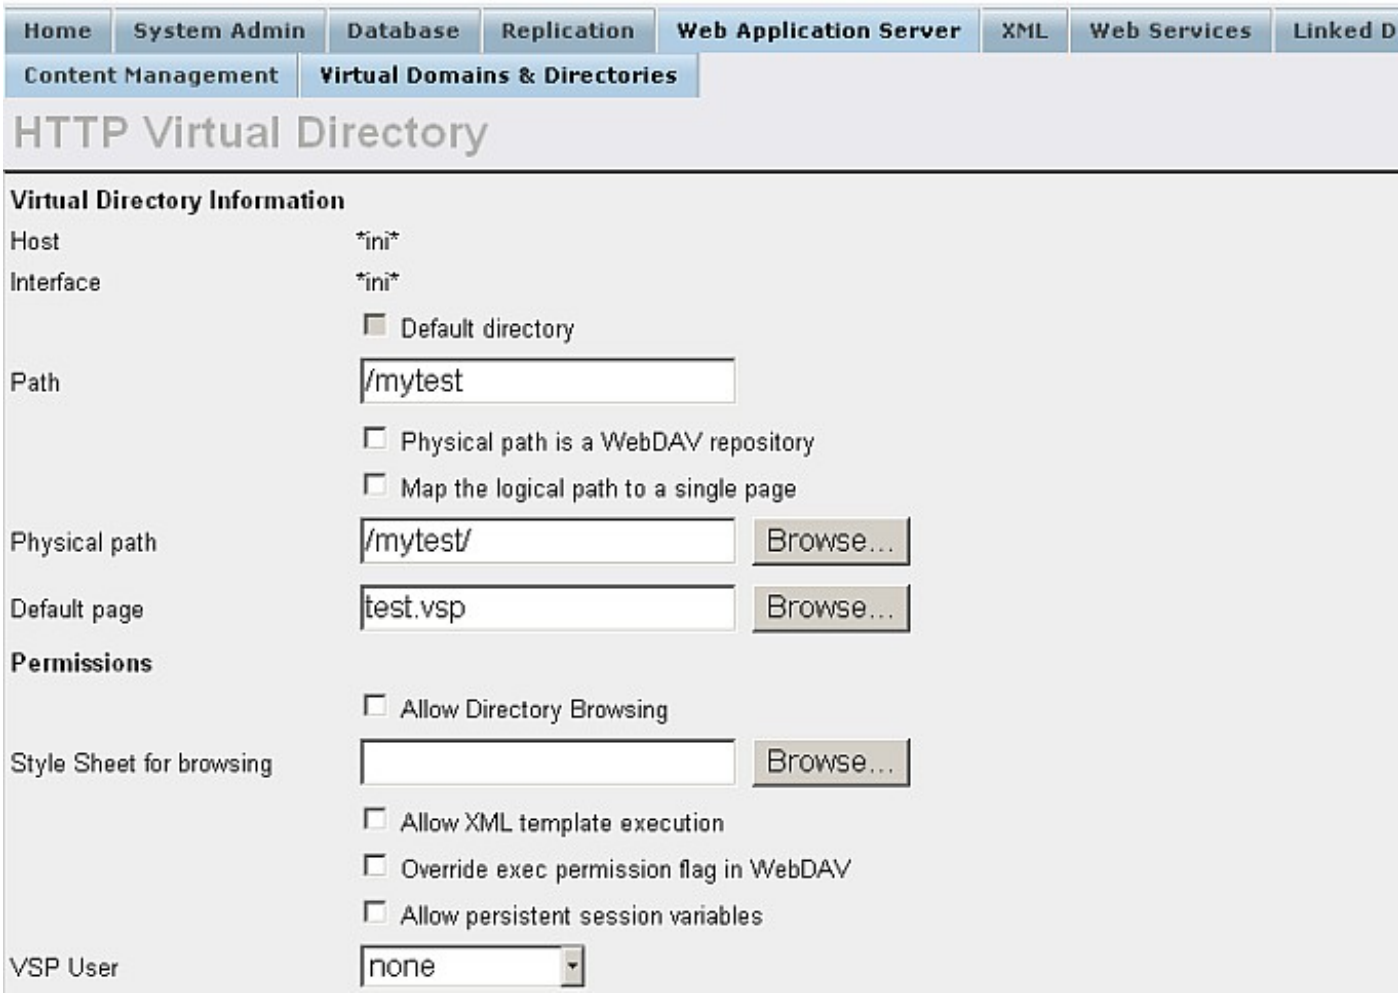
   .

6. Specify the

   Directory Path

   value.

   Figure 19.6. Server-side Cross-Origin Resource Sharing (CORS) Example Setup

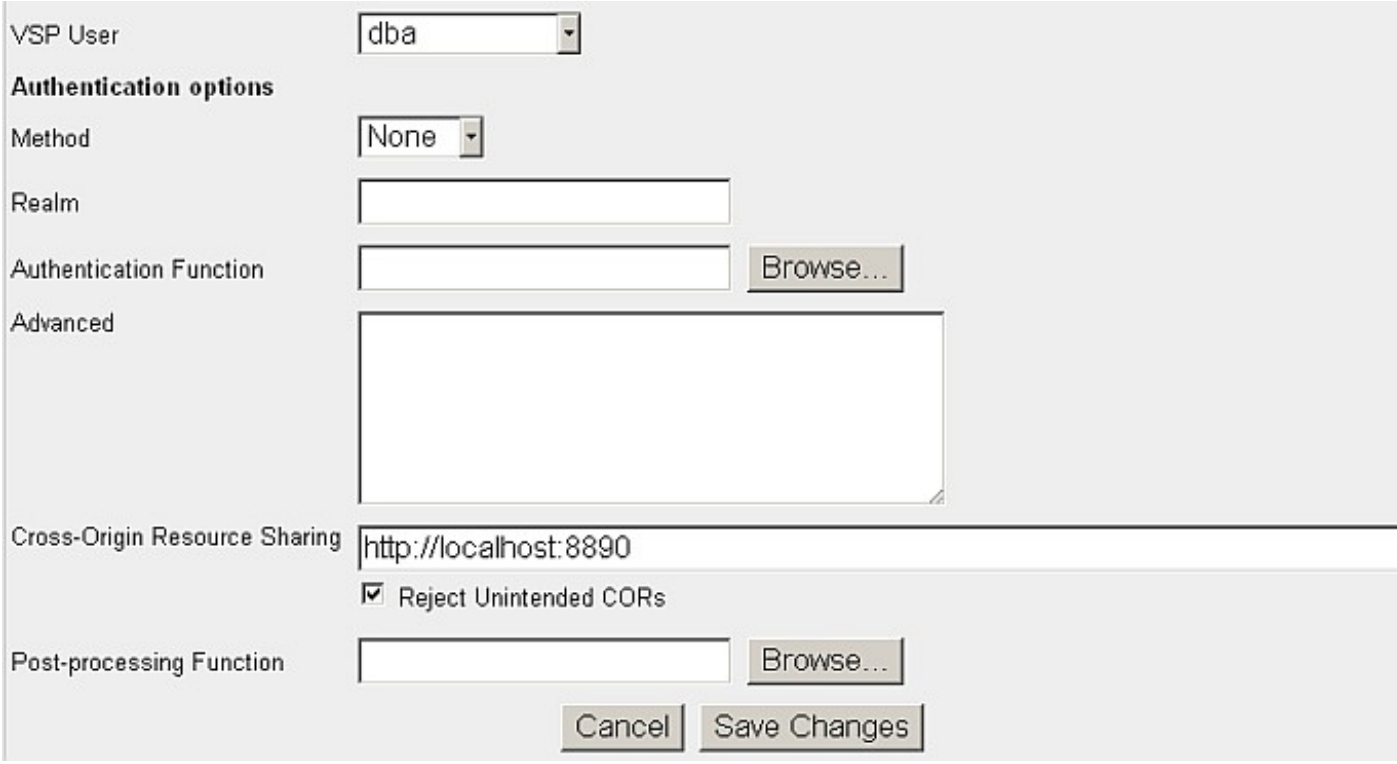


7. Set the

   CORS

   options.

Figure 19.7. Server-side Cross-Origin Resource Sharing (CORS) Example Setup



- *Cross-Origin Resource Sharing*

  : Contains a single wildcard asterisk, i.e., "

  *

  ", or a space-delimited list of HTTP server URIs, e.g., "

  http://example.com:8080 http://blah.example.com http://foo.example.com

  ". Scripts originating on the listed HTTP servers are authorized to retrieve the specified resource(s); the wildcard means scripts from any HTTP server will be authorized. For this example, enter the following single URI:

  ```
  http://demo.openlinksw.com
  ```

- *Reject Unintended CORs*

  checkbox: When ticked (and the application does not overwrite headers), unmatched Origins will be rejected by sending an empty response. For this example, tick this box.

8. Click Save changes.

Example Usage with cURL

Example 1

1. Suppose the example setup above is performed, and http://demo.openlinksw.com/ is in the CORS list.
2. In this case, the request below will return an empty response:

```
$ curl -i  http://demo.openlinksw.com/mytest/test.vsp
HTTP/1.1 200 OK
Server: Virtuoso/06.02.3128 (Win32) i686-generic-win-32  VDB
Connection: Keep-Alive
Content-Type: text/html; charset=ISO-8859-1
Date: Thu, 28 Oct 2010 09:27:54 GMT
Accept-Ranges: bytes
Content-Length: 0
```

Example 2

1. Suppose the example Setup above is performed, and http://demo.openlinksw.com/ is in the CORS list.
2. Also, suppose the curl command includes a proper Origin value, e.g.:

```
-H "Origin: http://demo.openlinksw.com"
```

3. In this case, the request below will return a response including the retrieved content, etc.

```
$ curl -i -H "Origin: http://demo.openlinksw.com"  http://demo.openlinksw.com/mytest/test.vsp
HTTP/1.1 200 OK
Server: Virtuoso/06.02.3128 (Win32) i686-generic-win-32  VDB
Connection: Keep-Alive
Content-Type: text/html; charset=ISO-8859-1
Date: Thu, 28 Oct 2010 09:40:21 GMT
Access-Control-Allow-Origin: http://demo.openlinksw.com
Accept-Ranges: bytes
Content-Length: 7
```

Example 3

1. Suppose the Example Setup above is performed, but reject is off (i.e., "Reject Unintended CORs" check-box is not ticked).
2. In this case, the request below will return a response that lacks Access-Control-Allow-Origin:

```
$ curl -i  http://demo.openlinksw.com/mytest/test.vsp
HTTP/1.1 200 OK
Server: Virtuoso/06.02.3128 (Win32) i686-generic-win-32  VDB
Connection: Keep-Alive
Content-Type: text/html; charset=ISO-8859-1
Date: Thu, 28 Oct 2010 09:45:01 GMT
Accept-Ranges: bytes
Content-Length: 7
```

19.9. LDAP

The Lightweight Directory Access Protocol (LDAP) is a protocol for accessing online directory services. It runs directly over TCP and can be used to access a standalone LDAP directory service or a directory service maintained by X.500. A directory is type of database that stores information that is read more often that written to and so services are typically geared for high volume read access and offer simpler transaction support than general purpose databases. The LDAP directory service model is based on entries. An entry is a collection of attributes that has a "distinguished name" (DN). The DN is used to refer to the entry unambiguously. Each of the entry's attributes has a type and one or more values. The types are typically mnemonic strings, like "cn" for common name, or "mail" for email address. The values depend on what type of attribute it is: an email attribute might contain the string value "foo@bar.org". A jpegPhoto attribute would contain a photograph in binary JPEG format.

LDAP directory entries are arranged in a hierarchical tree-like structure that may reflect political, geographic and/or organizational boundaries. Hence, entries representing countries appear at the top of the tree, below them are entries representing states or national organizations, then, entries representing people, printers, documents, anything else...

LDAP provides methods for authentication. Directories can be made accessible to the general public or protected however the case may be.

LDAP is made for finding people and resources on a network. It provides a completely different functionality from web searches such as yahoo or webcrawler, which work simply by text matching and often return many thousand's of entries. Using an LDAP directory to locate something however, if you know the approximate location of where it is, such as what organization and country it is in, then you can do a search and return much fewer entries. LDAP is a vendor independent open protocol. The fact that organizations can alter it to their own needs is key. Also, large companies can use it as the basis for their own more complex

directory servers.

There are common misconceptions about the role of LDAP. LDAP is not intended as a replacement for local databases. They are not built to be added and modified too easily and thus would not work in a situation such as an airline reservation system. Also, LDAP is not meant to be a replacement for DNS. DNS is a specialized well used service on the Internet for matching IP addresses to real names. However databases and DNS and LDAP like most Internet services work very well in collaboration.

Virtuoso has the ability to act as an LDAP client, using built-in functions, and has been tested as a back end for the OpenLDAP server.

19.9.1. LDAP Client

Virtuoso provides four functions for accessing an LDAP Directory Service:

`ldap_search()`
`ldap_delete()`
`ldap_add()`
`ldap_modify()`

You can call each function independently. Each invocation of a function creates a separate LDAP session which is closed at the end of the operation.

URLs beginning with

```
ldaps://
```

invoke a non-conditional SSL operation. Such URLs cannot be used with the *try_tls* flag set. If the URL does not contain a port number then Virtuoso will use the default port number 389 for <ldap://> and port number 636 for <ldaps://>.

The *username* and *password* optional parameters are used to bind LDAP connections using basic authentication. If the operation is permitted to all users then you can leave these parameters out.

19.9.2. LDAP Server

Virtuoso is not an LDAP server but can easily provide a data back-end to one, such as OpenLDAP. This section explains how to incorporate OpenLDAP with Virtuoso on the Linux platform. For other platforms the installation of OpenLDAP and configuration of the ODBC data source may differ.

1. download the OpenLDAP distribution from OpenLDAP.org .
2. Build OpenLDAP with the --enable-sql option.
3. You may need the iODBC library installed, which can be obtained from iODBC.org .
4. install the LDAP server using: make install
5. copy the following text into the slapd.conf

```
>>>>
include         /usr/local/etc/openldap/schema/core.schema

pidfile         /usr/local/var/slapd.pid
argsfile        /usr/local/var/slapd.args

database        sql
suffix          "c=BG"
rootdn          "cn=root,o=opl,c=US"
rootpw          secret
dbname          1111
dbuser          dba
dbpasswd        dba
subtree_cond    "UPPER(ldap_entries.dn) LIKE CONCAT('%',UPPER(?))"
upper_func      UPPER

access to attr=userPassword
  by self write
  by anonymous auth
  by dn="cn=root,o=opl,c=BG" write
```

```
          by * none

        access to *
          by self write
          by anonymous auth
          by * read
        <<<<
```

6. Configure the ODBC data source named '1111' for your running Virtuoso server.
7. Apply the virt_back.sql script against a running virtuoso server, for example with isql.
8. If you can also apply the virt_testdb.sql to insert some demo schema and entries into the DB.
9. Export ODBCINI variable: export ODBCINI=<location of your odbc.ini>.
10. Start the slapd executable with debug option: 'slapd -d5' to ensure that all settings are correct.

The virt_back.sql Script

```
create table ldap_oc_mappings (
        id              integer identity primary key,
        name            varchar (64) not null,
        keytbl          varchar (64) not null,
        keycol          varchar (64) not null,
        create_proc     varchar (255),
        delete_proc     varchar (255),
        expect_return   integer not null
);

create unique index ldap_oc_mappings_name on ldap_oc_mappings (name);

create table ldap_attr_mappings (
        id              integer identity primary key,
        oc_map_id       integer not null references ldap_oc_mappings(id),
        name            varchar (255) not null,
        sel_expr        varchar (255) not null,
        from_tbls       varchar (255) not null,
        join_where      varchar (255),
        add_proc        varchar (255),
        modify_proc     varchar (255),
        delete_proc     varchar (255),
        param_order     integer not null,
        expect_return   integer not null
);

create table ldap_entries (
        id              integer identity primary key,
        dn              varchar (255) not null ,
        oc_map_id       integer not null references ldap_oc_mappings(id),
        parent          integer not null ,
        keyval          integer not null
);

create unique index ldap_entries_oc_map_id_keyval on ldap_entries (oc_map_id, keyval);

create unique index ldap_entries_dn on ldap_entries (dn);

create table ldap_referrals
(
        entry_id        integer not null references ldap_entries(id),
        url             varchar not null
);

create index entry_idx on ldap_referrals(entry_id);

create table ldap_entry_objclasses
(
        entry_id        integer not null references ldap_entries(id),
        oc_name         varchar(64)
);

create index entry_idx_entry_id on ldap_entry_objclasses(entry_id);
```

The virt_testdb.sql Script

```
create table authors_docs (
        pers_id integer not null ,
        doc_id integer not null,
        primary key  (pers_id, doc_id)
);

create table documents (
        id integer identity not null ,
        abstract varchar (255) null ,
        title varchar (255) null ,
        body binary (255) null,
        primary key  (id)
);

create table institutes (
        id integer identity  not null ,
        name varchar (255) not null,
        primary key  (id)
);

create table persons (
        id integer identity  not null ,
        name varchar (255) null,
        sname varchar (255) null,
        email varchar (255) null,
        passw varchar (255) null,
        primary key  (id)

);

create table phones (
        id integer identity  not null ,
        phone varchar (255) not null ,
        pers_id integer not null,
        primary key  (id)

);

insert into institutes (id,name) values (1,'');
insert into institutes (id,name) values (2,'opl');

insert into persons (id,name,sname,email,passw)
  values (1,'Mitko Iliev', 'Iliev', 'imitko@openlinksw.com', 'abc');

Chapter 20. Free Text Search

Abstract

Virtuoso provides a compact and efficient free text indexing capability for text and XML data. A free text index can be created on any character column, including wide and long data.

The contains SQL predicate allows content based retrieval of textual data. This predicate takes a column and a text expression and is true if the pattern of words in the text expression occurs in the column value. There must exist a previously created text index of the column. The text expression can contain single words and phrases connected by boolean connectives or the proximity operator. Words can contain wildcards but must begin with at least three non-wildcard characters if a wildcard is to be used. While it is enough to declare a free text index on a column and then just use the contains predicate for many applications, Virtuoso offers a range of options for tailoring how the indexing works.

If a certain application specific order of search results is desired more frequently than others, it is possible to specify a single or multipart key in the order of which hits will be returned from contains searches. Both ascending and descending order of the key is supported. To restart a search in the middle it is possible to specify a starting and ending key value. This works if the results are generated in the order of the application specific doc ID .

If non-text criteria are often used to filter or sort results of contains searches, it is possible to cluster these non-text data inside the free text index for faster retrieval. It is often substantially faster to retrieve the extra data from inside the text index than to get them from the row referenced by the text index. Such data are called offband data , since they are not actually text but are stored similarly to text.

It is possible to pre-process the text before it is indexed or unindexed. This feature can be used for data normalization and/or for adding content from other than the primary text field being indexed into the index. One example is adding the names of all newsgroups where an article appears to the index when indexing a news article. Thus when retrieving articles based on text and newsgroup, group can be used to very efficiently filter out the hits that are not in the group, even if the text indexed does not itself contain the group name. Another application of the same technique is adding text from multiple columns into the same index.

If the column being indexed is XML data, this can be declared and enforced by the text index. XML data will be indexed specially to support efficient XPATH predicate evaluation with the xcontains predicate.

Text Triggers is a feature that allows the storage of a large body of free text queries and automatically generating hits when documents matching the criteria are added to the index. This is useful for personalized data feeds, user profiles, content classification etc, which Virtuoso can send the results to in an email message. The conditions can be either free text expressions or XPATH expressions for XML content.

The text index can be kept synchronous with the data being indexed, so that the index is updated in the same transaction as the data. The other possibility is to maintain the text index asynchronously as a scheduled task (batch mode), which can execute up to an order of magnitude faster. The asynchronous mode of operation offers substantially higher performance if changes of multiple entries are processed in one batch index refresh.

20.1. Basic Concepts

A text index is created with the CREATE TEXT INDEX statement. This creates a number of stored procedures and triggers which will transparently manage the text index. A text index is dropped by dropping the generated words table, called <table>_<column>_WORDS, where <table> and <column> are the table and column over which the index is made.

Example 20.1. Creating a Text Index

```
CREATE TABLE FTT (ID INTEGER, FILE varchar,  DT LONG VARCHAR );
CREATE TEXT INDEX ON FTT (DT);
```

This is the simplest case of making a text index. This process will add an extra column to the table being indexed which it will use to reference rows from the new text index. If there already exists an integer primary key then this will be used and no new column will be added. Such a column may not be 0 or negative.

Once the index is made the contains query can be used to retrieve rows:

```
insert into ftt (id, dt) values (1, 'foo');
select from ftt where contains (dt, 'foo');
```

The contains predicate is a normal SQL predicate and can be used together with other predicates in the where clause. Contains may however not figure inside an OR or NOT. Hence:

```
select * from ftt where contains (dt, 'foo or bar ');
```

is OK but

```
select * from ftt where contains (dt, 'foo ') or contains (dt, 'bar');
```

is not.

20.2. Creating Free Text Indexes

20.2.1. The CREATE TEXT INDEX statement

Define and optionally initialize a text index on a column.

```
create_freetext_index
```

```
        : CREATE TEXT [XML] INDEX ON q_table_name '(' column ')'
        [WITH KEY column]
        [NOT INSERT]
        [CLUSTERED WITH '(' column_commalist ')' ]
        [USING FUNCTION]
        [LANGUAGE STRING]
    [ENCODING STRING]
        ;
```

XML - The XML keyword specifies that the data is to be indexed as XML, hence element names and attributes will be processed separately for use with the XCONTAINS predicate.

The *q_table_name* is a qualified table name on which the index is created. The generated procedures and auxiliary tables will be with the owner and qualifier of this table.

The *column* must be a column of the above table, of the VARCHAR, NVARCHAR, LONG VARCHAR, LONG NVARCHAR, LONG XML or XMLTYPE data type. The column may additionally have the IDENTIFIED BY option if the content is XML. This will be used to provide a base URI for traversing relative references. The XML option for the index has to be specified if the content is LONG XML or XMLTYPE.

WITH KEY column - This allows optionally specifying a uniquely identifying column which will be used as a foreign key for referencing the table from the text index. If this is not specified and there is a single part integer primary key, this primary key is used as the key. If there is no suitable primary key and the option is not present, an integer column is added and a sequence object is used to supply distinct values.

When specified, the column must be non-NULL and its run time value must either be an integer or a composite (See composite data type). The length of the values of this column is crucially important since it is repeated for each distinct word of each row. This column is called the free text document id column in the rest of this documentation.

NOT INSERT - If present, specifies that the index is not filled when created. The VT_INDEX_<table> function is still created but not run. You can run this manually or scheduled at an appropriate time. If batching is enabled then the index will be filled up at that time.

CLUSTERED WITH - The column list must consist of columns of the table. Their values are stored in the text index so that the values can be more efficiently located for filtering than if they had to be retrieved from the table itself. The combined length of the columns should be relatively small, not much over 200 bytes for this to be effective. There is no hard upper limit but long blobs are not advisable.

USING FUNCTION - This allows specifying a hook function for indexing an unindexing a document. The index hook is called before processing the words of the column to be indexed. This can be used to index extra text in addition to the column value or to modify the text before indexing. If the hook function returns 1 the column is not additionally processed. If hook returns 0 the column is processed normally, in addition to the words the hook may have inserted. See the section on hook functions. The hook functions are always named <table>_<column>_INDEX_HOOK and <table>_<column>_UNINDEX_HOOK, in the owner and qualifier of the table, where <table> is the unqualified name of the table.

LANGUAGE - The string literal following this keyword may be a language name. See Internationalization for details.

ENCODING - The string literal following this keyword may be an encoding name.

Creating the text index may take a long time. All this time is in 'atomic' mode, so no other database activity is allowed during it and no log is generated. If there is an error, e.g. out of disk the created index is dropped and the error is reported. A checkpoint should be made after the index is complete. If the index should be created under a different qualifier or the generated tables altered after the index is created the NOT INSERT option should be used to delay filling the index.

The CREATE TEXT INDEX statement will automatically make a unique index based on the free text document id, if this is not the PK of the table. If one wishes to modify this index, it can be found and dropped with DROP INDEX and reconstructed, but make sure that the reference in SYS_VT_INDEX matches and that the new index has the same name as the previous version.

A freshly created text index is in synchronous mode. This means that that changes to the table are immediately reflected on the index as they occur. This is done through a set of automatically generated triggers. If large changes to data will be performed, the batch mode is far more efficient.

See Also:

Although it is recommended to use the methods described above, the vt_create_text_index function can also be used

20.2.2. Choosing An Application Specific Document ID

The free text index conceptually works by making an index entry for each distinct word of each indexed column value which references back to the row containing the data being indexed. Therefore the table must have a unique ID that will be stored in conjunction with each distinct word in the indexed column in the text index. For space efficiency this should be as short as possible. If nothing else is specified the CREATE TEXT INDEX statement makes such a unique column and fills it automatically from a sequence producing unique numbers. If a single part integer primary key exists then this key is used as the free text index document ID. Note However that the values <= 0 are prohibited. This is however not always optimal, hence the application may specify what column is used to identify the row for text indexing. Such a unique column is referred to as the *Free Text Document ID* .

Suppose that a table contains news articles that should most frequently be retrieved latest first, in descending order of a datetime field. This can be achieved by just selecting the matching articles and sorting them with a SQL ORDER BY clause but this can be very inefficient. The reason for this is that all hits will first have to be found, then sorted and only then can the first hit be returned to the user. Further, the sort key will have to be retrieved from the table, causing a random access for each text hit. The sorting can be totally avoided if the document ID that is used to refer to the table from the index is itself ordered by date. This has several advantages:

- To retrieve the n latest, one just takes the n first hits produced by the contains search, no sorting required.
- To get the next n hits, one repeats the search but now specifying that the start ID is the ID of the last row of the previous set. No sorting and no scrollable cursors are required and the first hits can be returned before generating all hits. This is specially useful if the search criteria match many articles.

This has a disadvantage in that a longer document ID will have to be stored for each distinct word of each distinct article. This may result in a 60% increase in the index size but largely offsets the penalties of sorting. One should however exercise the utmost care in making this ID as short as possible. The maximum length of the ID is 30 bytes, but with this length the storage is extremely wasteful, so an ID with fields adding up to some 10 bytes is much better.

We will note that the document ID can be an aggregate of several scalars. In the news article example, it could be a datetime, ID number pair. This is so because the datetime typically would not be unique and the ID is required itself to be unique.

However, rather than storing the datetime and an integer article number, it is advisable to compress the datetime into a number, e.g. a count of minutes after a given date. This maintains the temporal order to within a minute and takes less than half the space taken by the datetime with all its fractions, time zones etc.

For handling multi-part ID's like scalars there is a special data type, composite. Thus, if an application specific document ID is not an integer, it must be a composite totaling less than 30 bytes of content divided among its members.

20.2.3. The composite Data Type

A composite is like a heterogeneous array, except that it is limited in length, may be stored as a column value for a column declared as ANY, and may be a key part in a SQL index. Thus, comparison is defined for composites as follows:

- Composites are equal if all parts are equal.
- A composite is less than another if the first part of it which is not equal to the corresponding part of the other composite is less than that part.
- If a composite has less parts than another and all of its parts are equal to the corresponding parts of the longer composite, then the shorter is considered less.

The collation of composites is just like that of strings, except that in the place of characters, arbitrary run time typed scalars are compared.

When strings are compared inside composites, they are compared as binary, without any specific collation. Normal numeric coercion applies to comparison of composites. Narrow and wide strings are compared with binary collation. If two elements are of different types, e.g. a number and a string and are compared, the data type will decide the outcome. For example any integer is always less than any string.

The composite SQL function makes a composite. It takes a variable number of arguments and returns a composite. The composite_ref function takes a composite and a zero based index and returns the value. The serialized length of a composite is limited to 255 characters. If a composite is used in a free text index it is limited to 30 characters.

- composite()
- composite_ref()

See Also:

See the Data Types section for the storage requirement of each data type.

20.2.4. Free Text Index Examples

```
composite (1, 2) = composite (1, 2)  is true
composite (1, 2) < composite (1, 3) is true.
composite (1, 0) > composite (1) is true.

composite_ref (composite (1, 2), 1) = 2
```

Example of a Composite Application Specific Document ID

The below code creates a table for news articles and defines a text index with a composite document id.

```
create table article(author_name varchar(255),
                     description long varchar,
                     pub_date datetime,
                     id integer,
                     title varchar(255),
                     dtid any not null,
                     primary key(id));

create text index on article (description)
        with key dtid clustered with (pub_date, author_name);
```

Note:

The dtid must be unique, non null and must be a composite since it is used as a custom text index id.

Next we define a mapping between dates and integers. These will be minutes consecutive of 1990-1-1 0:00. With 525600 minutes per 365 day year we will not run out of values for a long time, the positive integer limit being 2**31.

```
create procedure date2short (in dt datetime)
{
  return (1440 * datediff ('day', {d'1990-1-1'}, dt)
        + hour (dt) * 60 + minute (dt));
}

create procedure short2date (in n integer)
{
  return (dateadd ('minute', mod (n, 1440),
        dateadd ('day', n / 1440, {d'1990-1-1'})));
}
```

Now we can insert an article:

```
insert into article (id, drtid, description, pub_date)
        values (1, composite (date2short ({dt '2001-1-15 12:44'}), 1),
                'sample news article', {dt '2001-1-15 12:44'});
```

Note:

The composite is the date2short of the datetime and the id. The dtid must be specified and cannot be generated by a trigger, since the free text index related triggers must have access to the value.

The text index will be in synchronous mode by default so we can now query the data:

```
select id from article where contains (description, 'sample');
select id from article where contains (description, 'sample', descending);
```

The first query will return the oldest hits first, the second the newest first. Note that inserting in ascending order of the document ID is incomparably more efficient than in descending order. There is no great speed difference between reading in ascending or descending order.

If no application specific ID were specified the order would reflect the insertion order. Note that in this example articles do not have to be received in publication order, although insertions will naturally tend to follow this.

Now since the ID has an application semantic, we can use it for filtering based on date:

Consider:

```
select id from article where contains (description, 'sample', descending,
        start_id, composite (date2short ({dt'2001-1-5'})));
```

Since the search goes in descending order of id and starts at an id beginning with the numeric value corresponding to 2001-1-5 0:00, we may only get hits where the id date component is less than this, newest first.

There is no time penalty for the start_id option. This is therefore incomparably faster than the query:

```
select id from article where contains (description, 'sample', descending)
and pub_date < {dt '2001-1-5'};
```

See Also:

The reference section for contains for a definition of these options.

20.2.5. Pre-processing and Extending the Content Being Indexed

Let us consider the news application. Assume now a many to many relationship between articles and numbered news channels.

```
create table article_channel (
        a_id integer references article,
        c_id integer,
        primary key (a_id, c_id);
```

Assume further that free text search criteria be combined to channel membership tests.

This could be expressed as follows

```
select * from article
        where contains (description, 'sample')
        and exists
                (select 1 from article_channel
                where a_id = id and c_id = ?);
```

We have a random access per each hit to a table with at least the population of the article table for each hit. The situation is yet worse if there is an OR of multiple channel id's to which the article may belong.

To optimize this, we may choose to add an extra word for each channel in which the article appears. Likewise, we may add the text of the title of the article to the text being index.

This can be done with the index hook feature.

```
create text index on article (description)
        with key dtid clustered with (pub_date, author_name)
        using function ;
```

We then define the hook functions

```
create procedure
        article_description_index_hook (inout vtb any, inout d_id any)
{
```

```
  for (select c_id from article_channel
        where a_id = composite_ref (d_id, 0))
  do
    {
      vt_batch_feed (vtb, sprintf ('ch%d', c_id), 0);
    }
  vt_batch_feed (vtb, coalesce ((select title from article
        where dtid = d_id), ''), 0);
  return 0;
}
```

This function gets all channel id's where the article appears and adds the word ch<nnnn> where <nnnnn> is the channel id. Thus to look for 'xx' on channel 1 or 10 one can use the text expression xx and (ch1 or ch10). Additionally, the text of the title is added to the text being indexed. Note that the d_id supplied is the free text document id and that the second part of it is the article id.

To reverse the effect, the unindex function works as follows:

```
create procedure
        article_description_unindex_hook (inout vtb any, inout d_id any)
{
  for (select c_id from article_channel
        where a_id = composite_ref (d_id, 0))
  do
    {
      vt_batch_feed (vtb, sprintf ('ch%d', c_id), 1);
    }
  vt_batch_feed (vtb, coalesce ((select title
        from article where dtid = d_id), ''), 1);
  return 0;
}
```

These hooks accept 2 inout parameters, the so called vt batch and the free text document ID of the row at hand.

The function returns 1 to indicate that it has processed all words of the row to be indexed and 0 to indicate that it expects the default text to be processed by the caller as normally. Returning 1 is useful for example if extra word normalization is applied by the hook.

If the resulting index is used by `xcontains()` special predicate then hook functions should not alter the indexing of XML documents. `xcontains()` reads both free-text index and the actual document in order to locate particular fragments and it may miss search hits or get false hits if free-text index of a column does not match to the actual content of the column. It is still safe to call `vt_batch_feed` more than once during a single call of a hook function: first call for an unmodified XML document in the column plus calls for additional data.

If offband columns are declared then any call of a hook function should either return 0 or call `vt_batch_feed_offband()` before returning a non-zero value. If this condition is violated for a document then NULL is returned instead of correct offband value for the document without signalling any error.

The vt batch is an opaque data structure that accumulates words that will be added to the text index entry for a given row. The `vt_batch_feed` function adds words to the batch, the first argument is the vt batch, the second is the text and the third is a flag 0 for insert and 1 for delete. The text to be associated to the d_id in the index is the concatenation of all the text supplied by successive calls to `vt_batch_feed` . Word proximity is defined as if all text were a single string in the order of calling `vt_batch_feed` .

It is possible to partially alter the rtext associated with an existing document. This could be done when adding channels to an article which already exists. This could be done with the procedure:

```
create procedure
        ch_add_article (in cid integer, in aid integer)
{
  declare vtb, _dtid, cname any;
  if (exists (select 1 from article_channel
        where c_id = cid and a_id = aid))
    return;

  insert into article_channel (c_id, a_id) values (cid, aid);
```

```
  select dtid into _dtid from article where id = aid;

  vtb := vt_batch (1);
  vt_batch_d_id (vtb, _dtid);
  vt_batch_feed (vtb, sprintf ('ch%d', cid), 0);
  vt_batch_process_db_dba_article (vtb);
}
```

This first checks if the article is already on the channel, and if not, it makes a vt batch, gets the free text document id of the article, associates it to the vt batch and then adds a single word, ch<nnnn>. The vt batch is applied by calling the generated procedure vt_batch_process_<table>_<column> with the vt batch as only argument.

If multiple documents should be processed in one batch, it is possible to call vt_batch_d_id multiple times to feed data about multiple documents. In this case the successive document ids must be given in ascending order. The batch can be processed (applied to the words table) by calling T_BATCH_PROCESS_<table>_<column>, generated by the index creation.

The sensitive columns of the UPDATE trigger generated are the free text document id, the CLUSTERED WITH columns and the main text column. If more columns are needed for hook functions etc., the triggers should be manually edited.

If an explicit integer document ID column is specified, its value may not be 0 or negative.

vt_batch , vt_batch_feed , vt_batch_feed_offband , vt_batch_d_id .

20.2.6. Hit Scores

When a document satisfies a text search expression a score is computed to reflect the closeness of the match. This is a positive integer, with a higher value meaning a closer match. The scores are only comparable between results of the same query against the same database. Moreover, the scoring rules are different for different versions of Virtuoso server, due to the progress in information retrieval theory. Thus the only really safe thing to do with scores is to sort the list of hits by descending score to produce more relevant hits first. In addition, the CONTAINS predicate allows specifying a lower limit to the score of produced hits so a smart application can reduce a number of retrieved documents by filtering out the less relevant documents.

While the real scoring rules of the server are too sophisticated to be listed here, the basic concept is simple: hits for restrictive terms are most important than hits for generic terms, frequent hits in same document are more important than occasional, hits that are probably concentrated in same sentence are more important than hits here and there in a long text:

The score of a single word term is proportional to the frequency of the word in the document.

The score of a phrase is proportional to both the frequency of the phrase in the document and the number of words in the phrase.

The score of a proximity term 'A NEAR B' depends on the distance between A and B in words - greater distances result in smaller scores. E.g. the score is 100 for zero distance, 80 for 5 word distance, 50 for distance 10, 20 for distance 20; then it slowly decreases to 1 for distance 100. If the distance is 100 words or greater then the condition A NEAR B is considered not to be satisfied. If the A-B pair occurs several times throughout the document the scores of each pair are added. Virtuoso searches for shortest possible pairs, so if there is more than one word A around B then the nearest A is selected for scoring.

Score of a term like A AND B AND C... AND Z is a minimum of scores of A, B,... Z plus some bonuses. Longer list of AND'ed terms get higher score. A special bonus for term A AND B is added if hits of subterm A are close to the hits of subterm B.

Score of a term like A OR B OR C... OR Z is a maximum of scores of A, B,... Z, with some additional corrections. Longer list of OR'ed terms get lower score. A special bonus for term A OR B is added if hits of subterm A are close to the hits of subterm B.

Score of a term like A AND NOT B is equal to the score of subterm A. The subterm B is used for filtering out redundant hits but it does not affect the scoring.

The XCONTAINS predicate can also return scores. These scores are somewhat similar to scores made by CONTAINS but rules for them are too complicated to be explained here.

20.2.7. Word Ranges

This feature allows returning the positions of matches of a query inside the indexed text. This is done by creating a virtual column which gets as its value an array of arrays, one array for each top level term of the text query expression. The component arrays in turn contain word positions, expressed as the ordinal number of the first and last word of each match of the term in question. The ordinal numbers are counted from 0, skipping noise words.

Example 20.2. Word Ranges

```
select dbg_obj_print (r), * from ftt
        where contains (dt, 'foo', ranges, r);
```

Prints the array

```
(L(0 0 ) )
```

to the server standard output, indicating that the match starts and ends at the 0'th word, inclusive.

This feature can be used to show specific portions of matching documents in applications. This is internally used as part of the xcontains predicate for XML text. Also see the function search_excerpt ().

20.2.8. Using Offband Data for Faster Filtering

When evaluating a select where there is a contains predicate and filtering conditions on columns of the table on which the text index is defined it is useful to store the most frequently used columns in the free text index instead of the table itself.

The rationale is that in order to access the filtering data the engine will do a merge join with the text index table instead of a nested loop join with the actual table. Further note that if the columns to be accessed are not in the index that begins with the free text document id actually 2 random accesses will be needed: 1. to get the primary key based on the document id and 2. to get the filtering criterion based on the primary key. It is vastly more efficient to do a merge join in the text index to get frequently needed non-text filtering or sorting keys.

If the text index is maintained in background mode the offband data will also be maintained with a delay. This should not be a problem however since this is no more delayed than the text data itself.

If a select with a contains does not reference any columns from the indexed table besides the document id, then no access to the actual table will be generated in the compiled query. Likewise, if only columns found in the index used to link the document id to the table are referenced, only that index will be accessed. A special case of the latter situation is where the document id is the primary key itself. This will speed up retrieving the row for free text hits.

Let us consider a query for getting articles where the author name is at a specific value:

```
select id from article where contains (description, 'sample')
        and author_name = 'John Pumpkin';
```

This can be alternately written as

```
select id from article
        where contains (description, 'sample', offband, author_name)
        and author_name = 'John Pumpkin';
```

In the latter case the author_name will be retrieved from the text index, saving 2 random accesses, one to the index on dtid and the other to the table itself per each free text hit.

The notation is different because the semantic is slightly different. The author_name in the latter case is the name at the time of indexing the article and in the latter case it is the name at the time of evaluating the query. There can be a difference if the index is maintained with a delay. For most applications this is however irrelevant. offband data should not be used for often changing, transactional data.

Now consider

```
select * from (select top 10  dtid from article
        where contains (description, 'sample', offband, author_name)
        order by author_name) a, article b where a.dtid = b.dtid;
```

The derived table select the 10 first articles matching the text condition in order of author_name. This does not itself access the article table at all. The outer select will then select the full row for these 10 articles. This is possible since the inner select only references dtid, which is the free text index document id and author_name which is declared an offband column in the text index.

This does less disk access than

```
select top 10 * from article
        where contains (description, sample', offband, author_name)
        order by author_name;
```

In this case, all matches are fetched, including the row in the article table and all are sorted and the top 10 are returned. This differs from the first by the fact that this accesses the article table for each of the text hits, not only the top 10. This can easily make a 3x speed difference when running in memory and much greater when I/O is involved, not to mention the adverse impact of more I/O on the working set.

20.2.9. Order of Hits

Rows from a select where there is a contains predicate and no exact match of the primary key of the table are produced in the order of the document id of the free text index if there is no ORDER BY. If there is an ORDER BY matching an index, the query is evaluated in the order of that index and each consecutive row in the order of the index is compared against the free text expression. This is practically never desirable.

If results are desired in the order of the free text document id, there MUST BE NO ORDER BY. The DESCENDING option of contains should be used to produce the reverse order, see contains reference section. If another sorting order is desired, an ORDER BY can be used but to avoid using an index the ordering columns should be expressions or ordinal numbers of result columns.

Therefore:

```
select * from article where contains (description, 'sample')
  order by id;
```

Will have the effect of traversing the table in the order of id and checking each row for free text match. This is practically NEVER good.

To produce the results in order of id instead of dtid it is better to write

```
select id, * from article where contains (description, 'sample')
  order by 1;
```

or

```
select * from article where contains (description, 'sample')
  order by id + 0;
```

20.2.10. Noise Words

Noise words are often occurring words which can be skipped to save space in the indexing, such as 'the', 'of', and' etc. These are ignored when they occur in queries or documents to be indexed. The set of noise words is configurable and is read from the noise.txt file, in the server's working directory, at server start up. Words mentioned in that file will be ignored for both indexing and querying.

The file noise.txt consists of control lines and text lines. A text line is just a string of one or more words to be declared as noise. Please keep them shorter than 1000 characters.

Control lines are those starting with "Language:" or "Encoding:" (case is important) "Language: lang-id" tells the system to use rules for language "lang-id" for subsequent text lines, until either another "Language:" control line or end of file. Similarly, "Encoding: enc-id" tells the system to use rules for encoding "enc-id". Control lines are always in plain ASCII, no matter which encoding is active for text lines. By default, the server default language and "UTF-8" encoding will be used.

The simplest way of composing noise.txt is to place every word on a separate line and save the file in UTF-8 encoding; this will work fine for most European languages.

Example 20.3. Example

```
AND
OF
THIS
THE
```

Noise words seem to be case-insensitive, but this is not so. If you enter a word on a text line, up to four noise words will be registered:

the word exactly as it was entered;

an uppercased form of this word, if it is defined for active language;

an lowercased form of this word, if it is defined for active language;

a capitalized form, with one (or more) first chars in upper case and the rest in lower case.

An error is signalled for a free text query consisting exclusively of noise words.

It is important to understand that changes in noise.txt may invalidate free text indexes that were filled with the previous version of noise.txt. For example, if a text contains a phrase 'A B C' and after indexing the word 'B' is added to the noise.txt then 'contains' predicate will properly search for words 'A' and 'C' but will fail to find the phrase 'A B C' or 'A C' due to differences in counting of word positions. The 'xcontains' predicate is even more sensitive to changes in word positions, because any change in word counting will corrupt the index for element names. In addition, "persistent XML" documents may contain pre-calculated word positions for all elements and these positions may become out of sync with positions in free text index, so it is best not to change noise.txt if the database contains any free text indexes on persistent XMLs.

20.3. Querying Free Text Indexes

20.3.1. CONTAINS predicate

Returns TRUE if a free text indexed column matches a text expression.

Syntax

```
contains_pred:
        contains (column, expr, opt_or_value ....)

opt_or_value:
          DESCENDING
          | START_ID ',' scalar_exp
          | END_ID ',' scalar_exp
          | SCORE_LIMIT ',' scalar_exp
          | RANGES ',' variable
          | OFFBAND column

variable: IDENTIFIER
```

The *column* must refer to a column for which there exists a free text index. The *expr* must be a narrow or wide string expression whose syntax matches the rules in 'Text Query Syntax'. The *START_ID* is the first allowed document ID to be selected by the expression in its traversal order, e.g. least or equal for ascending and greatest or equal for descending. *END_ID* is the last allowed ID in the traversal order. For descending order the START_ID must be >= END_ID for hits to be able to exist. For ascending order the START_ID must be <= END_ID for hits to be able to exist.

DESCENDING specifies that the search will produce the hit with the greatest ID first, as defined by integer or composite collation. RANGES specifies that the query variable following the RANGES keyword will be bound to the word position ranges of the hits of the expression inside the document. The variable is in scope inside the enclosing SELECT statement.

SCORE_LIMIT specifies a minimum score that hits must have or exceed to be considered matches of the predicate.

OFFBAND specifies that the following column will be retrieved from the free text index instead of the actual table. For this to be possible the column must have been declared as offband with the CLUSTERED WITH option of the CREATE TEXT INDEX statement.

See Also:

`contains()`

The XCONTAINS Predicate .

20.3.2. Comments

Order - If the select statement containing the contains predicate does not specify an exact match of the primary key of the table having the contains predicate, then the contains predicate will be the 'driving' condition, meaning that rows come in ascending or descending order of the free text document ID.

The *DESCENDING* keyword specifies the descending order of the free text index document ID and has nothing to do with a possible ORDER BY of the enclosing statement. Even if there is an ORDER BY in the enclosing statement the DESCENDING keyword of contains has an effect in the interpretation of the STRT_ID and END_ID contains options.

If there is a full equality match of the primary key of the table, this will be the driving predicate and contains will only be used to check if the text expression matches the single row identified by the full match of the primary key.

The contains predicate may not appear outside of a select statement and may only reference a column for which a free text index has been declared. The first argument must be a column for which there is such an index. The text expression may be variable and computed, although it must be constant during the evaluation of the select statement containing it.

The contains predicate must be a part of the top level AND of the WHERE clause of the containing select. It may not for example be a term of an OR predicate in the select but can be AND'ed with an OR expression.

20.3.3. Text Expression Syntax

```
expr ::= proximity_expr
        expr AND expr
        | expr OR expr
        | expr AND NOT  expr
        | '(' expr ')'

word_expr ::=
          word
        | '"' phrase '"'

proximity_expr ::=
          word_expr
        | proximity_expr NEAR word_expr

word ::=
        <word char>*

phrase ::=
          word
        | phrase <whitespace> word

word_char ::=  alphanumeric characters, '*',  ISO Latin accented characters.
```

A word is a sequence of word characters. A phrase is a sequence of words separated by white spaces and enclosed in double quotes. If a word contains a wildcard character it must be quoted with double quotes.

Note:

An expression may not consist of all negative terms, e.g. (not a) and (not b) is not a valid expression but 'c and not a and not b' is a valid expression.

Note that the NEAR connective may not be used between AND'ed or OR'ed terms. It can be used to combine words or phrases.

Example 20.4. Querying Free Text Indexed Columns

```
select count (*) from docs
where contains (text, '"virtual database"')
```

returns the count of documents with one or more occurrences of "virtual" immediately followed by "database".

```
'performance and (tuning or optimization)'
```

specifies documents with performance and either 'tuning' or optimization' in any respective positions.

```
'graphics and not (graphics near user near interface)'
```

matches documents with the word graphics more than 100 words away from 'user' or 'interface'.

```
'"sql interfac*"'
```

matches documents with SQL followed by a word beginning with 'interfac'.

```
'"dragon*" and not "once upon a time"'
```

matches documents with words beginning with 'dragon' and not containing the phrase 'once upon a time'.

20.4. Text Triggers

The text trigger mechanism allows implementing a broad range of content tracking functionality. The idea is storing free text or XPATH queries in association to a text indexed column of a table. When the content of the table changes through inserts or updates, the new data is matched against a base of stored queries and hits are marked into a separate table. The data being tracked may either be plain text or XML. In the event of XML, both free text and XPATH queries can be stored.

The benefit of the text trigger system as opposed to other forms of periodic content tracking is that the incoming data itself indexes a base of stored queries instead of a base of stored queries repeatedly indexing the database. This means that only the changes are compared to the stored queries and that queries that could not even in principle match will not be tried. This results in a qualitatively better performance and scalability than repeatedly running a batch of queries over updated data and thus makes possible personalized information filtering applications that would be impractical with other approaches.

20.4.1. Creating Text Triggers

The **CREATE TEXT TRIGGER** statement creates a set of tables and procedures named after the table and column being watched. The **TT_QUERY_<xx>** table contains the set of queries, the **TT_HIT_<xx>** table records the matches and the TT_USER_<xx> table can be used to map stored queries to specific users that should be notified.

Syntax:

```
CREATE TEXT TRIGGER ON <table> [(<data_column>)]
DROP TEXT TRIGGER ON <table> [(<data_column>)]
```

The <data_column> is optional and must be a text indexed column.

The table to be watched by a text trigger should have a free text indexed column. This may or may not be XML data.

The <table> must be text indexed before creating text trigger on it.

Example 20.5. Creating a Text Trigger

```
create table ftt (id integer not null primary key, dt long varchar);
create text xml index on ftt (dt);
create text trigger on ftt;
```

Adding queries to the text trigger

```
TT_QUERY_ftt ('virtuoso and server and international',
  1, 'Virtuoso international support', 'iam@foo.bar');
```

this adds a query which will filter only documents matching words 'virtuoso', 'server' and 'international', named 'Virtuoso international support' of the user with Id equal to 1 with e-mail notification.

```
TT_XPATH_QUERY_ftt ('/chapter[@label = ''XI'']',
  2, 'Chapter XI changes', '');
```

this will add an XPATH query which will filter only XML documents matching Chapter XI, named 'Chapter XI changes' of the user with Id equal to 2 without e-mail notification.

```
insert into ftt values (1, 'virtuoso server international');
insert into ftt values (2, 'virtuoso international');

select TTH_D_ID, TTH_T_ID, TTH_U_ID, TTH_TS from ftt_dt_HIT;
```

will produce

```
TTH_U_ID    TTH_D_ID         TTH_T_ID    TTH_TS
_____________________________________________

1           1                1           2001-01-17 12:35:30
```

Meaning that row from 'ftt' with id equal to 1 matches query with TT_ID equal to 1 defined for user with ID equal to 1. Also the hit is registered on '2001-01-17 12:35:30'.

20.4.2. Created Database Objects

Text trigger hits table. Text trigger stores hits on documents matching a condition within this table.

```
<table_name>_<data_column>_HIT (
  TTH_U_ID INTEGER,   -- references User table TTU_U_ID
  TTH_D_ID ANY,       -- references matching document id
  TTH_T_ID INTEGER,   -- references matching query TT_ID
  TTH_TITLE VARCHAR,  -- user application specific
  TTH_URL VARCHAR,    -- user application specific
  TTH_TS TIMESTAMP,   -- time of registering a hit
  TTH_NOTIFY VARCHAR, -- e-mail address for notification
  PRIMARY KEY (TTH_U_ID, TTH_TS, TTH_D_ID, TTH_T_ID)
)
```

Text trigger queries table, where the query definition procedure stores the user specific queries.

```
<table_name>_<data_column>_QUERY (
  TT_WORD VARCHAR,  -- the most effective word for searching
  TT_ID INTEGER,    -- id of query
  TT_QUERY VARCHAR, -- text of the query, in case of XPATH query this
                               -- column contains a serialized value
  TT_CD VARCHAR,    -- user data
  TT_COMMENT VARCHAR, -- Human readable label with general purpose
  TT_XPATH VARCHAR,   -- text of XPATH query
  TT_PREDICATE VARCHAR, -- Virtuoso/PL function hook
  PRIMARY KEY (TT_WORD, TT_ID)
)
```

One query can add one or more rows to the queries table.

Text trigger users table, in it query definition procedure add a reference between query and user.

```
<table_name>_<data_column>_USER (
  TTU_T_ID INTEGER, -- references text query TT_ID
  TTU_U_ID INTEGER, -- references application specific users table ID
  TTU_NOTIFY VARCHAR, -- e-mail address list for notification
  TTU_COMMENT VARCHAR, -- Human readable label of query definition.
  PRIMARY KEY (TTU_T_ID, TTU_U_ID)
)
```

Note:

Note:

In the case of e-mail notification to the main addresses the string passed as address list must be in the following format: '<u1@foo.com>, <u2@foo.bar>'.

Procedures that are used for adding text queries.

```
TT_QUERY_<table_name> (in query_text varchar, in user_id integer,
  in label varchar, in notification_address varchar)
```

Used for adding XPATH queries.

```
TT_XPATH_QUERY_<table_name> (in xpath_query_text varchar , in user_id integer,
in label varchar, in notification_address varchar)
```

Used to send notifications to the users. This procedure is usually called by the server event scheduler.

```
TT_NOTIFY_<table_name> ();
```

20.5. Generated Tables and Internals

20.5.1. Generated Tables and Procedures

vt_create_text_index makes a separate table for storing the text index information and separate procedures and triggers for maintaining this data. These are automatically dropped if the original table is dropped.

The updates to the indexed column are recorded in a separate update tracking table. This table, named VTLOG_<qualifier>_<owner>_<table> contains a row for each row in the indexed table that has been changed since the text index was last updated.

The text index is stored in a table named <table>_<column>_WORDS. The generated tables are made under the qualifier that is current at the time of their creation. The owner is the creating user.

20.5.2. The procedures are:

```
VT_INDEX_<qualifier>_<owner>_<table>  (in flag integer)
```

This re-indexes the table. A flag of 0 makes the index, a flag of 1 deletes data found in the table from the index.

```
VT_INC_INDEX_<qualifier>_<owner>_<table>  (in flag integer) ()
```

This function refreshes the index using the change tracking information in the VTLOG_ table.

20.5.3. Tables and Procedures Created By Text Triggers

```
- [TARGET_TABLE_NAME]_[DATA_COLUMN_NAME]_HIT

  columns

  TTH_D_ID          INTEGER   - document ID, references unique id of [TARGET_TABLE]
  TTH_T_ID          INTEGER   - query ID, references QUERY table
  TTH_U_ID          INTEGER   - user ID, references USER table
  TTH_TS            TIMESTAMP - date and time of retrieval
  TTH_NOTIFY        VARCHAR   - e-mail address of user for notification
  TTH_TITLE         VARCHAR   - not used (can be filled with user-defined trigger)
  TTH_URL           VARCHAR   - not used (can be filled with user-defined trigger)

- [TARGET_TABLE_NAME]_[DATA_COLUMN_NAME]_QUERY

  columns

  TT_ID             INTEGER   - Unique ID of query
  TT_QUERY          VARCHAR   - query text
  TT_WORD           VARCHAR   - the best word for query
  TT_COMMENT        VARCHAR   - Description
  TT_CD             VARCHAR   - user data (not used)
```

```
  TT_PREDICATE     VARCHAR   - not used
  TT_XPATH         VARCHAR   - XPATH expression.  If specified,
                                        the test is this XPATH predicate,
                                        see separate section.

- [TARGET_TABLE_NAME]_[DATA_COLUMN_NAME]_USER

  columns

  TTU_U_ID         INTEGER - unique user ID can reference SYS_USERS.
  TTU_T_ID         INTEGER - query ID, references QUERY table
  TTU_COMMENT      VARCHAR - Description
  TTU_NOTIFY       VARCHAR - e-mail address of user for notification
```

Note that the queries are available given a table wide query identifier and an 'entry point' word. Such a word is a word that must occur in the document in order for the query to have a possibility of matching the document, The query text and other attributes are denormalized so that the primary key is the word, id pair when the id itself is unique. Note that in the case of an AND of words, the least frequent of the words will be used as unique entry point of the query, so that it will not be tried on documents that do not contain this word. However, a query with OR'ed terms may have several such words, hence the possibility of multiple rows in the query table for the same query.

The TT_USER_<xx> table maps from the query to a user. The idea of this is to allow a single query to have multiple users. Consider an application which allows creating personalized information filtering profiles. It is to be expected that multiple users would store the same profiles. Therefore the link between the user and the query is entitized as this table. The user specific comment and notification mode are thus stored here, not with the query. The notification mode itself is application dependent. The user id is an application dependent id that can be used to reference application user entities. Some applications may use this whereas other applications will have all queries on a single user.

When a hit is noticed an entry is made into the TT_HIT_<xx> table. One row is inserted for each unique document id, query id, user id combination for which the document matches the query and there is a link to a user from the query through TT_USER_<xx>. A query with no row in TT_USEER_<xx> is an integrity error. The number of times the pattern is found in each document or its free text hit score has no effect on the hit insertion.

One may note that defining application specific triggers on the hit table can be used to add immediate application reactions to incoming data.

The free text triggers are matched against the new content immediately before the content is inserted into the free text index. Therefore the batch mode setting affects the time of matching. In all situations, the matching takes place after the data is inserted but before the free text index is updated. If text index maintenance is in synchronous (non-batched) mode, the text trigger match and hit generation is in the same transaction as the update to the content being watched.

Procedures

For queries definition

```
tt_query_[TARGET_TABLE_NAME] (
            in [query text] varchar,           - query expression
            in [user_id] integer,              - user id references SYS_USERS or SYS_DAV_USER
            in [comment] varchar,              - description
            in [e-mail or empty] varchar)      - e-mail address for user notification
```

or hits registration (used inside text index procedures)

```
vt_hits_[TARGET_TABLE_NAME] (inout [batch] any, inout [words array] any)
```

Triggers

for hits removal after document delete occurred

```
[TARGET_TABLE_NAME]_FTT_D
```

Examples

```
-- create a table
create table T1 (id integer, dt varchar, primary key (id));

-- define text index
create text index on T1 (dt);

-- create text trigger
create text trigger on T1;

-- define an query
tt_query_T1 ('xyz and abc', 1, 'This is a test query', null);

-- do some inserts
insert into T1 (id, dt) values (1, 'xyz');
insert into T1 (id, dt) values (2, 'xyz abc');
insert into T1 (id, dt) values (3, 'abc');
update T1 set dt = 'xyz qwe abc' where id = 2;

select TTH_TS, dt from T1, T1_dt_HIT where id = TTH_D_ID order by TTH_TS desc;
-- produces following
TTH_TS      dt
BINARY      VARCHAR
_______________________________________________________________________________

2000-10-24 18:25:53  xyz qwe abc
2000-10-24 18:25:53  xyz qwe abc
```

20.6. Removing A Text Index

A text index is dropped by dropping the words table with DROP TABLE. This will drop all triggers, procedures and auxiliary tables. The words table is in the qualifier and owner of the indexed table and is named <table>_<column>_WORDS.

Example 20.6. Example

```
drop table DB.DBA.XML_TEXT_XT_TEXT_WORDS;
```

-- drops the text index created in the vt_create_text_index example

20.7. Removing A Text Trigger

Used to drop text trigger definition on text indexed table. The operation also drop all tables created by create text trigger statement.

Syntax:

```
DROP TEXT TRIGGER ON <table> [(<data_column>)]
```

Example 20.7. Removing A Text Trigger

```
drop text trigger on ftt;
```

will drop the text trigger definition from table ftt.

Or using the stored procedure:

20.7.1. vt_drop_ftt_dedup

For detailed description and example use of the function, see vt_drop_ftt in the Functions Reference Guide.

20.8. Internationalization & Unicode

The text being indexed and the text query expression may both be wide strings. The word boundaries used to cut the text in words in both queries and index maintenance may depend on a language declared for the text index.

The default language has white space and punctuation as word delimiters and will recognize Unicode ideographic characters as self standing. A single non-ideographic character will always be considered noise and not indexed.

Non-ASCII Unicode values are converted to UTF8 before being stored into the word table as narrow strings. Narrow 8 bit strings are stored in the words table as is.

See Also:
The LANGUAGE option in CREATE TEXT INDEX .

20.9. Performance

For indexing large volumes it is critical to run the indexing process over large volumes of data. This is accomplished by using the batch update mode. This is activated with the VT_BATCH_UPDATE procedure.

When this mode is on the index will be updated after a settable interval, doing all the updates accumulated since the last batch in a single go. The size of a single batch is configurable in the virtuoso.ini file using the FreeTextBatchSize option. This is the number of bytes of text which will be processed as one sweep over the index. A value of 1MB is often suitable. Even All changes are processed in a batch at the set interval. If there are more characters of text to index / unindex than the batch size, the operation is broken into several transactions, each processing about FreeTextBatchSize bytes worth of text. This improves concurrency and cuts down on locking.

The command

```
DB.DBA.vt_batch_update ('DB.DBA.ARTICLE', 'ON', 1);
```

turns on the batch mode for the article table with a 1 minute delay between index refreshes. The table name must be fully qualified and is case sensitive. The correct case is seen in the administration interface tables list of the isql tables command etc.

20.9.1. Restrictions

If the free text document ID is an integer, which is encouraged for compactness, the values 0 and negative are reserved.

20.10. Free Text Functions

20.10.1. vt_batch_dedup

For detailed description and example use of the function, see vt_batch in the Functions Reference Guide.

20.10.2. vt_batch_d_id_dedup

For detailed description and example use of the function, see vt_batch_d_id in the Functions Reference Guide.

20.10.3. vt_batch_feed_dedup

For detailed description and example use of the function, see vt_batch_feed in the Functions Reference Guide.

20.10.4. vt_batch_feed_offband_dedup

For detailed description and example use of the function, see vt_batch_feed_offband in the Functions Reference Guide.

20.10.5. vt_batch_update_dedup

For detailed description and example use of the function, see vt_batch_update in the Functions Reference Guide.

20.10.6. vt_is_noise_dedup

For detailed description and example use of the function, see vt_is_noise in the Functions Reference Guide.

20.11.

Text index log table. In case of batch update mode this table is used to store a log of actions over text indexed table.

```
VTLOG_<table> (
  VTLOG_<document_id_col> ANY NOT NULL PRIMARY KEY,
                        -- references text indexed table by document id
  SNAPTIME DATETIME,
                        -- time of insert/update/delete action
  DMLTYPE VARCHAR (1),
                        -- type of log 'I' 'U' 'D' for insert, update or delete
  VT_DISTINCT_WORDS LONG VARBINARY,
                        -- in case of update or delete are stored words which should be deleted
  VT_OFFBAND_DATA LONG VARCHAR
                        -- in case of update or delete are stored offband data should be deleted
)
```

Text index batch procedure. This procedure log, process and stores already filled _vt_batch, caused storing of words in index table.

```
VT_BATCH_PROCESS_<table> (inout _vt_batch any)
```

Text trigger hook function. This function, for existing text trigger definition, applies the filtering queries (if defined) to the _strings, and if the _vt_batch matches any of them then add new record in HITS table (see Text trigger)

```
VT_HITS_<table> (inout _vt_batch any, inout _strings any);
```

Text index words table. This table maintains distinct words collected from all documents from text indexed table.

```
<table>_<column>_WORDS (
  VT_WORD VARCHAR,  -- distinct word
  VT_D_ID ANY,  -- referencing the first matching
                        -- document id in text indexed table
  VT_D_ID_2 ANY,  -- referencing the last matching document
                        -- id in text indexed table
  VT_DATA VARCHAR,  -- string with document id's and word
                        -- positions where the word is matched
  VT_LONG_DATA LONG VARCHAR, -- the same as VT_DATA but in a
                        -- case of large amount of data
  PRIMARY KEY (VT_WORD, VT_D_ID)
)
```

Text indexing procedure, using for clearing and creating the text index. If flag is equal to 1 then index data will be cleared, else if equal to 0 then index data will generated. Note that for large tables generating the index can run for a long time and the server will go into atomic mode.

```
VT_INDEX_<table> (in _flag integer)
```

Procedure for incremental update of text index. In case of batch mode update this procedure must be called to process the entries in log table and refresh text index data. Before calling this function the contains/xcontains predicate may not match the newest inserted, updated or deleted documents. This function is also registered for scheduled action if the vt_batch_update() function is called with refresh interval greater than zero. (See vt_batch_update function)

```
VT_INC_INDEX_<table> ()
```

Text indexing and unindexing hook procedures. These are user-defined procedure which can access additional related data and perform preprocessing and call vt_batch_feed inside. These procedures receive the free text id as argument and can use this to retrieve data related to the row being indexed. If the text index is created with 'USING FUNCTION' clause then internally generated procedures and functions will include calls to these. If these procedures return 1 then the caller will skip filling a vt_batch, assuming the hook function already filled it, otherwise the caller will proceed as if there had been no hook.

The difference between these two functions is that ..._INDEX_HOOK will be called upon insertion of new data or after update, but .._UNINDEX_HOOK will be called after delete or before update on the text indexed table.

Note:

This function is USER-DEFINED, the user can create it before or after creating a text index.

In the second case the text index MUST be create with the 'NOT INSERT' option. After the hook is defined, the index can be filled with with 'VT_INDEX_<table>(0)' procedure.

```
<table>_<column>_INDEX_HOOK (inout _vt_batch any, inout d_id any)
<table>_<column>_UNINDEX_HOOK (inout _vt_batch any, inout d_id any)
```

Example 20.8. Free Text

```
create table fth (id integer not null primary key, dt varchar, c1 varchar);

create procedure fth_dt_index_hook (inout vtb any, inout d_id integer)
{
  declare data any;
  data := coalesce ((select concat (dt, ' ', c1)
        from fth where id = d_id), null);
  if (data is null)
    return 0;
  vt_batch_feed (vtb, data, 0);
  return 1;
}

create procedure fth_dt_unindex_hook (inout vtb any, inout d_id integer)
{
  declare data any;
  data := coalesce ((select concat (dt, ' ', c1)
        from fth where id = d_id), null);
  if (data is null)
    return 0;
  vt_batch_feed (vtb, data, 1);
    return 1;
}

insert into fth values (1, 'abc', 'one');

create text index on fth (dt) with key id using function;
```

test the text index:

```
select id from fth where contains (dt, 'abc');
select id from fth where contains (dt, 'one');
```

Both select statements will return 1 because the content is concatenated with an additional column.

Note that in the case of using additional columns, they should be added as offband data to the text index, otherwise update them will not affect the index.

```
<table>_<column>_QUERY table (see Text trigger definition)
<table>_<column>_USER table (see Text trigger definition)
<table>_<column>_HIT table (see Text trigger definition)
TT_QUERY_<table>_<column> procedure (see Text trigger definition)
```

Table for text indexes system information

```
SYS_VT_INDEX (
  VI_TABLE VARCHAR,  -- Fully qualified text indexed table name
  VI_INDEX VARCHAR,  -- Index name
  VI_COL VARCHAR,  -- Data column name
  VI_ID_COL VARCHAR,  -- Document id column name
  VI_INDEX_TABLE VARCHAR,  -- fully qualified name of table with words
                           -- (See: <table>_<column>_WORDS table)
  VI_ID_IS_PK INTEGER,  -- if the document id is specified by user or
```

```
                        -- used primary key then it equal to 1
VI_ID_CONSTR VARCHAR,  -- serialized value with id column(s) names
VI_OFFBAND_COLS VARCHAR,  -- serialized value of offband data columns names
VI_OPTIONS VARCHAR,  -- reserved
VI_LANGUAGE VARCHAR,  -- language which applied to the document contents
PRIMARY KEY (VI_TABLE, VI_COL))
```

Chapter 21. TPC C Benchmark Kit

Abstract

The Virtuoso TPC C Kit is a database benchmark written in C and SQL stored procedures using the CLI or ODBC API. It is modeled after the industry standard Transaction Processing Performance Council (TPC) C benchmark and can be used as a component in an official benchmark but does not in itself constitute a complete test driver.

See Also:

A complete description of the benchmark and its metric can be found at the TPC Web Site . This document assumes the reader is familiar with the general content of the benchmark.

The C and SQL source of the benchmark is contained in the sample directory of the Virtuoso tree. The tpcc executable is built by running make after choosing the target (see makefile).

21.1. Building the Test Database

To build a 1 warehouse test database (approximately 100 MB), go through the following procedure:

Start the database server.

Assuming the server is listening at the default port of 1111 on the local host execute:

```
isql 1111 dba dba tpccddk.sql
tpcc 1111 dba dba I 1
```

to create a 1 warehouse database. This may take some time. As long as the file gets longer everything is OK. You may follow the progress with interactive SQL.

Once the tpcc program exits you can load the stored procedures used by the benchmark. Assuming the server is listening at the default port of 1111 and that the dba password is the default `dba', type:

```
../isql 1111 dba dba tpcc.sql
```

This will exit when the procedures are loaded, typically a few seconds.

To complete the initialization make a checkpoint to freeze the initial database state:

```
./isql 1111
SQL> checkpoint;
Done.
SQL> exit;
```

The database is now ready for use.

21.2. Using the Test Program

The tpcc program simulates one user making random transactions according to the specified mix of:

```
10 new order transactions, each with 10 order lines
10 payment transactions, 60% by name
1 delivery transaction
1 stock level transaction
1 order status transaction, 60% by name.
```

Each instance of the test program has a home warehouse on which it does most of its operations. If there are more than one operation the test program will give a supply warehouse different from the local warehouse to 10% of new order lines.

The test is started with:

```
tpcc <database> <username> <password> r
        <n-10-new-order-sets> <local warehouse> <n warehouses>
```

e.g.

```
./tpcc 1111 dba dba r 10
```

for 10 sets of the transaction mix on warehouse 1 in a 1 warehouse database or,

```
./tpcc 1111 r 100 12 100
```

to perform 100 sets of transactions on warehouse 12 in a 100 warehouse database.

The program reports a tpmC rate after performing each set of 10 new orders and the related support transactions. A statistic will be printed every 10 sets of 10 new orders showing the time spent on each of the benchmark transactions done during the last run of 100 new orders, 100 payments 10 deliveries, stock levels and order status queries.

The throughput will increase during the first minutes of the run to level off at the attained rate.

21.3. Tuning Parameters and Number of Users

You may run several instances of tpcc, each representing one user. You will see CPU utilization improve as users are added since there are more possibilities of interleaving I/O and CPU.

The amount of RAM (number_of_buffers: in wi.cfg) is the single most important factor influencing throughput. Setting this to about half the system RAM is usually good. One will remember that each buffer takes 8.5K of actual RAM. One should be careful not to cause the server process to swap.

Striping should be used if there are multiple independent disks, one stripe per physically independent volume. Each stripe should have its own I/O queue. If there is a RAID, then striping is less beneficial. Also one should have multiple handles per files, see FDSPerFile in the configuration file.

21.4. Omissions, Exceptions from the Definition

Running the benchmark by the book is a complex and costly process which requires hardware and software that is not commonly available.

To measure tpmC rates that are directly comparable with published figures the benchmark must comply with the scaling rule of a maximum of 12.5 tpmC per warehouse. Therefore to measure 1250 tpmC, one must have a database of 100 warehouses, approximately 10 GB.

Obtaining a good figure will require the maximum RAM configuration of the platform in question.

One will further remember the 180 day rule which states that the disk configuration quoted in the pricing section must be large enough to accommodate 180 8 hour days worth of new orders coming in at the reported rate.

The number of users will also be large, e.g. 1000 users for the 1200 tpmC result, based on 10 terminals per warehouse.

Almost all published results have been obtained with a transaction monitor, typically Tuxedo.

Note that the driver in this kit initiates a new transaction as soon as the previous one is completed. The correct behavior is to generate transactions at a basically constant rate, load being increased by adding clients and a new warehouse every 10 clients.

See Also:

The complete benchmark specification is available at the TPC Web Site .

21.5. Sample Configuration

This section describes how to set up disks and I/O for a sample run. To begin with, the scaling rule is 12.5 tpmC per warehouse. This means that in order to measure 1000 tpmC you must have a 1000 / 12.5 = 81 warehouses. These take about 100 MB apiece.

The benchmark's working set consists of the STOCK and CUSTOMER tables of each warehouse and of the ITEM table of the database. Other tables are accessed more or less sequentially, i.e. inserts to end or deletes from start. There is a particular distribution of hits for the STOCK and CUSTOMER rows of each warehouse, leading to a specific working set within each.

The 160 day rule requires a disk configuration sufficient for accumulating 160 days worth of transactions at the reported rate. For practical reasons we will ignore this rule here. To just run the benchmark for the required 20 minutes we will need about twice the space of the initial data. Let's assume we have an initial database of 8 GB and have another 16 GB for working space, a total of 24 GB. This is 6 4 GB disks or 12 2 GB ones.

Let's now look at the relationship between CPU and disk usage. The New Order transaction, which mostly defines the benchmark's working set consists of an average of 10 updates to the STOCK table, which mostly cause disk reads, 10 reads of the ITEM table which is always in cache, 10 ascending ORDER_LINE inserts, 1 ascending ORDERS insert and 1 CUSTOMER read plus a DISTRICT update and WAREHOUSE read.

If this happens entirely in RAM this takes about 10 milliseconds on a 200 MHz Pentium Pro, 13 on an Ultra SPARC and so on. Which is roughly as long a one random disk seek takes.

Because the scaling rule limits RAM to cover only 10% to 20% of the working set, the STOCK updates will miss the cache most of the time. This with a transaction mix of New Orders only, we would need about 8 disk seeks to be in progress concurrently in order to feed one CPU. The other transactions are either more local or repeat the New Order access profile. Thus we end up needing about 5 concurrent 10 msec disks for one Power PC 604 and almost double for a 200 MHz Pentium Pro.

For our 24 GB configuration we may as well divide it over as many stripes as we have disks. For 6 4 GB disks, we would have:

```
[Striping]
Segment1 = 24G,  /disk1/tpcc-1-1.db = q1, /disk2/tpcc-1-2.db = q2,  /disk3/tpcc-1-3.db = q3,  /disk4/tpcc
```

Assuming we have file systems. Note the I/O queue names q1...q6, meaning that each stripe gets processed on a separate thread for I/O.

See

Disk Configuration for more on this.

Your Virtuoso may or may not support raw devices. If it does, they are specified here.

For the other configuration parameters, we will have sufficient RAM configured for the DBMS, counting 8.5K of RAM for each buffer. For 512 MB of RAM, we would have about 25000 buffers. The maximum dirty parameter is more tricky. A low number causes unnecessary writing and a high value causes the number of clean buffers at any time being too low, causing an imperfect match of the read working set. The read-only set is only the ITEM table, about 20 MB.

Note:

Note that about half of the available RAM can efficiently be allocated to the database, allocating all RAM may result in swapping due to the OS's disk caching. In terms of kernel tuning, if one can decrease the OS cache, one may increase the RAM utilizable by the DBMS without the OS's disk cache getting in the way.

The Stock Level transaction reads lines written by recent New Order transactions, which are likely to be in RAM and still dirty. The reads and updates of CUSTOMER are random and generally speaking what is read is also likely to be or have been updated.

We could start with a guess of 70% maximum dirty, i.e. a value of 70000 for 100000 buffers.

The checkpoint remap should be as large as possible and the unremap quota should be small. The benchmark does practically no sequential reads and therefore does not care about disk locality. No limit on remapping means that a checkpoint can be made in the time it takes to flush the disk cache. This is done in the background, so that the atomic checkpoint time is limited to the time it takes to write out those buffers that became dirty while the first sweep was in progress.

Thus we could have:

```
MaxCheckpointRemap = 2000000
UnremapQuota = 3000
```

21.6. Other Factors

Benchmarks are run with a transaction monitor, usually Tuxedo. This has not been discussed here. Multiprocessor questions have not been addressed either. Virtuoso off the box should scale to about 4 CPU's on any appropriate multithreaded, multiprocessor OS. Past 4 CPU's the returns will diminish.

Operating systems have different caching policies which must be taken into account. If an OS does read ahead, that's OK. Generally OS intelligence is harmful and should be turned off. For example, AIX reacts to its disk write queue being full by turning off the writing process until it has flushed enough of its own file cache. This instead of blocking the writing thread and leaving the rest of the process to run.

We may release more information on OS tuning in the future.

21.7. TPC C Procedures

21.7.1. Introduction

This document goes through the TPC C sample and explains how and why the transaction procedures are written as they are.

This describes the five transactions in the benchmark and points out how the procedures are written and which features of the language are used where. See the sample/tpcc.sql and sample/tpcctrx.c files along with this commentary.

See Also:

For a formal benchmark definition, see the documentation at the TPC Web Site .

21.7.2. New Order

- Passing parameters
- Using positioned operations
- Using read for update
- Order of locking
- Application-defined SQL STATE

The new_order procedure implements this transaction. It accepts the warehouse, district and customer data and the item, quantity and supply warehouse id for up to ten order lines.

The transaction profile requires this to update the stock level for each order line, add a row to ORDERS and NEW_ORDER and a row to ORDER_LINE for each order line. This also reads the customer, updates the district and reads the warehouse. This all needs to take place as one transaction with a high integrity requirement.

The procedure begins by updating the stock levels. This is the part with lowest locality and thus most likely to cause I/O and least likely to cause lock contention. Most of the transaction's real time will be spent inside ol_stock. If the order lines are sorted in order of item id, new order transactions will never deadlock on the stock level part. This will maximize the number of concurrent new orders on one warehouse.

```
CREATE PROCEDURE OL_STOCK (
        INOUT   OL_I_ID          INTEGER,
        IN      OL_SUPPLY_W_ID   INTEGER,
        IN      OL_QTY           INTEGER,
        OUT     AMOUNT           FLOAT)
```

```
{
    IF (OL_I_ID = -1) RETURN;

    DECLARE S_DATA,
        S_DIST_01, S_DIST_02, S_DIST_03, S_DIST_04, S_DIST_05,
        S_DIST_06, S_DIST_07, S_DIST_08, S_DIST_09, S_DIST_10 VARCHAR;
    DECLARE S_QUANTITY INTEGER;
    DECLARE I_PRICE FLOAT;

    WHENEVER NOT FOUND GOTO NO_ITEM;

    SELECT I_PRICE INTO I_PRICE FROM ITEM WHERE I_ID = OL_I_ID;

    DECLARE S_CUR CURSOR FOR
        SELECT
            S_QUANTITY, S_DATA,
            S_DIST_01, S_DIST_02, S_DIST_03, S_DIST_04, S_DIST_05,
            S_DIST_06, S_DIST_07, S_DIST_08, S_DIST_09, S_DIST_10
        FROM
            STOCK
        WHERE
              S_I_ID = OL_I_ID
          AND S_W_ID = OL_SUPPLY_W_ID;

    WHENEVER NOT FOUND GOTO NO_STOCK;

    OPEN S_CUR (EXCLUSIVE);

    FETCH S_CUR INTO
        S_QUANTITY, S_DATA,
        S_DIST_01, S_DIST_02, S_DIST_03, S_DIST_04, S_DIST_05,
        S_DIST_06, S_DIST_07, S_DIST_08, S_DIST_09, S_DIST_10;

    IF (S_QUANTITY < OL_QTY)
        S_QUANTITY := S_QUANTITY - OL_QTY + 91;
    ELSE
        S_QUANTITY := S_QUANTITY - OL_QTY;

    UPDATE STOCK SET S_QUANTITY = S_QUANTITY WHERE CURRENT OF S_CUR;

    AMOUNT := OL_QTY * I_PRICE;

    RETURN;

NO_STOCK: SIGNAL ('NOSTK', 'NO STOCK ROW FOUND.');
NO_ITEM:  SIGNAL ('NOITM', 'NO ITEM ROW FOUND.');
}
```

This procedure first reads the I_PRICE from ITEM and update the S_QUANTITY in STOCK. The price of the order line is returned as output parameter amount.

 **Note**

- Use inout parameters if possible. The inout (call by reference) is the fastest way of passing parameters.
- When reading a table with the intention of updating the row afterwards, use a cursor and positioned update.
- Use the EXCLUSIVE option in opening the cursor. This causes the read to put an exclusive lock on the row, which eliminates deadlocks caused by a shared read followed by an update. This deadlocks if there are more than one readers at the time of the update.
- Use `whenever not found' and signal to signal exceptions (no item or stock line).

When the stock level for all order lines has been updated this reads the customer data.

The bottleneck in terms of serialization is the read-update of the district, where the order gets an O_ID. This must be done as late as possible but has to precede the inserts, since these will use the O_ID. Note the exclusive cursor again.

To finish the transaction new_order insert ORDERS, NOW_ORDER and ORDER_LINE. These are basically in ascending order for each district and have high locality. Note the call by reference (inout) for ol_insert.

21.7.3. Payment

The payment transaction reads and updates the customer. The customer may either be identified by its last name or its C_ID. In the case the last name this chooses the middle row of the set of customers sharing the same last name, ordered by first name. Note the select count and the cursor.

The transaction profile does not offer possibilities of optimization.

21.7.4. Delivery

The delivery transaction reads and deletes a line from NEW_ORDER and updated the corresponding ORDERS and ORDER_LINE rows. The rules allow committing the transaction after processing each order. The client calls this procedure ten times with a different d_id parameter once every ten new orders. It is better to have the 1 to 10 loop in the client in order to keep locks on for the least time possible.

We use a cursor to read NEW_ORDER. Note the open no_cur (exclusive, prefetch 1). The prefetch 1 means we only intend to get one row. This prevents the cursor from prefetching more rows, which would be useless here.

Otherwise the transaction does not leave room for optimization.

21.7.5. Order Status

This transaction picks the last order of a given customer. It uses a select in descending order to locate it.

This is a read only transaction. Note the use of SQL_CONCURRENCY in the client code for specifying historical read mode. This eliminates locking.

Note

The ORDER BY clause must list all key parts of the index to be used, all with either ASC or DESC ordering in order to specify that index.

This transaction could be implemented in principle using the ORDERS primary key, O_W_ID, O_D_ID, O_ID. This would read in descending order until finding a row with a given C_IC. There being 3000 customers per district this could cause an average 1500 lines to check before finding the right one. Since the distribution of O_C_ID is not even the above is not entirely correct but close enough. The other possibility is having a separate index, O_W_ID, O_D_ID, O_C_ID, O_ID for this transaction. The trade-off being 1500 serial reads against 10 random insert (10 new order per one order status) we choose to have the extra index.

21.7.6. Stock Level

This is a complex read-only transaction. This finds all distinct items which have been ordered within the last n orders from a district having a stock level lower than a given threshold. The SQL statement:

```
SELECT
    COUNT (DISTINCT S_I_ID) INTO N_ITEMS
FROM
    ORDER_LINE, STOCK
WHERE
        OL_W_ID = W_ID
    AND OL_D_ID = D_ID
    AND OL_O_ID < LAST_O
    AND OL_O_ID >= LAST_O - 20
    AND S_W_ID = W_ID
    AND S_I_ID = OL_I_ID
    AND S_QUANTITY < THRESHOLD;
```

is the fastest way of getting this. Note that the ORDER_LINE is the driving table of join (leftmost in FROM). Also not the use of historical read in the client (SQL_CONCURRENCY option).

21.8. DDL Statements

```
CREATE TABLE WAREHOUSE (
    W_ID                INTEGER,

Chapter 22. Using Virtuoso with Tuxedo

Abstract

BEA Tuxedo provides the framework, or middleware, for building scalable multi-tier client/server applications in heterogeneous (dissimilar), distributed environments that extend from the Web to the Enterprise. Using BEA Tuxedo, users can develop, manage, and deploy distributed applications independently of the underlying hardware, operating system, network, and database environment.

The current document covers linkage between Virtuoso server and Tuxedo by ATMI (Application-to-Transaction Monitor Interface) only.

In contrast to classic 2-tier client/server configuration of SQL servers, the Tuxedo brings 3-tier paradigm (clients, services, resource managers).

At the foundation of BEA Tuxedo ATMI is a proven, reliable transaction processor, also known as a transaction processing (TP) monitor. A transaction processor is an example of a 3-tier client/server architecture, where the transaction processor supports the application logic (represented by "services" between the GUI front-end and the back-end resource managers. Examples of resource managers are SQL databases, message queues, legacy applications, and other back-end services.

This document explains how to build support binaries for Tuxedo and Virtuoso and how to write services which use the Virtuoso as resource manager.

22.1. Building the Transaction Manager Server

First of all, the administrator needs to build Virtuoso Transaction Manager Server application in order to use Virtuoso server as Resource Manager of global transactions operated by Tuxedo.

Then, the following line needs to be put in the $TUXDIR/udataobj/RM file:

```
Virtuoso:virt_xa_switch: libvirtxa.a -L${HOME}/lib  -lwic -ldk1t -lthrp -lutil2 -
```

The libvirtxa.a library could be found in tuxedo/lib directory.

This allows to build TP monitor with Virtuoso support (VirtTMS) and services which could use Virtuoso as resource manager. libvirtxa.a and other libraries must be accessible by the compiler. The following command builds the VirtTMS:

```
buildtms -o ${TUXDIR}/bin/VirtTMS -r Virtuoso
```

22.2. Configuration

In order to use Virtuoso as resource manager the UBB config file (Tuxedo main configuration file) must contain reference to VirtTMS. The following example of UBB config file configures two services and two virtuoso servers (resource managers) behind them.

```
*RESOURCES
IPCKEY          52617
DOMAINID        qsample
MASTER          NODE
```

```
MODEL           SHM
#
*MACHINES
#
NODE
        LMID = NODE
        TUXDIR = "TUXEDODIR"
        TUXCONFIG = "SERVDIR/tuxconfig"
        TLOGDEVICE ="SERVDIR/tuxconfig"
        TLOGSIZE=10
        APPDIR = "SERVDIR"
        ULOGPFX = "SERVDIR/ULOG"
*GROUPS

DEFAULT:        TMSNAME=VirtTMS TMSCOUNT=2 LMID=NODE
GROUP1  GRPNO=1 OPENINFO = "Virtuoso:dba:dba@NODE:1111"
GROUP2  GRPNO=2 OPENINFO = "Virtuoso:dba@NODE:1112"

*SERVERS
#
DEFAULT:        CLOPT="-A"
VirtRMtest      SRVGRP=GROUP1 SRVID=1
# VirtRMtest    SRVGRP=GROUP2 SRVID=1

# VirtRMtest2   SRVGRP=GROUP1 SRVID=2
VirtRMtest2     SRVGRP=GROUP2 SRVID=2

#server         SRVGRP=GROUP1 SRVID=1
*SERVICES
DEFAULT:        LOAD=50
VRMTEST         PRIO=50
VRMTEST2        PRIO=50
```

22.3. Services

22.3.1. Introduction

The services (in the Tuxedo's term) are special programs which implement business logic. The services could be in the context of a global XA transaction, in this case 2PC control will be set in motion. Each service which uses Virtuoso as resource manager has hdbc connection to the Virtuoso server. This connection is automatically opened when service activated. The connection string (OPENINFO) to the Virtuoso server is the connection string of the group of the service (see GROUPS section in the sample config file). The OPENINFO has the following format: "Virtuoso:user:password@NODENAME:port". The user,password and port are optional.

22.3.2. VQL functions

VQL functions are used to receive access to hdbc for further work with the Virtuoso server. Only HDBCs received by the VQL functions are operated in the context of the distributed transactions.

```
int vql_get_connection (HDBC * hdbc, int type);
```

returns result of setting hdbc to current hdbc connection. "type" argument indicates which hdbc is to select, currently only VQL_CTX_TYPE is supported, other values are reserved.

```
int vql_get_env (HENV * env);
```

returns result of setting current ODBC environment.

Header: vql_client.h

Library: libvirtxa.a

22.3.3. Services concept

Each service has an entry point (some function), which is supposed to perform the application task. The result of whole transaction depends on result of the service's entry function. The scenario of typical workflow is as follows:

- client begins global transaction by ATMI tpbegin() call,
- client calls the service N1 to update some tables on the first Virtuoso server (resource manager),
- client calls the service N2 to update some tables on the second Virtuoso server (resource manager),
- client finishes global transaction by either tpcommit() or tpabort() call of ATMI.

The tx_* functions also could be used, See TUXEDO TxRPC related or ORACLE XA documentation.

- tx_begin()
- tx_commit()
- tx_open()

Services can be built with the following command:

```
buildserver -v -f virt_service1.o -o VirtService1 -r Virtuoso -s VService1
```

where "virt_service1.o" is the service object file which contains VService1 entry function. "-r Virtuoso" indicates that service must be assembled with Virtuoso XA support library.

22.3.4. OPENINFO

OPENINFO is necessary for services to connect to the certain Virtuoso server. OPENINFO for the services (see GROUPS section in the example) consists of 2 parts: "Virtuoso" term and connection string. Connection string provides the service name, password, server and port of Virtuoso server. Common format of connection string is [USER[:PASSWORD]]@SERVER[:PORT]. Only the SERVER name is required, the others are optional.

22.4. Clients

There are no special requirements for the clients of services which use Virtuoso as resource manager. See Tuxedo 8.x documentation

22.5. Service example

```
#include <stdio.h>

Chapter 23. Appendix A

Abstract

This reference chapter contains information that needs to be found quickly and accurately without specific guide lines to the topics in question. This chapter contains the SQL Grammar, listings of all system errors messages, release notes for the product, how to get support on the product and a list of the system tables and there schema definitions.

23.1. YACC SQL Grammar Reference

<title>SQL Runtime Error</title>
SR000 22023 <function_name> expects a vector, not an arg of type <dv_type>

SR001 37000 More than one resultset not supported in a procedure called from exec

SR002 22023 Function <function_name> needs a string output as argument <index>, not an arg of type <type_name> (<dv_type>)

SR003 22023 Function <function_name> needs an XML entity as argument <index>, not an arg of type <type_name> (<dv_type>)

SR004 22023 Function <function_name> needs a binary as argument <index>, not an arg of type <type_name> (<dv_type>)

SR005 22023 Function <function_name> needs a string or NULL as argument <index>, not an arg of type <type_name> (<dv_type>)

SR006 22023 Function <function_name> needs a string or NULL as argument <index>, not an arg of type <type_name> (<dv_type>)

SR007 22023 Function <function_name> needs a string or NULL as argument <index>, not an arg of type <type_name> (<dv_type>)

SR008 22023 Function <function_name> needs an integer as argument <index>, not an arg of type <type_name> (<dv_type>)

SR009 22023 Function <function_name> needs a float as argument <index>, not an arg of type <type_name> (<dv_type>)

SR010 22023 Function <function_name> needs a double as argument <index>, not an arg of type <type_name> (<dv_type>)

SR011 22023 Function <function_name> needs an int or a string as argument <index>, not an arg of type <type_name> (<dv_type>)

SR012 22023 Function <function_name> needs a string or an array as argument <index>, not an arg of type <type_name> (<dv_type>)

SR013 22023 Function <function_name> needs a string or an array as argument <index>, not an arg of type <type_name> (<dv_type>)

SR014 22023 Function <function_name> needs a string as argument <index>, not an arg of type <type_name> (<dv_type>)

SR015 22023 Function length is not applicable to XML tree entity

SR016 22023 Function length needs a string or array as its argument, not an argument of type <type_name> (<dv_type>)

SR017 22003 aref: Bad array subscript (zero-based) <index> for an arg of type <type_name> and length <length>.

SR018 22023 non-generic vector for aref_set_0

SR019 22003 Bad subscript for aref_set_0

SR020 22003 Bad array subscript <index> in aset.

SR021 22003 make_array called with an invalid count <count>

SR022 22023 Type for make_array must be float, double, long or any

SR023 22023 Function subseq needs a string or object id as its first argument, not an arg of type <type_name> (<dv_type>)

SR024 22023 Function subseq needs integers or NULLs as its arguments 2 and 3, not an argument of type <type_name> (<dv_type>)

SR025 22011 subseq: Bad string subrange: from=<from>, to=<to>, len=<length>.

SR026 22011 substr: Bad string subrange: from=<from>, to=<to>, len=<length>.

SR027 22023 Source string arg (#1) to replace was not a wide string

SR028 22023 From arg (#2) to replace was not a wide string

SR029 22023 To arg (#3) to replace was not a wide string

SR030 22003 Too few arguments for <function_name>

SR031 22023 Invalid format string for sprintf at escape <index>

SR032 22026 sprintf escape <index> (<escape>) exceeds the internal buffer of 2000

SR033 22026 The length of the data for sprintf argument <index> exceed the maximum of 2000

SR034 22026 The length of the data for sprintf argument <index> exceed the maximum of 2000

SR035 22026 The length of the data for sprintf argument <index> exceed the maximum of 2000

SR036 22025 The URL escaping sprintf escape <index> doesn't support modifiers

SR037 22025 The HTTP escaping sprintf escape <index> doesn't support modifiers

SR038 22023 Invalid format string for sprintf

SR039 22023 The first argument to strstr is not a wide string

SR040 22023 The second argument to strstr is not a wide string

SR041 22023 Argument 1 of locate is not a wide string

SR042 22023 Argument 2 of locate is not a wide string

SR043 22019 the escape should be non-empty string in matches_like

SR044 22023 Function ascii needs a string or similar thing as its argument, not an argument of type <type_name> (<dv_type>)

SR045 22023 Function mod needs two integers as its arguments, not an argument of type <type_name> (<dv_type>)

SR046 22012 Division by zero in mod(<n1>,<n2>)

SR047 22023 Function sign needs a numeric type as its argument, not an argument of type <type_name> (<dv_type>)

SR048 22023 Function abs needs a numeric type as its argument, not an argument of type <type_name> (<dv_type>)

SR049 22023 Data type is not suitable for storage into a global variable (connection_set)

SR050 22023 connenction_vars_set expects a vector or null as argument not of type <type_name> (<dv_type>)

SR051 22023 connenction_vars_set expects a vector of even length, not of length <length> (of type <type_name> (<dv_type>))

SR052 22023 connenction_vars_set expects a string as name of connection variable not of type <type_name> (<dv_type>)

SR053 22023 Data type is not suitable for storage into a global variable (connection_set)

SR054 22023 Function oid_class_spec needs an object id as its argument, not an argument of type <type_name> (<dv_type>)

SR055 22023 Function oid_class_spec detected an object id whose length <length> < 4. oid[0]=<u1>. oid[1]=<u2>. oid[2]=<u3>

SR056 22023 <function_name> expects the type of item searched for <type_name> (<dv_type>) and the type of the vector searched from <type_name> (<dv_type>) to match. Veclen=<length>

SR057 22023 get_keyword expects a vector of even length, not of length <length> (of type <type_name> (<dv_type>))

SR058 22023 get_keyword expects a vector

SR059 22024 get_keyword_ucase expects a vector of even length, not of length <length> (of type <type_name> (<dv_type>))

SR060 22003 position: cannot check every 0th element of vector of type <type_name>

SR061 22023 position: expects a vector whose length is divisible by <d>, not of length <d2> (of type <type_name> (<dv_type>))

SR062 22023 Row in a row function is not a valid row string

SR063 22023 row string must begin with container header

SR064 22015 Conversion overflow from numeric

SR065 22023 Can't convert SQL_DATA_AT_EXEC blob to varchar. Parameter may only be used in insert or update

SR066 22023 Unsupported case in CONVERT

SR067 22023 Collation specified in cast for non-string datatype <type_name>

SR068 22023 XML tree cannot be used as argument of blob_to_string[_output]

SR069 22001 Attempt to convert a persistent XML document longer than VARCHAR maximum in blob_to_string

SR070 22023 blob_to_string[_output] requires a blob or string argument

SR071 22023 Blob argument to blob_to_string[_output] must be a non-interactive blob

SR072 22001 Blob longer than maximum string length not allowed in blob_to_string

SR073 22023 Function log_text needs an array as argument <index> not BLOB HANDLE

SR074 25000 replay must be run in a fresh transaction.

SR075 22023 Bad isolation. Must be uncommitted / committed / repeatable / serializable

SR076 22023 ISOLATION option needs a string as value (uncommitted / committed / repeatable / serializable)

SR077 42S22 Bad option for SET

SR078 22005 The cursor parameter is not settable

SR079 22023 Too few arguments to exec_next(cursor, state, message, row)

SR080 22023 Parameter 4 is not a valid local exec handle

SR081 22023 Parameter 1 is not a valid local exec handle

SR082 22003 Non numeric comparison

SR083 Numeric error (22003 Numeric value out of range | 22012 Division by zero | 37000 Syntax error | S1000 General error | S1107 Row value out of range | 22012 Division by 0)

SR084 42S22 The column <column_name> is not defined in the given table

SR085 22012 Division by 0

SR086 22012 Division by 0

SR087 22003 Non numeric arguments to arithmetic operation

SR088 22012 Division by 0

SR089 22012 Division by 0

SR090 22012 Division by 0

SR091 22003 Non numeric arguments to arithmetic operation modulo

SR092 42000 system call not allowed on this server

SR093 22000 Error in compressing

SR094 22023 string_output_gz_compress needs a string_output as a first argument, not an argument of type <type> (<DV_type>)

SR095 22023 gz_uncompress needs a string_output as a second argument, not an argument of type <type> (<DV_type>)

SR096 21S01 Function crypt needs a string or integer as its second argument. Not an arg of type <type> (<DV_type>)

SR097 2201B regexp error : could not obtain substring (<offset> of <length>)

SR098 2201B regexp error after: <pattern> (<error>)

SR099 22023 BLOB submitted by client as SQL_DATA_AT_EXEC cannot be converted into anything. It must first be stored into a BLOB column

SR100 22003 The requested subsequence of BLOB is longer than 10Mb, thus it cannot be stored as a string

SR101 22023 BLOB submitted by client as SQL_DATA_AT_EXEC cannot be converted into anything. It must first be stored into a BLOB column

SR102 22026 Error in compressing (invalid input)

SR103 Zlib error (22000 Error in compressing | 22003 Error in compressing (compression level parameter is invalid) | 22005 Error in compressing (not enough memory) | 22026 Error in compressing (not enough room in the output buffer))

SR104 22025 Error in decompressing

SR105 42000 Unclassified SQL error

SR106 40009 Out of disk on database

SR107 42000 Read only transaction for modify operation.

SR108 4000X Transaction could not commit after DDL statement. Last DDL statement rolled back.

SR109 42000 Cannot free global server lock if one does not hold it

SR110 42000 backup () must be the first operation in its transaction if the transaction is not read only

SR111 40009 Backup transaction failed

SR112 42000 Transaction not in backup mode

SR113 42000 backup_row needs a _ROW as argument

SR114 42000 Transaction not in backup mode

SR115 42000 Error writing backup_flush

SR116 42000 Transaction not in backup mode

SR117 42000 db_check () must be in read only, non-autocommit transaction mode. e.g. do it from isql in RO mode.

SR118 40009 Database check transaction failed

SR119 42S11 Key <key> has 0 parts. Create index probably failed

SR120 23000 Convert error or not possible to insert a value into a blob column

SR121 42000 Ruling part too long on <key>

SR122 42000 Row too long on <key>

SR123 42S12 Bad key id in row_insert

SR124 42S12 Bad key id in row_insert

SR125 42S12 key_insert: This table does not have this key

SR126 22018 Can't convert <column_name> to numeric

SR127 22003 Can't convert <column_name> to numeric

SR128 22003 Numeric value out of range for <column_name> (<col_scale>, <col_prec>)

SR129 22003 Numeric value out of range

SR130 22005 Bad value for numeric column <column_name>, dtp = <dtp_value>

SR131 22005 Cannot convert <string_value> to number for column <column_name>

SR132 22007 Bad value for date / time column

SR133 23000 Null assigned to non-null column

SR134 42000 A data at exec blob must be assigned to a blob column

SR135 42000 Blob too long to store in a non-blob column

SR136 42S02 Bad table name in GRANT / REVOKE <table_name>

SR137 42000 Bad user name in GRANT/REVOKE

SR138 37000 Operation not allowed for PUBLIC

SR139 42000 No group <group_name>

SR140 42000 The group <group_name> is already a secondary group for the user <user_name>. Delete it first with DELETE USER GROUP.

SR141 42000 No user <user_name>

SR142 37000 Operation not allowed for PUBLIC

SR143 42000 No group <group_name>

SR144 42000 Group <group_name> already assigned as a secondary group of <user_name>

SR145 42000 Group <group_name> already is a primary group of <user_name>

SR146 42000 No user <user_name>

SR147 37000 Operation not allowed for PUBLIC

SR148 42000 No group <group_name>

SR149 42000 No group <group_name> granted to <user_name>

SR150 42000 No Group <group_name> granted to <user_name>

SR151 42000 Group <group_name> is a primary group of <user_name>. Use SET USER GROUP instead

SR152 42000 No user <user_name>

SR153 28000 No user in delete user

SR154 42S02 No table or view in drop table

SR155 42S02 No table in alter table drop column

SR156 42S02 No table in table rename

SR157 42S02 No table alter table add column

SR158 42000 Permission denied. Must be owner of object or member of dba group.

SR159 42000 Function <function_name> restricted to dba group.

SR160 42000 Incorrect old password in set password

SR161 42000 Unsupported security statement.

SR162 07006 BLOB's not allowed in function refs.

SR163 42000 Ruling part too long.

SR164 42000 Error writing the BLOB onto a procedure view temp space

SR165 07006 Parameter BLOB in sorted result.

SR166 42000 Key too long in ORDER BY or DISTINCT temp table.

SR167 07006 Parameter BLOB in sorted result.

SR168 42000 Data too long in ORDER BY or DISTINCT temp table.

SR169 22023 signal state should be an integer 100 (NO DATA FOUND) or a string value, not an <type_name>

SR170 42000 Unsupported arithmetic op.

SR171 S1T00 Transaction timed out.

SR172 40001 Transaction deadlocked

SR173 40003 Transaction out of disk.

SR174 40004 Log out of disk.

SR175 23000 Uniqueness violation. Transaction killed.

SR176 4000X Transaction rolled back due to previous SQL error.

SR177 4000X Misc Transaction Error.

SR178 42000 Stack overflow

SR179 07S01 The function <function_name> does not accept a keyword parameter <param_name>

SR180 07S01 Extra arguments to <function_name>, takes only <number>

SR181 HY105 Cannot pass literal as reference parameter.

SR182 HY502 inout or out parameter <param_name> not supplied in keyword parameter call

SR183 07S01 Required argument <param_name> (no <index>) not supplied to <function_name>

SR184 42000 Built-in function is not allowed as the outermost function in a procedure view. Define an intermediate PL function to call the bif.

SR185 42001 Undefined procedure <procedure name>

SR186 42000 No permission to execute procedure <procedure_name>

SR187 07001 Too few actual parameters for <procedure_name>

SR188 HY105 Cannot pass literal as reference parameter.

SR189 HY008 Async statement killed by SQLCancel.

SR190 24000 Fetch of unopened cursor.

SR191 39000 Unsupported instruction AREF");

SR192 HY105 Like pattern not a string

SR193 HY105 Blob of <length> bytes in like

SR194 HY105 LIKE must be between strings.

SR195 HY001 No starting point for ancestor join

SR196 HY001 No place in from_position clause.

SR197 23000 Non unique primary key on <table_name>

SR198 HY109 Cursor not positioned on delete. <cursor_name>

SR199 HY109 The cursor in positioned DELETE was not on any row.

SR200 42S12 The row being deleted has no valid key.

SR201 42S12 Primary key not found in delete.

SR202 42000 Bad admin op code.

SR203 HY008 Async statement killed by SQLCancel.

SR204 22002 Missing named parameter

SR205 07001 Not enough actual parameters.

SR206 07001 Not enough actual parameters.

SR207 08004 Maximum licensed connections exceeded

SR208 08004 Application access is denied

SR209 S1010 Statement active

SR210 S1010 Async exec busy

SR211 41000 Aborted

SR212 S1010 Statement not prepared.

SR213 S1010 SQLFetch of busy

SR214 40001 Out of server threads. Server temporarily unavailable. Transaction rolled back.

SR215 42000 Too many triggers on <table_name>

SR216 22003 PL Scrollable cursor with a rowset > 1

SR217 01001 Optimistic cursor updated since last read"

SR218 HYC00 Cursor not capable of requested SQLSetPos operation

SR219 HY107 Row in SQLSetPos does not exist in the rowset

SR220 S1010 Unopened cursor referenced by SQLSetPos

SR221 S1010 Not a scrollable cursor in SQLSetPos

SR222 22003 PL cursor with a rowset greater then 1

SR223 HY111 Non static bookmark for a static cursor

SR224 HY111 Incompatible bookmark. Must be identical ordering and primary key columns

SR225 HY111 Static bookmark for a dynamic / keyset cursor

SR226 42000 Misc. cursor error

SR227 3C000 Non unique cursor name

SR228 07001 Too few actual parameters

SR229 42000 Misc. cursor error

SR230 S1010 Statement not executing or not scrollable cursor in SQLExtendedFetch

SR231 42S02 Cursor does not have table <table_name>

SR232 34000 No cursor <cursor_name>

SR233 22023 Wrong type of argument to __scroll_cr_init

SR234 22023 Function <function_name> needs a cursor as argument <index> , not an arg of type <type_name> (<dv_type>)

SR235 24000 Virtuoso/PL Scrollable cursor not opened

SR236 07001 scrollable fetch with different number of output columns

SR237 HY109 Row deleted

SR238 24000 Virtuoso/PL Scrollable cursor not opened

SR239 HY109 Virtuoso/PL Scrollable cursor not positioned on a row

SR240 HY090 Ruling part too long in scrolled current of reference.

SR241 HY109 Row referenced in where current of not present

SR242 42S22 No system status variable <name>

SR243 42S02 No table <table_name> in key_stat

SR244 22023 Allowed stat names are touches, reads, lock_set, lock_waits, deadlocks.

SR245 42S12 Index <key_name> not found in key_stat.

SR246 23000 Error or type mismatch inserting a blob

SR247 42000 Primary key ruling part too long in update

SR248 42000 Row too long in update

SR249 42000 Ruling part too long on <key_name>.

SR250 24000 Cursor not positioned on update. <cursor_name>

SR251 24000 Cursor not on row in positioned UPDATE

SR252 01001 Row deleted while waiting to update

SR253 42S12 Could not find primary key on update.

SR254 42000 The cursor specified is not a SELECT.

SR255 24000 Cursor before first or after end. No current row.

SR256 HY109 Cursor <cursor_name> does not have place.

SR257 34000 No cursor named <cursor_name>.

SR258 42000 The cursor specified is not a SELECT.

SR259 24000 Cursor <cursor_name> before first or after end. No current row.

SR260 HY109 Cursor <cursor_name> does not have place <name>.

SR261 23000 Non unique primary key.

SR262 24000 Cursor not positioned on positioned reference. <cursor_name>

SR263 24000 Cursor not on row in positioned UPDATE

SR264 42S12 Could not find primary key on update.

SR265 37000 Table being dropped is referenced in FOREIGN KEY

SR266 S0002 No table in drop table

SR267 37000 Table being dropped is referenced in FOREIGN KEY

SR268 42S02 No table in drop table

SR269 S0002 No trigger in drop trigger. Make sure the name is qualified with the subject table's qualifier and owner if these are not the default qualifier and owner

SR270 42000 No procedure in DROP PROCEDURE <proc_name>

SR271 42000 Must be in dba group to drop non-owned procedures

SR272 01006 Privilege has not been granted. Use list_grants (0) to see what you can revoke

SR273 42000 No user to delete

SR274 S1001 Column already exists in ALTER TABLE

SR275 42000 Column count too large

SR276 42S02 No table in add column

SR277 42S01 Table already exists in rename table.

SR278 42S02 Bad table in rename table

SR279 22023 parse_collation : invalid table size <size>

SR280 37000 The column is a key or primary key part. Drop the index first

SR281 37000 The column is referenced in foreign key constraint. Drop the foreign key first

SR282 42S22 The column to drop is not defined in the given table

SR283 42S02 No table in add column

SR284 22023 Charset definition is not correct

SR285 42000 Function user_set_password restricted to dba group

SR286 42000 The user <user_name> does not exist

SR287 42000 The new password for <user_name> cannot be empty

SR288 42S22 No columns in the source table <table_name>

SR289 42S22 No columns in the source table <table_name>

SR290 42S22 The column <column_name> in the source table <table_name> doesn't have a match in the destination table <table_name>

SR291 42S11 Primary key modification is prohibited if: Table is a subtable or has subtables, is attached or has a free text index

SR292 42S22 Bad new pk column list

SR293 22023 function fk_check_input_values expect -1, 0 or 1 as first parameter

SR294 42S22 Foreign key references invalid column <column_name> in referenced table <table_name>

SR295 37000 Foreign key references non-unique column <column_name> in table <table_name>

SR296 37000 To add foreign key REFERENCES should be specified

SR297 42S12 Foreign key does not exist in table <table_name> referencing table <table_name>

SR298 42S12 Foreign key <key_name> does not exists

SR299 37000 To drop foreign key should be specified NAME or REFERENCES

SR300 42S11 To modify a foreign key first drop the old and then add the new

SR301 37000 A primary key cannot be added or dropped. It can only be modified. Use alter table .. modify primary key ...

SR302 37000 To modify a unique constraint first drop the old and then add the new

SR303 22023 Function check_col needs string as argument

SR304 S1000 DELETE statement conflicted with COLUMN REFERENCE constraint <name>

SR305 S1000 UPDATE statement conflicted with COLUMN REFERENCE constraint <name>

SR306 S1000 INSERT statement conflicted with FOREIGN KEY constraint referencing table <table_name>

SR307 S1000 UPDATE statement conflicted with FOREIGN KEY constraint referencing table <table_name>

SR308 22023 exec() called with an invalid text to execute

SR309 22023 Non-encrypted session

SR310 22023 Invalid certificate info index

SR311 08004 Shutting down the server permitted only to DBA group

SR312 08004 The server is shutting down

SR313 42000 The procedure <proc_name> is part of a module <module>. Drop the module first.

SR314 42000 Trying to drop a module with drop procedure.

SR315 37000 Invalid module name in soap_sdl.

SR316 37000 No URL specified & soap_sdl called outside HTTP context.

SR317 37000 Invalid module name in soap_wsdl.

SR318 37000 No URL specified & soap_wsdl called outside HTTP context.

SR319 22026 Value too long to insert into VARCHAR column <col_name>.

SR320 42S12 Constraint <constraint name> does not exists for table <table>

SR321 37000 A RETURN statement with a return status can only be used in a stored procedure

SR322 22005 <option> is not valid trace_on option

SR323 22005 <option> is not valid trace_off option

SR324 08U01 Remote server has disconnected making the transaction uncommittable. Transaction has been rolled back.

SR325 S1T00 Transaction aborted due to a database checkpoint or database-wide atomic operation. Please retry transaction

SR326 42S02 No table in alter table modify column

SR327 42S02 ALTER TABLE not supported for views. Drop the view and recreate it instead.

SR328 42S02 ALTER TABLE not supported for views. Drop the view and recreate it instead.

HO001 22023 Invalid params type <tag> (<name>)

23.2.2. Data Type Errors

Each function that accepts parameters will check that each parameter is of the correct data type. A function will generate a SQL 22023 error value if a supplied parameter is not of the type expected.

23.3. Signals and Exit codes

This section presents the most important exit codes and signals for Virtuoso on Unix/Linux.

23.3.1. Exit codes

Table 23.2. Exit codes

Exit Code	Category	Comment
-1	FATAL	Unrecoverable condition detected like disk or memory full
0	NORMAL	Normal exit with success
1	WARNING	Some kind of failure at startup/shutdown, typically shown with a reason for this error
>1	UNKNOWN	Not used under normal operations
>128	SIGNAL	Virtuoso was killed by a signal it could not process. (error code = signal + 128)

23.3.2. Signals

Table 23.3. Signals

Signal	Name	Category	Comment
1	SIGHUP	NORMAL	Initiate quick shutdown when shell exits while running virtuoso in foreground mode
2	SIGINT	NORMAL	User pressed CTRL-C on Virtuoso running in foreground mode to initiate normal shutdown
3	SIGQUIT	NORMAL	User pressed CTRL-\ on Virtuoso running in foreground mode to initiate quick shutdown
4	SIGILL	FAULT	Illegal instruction resulting in a program crash
7	SIGBUS	FAULT	Misaligned mem read/write resulting in a program crash
8	SIGFPE	FAULT	Divide by 0 or other arithmetical error
9	SIGKILL	SPECIAL	Terminate Virtuoso without flushing dirty pages etc. This signal should NOT be used under normal operations.
11	SIGSEGV	FAULT	Buffer/stack overrun resulting in a program crash
13	SIGPIPE	IGNORED	Other side of a pipe was killed while this side tried to write data to it
15	SIGTERM	NORMAL	Initiate quick shutdown

Signals that are marked as *NORMAL* indicate that these signals can be sent by root or the owner of the virtuoso process to shutdown Virtuoso. The *SIGINT* and *SIGQUIT* signals also work when Virtuoso is running in background mode and can be used in shell scripts.

Signals that are marked as *FAULT* indicate an abnormal condition which should be checked. If enabled (e.g. with ulimit -c unlimited), the operating system can write a core dump allowing post-mortem debugging if the Virtuoso executable was compiled with debugging symbols.

Signals that are marked as *IGNORED* are handled inside Virtuoso.

The *SIGTERM* signal is mostly used by rc.d type shell scripts on Unix/Linux which are called during shutdown, but can also be used inside shell scripts.

The *SIGKILL* signal should only be used as a last resort when all other efforts to stop Virtuoso have failed.

Quick shutdown

In quick shutdown mode, Virtuoso will only flush dirty disk buffers, close transaction log and database files and exit to the operating system. Since Virtuoso does not perform a checkpoint, the next startup will take extra time as Virtuoso first needs to perform a rollback and a checkpoint before it can resume operation. The *SIGTERM* signal mostly used by rc.d type scripts on Unix/Linux which are called during shutdown as such instances it is better to quickly finish operations and delay the checkpoint until the next boot.

Normal shutdown

In normal shutdown mode, Virtuoso will do first do a full checkpoint, then flush dirty disk buffers, close transaction log and database files before exiting to the operating system. Depending on the size of the transaction log this can take some time. The

SIGINT signal can be used in stop scripts to cleanly shutdown the database by the dba or by root.

Note that in all cases signals can only be sent by the kernel, the root user or the uid of the person who started Virtuoso. Anyone else that wants to shutdown the Virtuoso instance should use the isql program to connect to Virtuoso and run the 'shutdown' command.

23.4. Release Notes

23.4.1. New Features

- *SOAP 1.1 Implementation* - this new release includes a wide range of new SOAP features, bringing it up to date with the most recent developments of this rapidly evolving technology :
  - Flexibility in configuring SOAP access points using a WEB based user interface allowing exposure of selected stored procedures as SOAP services. These procedures may be local or linked from any 3rd party databases. The effective privileges for running SOAP exposed procedures can also be set at the access point level.
  - Improved SOAP to Virtuoso/PL Language Binding allowing the receiving and returning of arbitrarily complex arrays and structures, using XML Schema to describe the mapping of Virtuoso internal types to precisely match specification expressed in XML Schema.
  - Automated generation of WSDL descriptions of SOAP access points - Simple procedure parameter lists map automatically to SOAP types described in XML Schema. For complex types, procedures can be annotated with explicit references to XML Schema types. Thus the developer has complete control over the presentation of web services.
  - Import of WSDL descriptions of outside web services. Virtuoso automatically generates Virtuoso/PL wrappers based on an outside WSDL file, making all its services transparently callable as stored procedures from Virtuoso/PL.
  - Virtuoso's SOAP client and server implementations pass the SOAP Interop tests levels 1, 2 and most of 3.
  - Virtuoso Service Module for XML (VSMX) is a mechanism provided by Virtuoso for testing SOAP messages by automatically generating a test page - a VSMX file - that has the extension .vsmx. The VSMX file is generated at the same time as the WSDL file is generated, giving instant access to your SOAP messages to test they perform as expected. Web Service developers would use VSMX to forego the test bed creation step in light of automatic test page generation. Project managers can easily keep track of their developers progress by checking the test page periodically.
- *XSLT 1.1 Implementation* - support for the XSLT 1.1 Draft Specification has been added.
- *Exposure of Stored Procedures as Web Services* - Stored procedures can be exposed as SOAP services very simply from Virtuoso, whether the procedures are native Virtuoso or on remote data sources. This powerful ability means that any database servers already existing within an organization can easily become a component in an eBusiness solution using Virtuoso.
- *XML Schema* - contains a built-in XML Schema 2001 validator. This is accessible from Virtuoso/PL as a function and is used for SOAP and XQuery where appropriate.
- *XML Templates* - Virtuoso XML templates allow execution of SQL/XML queries over HTTP to obtain an XML document in response and/or perform some operation in the database using updategrams. The XML Template file can be stored either on the file system, WebDAV repository or stored on another HTTP server being referenced by a URL parameter.
- *XQuery* - Virtuoso provides support for the XQuery 1.0 XML Query Language specification. This specification is currently in the working draft stage at the W3C XML Query Working Group working in collaboration with the W3C XSL Working Group.
- *Web DAV* - support for redirection of resources, using the Web DAV Redirect Reference Resource Protocol draft 02 specification.
- *Remote Stored Procedures* - Stored Procedures located in remote databases can now be linked into the Virtuoso Server in the same manner as you would link in tables or views. This enables remote stored procedures to be readily and easily exposed as WEB Services.
- *OLE DB Provider* - native OLE DB Provider is now available allowing direct connection from ADO and .Net applications.
- *JDBC Driver* - enhanced JDBC support with full compliance with JDBC J2EE standard.
- *Free Text* - The full text indexing capability has been extended, giving the developer flexibility in choosing complex, multi-part document id's for application specific sorting of hits, efficient storage of secondary, non-free text data in the free text index for best retrieval performance, options for restarting searches at a specific hit, ascending and descending orders of document id's and more.
- *Free Text Triggers* - The free text triggers system allows persisting free text queries into a table, so that when a free text index is updated, the incoming data gets automatically matched against these persisted criteria, generating hits as the

index is updated. This allows very high performance filtering of fast changing text data, e.g. news feeds without having to run periodic query batches and is ideal for creating personalized information feeds.
- *LDAP* - support for the Lightweight Directory Access Protocol (LDAP) protocol for accessing online directory services.
- *Enhanced Flexibility of Database and VDB security* - New SQL hooks allow the developer to customize password checking at the time of accepting SQL connections into the server. Another hook allows an application to dynamically determine the login/password to use when connecting to a remote database. These hooks make it possible for example to consult an LDAP directory for user information when validating logins.
- *File DSN support* - with the ability to describe a database connection in a simple disk file, Virtuoso becomes more portable, and no longer dependent on per-machine DSNs. If you use file DSNs you can move your database file and your connection information to any computer that has the appropriate drivers installed.
- *Scrollable cursor support in the stored Procedure Language (PL)* - Virtuoso PL now allows you direct access to all ODBC standard features of scrollable cursors through PL routines. ODBC calls are still supported but you have a choice of which level to write your code.

23.4.2. Bugs Fixed

- *Bug 3889* Change label of tab "XML Services/Queues".
- *Bug 3891* Admin UI Home Page Update for 3.0.
- *Bug 3892* Server Startup Information (Branding Info).
- *Bug 3893* When v:data-set @nrows = 1 the 'next' and 'prev' buttons do.
- *Bug 3895* Segmentation fault after running dbpump from Yacutia.
- *Bug 3907* Explain HO-S-4 and HO-S-5 login.
- *Bug 3918* Validators can't work inside Data-Set.
- *Bug 3919* There is no way to format columns data in editing controls.
- *Bug 3920* v:button @style=url or @style=image not working properly.
- *Bug 3921* Logical validators error in Data-Set.
- *Bug 3923* xslt_format_number doesn't work properly with value 0.
- *Bug 3924* "Cancel" failed after Edit mode in Data-Set.
- *Bug 3925* v:column is not more needed in v:data-set.
- *Bug 3926* v:update-field obsoleted.
- *Bug 3931* Initializing JAVA Hosting Tutorials hangs server.
- *Bug 3932* Position Holding in Tutorial Frames.
- *Bug 3936* Virtuoso Unix Installer script.
- *Bug 3943* Data-Set don't work properly inside 'if-login' template.
- *Bug 3950* PDF Version of Documentation is not match HTML.
- *Bug 3956* Tutorial Reorganization.
- *Bug 3969* Install.sh text changes.
- *Bug 3972* Configs, Makefile and installer are not "unpublished propriety.
- *Bug 3973* Virtuoso crashes.
- *Bug 3984* Dynamic Generation of Runtime Tutorial Heading.
- *Bug 3998* bad xpath_eval with //.
- *Bug 3999* Group by clause works wrong.
- *Bug 4000* end_result() has wrong side effect when procedure called from procedure view.
- *Bug 4003* Some catalogs missing in drop down in SOAP expose.
- *Bug 4004* Move Reload button in SOAP expose.
- *Bug 4005* Rename Grant and revoke buttons in SOAP expose.
- *Bug 4006* SQL Error 22023 SR016 in SOAP endpoint hierarchical list.
- *Bug 4013* Install.sh conclusion text needs changing.
- *Bug 4017* Installer is broken - uid and password update.
- *Bug 4021* Lack of pre_render_ method for most of controls.
- *Bug 4025* Service Tray Service Manger About contains a typing mistake.
- *Bug 4026* UDDI; typo in Contact details tab "Address".
- *Bug 4030* DB - TABLE CREATION : Data entered by user is lost.
- *Bug 4034* Absence of the strong KEY column for the UDDI.DESCRIPTION t.
- *Bug 4044* style="url" for "Delete" v:button in data-set caused error.
- *Bug 4049* V:URL unsuitable.
- *Bug 4054* WSDL import uncatched error.
- *Bug 4062* Virgin XP installation of Mono Based Server fails to start.
- *Bug 4063* Installer does not set CLASSPATH to point to Virtuoso JDBC.
- *Bug 4066* Virtuoso Java Based Server fails to start.
- *Bug 4067* Linux installer does not present best default Server for install.

- *Bug 4076* System Tray Icon doe not get removed.
- *Bug 4078* gacutil is missing for RT framework.
- *Bug 4079* VSCM toggles the wrong DB.
- *Bug 4084* Server Crash - ASP.NET hosting.
- *Bug 4090* Retrieve in tables list.
- *Bug 4095* Browse button in column name for v:text inspector does not work.
- *Bug 4096* v:login + page-decor + buttons failed.
- *Bug 4099* Problem with ORDER BY.
- *Bug 4100* Problems with using xpath_contains and xquery_eval in SQL statement.
- *Bug 4102* Kill foreground process misses php java mono servers.
- *Bug 4106* SQL-XML unhandled error.
- *Bug 4109* DB hang when running backup with clear backup context checker.
- *Bug 4110* SQL-XML Error message upon unsuccessful execution of query.
- *Bug 4111* SQL-XML Error attempting to reset the form.
- *Bug 4114* Virtuoso service starts even though no valid license found.
- *Bug 4115* Installer doesn't alert user of non-started instance.
- *Bug 4118* case expression incorrectly works in select statement.
- *Bug 4125* eNews fails to display scrolling items.
- *Bug 4126* Driver does not display SQLSTATE error messages.
- *Bug 4129* Views do not show up via SQLTables call.
- *Bug 4130* entity reference   breaks XSLT processor.
- *Bug 4159* Can't insert date/datetime values as string literals.
- *Bug 4169* Page with list of saved SQL->XML queries missing.
- *Bug 4170* Successful/unsuccessful messages in SQL->XML.
- *Bug 4171* SQL-XML misplaced option.
- *Bug 4173* Missing owner/group params in SQL-XML page.
- *Bug 4174* Missing default root element name in SQL-XML execution.
- *Bug 4175* SQL-XML execution Apply XSLT?.
- *Bug 4177* Button names in Profiling.
- *Bug 4181* Can not "manage" the default "db30" instance.
- *Bug 4188* Open Demo.openlinksw.com in New Window.
- *Bug 4196* Min And Max attributes for v:validator.
- *Bug 4197* v:validator with test="sql".
- *Bug 4207* Visit the online tutorials links are inconsistent.
- *Bug 4217* Declare continue handler for block don't work.
- *Bug 4222* ho-s-7 (DataGrid Demo) problems.
- *Bug 4234* Tutorial and offline documentation creation failure in demo.
- *Bug 4245* .NET client can't work properly with ODBC driver.

23.6. Virtuoso System Tables

23.6.1. Core System Tables

```
create table SYS_COLS (
        TABLE                   varchar,
        COLUMN                  varchar,
        COL_ID                  integer,
        COL_DTP                 integer,
        primary key (COL_ID))

create index SYS_COLS_BY_NAME on SYS_COLS (TABLE, COLUMN)
```

```
create table SYS_KEYS (
        KEY_TABLE               varchar,
        KEY_NAME                varchar,
        KEY_ID                  integer,
        KEY_N_SIGNIFICANT       integer,
        KEY_CLUSTER_ON_ID       integer,
        KEY_IS_MAIN             integer,
        KEY_IS_OBJECT_ID        integer,
        KEY_IS_UNIQUE           integer,
        KEY_MIGRATE_TO          integer,
        primary key (KEY_TABLE, KEY_NAME))

create index SYS_KEYS_BY_ID on SYS_KEYS (KEY_ID)

create table SYS_KEY_PARTS (
        KP_KEY_ID               integer,
        KP_NTH                  integer,
        KP_COL                  integer
        primary key (KP_KEY_ID, KP_NTH))

create table SYS_KEY_SUBKEY (
        SUPER                   integer,
        SUB                     integer,
        primary key (SUPER, SUB))
```

The SYS_COLS table defines all tables and columns. Each column appears once in this table. No entries are made for inherited columns. The SYS_KEYS table defines all indices. A row in this table corresponds to each key in the database, either originally defined or inherited.

KEY_IS_MAIN is non-zero if this is the primary key of its table. The KEY_MIGRATE_TO is the key ID of a new version of this key if this key is obsolete (e.g. the primary key of a table from before an ALTER TABLE). The KEY_N_SIGNIFICANT indicates how many leading key parts are used in ordering keys.

The KEY_ID references the KP_KEY_ID in the SYS_KEY_PARTS table. This table embodies the actual layout of keys and rows. The KP_NTH is a number positioning the KP_COL to the appropriate place in the row. The KP_COL references the COL_ID in SYS_COLS. The KP_NTH is not necessarily a series of consecutive integers but the order matches the order of columns on the row.

The SYS_KEY_SUBKEY table has a row for each pair of keys where one is the immediate subkey of the other. Note that when a table is altered, the obsolete layout is marked as a subtable of the new layout of the primary key. Thus a select on the new primary key will also get the obsolete rows.

The following SQL procedure exemplifies how the SYS_COLS, SYS_KEYS and SYS_KEY_PARTS tables combine. Given a table name it produces the set of columns and the set of indices and their parts.

```
create procedure dt (in tn varchar)
{
        declare index_name, col, dtp varchar;
        declare t, nth integer;

        dtp := '-';

        result_names (col, t);    --- first result set

        declare cr cursor for select COLUMN, COL_DTP
          from SYS_COLS where TABLE = tn;

        whenever not found goto done;
        open cr;
        while (1=1) {
                fetch cr into col, t;
                result (col, t);
        }
done:
        result_names (index_name, nth, col);     -- 2nd result set
        end_result ();

        declare icr cursor for select KEY_NAME, KP_NTH, COLUMN
```

```
                from SYS_KEYS, SYS_KEY_PARTS, SYS_COLS
                where KEY_TABLE = tn and KP_KEY_ID = KEY_ID
                and KP_NTH < KEY_N_SIGNIFICANT and     COL_ID = KP_COL;

              whenever not found goto k_done;
              open icr;
              while (1=1) {
                      fetch icr into index_name, nth, col;
                      result (index_name, nth, col);
              }
      k_done:
              return 0;
      }
```

23.6.2. System Tables

DB objects related to the User and Role objects are created as follows. The terms group and role are used interchangeably.

```
create table
  SYS_USERS (
    U_ID                integer unique,   -- unique id identifying the security object
    U_NAME              char (128),       -- unique name identifying the security object
    U_IS_ROLE           integer         default 0, -- if true it's a group
    U_FULL_NAME         char (128),     -- for information only, name of that user or group
    U_E_MAIL            char (128)      default '', -- e-mail for contact
    U_PASSWORD          char (128),     -- encrypted password
    U_GROUP             integer,        /* the primary group references SYS_USERS (U_ID), */
    U_LOGIN_TIME        datetime,       -- last login time, can be set in login hooks,
        -- otherwise is set when login in webDAV repository
    U_ACCOUNT_DISABLED integer  default 1, -- if true the account is not functional
    U_DAV_ENABLE        integer         default 0, -- true if DAV login allowed
    U_SQL_ENABLE        integer         default 1, -- true if  SQL/(ODBC/JDBC/OLE/DB etc)  login allowed.
    U_DATA              varchar,        /* reserved */
    U_METHODS           integer,        /* reserved */
    U_DEF_PERMS         char (10)       default '110100000R', -- see PERMISSIONS option value
    U_HOME              varchar (128),  -- see HOME option value
    U_PASSWORD_HOOK     varchar,        -- see PASSWORD_MODE option value
    U_PASSWORD_HOOK_DATA varchar,       -- see PASSWORD_MODE_DATA option value
    U_GET_PASSWORD      varchar,        -- see GET_PASSWORD option data
    U_DEF_QUAL          varchar,        -- default qualifier for SQL/ODBC login
    U_OPTS              long varchar,   -- extensibility options for user&group objects
    primary key (U_NAME)
 )

create table
SYS_ROLE_GRANTS (
   GI_SUPER     integer references SYS_USERS (U_ID), -- user object id
         GI_SUB         integer references SYS_USERS (U_ID), -- granted role object id
         GI_DIRECT      integer default 1,      -- false if indirect, i.e.
         -- true by inheritance, not direct grant.
         GI_GRANT       integer,                            -- who has granted this role
         GI_ADMIN       integer default 0,                   -- true if granted with admin option
         primary key (GI_SUPER, GI_SUB, GI_DIRECT));
```

For Backwards compatibility the system tables SYS_DAV_USER, SYS_DAV_GROUP, SYS_DAV_USER_GROUP and SYS_USER_GROUP are re-defined as views:

```
-- WebDAV Users
create view WS.WS.SYS_DAV_USER (U_ID, U_NAME, U_FULL_NAME, U_E_MAIL, U_PWD,
    U_GROUP, U_LOGIN_TIME, U_ACCOUNT_DISABLED, U_METHODS, U_DEF_PERMS, U_HOME)
  as select U_ID, U_NAME, U_FULL_NAME, U_E_MAIL, U_PASSWORD as U_PWD,
    U_GROUP, U_LOGIN_TIME, U_ACCOUNT_DISABLED, U_METHODS, U_DEF_PERMS, U_HOME
        from DB.DBA.SYS_USERS where U_IS_ROLE = 0 and U_DAV_ENABLE = 1;

-- WebDAV Groups
create view WS.WS.SYS_DAV_GROUP (G_ID, G_NAME)
    as select U_ID as G_ID, U_NAME as G_NAME
        from DB.DBA.SYS_USERS where U_IS_ROLE = 1 and U_DAV_ENABLE = 1;

-- The granted groups to the WebDAV user
create view WS.WS.SYS_DAV_USER_GROUP (UG_UID, UG_GID) as select GI_SUPER, GI_SUB from DB.DBA.SYS_ROLE_GRA
```

```
        where GI_DIRECT = 1;

create view SYS_USER_GROUP (UG_UID, UG_GID) as select GI_SUPER, GI_SUB
   from SYS_ROLE_GRANTS where GI_DIRECT = 1;

         create table SYS_GRANTS  (
                G_USER          varchar,
                G_OP            integer,
                G_OBJECT        varchar,
                G_COL           varchar,
                primary key (G_USER, G_OP, G_OBJECT, G_COL));
```

These tables are visible only to dba members. The procedure list_grants shows a summary of granted privileges:

```
SQL> list_grants (0);
```

These tables should not be modified by applications. Only the SQL statements GRANT, REVOKE, CREATE USER, DELETE USER, SET USER GROUP and SET PASSWORD should be used to maintain user and security information. Security information is cached in RAM during the execution of a Virtuoso process and these statements ensure that the cache stays consistent with the tables.

23.6.3. Row Level Security Table

```
create table SYS_RLS_POLICY (
  RLSP_TABLE varchar, - the FQN of the table
  RLSP_OP varchar, - the operation (one per row : I/U/D/S)
  RLSP_FUNC varchar, - the FQN of the stored procedure to be called
  PRIMARY KEY (RLSP_TABLE, RLSP_OP))
```

That system table is used for persisting the definitions

23.6.4. SYS_CHARSETS

```
CREATE TABLE SYS_CHARSETS (
    CS_NAME varchar,                    -- The "preferred" charset name
    CS_TABLE long nvarchar,             -- the mapping table of length 255 Wide chars
    CS_ALIASES long varchar             -- serialized vector of aliases
);
```

23.6.5. Collations System Table

The SYS_COLLATIONS system table holds the data for all the defined collations. It has the following structure:

```
CREATE TABLE SYS_COLLATIONS (
    COLL_NAME VARCHAR,
    COLL_TABLE LONG VARBINARY,
    COLL_IS_WIDE INTEGER);
```

COLL_NAME is the fully qualified name of the collation (it's identifier)

COLL_TABLE holds the collation table (256 bytes or 65536 wide chars)

COLL_IS_WIDE show the collation's type (0 for CHAR and 1 for NCHAR). Note that a 8bit collation cannot be used by a NCHAR data and vice versa.

Collation can be deleted by deleting its row from SYS_COLLATIONS.

Note

The collation will still be available until the server is restarted, as it's definition is cached into memory.

23.6.6. UDDI Schema

```
---=====================
--- Business Entity Table
---=====================
create table UDDI..BUSINESS_ENTITY (
```

```
        BE_BUSINESS_KEY         varchar,
        BE_AUTHORIZED_NAME      varchar,
        BE_OPERATOR             varchar,
        BE_NAME                 varchar not null,
        BE_CREATED              datetime,
        BE_CHANGED              timestamp,
        BE_OWNER                integer,
 PRIMARY KEY (BE_BUSINESS_KEY)
)
;

---=======================
--- Business service Table
---=======================
create table UDDI..BUSINESS_SERVICE (
        BS_BUSINESS_KEY         varchar,                -- references business entity (optional)
        BS_SERVICE_KEY          varchar not null,       -- Unique Key
        BS_NAME                 varchar not null,       -- Name
        BS_CREATED              datetime,
        BS_CHANGED              timestamp,
        BS_OWNER                integer,
PRIMARY KEY (BS_SERVICE_KEY)
)
;

---=========================
--- Binding Templates Table
---=========================
create table UDDI..BINDING_TEMPLATE (
        BT_BINDING_KEY          varchar,
        BT_SERVICE_KEY          varchar,
        BT_ACCESS_POINT         varchar,
        BT_HOSTING_REDIRECTOR   varchar,
        BT_URL_TYPE             varchar,
        BT_CREATED              datetime,
        BT_CHANGED              timestamp,
        BT_OWNER                integer,
        PRIMARY KEY (BT_BINDING_KEY)
)
;

---======================
--- tModel Table
---======================
create table UDDI..TMODEL (
        TM_TMODEL_KEY           varchar,
        TM_AUTHORIZED_NAME      varchar,
        TM_OPERATOR             varchar,
        TM_NAME                 varchar,
        TM_CREATED              datetime,
        TM_CHANGED              timestamp,
        TM_OWNER                integer,
        primary key (TM_TMODEL_KEY)
)
;

---====================
--- Descriptions Table
---====================
create table UDDI..DESCRIPTION (
        UD_DESC                 varchar,          -- Description Text
        UD_LANG                 varchar,
        UD_PARENT_ID            varchar,          -- Parent ID (references tmodel,
                                    -- businessService etc.)
        UD_TYPE                 varchar           -- ParentType (name of parent table)
)
create index DESC_PARENT on DESCRIPTION (UD_TYPE, UD_PARENT_ID)
;

--=============================================================================================
-- Discovery URL table: contains structure - holds a URL addressable discovery documents
--=============================================================================================
```

```
create table UDDI..DISCOVERY_URL (
        DU_PARENT_ID            varchar not null,       -- parent ID
        DU_PARENT_TYPE          varchar not null,       -- name of parent element
        DU_URL                  varchar,                -- URI
        DU_USE_TYPE             varchar                 -- UseType element
)
create index DISCOVERY_URLS_PARENT on DISCOVERY_URL (DU_PARENT_TYPE, DU_PARENT_ID)
;

--====================

;

---================================
--- TModel Instance Details Table
---================================
create table UDDI..INSTANCE_DETAIL  (
    ID_KEY              varchar not null,
    ID_BINDING_KEY      varchar,                -- references btemplate(bindingkey)
    ID_TMODEL_KEY       varchar,                -- references tmodel(tmodelkey)
    ID_PARMS            varchar,
    primary key (ID_KEY)
)
create index IN_IDPARENT on INSTANCE_DETAIL (ID_BINDING_KEY, ID_TMODEL_KEY)
;
```

23.6.7. Web Robot System Tables

Target sites table.

```
create table WS.WS.VFS_SITE (
  VS_DESCR   varchar,   -- Human readable description
  VS_HOST    varchar,   -- target hostname (eq. www.foo.com)
  VS_URL     varchar,   -- target path (eq. /cgi-bin/ or /)
  VS_INX     char(5),   -- not used
  VS_OWN     integer,   -- ID of the local WebDAV owner
  VS_ROOT    varchar,   -- target WebDAV collection
  VS_NEWER   datetime,  -- Update the link if newer than
  VS_DEL     char(3),   -- Delete local copy if delete on remote detected flag
  VS_FOLLOW  varchar,   -- follow list (list of masks to allow following the links)
  VS_NFOLLOW varchar,   -- the do not follow list
  VS_SRC     char(3),   -- do get of the images - flag
  VS_OPTIONS varchar,   -- username/password credentials for
                        --  authorization on target site
  VS_METHOD  varchar,   -- use HTTP or HTTP/WebDAV to retrieve the target site
  VS_OTHER   char(10),  -- go to other sites flag
  primary key (VS_HOST, VS_ROOT)
)
;
```

The queues table.

```
create table WS.WS.VFS_QUEUE (
  VQ_HOST    varchar,  -- target host
  VQ_TS      datetime, -- when added to the queue
  VQ_URL     varchar,  -- path on target
  VQ_ROOT    varchar,  -- the WebDAV local collection
  VQ_STAT    char (15),-- status of the entry
  VQ_OTHER   varchar,  -- flag for other site generated link
  primary key (VQ_HOST, VQ_URL, VQ_ROOT)
```

```
)
;
```

The retrieved URLs table.

```
create table WS.WS.VFS_URL (
  VU_HOST     varchar,  -- target host
  VU_URL      varchar,  -- path on target
  VU_ROOT     varchar,  -- the local WebDAV collection containing
                        -- content of the retrieved link
  VU_CHKSUM   varchar,  -- checksum
  VU_ETAG     varchar,  -- Etag from target
  VU_CPTIME   datetime, -- when is copied
  VU_OTHER    varchar,  -- is the link retrieved from foreign site
  primary key (VU_HOST, VU_URL, VU_ROOT)
)
;
```

23.6.8. Web Server & DAV System Tables

All Web Server and DAV related tables and procedures are held in the WS catalogue. This reference section illustrates their structure.

Collections (folders)

```
create table WS.WS.SYS_DAV_COL (
  COL_ID        integer,  -- unique collection id
  COL_NAME      char(256),-- collection name
  COL_OWNER     integer,  -- collection owner id (FK SYS_DAV_USER (U_ID))
  COL_GROUP     integer,  -- collection owner group id (FK SYS_DAV_GROUP (G_ID))
  COL_PARENT    integer,  -- parent collection id (FK SYS_DAV_COL (COL_ID))
  COL_CR_TIME   datetime, -- creation time
  COL_MOD_TIME  datetime, -- modification time
  COL_PERMS     char(9),  -- collection access permissions (like UNIX ugo style)
  primary key (COL_NAME, COL_PARENT)
)
;
```

Groups

Locks

```
create table WS.WS.SYS_DAV_LOCK (
  LOCK_TYPE     char (1),     -- type of the lock (R (read) or W (write))
  LOCK_SCOPE    char (1),     -- lock scope (X (exclusive) or S (shared))
  LOCK_TOKEN    char(256),    -- unique lock token
  LOCK_PARENT_TYPE  char (1), -- lock parent type (R (resource), C (collection))
  LOCK_PARENT_ID  integer,    -- lock parent (resource/collection)
                              -- id (FK SYS_DAV_COL (COL_ID) or SYS_DAV_RES (RES_ID))
  LOCK_TIME     datetime,     -- lock creation time
  LOCK_TIMEOUT  integer,      -- lock time-out
  LOCK_OWNER    integer,      -- lock owner id (FK SYS_DAV_USER (U_ID))
  LOCK_OWNER_INFO varchar,    -- lock owner info (if WebDAV client sent
                              -- additional info eq. e-mail etc.)
  primary key (LOCK_PARENT_TYPE, LOCK_PARENT_ID)
)
;
```

Properties

```
create table WS.WS.SYS_DAV_PROP (
  PROP_ID      integer,   -- unique property id
  PROP_NAME    char(256), -- property name
  PROP_TYPE    char (1),  -- property parent type (R (resource), C (collection))
  PROP_PARENT_ID integer, -- parent resource/collection id (FK SYS_DAV_COL (COL_ID)
                          -- or SYS_DAV_RES (RES_ID))
  PROP_VALUE   varchar,   -- value of the property (plain text or serialized XML entity)
  primary key (PROP_NAME, PROP_TYPE, PROP_PARENT_ID)
)
```

```
;
```

Resources (documents)

```
create table WS.WS.SYS_DAV_RES (
  RES_ID                integer,        -- unique resource id
  RES_NAME      char(256),-- resource name
  RES_OWNER     integer,        -- resource owner id (FK SYS_DAV_USER (U_ID))
  RES_GROUP     integer,        -- resource owner group id (FK SYS_DAV_GROUP (G_ID))
  RES_COL       integer,        -- parent collection id (FK SYS_DAV_COL (COL_ID))
  RES_CONTENT   long varchar IDENTIFIED BY RES_FULL_PATH,
                        -- resource content
  RES_TYPE      varchar,        -- resource MIME type (eq. text/plain etc.)
  RES_CR_TIME   datetime,       -- creation time
  RES_MOD_TIME  datetime,       -- modification time
  RES_PERMS     char (9),       -- resource access permissions (like UNIX ugo style)
  RES_FULL_PATH         varchar,        -- resource full path (eq. /DAV/docs/name.txt)
  primary key (RES_COL, RES_NAME)
)
;
```

Resource Types (MIME types)

```
create table WS.WS.SYS_DAV_RES_TYPES (
  T_EXT         varchar,        -- extension
  T_TYPE                varchar,        -- associated MIME type
  T_DESCRIPTION varchar,        -- optional description
  primary key (T_EXT)
)
;
```

Note:
The Resource Types table is also used by the HTTP server for determining the appropriate 'Content-Type' header for any deliverable, either from WebDAV or the file system.

HTTP Virtual Directory Mappings

```
create table DB.DBA.HTTP_PATH (
  HP_HOST             varchar not null, -- mapping Host in HTTP header note: *ini*
  HP_LISTEN_HOST      varchar not null, -- IP address & port for
                                        -- mapping listening session
  HP_LPATH            varchar not null, -- logical path
  HP_PPATH            varchar not null, -- physical path
  HP_STORE_AS_DAV     integer not null, -- flag for webDAV storage
  HP_DIR_BROWSEABLE   integer not null, -- directory listing allowed
  HP_DEFAULT          varchar,  -- default page
  HP_SECURITY         varchar,  -- which method allowed all/https/digest (NULL/SSL/DIGEST)
  HP_REALM            varchar,  -- authentication realm
  HP_AUTH_FUNC        varchar,  -- which function authenticate this directory
  HP_POSTPROCESS_FUNC varchar,  -- function call after request
  HP_RUN_VSP_AS       varchar,  -- uid for VSPs REFERENCES SYS_USERS (U_NAME)
                                --   ON DELETE SET NULL
  HP_RUN_SOAP_AS      varchar,  -- uid for SOAP REFERENCES SYS_USERS (U_NAME)
                                --   ON DELETE SET NULL
  HP_PERSIST_SES_VARS integer,  -- have a persistent session variables
  HP_SOAP_OPTIONS     varchar,  -- SOAP options
  HP_AUTH_OPTIONS     varchar,  -- options for authentication hook function
  primary key (HP_LISTEN_HOST, HP_HOST, HP_LPATH)
)
;
```

HTTP Access Control List

```
create table HTTP_ACL (
HA_LIST         varchar not null,               -- ACL name
HA_ORDER        integer not null,               -- Position  in the list
HA_OBJECT       integer not NULL default -1,    -- Object ID (applicable to news groups also)
HA_CLIENT_IP    varchar not NULL,               -- *PATTERN*
HA_FLAG         integer not NULL default 1,     -- Allow/Deny flag, 0 - allow, 1 - deny
HA_RW           integer default 0,              -- Read/Write flag, 0 - read,  1 - post
HA_DEST_IP      varchar default '*',            -- Destination IP/Host (applicable to the proxy also)
```

```
PRIMARY KEY (HA_LIST, HA_ORDER, HA_CLIENT_IP, HA_FLAG)
);
```

23.6.9. Mail Table Description

```
- - Message queue
create table MAIL_MESSAGE_QUEUE (
    MQ_ID               varchar,    - - FK MAIL_MESSAGE (MM_ID)
    MQ_RECIEVER         varchar,    - - foreign mail exchanger
    primary key (MQ_ID))
;

create index MAIL_MSG_Q_REC on MAIL_MESSAGE_QUEUE (MQ_RECIEVER)
;

-- Mail Table
create table DB.DBA.MAIL_MESSAGE (
    MM_ID               integer,        -- Unique id of message (per user)
    MM_OWN      varchar (128),  -- Local WebDAV account (recipient, mail box owner) name,
                                        FK references WS.WS.SYS_DAV_USER (U_NAME)
    MM_FLD      varchar (128), -- Message Folder (initial 'Inbox')
    MM_FROM     varchar (512),          -- From: RFC822 header field
    MM_TO               varchar (512),          -- To: RFC822 header field
    MM_CC               varchar (512),          -- Cc: RFC822 header field
    MM_BCC      varchar (512),  -- Bcc: RFC822 header field
    MM_SUBJ     varchar (512),  -- Subject of the message
    MM_REC_DATE varchar (50),   -- Date of arrival
    MM_SND_TIME varchar (50),   -- Date of posting
    MM_IS_READED        integer,                -- Read flag (0/1 not read, 1 - read)
    MM_BODY     long varchar,   -- Message content (including message header)
    primary key (MM_OWN, MM_FLD, MM_ID)
)
;
```

Note:

MM_FROM, MM_TO, MM_CC, MM_BCC, MM_SUBJ, MM_SND_TIME exists only if there exists corresponding RFC822 headers in mail message

```
-- Temporary message MIME parts table (for message composition)
create table DB.DBA.MAIL_PARTS (
    MP_ID       integer,                -- Unique id per user (order of parts)
    MP_PART     long varbinary, -- Message MIME part body
    MP_ATTRS    long varbinary, -- Message MIME part attributes
    MP_OWN      varchar (128),  -- WebDAV user name - FK REFERENCES WS.WS.SYS_DAV_USER (U_NAME)
    primary key (MP_OWN, MP_ID)
)
;

- - Local mail users
(this table will be needed only in case of different DB, DAV and MAIL users)
create table MAIL_USERS (
    MU_NAME     varchar,
    MU_PWD      varchar,
    primary key (MU_NAME))
;

- - Allowed relay domains
(only in case of allowed relaying)
create table MAIL_RELAY (
    MR_ALLOWED  varchar;
    primary key (MR_ALLOWED))
;
```

23.6.10. NNTP Server Tables

The server uses the following tables:

```
create table NEWS_MESSAGES (
  NM_ID         varchar (128) not null, -- Message-ID (unique)
  NM_REF        varchar (128),          -- References
  NM_GROUP      varchar (128) not null, -- Newsgroups ID
```

```
  NM_NUM_GROUP  integer not null,       -- ID unique for group
  NM_READED     integer,                -- How many times this message is read
  NM_OWN        varchar (128),          -- Local sender (if sender is non
                                           local should be null)
  NM_REC_DATE   datetime,               -- Receiving date
  NM_STAT       integer,                -- Post from the local user
  NM_HEAD       long varchar,           -- Message header
  NM_BODY       long varchar,           -- Message content
  primary key (NM_ID))

create table NEWS_GROUPS (
  NG_GROUP      integer identity,  -- Newsgroups ID
  NG_NAME       varchar (128) NOT NULL, -- Local name
  NG_DESC       varchar (128), -- Comment
  NG_SERVER     varchar (128), -- Server
  NG_SERV_PORT  integer,       -- Server port
  NG_OUT_GROUP  varchar (128), -- Out name
  NG_POST       integer,       -- Flag 0/1 posting allowed
  NG_UP_TIME    datetime,      -- Last Update
  NG_CREAT      datetime,      -- When group is created (attached)
  NG_UP_INT     integer,       -- Update interval (min)
  NG_CLEAR_INT  integer,       -- Drop interval for messages
  NG_LIFE_READ  integer,       -- Flag 0/1 read messages exist longer
  NG_STAT       integer,       -- Flag 0/3 Result from last update.
              0 - Unsuccessful
              1 - Successful
              3 - Successful  but does not get all available messages.

  NG_AUTO       integer,       -- Flag 0/1 Auto download.
  NG_PASS       integer,       -- Download messages for one pass.
  NG_UP_MESS    integer,       -- Messages from last update.
  NG_NUM        integer,       -- Estimated number of articles in group
  NG_FIRST      integer,       -- First article number in the group
  NG_LAST       integer,       -- Last article number in the group

  primary key (NG_GROUP))

create table NEWS_ACL (
  NA_GROUP  integer not NULL, -- News Group number, referencing
                                 NEWS_GROUPS (NG_GROUP)
  NA_IP     varchar not NULL, -- Client IP (the mask is %)
  NA_A_D    integer not NULL, -- flag  0 - allow, 1 - deny (action)
  NA_RW     integer not NULL, -- flag  0 - read,  1 - post (reading
                              or posting action is allowed/disallowed)
  PRIMARY KEY (NA_GROUP, NA_IP, NA_A_D, NA_RW));
```

23.6.11. WS Reliable Messaging

Receiver-Side Schema Objects

Incoming messages table used to keep successfully received messages. An application on receiver side can access it in order to process the messages.

```
CREATE TABLE SYS_WSRM_IN_MESSAGE_LOG (
  IML_INDENTIFIER varchar,             -- references SYS_WSRM_IN_SEQUENCES.WIS_IDENTIFIER
  IML_MESSAGE_ID int NOT NULL,         -- unique per sequence
  IML_EXPIRE_DATE datetime,            -- when expires
  IML_RECEIVE_DATE timestamp NOT NULL ,
  IML_MESSAGE long varchar NOT NULL,   -- the message itself
  IML_STATE     int,
  primary key (IML_INDENTIFIER, IML_MESSAGE_ID)
)
;
```

Incoming sequences table; used to keep the successfully established message sequence and policy to be applied to it.

```
CREATE TABLE SYS_WSRM_IN_SEQUENCES
       (
  WIS_IDENTIFIER varchar, -- sequence identifier
  WIS_VERSION varchar,
  WIS_DELIVERY_ASSURANCE varchar,
```

```
  WIS_SEQUENCE_EXPIRATION datetime,
  WIS_INACTIVITY_TIMEOUT integer,
  WIS_RETRANSMISSION_INTERVAL integer,
  WIS_ACKNOWLEDGEMENT_INTERVAL integer,
  primary key (WIS_IDENTIFIER)
)
;
```

Sender's Schema Objects

Outgoing messages log table is used to keep the outgoing messages, to track their state. It also keeps parameter to the soap request in order to re-send if are not already accepted.

```
CREATE TABLE SYS_WSRM_OUT_MESSAGE_LOG (
  OML_INDENTIFIER varchar,          -- references SYS_WSRM_OUT_SEQUENCES.WOS_IDENTIFIER
  OML_MESSAGE_ID int NOT NULL,      -- unique per sequence
  OML_EXPIRE_DATE datetime,         -- when expires
  OML_SEND_DATE timestamp NOT NULL, -- when is sent
  OML_MESSAGE long varchar NOT NULL,-- soap call parameters
  OML_STATE int,
  primary key (OML_INDENTIFIER, OML_MESSAGE_ID)
)
;
```

Outgoing sequences table is used to keep parameters for outgoing message sequences. It's used to persist their state.

```
CREATE TABLE SYS_WSRM_OUT_SEQUENCES (
  WOS_IDENTIFIER varchar,           -- sequence identifier
  WOS_VERSION varchar,
  WOS_DELIVERY_ASSURANCE varchar,
  WOS_SEQUENCE_EXPIRATION datetime,
  WOS_INACTIVITY_TIMEOUT integer,
  WOS_RETRANSMISSION_INTERVAL integer,
  WOS_ACKNOWLEDGEMENT_INTERVAL integer,
  primary key (WOS_IDENTIFIER)
)
;
```

23.6.12. WS Trust

```
create table WST_SERVER_ISSUER_TOKENS
(
  WSK_TOKEN_TYPE        varchar,
  WSK_REQUEST_TYPE      varchar,
  WSK_APPLIES_TO        varchar,
  WSK_FROM              varchar,
  WSK_SERVICE_NAME      varchar,
  WSK_PORT_TYPE         varchar,
  WSK_TOKEN             varchar,
  PRIMARY KEY (WSK_TOKEN_TYPE, WSK_FROM, WSK_TOKEN)
)
;
```

23.6.13. SyncML Schema Objects

SyncML Devices

```
create table SYNC_DEVICES (
  DEV_ID integer identity,
  DEV_USER_ID integer,   -- references WS.WS.SYS_DAV_USER(U_ID)
  DEV_URI varchar,
  DEV_MAN varchar,       -- manufacturer
  DEV_MOD varchar,       -- model
  DEV_OEM varchar,       -- OEM
  DEV_FWV varchar,       -- firmware version
  DEV_SWV varchar,       -- software version
  DEV_HWV varchar,       -- hardware version
  DEV_DEVID varchar,     -- device id ; must be unique
  DEV_DEVTYP varchar,    -- device type
  DEV_UTC integer,       -- requires datetime in UTC
```

```
  DEV_SUPP_LOB integer,  -- supports large objects
  DEV_SUPP_NOC integer,  -- supports "number of changes"
  primary key (DEV_URI)  -- constraint foobar unique(DEV_USER_ID, DEV_URI)
)
;
```

SyncML Maps

```
create table SYNC_MAPS (
  MAP_DEV_ID integer, -- references SYNC_DEVICES(DEV_ID)
  MAP_COL_ID int,     -- references WS.WS.SYS_DAV_COL (COL_ID)
  MAP_LUID varchar,   -- local id (from client's view)
  MAP_GUID varchar,   -- references WS.WS.SYS_DAV_RES (RES_ID)
  primary key (MAP_DEV_ID, MAP_LUID, MAP_GUID)
)
;
```

SyncML Sync Anchors

```
create table SYNC_ANCHORS (
  A_COL_ID integer,   -- references WS.WS.SYS_DAV_COL(COL_ID)
  A_DEV_ID integer,   -- references SYNC_DEVICES(DEV_ID)
  A_LAST_LOCAL datetime,    -- last local anchor
  A_LAST_REMOTE varchar,    -- last remote anchor
  A_NEXT_LOCAL datetime,    -- last local anchor
  A_NEXT_REMOTE varchar,    -- last remote anchor
  primary key (A_COL_ID, A_DEV_ID)
)
;
```

SyncML Sync Log

```
create table SYNC_RPLOG (
  RLOG_RES_ID int,      -- references WS.WS.SYS_DAV_RES (RES_ID)
  RLOG_RES_COL int,     -- references WS.WS.SYS_DAV_COL (COL_ID)
  DMLTYPE varchar,      -- IUD - insert/update/delete
  SNAPTIME datetime,    -- timestamp
  primary key (RLOG_RES_ID)
)
;
```

SyncML Device's Sessions

```
create table SYNC_SESSION
        (
        S_ID varchar,   -- session ID (unique per device)
        S_DEV varchar,  -- device URI
        S_DEV_ID int,   -- references SYNC_DEVICES(DEV_ID)
        S_UID int,      -- user ID SYS_USERS.U_ID
        S_LAST_MSG int, -- last massage no
        S_LAST_CMD int, -- last command no
        S_DATA long varbinary,  -- internal use
        S_TS timestamp,         -- last used
        S_AUTH int default 0,   -- authenticated for this session
        S_NONCE varchar default '', -- nonce value
        S_INIT int default 1,       -- init state flag
        primary key (S_ID, S_DEV)
        )
;
```

23.6.14. INFORMATION_SCHEMA views

The INFORMATION_SCHEMA views are described in the SQL200n standard. These views are defined in every qualifier and describe the objects in that qualifier.

TABLES

```
    INFORMATION_SCHEMA.TABLES
        TABLE_CATALOG                   VARCHAR(128),
```

```
    TABLE_SCHEMA                    VARCHAR(128),
    TABLE_NAME                      VARCHAR(128),
    TABLE_TYPE                      VARCHAR(128),
    V_KEY_TABLE                     VARCHAR,
    V_KEY_NAME                      VARCHAR,
    V_KEY_ID                        INTEGER,
    V_KEY_N_SIGNIFICANT             SMALLINT,
    V_KEY_CLUSTER_ON_ID             SMALLINT,
    V_KEY_IS_MAIN                   SMALLINT,
    V_KEY_IS_OBJECT_ID              SMALLINT,
    V_KEY_IS_UNIQUE                 SMALLINT,
    V_KEY_MIGRATE_TO                INTEGER,
    V_KEY_SUPER_ID                  INTEGER,
    V_KEY_DECL_PARTS                SMALLINT,
    V_KEY_STORAGE                   VARCHAR,
    V_KEY_OPTIONS                   ANY
```

COLUMNS

```
INFORMATION_SCHEMA.COLUMNS
    TABLE_CATALOG                   VARCHAR(128),
    TABLE_SCHEMA                    VARCHAR(128),
    TABLE_NAME                      VARCHAR(128),
    COLUMN_NAME                     VARCHAR(128),
    ORDINAL_POSITION                INTEGER,
    COLUMN_DEF                      VARCHAR,
    NULLABLE                        VARCHAR (3),
    DATA_TYPE                       VARCHAR(128),
    CHARACTER_MAXIMUM_LENGTH        INTEGER,
    CHARACTER_OCTET_LENGTH          INTEGER,
    NUMERIC_PRECISION               SMALLINT,
    NUMERIC_PRECISION_RADIX         SMALLINT,
    NUMERIC_SCALE                   SMALLINT,
    DOMAIN_CATALOG                  VARCHAR(128),
    DOMAIN_SCHEMA                   VARCHAR(128),
    DOMAIN_NAME                     VARCHAR(128),
    IS_IDENTITY                     VARCHAR(3),
    IDENTITY_GENERATION             VARCHAR(10),
    IDENTITY_START                  VARCHAR,
    IDENTITY_INCREMENT              VARCHAR,
    V_TABLE                         VARCHAR,
    V_COLUMN                        VARCHAR,
    V_COL_ID                        INTEGER,
    V_COL_DTP                       SMALLINT,

23.7. Basic Syntax of Regular Expressions

The two special symbols: `'^'` and `'$'` indicate the *start* and the *end* of a string respectively, like so:

`^The` : matches any string that starts with The;

`of despair$` : matches a string that ends in the substring of despair;

`^abc$` : a string that starts and ends with abc -- that could only be abc itself!

`notice` : a string that has the text notice in it.

Without either of the above special character you are allowing the pattern to occur anywhere inside the string.

The symbols `'*'` , `'+'` , and `'?'` denote the number of times a character or a sequence of characters may occur. What they mean is: zero or more, one or more, and zero or one. Here are some examples:

`ab*` : matches a string that has an *a* followed by zero or more *b* 's (a, ab, abbb, etc.);

`ab+` : same, but there is at least one *b* (ab, abbb, etc.);

`ab?` : there might be a *b* or not;

`a?b+$` : a possible *a* followed by one or more *b* 's ending a string.

You can also use *bounds* , which come inside braces and indicate ranges in the number of occurrences:

`ab{2}` : matches a string that has an *a* followed by exactly two *b* 's (abb);

`ab{2,}` : there are at least two *b* 's (abb, abbbb, etc.);

`ab{3,5}` : from three to five *b* 's (abbb, abbbb, or abbbbb).

Note, that you must always specify the first number of a range (i.e, `{0,2}` , not `{,2}`). Also, as you may have noticed, the symbols '*', '+', and '?' have the same effect as using the bounds `{0,}` , `{1,}` , and `{0,1}` , respectively.

Now, to quantify a sequence of characters, put them inside parentheses:

`a(bc)*` : matches a string that has an *a* followed by zero or more copies of the sequence bc;

`a(bc){1,5}` : one through five copies of bc.

There's also the '|' symbol, which works as an OR operator:

`hi|hello` : matches a string that has either hi or hello in it;

`(b|cd)ef` : a string that has either bef or cdef;

`(a|b)*c` : a string that has a sequence of alternating *a* 's and *b* 's ending in a *c* ;

A period ('.') stands for any single character:

`a.[0-9]` : matches a string that has an *a* followed by one character and a digit;

`^.{3}$` : a string with exactly 3 characters.

Bracket expressions specify which characters are allowed in a single position of a string:

`[ab]` : matches a string that has either an *a* or a *b* (that's the same as `a|b`);

`[a-d]` : a string that has lowercase letters 'a' through 'd' (that's equal to `a|b|c|d` and even `[abcd]`);

`^[a-zA-Z]` : a string that starts with a letter;

`[0-9]%` : a string that has a single digit before a percent sign;

`,[a-zA-Z0-9]$` : a string that ends in a comma followed by an alphanumeric character.

You can also list the characters that do NOT want -- just use a '^' as the first symbol in a bracketed expression (i.e., `%[^a-zA-Z]%` matches a string with a character that is not a letter between two percent signs).

Do not forget that bracket expressions are an exception to that rule--inside them, all special characters, including the backslash ('\'), lose their special powers (i.e., `[*\+?{}.]` matches exactly any of the characters inside the brackets). To include a literal ']' in the list, make it the first character (following a possible '^'). To include a literal '-', make it the first or last character, or the second endpoint of a range.

23.8. Server & client versions compatibility

The RPC protocol has changed between 2.7 and 3.0 versions. Thus, not all clients can connect to all servers. For best results, the version should be identical on both ends of ODBC and JDBC connections. However, the following table shows which combinations should generally be successful.

Table 23.7.

Driver/Server	4.0	3.5	3.2	3.1	3.0	2.7	2.5	2.1
4.0	Y	Y	Y	Y	Y	N	N	N
3.5	Y	Y	Y	Y	Y	N	N	N
3.2	Y	Y	Y	Y	Y	N	N	N
3.1	Y	Y	Y	Y	Y	N	N	N
3.0	Y	Y	Y	Y	Y	N	N	N
2.7	N	N	N	N	N	Y	Y	Y
2.5	N	N	N	N	N	Y	Y	Y
2.1	N	N	N	N	N	Y	Y	Y

Chapter 24. Virtuoso Functions Guide & Reference

Abstract

The Virtuoso SQL Functions Guide contains reference manual entries for built-in SQL functions and procedures.

The Virtuoso XPATH & XQUERY Functions Guide contains reference manual entries of the built-in functions of the Virtuoso XPATH Processor. These can be used in XPATH, XSLT, XQuery.

VAR

VAR — Returns the variance.

Synopsis

```
numeric VAR ( in expr any );
```

Description

VAR (VARIANCE) returns variance of expr. Virtuoso calculates the variance of expr as follows: 0 if the number of rows in expr = 1; VAR_SAMP if the number of rows in expr > 1

Parameters

expr
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

VAR_SAMP

VAR_SAMP — Returns the sample variance.

Synopsis

```
numeric VAR_SAMP ( in expr any );
```

Description

VAR_SAMP returns the sample variance of a set of numbers after discarding the nulls in this set. The expr is a numeric expression, and the function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null. The function makes the following calculation:

```
(SUM(expr2) - SUM(expr)2 / COUNT(expr)) / (COUNT(expr) - 1)
```

This function is similar to VAR, except that given an input set of one element, VAR returns 0 and VAR_SAMP returns null.

Parameters

expr
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

VAR_POP

VAR_POP — Returns the population variance.

Synopsis

```
numeric VAR_POP ( in expr any );
```

Description

VAR_POP returns the population variance of a set of numbers after discarding the nulls in this set. The expr is a number expression, and the function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null. The function makes the following calculation:

```
(SUM(expr2) - SUM(expr)2 / COUNT(expr)) / COUNT(expr)
```

Parameters

expr
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

STDDEV

STDDEV — Returns the standard deviation.

Synopsis

```
numeric STDDEV ( in expr1 any ,
                 in expr2 any ) ;
```

Description

STDDEV returns standard deviation. It returns STDDEV_SAMP if the number of pairs is more than one, or NULL.

Parameters

expr1
: Number expression.

expr2
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

STDDEV_SAMP

STDDEV_SAMP — Returns the cumulative sample standard deviation.

Synopsis

```
numeric STDDEV_SAMP ( in expr any );
```

Description

STDDEV_SAMP computes the cumulative sample standard deviation and returns the square root of the sample variance. The expr is a numeric expression, and the function returns a value of type NUMERIC. This function is same as the square root of the VAR_SAMP function. When VAR_SAMP returns null, this function returns null.

Parameters

expr
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

STDDEV_POP

STDDEV_POP — Returns the population standard deviation.

Synopsis

```
numeric STDDEV_POP ( in expr any );
```

Description

STDDEV_POP computes the population standard deviation and returns the square root of the population variance. This function is the same as the square root of the VAR_POP function. When VAR_POP returns null, returns null.

Parameters

expr
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

REGR_SYY

REGR_SYY — Auxiliary function used to compute various diagnostic statistics.

Synopsis

```
numeric REGR_SYY ( in expr1 any ,
                   in expr2 any );
```

Description

REGR_SYY makes the following computation after eliminating NULL (expr1, expr2) pairs:

```
REGR_COUNT(expr1, expr2) * VAR_POP(expr1)
```

Parameters

expr1
: Number expression.

expr2
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

REGR_SXX — Auxiliary function used to compute various diagnostic statistics.

Synopsis

```
numeric REGR_SXX ( in expr1 any ,
                   in expr2 any );
```

Description

REGR_SXX makes the following computation after eliminating NULL (expr1, expr2) pairs:

```
REGR_COUNT(expr1, expr2) * VAR_POP(expr2)
```

Parameters

expr1
: Number expression.

expr2
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

REGR_SXY — Auxiliary function used to compute various diagnostic statistics.

Synopsis

```
numeric REGR_SXY ( in expr1 any ,
                   in expr2 any );
```

Description

REGR_SXY makes the following computation after eliminating NULL (expr1, expr2) pairs:

```
REGR_COUNT(expr1, expr2) * COVAR_POP(expr1, expr2)
```

Parameters

expr1
: Number expression.

expr2
: Number expression.

REGR_AVGX

REGR_AVGX — Evaluates the average of the independent variable (expr2) of the regression line.

Synopsis

```
numeric REGR_AVGX ( in expr1 any ,
                    in expr2 any ) ;
```

Description

REGR_AVGX evaluates the average of the independent variable (expr2) of the regression line. It makes the following computation after the elimination of null (expr1, expr2) pairs:

```
AVG(expr2)
```

Parameters

expr1
: Number expression.

expr2
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

REGR_R2

REGR_R2 — Returns the coefficient of determination (R-squared) of the regression line.

Synopsis

```
numeric REGR_R2 ( in expr1 any ,
                  in expr2 any ) ;
```

Description

REGR_R2 returns the coefficient of determination (also called "R-squared" or "goodness of fit") for the regression. `VAR_POP(expr1)` and `VAR_POP(expr2)` are evaluated after the elimination of null pairs. The return values are:

NULL if VAR_POP(expr2) = 0
1 if VAR_POP(expr1) = 0 and VAR_POP(expr2) != 0
(CORR(expr1,expr2) * CORR(expt1, expr2)) if VAR_POP(expr1) > 0 and VAR_POP(expr2) != 0

Parameters

expr1
: Number expression.

expr2
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

REGR_COUNT

REGR_COUNT — Returns the number of non-null numbers used to fit the regression line.

Synopsis

```
numeric REGR_COUNT ( in expr1 any ,
                     in expr2 any );
```

Description

REGR_COUNT Returns the number of non-null numbers used to fit the regression line.

Parameters

expr1
: Number expression.

expr2
: Number expression.

Return Types

The function returns a value of type NUMERIC.

REGR_INTERCEPT

REGR_INTERCEPT — Returns the y-intercept of the regression line.

Synopsis

```
numeric REGR_INTERCEPT ( in expr1 any ,
                         in expr2 any ) ;
```

Description

REGR_INTERCEPT returns the y-intercept of the regression line. After the elimination of null (expr1, expr2) pairs, it makes the following computation:

```
AVG(expr1) - REGR_SLOPE(expr1, expr2) * AVG(expr2)
```

Parameters

expr1
: Number expression.

expr2
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

REGR_SLOPE

REGR_SLOPE — Returns the slope of the line.

Synopsis

```
numeric REGR_SLOPE ( in expr1 any ,
                     in expr2 any ) ;
```

Description

REGR_SLOPE returns the slope of the line. After the elimination of null (expr1, expr2) pairs, it makes the following computation:

```
COVAR_POP(expr1, expr2) / VAR_POP(expr2)
```

Parameters

expr1
: Number expression.

expr2
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

COVAR_SAMP

COVAR_SAMP — Returns the sample covariance of a set of number pairs.

Synopsis

```
numeric COVAR_SAMP ( in expr1 any ,
                     in expr2 any ) ;
```

Description

COVAR_SAMP returns the sample covariance of a set of number pairs. Both expr1 and expr2 are numeric expressions. Virtuoso applies the function to the set of (expr1, expr2) pairs after eliminating all pairs for which either expr1 or expr2 is null. Then Virtuoso makes the following computation:

```
(SUM(expr1 * expr2) - SUM(expr2) * SUM(expr1) / n) / (n-1)
```

where n is the number of (expr1, expr2) pairs where neither expr1 nor expr2 is null.

Parameters

expr1
: Number expression.

expr2
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

COVAR_POP — Returns the population covariance of a set of number pairs.

Synopsis

```
numeric COVAR_POP ( in expr1 any ,
                    in expr2 any );
```

Description

COVAR_POP returns the population covariance of a set of number pairs. Both expr1 and expr2 are numeric expressions. Virtuoso applies the function to the set of (expr1, expr2) pairs after eliminating all pairs for which either expr1 or expr2 is null. Then Virtuoso makes the following computation:

```
(SUM(expr1 * expr2) - SUM(expr2) * SUM(expr1) / n) / n
```

where n is the number of (expr1, expr2) pairs where neither expr1 nor expr2 is null.

Parameters

expr1
: Number expression.

expr2
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

CORR

CORR — Returns the coefficient of correlation of a set of number pairs.

Synopsis

```
numeric CORR ( in expr1 any ,
               in expr2 any );
```

Description

CORR returns the coefficient of correlation of a set of number pairs. Both expr1 and expr2 are number expressions. Virtuoso applies the function to the set of (expr1, expr2) after eliminating the pairs for which either expr1 or expr2 is null. Then Virtuoso makes the following computation:

```
COVAR_POP(expr1, expr2) / (STDDEV_POP(expr1) * STDDEV_POP(expr2))
```

Parameters

expr1
: Number expression.

expr2
: Number expression.

Return Types

The function returns a value of type NUMERIC. If the function is applied to an empty set, then it returns null.

DB.DBA.XQ_SEQUENCE_AGG

DB.DBA.XQ_SEQUENCE_AGG — Creates an XQuery sequence object that consists of all values passed the the aggregate.

Synopsis

```
vector DB.DBA.XQ_SEQUENCE_AGG ( value_expression any );
```

Description

DB.DBA.XQ_SEQUENCE_AGG creates an XQuery sequence object that consists of all values passed the aggregate.

Parameters

value_expression
: Values are "flatten" before being added to the sequence. It means that --- NULLs are not added at all.

Return Types

Any

See Also

xquery_eval()

DB.DBA.SAMPLE()

DB.DBA.VECTOR_AGG

DB.DBA.VECTOR_AGG — Returns a vector of passed values.

Synopsis

```
vector DB.DBA.VECTOR_AGG ( value_expression any );
```

Description

DB.DBA.VECTOR_AGG returns a vector of passed values. The order of items in the vector repeats the order of passing individual values to the aggregate.

Parameters

value_expression
: Value of item for aggregation.

Return Types

Any

Examples

Example 24.1.

As the order of items in the vector repeats the order of passing individual values to the aggregate, it is possible to write, for instance:

```
-- Get an ordered vector of X-es
SELECT DB.DBA.VECTOR_AGG (subquery.X)
FROM (SELECT X FROM ... ORDER BY X) as subquery
```

or

```
SELECT DB.DBA.VECTOR_AGG (subquery.Y)
FROM (SELECT Y FROM ... ORDER BY X) as subquery
```

and get vector of Y-s that are ordered by matching values of X-es.

DB.DBA.GROUP_CONCAT_DISTINCT()

DB.DBA.GROUP_DIGEST()

DB.DBA.SAMPLE()

DB.DBA.VECTOR_OF_NONNULLS_AGG

DB.DBA.VECTOR_OF_NONNULLS_AGG — Returns a vector of passed values ingoring NULL arguments.

Synopsis

```
vector DB.DBA.VECTOR_OF_NONNULLS_AGG ( value_expression any );
```

Description

DB.DBA.VECTOR_OF_NONNULLS_AGG returns a vector of passed values. Similar to DB.DBA.VECTOR_AGG() but ignores NULL arguments.

The order of items in the vector repeats the order of passing individual values to the aggregate.

Parameters

value_expression
: Value of item for aggregation.

Return Types

Any

Examples

Example 24.2. Simple Use

As the order of items in the vector repeats the order of passing individual values to the aggregate, it is possible to write, for instance:

```
-- Get an ordered vector of X-es
SELECT DB.DBA.VECTOR_OF_NONNULLS_AGG (subquery.X)
FROM (SELECT X FROM ... ORDER BY X) as subquery
```

or

```
SELECT DB.DBA.VECTOR_OF_NONNULLS_AGG (subquery.Y)
FROM (SELECT Y FROM ... ORDER BY X) as subquery
```

and get vector of Y-s that are ordered by matching values of X-es.

DB.DBA.GROUP_DIGEST()

DB.DBA.SAMPLE()

DB.DBA.VECTOR_OR_NULL_AGG

DB.DBA.VECTOR_OR_NULL_AGG — Returns a vector of passed values.

Synopsis

```
vector DB.DBA.VECTOR_OR_NULL_AGG ( value_expression any );
```

Description

DB.DBA.VECTOR_OR_NULL_AGG returns a vector of passed values. Similar to DB.DBA.VECTOR_AGG() but returns NULL instead of an empty vector if no arguments were actually passed.

The order of items in the vector repeats the order of passing individual values to the aggregate.

Parameters

value_expression
: Value of item for aggregation.

Return Types

Any. If no arguments were actually passed returns NULL instead of an empty vector.

Examples

Example 24.3. Simple Use

As the order of items in the vector repeats the order of passing individual values to the aggregate, it is possible to write, for instance:

```
-- Get an ordered vector of X-es
SELECT DB.DBA.VECTOR_OR_NULL_AGG (subquery.X)
FROM (SELECT X FROM ... ORDER BY X) as subquery
```

or

```
SELECT DB.DBA.VECTOR_OR_NULL_AGG (subquery.Y)
FROM (SELECT Y FROM ... ORDER BY X) as subquery
```

and get vector of Y-s that are ordered by matching values of X-es.

DB.DBA.VECTOR_OF_NONNULLS_OR_NULL_AGG

DB.DBA.VECTOR_OF_NONNULLS_OR_NULL_AGG — Returns a vector of passed values ingoring NULL arguments.

Synopsis

```
vector DB.DBA.VECTOR_OF_NONNULLS_OR_NULL_AGG ( value_expression any );
```

Description

DB.DBA.VECTOR_OF_NONNULLS_OR_NULL_AGG returns a vector of passed values. Similar to DB.DBA.VECTOR_OF_NONNULLS_AGG() but returns NULL instead of an empty vector if no arguments were passed or only NULLs were passed.

Parameters

value_expression
: Value of item for aggregation.

Return Types

Any. If no arguments were passed teturns NULL instead of an empty vector or only NULLs were passed.

Examples

Example 24.4. Simple Use

As the order of items in the vector repeats the order of passing individual values to the aggregate, it is possible to write, for instance:

```
-- Get an ordered vector of X-es
SELECT DB.DBA.VECTOR_OF_NONNULLS_OR_NULL_AGG (subquery.X)
FROM (SELECT X FROM ... ORDER BY X) as subquery
```

or

```
SELECT DB.DBA.VECTOR_OF_NONNULLS_OR_NULL_AGG (subquery.Y)
FROM (SELECT Y FROM ... ORDER BY X) as subquery
```

and get vector of Y-s that are ordered by matching values of X-es.

DB.DBA.GROUP_DIGEST()

DB.DBA.SAMPLE()

DB.DBA.VECTOR_CONCAT_AGG

DB.DBA.VECTOR_CONCAT_AGG — Expects SQL vectors as arguments and the result is a concatenation of all passed vectors.

Synopsis

```
vector DB.DBA.VECTOR_CONCAT_AGG ( _items any );
```

Description

DB.DBA.VECTOR_CONCAT_AGG expects SQL vectors as arguments and the result is a concatenation of all passed vectors.

Parameters

_items
: SQL vectors.

Return Types

Any

Examples

Example 24.5. Simple Use

The most typical usage is the composing of get-keyword style vector, for ex:

```
  SELECT DB.DBA.VECTOR_CONCAT_AGG (vector (U_NAME, U_ID))
    FROM DB.DBA.SYS_USERS
ORDER BY U_NAME;
```

which returns a vector of passed values. The order of items in the vector repeats the order of passing argument vectors to the aggregate.

```
 (dba, 0, dav, 2, administrators, 3, nobody, 5, nogroup, 6, __rdf_repl, 7, SPARQL_SELECT, 100, SPARQL_SPO
No. of rows in result: 1
```

DB.DBA.GROUP_CONCAT_DISTINCT()

DB.DBA.GROUP_DIGEST()

DB.DBA.SAMPLE()

DB.DBA.BAG_AGG

DB.DBA.BAG_AGG — Returns a vector of passed values.

Synopsis

```
vector DB.DBA.BAG_AGG ( value_expression any );
```

Description

`DB.DBA.BAG_AGG()` returns a vector of passed values.

This is similar to DB.DBA.VECTOR_AGG() and returns a vector of passed values but the order of items in the vector is not predefined and may vary from run to run.

A query with `DB.DBA.BAG_AGG()` may work faster than a similar query with DB.DBA.VECTOR_AGG() because `DB.DBA.BAG_AGG()` gives more freedom to the SQL optimizer. If the order is not important for your application, consider using of `DB.DBA.BAG_AGG()` .

Parameters

value_expression
: Value of item for aggregation.

Return Types

Any

Examples

Example 24.6. Simple Use

```
SELECT DB.DBA.BAG_AGG (subquery.X)
FROM (SELECT X FROM ... ORDER BY X) as subquery
```

abs

abs — Return the absolute value of a number

Synopsis

abs (in *num* any);

Description

`abs` returns the absolute value of its argument.

Parameters

num
: Numeric value whose absolute value is to be returned

Return Types

Same as parameter type.

Examples

Example 24.11. Simple example

Get absolute values of several numeric values

```
SQL> select cast (abs (-2.343) as numeric),
  cast(abs (0) as numeric),
  cast (abs (3.1415) as numeric);

callret          callret         callret
DECIMAL          DECIMAL         DECIMAL
_____________________________________________

2.343            0               3.1415

1 Rows. -- 5 msec.
```

__any_grants

__any_grants — Checks a table for grants.

Synopsis

```
integer __any_grants ( in tablename varchar );
```

Description

The `__any_grants()` can be used to test whether there are any rights granted (for insert/update/delete) to a table for current SQL account.

Parameters

tablename
: The table name to be tested.

Return Types

An integer will be returned to indicate whether the table supplied has any privileges granted (1) or not granted (zero 0) for current SQL user.

Errors

Table 24.1. Errors signalled by

SQLState	Error Code	Error Text	Description
22023	SR014	Function any_grants needs a string as argument 1, not an arg of type [type]	

Examples

Example 24.12. Using the __any_grants() function

This simple example shows testing a grant rights for a table, using the __any_grants() function from ISQL and demo SQL user accout.

```
$isql localhost:1112 demo demo
-- the demo account owns an Orders table, so it's granted
SQL> select __any_grants ('Demo.demo.Orders');
callret
INTEGER
_______________________________________________________________________________

1

1 Rows. -- 1 msec.

-- but it has no permission to access the table SYS_REPL_ACCOUNTS
SQL> select __any_grants ('DB.DBA.SYS_REPL_ACCOUNTS');
callret

aref

aref — returns specific element of an array or string

Synopsis

aref (*arg* any ,
nth integer) ;

Description

`aref` returns the *`nth`* element of an array , string or string_session , where *`nth`* is a zero-based index. If the first argument is a string or string_session , the integer ASCII value of the *`nth`* character is returned. If the first argument is an array of any , then the corresponding element is returned.

Parameters

arg
: array , vector or string .

nth
: integer zero-based index.

Return Values

An integer character code or *`nth`* element as whatever type the element is if *`arg`* is an array or vector (heterogeneous array.)

Errors

Table 24.2. Errors signalled by aref

SQLState	Error Code	Error Text	Description
22003	SR017	aref: Bad array subscript (zero-based) %d for an arg of type %s (%d) and length %d.	
22023	SR000	aref expects an array or vector, not an arg of type %d.	

Examples

Example 24.13. Simple examples

```
SQL> select aref ('Abacus', 0);
callret
VARCHAR
_______________________________________________________________________________

`vector aset ascii`

ascii

ascii — Get ASCII value of a character

Synopsis

```
integer ascii ( arg any );
```

Description

`ascii` returns the ASCII value of the first character of a string. If an empty string is given, then zero is returned.

Parameters

arg
: A string

Return Values

The integer ASCII value of the first character of the input string is returned. If the input string is empty, then zero is returned

Errors

Table 24.3. Errors signalled by ascii

SQLState	Error Code	Error Text	Description
22023	SR044	Function ascii needs a string as an argument, not an argument of type %d (= %s)	

Examples

Example 24.14. Simple example

```
SQL> select ascii('Zardoz');
callret

`aref`, `chr`

aset

aset — set array element

Synopsis

aset (in *arg* any ,
in *nth* integer ,
in *new_elem* any) ;

Description

aset sets the nth element of a string, array or vector where nth is a zero-based index. If the first argument is a string, the nth character of string is replaced with the ASCII value given in the third argument elem.

Parameters

arg
: A string, array or vector.

nth
: Zero-based element index.

nelem
: The new element. If arg is a string, its nth element will be replaced by the ASCII value given in new_elem .

Return Values

`Aset` returns *`nelem`* . It modifies its first argument.

Errors

Table 24.4. Errors signalled by aset

SQLState	Error Code	Error Text	Description
22003	SR020	Bad array subscript %d in aset.	

Examples

Example 24.15. Using `make_string` and `aref`

Make a string, fill with character sequence from A to Z.

```
SQL> create procedure
alphabet_string ()
{
  declare _inx integer;
  declare _str varchar;
  _str := make_string (26);

  while (_inx < 26)
    {
      aset (_str, _inx, _inx + 65);
      _inx := _inx + 1;
    }

  return (_str);
}
;
```

```
Done. -- 6 msec.
SQL> select alphabet_string ();
callret
VARCHAR NOT NULL
_______________________________________________________________________________

ABCDEFGHIJKLMNOPQRSTUVWXYZ

1 Rows. -- 4 msec.
```

Example 24.16. Reverse a string using aset

Note that str is modified by aset.

```
SQL> create procedure
revstr (in str varchar)
{
    declare len, inx1, inx2, tmp integer;

    if (str is null) return (str);

    len := length (str);
    if (len < 2)
      return (str); -- No need for further processing

    inx1 := 0;       -- Index from the left.
    inx2 := len - 1; -- Index from the right.
    len  := len / 2; -- Upper limit for inx1.

    while (inx1 < len)
      {
        tmp := aref (str, inx1);
        aset (str, inx1, aref (str, inx2));
        aset (str, inx2, tmp);
        inx1 := inx1 + 1;
        inx2 := inx2 - 1;
      }
    return (str);
}
;

Done. -- 7 msec.
SQL> select revstr ('repaid'), revstr ('Alli, tapa pulu papatilla!');
callret   callret

`aref()`,`vector()`,`make_string()`

atof

atof — Convert a string to single precision float

Synopsis

atof (in *arg* string
);

Description

atof returns its argument as a single precision floating point. If the string cannot be parsed and converted to a valid float, a value 0.0 is returned.

Parameters

arg
: A string input parameter

Return Types

Single precision floating point

Examples

Example 24.17. Simple examples

```
SQL> select atof('1.23456789');
callret
REAL
_______________________________________________________________________________

1.234568

1 Rows. -- 5 msec.

atoi

atoi

atoi — Convert a string to an integer

Synopsis

atoi (in *arg* string
);

Description

atoi returns its argument as an integer. If the string cannot be parsed and converted to a valid integer, a value 0 is returned.

Parameters

arg
: A string input parameter

Return Types

The string converted to an integer. If the string is a number then the absolute value of the literal will be returned as an integer. Otherwise 0 is returned.

Examples

Example 24.18. Simple examples

```
SQL> select atoi('1.23456789');
callret
INTEGER
_______________________________________________________________________________

1

1 Rows. -- 5 msec.

att_local_name

att_local_name — Compose a fully qualified table name based on DSN and remote table name.

Synopsis

```
varchar att_local_name ( in dsn varchar ,
                         in table varchar ) ;
```

Description

The utility function, `att_local_name()` , can be used to make a fully qualified table name from non-qualified or qualified one, i.e. the qualifier and owner will be added if they are missing. The schema name will be replaced with current qualifier on execution, owner will be replaced or added with name of supplied DSN name. All non-alphanumeric characters in the name will be replaced with underscore symbol.

Parameters

dsn
: The name of remote data source.

table
: The name of remote table.

Return Types

A string will be returned containing the fully qualified table name.

Examples

Example 24.19. Using the att_local_name() function

This simple example shows retrieval of fully qualified table name. using the att_local_name() function from ISQL.

```
SQL> select att_local_name ('Oracle', 'DEMO.EMP');
callret
VARCHAR
_______________________________________________________________________________

DB.ORACLE.EMP

1 Rows. -- 9 msec.
```

backup

backup , backup_close , backup_flush , backup_prepare , backup_row — Write data into transaction log format for backup purposes. Deprecated.

Synopsis

backup (in *file* varchar);

backup_close ( );

backup_flush ( );

backup_prepare (in *file* varchar);

backup_row (in *row* any);

Description

Important

These functions are deprecated. The use of backup_online () is preferred for database backups. Performing a backup with the destination file /dev/null is a good way of verifying a database's physical integrity.

All backup files, whether complete (created with `backup`) or partial (created with `backup_prepare` and `backup_row` of selected rows), begin with the complete schema that was effective at the time of the backup.

Backup and log files contain assumptions about the schema and row layout of the database. Hence it is not possible to use these for transferring data between databases. Attempt to do so will result in unpredictable results. Thus a log or backup may only be replayed on the same database, an empty database or a copy of the database which has had no schema changed since it was made. Also, when replaying a backup file onto an empty database, the +replay-crash-dump switch should be given on the executable command line.

This function requires dba privileges.

Full backup
: The backup function takes a file name as argument. The file produced will be in the log format and will recreate the database as it was at the time of the last checkpoint when replayed on an empty database. Such a file cannot be replayed on anything except an empty database. Logs made after the backup can be replayed over the database resulting from the backup file's replay. No schema operations are allowed between replays.

Partial backups
: The backup_prepare , backup_row and backup_close operations allow making specific partial backups.

Parameters

file
: varchar file filename for the generated log.

backup_row
: any row a value of the pseudo column _ROW .

See Also

replay

`backup_online()` , `backup_context_clear()`

backup_online

backup_online — perform online backup of database

Synopsis

```
int backup_online ( in file_prefix varchar ,
                    in pages integer ,
                    in timeout integer ,
                    in dirs any ) ;
```

Description

This procedure will backup all information from the checkpoint space to a series of files named "<file_prefix><n>.bp ", where <n> is the sequence number of the file in the backup series. The first backup will be a full gzip compressed dump of database pages in the checkpoint space. Any subsequent call will only backup pages which have changed since the last backup was made. To start with a fresh full backup, use backup_clear_context to clear the change tracking data. At each checkpoint the checkpoint space will be updated, and the next "backup_online;" procedure will create new files. Once backup_online() has been called for the first time, the arguments supplied will be used for subsequent calls to it. Hence, arguments supplied to this procedure (except the "dirs" argument) will be ignored in subsequent calls.

Before a new backup series can be started, the `backup_context_clear();` procedure must be called first. This procedure will clear the current backup context and mark all pages in the checkpoint space as ready for backup.

A database checkpoint cannot be performed while an online backup is in progress. Attempt to do a checkpoint will wait until the backup is complete.

This is the preferred means of backing up databases and replaces any other prior means. As an alternative, copying database files while the database is running will still work, as long as no checkpoint is made during the copy process.

Parameters

file_prefix
: A string to prefix to the filename of the backup files.

pages
: The pages argument indicates the maximum number of 8K pages that will be backed up into each file. This argument must be larger than 100. If pages < 100 an error will be returned.

timeout
: This parameter has no effect.

dirs
: This optional parameter must be an array of directory names (array of strings). The backup files are first stored in the first directory. When running out of disk any consecutive backup files are stored in the next directory in the list. If there are no more directories then an error is signalled and all the files written by this call to backup_online are deleted so as not to leave half made backups.

Return Types

This function will return the number of 8k pages that were backed-up.

Errors

This function can generate the following errors: IB001 IB002 IB003 IB004 IB005 IB006 IB007 IB008 IB009 IB010

Examples

Example 24.20. Performing an online backup

If there are 2010 new pages in the checkpoint space and user invokes:

```
"backup_online ('dump-20021010_#', 500);"
```

from ISQL, then the following series of backup files will be created in the Virtuoso database directory:

```
dump-20011010_#1.bp
dump-20011010_#2.bp
dump-20011010_#3.bp
dump-20011010_#4.bp
dump-20011010_#5.bp
```

The first 4 files will each contain 500 8K pages. The actual length of the files will vary due to varying compression ratio.

Example 24.21. Restoring an Online Backup

The following command could be used to restore the database from the backup files created:

```
virtuoso-iodbc-t +restore-backup dump-20011010_#
```

or:

```
virtuoso-odbc-t.exe +restore-backup dump-20011010_#
```

See Also

`backup_context_clear();`

backup_context_clear

backup_context_clear — Clears the backup context and marks all pages in checkpoint space as ready for online backup

Synopsis

```
backup_context_clear (  );
```

Description

This procedure must be called before a new backup series can be started, This procedure will clear the current backup context and mark all pages in the checkpoint space as ready for backup.

                         char * func ) ;
```

Description

The bif_...._arg functions are used in the Virtuoso shared object. They allow customization of the Virtuoso server. They are written in C code, and linked with the Virtuoso shared object.

The _or_null_ variants of these functions represent the SQL null value as a 00 pointer, even though getting the same argument with bif_arg() would return a box with the DV_DB_NULL tag. All number functions will coerce other types of numbers to the result type. All array argument functions will accept any type of array. It is up to the VSE itself to distinguish.

Virtuoso Server Extensions (VSEs) were formally referred to as Built-In Functions (BIFs).

Parameters

qst
: Query instance.

args
: input arguments.

nth
: which argument to retrieve (zero indexed).

func
: name of calling function. This will be printed in the SQL error message.

Return Values

On success, return a valid pointer to the data retrieved, or NULL. A SQL error is generated if the datatype is not valid. The bif_arg is the only function not to have validation of a data type.

The values returned by any of these belong to the query instance, and the bif is not authorized to modify or free them.

Table 24.5. Return types

Function	Type validated and returned
bif_arg	Any type of data. (no data type check)
bif_array_arg	string or array data
bif_array_or_null_arg	string or array or NULL data
bif_bin_arg	binary data
bif_double_arg	double data
bif_entity_arg	XML entity data
bif_float_arg	float data
bif_long_arg	long data
bif_long_or_char_arg	long or character data
bif_string_arg	string data
bif_string_or_null_arg	string or null data
bif_string_or_wide_or_null_arg	strings, widestrings or null data
bif_strses_arg	string session data

Examples

Example 24.22. Creating a function my_length()

A function called `my_length` written by developers, may process a string argument by making a call to `bif_string_arg` .

bit_and

bit_and — Returns bitwise AND of two 32-bit integers.

Synopsis

bit_and (in *n1* integer ,
in *n2* integer) ;

Description

The function returns bitwise AND of two given integers.

On 64-bit platforms, both arguments are intentionally truncated to 32 bits to maintain compatibility.

Return Types

Integer.

Examples

Example 24.23. Using bitwise-AND

```
select bit_and (18, 6);
2

select bit_and (-18, -6);
-22
```

See Also

`bit_not()`

`bit_or()`

`bit_shift()`

`bit_xor()`

bit_or

bit_or — Returns bitwise OR of two 32-bit integers.

Synopsis

bit_or (in *n1* integer ,
in *n2* integer) ;

Description

The function returns bitwise OR of two given integers.

On 64-bit platforms, both arguments are intentionally truncated to 32 bits to maintain compatibility.

Return Types

Integer.

Examples

Example 24.24. Using bitwise-OR

```
select bit_or (18, 6);
22

select bit_or (-18, -6);
-2
```

See Also

`bit_and()`

`bit_not()`

`bit_shift()`

`bit_xor()`

bit_not

bit_not — Returns bitwise NOT of a 32-bit integer.

Synopsis

bit_not (in *n1* integer);

Description

The function returns bitwise NOT of a given integer.

On 64-bit platforms the argument is intentionally truncated to 32 bits to maintain compatibility.

Return Types

Integer.

Examples

Example 24.25. Using bitwise-NOT

```
select bit_not (18);
-19

select bit_not (-18);
-17
```

See Also

`bit_and()`

`bit_or()`

`bit_shift()`

`bit_xor()`

bit_shift

bit_shift — Returns the result of bitwise shift operation over two 32-bit integers.

Synopsis

bit_shift (in *value* integer ,
in *distance* integer) ;

Description

The function returns bitwise shift of two given integers. Depending on the arguments, the shift may be left or right. For right-shift, leftmost bits of the result are filled by the value of the 31-st bit.

On 64-bit platforms, both arguments are intentionally truncated to 32 bits and the shift is restricted to 32 bits to maintain compatibility.

Parameters

value
: The value to be shifted.

distance
: The sign of the parameter specifies the direction of the shift: positive values indicate shift to the left, negative values indicate shift to the right. The absolute value of the parameter specifies the number of bits to shift. The value of zero means that the result is equal to the value of the first argument.

Return Types

Integer.

Examples

Example 24.26. Bitwise-shifting

```
select bit_shift (18, 6);
1152

select bit_shift (-18, 6);
-1152

select bit_shift (1152, -6);
18

select bit_shift (-1152, -6);
-18
```

`bit_and`

`bit_or`

`bit_not`

`bit_xor`

bit_xor

bit_xor — Returns bitwise XOR (exclusive "or") of two 32-bit integers.

Synopsis

bit_xor (in *n1* integer ,
in *n2* integer) ;

Description

The function returns bitwise XOR (exclusive "or") of two given integers.

On 64-bit platforms, both arguments are intentionally truncated to 32 bits, to provide compartibility.

Return Types

Integer.

Examples

Example 24.27. Bitwise-XOR

```
select bit_xor (18, 6);
20

select bit_xor (-18, -6);
20

select bit_xor (-18, 6);
-24
```

blob_to_string

blob_to_string — Convert a blob to string

Synopsis

```
varchar blob_to_string (     in blob any
);
```

Description

Although primarily used for converting blobs (long varbinary , long varchar) to string , `blob_to_string` may also be used to convert from wide string , persistent XML (XPER) and string_output streams . If the data being converted is longer than maximum length of a string , `blob_to_string` will signal an error.

Note

This function is equivalent to

```
cast (x as varchar)
```

. Using `cast` is preferred.

Parameters

blob
: blob handle (long varbinary or long varchar), string_output or XPER (persistent XML)

Return Types

Varchar contents of *`blob`* .

Errors

Table 24.6. Errors signalled by `blob_to_string`

SQLState	Error Code	Error Message	Description
22023	SR068	XML tree cannot be used as argument of blob_to_string	
22001	SR069	Attempt to convert a persistent XML document longer than VARCHAR maximum in blob_to_string	
22023	SR070	blob_to_string requires a blob as argument	
22023	SR071	Blob argument to blob_to_string must be a non-interactive blob	
22001	SR072	Blob too long for the string.	

Examples

Example 24.28. Various conversions

```
SQL> use Demo;

Done. -- 20 msec.
SQL> select blob_to_string (Description) from Categories;
callret
VARCHAR
_______________________________________________________________________________

blob_to_string_output

blob_to_string_output — Convert a blob to string session

Synopsis

`varchar` **`blob_to_string_output`** `(` in *blob* any `);`

Description

Although primarily used for converting blobs (long varbinary , long varchar) to string output object , `blob_to_string_output` may also be used to convert from wide string , persistent XML (XPER) and string_output streams .

Parameters

blob
: blob handle (long varbinary or long varchar), string_output or XPER (persistent XML)

Return types

string output object contents of *`blob`* .

Errors

Table 24.7. Errors signalled by

SQLState	Error Code	Error Text	Description
22023	SR068	XML tree cannot be used as argument of blob_to_string_output	
22023	SR070	blob_to_string_output requires a blob or string argument	
22023	SR071	Blob argument to blob_to_string_output must be a non-interactive blob	

Examples

Example 24.29. Various conversions

```
SQL> use Demo;

Done. -- 20 msec.
SQL> select string_output_string (blob_to_string_output ("Description")) from "Categories";
callret
VARCHAR
_______________________________________________________________________________

Soft drinks, coffees, teas, beers, and ales
Sweet and savory sauces, relishes, spreads, and seasonings
Desserts, candies, and sweet breads

Breads, crackers, pasta, and cereal
Prepared meats
Dried fruit and bean curd
Seaweed and fish

8 Rows. -- 37 msec.
SQL>
```

See Also

`blob_to_string`

bookmark

bookmark — Return the bookmark for current row of a scrollable cursor

Synopsis

```
any bookmark ( in cursor CURSOR );
```

Description

`bookmark` returns a bookmark for the current row of an open scrollable cursor. Given an invalid argument, i.e. no cursor, no current row or non-open cursor, it signals an error. The returned value can be used in subsequent FETCH .. BOOKMARK over the same cursor.

Parameters

bookmark
: Given Bookmark.

cursor
: Open scrollable cursor.

Return Types

`integer` bookmark id.

Errors

Table 24.8. Errors signalled by

SQLState	Error Code	Error Text	Description
24000	SR238	Virtuoso/PL Scrollable cursor not opened	
HY109	SR239	Virtuoso/PL Scrollable cursor not positioned on a row

Cursors in Virtuoso/PL guide

ceiling

ceiling — Round a number to positive infinity.

Synopsis

ceiling (in *x* double precision) ;

Description

`ceiling` calculates the smallest integer greater than or equal to *x* .

Parameters

x
: double precision

Return Values

`ceiling` returns a 32-bit integer .

Examples

Example 24.30. Simple Examples

```
SQL> select ceiling (12.3456), ceiling (-12.3456), ceiling (0.513513);
callret   callret   callret
INTEGER   INTEGER   INTEGER
_______________________________________________________________________________

13        -12       1

1 Rows. -- 4 msec.
```

`floor`

cfg_item_count

cfg_item_count — return number of items in a section in configuration file

Synopsis

cfg_item_count (in *path* varchar ,
in *section* varchar) ;

Description

Return the number of items that exist in the specified section of the INI file.

Parameters

path
: Name of the INI file.

section
: Name of the section in the INI file.

Return Values

An integer containing the number of items that exist in the section.

Examples

Example 24.31. Simple examples

Find number of items in the [Parameters] section of the current virtuoso.ini file.

```
SQL> select cfg_item_count(virtuoso_ini_path(), 'Parameters');
callret
INTEGER
_______________________________________________________________

19
```

See Also

`virtuoso_ini_path cfg_section_count cfg_section_name cfg_item_name cfg_item_value cfg_write`

cfg_item_name

cfg_item_name — get nth item name from ini file

Synopsis

cfg_item_name (in *path* varchar ,
in *section* varchar ,
in *item_index* integer) ;

Description

Returns the name of the item specified by item_index (begins from zero). If the index and section name do not point to a valid item, then zero is returned, otherwise on success the function returns the item name.

Parameters

path
: Name of the INI file.

section
: Name of the section in the INI file.

item_index
: Zero based index to the item within the section to be listed.

Return Values

A varchar containing the name of item referenced by *section* and *item_index*.

Examples

Example 24.32. Simple examples

Display the first keyname in the [Parameters] section of the current virtuoso.ini file.

```
SQL> select cfg_item_name(virtuoso_ini_path(), 'Parameters',0);
callret
VARCHAR
_______________________________________________

ServerPort
```

See Also

virtuoso_ini_path cfg_section_count cfg_section_name cfg_item_count cfg_item_value cfg_write

cfg_item_value

cfg_item_value — returns the value of an item from the ini file

Synopsis

```
cfg_item_value ( in path varchar ,
                 in section varchar ,
                 in item_name varchar ) ;
```

Description

Return the value of an item identified by *item_name* and *section* parameters from the specified INI file.

Parameters

path
: Name of the INI file.

section
: Name of the section in the INI file.

item_name
: Name of the item in the section.

Return Values

A varchar containing the item value. Return zero if section or item_name is invalid.

Examples

Example 24.33. Simple examples

Read the value of the ServerPort item from the [Parameters] section of the current virtuoso.ini file.

```
SQL> select cfg_item_value(virtuoso_ini_path(), 'Parameters','ServerPort');
callret
VARCHAR
_______________________________________________________________________________

1112
```

See Also

virtuoso_ini_path cfg_section_count cfg_section_name cfg_item_count cfg_item_name cfg_write

cfg_section_count

cfg_section_count — get number of sections in an INI file

Synopsis

cfg_section_count (in *path* varchar) ;

Description

Returns the number of sections in an INI file.

Parameters

path
: Name of the INI file.

Return Values

An integer containing the number of sections in the INI file.

Examples

Example 24.34. Simple examples

Find out how many sections are in the current virtuoso.ini file.

```
SQL> select cfg_section_count(virtuoso_ini_path());
callret
INTEGER
_______________________________________________________

7
```

See Also

`virtuoso_ini_path cfg_section_name cfg_item_count cfg_item_name cfg_item_value cfg_write`

cfg_section_name

cfg_section_name — returns INI file section name

Synopsis

```
cfg_section_name ( in path varchar ,
                   in index integer ) ;
```

Description

Returns the name of section specified by the index (begins from zero). If the index can reference a section, the that section name is returned, otherwise returns zero on error.

Parameters

path
: Name of the INI file.

index
: Zero based index that references a section.

Return Values

An varchar containing the name of section.

Examples

Example 24.35. Simple examples

Get the second section name from the current virtuoso.ini file.

```
SQL> select cfg_section_name(virtuoso_ini_path(), 1);
callret
VARCHAR
_______________________________________________________

Parameters
```

See Also

`virtuoso_ini_path cfg_section_count cfg_item_count cfg_item_name cfg_item_value cfg_write`

cfg_write

cfg_write — Writes the item=value to an INI file

Synopsis

cfg_write (in *path* varchar ,
in *section* varchar ,
in *item_name* varchar ,
in *item_value* varchar) ;

Description

This function requires dba privileges.

This function allows modification of existing entries, or update updating existing items in an INI file.

Parameters

path
: Name of the INI file.

section
: Name of the section in the INI file.

item_name
: Name of item that will be assigned the item_value.

item_value
: Value to be assigned to the item_name.

Examples

Example 24.36. Simple examples

Write ServerPort=2222 under the [Parameters] section of the current virtuoso.ini file.

```
SQL> cfg_write(virtuoso_ini_path(), 'Parameters','ServerPort','2222');

-- Verification
SQL> select cfg_item_value(virtuoso_ini_path(), 'Parameters','ServerPort');
callret
VARCHAR
_______________________________________________________________________________

2222
```

See Also

`virtuoso_ini_path cfg_section_count cfg_section_name cfg_item_count cfg_item_name cfg_item_value`

charset_define

charset_define — Define a character set.

Synopsis

charset_define (in *name* varchar ,
in *charset_string* any ,
in *aliases* any) ;

Description

This function creates a new narrow language-specific character set, or redefines an existing one.

Parameters

name
: The name of the character set to define. This becomes the "preferred" name of the character set.

charset_string
: Wide string with the character codes for each given character from 1 to 255. That is, a 255-byte long NCHAR defining the Unicode codes for narrow chars 1-255.

aliases
: Vector of character set names that are to be aliases of the character set being defined. Use NULL if there are to be no aliases.

Return Types

None

Errors

Table 24.9. Errors signalled by

sqlstate	error code	error text
2C000	IN001	The UTF-8 is not a redefinable charset
2C000	IN002	charset_define : Charset table not a wide string
2C000	IN003	charset_define : 0 not allowed as a charset definition
2C000	IN004	charset <name> already defined. Drop it first
2C000	IN005	Alias <position> is not of type STRING

Examples

Example 24.37. New 4th character, and aliases

To setup the 4th character to be Unicode 0xffce, and give the character set 2 aliases, you would make a call like this:

```
charset_define ('NEW-CHARSET',
      N'\x1\x2\x3\xffce\x5....' , vector ('SOME-CHARSET', 'ANOTHER-CHARSET'));
```

The character string should contain 255 wide characters that are arbitrary unicode values.

See Also

`charsets_list()`

charset_recode

charset_recode — Translate a string to another character set

Synopsis

```
any charset_recode ( in src_string varchar/nvarchar ,
                     in src_charset varchar ,
                     in dst_charset varchar ) ;
```

Description

This function translates a string from a given source charset to a destination charset. It provides a generic way of recoding string entities.

The *src_charset* may be a narrow or a wide string . If it's a narrow string (VARCHAR) then the *src_charset* is taken into account and defines the current encoding of the *src_string* . In any other case *src_charset* is ignored.

src_charset and *dst_charset* are names of system-defined 8 bit charset tables. Use charsets_list to obtain a list of currently defined character sets and aliases. If either of these is null, then the charset in effect is used. There are two special character set names - "UTF-8" and "_WIDE_" - that are recognized by this function. These represent UTF-8 encoding of characters and wide string (NVARCHAR).

Parameters

src_string
: The input data to be converted. String or wide string.

src_charset
: Input data character set, string .

dst_charset
: The charset to convert to, string .

Examples

Example 24.38. Recoding a narrow ISO-8859-1 string as UTF-8

```
select cast (charset_recode ('\xA9', 'ISO-8859-1', 'UTF-8') as varbinary)
  -- converts "Copyright sign" to UTF-8 (output 0xC2A9)
select cast (charset_recode ('\xC0', 'WINDOWS-1251', 'ISO-8859-5') as varbinary)
  -- converts "Cyrillic A" from WINDOWS-1251 charset to ISO-8859-5 (output 0xB0).
select cast (charset_recode (N'\x410', '_WIDE_', 'WINDOWS-1251') as varbinary)
  -- converts "Cyrillic A" from Unicode to WINDOWS-1251 charset (result '\xC0').
select charset_recode (N'\x410', '_WIDE_', 'ISO-8859-1')
  -- converts "Cyrillic A" from Unicode to ISO-8859-1 charset (Not available : result '?').
```

elh_load_handler

lh_get_handler

lh_load_handler

charsets_list

charsets_list — List known character set names and aliases.

Synopsis

any **charsets_list** (in *gen_res_set* integer);

Description

This function produces a list of all character set names and aliases known to Virtuoso. The returned value is an array of string s with a character set name as each element. If the *gen_res_set* flag is 1, the function also produces a result set in which each row contains one varchar column with a name of a character set or alias.

Parameters

gen_res_set
: Integer flag to determine whether to produce a result set: 0 means no, 1 means yes.

Return Types

An array of string , optionally generates a result set of single varchar columns.

Errors

This function can generate the following errors: SR008 SR001

Examples

Example 24.39. List character sets as a result set

```
SQL> charsets_list(1);
CS_NAME
VARCHAR
_______________________________________________

437
819
850
855
866
874
999
CP1250
CP1251
CP1252
CP1257
CP437
....
```

There are 132 predefined character sets in total that would be listed.

Example 24.40. Get first 2 character set names/aliases

```
....
x:= charsets_list (0);
y := aref (x, 0); -- will be '437'
y := aref (x, 1); -- will be '819'
....
```

See Also

`charset_define()`

checkpoint_interval

checkpoint_interval — Configure database checkpointing

Synopsis

```
integer checkpoint_interval ( in minutes integer );
```

Description

This function changes the database checkpointing interval to the given value in minutes. It may also be used to disable checkpointing in two ways: By setting checkpoint interval to 0, the checkpoint will only be performed after roll forward upon database startup. A setting of -1 will disable all checkpointing. Main use for this function is to ensure a clean online backup of the database slices. Copying of the database may take long and checkpointing would modify those files in mid-copy, thus rendering the resulting copy unusable. In case the system should, for some reason or another, become unstable, it is sometimes better to disable checkpointing after a database restart to resume backing up from where it was left prior to a system crash. Disabling all checkpointing by giving checkpoint_interval the value of -1 will do just that.

The interval setting will be saved in the server configuration file as value of CheckpointInterval in section [Parameters], thus it will persist over consecutive server shutdown/restart cycles. A long checkpoint_interval setting will produce longer transaction logs, which in turn prolongs the time it takes for the database to perform a roll forward upon restart in case it was shut down without making a checkpoint.

Parameters

minutes
: integer number of minutes between checkpoints.

Return Types

Previous value of CheckpointInterval in the configuration file as an integer.

Errors

Parameter data type checking errors

Examples

Example 24.41. Simple examples

Disable checkpoints:

```
SQL> checkpoint_interval(-1);

Done. -- 25 msec.
```

Re-enable checkpoints (every 2 hrs):

```
SQL> checkpoint_interval(120);
callret
VARCHAR
_______________________________________________________________

-1

Done. -- 4 msec.
```

See Also

`backup`

CheckpointInterval setting in Configuring Server Startup Files section

chr

chr — Convert a long character code to a character or wide character

Synopsis

```
varchar chr ( in chr_code long );
```

Description

`chr` returns a new one character long string containing the character with character code given as parameter.

Parameters

chr_code
: The LONG character code value for the character or wide character to be produced.

Return Values

If the *chr_code* is smaller than or equal to 255, the returned 1 character string will be of type VARCHAR . Otherwise the returned type is NVARCHAR .

Errors

Table 24.10. Errors signalled by chr

Examples

Example 24.42. Simple example

```
SQL> select chr (33);
callret
VARCHAR
_______________________________________________________________________________

!

1 Rows. -- 3 msec.
```

Example 24.43. Stored procedure example

This stored procedure lists the ASCII values and characters in a string given as argument.

```
SQL> create procedure
test_chr (in str varchar)
{
  declare pos integer; pos := 0;
  declare c_code, c_code2 integer; declare c_char varchar;

  result_names (c_code, c_code2, c_char);

  while (pos < length (str))
    {
      result (aref (str, pos), ascii (subseq (str, pos, pos+1, 1)),
        chr (aref (str, pos)));
      pos := pos + 1;
    }
}
```

```
;

Done. -- 7 msec.
SQL> test_chr ('Nebuchadnessar');
c_code             c_code2            c_char

See Also

aref, ascii

client_attr

client_attr — returns a varchar containing the requested information from the connection

Synopsis

```
varchar client_attr ( in attr varchar );
```

Parameters

attr
: can by one of the following:

Errors

Table 24.11. Errors signalled by `client_attr`

SQLState	Error Code	Error Text
22005	SR401	Server address not known.
22005	SR402	Cannot allocate temp space. SSL error : xxx
22005	SR403	xxx is not valid client_attr option.

collation_define

collation_define — define a new collation

Synopsis

```
collation_define ( in COLLATION_NAME varchar ,
                   in FILE_PATH varchar ,
                   in ADD_TYPE integer ) ;
```

Description

This function lets you define a new collation.

Parameters

COLLATION_NAME
: The name to be assigned to the new collation.

FILE_PATH
: The path and file name of the collation definition file. The path must be specified in the format appropriate to the operating system hosting the Virtuoso server.

ADD_TYPE
: is the type of the new collation: 1 for 8-bit collation (256-byte blob); 2 for UNICODE collation (65536-byte Unicode blob). A value of 0 instructs the function only to check the validity of the definition file and to return a resultset containing the codes of the valid exception definitions.

Return Types

If 0 is supplied to the ADD_TYPE parameter then a result set will be returned containing the codes of the valid definitions.

complete_table_name

complete_table_name — Returns a fully qualified table name.

Synopsis

```
varchar complete_table_name ( in tablename varchar ,
                              in mode integer ) ;
```

Description

The `complete_table_name()` can be used to make a fully qualified table name from non-qualified one, i.e. the qualifier and owner will be added if they are missing.

Parameters

tablename
: The table name to be retrieved.

mode
: If this mode parameter is set to 1 this function will first look-up the supplied tablename for a match in the system tables. If a match is found the full name will be returned, if the table is not found the function will continue as if the mode were set to 0.

Return Types

A string will be returned containing the fully qualified table name.

Errors

Table 24.12. Errors signalled by

SQLState	Error Code	Error Text	Description
22023	SR014	Function complete_table_name needs a string as argument 1, not an arg of type [type]	
22023	SR008	Function complete_table_name needs an integer as argument 2, not an arg of type [type]	

Examples

Example 24.44. Using the complete_table_name() function

This simple example shows retrieval of a fully qualified table name using the complete_table_name() function from ISQL. In the first case the table name supplied is a system table, in the second case the table does not exist and the result is generated based on the users details:

```
SQL> use WS;

Done. -- 4 msec.
SQL> select complete_table_name('SYS_DAV_RES', 1);
callret
VARCHAR
_______________________________________________________________________________

WS.WS.SYS_DAV_RES

1 Rows. -- 1 msec.

SQL> select complete_table_name('SYS_DAV_RES__', 1);
callret
VARCHAR
_______________________________________________________________________________
```

```
WS.DBA.SYS_DAV_RES__

1 Rows. -- 1 msec.
```

composite

composite — create a composite object

Synopsis

```
composite obj composite (  in x any
                           ,
                           ... );
```

Description

Create a composite object

Returns a composite object containing the serialization of each argument. The total serialized length of the arguments may not exceed 255.

Parameters

x ...
: The function takes a variable number of parameters of any type.

Return Values

A composite object

Errors

Table 24.13. Errors signalled by composite

SQLState	Error Code	Error Text	Description
22026	FT001	Length limit of composite exceeded.	The sum of length of the components exceeds 255.

Examples

Example 24.45. Simple example

Get second component of a composite of two integers. See reference page for composite_ref .

```
SQL> select composite_ref (composite (10,20), 1);
callret
VARCHAR
_______________________________________________________________________________

20

1 Rows. -- 6 msec.
```

See Also

`composite_ref` . The chapter Composite Data Type for a definition of properties of composite objects.

composite_ref

composite_ref — get member of a composite object

Synopsis

```
integer composite_ref ( in c any ,
                        in nth integer ) ;
```

Description

`composite_ref` returns the *`nth`* element of the composite. The index is 0 based.

Parameters

nth
: integer

Return types

The type returned is the type of the composite member referred to.

Errors

Table 24.14. Errors signalled by `composite_ref`

22023	FT002	composite expected for composite ref	
22003	FT003	composite index out of range %d for length %d	

Examples

Example 24.46. Simple example

Get first member of a composite consisting of VARCHAR values.

```
SQL> select composite_ref (composite ('Miles','Herbie','Wayne','Ron','Tony'), 0);
callret
VARCHAR
_______________________________________________________________________________

Miles

1 Rows. -- 4 msec.
```

See Also

The Composite Data Type for a definition of the properties of composite objects.

The function `composite` .

concat

concat — Concatenate strings

Synopsis

concat (*str1* varchar ,
str2 varchar ,
... ,
strn varchar) ;

Description

`concat` returns a new string , concatenated from a variable number of strings given as arguments. NULL arguments are handled as empty strings.

```
concat (str)
```

returns a copy of *str* .

```
concat ()
```

returns an empty string .

Parameters

Concat takes a variable number of string arguments.

Return types

The `concat` returns a single string . If there are wide strings amongst the arguments, the string returned will also be wide .

Errors

Table 24.15. Errors signalled by concat()

sqlstate	error code	error text
22023	SR007	Function concat needs a string or NULL as argument <argument number>, not an arg of type <offending type>

Examples

Example 24.47. Simple Example

Cross a mule with an ass.

```
SQL> select concat ('Muuli', 'aasi');
callret
VARCHAR
_______________________________________________________________________________

Muuliaasi

1 Rows. -- 4 msec.
```

concatenate

concatenate — concatenate strings

Synopsis

```
string concatenate ( in arg_1 any ,
                     ... );
```

Description

`Concatenate` is an alias of `concat` .

See Also

`concat`

connection_get

connection_get — Get connection variable

Synopsis

```
any connection_get ( in name varchar );
```

Description

`connection_get` is used to retrieve values stored within the current connection context. See `connection_set` for a more detailed discussion of connection variables.

Parameters

name
: Name of the connection variable

Return Values

A value associated to the connection by connection_set in the datatype of the original value. If the variable does not exist, a NULL is returned.

Examples

Example 24.48. Setting and Retrieving Connection Variables

```
SQL> select connection_get('var_demo');
callret
VARCHAR
_______________________________________________________________________

NULL

SQL> connection_set('var_demo', 'some arb data');

SQL> select connection_get('var_demo');
callret
VARCHAR
_______________________________________________________________________

some arb data
```

In a VSP page...

```
<?vsp
  declare id integer;
  declare saved_req any;
  id := connection_get ('ID');
  saved_req := connection_set ('saved_request');
?>
```

See Also

connection_set

connection_id

connection_id — get connection identifier

Synopsis

```
connection_id (   );
```

Description

This function returns a string uniquely identifying the connection in this server instance. It is usually a combination of server's port number and a serial number of the client.

Note

The value returned is usually not useful in HTTP invocation context (VSP or SOAP), since consecutive requests by the same client will typically not be on the same connection the way the server sees it.

Return Values

A VARCHAR connection identifier.

Examples

Example 24.49. Return The Current Connection ID

```
SQL> select connection_id();
callret
VARCHAR
_______________________________

1111:4
```

connection_is_dirty

connection_is_dirty — check if current session connection variables have been altered

Synopsis

```
integer connection_is_dirty ( );
```

Description

This function is used to determine if the session variables have changed between a call to `connection_vars_set` and current point of execution. A call to connection_vars_set will cause subsequent calls to `connection_is_dirty` to return true.

The function is useful in postprocessing functions for making conditional storage of session variables in a database table.

Return Values

An INTEGER indicating true (1) or false (0).

Examples

Example 24.50. Checking Connection Variables

```
<?vsp
  declare rc integer;
  connection_vars_set ();
  rc := connection_is_dirty (); -- rc is equal to 0
  connection_set ('ID', 14);
  rc := connection_is_dirty (); -- rc is equal to 1
?>
```

connection_vars

connection_vars_set

connection_set

connection_set — Associates a value to the name in the context of the present connection

Synopsis

connection_set (in *name* varchar ,
in *value* any) ;

Description

This associates a value to the name in the context of present connection. The name should be a string and the value can be any data type except blob, open cursor or an XML entity. If the value is an array it may not contain the restricted types.

Connection variable setting is not logged and information stored will be lost when the connection is closed. The value can be retrieved by any future statement executing within the same connection. Connection variables can be used as a global variable mechanism for stored procedures, the scope being the client connection.

In the case of VSP or SOAP this mechanism cannot be used to pass information between requests by the same client. It will however, be useful for having 'global variables' between procedures called within the same HTTP request. Note that this mechanism is used to provide persistent HTTP session variables in some cases but this works through special before and after code which stores the values set with this function into an external session structure. In this sense this function itself has nothing to do with web session management although it can be used as a component for such.

Parameters

name
: VARCHAR name to associate the value with.

value
: value to be stored. May be any data type except LOB , open cursor or XML entity. If the value is an array , it may not contain the restricted types.

Return Values

None

Errors

Table 24.16. Errors signalled by connection_set

SQLState	Error Code	Error Text	Description
22023	SR049	Data type is not suitable for storage into a global variable (connection_set)	

Examples

Example 24.51. Setting and Retrieving Connection Variables

From SQL

```
SQL> select connection_get('var_demo');
callret
VARCHAR
_______________________________________________________________________

NULL

SQL> connection_set('var_demo', 'some arb data');
```

```
SQL> select connection_get('var_demo');
callret
VARCHAR
_______________________________________________________________________

some arb data
```

From a VSP page

```
<?vsp
  declare id integer;
  id := 12;
  connection_set ('ID', id);
  connection_set ('saved_request' , lines);
?>
```

See Also

connection_get

connection_is_dirty

connection_vars_set

connection_vars

connection_vars — Retrieve all connection variables

Synopsis

```
any connection_vars ( );
```

Description

This function returns all stored session variables in an array with name/value pairs.

Connection variables do not persist across sessions, one may maintain persistence of variables by storing them in a database table: see the Session Variables Section.

Return Types

Array of name-value pairs of all connection variables.

Examples

Example 24.52. Retrieving Connection Variables

```
<?vsp
  declare ses_vars any;
  ses_vars := connection_vars ();
  update session set s_vars = serialize (ses_vars) where s_id = get_keyword ('sid', params);
?>
```

See Also

connection_get

connection_set

connection_vars_set

connection_vars_set

connection_vars_set — set all connection variables

Synopsis

connection_vars_set (in *var_array* any) ;

Description

This function clears all connection variables for current session and sets new ones defined in the array passed as parameter.

Connection variables do not persist across sessions, one may maintain persistence of variables by storing them in a database table, as discussed in Session Variables -section.

Parameters

var_array
: An array of even number of elements, containing name-value pairs. NULL, will cause all connection variables for current connection to be erased.

Examples

Example 24.53. Usage

```
<?vsp
  connection_vars_set (vector ('ID', 12));
?>
```

Example 24.54. Setting and Retrieving Connection Variables

```
SQL>connection_vars_set(vector('v1', 'a', 'v2', 1));

Done. -- 0 msec.
SQL> select connection_vars();

contains

contains — A text contains predicate

Synopsis

```
boolean contains ( column varchar ,
                   expression varchar ,
                   opt_or_value integer ,
                   ...) ;
```

Description

This is a SQL predicate that specifies a condition on a column on which a free text index exists. The expression is a string matching the grammar of a text search expression. This is computed for each evaluation of the contains predicate and does not have to be a constant. For example a parameter or variable of a containing score (e.g. procedure) is accepted.

The *score_limit* is optional. If specified, it should be a numeric expression determining the minimum score required to produce a hit.

A virtual column named 'SCORE' is available in queries involving a `contains` predicate. This can for example be returned in a result set or used for sorting. Note that the name is in upper case and is case sensitive in all case modes.

Parameters

column
: The table column whose contents are free text indexed

expression
: A string matching the grammar of a text search expression.

opt_or_value
: May be one or more of the following: DESCENDING specifies that the search will produce the hit with the greatest id first, as defined by integer or composite collation.START_ID ',' scalar_exp the first allowed document id to be selected by the expression in its traversal order, e.g. least or equal for ascending and greatest or equal for descending.END_ID ',' scalar_exp the last allowed id in the traversal order. For descending order the START_ID must be >= END_ID for hits to be able to exist. For ascending order the START_ID must be <= END_ID for hits to be able to exist.SCORE_LIMIT ',' scalar_exp Minimum score that hits must have or exceed to be considered matches of the predicate.RANGES ',' scalar_exp specifies that the query variable following the RANGES keyword will be bound to the word position ranges of the hits of the expression inside the document. The variable is in scope inside the enclosing SELECT statement. OFFBAND ',' column Specifies that the following column will be retrieved from the free text index instead of the actual table. For this to be possible the column must have been declared as offband with the CLUSTERED WITH option of the CREATE TEXT INDEX statement.

Return Types

The contains is a predicate, therefore returning a boolean .

Examples

Example 24.55. Querying Free Text Indexed Columns using contains()

- Return the number of documents with one or more occurrences of "virtual" immediately followed by "database".

```
select count (*) from docs
where contains (text, '"virtual database"')
```

- Specify documents with performance and either 'tuning' or optimization' in any respective positions.

```
'performance and (tuning or optimization)'
```

- Match documents with the word graphics more than 100 words away from 'user' or 'interface'.

```
'graphics and not (graphics near user near interface)'
```

- Match documents with SQL followed by a word beginning with 'interfac'.

```
'"sql interfac*"'
```

- Match documents with words beginning with 'dragon' and not containing the phrase 'once upon a time'.

```
'"dragon*" and not "once upon a time"'
```

Note:
An expression may not consist of all negative terms, e.g. (not a) and (not b) is not a valid expression but 'c and not a and not b' is a valid expression.

Note that the NEAR connective may not be used between AND'ed or OR'ed terms. It can be used to combine words or phrases.

cov_load

cov_load — Load test coverage data from file.

Synopsis

cov_load (in *fname* varchar) ;

Description

This function accepts one argument with name of file containing test coverage data. The expected format of the file is described in the Branch Coverage section. The loaded file is merged with the data already collected by Virtuoso. More than one file can be loaded. The ultimate report will be the union of all files.

Parameters

fname
: Name of coverage file to load.

Return Types

None.

See Also

`cov_store()`

`cov_report()`

`pldbg_stats()`

`pldbg_stats_load()`

cov_report

cov_report — Produce a text coverage report.

Synopsis

```
cov_report ( in fname varchar ,
             in outdir varchar ) ;
```

Description

This function is used to produce a coverage report in text format. The format of the file is described in the Branch Coverage section. This function takes a filename 'fname' as a path to the extended coverage report file and 'outdir' as a path to a directory where .cov files will be stored. The profile.prof file in the output directory is a summary of function call counts and execution times, once ranked by self time, once by time spent inside the function and functions called from there. Note that directory must exists before calling this function.

Parameters

fname
: Name of coverage report file.

outdir
: Destination directory for storing .cov coverage files.

Return Types

None.

See Also

`cov_load()`

`cov_store()`

`pldbg_stats()`

`pldbg_stats_load()`

cov_store

cov_store — Writes a test coverage to a file.

Synopsis

cov_store (in *fname* varchar ,
in *add_comments* integer) ;

Description

This function is used to produce a coverage file called `fname` . The expected format of the file is described in the Branch Coverage section. By default a normal concise coverage will be produced. If the `add_comment` parameter is set to 1 then the coverage will include code excerpts contained in line entities.

Parameters

fname
: Name of coverage file to load.

add_comments
: This flag controls whether to use coverage extensions. By default this is 0. If 1 is supplied then extensions are used.

Return Types

None.

createXML

createXML

Synopsis

```
XMLType createXML ( in src any ,
                    in schema_uri any ,
                    in validated any ,
                    in wellformed any ) ;
```

Description

This function creates an XMLType instance. It works absolutely identically to the `XMLType()` constructor and is provided solely for compatibility.

Parameters

src
: An XML entity or a value that can be converted to an XML entity.

schema_uri
: An URI of the schema of the document. The default is NULL to make result non-schema based.

validated
: An integer flag that indicates if the document is already validated against the schema of the document (this is to avoid redundant validations). The default is 0.

wellformed
: This parameter is unused and is listed solely for compatibility.

Return Types

The function returns a new instance of XMLType.

Examples

Example 24.56. Sample example

```
create table XMLTYPE_TEST (I integer primary key, XMLVAL long xml)

Done. -- 00000 msec.

insert into XMLTYPE_TEST values (1, createXML('<emp><empno>221</empno><ename>John</ename></emp>'))

Done. -- 00000 msec.

insert into XMLTYPE_TEST values (2, createXML('<po><pono>331</pono><poname>PO_1</poname></po>'))

Done. -- 00000 msec.

select e.XMLVAL.extract ('//empno/text()').getNumVal() as EMPNO
  from XMLTYPE_TEST as e
  where e.XMLVAL.existsNode('/emp/empno') = 1
EMPNO
DECIMAL
_______________________________________________________________________________

curdate

curdate , curtime , curdatetime — get current date and time

Synopsis

```
datetime curdate ( );

datetime curdatetime ( );

time curtime ( );
```

Description

These functions return the current date or time as a date, time or datetime, respectively. Internally they all return the same value but data type reported to client differs.

Parameters

None.

Return Types

In a result set to client, the column types reported are as follows: TIME for `curtime` , DATE for `curdate` and DATETIME for `curdatetime` .

Errors

These functions do not signal errors.

Examples

Example 24.57. Simple example

Get current date in different datatypes

```
SQL> select curdate(), curtime(), curdatetime();
callret     callret   callret
DATE        TIME      BINARY
_______________________________________________________________________________

2001.10.12  11:21.51  2001-10-12 11:21:51
```

forget_timezone

forget_timezone — returns its first argument as a timezoned value

Synopsis

```
datetime forget_timezone ( in dt datetime ,
                           in ignore_timezone integer ) ;
```

Description

The function returns its first argument as a timezoned value. If the first argument is timezoneless then it is returned unchanged. If the first argument is timezoned and second argument is missing or zero then the result is timezoneless value that "looks like" local time notation. If the first argument is timezoned and second argument is nonzero then the value is first made GMT and then it becomes timezoneless.

Parameters

dt
: Datetime value.

ignore_timezone
: Flag

Examples

Example 24.58. Simple example

```
SQL> select cast (forget_timezone (cast ('1999-12-31 11:59+02:00' as datetime)) as varchar);
VARCHAR
'1999-12-31 11:59:00'
No. of rows in result: 1
```

`datestring`

is_timezoneless

is_timezoneless — returns 1 for timezoneless arguments, zero for timezoned

Synopsis

```
datetime is_timezoneless ( in dt datetime );
```

Description

The function returns 1 for timezoneless arguments, zero for timezoned.

Parameters

dt
: Datetime value.

Examples

Example 24.59. Simple example

```
SQL> select is_timezoneless (cast ('1999-12-31 11:59' as datetime));
INTEGER
 0
No. of rows in result: 1
```

curdatetime

curdatetimeoffset

curutcdatetime

sysutcdatetime

stringdate

datestring

adjust_timezone

adjust_timezone — returns its first argument with unchanged GMT value but new timezone offset, as it is specified by the second argument

Synopsis

```
datetime adjust_timezone ( in dt datetime ,
                           in tz_offset integer ,
                           in ignore_timezone integer ) ;
```

Description

The function returns its first argument with unchanged GMT value but new timezone offset, as it is specified by the second argument. If the first argument is timezoneless and third argument is missing or zero then error 22023 is signaled. If the first argument is timezoneless and third argument is nonzero then no error is signaled and the argument is handled like it is a GMT value.

Parameters

dt
: Datetime value.

tz_offset
: Timezone offset.

ignore_timezone
: Flag.

Examples

Example 24.60. Simple example

```
SQL> SELECT adjust_timezone(cast('2014-12-31 15:00-12:00' as datetime),0,1) ;
DATETIME
2015-01-01 03:00:00
No. of rows in result: 1
```

stringdate

datestring

rdf_now_impl

rdf_now_impl — returns the current transaction timestamp

Synopsis

```
rdf_now_impl (  );
```

Description

This function returns the timestamp associated with current transaction as a DATETIME . The function name refer to one function (alias of `now()`) that returns the timestamp of current transaction. It is the datetime of the beginning of current transaction with the fractional part of seconds replaced with serial number of a transaction within the second. If `TimezonelessDatetimes=0` then the time has local timezone offset (as it was set at the time of last server start); otherwise it is timezoneless.

Parameters

None

Examples

Example 24.61. Simple example

Get a timestamp in human-readable form:

```
SQL> select rdf_now_impl();
DATETIME
2015-05-04 08:28:18.228407
No. of rows in result: 1
```

`stringdate`

`datestring`

current_timestamp

current_timestamp — returns the current transaction timestamp

Synopsis

```
current_timestamp (  );
```

Description

Now returns the timestamp associated with current transaction as a DATETIME .

The function name refer to one function (alias of `now()`) that returns the timestamp of current transaction. It is the datetime of the beginning of current transaction with the fractional part of seconds replaced with serial number of a transaction within the second. If `TimezonelessDatetimes=0` then the time has local timezone offset (as it was set at the time of last server start); otherwise it is timezoneless.

Parameters

`current_timestamp` has no parameters.

Return Types

A DATETIME timestamp.

Errors

`current_timestamp` does not return errors.

Examples

Example 24.62. Simple example

```
SQL>select current_timestamp ;
DATETIME
 2015-05-05 03:36:41.225581
```

curdatetime

curdatetime — returns current datetime with adjusted fractional part of seconds

Synopsis

curdatetime (in *fraction_microseconds* integer);

Description

The function returns current datetime, like `now()` , but fractional part of seconds can be adjusted by providing the number of "microseconds" as the argument.

Parameters

fraction_microseconds
: Microseconds.

Return Types

A DATETIME timestamp.

Errors

`curdatetime` does not return errors.

Examples

Example 24.63. Get a timestamp

Get a timestamp in human-readable form.

```
SQL> select curdatetime();
DATETIME
2015-05-04 09:02:05.242215
No. of rows in result: 1

SQL>select curdatetime(1);
DATETIME
2015-05-04 09:02:47
No. of rows in result: 1
```

casting

curdate(), curdatetime(), curtime()

curdatetimeoffset

curdatetimeoffset — returns current datetime in GMT timezone with adjusted fractional part of seconds

Synopsis

curdatetimeoffset (in *fraction_microseconds* integer) ;

Description

The function returns current datetime, like `now()` , but fractional part of seconds can be adjusted by providing the number of "microseconds" as the argument. It is like `curdatetime()` but the returned datetime is in GMT timezone.

Parameters

fraction_microseconds
: Microseconds.

Return Types

A DATETIME timestamp.

Errors

`curdatetimeoffset` does not return errors.

Examples

Example 24.64. Get a timestamp

Get a timestamp in human-readable form.

```
SQL> select curdatetimeoffset();
DATETIME
2015-05-04 09:07:57.847185
No. of rows in result: 1

SQL>select curdatetimeoffset(1);
DATETIME
2015-05-04 09:07:34
No. of rows in result: 1

curutcdatetime

curutcdatetime — returns current datetime in GMT timezone with adjusted fractional part of seconds

Synopsis

curutcdatetime (in *fraction_microseconds* integer);

Description

The function returns current datetime, like `now()` , but fractional part of seconds can be adjusted by providing the number of "microseconds" as the argument.

The function is similar to `curdatetime()` but the returned datetime is in GMT timezone.

Parameters

fraction_microseconds
: Microseconds.

Return Types

A DATETIME timestamp.

Errors

`curutcdatetime` does not return errors.

Examples

Example 24.65. Get a timestamp

Get a timestamp in human-readable form.

```
SQL> select curutcdatetime();
DATETIME
2015-05-04 13:11:30.701568
No. of rows in result: 1

SQL>select curutcdatetime(1);
DATETIME
2015-05-04 13:11:41
No. of rows in result: 1

sysutcdatetime

sysutcdatetime — returns current datetime in GMT timezone with adjusted fractional part of seconds

Synopsis

sysutcdatetime (in *fraction_microseconds* integer);

Description

The function returns current datetime, like `now()` , but fractional part of seconds can be adjusted by providing the number of "microseconds" as the argument.

The function is similar to `curdatetime()` but the returned datetime is in GMT timezone.

Parameters

fraction_microseconds
: Microseconds.

Return Types

A DATETIME timestamp.

Errors

`sysutcdatetime` does not return errors.

Examples

Example 24.66. Get a timestamp

Get a timestamp in human-readable form.

```
SQL> select sysutcdatetime();
DATETIME
2015-05-04 13:11:30.701568
No. of rows in result: 1

current_charset

current_charset — Get name of current charset.

Synopsis

```
current_charset (  );
```

Description

This function returns the "preferred" name of the current charset as a string.

It returns value which is set in the INI file or those which is set with 'SET CHARSET=..' call. This cannot be used to return charset for the current HTTP connection in the VSP or VSPX context.

Parameters

None.

Return Types

A string containing the name.

Errors

None signalled.

Examples

Example 24.67. Get name of current charset

```
SQL> select current_charset();
callret
VARCHAR
_______________________________________________________________________________
ISO-8859-1
```

See Also

DB.DBA.VACUUM

DB.DBA.VACUUM — Compact the database

Synopsis

DB.DBA.VACUUM (in *table_name* varchar (default %) ,
in *index_name* varchar (default %)) ;

Description

This function reads through the specified tables and indices and finds groups of adjacent pages holding data that will fit on fewer pages than it currently occupies. If such a compression can be made, the pages are thus compacted.

The pages become part of the committed state and will be written to the checkpoint space on the next checkpoint.

The vacuum operation is non-locking and can be run on a busy database. It will simply skip pages with ongoing activity such as pending cursors or locks. The vacuum procedure returns only after it has read through the indices it affects but it will not prevent other activity on the indices. The vacuum operation may run out of disk space even if it makes net gains because the modified pages will not be final until the next checkpoint and the originals will not be free until this same checkpoint. Thus manually running a checkpoint after vacuum runs out of space will free the space and vacuum may be rerun.

Parameters

table_name
: This is a LIKE pattern for tables to vacuum. The default is all tables. The name is case sensitive and must have all the three parts given, e.g. APP.USER.DATA

index_name
: This allows specifying an individual index to compress. The specified table(s) must have this index. The index name is a LIKE pattern and if given should match the case and spelling of index names as returned by the ODBC call SQLStatistics or equivalent, which is also the KEY_NAME column of SYS_KEYS.

Examples

Example 24.68. Simple example

Compact the entire database:

```
SQL> DB.DBA.vacuum ();
```

sparql_to_sql_text

sparql_to_sql_text — Converts a sparql query directly to SQL.

Synopsis

```
varchar sparql_to_sql_text ( in squery varchar );
```

Description

The `sparql_to_sql_text()` function can be used to convert a SPARQL query directly to the SQL it would be executed as.

Parameters

squery
: The sparql query to be converted.

Return Types

A string will be returned containing the converted sparql query.

Examples

Example 24.69. Using the sparql_to_sql_text() function

This simple example shows how to covert sparql query in SQL:

```
SQL> select sparql_to_sql_text('select * where {?s ?p ?o}');
sparql_to_sql_text
VARCHAR
_______________________________________________________________________________

SELECT __id2i ( /*retval[*/ "s-1-1-t0"."S" /* s */ /*]retval*/ ) AS /*tmpl*/ "s",
  __id2i ( /*retval[*/ "s-1-1-t0"."P" /* p */ /*]retval*/ ) AS /*tmpl*/ "p",
  __ro2sq ( /*retval[*/ "s-1-1-t0"."O" /* o */ /*]retval*/ ) AS /*tmpl*/ "o"
FROM DB.DBA.RDF_QUAD AS "s-1-1-t0"
OPTION (QUIETCAST)

1 Rows. -- 15 msec.
```

dateadd

dateadd — arithmetic add to a date

Synopsis

dateadd (in *unit* string ,
in *number* integer ,
in *date* datetime) ;

Description

dateadd adds a positive or negative quantity of units to a date (in the internal date time format), and returns a new date so formed. The unit is specified as a string and can be one of the following: 'second', 'minute', 'hour', 'day', 'month', or 'year'. Use datestring to convert the result to a human-readable string.

Parameters

unit
: String value denoting the unit to use in the addition.

number
: Integer number of unit units to be added.

date
: Datetime value to which the number of unit s is to be added

Examples

Example 24.70. Simple date addition

Add 10 days to 1996.10.10.

```
SQL> select dateadd ('day', 10, stringdate ('1996.10.10'));
callret
BINARY
_______________________________________________________________________________

1996-10-20 01:00:00

```

See Also

datediff , datestring , stringdate

datediff

datediff — get difference of 2 dates

Synopsis

datediff (in *unit* string ,
in *date1* datetime ,
in *date2* datetime) ;

Description

datediff subtracts date1 from date2 and returns the difference as an integer in the specified units.

Parameters

unit
: The resulting unit name as a string. May be 'millisecond', 'second', 'minute', 'hour', 'day', 'month', or 'year'

date1
: The datetime value that will be subtracted from date2

date2
: The datetime value date1 is subtracted from

Return Values

Difference of *date1* and *date2* as an integer .

Errors

Table 24.17. Errors signalled by datediff

SQLState	Error Code	Error Text	Description
22023	DT002	Bad unit in datediff: >offending unit string<	The unit given was not one of the units listed above.

Examples

Example 24.71. A simple example

Get hour difference of 1996.10.10 and 1996.10.11.

```
SQL> SELECT datediff ('hour',  stringdate ('1996.10.10'), stringdate ('1996.10.11'));
callret

dateadd, datestring

datestring , datestring_gmt ,

datestring , datestring_gmt — convert a datetime from internal to external date-time representation

Synopsis

datestring (in *date* datetime) ;

datestring_gmt (in *date* datetime) ;

Description

datestring and datestring_gmt convert timestamps or datetimes from internal to external date-time representation. The external representation is a human-readable ASCII string of up to 30 characters.

The external format is: YYYY-MM-DD hh:mm:ss uuuuuu where uuuuuu represents microseconds.

Note:
Using cast (dt as varchar) is preferred over datestring .

Parameters

date
: A datetime value.

Return values

datestring and datestring_GMT return a varchar .

Examples

Example 24.73. Simple Example

Get current date in human-readable form.

```
SQL> select datestring(now());
callret
VARCHAR
_______________________________________________________________________________

2001-03-01 12:49:59.000000

datestring_GMT

datestring_GMT — convert a timestamp to external format string in GMT

Synopsis

datestring_GMT (in *dt* datetime) ;

Description

Converts the local datetime to GMT and returns its external representation as a string.

Parameters

dt
: A datetime value.

Return values

A VARCHAR containing the external representation.

Examples

Example 24.75. Example with datestring_GMT

We are at central european time zone CET(GMT+1).

```
SQL> use Demo;

 Done. -- 3 msec.
 SQL> select (datestring_GMT (stringdate ('2000-01-01 22:00')));
 callret
 VARCHAR
 _______________________________________________________________________________

 2000-01-01 21:00:00.000000

 1 Rows. -- 45 msec.
```

DAV add & update functions

DAV_COL_CREATE , DAV_RES_UPLOAD , DAV_DELETE — functions for adding, updating, deleting of DAV collections or resources

Synopsis

```
integer DAV_COL_CREATE ( in path varchar ,
                         in permissions varchar ,
                         in uname varchar ,
                         in gname varchar ,
                         in auth_uname varchar ,
                         in auth_pwd varchar ) ;

varchar DAV_RES_UPLOAD ( in path varchar ,
                         in content any ,
                         in type varchar ,
                         in permissions varchar ,
                         in uname varchar ,
                         in gname varchar ,
                         in auth_uname varchar ,
                         in auth_pwd varchar ) ;

integer DAV_DELETE ( in path varchar ,
                     in silent integer ,
                     in auth_uname varchar ,
                     in auth_pwd varchar ) ;
```

Description

DAV_COL_CREATE creates a new collection on path, with supplied security permissions, returning a collection id (COL_ID) upon success.

DAV_RES_UPLOAD creates or replaces an existing resource on path with content, mime type and supplied security permissions. Returns a resource id (RES_ID) on success.

DAV_DELETE Removes an existing collection/resource. If *silent* is set to a nonzero value, no errors codes will be returned. returns 1 on success.

Parameters

path
: Collection (directory) path and name of destination of upload.

content
: The resource data to upload.

type
: Mime type of the uploaded resource. Defaults to '' if not supplied.

permissions
: Access permission string of Dav collection or resource. Defaults to '110100000R' if not supplied.

silent

If non-zero, no errors will be returned. Default is 0, meaning errors are returned.

uname
: Owner user name. Default is 'dav'.

group name
: Owner group name. Default is 'dav'.

auth_uname
: Name of administration user capable of performing the operation. default is null.

auth_pwd
: Administrator password. Default is null.

Errors

Table 24.18. Errors signalled by DAV_* functions

Error Code	Description
>=0	success
-1	The path (target of operation) is not valid
-2	The destination (path) is not valid
-3	Overwrite flag is not set and destination exists
-4	The target is resource, but source is collection (in copy move operations)
-5	Permissions are not valid
-6	uid is not valid
-7	gid is not valid
-8	Target is locked
-9	Destination is locked
-10	Property name is reserved (protected or private)
-11	Property does not exists
-12	Authentication failed
-13	Operation is forbidden (the authenticated user do not have a permissions for the action)
-14	the target type is not valid
-15	The umask is not valid
-16	The property already exists
-17	Invalid property value
-18	no such user
-19	no home directory

Examples

Example 24.76. Creating a resource and collection

The following example shows collection creation, resource upload and removal. This sequence of commands would leave a resource A.txt in `http://[host:port]/DAV/user/A/`

```
SQL> select DB.DBA.DAV_COL_CREATE ('/DAV/user/','110100000R', 'dav','dav','dav','dav');
SQL> select DB.DBA.DAV_COL_CREATE ('/DAV/user/A/','110100000R','dav','dav','dav','dav');
SQL> select DB.DBA.DAV_RES_UPLOAD ('/DAV/user/A/A.txt','this is a test','text/plain','110100000R','dav','
SQL> select DB.DBA.DAV_RES_UPLOAD ('/DAV/user/A/B.txt','this is a second test','text/plain','110100000R',
SQL> select DB.DBA.DAV_DELETE ('/DAV/user/A/B.txt', 0, 'dav', 'dav');
```

DAV_COPY , DAV_MOVE , DAV_PROP_SET , DAV_PROP_REMOVE — Functions for manipulating an existing DAV collection or resource

Synopsis

```
integer DAV_COPY ( in path varchar ,
                   in destination varchar ,
                   in overwrite integer ,
                   in permissions varchar ,
                   in uname varchar ,
                   in gname varchar ,
                   in auth_uname varchar ,
                   in auth_pwd varchar ) ;

varchar DAV_MOVE ( in path varchar ,
                   in destination varchar ,
                   in overwrite integer ,
                   in auth_uname varchar ,
                   in auth_pwd varchar ) ;

integer DAV_PROP_SET ( in path varchar ,
                       in propname varchar ,
                       in propvalue any ,
                       in auth_uname varchar ,
                       in auth_pwd varchar ) ;

varchar DAV_PROP_REMOVE ( in path varchar ,
                          in propname varchar ,
                          in silent integer ,
                          in auth_uname varchar ,
                          in auth_pwd varchar ) ;
```

Description

DAV_COPY copies the resource or collection taken from path to the destination. returns COL_ID or RES_ID on success.

DAV_MOVE moves the collection or resource to the destination path returns 1 on success.

DAV_PROP_SET defines or updates the property with name *propname* with *propvalue* . Returns PROP_ID on success.

DAV_PROP_GET returns the value of previously defined property with name *propname* .

DAV_PROP_REMOVE removal of the existing property on target path. If silent supplied then no error will be returned.

Some attributes of resources and collections are accessible as predefined properties. E.g., owner user ID of the resource can be retrieved or changed by DAV_PROP_GET or DAV_PROP_SET with *propname* equal to ':virtowneruid'. Some of these properties are read-only for all resources, some are writable for some but not for all resources. Names of all predefined properties starts with ':' so application-specific properties should not start with colon. Moreover, it is strongly suggested to use "unqualified XML names" as property names, otherwise PROPGET and PROPPATH DAV requests may return invalid XML responses. *propname* .

Parameters

path
: Directory and name of source to be operated on.

destination
: Directory and name of destination.

overwrite
: If non zero then overwrite is enabled. Default is 0.

permissions
: Access permission of Dav collection or resource. Defaults to '110100000R' if not supplied.

propname
: Property name.

propvalue
: Property value.

silent
: If specified as non zero, then no error will be returned. Default is 0, so errors are returned.

uname
: User identifier. Default is 'dav'.

gname
: Group identifier. Default is 'dav'.

auth_uname
: Administration user capable of performing the operation. Default is null.

auth_pwd
: Password of Administrator. Default is null.

System Properties

Names of 'standard live properties' matches tag names used in PROPFIND response for same purposes.

Names of virtuoso-specific system properties starts with ':virt' substring.

In the table below, 'Read/Write' access type means that the application can try to set the property. This does not mean that the property can be successfully changed for any particular resource or collection.

Table 24.19. System properties supported by DAV_PROP_GET and DAV_PROP_SET functions

propname	Access Type	Data Type	Description
:getlastmodified	Read/Write	datetime	Time of the last modification.
:creationdate	Read/Write	datetime	Time of creation.
:lastaccessed	Read Only	datetime	Time of the last access to the resource, may be inaccurate by a large amount.
:getetag	Read Only	varchar	The value of 'Etag' field of response header as reported by HEAD HTTP request.
:getcontenttype	Read/Write	varchar	MIME type of the resource ('dav/unix-directory' for collections).
:getcontentlength	Read Only	integer	Resource length in bytes. 0 for collections.
:resourcetype	Read Only	XML entity	'<D:collection/>' for collections, NULL for resources.
:virtowneruid	Read/Write	integer	User ID of resource owner user.
:virtownergid	Read/Write	integer	Group ID of resource owner group.
:virtpermissions	Read/Write	char(10)	Access permissions string.
:virtacl	Read/Write	long varbinary	Access Control List.

propname	Access Type	Data Type	Description
:virtdet	Read/Write	varchar	DAV Extension Type of special collection, NULL for plain collections and resources.

Note that the value of 'Etag' field depends on ':getlastmodified' value. Some HTTP clients, such as download managers, web indexing robots and proxy servers, use 'Etag' field to support caching and/or partial document transfer. It is unsafe to decrement ':getlastmodified' because it can confuse such clients.

Only resource/collection owner or DAV administrator can change ':virtowneruid', ':virtownergid', ':virtpermissions' and ':virtacl'.

Only DAV administrator can change ':virtdet' property.

Errors

Table 24.20. Errors signalled by DAV_* functions

Error Code	Description
>=0	success
-1	The path (target of operation) is not valid
-2	The destination (path) is not valid
-3	Overwrite flag is not set and destination exists
-4	The target is resource, but source is collection (in copy move operations)
-5	Permissions are not valid
-6	uid is not valid
-7	gid is not valid
-8	Target is locked
-9	Destination is locked
-10	Property name is reserved (protected or private)
-11	Property does not exists
-12	Authentication failed
-13	Operation is forbidden (the authenticated user do not have a permissions for the action)
-14	the target type is not valid
-15	The umask is not valid
-16	The property already exists
-17	Invalid property value
-18	no such user
-19	no home directory

Examples

Example 24.77. Copy and move operations

Renaming of the resource and copy the folder. After executing the commands in the http://[host:port]/DAV/user/B/ we will show the resource B.txt

```
-- initial upload
SQL> select DB.DBA.DAV_COL_CREATE ('/DAV/user/','110100000R', 'dav','dav','dav','dav');
SQL> select DB.DBA.DAV_COL_CREATE ('/DAV/user/A/','110100000R','dav','dav','dav','dav');
SQL> select DB.DBA.DAV_RES_UPLOAD ('/DAV/user/A/A.txt','this is a test','text/plain','110100000R','dav','
SQL> DB.DBA.DAV_MOVE('/DAV/user/A/A.txt', '/DAV/user/A/B.txt', 1,'dav','dav');
SQL> DB.DBA.DAV_COPY('/DAV/user/A/', '/DAV/user/B/', 1, '110110000R','dav','dav','dav','dav');
```

                   in depth varchar ,
                   in timeout_sec integer ,
                   in auth_uname varchar ,
                   in auth_pwd varchar ) ;

any DAV_UNLOCK ( in path varchar ,
                 in token varchar ,
                 in auth_uname varchar ,
                 in auth_pwd varchar ) ;

integer DAV_IS_LOCKED ( in id any ,
                        in type char(1) ,
                        in owned_tokens any := 1 ) ;

integer DAV_LIST_LOCKS ( in id any ,
                         in type char(1) ) ;
```

Description

DAV_LOCK sets a new lock or refresh an existing lock or creates a lock object.

DAV_UNLOCK releases a lock.

DAV_IS_LOCKED reports whether the resource or collection is locked.

DAV_LIST_LOCKS returns a full list of all locks on a resource or collection.

It is strongly recommended to carefully study DAV standards before using these functions in applications. Improper use of DAV locks may result in subtle application errors that are hard to debug.

Parameters

path
: Resource or collection path. As usual, collection names must end with '/' and both sorts of path strings should begin with '/'. If the path specifies a non-existing resource in an existing collection then a lock object is created and only lock owner can create a resource with this name in future.

locktype
: The type of lock. Current set of DAV standards specifies only one type of locks, called 'D:write'; the parameter value is stored 'as is' and never used, so the recommended value is an empty string.

scope
: The scope of lock as a single-char string: 'S' for shared lock, 'X' for exclusive.

token
: The token to update. Empty string or NULL means creation of a new lock, not an update of the existing one.

owner_name
: Lock owner name as it will be displayed to other users that will query for existing locks. It is strongly recommended to provide commonly used names such as e-mails to let users ask each other to remove forgotten locks.

owned_tokens
: String of tokens owned by a user, to let user ignore his own tokens. The string should match syntax of DAV HTTP 'If' parameter. This can be also an integer, this will work as empty list of tokens.

depth
: This specifies the recursive depth of the lock. The string can be '0' to lock the specified collection only, '1' to lock the collection and its subcollections, 'infinity' to lock the whole subtree. When the lock is added to a resource, the value '0' is used, for obvious reason. If NULL is passed to the function then the effective value is 'infinity' for collection lock or '0' for resource lock.

timeout_sec
: Expiration interval for the lock, in seconds. If 0 or NULL is passed then HTTP DAV default is used that is equal to 604800 seconds (one week).

auth_uname
: DAV user name to authenticate access. Lock, Lock refresh and unlock operations on existing resource or collection require write permission. To create a lock object in a collection, user should have write permission on that collection. This may cause problem when user first locks a resource and then loose write permission for some reason: the user is unable to remove his own lock. Default is NULL that means public access.

auth_pwd
: User password. Default is NULL.

id
: Internal identifier of a resource or collection as returned by DAV_SEARCH_ID().

Examples

Example 24.78. Two concurrent users

The following example shows how two users can prevent each other from undesired operations.

The sample function DAV_LOCK_DEMO() uses a function DUMP_VEC() that print the content of vector in Virtuoso/PL syntax. Yon can find the implementation of this function as one of examples for `vector()` Virtuoso/PL function.

```
create procedure DAV_LOCK_DEMO (in dav_passwd varchar := 'dav')
{
  declare ACTION, RETVAL, token_s1, token_s2, token_x varchar;
  result_names (ACTION, RETVAL);
  result ('Adding group lock_demo_grp:',
    DAV_ADD_GROUP ('lock_demo_grp', 'dav', dav_passwd) );
  result ('Adding user lock_u1:',
    DAV_ADD_USER ('lock_u1', 'lock_u1_pwd', 'lock_demo_grp', '110110000T', 0, '/DAV/lock_demo_u1_home/',
  result ('Adding user lock_u2:',
    DAV_ADD_USER ('lock_u2', 'lock_u2_pwd', 'lock_demo_grp', '110110000T', 0, '/DAV/lock_demo_u2_home/',
  result ('Adding a collection:',
    DAV_COL_CREATE ('/DAV/lock_demo/', '110110000R', 'lock_u1', 'lock_demo_grp', 'dav', dav_passwd) );
  result ('Uploading /DAV/lock_demo/sample.htm:',
    DAV_RES_UPLOAD ('/DAV/lock_demo/sample.htm', '<html><body>This is /DAV/lock_demo/sample.htm</body></h
  token_s1 := DAV_LOCK ('/DAV/lock_demo/sample.htm', '', 'S', NULL, 'user1@example.com', '', '0', NULL, '
  result ('First user set a shared lock:', token_s1);
  token_s2 := DAV_LOCK ('/DAV/lock_demo/sample.htm', '', 'S', NULL, 'user2@example.com', '', '0', NULL, '
  result ('Second user set a shared lock:', token_s2);
  token_x := DAV_LOCK ('/DAV/lock_demo/sample.htm', '', 'X', NULL, 'user1@example.com', token_s1, '0', NU
```

```
  result ('Lock dump',
    DUMP_VEC (DAV_LIST_LOCKS (DAV_SEARCH_ID ('/DAV/lock_demo/sample.htm', 'R'), 'R')) );
  result ('First user tries to set an exclusive lock:', token_x);
  result ('Second user releases his lock:',
    DAV_UNLOCK ('/DAV/lock_demo/sample.htm', token_s2, 'lock_u2', 'lock_u2_pwd') );
  token_x := DAV_LOCK ('/DAV/lock_demo/sample.htm', '', 'X', NULL, 'user1@example.com', token_s1, '0', NU
  result ('First user sets an exclusive lock:', token_x);
  result ('First user releases his lock:',
    DAV_UNLOCK ('/DAV/lock_demo/sample.htm', token_s1, 'lock_u1', 'lock_u1_pwd') );
  token_x := DAV_LOCK ('/DAV/lock_demo/sample.htm', '', 'X', NULL, 'user1@example.com', token_s1, '0', NU
  result ('First user sets an exclusive lock:', token_x);
  result ('Second user tries to add a property to the resource:',
    DAV_PROP_SET ('/DAV/lock_demo/sample.htm', 'sample_prop', 'sample value', 'lock_u2', 'lock_u2_pwd') )
  result ('First user releases his shared:',
    DAV_UNLOCK ('/DAV/lock_demo/sample.htm', token_x, 'lock_u1', 'lock_u1_pwd') );
  result ('Second user adds a property to the resource:',
    DAV_PROP_SET ('/DAV/lock_demo/sample.htm', 'sample_prop', 'sample value', 'lock_u2', 'lock_u2_pwd') )
}

                        ,
                        in what char(1)
                        ) ;

varchar DAV_SEARCH_PATH ( in id integer ,
                          in what char(1) ) ;

any DAV_DIR_LIST ( in path varchar ,
                   in recursive integer ,
                   in auth_uid varchar ,
                   in auth_pwd varchar ) ;
```

Description

DAV_SEARCH_ID() returns the RES_ID or COL_ID, depending on the '*what* ' parameter passed. ('R'esource or 'C'ollection or 'P'arent collection).

DAV_SEARCH_PATH() returns full path string of resource or collection, depending on parameter passed. ('R'esource or 'C'ollection or 'P'arent collection).

DAV_DIR_LIST() returns an array of arrays that contains the following information about the requested path:

fullpath
type ('r' or 'c') which indicates resource or collection.
length
modification time
id
permissions
group id
owner id
created
mime type

Parameters

path
: Name of DAV location to search.

what
: The type of DAV item to search for: 'R' for resource, 'C' for collection or 'P' for parent collection.

id
: Identifier of resource or collection, for example from DAV_SEARCH_ID().

recursive
: If non zero then recurse into subdirectories during the search. Default is 0 which causes a search in current path only.

auth_uid

Administration user capable of performing the operation. Default is null.

auth_pwd
: Password of Administrator. Default is null.

Errors

Table 24.21. Errors signalled by DAV_* functions

Error Code	Description
>=0	success
-1	The path (target of operation) is not valid
-2	The destination (path) is not valid
-3	Overwrite flag is not set and destination exists
-4	The target is resource, but source is collection (in copy move operations)
-5	Permissions are not valid
-6	uid is not valid
-7	gid is not valid
-8	Target is locked
-9	Destination is locked
-10	Property name is reserved (protected or private)
-11	Property does not exists
-12	Authentication failed
-13	Operation is forbidden (the authenticated user do not have a permissions for the action)
-14	the target type is not valid
-15	The umask is not valid
-16	The property already exists
-17	Invalid property value
-18	no such user
-19	no home directory

Examples

Example 24.79. Searching in WebDAV

The example shows retrieval of the resource id by given path string

```
SQL> select DB.DBA.DAV_SEARCH_ID ('/DAV/','c');
callret
VARCHAR
_______________________________________________________________________________

1

SQL> select DB.DBA.DAV_SEARCH_PATH (1,'c');
callret
VARCHAR
_______________________________________________________________________________

/DAV/
```

DAV_ADD_USER , DAV_DELETE_USER , DAV_HOME_DIR , DAV_ADD_GROUP , DAV_DELETE_GROUP — Functions for manipulating an existing DAV collection or resource

Synopsis

```
integer DAV_ADD_USER ( in uid varchar ,
                       in pwd varchar ,
                       in gid varchar ,
                       in permis varchar ,
                       in disable integer ,
                       in home varchar ,
                       in full_name varchar ,
                       in email varchar ,
                       in uid varchar ,
                       in auth_uid varchar ,
                       in auth_pwd varchar ) ;

varchar DAV_DELETE_USER ( in uid varchar ,
                          in auth_uid varchar ,
                          in auth_pwd varchar ) ;

varchar DAV_HOME_DIR ( in uid varchar ) ;

integer DAV_ADD_GROUP (   in gid varchar ,
                          in auth_uid
                          varchar ,
                          in auth_pwd
                          varchar ) ;

varchar DAV_DELETE_GROUP ( in gid varchar ,
                           in auth_uid varchar ,
                           in auth_pwd varchar ) ;
```

Description

DAV_ADD_USER() create a new WebDAV user with login name 'uid' and password 'pwd'. User will belong to the group named 'gid'. 'perms' are the default user permissions for creation of new resources. Additional user info supplied is 'home' directory, 'full name' and 'e-mail'.

DAV_DELETE_USER() remove the existing webDAV user named 'uid'.

DAV_HOME_DIR() returns the home folder for specified WebDAV user named 'uid'.

DAV_ADD_GROUP() create a new webDAV group named 'gid'.

DAV_DELETE_GROUP() remove the existing webDAV group named 'gid'.

Parameters

uid
: User identifier. Default is 'dav'.

pwd
: Password

gid
: Group identifier. Default is 'dav'.

perms
: Permissions

disable
: Disable flag

home
: The User's home directory path

full_name
: Full name of user

email
: User's email

auth_uid
: Administration user capable of performing the operation. Default is null.

auth_pwd
: Password of Administrator. Default is null.

Errors

Table 24.22. Errors signalled by DAV_* functions

Error Code	Description
>=0	success
-1	The path (target of operation) is not valid
-2	The destination (path) is not valid
-3	Overwrite flag is not set and destination exists
-4	The target is resource, but source is collection (in copy move operations)
-5	Permissions are not valid
-6	uid is not valid
-7	gid is not valid
-8	Target is locked
-9	Destination is locked
-10	Property name is reserved (protected or private)
-11	Property does not exists
-12	Authentication failed
-13	Operation is forbidden (the authenticated user do not have a permissions for the action)
-14	the target type is not valid
-15	The umask is not valid
-16	The property already exists
-17	Invalid property value
-18	no such user
-19	no home directory

Examples

Example 24.80. WebDAV users operations

The example will create a WebDAV user named 'davuser' belongs to the group 'davgroup'. No home directory supplied. The user account is enabled after operaion.

```
SQL> DB.DBA.DAV_ADD_GROUP ('davgroup', 'dav', 'dav');
SQL> DB.DBA.DAV_ADD_USER ('davuser', 'secret', 'davgroup', '110100000', 0, NULL, 'Test User Account', 'no
```

DAV_EXP

DAV_EXP — Export a retrieved Web site to another WebDAV enabled server

Synopsis

```
WS.WS. DAV_EXP ( in host varchar ,
                 in url varchar ,
                 in root varchar ,
                 in dst varchar ) ;
```

Description

This function is used to export local content retrieved from a Web Robot Copy to the local file system.

Parameters

host
: The target host name

url
: start path on target

root
: local WebDAV collection that contains the retrieved content

dst
: absolute URL to the WebDAV folder to export content to

Return Types

The function returns a non-zero value (can be an error description) if an error occurred while exporting.

Errors

Table 24.23. Errors signalled by DAV_* functions

Error Code	Description
>=0	success
-1	The path (target of operation) is not valid
-2	The destination (path) is not valid
-3	Overwrite flag is not set and destination exists
-4	The target is resource, but source is collection (in copy move operations)
-5	Permissions are not valid
-6	uid is not valid
-7	gid is not valid
-8	Target is locked
-9	Destination is locked
-10	Property name is reserved (protected or private)
-11	Property does not exists
-12	Authentication failed
-13	Operation is forbidden (the authenticated user do not have a permissions for the action)
-14	the target type is not valid

Error Code	Description
-15	The umask is not valid
-16	The property already exists
-17	Invalid property value
-18	no such user
-19	no home directory

Examples

Example 24.81. Exporting to the Filesystem

```
WS.WS.LFS_EXP ('www.foo.com', '/help/', 'sites/www_foo_com', '/tmp/');
WS.WS.DAV_EXP ('www.foo.com', '/help/', 'sites/www_foo_com',
  'http://www.mydrive.com:8990/DAV/sites/');
```

dayname

dayname , monthname , dayofmonth , dayofweek , dayofyear , quarter , week , month , year , hour , minute , second , timezone — decompose a datetime to its components

Synopsis

dayname (in *dt* datetime);

monthname (in *dt* datetime);

dayofmonth (in *dt* datetime);

dayofweek (in *dt* datetime);

dayofyear (in *dt* datetime);

quarter (in *dt* datetime);

week (in *dt* datetime);

month (in *dt* datetime);

year (in *dt* datetime);

hour (in *dt* datetime);

minute (in *dt* datetime);

second (in *dt* datetime);

timezone (in *dt* datetime);

Description

These functions decompose a datetime to its components. These can be used on timestamps , datetimes , dates and times , all being the same internal data type.

```
:  dayname      name of day
:  monthname    name of month
:  dayofmonth   day of month
:  dayofweek    day of week
:  dayofyear    day since start of year
:  quarter      quarter number,
:  week                 week number
:  month                month number, starting at 1 for January
:  year                 year
:  hour                 hour
:  minute               minute
:  second               second
:  timezone     offset from UTC in minutes
```

Parameters

dt
: A datetime value.

Return Values

`monthname` and `dayname` return a varchar . The others return an integer .

Examples

Example 24.82. Simple example

```
SQL> select dayname(stringdate('2001-03-02'));
callret
VARCHAR
_______________________________________________________________________________

Friday

1 Rows. -- 3 msec.
```

See Also

`stringdate` , `datestring` , `datestring_GMT` , The TIMESTAMP datatype

dayofmonth

dayofmonth — get day of month from a datetime

Synopsis

dayofmonth (in *dt* datetime) ;

Description

`dayofmonth` takes a datetime and returns an integer containing day of the month represented by the datetime

Parameters

dt
: A datetime .

Return Values

An INTEGER containing the day of month.

Examples

Example 24.83. Simple example

Get current day of month.

See Also

`dayname` , `monthname` , `dayofweek` , `dayofyear` , `quarter` , `week` , `month` , `year` , `hour` , `minute` , `second` , `timezone`

dayofweek

dayofweek — get day of week from a datetime

Synopsis

dayofweek (in *dt* datetime);

Description

dayofweek takes a datetime and returns an integer containing a number representing the day of week of the datetime.

Parameters

dt
: A datetime .

Return Values

An INTEGER containing number of the day of week.

Examples

Example 24.84. Simple example

Get current day of week.

```
SQL> select dayofweek(now());
callret
INTEGER
_______________________________________________________________________________

6
```

See Also

dayname , monthname , dayofmonth , dayofyear , quarter , week , month , year , hour , minute , second , timezone

dayofyear

dayofyear — get day of year from a datetime

Synopsis

dayofyear (in *dt* datetime);

Description

dayofyear takes a datetime and returns an integer containing a number representing the day of year of the datetime.

Parameters

dt
: A datetime .

Return Values

An INTEGER containing number of the day of year.

Examples

Example 24.85. Simple example

Get current day of year.

```
SQL> select dayofyear (now ());
callret
INTEGER
_______________________________________________________________________________

282
```

See Also

dayname , monthname , dayofmonth , dayofweek , quarter , week , month , year , hour , minute , second , timezone

dbg_obj_print

dbg_obj_print — print to the Virtuoso system console

Synopsis

dbg_obj_print (in *arg1* any ,
...) ;

Description

dbg_obj_print prints a variable number of arguments onto the system console (stdout) of Virtuoso server, each argument in its own native format, on the same line, which is followed by one newline.

Parameters

dbg_obj_print takes a variable number of any type.

Return Values

None

Errors

Table 24.24. Errors signalled by

SQLState	Error Code	Error Text	Description

Examples

Example 24.86. Simple Use

```
...
declare vec any;
vec := vector ('a', 'b', 'c');
dbg_obj_print (vec)
...
```

Would output this on the console:

```
("a" "b" "c" )
```

See Also

dbg_printf

dbg_printf

dbg_printf — print formatted output onto the system console

Synopsis

dbg_printf (in *format* varchar ,
in *arg1* any ,
... ,
in *argn* any) ;

Description

`dbg_printf` prints a variable number (max. eight) of arguments to the system console of Virtuoso server, each argument formatted in C `printf` style, according to the format string specified in the first argument.

Parameters

format
: a C sprintf -style format string

argn
: The arguments to format and print in any type

Return Values

None

Examples

Example 24.87. Simple example

The frammitz just zilched!

```
if (frammitz_status 0)
{
dbg_printf ('Error: Frammitz status: %d.\nProgram terminated',
frammitz_status);
signal ('42666', 'Frammitz zilched');
}
```

Hitting these lines would cause something like this in a client:

```
*** Error 42666: [Virtuoso Driver][Virtuoso Server]Frammitz zilched at line 84 (84) of Top-Level:
zappi()
```

The console output would look like this:

```
Error: Frammitz status: 2.
Program terminated
```

See Also

sprintf()

log_message()

dbname

dbname — get current catalog

Synopsis

```
dbname (   void);
```

Description

Returns the current qualifier as set by the USE statement or default.

Parameters

None

Return Values

A varchar containing the current catalog name/qualifier.

Examples

Example 24.88. Simple Example

Get current catalog/qualifier

```
SQL> select dbname();
callret
VARCHAR
_______________________________________________________________________________

DB

1 Rows. -- 117 msec.
SQL> use Demo;

Done. -- 73 msec.
SQL> select dbname();
callret
VARCHAR
_______________________________________________________________________________

Demo

1 Rows. -- 4 msec.
SQL>
```

delay

delay — sleep for n seconds

Synopsis

delay (in *n_seconds* integer);

Description

This will halt calling procedure execution for specified interval in seconds.

Parameters

n_seconds
: INTEGER number of seconds to sleep.

Return Types

None

Examples

Example 24.89. Simple example

```
create procedure
waitsome (in _interval integer)
{
  delay (_interval);
}

SQL> waitsome (10);

Done. -- 10004 msec.
```

cl_exec

cl_exec — executes things on all nodes of a cluster

Synopsis

cl_exec (in *cmd* varchar ,
in *params* any := NULL ,
in *is_txn* int := 0) ;

Description

The cl_exec SQL function can be used for executing things on all nodes of a cluster.

Parameters

cmd
: A SQL string. If it contains parameter markers (?), the params array is used for assigning values, left to right.

params
: Any params.

is_txn
: If set to 1, the cl_exec makes a distributed transaction and does not automatically commit on locally on each node. Thus cl_exec can be used as part of a containing distributed transaction.

Examples

Example 24.90. Simple example

```
SQL> cl_exec ('shutdown')
--will shut all nodes.

SQL> cl_exec ('dbg_obj_print (?)', vector ('hello'));
--will print hello to the standard output of all the processes of the cluster.
```

Backup and Restore Example

dict_dec_or_remove

dict_dec_or_remove — Decrement a counter in a dictionary of counters or deletes it if it becomes zero or negative.

Synopsis

dict_dec_or_remove (inout *dict* dictionary ,
in *key* any ,
in *value_decrement* integer) ;

Description

The function checks whether *dict* contains *key* . If it isn't so then the function checks the datatype of the value associated with the key. An error 42000 is signalled in case of non-integer value or a negative integer value. If the value is positive and greater than *value_decrement* then *value_decrement* is subtracted from it and the result become the new value associated with *key* in *dict* . If the value is positive and less than or equal to *value_decrement* then *key* is removed from *dict* . If key is not in the dictionary then the dictionary remains unchanged.

Informally, the function reverts the effect of dict_inc_or_add .

Parameters

dict
: Dictionary of counters. The NULL value is equivalent to an empty dictionary.

key
: Key of a dictionary item to process.

value decrement
: A nonnegative integer (typically 1) that is subtracted from the value associated with key .

Return Types

The function returns the changed value associated with the *key* , or zero in any other case.

dict_to_vector()

dict_list_keys()

dict_destructive_list_rnd_keys()

dict_iter_rewind()

dict_iter_next()

dict_duplicate

dict_duplicate — Creates a copy of the given dictionary.

Synopsis

```
dictionary dict_duplicate ( in dict dictionary );
```

Description

The function creates a full copy of the given dictionary.

Dictionary objects are always passed by reference, even if dictionary is passed as an 'in' argument of a function. If value of a variable is a dictionary and it is assigned to other variable then both variables refer to the same internal hash table. This function returns a really independent dictionary object.

This function duplicates the given dictionary but does not duplicate dictionaries that may be stored in key-value pairs.

Parameters

dcit
: The dictionary to be duplicated.

Return Types

The function returns a new dictionary object.

dict_get

dict_get — Returns the dependent part that corresponds to the given key in the given dictionary.

Synopsis

```
any dict_get ( in dict dictionary ,
               in key any ,
               in default_value any );
```

Description

The function returns the dependent part that corresponds to the given key in the given dictionary. The function returns *default_value* if the dictionary does not contain a pair whose key is equivalent to the given one. When only two arguments are passed to the function the default value is integer zero.

Parameters

dict
: Dictionary object to search in.

key
: Key whose dependent part should be found.

default_value
: The default value to be returned if the key is not found in the dictionary.

Return Types

The function can return a value of any type.

dict_inc_or_put

dict_inc_or_put — Creates or increments an integer counter for a given key and a dictionary.

Synopsis

dict_inc_or_put (inout *dict* dictionary ,
in *key* any ,
in *value_increment* integer) ;

Description

The function checks whether *dict* contains *key* . If it isn't so then the function checks the datatype of the value associated with the key. An error 42000 is signalled in case of non-integer value or a negative integer value. If the value is positive then *value_decrement* is added to it and the result become the new value associated with *key* in *dict* . If key is not in the dictionary then a new item is added to the *dict* in order to associate the *key* with *value_increment* .

Parameters

dict
: Dictionary of counters. If the value is NULL then the function immediately returns zero.

key
: Key of a dictionary item to process.

value decrement
: A nonnegative integer (typically 1) that is added to the value associated with key or used as a starting value of a newly created counter.

Return Types

The function returns zero (for NULL *dict*) or the changed (or the added) value associated with the *key* .

Example

Example 24.91. Simple Use

The function is convenient to deal with multisets, i.e., sets with repeating elements. In this case the dictionary contains distinct items as keys and counts of duplicates as associated values. `dict_inc_or_add` is to add a member, `dict_dec_or_remove` is to remove. The following example gets an array of multisets and return the sum of them.

```
create function DB.DBA.SUM_MULTISETS (inout msets any) returns any
{
  declare sum_of_msets any;
  sum_of_msets := dict_new (17);
  foreach (any mset in msets) do
    {
      declare iter any;
      declare memb any;
      declare dup_count integer;
      iter := mset; --- unlike dict_duplicate() this does not make copy of mset so it's fast.
      dict_iter_rewind (iter);
      while (dict_iter_next (iter, memb, dup_count))
        dict_inc_or_put (sum_of_msets, memb, dup_count);
    }
  return sum_of_msets;
};
```

dict_size()

dict_duplicate()

dict_to_vector()

dict_list_keys()

dict_destructive_list_rnd_keys()

dict_iter_rewind()

dict_iter_next()

dict_iter_next

dict_iter_next — Fetches a pair of key and value from a dictionary iterator and moves the iterator to the next pair.

Synopsis

```
dict_iter_next ( inout dict dictionary ,
                 out ret_key any ,
                 out ret_value any ) ;
```

Description

The function gets the dictionary iterator initialized earlier by `dict_iter_rewind` and checks whether the iterator is still valid and not in conflict with any changes made by `dict_put` or the like. After that, if the iterator is in the position past the last item of the dictionary then zero is returned. If the iterator points to some item then *`ret_key`* and *`ret_value`* parameters are set to the key and value of the current item, the iterator is advanced to the next position (next item if present, otherwise past the end of the dictionary) and a nonzero integer is returned. If *`ret_value`* is a constant or an expression but not a plain variable then it is left unchanged but no error is signalled, so if the caller procedure needs only values of keys from dictionary then any constant like zero can be passed as a third parameter. Similarly, *`ret_key`* is not necessarily a variable.

Note that the values of *`ret_key`* and *`ret_value`* are left unchanged if the iterator points past the end of the dictionary. They are not filled in with NULLs or something like that.

Parameters

dict
: Dictionary iterator

ret_key
: The variable to be filled in with the key of the item. The parameter is ignored if it is not a plain variable.

ret_value
: The variable to be filled in with the value (dependant part) of the item. The parameter is ignored if it is not a plain variable.

Return Types

The function returns a nonzero integer if the item is successfully fetched, zero otherwise

Errors

This function can generate the following errors:

Table 24.25.

Error Code	Description
22023	SR630 Function dict_iter_next() tries to iterate a volatile dictionary changed after last `dict_iter_rewind` (). Not every change in the dictionary results in this error. If the dict_iter_next() and `dict_put` () (or similar function) are both called with same variable passed as *`dict`* parameter then the function might adjust the iterator to match the changed state of the dictionary so it remains valid. In addition, if `dict_put` () changes only the value associated with some key but does not extend the dictionary with a new item then it does not invalidate any iterators.

Example

Example 24.92. Simplest read throughout the dictionary.

The procedure creates a dictionary, puts couple of items into it and then print them to the server's console

```
create function dict_iterator_test ()
{
  declare dict, dkey, dvalue any;
  dict := dict_new (10);
  dict_put (dict, 'a', 1); dict_put (dict, 'b', 2);
  dict_iter_rewind (dict);
  while (dict_iter_next (dict, dkey, dvalue))
    dbg_obj_princ (' key is ' dkey, ', corresponding value is ', dvalue);
}
```

dict_to_vector

dict_list_keys

dict_destructive_list_rnd_keys

dict_iter_rewind

dict_iter_rewind

dict_iter_rewind — Resets the iterator before fetching keys and values by dict_iter_next()

Synopsis

dict_iter_rewind (inout *dict* dictionary);

Description

The dictionary is always passed by reference, due to its (potentialy big) size. The reference variable contains not only pointer to the whole dictionary but also a forward-only iterator (a "cursor") that can be used to retrieve items of the dictionary one after the other. The function sets the iterator to the very first item of the dictionary.

Parameters

dict
: The reference to a dictionary to use as an iterator

Return Types

The function returns an integer that is the expected number of items in the dictionary; the value may not match to the number of items retrieved later by dict_iter_next() if a dictionary is edited by some thread.

Example

Example 24.93. Simplest read throughout the dictionary.

The procedure creates a dictionary, puts couple of items into it and then print them to the server's console

```
create function dict_iterator_test ()
{
  declare dict, dkey, dvalue any;
  dict := dict_new (10);
  dict_put (dict, 'a', 1); dict_put (dict, 'b', 2);
  dict_iter_rewind (dict);
  while (dict_iter_next (dict, dkey, dvalue))
    dbg_obj_princ (' key is ' dkey, ', corresponding value is ', dvalue);
}
```

dict_to_vector

dict_list_keys

dict_destructive_list_rnd_keys

dict_iter_next

dict_list_keys

dict_list_keys — Returns an array of all keys stored in the given dictionary.

Synopsis

```
vector dict_list_keys ( inout dict dictionary ,
                        in destructive any ) ;
```

Description

The function returns an array of all keys stored in the given dictionary, ignoring dependent parts of key-value pairs. This is especially useful when dictionary is used to form a set of distinct keys, when dependent parts are fake (typically zeroes). If the *destructive* parameter is 1 or 2 then the function may avoid copying of keys to the resulting array by moving them out from the dictionary. This is faster but the dictionary will become empty at the end of operation. The *destructive* parameter equal to 1 does not have any effect if the dictionary is used as a value of more than one variable. Thus it is safe to make this parameter equal to 1 as soon as the variable passed to the function as *dict* is no longer in use after the function call and there's no need to inspect the whole program to check if other variables may be affected. The parameter equal to 2 ignores the presence of multiple variables so the operation may cause unexpected results in other fragments of code that share the dictionary.

The created array can not be longer than the system limit and even if it is below limit but longer than hundreds of thousands items then memory allocation can be inefficient. If the dictionary can be large and it is possible to process the content of the dictionary in parts, consider using dict_destructive_list_rnd_keys () instead.

Parameters

dict
: The dictionary to scan

destructive
: Flag that indicates whether the dictionary can be cleaned during the operation (0 = never clean, 1 = only if there is no other variables, 2 = clean unconditionally).

Return Types

The function returns a vector.

dict_iter_next()

dict_destructive_list_rnd_keys

dict_destructive_list_rnd_keys — Returns all or some keys from the given dictionary

Synopsis

dict_destructive_list_rnd_keys (inout *dict* dictionary ,
in *batch_size* integer) ;

Description

The function returns an array of keys stored in the given dictionary, ignoring dependent parts of key-value pairs, but unlike `dict_list_keys` it may return only some keys, not all, and it always remove the returned keys from the dictionary. The returned array is *`batch_size`* items long (if the dictionary is big enough to fill it).

The order of items returned (and hence the content of the dictionary after function call) is undefined. It is not randomized artificially but it may vary from run to run depending on barely predictable factors. As a result, the most typical use of the function is calling it in a loop that ends when the size of returned array falls down to zero indicating that the dictionary is exausted.

Parameters

dict
: The dictionary where result keys come from.

batch_size
: The maximum size of array to be constructed. The value can not be less than 65535 and more than the maximum allowed length of array (1250000 for 64-bit machines, 25000000 for 32-bit machines). All other equal, it is preferable to keep it below 200000.

Return Types

The function always returns an array; the array is empty if *`dict`* is NULL or an empty dictionary.

Example

Example 24.94. Simple Use

The function gets a dictionary with RDF triples stored as keys and inserts all these triples into a given graph.

```
create function DB.DBA.INSERT_DICT_IN_GRAPH (in graph_iri varchar, in triples_dict any) returns varchar
{
  declare triples any;
  declare ins_count integer;
  ins_count := 0;
  while (dict_size (triples_dict) > 0)
    {
      triples := dict_destructive_list_rnd_keys (triples_dict, 80000);
      DB.DBA.RDF_INSERT_TRIPLES (graph_iri, triples, 1);
      ins_count := ins_count + length (triples);
    }
  return sprintf ('The function INSERT_DICT_IN_GRAPH has inserted %d triples in graph <%s>',
    ins_count, graph_iri );
}
;
```

`dict_iter_next()`

dict_new

dict_new — Creates a new dictionary to store key-value pairs.

Synopsis

```
dictionary dict_new ( in size integer );
```

Description

This function creates a new dictionary. A dictionary is a memory-resident hash table that can store an arbitrary number of key-value pairs. Both key and dependent part can be of any type, including vectors. Two keys of different data types are always considered as different even if SQL '=' operator return 'true', e.g. integer zero and double precision 0.0 are two different keys. Vectors are equivalent if their corresponding members are either equal scalars or equivalent vectors. XML entities are equivalent if they refer to the same node or attribute in the same document.

Dictionary objects are always passed by reference, even if dictionary is passed as an 'in' argument of a function. If value of a variable is a dictionary and it is assigned to other variable then both variables refer to the same internal hashtable. To create two really independent dictionary objects, use `dict_duplicate ()`.

Parameters

size
: The guessed side of hashtable. overestimation of the size will result in needless memory consumption whereas underscore leads to a bit slower insertion, because the internal hash table will grow dynamically. The simplest approach is to omit the parameter at all if you don't know the number of keys to be stored.

Return Types

The function returns a new empty dictionary object.

dict_put

dict_put — Adds a key-value pair to a dictionary

Synopsis

```
int dict_put ( inout dict dictionary ,
               in key any ,
               in value any );
```

Description

The function adds or updates a key-value pair in the given dictionary. If the dictionary contains a pair with the key part equivalent to the given one then old value is replaced with a new one. Otherwise, a new pair is added to the dictionary.

Parameters

dict
: The dictionary to be updated or extended.

key
: The key part of the dictionary pair to be added or updated.

value
: The dependent part of the pair.

Return Types

The function returns the total number of pairs stored in the dictionary as counted after the modification.

dict_remove

dict_remove — Removes the given key and associated dependent value from the given dictionary.

Synopsis

```
int dict_remove ( inout dict dictionary ,
                  inout key any );
```

Description

The function removes the given key and the associated dependent value from the given dictionary. If the key-value pair is found (and removed) the function returns 1. If the dictionary does not contain a key equivalent to the given one the function returns zero.

Parameters

dict
: Dictionary object to process.

key
: Key of a key-value pair that should be removed from the dictionary.

Return Types

Integer flag indicating if a key-value pair has been found and removed.

dict_size

dict_size — Returns the number of items in the given dictionary.

Synopsis

dict_size (inout *dict* dictionary);

Description

The function returns the number of items in the *dict* dictionary. For NULL value of *dict* , zero is returned.

Parameters

dict
: Reference to the dictionary in question.

Return Types

The function returns an interger.

dict_destructive_list_rnd_keys()

dict_iter_rewind()

dict_iter_next()

dict_to_vector

dict_to_vector — Returns a get_keyword style vector of all items stored in the given dictionary.

Synopsis

```
vector dict_to_vector ( inout dict dictionary ,
                        in destructive any ) ;
```

Description

The function returns an array of all data stored in the given dictionary, every pair is represented as two consecutive element of the resulting array. Thus the dictionary of N pairs is converted into a vector of length 2N where keys are at positions 0, 2, 4, ..., 2N-1 and corresponding dependent data are at positions 1, 3, 5, ..., 2N. If keys are all scalars of same type then `get_keyword` function can be used to search in the resulting array.

If the *destructive* parameter is 1 or 2 then the function may avoid copying of keys and values to the resulting array by moving them out from the dictionary. This is faster but the dictionary will become empty at the end of operation. The *destructive* parameter equal to 1 does not have any effect if the dictionary is used as a value of more than one variable. Thus it is safe to make this parameter equal to 1 as soon as the variable passed to the function as *dict* is no longer in use after the function call and there's no need to inspect the whole program to check if other variables may be affected. The parameter equal to 2 ignores the presence of multiple variables so the operation may cause unexpected results in other fragments of code that share the dictionary.

Parameters

dict
: The dictionary to scan.

destructive
: Flag that indicates whether the dictionary can be cleaned during the operation (0 = never clean, 1 = only if there is no other variables, 2 = clean unconditionally).

Return Types

The function returns a vector of even length.

```

dict_zap

dict_zap — Removes all data from the given dictionary

Synopsis

dict_zap (inout *dict* dictionary ,
in *destructive* integer) ;

Description

The function removes all items from the given dictionary.

If the *destructive* parameter is 0 or 1 then an error 22023 is signalled if the dictionary is used as a value of more than one variable. The parameter equal to 2 forces the function to ignore the presence of multiple variables; in this case the operation may cause unexpected results in other fragments of code that share the dictionary.

In most of cases, this function is used specifically for its side effect on other variables. With only one variable in use, one may simply set that variable to the value returned by dict_new () (or to NULL if the dictionary is no longer needed). If the dictionary is no longer referenced by any variable, it is destroyed and the occupied memory is freed. However one may wish to zap the dictionary in order to not worry about number of variables that refers to the dictionary, e.g., when dictionary is used only in some part of a long procedure.

Parameters

dict
: The dictionary to zap. If it is NULL then the function call has no effect and returned value is zero.

destructive
: Flag that indicates whether the dictionary can be cleaned if multiple references exist (0 and 1 = zap only if there is no other variables and signal an error otherwise, 2 = clean unconditionally).

Return Types

The function returns the number of intems in the dictionary before the operation.

disconnect_user

disconnect_user — Disconnect client connections of a given user

Synopsis

disconnect_user (in *username_pattern* string) ;

Description

disconnect_user disconnects clients whose username matches the username_pattern string given as an argument, and returns an integer value giving the number of clients disconnected. This can be used after DELETE USER or REVOKE statement to make sure that the affected user has no open connections.

Parameters

username_pattern
: A string pattern to match users to be disconnected. SQL wildcards including Virtuoso extensions may be used:

Return Values

The number of clients disconnected is returned.

Errors

Parameter data type checking errors

Examples

Example 24.95. Disconnect users

This is how the DBA can close all sessions for all users who name starts with db, including 'dba' which is the DBA itself.

```
SQL> disconnect_user ('db*');

*** Error 08S01: [Virtuoso Driver]CL065: Lost connection to server
at line 7 (7) of Top-Level: disconnect_user ('db*')
bash$
```

See Also:

username

dt_set_tz

dt_set_tz — modifies the timezone component of a datetime

Synopsis

dt_set_tz (in *dt* datetime ,
in *tz* integer) ;

Description

This modifies the timezone component of a datetime. The value remains equal for purposes of comparison but will look different when converted to a string. The timezone component is an offset from UTC in minutes. It can be retrieved with the timezone function.

Timezoneless: The function returns its first argument with unchanged GMT value but new timezone offset. Unlike `adjust_timezone()` , if the argument is timezoneless then no error is signaled.

Parameters

dt
: The original DATETIME .

tz
: INTEGER new timezone offset.

Return Types

A DATETIME with the new timezone set

dvector

lvector , fvector , dvector — return an array of either long, float or double

Synopsis

```
array lvector ( elt1 ,
                .... ,
                elt-n );

array fvector ( elt1 ,
                .... ,
                elt-n );

array dvector ( elt1 ,
                .... ,
                elt-n );
```

Description

These functions are like vector but return an array of either long, float or double whereas vector returns a generic, untyped array.

Example 24.96. Examples:

```
aref (lvector (1, 2), 1) = 1    is true.
```

end_result

end_result — End the current result set.

Synopsis

```
end_result (   );
```

Description

The `result_names()` predefines variables to be used in a result set to follow. The variables must be previously declared, from which the column data types are ascertained. This assigns the meta data but does not send any results. The `result()` function sends its parameters as a single row of results. These parameters should be compatible with those in the previous `result_names()` . The `end_result()` function can be used to separate multiple result sets. The `result_names()` can then be used to alter the result set structure.

The `result_names()` call can be omitted if the application already knows what columns and their types are to be returned.

See Also

`result()`

`result_names()`

either

either — conditionally return one of specified parameters

Synopsis

either (in *cond* any ,
in *arg1* any ,
in *arg2* any) ;

Description

either returns a copy of arg1 if cond is something else than integer 0 (zero). Otherwise, a copy of arg2 is returned.

Parameters

cond
: Anything

arg1
: Anything

arg2
: Anything

Return values

A copy of arg1 or arg2, which could be of any type.

Errors

Table 24.26. Errors signalled by `either` and `stringdate`

SQLState	Error Code	Error Text	Description

Examples

Example 24.97. Simple Example

```
SQL> select either (mod (1, 2), 'odd', 'even');
callret
VARCHAR
_______________________________________________________________________________

odd

1 Rows. -- 33 msec.
SQL> select either (isnull (strstr ('Simurg', 'imu')), 'imu not found', 'imu found');
callret
VARCHAR
_______________________________________________________________________________

imu found

1 Rows. -- 4 msec.
```

elh_get_handler

elh_get_handler — get localization function handler

Synopsis

```
encodedlang_handler_t * elh_get_handler ( encoding_handler_t * encoding ,
                                          language_handler_t * language ) ;
```

Description

Gets localization.

Parameters

encoding
: Name of the encoding to be used.

language
: Name of the text language

Return Types

Returns "encoded language" handler for optimized processing of texts on given language with given encoding as described in section Adding New Languages and Encodings Into Virtuoso of the main documentation. If *encoding* is NULL, or if there's no optimized handler for given encoding/language combination, then NULL will be returned, indicating failure, otherwise combination's handler will be returned.

Examples

Example 24.98. Returning a Handler Pointer

```
encodedlang_handler_t *elh =
  elh_get_handler(eh_get_handler("MY-ENCODING"),
    lh_get_handler("x-my-language")
  );
```

See Also

elh_load_handler

lh_get_handler

lh_load_handler

Adding New Languages and Encodings Into Virtuoso

elh_load_handler

elh_load_handler — load encoding handler into system

Synopsis

```
int elh_load_handler ( encodedlang_handler_t * new_handler );
```

Description

Loads given handler in table of handlers bound to encoding specified in the handler, using ISO 639 and RFC 1766 language IDs of the handler as keys for future table lookups. If another handler was already specified for given RFC 1766 id, table entry will be updated and will refer to new handler. If another handler was already specified for given ISO 639 id, it will be replaced only if new handler has ISO 639 language ID equal to its RFC 1766 ID.

Please do not load custom versions of 'x-any' and 'x-ftq-x-any' handlers.

Parameters

new_handler
: Pointer to the structure that lists names of the handler and its callback functions.

See Also

elh_get_handler

lh_get_handler

lh_load_handler

encode_base64

encode_base64 , decode_base64 — base64-encode/decode a string

Synopsis

encode_base64 (in *str* varchar) ;

decode_base64 (in *str* varchar) ;

Description

These functions convert strings from/to base64-encoding.

Parameters

str
: A varchar value.

Return Values

`encode_base64` returns a varchar containing base64-encoded data. `decode_base64` returns a varchar containing the result of the base64-decoding.

Examples

Example 24.99. Simple Example

Base64-encode a string

```
SQL> select encode_base64('Rutabaga');
callret
VARCHAR
_______________________________________________________________________________

UnV0YWJhZ2E=

1 Rows. -- 25 msec.
```

Example 24.100. Web example

Using encode-base64 with serialize to persist complex data

```
declare n any; n := vector ('a', 3.14157, 4711, 'Hic Iacet Corpus.');
http (sprintf ('<input type="hidden" name="saved" value="%s">', encode_base64 (serialize (n))));
```

To retrieve this data in VSP context when handling a form submit:

```
declare n any; n := deserialize (decode_base64 (get_keyword ('saved', params, '')));
```

See Also

`serialize`

equ

lt , lte , gt , gte , equ , neq — comparison functions

Synopsis

lt (in *arg1* any ,
in *arg2* any) ;

lte (in *arg1* any ,
in *arg2* any) ;

gt (in *arg1* any ,
in *arg2* any) ;

gte (in *arg1* any ,
in *arg2* any) ;

equ (*arg1* any ,
arg2 any) ;

neq (in *arg1* any ,
in *arg2* any) ;

Description

These functions return 1 if their first argument is less than (lt), less than or equivalent (lte), greater than (gt), greater than or equivalent (gte), equivalent (equ), or not equivalent (neq) to the second argument, respectively. If the arguments are not of the same type, then an appropriate type coercion is done for them before comparison.

These functions correspond to SQL query operators <, <=, >, >=, = and <> and are needed because the SQL syntax does not allow these operators to be used on the left side of `FROM` keyword in a `SELECT` statement.

Parameters

arg1 , arg2
: integer , float , double precision , varchar or NULL .

Return Values

An integer value of 1 or 0 is returned.

Examples

Example 24.101. Simple Example

```
lt('pata','pato')  -> 1 (Yes, 'pata' is less than 'pato')
gt('barbar','bar')  -> 1 (Yes, 'barbar' is greater than 'bar')
equ(17,17)    -> 1 (seventeen is seventeen)
equ(17,17.0)    -> 1 (regardless of number format)
equ(atof('17.0'),17.0))  -> 1 (as it seems be)
equ(atof('17.1'),17.1))  -> 0 (But not always! Beware!)
gte(1234,NULL)    -> 0 (No, 1234 is not "greater"
        than or equal to NULL)
lt(1234,NULL)    -> 1 (Instead, it is "less" than NULL)
```

exec

exec — dynamic execution of SQL returning state and result set

Synopsis

```
exec ( in str varchar ,
       out state varchar ,
       out message varchar ,
       in params any ,
       in maxrows integer ,
       out metadata vector ,
       out rows vector ,
       out cursor_handle long ) ;
```

Description

This function provides dynamic SQL capabilities in Virtuoso PL. The first argument is an arbitrary SQL statement, which may contain parameter placeholders. The function returns as output parameters a SQL state, error message, column metadata and result set rows if the statement is a select.

A stored procedure can be invoked by exec but a procedure's result set will not be received in the rows output parameter but rather sent to the client.

Parameters

str
: A varchar containing arbitrary SQL using ?'s for parameter markers.

state
: An output parameter of type varchar set to the 5 character SQL state if the exec resulted an error. Not set if an error is not present.

message
: An output parameter of type varchar set to SQL error message associated with the error. Not set if an error is not present.

params
: A vector containing the parameters for the SQL being executed. Element 0 corresponding to first ?, etc.

maxrows
: The integer maximum number of rows to retrieve in case of a statement returning a result set.

metadata
: An output parameter of type vector returning the metadata of the statement and its result.

rows
: An output array with one element per result row containing an array with the leftmost column as element 0 and so forth.

cursor_handle
: The cursor handle for use with related functions.

Examples

Example 24.102. Procedure Example

This stored procedure returns 1 if a given table is empty. An error such as a timeout or deadlock would be reported back to the caller as an exception. Exec always returns, no matter the type of exception. Thus it is also useful as a universal error catcher.

```
create procedure tb_is_empty (in tb varchar)
{
  declare state, msg, descs, rows any;
  state := '00000';
  exec (sprintf ('select 1 from %s', tb), state,
    msg, vector (), 1, descs, rows);

  if (state <> '00000')
    signal (state, msg);

  if (length (rows) = 0)
    return 1;

  else
    return 0;
}
```

See Also

rexecute()

exec_next()

exec_close()

close

exec_close — Closes cursor created by exec()

Synopsis

exec_close (in *cursor_handle* long);

Description

Closes the cursor opened by the exec() function.

Parameters

cursor_handle
: The cursor handle used.

See Also

`exec_next()`

`exec()`

exec_next

exec_next — Get next result from a result set

Synopsis

```
integer retcode exec_next ( in cursor_handle long ,
                            out sql_state varchar ,
                            out sql_error varchar ,
                            out row_array vector ) ;
```

Description

Use `exec_next()` to iterate over a result set produced by a statement run with `exec` .

open a cursor with exec .
loop over the results with exec_next
if exec_next does not return an error or SQL_NO_DATA_FOUND continue the loop with exec_next, otherwise
close the cursor with exec_close

Parameters

cursor_handle
: The long cursor handle as obtained from exec().

row_array
: An output vector that will contain the result columns.

sql_state
: Optional varchar output parameter for SQL state.

sql_error
: Optional varchar output parameter for any error message.

Return Values

All data is returned in output parameters.

See Also

`exec()` , `exec_close()` .

exec_result

exec_result — Returns a result set row to the calling procedure context

Synopsis

any **exec_result** (in *res_values_array* any);

Description

This function returns a result set row to the calling procedure's context, whether it is the client, exec function or a procedure view). The row's values are the elements of the supplied res_values_array vector.

Parameters

res_values_array
: This parameter can be one of two things:

Return Types

The row's values are the elements of the supplied res_values_array vector. For example: `exec_result (vector (1, 'a'))` will return a row of two columns: 1 and 'a'. This is similar to the `result()` function, but it uses an array instead of parameter list

Examples

Example 24.103. Result set rows

```
create procedure XX1 ()
{
  declare meta, _dt any;
  declare inx integer;
  exec ('select U_ID, U_NAME from SYS_USERS', null, null, null, 0, meta, _dt);
  inx := 0;

  exec_result_names (meta[0]);
  while (inx < length (_dt))
    {
      exec_result (_dt[inx]);
      inx := inx + 1;
    }
};
```

See Also

`exec()`

`rexec()`

`exec_result_names()`

`result_names()`

exec_result_names

exec_result_names — Supplies column details for procedure result set output.

Synopsis

exec_result_names (in *res_names_array* any) ;

Description

This function allows you to define the column details for result sets returned by procedures, in particular for use with the `exec()` function. This function is similar to `result_names()` .

Parameters

res_names_array
: This parameter can be one of two things:

Return Types

None.

Examples

Example 24.104. Result set column names

The procedure below uses the metadata from exec() to generate result set column names.

```
create procedure XX1 ()
{
  declare meta, _dt any;
  declare inx integer;
  exec ('select U_ID, U_NAME from SYS_USERS', null, null, null, 0, meta, _dt);
  inx := 0;

  exec_result_names (meta[0]);
  while (inx < length (_dt))
    {
      exec_result (_dt[inx]);
      inx := inx + 1;
    }
};

exec_metadata

exec_metadata — Compiles a SQL statement and returns the metadata

Synopsis

exec_metadata (in *str* varchar ,
out *state* varchar ,
out *message* varchar ,
out *metadata* vector) ;

Description

This function provides dynamic SQL capabilities in Virtuoso PL. The first argument is an arbitrary SQL statement, which may contain parameter placeholders. The function returns as output parameters a SQL state, error message, column metadata if the statement is a select.

Parameters

str
: A varchar containing arbitrary SQL using ?'s for parameter markers.

state
: An output parameter of type varchar set to the 5 character SQL state if the exec resulted an error. Not set if an error is not present.

message
: An output parameter of type varchar set to SQL error message associated with the error. Not set if an error is not present.

metadata
: An output parameter of type vector returning the metadata of the statement and its result.

Errors

The function will generate a SQL 22023 error value if a supplied parameter is not of the type expected.

See Also:
List of SQL 22023 errors.

Examples

Example 24.105. Simple Use

```
create procedure get_meta (in str varchar)
{
  declare state, message, mdta any;
  state := '00000';
  exec_metadata (str, state, message, mdta);
  if (state <> '00000')
    signal (state, message);
  return mdta;
}
```

See Also

`exec()`

`exec_next()`

```
exec_close()
```

exec_score

exec_score — Compiles a SQL statement and returns the estimate time cost

Synopsis

```
exec_score ( in str varchar ,
             out state varchar ,
             out message varchar ) ;
```

Description

This function provides dynamic SQL capabilities in Virtuoso PL. The first argument is an arbitrary SQL statement, which may contain parameter placeholders. The function returns as output parameters a SQL state, error message and returns the estimate time cost in milliseconds.

Parameters

str
: A varchar containing arbitrary SQL using ?'s for parameter markers.

state
: An output parameter of type varchar set to the 5 character SQL state if the exec resulted an error. Not set if an error is not present.

message
: An output parameter of type varchar set to SQL error message associated with the error. Not set if an error is not present.

Return Types

The function returns a float number which is the calculated estimate time cost for the query execution.

Errors

The function will generate a SQL 22023 error value if a supplied parameter is not of the type expected.

See Also:
List of SQL 22023 errors.

Examples

Example 24.106. Simple Use

```
SQL> select exec_score ('select * from T1');
```

See Also

`exec()`

`exec_metadata()`

`exec_close()`

exp

exp — calculate exponent

Synopsis

exp (in *x* double precision) ;

Description

The function raises e to the power of *x* , it works with double precision floating point numbers, converts its argument to an IEEE 64-bit float and returns a result of that type.

Parameters

x
: double precision

Return Values

`exp` returns a IEEE 64-bit float .

Examples

Example 24.107. Simple Examples

```
SQL> select concat ('the EXP of 0.513513 is: ', cast (exp (0.513513) as varchar));
callret
VARCHAR
_______________________________________________________________________________

the EXP of 0.513513 is: 1.671152

1 Rows. -- 3 msec.
```

See Also

`log` , `log10` , `power` , `sqrt` ,

explain

explain — describe SQL statement compilation

Synopsis

```
explain ( in text varchar ,
          in cursor_type integer ) ;
```

Description

The explain function compiles a SQL statement and returns a description of that compilation as a result set, return value or parse tree. The result set consists of one VARCHAR column with one line of the description in each row. Any given line may be quite long, even several hundred characters.

The output is not a complete disassembly of the query graph, but it is detailed enough to show the join order, the sub-query structure, and the order of evaluation of query predicates, as well as the splitting of a distributed VDB query over different data sources.

The optional cursor type can be one of the SQL_CURSOR_<xx> constants, or one of the special values listed below. The default is 0, for FORWARD ONLY. The special values each have special effect, as listed. If the statement is a SELECT and the cursor type is not FORWARD ONLY, the auxiliary SQL statements used by the cursor implementation are shown.

Table 24.31. Cursor Type

Cursor Type	Effect
3	SQL_CURSOR_STATIC
2	SQL_CURSOR_DYNAMIC
1	SQL_CURSOR_KEYSET_DRIVEN
0	SQL_CURSOR_FORWARD_ONLY
-1	A result set is printed. Same effect as 0.
-2	A parse tree is returned.
-5	A result set is printed, and a diagnostic dump is delivered to the server's standard output. This can be viewed if the server was started with +foreground option.
-7	Cost estimates are returned, associated with any different join orders tried during the compilation.

Parameters

text
: varchar SQL statement

cursor_type
: integer cursor type

Return Types

Returns types vary with the specified cursor type.

Table 24.32. Return Types

Cursor Type	Return Type
0, 1, 2, 3, -5, -1	Result set.
-7	Return value.
-2	Parse tree.

Examples

Example 24.108. Simple Example Usage

Execute from ISQL:

```
SQL> explain('select * from sys_users');
REPORT
VARCHAR
_______________________________________________________________________________

{
from DB.DBA.SYS_USERS by SYS_USERS         17 rows

Select ($47 ".U_ID", $46 ".U_NAME", $45 ".U_IS_ROLE", $44 ".U_FULL_NAME", $43 ".U_E_MAIL", $42 ".U_PASSWO
 ".U_ACCOUNT_DISABLED", $38 ".U_DAV_ENABLE", $37 ".U_SQL_ENABLE", $36 ".U_DATA", $35 ".U_METHODS", $34 ".
_HOOK", $31 ".U_PASSWORD_HOOK_DATA", $30 ".U_GET_PASSWORD", $29 ".U_DEF_QUAL", $28 ".U_OPTS", <$49 "<DB.D
}

8 Rows. -- 10 msec.
```

Example 24.109. Example with type -1

Execute from ISQL:

```
SQL> explain('sparql
select *
from <http://myopenlink.net/dataspace/person/kidehen#this>
where {?s ?p ?o} limit 10',-1);
REPORT
VARCHAR
_______________________________________________________________________________

{

Precode:
      0: $27 "hen#this" := Call iri_to_id_nosignal (<constant (http://myopenlink.net/dataspace/person/kid
      5: BReturn 0
from DB.DBA.RDF_QUAD by RDF_QUAD        0.4 rows
Key RDF_QUAD  ASC ($31 "s-1-1-t0.S", $30 "s-1-1-t0.P", $29 "s-1-1-t0.O")
 inlined <col=412 G = $27 "hen#this">

Current of: <$33 "<DB.DBA.RDF_QUAD s-1-1-t0>" spec 5>

After code:
      0: $34 "s" := Call id_to_iri ($31 "s-1-1-t0.S")
      5: $35 "p" := Call id_to_iri ($30 "s-1-1-t0.P")
      10: $36 "o" := Call __rdf_sqlval_of_obj ($29 "s-1-1-t0.O")
      15: BReturn 0
Select (TOP <constant (10)>) ($34 "s", $35 "p", $36 "o", <$33 "<DB.DBA.RDF_QUAD s-1-1-t0>" spec 5>)
}

18 Rows. -- 10 msec.
```

Example 24.110. Example with type -2

Execute from ISQL:

```
SQL> select dbg_obj_print(explain('sparql
select *
```

```
from <http://myopenlink.net/dataspace/person/kidehen#this>
where {?s ?p ?o} limit 10',-2));
callret
VARCHAR
_______________________________________________________________________________

0

1 Rows. -- 20 msec.
```

As result on the Server console will be shown this output:

```
(100 (122 0 10 0 0 0 ) ((21 (609 'id_to_iri' ((201 's-1-1-t0' 'S' ) ) ) 0 's' 0 ) (21 (609 'id_to_iri' ((
__rdf_sqlval_of_obj' ((201 's-1-1-t0' 'O' ) ) ) 0 'o' 0 ) ) 0 (106 ((107 (200 'DB.DBA.RDF_QUAD' 's-1-1-t0
 'iri_to_id_nosignal' ('http://myopenlink.net/dataspace/person/kidehen#this' ) ) 0 0 0 0 0 0 ) 0 0 0 0 (9
```

Example 24.111. Example with type -5

Execute from ISQL:

```
SQL> explain('sparql select * from <http://myopenlink.net/dataspace/person/kidehen#this> where {?s ?p ?o}
REPORT
VARCHAR
_______________________________________________________________________________

{

Precode:
      0: $27 "hen#this" := Call iri_to_id_nosignal (<constant (http://myopenlink.net/dataspace/person/kid
      5: BReturn 0
from DB.DBA.RDF_QUAD by RDF_QUAD        0.4 rows
Key RDF_QUAD  ASC ($31 "s-1-1-t0.S", $30 "s-1-1-t0.P", $29 "s-1-1-t0.O")
 inlined <col=412 G = $27 "hen#this">

Current of: <$33 "<DB.DBA.RDF_QUAD s-1-1-t0>" spec 5>

After code:
      0: $34 "s" := Call id_to_iri ($31 "s-1-1-t0.S")
      5: $35 "p" := Call id_to_iri ($30 "s-1-1-t0.P")
      10: $36 "o" := Call __rdf_sqlval_of_obj ($29 "s-1-1-t0.O")
      15: BReturn 0
Select (TOP <constant (10)>) ($34 "s", $35 "p", $36 "o", <$33 "<DB.DBA.RDF_QUAD s-1-1-t0>" spec 5>)
}

18 Rows. -- 40 msec.
```

As result on the Server console will be printed this output:

```
New best dt0 is:
sequence for dt0 cost       6.9 (0.0135757 msec):RDF_QUAD as t1  on RDF_QUAD ,

```

```
    call id_to_iri: (609 'id_to_iri' ((201 't1' 'P' ) ) )

    call __rdf_sqlval_of_obj: (609 '__rdf_sqlval_of_obj' ((201 't1' 'O' ) ) )
}
```

Example 24.112. Example with type -7

Execute from ISQL:

```
SQL> select explain('sparql
select *
from <http://myopenlink.net/dataspace/person/kidehen#this>
where {?s ?p ?o} limit 10',-7);
callret
VARCHAR
_______________________________________________________________________________

6.957722663879395

1 Rows. -- 0 msec.
```

Example 24.113. Example with vsp printing the result from executing explain:

```
<?vsp
  declare meta, data any;
  exec ('explain (?)', null, null, vector ('select * from sys_users'),  0, meta, data);
  foreach (any row in data) do
  {
     http_value (row[0], 'p');
  }
?>
```

Equivalent is:

```
<?vsp
  declare meta, data any;
  exec ('explain (?)', null, null, vector ('select * from sys_users'), 0, meta, data);
  for (declare i,l int, i := 0, l := length (data); i < l; i := i + 1)
   {
     http_value (data[i][0], 'p');
   }
?>
?>
```

As result, after accessing this sample vsp, the following output will be printed:

```
{

from DB.DBA.SYS_USERS by SYS_USERS 17 rows

Key SYS_USERS ASC ($47 ".U_ID", $46 ".U_NAME", $45 ".U_IS_ROLE", $44 ".U_FULL_NAME", $43 ".U_E_MAIL", $42

Current of: <$49 "<DB.DBA.SYS_USERS >" spec 5>

Select ($47 ".U_ID", $46 ".U_NAME", $45 ".U_IS_ROLE", $44 ".U_FULL_NAME", $43 ".U_E_MAIL", $42 ".U_PASSWO

}
?>
```

file_delete

file_delete — Delete a file from the file system

Synopsis

```
integer file_delete ( in path varchar ,
                      in silent integer ) ;
```

Description

This function requires dba privileges.

This function is used to delete a file from file system. This function has a silent mode, where no errors will be signalled upon failure.

Parameters

path
: Path name of the file to delete.

silent
: Flag which if true (integer 1) will suppress signalling file system errors.

Errors

Parameter data type checking errors

file_open

file_open — returns the contents of a file.

Synopsis

```
varchar file_open ( in path varchar );
```

Description

Returns the contents of a file. The path is relative to the working directory of the database server.

Parameters

path
: Path name of the file to read.

Examples

Example 24.114. Simple Use

For loading N3 and Turtle files you can use:

```
SQL>DB.DBA.TTLP_MT (file_open('tmp/file1.n3'), 'base uri', 'graph uri', 255);
```

See Also

`file_delete()`

`DB.DBA.TTLP()`

`DB.DBA.TTLP_MT()`

ft_set_file

ft_set_file — associates table with tabular data structure represented by CSV document content with external CSV file.

Synopsis

```
varchar ft_set_file ( in tb varchar ,
                      in fname varchar ,
                      in delimiter varchar ,
                      in newline varchar (default '\n') ,
                      in esc varchar (default NULL) ,
                      in skip_rows integer (default 0) ) ;
```

Description

Associates table with tabular data structure represented by CSV document content with external CSV file.

Parameters

tb
: The name of the table that has tabular data structure represented by CSV document content.

fname
: External CSV file name

delimiter
: Delimiter to be used.

newline
: Set new line encoding. By default is '\n'.

esc
: Set escape character. By default is NULL.

skip_rows
: Use to skip n rows from the begining. By default is 0. When set to 1 for ex., treats the first row as header and skips it. When set to 2 skips 2 rows etc.

Examples

Example 24.115. Using a Table as a Placeholder for CSV Attachment

In this example a SQL TABLE is created and then associated with an external CSV file. This file is situated in a host operating system location that is accessible to the Virtuoso instance using relative (to instance .db file) or full path file name reference (constrained by `DirsAllowed` entry in `Virtuoso INI`).

CSV filename: contacts.csv (which can also be referred to as file:contacts.csv) .

File Content:

```
Id,Fname,Sname,Age
0,John,Smith,48
1,Anna,Clarks,62
2,Rojer,Danrette,27
3,Kate,Sigton,56
4,Tim,Craft,41
```

CSV File to SQL Table association steps:

1. CREATE an empty TABLE , using the SQL command:

```
CREATE TABLE csv.tutorial.contacts
  (
    Id INTEGER NOT NULL,
    Fname VARCHAR(20),
    Sname VARCHAR(20),
    Age INTEGER,
    CONSTRAINT demo_table_pk PRIMARY KEY (Id)
  );
```

   a. Notes:

      i. There is no special object type for File Tables corresponding to the tabular data structure represented by the CSV document content;
      ii. To create a File Table, a user must have DBA group privileges. In addition, access to the referenced file is subject the same file system access functions (e.g., file_to_string and DirsAllowed INI file settings) that govern the whole Virtuoso instance.

2. Use Virtuoso `ft_set_file` function to associate the above newly created internal TABLE (first procedure argument) with the external CSV file (second procedure argument, in the form of a file name relative to the Virtuoso instance); optional arguments may be used to specify delimiter, newline, and escape characters, respectively:

```
ft_set_file ('csv.tutorial.contacts', 'contacts.csv', ',', 1) ;
```

   a. Notes:

      i. The text in each field is parsed according to the data type declared for the column whose position in the CREATE TABLE statement corresponds to that field's position on the line. The parsing is as by the SQL CAST function from a VARCHAR value. If the CAST fails, the line is silently ignored.
      ii. The newline and escape characters must be single character strings. A newline or escape character following the escape character will be added to the parsed input as a literal character, without its special interpretation.
      iii. Each column in the CSV file is expected to end with the delimiter character. A field of zero length is considered a SQL NULL value; i.e., if two delimiters are adjacent, the field is considered NULL. Likewise, if a line begins with the delimiter, the first field is considered NULL.

3. Check the inserted data in the csv.tutorial.contacts table:

```
SQL>SELECT * FROM csv.tutorial.contacts;

Id                 Fname      Sname        F_AGE
INTEGER NOT NULL   VARCHAR    VARCHAR      INTEGER
_______________________________________________________________________

0                  John       Smith        48
1                  Anna       Clarks       62
2                  Rojer      Danrette     27
3                  Kate       Sigton       56
4                  Tim        Craft        41

5 Rows. -- 15 msec.
```

file_dirlist

file_dirlist — Returns list with content of file system directory

Synopsis

```
file_dirlist ( in path varchar ,
               in what integer ,
               out error any ) ;
```

Description

This function requires dba privileges.

This returns the list of the contents of a given file system directory.

Parameters

path
: string containing valid path to directory in file system

what
: flag designating what to return in the list: 0 - directories, 1 - regular files, 2 - symbolic links, 3 - all entries

error
: A variable for returning error messages. If supplied, errors are not signalled.

Return Types

an array of strings containing directory entries.

Errors

Table 24.33. Errors signalled by

SQLState	Error Code	Error Text	Description
42000	FA016	Access to %s is denied due to access control in ini file	
39000	FA017	Path string is too long.	
42000	FA018	Access to %s is denied due to access control in ini file	
39000	FA019	Path string is too long.

file_mkdir

file_mkdir — Creates a directory in the file system

Synopsis

```
file_mkdir ( in path varchar ,
             out error any ) ;
```

Description

This function requires dba privileges.

This function creates a file system directory.

Parameters

path
: A string containing path to the directory to be created, absolute or relative to server working directory.

error
: The error message is stored into this variable. If present, errors are not signalled.

Return Types

On success returns zero.

Errors

Table 24.34. Errors signalled by

SQLState	Error Code	Error Text	Description
42000	FA014	Access to %s is denied due to access control in ini file	
42000	FA015	Access to %s is denied due to access control in ini file	

See Also

`file_delete()` `file_unlink()` `file_mkpath()` `file_stat()`

file_mkpath

file_mkpath — Make a directory chain

Synopsis

```
file_mkpath ( in path varchar ,
              inout istest integer ) ;
```

Description

This function requires dba privileges.

This is to create a directory chain i.e. 'a/b/c/d', where one or more elements in the path may not exist.

Parameters

path
: string containing file system path to be crated as directory chain

istest
: Variable for returning the error message. If specified, errors are not signalled.

Return Types

On success returns zero.

Errors

Table 24.35. Errors signalled by

SQLState	Error Code	Error Text	Description
42000	FA014	Access to %s is denied due to access control in ini file	
42000	FA015	Access to %s is denied due to access control in ini file	
42000	FA116	Abnormally long path is passed as argument to sys_mkpath()	

See Also

`file_unlink() file_delete() file_mkdir() file_mkpath() file_stat()`

file_stat

file_stat — get various OS statistics about a file

Synopsis

file_stat (in *path* varchar ,
in *what* integer) ;

Description

`file_stat` returns various information for an OS file by calling stat () system call and converting the relevant value to a varchar . The path is relative to the server's working directory. The what is an integer value selecting what information to return. If you don't supply second argument to the function it defaults to mode = 0.

The DirsAllowed and DirsDenied lists in Parameters section of the virtuoso configuration file (virtuoso.ini by default) are not used to control disk access.

Parameters

path
: varchar relative path.

what
: integer info to be returned.

Examples

Example 24.116. Simple example

Get the size of the virtuoso INI file

```
SQL>select file_stat (virtuoso_ini_path(), 1);
callret
VARCHAR
_______________________________________________________________________________

958
```

See Also

`file_delete`

`os_chmod`

`os_chown`

`virtuoso_ini_path`

file_to_string

file_to_string — returns the contents of a file as a varchar

Synopsis

```
varchar file_to_string ( in path varchar );
```

Description

This function requires dba privileges.

Returns the contents of a file as a varchar value. The file's length is limited to 16 MB. The path is relative to the working directory of the database server.

Parameters

path
: Path name of the file to read.

Errors

Parameter data type checking errors

file_to_string_output

file_to_string_output — get contents of a file as a string output stream

Synopsis

file_to_string_output (in *file* varchar ,
in *from* integer ,
in *to* integer) ;

Description

This function requires dba privileges.

This function returns a string output stream initialized to contain the text of the file or its segment, on local file system path relative to the server's working directory.

`file_to_string_output` can handle longer files than `file_to_string` and the resulting string output, if too long to be converted into a varchar, can be stored inside a blob.

Access controls in the server configuration file apply. An attempt to access a file in a directory where access is not explicitly allowed will signal an error.

Parameters

file
: a varchar path relative to server's working directory.

from
: an optional integer byte offset of the start of the segment to extract. Defaults to 0.

to
: an optional integer byte offset of the end of the requested segment. Defaults to file length.

Examples

Example 24.117. Insert file contents into a table

This example shows how to insert file contents into a table `file_table` with two columns.

```
create table
file_table (
  ft_name varchar,
  ft_cont long varbinary,
  primary key (ft_name));

create procedure
insert_files (in fname varchar)
{
  declare strout_handle any;

  strout_handle := file_to_string_output (fname);
  insert into file_table (ft_name, ft_cont)
    values (fname, strout_handle);

  strout_handle := file_to_string_output (fname, 10);
  insert into file_table (concat (ft_name, '_1'), ft_cont)
    values (fname, strout_handle);

  strout_handle := file_to_string_output (fname, 10, 20);
  insert into file_table (concat (ft_name, '_2'), ft_cont)
    values (fname, strout_handle);
```

```
};

file_unlink

file_unlink — Delete a file from the file system

Synopsis

file_unlink (in *path* varchar) ;

Description

This function requires dba privileges.

This function deletes a file from the file system. sys_unlink is a synonym of this function.

Parameters

path
: Path name of the file to delete.

Return Types

On success returns zero. Otherwise signals an error.

Errors

Table 24.36. Errors signalled by

SQLState	Error Code	Error Text	Description
42000	FA003	Access to %s is denied due to access control in ini file	
42000	FA004	Access to %s is denied due to access control in ini file	
42000	SR426	Permission is denied for the file '%s' in sys_unlink()	
42000	SR427	Path name '%s' too long in sys_unlink()	
42000	SR428	A directory component in '%s' does not exist or is a dangling symbolic link in sys_unlink()	
42000	SR429	A component used as a directory in '%s' is not, in fact, a directory in sys_unlink()	
42000	SR430	'%s' refers to a directory in sys_unlink()	
42000	SR431	Insufficient kernel memory was available in sys_unlink()	
42000	SR432	'%s' refers to a file on a read-only filesystem in sys_unlink()	
42000	SR433	Too many symbolic links were encountered in translating '%s' in sys_unlink()	
42000	SR434	An I/O error occurred in sys_unlink()

fk_check_input_values

fk_check_input_values — alter default foreign key checking behavior

Synopsis

DB.DBA. **fk_check_input_values** (in *mode* integer);

Description

mode = 1 - on

mode = 0 - off

Enforcing foreign key constraints is enabled by default. This function allows globally disabling it without however disabling all triggers. This may be useful for large data imports or other special circumstances. The return value is the previous state of this setting, 0 for off, 1, for on. The effect of this function is persistent and survives server restart.

floor

floor — Round a number to negative infinity.

Synopsis

floor (in *x* double precision);

Description

floor calculates the largest integer smaller than or equal to *x* .

Parameters

x
: double precision

Return Values

floor returns a 32-bit integer .

Examples

Example 24.118. Simple Examples

```
SQL> select floor (-0.513513), floor (0.513513), floor (123.4567);
callret   callret   callret
INTEGER   INTEGER   INTEGER

ftp_get

ftp_get — FTP get command; Virtuoso FTP client

Synopsis

```
integer ftp_get ( in server varchar ,
                  in user varchar ,
                  in pass varchar ,
                  in remote_file_name varchar ,
                  in local_file_name varchar ,
                  in is_pasv integer ) ;
```

Description

Virtuoso has FTP client functionality, that can be used inside Virtuoso/PL. This Virtuoso function mimics the FTP get command. As with any PL, this can be combined with Web Services and SOAP.

Parameters

server
: The remote server address or IP Address.

user
: The username for authentication at the FTP server.

pass
: The accompanying password for authentication at the FTP server.

remote_file_name
: Full path and file name to the file on the FTP server to be downloaded.

local_file_name
: The full path and file name of the local save point. This is relative to the server root directory. This directory must be included in DirsAllowed ACL list in the Virtuoso.INI file.

is_pasv
: Flag to specify whether to use passive mode. This can be one "1" for passive mode, or zero "0" for active mode. One "1" is assumed by default.

Return Types

This function returns the size of the file written to the local file system.

Errors

This function will return any errors returned by the remote FTP server.

Examples

Example 24.119. Retrieving a file from an FTP server

To get the file virtuoso30.tar.gz from the ftp server ftp.openlinksw.com, one can use:

```
select ftp_get ('ftp.openlinksw.com', 'user_name', 'password', 'virtuoso30.tar.gz', 'virtuoso30.tar.gz');
```

This will download the file which occurs on the root directory of the server, and save it to the local server root directory.

See Also

`ftp_put()`

`ftp_ls()`

ftp_ls

ftp_ls — FTP dir command; Virtuoso FTP client

Synopsis

```
any ftp_ls ( in server varchar ,
             in user varchar ,
             in pass varchar ,
             in remote_dir_name varchar ,
             in is_pasv integer ) ;
```

Description

Virtuoso has FTP client functionality, that can be used inside Virtuoso/PL. This Virtuoso function mimics the FTP dir command. As with any PL, this can be combined with Web Services and SOAP.

Parameters

server
: The remote server address or IP Address.

user
: The username for authentication at the FTP server.

pass
: The accompanying password for authentication at the FTP server.

remote_dir_name
: The full path of the remote directory to list the contents of.

is_pasv
: Flag to specify whether to use passive mode. This can be one "1" for passive mode, or zero "0" for active mode. One "1" is assumed by default.

Return Types

This function returns a vector of descriptions from the result of performing the dir command on the remote server. If errors occur then these will be returned instead.

Errors

This function will return any errors returned by the remote FTP server.

Examples

Example 24.120. Listing files on the remote FTP server

The following command will send the vector of the descriptions of the files in the virtuoso30 directory on the remote sever to the Virtuoso debug console, assuming the server was started with the -d or +debug option:

```
select dbg_obj_print(ftp_ls ('ftp.openlinksw.com', 'user_name', 'password', 'virtuoso30'));
```

See Also

`ftp_put()`

`ftp_get()`

ftp_put

ftp_put — FTP put command; Virtuoso FTP client

Synopsis

```
integer ftp_put ( in server varchar ,
                  in user varchar ,
                  in pass varchar ,
                  in local_file_name varchar ,
                  in remote_file_name varchar ,
                  in is_pasv integer ) ;
```

Description

Virtuoso has FTP client functionality, that can be used inside Virtuoso/PL. This Virtuoso function mimics the FTP put command. As with any PL, this can be combined with Web Services and SOAP.

Parameters

server
: The remote server address or IP Address.

user
: The username for authentication at the FTP server.

pass
: The accompanying password for authentication at the FTP server.

local_file_name
: The full path and file name of the local file to be uploaded. This is relative to the server root directory. This directory must be included in DirsAllowed ACL list in the Virtuoso.INI file.

remote_file_name
: Full path and file name to the file on the FTP server to be uploaded.

is_pasv
: Flag to specify whether to use passive mode. This can be one "1" for passive mode, or zero "0" for active mode. One "1" is assumed by default.

Return Types

This function returns either 1 for success, or the error returned from the server.

Errors

This function will return any errors returned by the remote FTP server.

Examples

Example 24.121. Uploading a file to an FTP server

To upload the file virtuoso30.tar.gz to the ftp server ftp.openlinksw.com, one can use:

```
select ftp_put ('ftp.openlinksw.com', 'user_name', 'password', 'virtuoso30.tar.gz', 'virtuoso30.tar.gz');
```

This will upload the file that occurs on the local server root directory, and save it to the remote servers root directory.

See Also

`ftp_put()`

`ftp_ls()`

gz_file_open

gz_file_open — returns the contents of a gzipped file

Synopsis

```
varchar gz_file_open ( in path varchar );
```

Description

Returns the contents of a file. The path is relative to the working directory of the database server.

Parameters

path
: Path name of the file to read.

Examples

Example 24.122. Simple Use

For loading gzipped N3 and Turtle files you can use:

```
SQL>DB.DBA.TTLP_MT (gz_file_open('path/myfile.n3.gz'), 'base uri', 'graph uri', 255);
```

Note that the last parameter means the parser uses relaxed parsing rules, the default value of 0 means strict syntax rules.

`DB.DBA.TTLP()`

`DB.DBA.TTLP_MT()`

`DB.DBA.TTLP_MT_LOCAL_FILE()`

get_csv_row

get_csv_row — This function takes a string_session containing CSV data, parses a row and returns a vector with field values.

Synopsis

get_csv_row (in *ses* any ,
in *delim* char ,
in *quote* char) ;

Description

This function takes a string_session containing CSV data, parses a row and returns a vector with field values.

Calling the function in a loop with same input will parse file line by line.

The function is also making a basic prediction of field types for varchar, integer and float values, so the result data may have one of these. If come other datatype is need to be produced the caller can convert the string using the BIF like cast sprintf_inverse and so on.

Parameters

ses
: string_session containing CSV data

delim
: Optional argument to handle tab, space delimited etc. formats.

quote
: Optional argument to handle tab, space delimited etc. formats.

Return Types

Returns a vector with field values.

Examples

Example 24.123. Simple Use

The following example prints on the Virtuoso Server console the CSV columns names:

```
SQL>create procedure my_csv (in file_name varchar)
{
   dbg_obj_print(get_csv_row(file_open('tmp/MyContacts.csv')));
}
;

Done. -- 10 msec.

SQL>select my_csv('tmp/MyContacts.csv');
callret
VARCHAR
_______________________

0

1 Rows. -- 10 msec.

-- and on the Virtuoso Server console will be shown:

('First Name;Last Name;Middle Name;Name;Nickname;E-mail Address;Home Street;Home City;Home Postal Code;Ho
```

```
Fax;Mobile Phone;Personal Web Page;Business Street;Business City;Business Postal Code;Business State;Busi
s Phone;Business Fax;Pager;Company;Job Title;Department;Office Location;Notes' )
```

See Also

csv_load_file()

csv_load()

csv_parse()

csv_cols_def()

csv_table_def()

csv_load_file

csv_load_file — Imports a CSV file into table.

Synopsis

csv_load_file (in *file_name* varchar ,
in *from_line* integer ,
in *to_line* integer ,
table_name varchar ,
in *trx_log_mode* integer ,
in *opts* any) ;

Description

Imports a CSV file into table.

Parameters

file_name
: Given as an input file_name will be parsed as CSV where it will insert into the table specified as table_name the lines between from_line and to_line offsets.

from_line
: Default - 0, This means counted from the begining.

to_line
: Default - null, This means counted to the end.

table_name
: The table the data to be inserted into.

trx_log_mode
: Default - 2. The trx_log_mode is used to do row auto commit and to log or not the transaction. The default mode is to do not log and do auto commit.

opts
: Default - null. The opts paramater is used to specify the delimiter and quote. It should look like this:

Errors

If table is not suitable in respect of number of columns or type of columns error will be signaled.

Examples

Example 24.124. Simple Use

```
SQL>create procedure my_csv_lf (in file_name varchar)
{
  declare tb_name varchar;
  declare ar any;

  -- to get the name of the table
  ar := csv_table_def(file_name);
  ar := split_and_decode(ar, 0,'\0\0 ');
  tb_name := trim (ar[2], '"');

  dbg_obj_print(tb_name);
```

```
  -- to create the table
  exec(csv_table_def(file_name));

  -- loading the data
  csv_load_file(file_name,0, null, concat('DB.DBA.', tb_name));
}
;

Done. -- 10 msec.

get_csv_row

csv_load

csv_parse

csv_cols_def

csv_table_def

attach_from_csv

attach_from_csv — Attaches CSV files as virtual tables in Virtuoso.

Synopsis

attach_from_csv (in *tb* varchar ,
in *fname* any ,
in *delimiter* varchar (default '') ,
in *newline* varchar (default '\n') ,
in *esc* varchar (default null) ,
in *skip_rows* int (default 1) ,
in *pkey_columns* any (default null)) ;

Description

This function attaches CSV files as virtual tables in Virtuoso, enabling them to be queried as if local to the Virtuoso database schema.

Parameters

tb
: Name of the Virtuoso SQL table to be associated with the attached CSV file

fname
: Name of the CSV file, which must be situated in a file system location within the scope of 'DirsAllowed' INI setting, in one of the following forms:

delimiter
: Specifies a single character to be treated as the field delimiter.

newline
: Specifies a single character to be treated as newline.

esc
: Specifies a single character to be treated as escape.

skip_rows
: Specifies a number of rows to be ignored as instance data. Default is '1', this typically being the CSV header row.

pkey_columns
: Specifies which ordinal column(s) of the CSV to use as the primary key of the virtual table.

Errors

Issues associated with CSV file structure, in regards to virtual table creation suitability, will be reported back as errors.

Examples

Example 24.125. Simplified CSV File Attachment

This example demonstrates how to directly attach external CSV file to Virtuoso that functions like any other internal TABLE:

1. Create CSV file named `contacts1.csv` :

```
$ cat > contacts1.csv
Id,Fname,Sname,Age
```

```
0,John,Smith,48
1,Anna,Clarks,62
2,Rojer,Danrette,27
3,Kate,Sigton,56
4,Tim,Craft,41
```

2. Place the created `contacts1.csv` file within scope of `DirsAllowed` INI setting.
3. Call the attach_from_csv function from iSQL or Virtuoso Conductor UI (http://host:port/conductor) . Note: As the pkey_columns parameter value is not specified, by default the virtual table will have no Primary Key:

```
SQL> attach_from_csv ('csv.tutorials.contacts1', 'file:contacts1.csv', ',', '\n', null, 1);
Done. -- 109 msec.
```

4. Check the inserted data in the csv.tutorials.contacts1 table:

```
SQL> SELECT * FROM csv.tutorials.contacts1 ;
Id          Fname         Sname       Age
INTEGER     VARCHAR       VARCHAR     INTEGER
_____________________________________________

0           John          Smith       48
1           Anna          Clarks      62
2           Rojer         Danrette    27
3           Kate          Sigton      56
4           Tim           Craft       41

5 Rows. -- 78 msec.
```

5. Check the Primary Key columns:

```
SQL> primarykeys csv.tutorials.contacts1;
Showing SQLPrimaryKeys of tables like 'csv.tutorials.contacts1', tabletype/colname like 'NULL'
TABLE_QUALIFIER  TABLE_OWNER  TABLE_NAME   COLUMN_NAME   KEY_SEQ   PK_NAME  ROOT_QUALIFIER  ROOT_C
VARCHAR          VARCHAR      VARCHAR      VARCHAR       SMALLINT  VARCHAR  VARCHAR         VARCHA
_____________________________________________________________________________________________

0 Rows. -- 47 msec.
```

Example 24.126. Simplified CSV File Attachment with Compound Key Generation

In this example a CSV File System is not only attached to Virtuoso, but as part of the process a Primary Key is generated using the first and second ordinal columns from the CSV file content:

1. Create CSV file named `contacts2.csv`:

```
$ cat > contacts2.csv
Fname,Sname,Age
John,Smith,48
Anna,Clarks,62
Rojer,Danrette,27
Kate,Sigton,56
Tim,Craft,41
```

2. Place the created `contacts2.csv` file within scope of `DirsAllowed` INI setting.
3. Call the attach_from_csv function from iSQL or Virtuoso Conductor UI (http://host:port/conductor):

```
SQL> attach_from_csv ('csv.tutorials.contacts2', 'file:contacts2.csv', ',', '\n', null, 1, vector(
Done. -- 109 msec.
```

4. Check the inserted data in the csv.tutorials.contacts2 table:

```
SQL> SELECT * FROM csv.tutorials.contacts2 ;
Fname         Sname       Age
VARCHAR       VARCHAR     INTEGER
_____________________________________________

John          Smith       48
Anna          Clarks      62
Rojer         Danrette    27
Kate          Sigton      56
Tim           Craft       41
```

```
5 Rows. -- 78 msec.
```

5. Check the Primary Key columns:

```
SQL> primarykeys csv.tutorials.contacts2;
Showing SQLPrimaryKeys of tables like 'csv.tutorials.contacts2', tabletype/colname like 'NULL'
TABLE_QUALIFIER  TABLE_OWNER  TABLE_NAME               COLUMN_NAME  KEY_SEQ   PK_NAME
VARCHAR          VARCHAR      VARCHAR                  VARCHAR      SMALLINT  VARCHAR
_______________________________________________________________________________

DB               DBA          csv.tutorials.contacts2  Fname        1         csv.tutorials.contac
DB               DBA          csv.tutorials.contacts2  Sname        2         csv.tutorials.contac

2 Rows. -- 32 msec.
```

Example 24.127. Simplified CSV File Attachment with Composite Key Generation

In this example a CSV File System is not only attached to Virtuoso, but as part of the process a Primary Key is generated using the second (`CompanyID`), third (`Fname`) and forth (`Sname`) ordinal columns. In this example the CompanyID column (which uniquely identifies a company) is combined with the `Fname` and `Sname` columns to create a primary key for each contact:

1. Create CSV file named `contacts3.csv`:

```
$ cat > contacts3.csv
CompanyName,CompanyID,Fname,Sname,Age
MLogistic,12,John,Smith,48
ZiAirLines,13,Anna,Clarks,62
MLogistic,12,Rojer,Danrette,27
MLogistic,12,Kate,Sigton,56
ZiAirLines,13,Tim,Craft,41
```

2. Place the created `contacts3.csv` file within scope of `DirsAllowed` INI setting.
3. Call the attach_from_csv function from iSQL or Virtuoso Conductor UI (http://host:port/conductor):

```
SQL> attach_from_csv ('csv.tutorials.contacts3', 'file:contacts3.csv', ',', '\n', null, 1, vector
Done. -- 109 msec.
```

4. Check the inserted data in the csv.tutorials.contacts3 table:

```
SQL> SELECT * FROM csv.tutorials.contacts3 ;
CompanyName     CompanyID   Fname     Sname       Age
VARCHAR               INTEGER     VARCHAR   VARCHAR     INTEGER
_____________________________________________________________

MLogistic       12          John      Smith       48
ZiAirLines      13          Anna      Clarks      62
MLogistic       12          Rojer     Danrette    27
MLogistic       12          Kate      Sigton      56
ZiAirLines      13          Tim       Craft       41

5 Rows. -- 78 msec.
```

5. Check the Primary Key columns:

```
SQL> primarykeys csv.tutorials.contacts3;
Showing SQLPrimaryKeys of tables like 'csv.tutorials.contacts3', tabletype/colname like 'NULL'
TABLE_QUALIFIER  TABLE_OWNER  TABLE_NAME               COLUMN_NAME  KEY_SEQ    PK_NAME
VARCHAR          VARCHAR      VARCHAR                  VARCHAR      SMALLINT   VARCHAR
_______________________________________________________________________________

DB               DBA          csv.tutorials.contacts3  CompanyID    1          csv.tutorials.conta
DB               DBA          csv.tutorials.contacts3  Fname        2          csv.tutorials.conta
DB               DBA          csv.tutorials.contacts3  Sname        3          csv.tutorials.conta

3 Rows. -- 47 msec.
```

csv_load

csv_load — Import CSV file from string session.

Synopsis

csv_load (in *string_session_input* any ,
in *from_line* integer ,
in *to_line* integer ,
in *table_name* varchar ,
in *trx_log_mode* integer ,
in *opts* any) ;

Description

Import CSV file from string session.

Parameters

string_session_input
: String session containing CSV data will be parsed as CSV where it will insert into the table specified as table_name the lines between from_line and to_line offsets.

from_line
: Default - 0, This means counted from the begining.

to_line
: Default - null, This means counted to the end.

table_name
: The table the data to be inserted into.

trx_log_mode
: Default - 2. The trx_log_mode is used to do row auto commit and to log or not the transaction. The default mode is to do not log and do auto commit.

opts
: Default - null. The opts paramater is used to specify the delimiter and quote it should look like this:

Errors

If table is not suitable in respect of number of columns or type of columns error will be signaled.

Examples

Example 24.128. Simple Use

```
SQL>create procedure my_csv_load (in file_name varchar)
{
  declare tb_name varchar;
  declare sess any;
  declare ar any;

  sess := file_open(file_name);

  -- to get the name of the table
  ar := csv_table_def(file_name);
  ar := split_and_decode(ar, 0,'\0\0 ');
  tb_name := trim (ar[2], '"');
```

```
  dbg_obj_print(tb_name);

  -- to create the table
  exec(csv_table_def(file_name));

  -- loading the data
  csv_load(sess,0, null, concat('DB.DBA.', tb_name));
}
;

Done. -- 10 msec.

get_csv_row

csv_load_file

csv_parse

csv_cols_def

csv_table_def

csv_parse

csv_parse — Parses a CSV file.

Synopsis

csv_parse (in *string_session_input* any ,
in *callback_sp_name* varchar ,
inout *callback_user_data* varchar ,
in *from_line* integer ,
in *to_line* integer ,
in *opts* any) ;

Description

Parses string session containing CSV data and then calls stored procedure by given callback_sp_name parameter. The call back will be invoked for lines between from_line and to_line argument's values. The default from/to is 0/null which means from begining to end. The callback function must take three arguments: the vector which contains parsed csv row, the line number, inout the callback_user_data.

Parameters

string_session_input
: String session containing CSV data will be parsed as CSV where it will insert into the table specified as table_name the lines between from_line and to_line offsets.

callback_sp_name
: The name of the stored procedure.

callback_user_data
: The user data.

from_line
: Default - 0, This means counted from the begining.

to_line
: Default - null, This means counted to the end.

opts
: Default - null. The opts paramater is used to specify the delimiter and quote it should look like this:

Examples

Example 24.129. Simple Use

```
create procedure y_csv_cb (inout r any, in inx int, inout cbd any)
{
 if (cbd is null)
   cbd := vector ();
 cbd := vector_concat (cbd, vector (r));
}
;

....
 h := null;
 csv_parse (ss, 'DB.DBA.y_csv_cb', h, 0, 10);
....
```

csv_cols_def

csv_cols_def — Guess columns and column types from CSV file.

Synopsis

csv_cols_def (in *file_name* varchar) ;

Description

This function will try to guess the columns by given CSV file. It would work if CSV file begins with a header row.

Parameters

file_name
: The name of the CSV file.

Examples

Example 24.130. Simple Use

```
SQL>create procedure my_csv_get_columns (in file_name varchar)
{
   dbg_obj_print(csv_cols_def(file_name));
}
;

Done. -- 10 msec.

SQL>select my_csv_get_columns('tmp/MyContacts.csv');
callret
VARCHAR
_______________________

0

1 Rows. -- 10 msec.
-- and on the Virtuoso Server console will be shown:

(('First_Name_Last_Name_Middle_Name_Name_Nickname_E_mail_Address_Home_Street_Home_City_Home_Postal_Code_H
_Fax_Mobile_Phone_Personal_Web_Page_Business_Street_Business_City_Business_Postal_Code_Business_State_Bus
ss_Phone_Business_Fax_Pager_Company_Job_Title_Department_Office_Location_Notes' 'VARCHAR' ) )
```

csv_parse

csv_table_def

csv_table_def

csv_table_def — Guess table definition from CSV file.

Synopsis

csv_table_def (in *file_name* varchar) ;

Description

This function will return table definition appropriate for CSV file specified by file_name.

Parameters

file_name
: The name of the CSV file.

Examples

Example 24.131. Simple Use

```
SQL>select csv_table_def('tmp/MyContacts.csv');
callret
VARCHAR
_______________________________________________________________________________

CREATE TABLE "tmp_MyContacts_csv" (
        "First_Name_Last_Name_Middle_Name_Name_Nickname_E_mail_Address_Home_Street_Home_City_Home_Postal_
e_Home_Fax_Mobile_Phone_Personal_Web_Page_Business_Street_Business_City_Business_Postal_Code_Business_Sta
Business_Phone_Business_Fax_Pager_Company_Job_Title_Department_Office_Location_Notes" VARCHAR)

1 Rows. -- 10 msec.
```

get_certificate_info

get_certificate_info — Returns information about the current client X509 certificate

Synopsis

```
integer or string get_certificate_info ( in type integer ,
                                         in cert_or_key_name varchar ,
                                         in in_format int ,
                                         in passwd varchar ,
                                         in ext_oid varchar ) ;
```

Description

This function will return information about the current client X509 certificate (if successfully verified). If there is no valid X509 certificate or the requested information is not available it will return NULL.

If the optional *cert_or_key_name* is supplied it should contain a encoded certificate (by default format is PEM). The certificate info is read from the first certificate in that string.

If the optional *cert_or_key_name* is supplied and *in_format* is equal to 3 (integer) the function will try to retrieve the certificate registered in the current user's key store by name contained in *cert_or_key_name* .

Parameters

type
: type must be an integer. It can be one of the following values:

cert_or_key_name
: A string containing an encoded X.509 certificate or name of a key from current user store.

in_format
: This is to designate encoding type of the value 'cert_or_key_name'

passwd
: Password to unlock PKCS#12 encoded certificate

ext_oid
: X.509 extension object identifier

Return Types

The requested information or NULL if the certificate is found to be invalid.

Examples

Example 24.132. Simple examples

```
CREATE PROCEDURE get_mail_example (in cert any := null, in cert_type int := 0)
{
  declare alts, mail any;
  mail := get_certificate_info (10, cert, cert_type, '', 'emailAddress');
  if (mail is null)
    {
      alts := get_certificate_info (7, cert, cert_type, '', '1.10.16.25');
      if (alts is not null)
        {
          alts := regexp_replace (alts, ',[ ]*', ',', 1, null);
          alts := split_and_decode (alts, 0, '\0\0,:');
```

```
          mail := get_keyword ('email', alts);
        }
    }
  return mail;
}
;
```

get_keyword

get_keyword — Find a value in keyword vector

Synopsis

get_keyword (*keyword* any ,
searched_array vector ,
default any ,
no_copy integer) ;

Description

`get_keyword` performs a case sensitive seek for the occurrence of *`keyword`* from each even position of *`searched_array`*. If found,this returns the element following the occurrence of the keyword. If the keyword is not found this returns the default argument or NULL if the default is not supplied.

Parameters

keyword
: String key value to be searched in the searched_array at even positions.

searched_array
: An array of even length to be searched. Each even position is a string to search. Each odd position can be any value that may then be returned.

default
: Any data to be returned if keyword is not matched in the searched_array.

no_copy
: By default no_copy is false (0). If passed as true (non-zero integer) then the element to return is the original content of the array and the place in the array from which the element came gets set to 0.

Errors

Parameter data type checking errors

Table 24.37. Errors signalled by `openxml`

SQL Code	Error Message	Virtuoso Code
22023	get_keyword expects a vector of even length, not of length <n>	SR057

Return Values

`get_keyword` returns the matched data if it is found. Otherwise it returns the *`default`*. When no *`default`* is defined, NULL is returned.

Examples

Example 24.133. Sample calls

```
get_keyword(2,vector(1,'primero',2,'segundo',
        3,'tercero'),NULL)              -> segundo
get_keyword('tercero',vector('primero',1,'segundo',
        2,'tercero',3), 'NOT FOUND!'))  -> 3

x := vector ('a', 2);
y := get_keyword ('a', x, -1, 1);
```

```
The first call returns 2
y := get_keyword ('a', x, -1, 1);
the second call returns 0 as the data was set to 0 by the previous call.
```

get_keyword_ucase

get_keyword_ucase

get_keyword_ucase — Find a value in keyword vector (search uppercase)

Synopsis

get_keyword_ucase (*keyword* anything ,
searched_array vector ,
default anything ,
no_copy integer) ;

Description

Identical to `get_keyword` except all comparisons are performed case insensitively.

See Also

get_keyword

get_timestamp

get_timestamp — returns the timestamp of the current transaction

Synopsis

```
timestamp get_timestamp ( );
```

Description

`get_timestamp` is merely an alias for now and is provided for backward compatibility.

getdate

getdate — returns the current transaction timestamp, alias of `now`

Synopsis

```
getdate (  );
```

Description

`getdate()` returns the timestamp associated with current transaction. This is an alias of `now()` .

Date & Time Manipulation section of the SQL Reference Chapter.

gvector_sort

gvector_sort — Performs quicksort of a given array.

Synopsis

gvector_sort (inout *data* vector ,
in *elements_in_group* integer ,
in *key_idx_in_group* integer ,
in *sort_ascending* integer) ;

Description

The function gets an vector that consists of groups of elements. All groups are of equal size, namely *elements_in_group* , so the total length of *data* vector should be whole multiple of *elements_in_group* . One element of each group is a key of sorting; it is identified by its zero-based position within the group, *key_idx_in_group* . The sorting procedure edits *data* and reorders groups in such a way that their keys become ordered ascending or descending, depending on *sort_ascending* flag.

The simplest case is plain sorting of a uniform array. In this case every element is an individual group, *elements_in_group* is 1 and *key_idx_in_group* is 0.

Other popular case is sorting of result of dict_to_vector (). In this case, every item of the original dictionary is represended in the vector by a pair of elements (*elements_in_group* is 2), so to sort items by their keys, the *key_idx_in_group* is 0 and to sort them by associated values, the *key_idx_in_group* is 1.

Similarly, *elements_in_block* is 2 for arrays like "lines" or "params" of a VSP page.

Parameters

data
: A group vector (gvector) to sort.

elements_in_group
: The number of vector elements in every group, usually 1, should be in range 1 to 1024.

key_idx_in_group
: Zero-based position of key element in group, should be nonnegative and less than elements_in_group .

sort_ascending
: Direction of sorting, nonzero for ascending sort, zero for descending.

Return Types

The function returns number of groups in the *data* vector .

See Also

gvector_digit_sort()

rowvector_digit_sort()

gvector_digit_sort

gvector_digit_sort — Performs a stable "digit" sort of a given array.

Synopsis

gvector_digit_sort (inout *data* vector ,
in *elements_in_group* integer ,
in *key_idx_in_group* integer ,
in *sort_ascending* integer) ;

Description

The function gets an vector that consists of groups of elements. All groups are of equal size, namely *elements_in_group* , so the total length of *data* vector should be whole multiple of *elements_in_group* . One element of each group is a key of sorting; it is identified by its zero-based position within the group, *key_idx_in_group* . The sorting procedure edits *data* and reorders groups in such a way that their keys become ordered ascending or descending, depending on *sort_ascending* flag.

The simplest case is plain sorting of a uniform array. In this case every element is an individual group, *elements_in_group* is 1 and *key_idx_in_group* is 0.

Other popular case is sorting of result of dict_to_vector (). In this case, every item of the original dictionary is represended in the vector by a pair of elements (*elements_in_group* is 2), so to sort items by their keys, the *key_idx_in_group* is 0 and to sort them by associated values, the *key_idx_in_group* is 1.

The performed sorting is stable. It means that it will not permutate groups in vain: it will preserve the relative order of any two groups that have equal keys. Using this property, one may sort groups by a "secondary" key and then by "primary" key. E.g., if each group contain elements for country code and province code then it is possible to make two-field sorting by sorting first by province and then by country; that will work even if province codes are not globally unique (say, if they're enumerated from 1 in each country).

This function supports only integer values of sorting keys. To sort by strings, floating-point numbers etc., use gvector_sort (). However, out of these two similar functions, only gvector_digit_sort() is stable-sort.

Parameters

data
: A group vector (gvector) to sort.

elements_in_group
: The number of vector elements in every group, usually 1, should be in range 1 to 1024.

key_idx_in_group
: Zero-based position of key element in group, should be nonnegative and less than elements_in_group .

sort_ascending
: Direction of sorting, nonzero for ascending sort, zero for descending.

Return Types

The function returns number of groups in the *data* vector .

gz_compress

gz_compress — Compress data using gzip algorithm

Synopsis

gz_compress (in *str* varchar) ;

Description

The gz_compress returns its argument compressed with the gzip algorithm. The argument and return values are arbitrary strings, possibly including any 8 bit characters.

Parameters

str
: The string containing data to be compressed.

Return Types

A string containing the compressed data.

Examples

Example 24.134. GZIP test 2

Just see how it compresses.

```
create procedure
gz_test_2 (in str varchar)
{
  declare res any;
  declare _out varchar;
  declare _len integer;

  result_names (_out, _len);

  res := string_output ();
  result (str, length (str));
  str := gz_compress (str);
  result ('binary', length (str));
  gz_uncompress (str, res);
  result (res, length (res));
}

SQL> gz_test_2 ('f00f f00f m0053 2 w3r h4x0r7 ch002 00000000000000000000');
_out                      _len

gz_uncompress

gz_uncompress — Uncompress a string using gzip algorithm

Synopsis

gz_uncompress (in *str* varchar ,
out *str_out* string_output) ;

Description

`gz_uncompress` takes a string argument, uncompresses it using the gzip algorithm, writing it to a string_output given as the second argument.

Parameters

str
: A string to be uncompressed.

str_out
: A string_output where the uncompressed output should be written.

Return Types

Always returns NULL.

Errors

Examples

See `gz_compress` .

ST_Affine

ST_Affine — performs standard 2d affine transformation

Synopsis

ST_Affine (in *XXa* any ,
in *XYb* any ,
in *YYe* any ,
in *Xoff* any ,
in *Yoff* any) ;

Description

performs standard 2d affine transformation with matrix:

```
XXa XXb 0
YXd YYe 0
0    0    0
```

and shift (Xoff, Yoff, 0)

Parameters

XXa
: matrix a

XYb
: matrix b

YYe
: matrix e

Xoff
: x

Yoff
: y

Return Types

Returns any.

Examples

Example 24.135. Simple Use

```
select st_affine (st_ewkt_read ('POLYGON((1 3,2 4,1 5,0 4,1 3),
                                         (1 3.5,1.5 4,1 4.5,0.5 4,1 3.5))'),
                  30, 3, 1, 0.3, 0.001, 0.002)
VARCHAR NOT NULL
--------------------------------------------------------------------------------

POLYGON((39.001000 1.902000,
         72.001000 3.202000,

st_point — Returns a point geometry.

Synopsis

st_point (in *x* double precision ,
in *y* double precision) ;

Description

Returns a point geometry. The x coordinate corresponds to longitude.

Parameters

x
: X coordinate. Corresponds to longitude.

y
: Y coordinate.

Return Types

Returns a point geometry.

st_distance

st_distance — Returns the shortest distance between two points.

Synopsis

```
st_distance ( in g1 any ,
              in g2 any ) ;
```

Description

Returns the shortest distance between two points such that the first point is part of g1 and the second of g2. The srid of g1 and g2 must be the same. If the srid is 4326, the haversine function is used to compute a great circle distance in kilometers on Earth. Otherwise the distance is calculated as on a flat Euclidean plane.

Parameters

g1
: Geometry.

g2
: Geometry.

Return Types

Returns double precision.

Examples

Example 24.139. Simple Use

```
SQL>SELECT st_distance (st_point(0, 52),st_point(0, 70));
callret
VARCHAR
_______________________________

ST_SRID

ST_SRID — returns SRID of shape's spatial reference system or 0 for shape on plane.

Synopsis

ST_SRID (in *g* any);

Description

Returns the SRID of a geometry.

Parameters

g
: Geometry.

Return Types

Returns int.

Examples

Example 24.140. Simple Use

```
SQL>SPARQL
SELECT (bif:ST_SRID (?geo))
WHERE
  {
    ?m geo:geometry ?geo .
  }
LIMIT 10;
callret-0
INTEGER

ST_SetSRID

ST_SetSRID — replaces the SRID of a shape but does not transform the shape or its coordinates from old SRID to a new one.

Synopsis

ST_SetSRID (in *g* any ,
in *SRID* int) ;

Description

The geometry given as argument is modified to have the specified SRID and the modified geometry is returned.

Parameters

g
: The geometry to be modified.

SRID
: The specified SRID.

Return Types

Returns any.

Examples

Example 24.141. Simple Use

```
SQL>SELECT ST_SetSRID( st_point (10,2), 4335);
callret
ANY
_______________________________
POINT(0.0197 51.1005)
No. of rows in result: 1

st_astext

st_astext — Returns the well known text (WKT) representation of the geometry.

Synopsis

st_astext (in *g* any);

Description

Returns the well known text (WKT) representation of the geometry.

Parameters

g
: Geometry point

Return Types

Returns varchar.

Examples

Example 24.142. Simple Use

```
SQL>SPARQL
SELECT DISTINCT (bif:st_astext(?geo))
WHERE
  {
    ?m geo:geometry ?geo .

  }

st_geomfromtext

st_geomfromtext — Parses the string and returns the corresponding geometry.

Synopsis

st_geomfromtext (in *string* varchar) ;

Description

Parses the string and returns the corresponding geometry. The string is to be in well known text representation (WKT).

Parameters

string
: String for the corresponding geometry to be extracted from.

Return Types

Returns any.

Examples

Example 24.143. Simple Use

```
SQL>SELECT st_geomfromtext ('point (10.03 30.01)', 2000);
callret
VARCHAR
_______________________________

st_intersects

st_intersects — Returns intersects between two geometries.

Synopsis

st_intersects (in *g1* any ,
in *g2* any ,
in *prec* double precision) ;

Description

Returns intersects between two geometries. If prec is supplied, this is a tolerance for the matching in units of linear distance appropriate to the srid. Both geometries should have the same srid. st_intersects is true if there is at least one point in common.

Parameters

g1
: The first geometry.

g2
: The second geometry.

prec
: A tolerance for the matching in units of linear distance appropriate to the srid. Default is 0.

Return Types

Returns int.

Examples

Example 24.144. Simple Use

```
SQL>SELECT st_intersects (st_point (0, 51), st_point (0, 52), 100);
callret
INTEGER

geo_insert

geo_insert — Inserts a geometry from an R tree index.

Synopsis

geo_insert (in *tb* any ,
in *geo* any ,
in *id* int) ;

Description

Inserts a geometry from an R tree index. The tb must be a fully qualified name of an R tree table. This function is typically used from triggers on a geometry column. The function is transactional and makes a transaction log record of the action.

Parameters

tb
: A fully qualified name of an R tree table.

geo
: A geometry.

id
: Geometry id.

Return Types

Returns int.

Examples

Example 24.148. Simple example

hour

hour — get hour from a datetime

Synopsis

hour (in *dt* datetime) ;

Description

`hour` takes a datetime and returns an integer containing a number representing the hour of the datetime.

Parameters

dt
: A datetime .

Return Values

An INTEGER containing the hour.

Examples

Example 24.150. Simple example

Get current hour.

```
SQL> select hour (now ());
callret
INTEGER
_______________________________________________________________________________

21
```

See Also

http

http — write to HTTP client or a string output stream

Synopsis

http (in *val_expr* any ,
in *stream* any) ;

Description

`http` writes *`val_expr`* to HTTP client or, if parameter *`stream`* is given, to the given string output stream.

`val_expr` may be any scalar object, i.e. string , date or number and will automatically be cast to varchar before further processing. http will print out the string without escapes. `http_value` uses HTML escapes and `http_url` URL escapes.

Parameters

val_expr
: A value expression. May be any scalar expression.

stream
: Optional parameter. If omitted or is 0 and the function is executed within a VSP context, the val_expr will be written to the HTTP client. If present and non-zero, val_expr will be written to the specified stream. If non-zero, the value must be a valid stream obtained from function string_output

Errors

Table 24.38. Errors signalled by `http`

SQLState	Error Code	Error Text	Description
22023	HT007	An interactive blob can't be passed as argument to http	
22023	HT008	http requires string, blob, or string session as argument 1	
37000	HT006	http output function outside of http context and no stream specified: %s.	

Examples

Example 24.151. HTTP output

Output of various flavours of http. See `string_output` and `string_output_string` for examples how to use http to write to streams other than the HTTP output.

```
http (' % <b>')      ' <b>
http_value (' % <b>')    % &lt;b&gt;
http_url (' % <b>')  +%25+<b>
http_value (12, 'li')  <li>12</li>
```

See Also

`http_value` , `http_url` , `string_output` , `http_rewrite` .

http_lock

http_lock — Locks the HTTP Web Server port

Synopsis

```
any http_lock (
    in pwd varchar
);
```

Description

This function takes as parameter the password of the dba user, locks the HTTP Web Server port and on any http access attempt shows the content of the html file given as value for the *MaintenancePage* parameter in the Virtuoso ini [HTTPServer] section:

```
-- Virtuoso ini
...
[HTTPServer]
...
MaintenancePage = atomic.html
..
```

Note: the html file should be placed in the HTTP root.

Parameters

pwd
: The password of the dba user.

Examples

Example 24.152. Simple Use

```
SQL> http_lock('password');

Done. -- 0 msec.
SQL>
```

See Also

`http_unlock()`

http_unlock

http_unlock — Unlocks the HTTP Web Server port

Synopsis

any **http_unlock** (in *pwd* varchar);

Description

This function takes as parameter the password of the dba user and unlocks the HTTP Web Server port

Parameters

pwd
: The password of the dba user.

Examples

Example 24.153. Simple Use

```
SQL> http_unlock('password');

Done. -- 0 msec.
SQL>
```

See Also

http_lock()

http_acl_set

http_acl_set — Set conditions against web server ACL's

Synopsis

```
integer http_acl_set ( in list_name varchar ,
                       in order integer ,
                       in client_ip varchar ,
                       in flag integer ,
                       in destination_ip_or_host varchar ,
                       in object_id integer ,
                       in read_write_flag integer ,
                       in rate integer ) ;
```

Description

This function can be used within application logic to set ACLs rule.

Parameters

list_name
: a string designating which list to be used for matching

order
: a string designating order

client_ip
: a string containing the IP number of client to set rules

flag
: 0 - allow, 1 - deny

destination_ip_or_host
: a string containing the IP number of destination requested by client

object_id
: is a integer designating a object to match

read_write_flag
: an integer designating action to match: 0 - read, 1 - write

rate
: When set, the filter will calculate hit rate average and will compare with limit for http acl rule. If it is larger then will drop connection. Once per day the statistics will be reset.

Return Types

The function returns the value of the HA_FLAG of the first matching rule. If no rule matches it returns -1.

See Also

`http` , `http_acl_get` , `http_acl_remove` , `http_url` , `string_output` , `http_rewrite` , General ACLs .

http_acl_get

http_acl_get — Test conditions against web server ACL's

Synopsis

```
integer http_acl_get ( in list_name varchar ,
                       in source_ip varchar ,
                       in destination_ip_or_host varchar ,
                       in object_id integer ,
                       in read_write_flag integer ) ;
```

Description

This function can be used within application logic to test that an internet client would not violate the ACL.

Parameters

list_name
: a string designating which list to be used for matching

source_ip
: a string containing the IP number of client to test against rules

destination_ip_or_host
: a string containing the IP number of destination requested by client

object_id
: is a integer designating a object to match

read_write_flag
: an integer designating action to match

Return Types

The function returns the value of the HA_FLAG of the first matching rule. If no rule matches it returns -1.

See Also

`http()` , `http_value()` , `http_url()` , `string_output()` , `http_rewrite()` , General ACLs .

http_acl_remove

http_acl_remove — Removes conditions against web server ACL's

Synopsis

```
integer http_acl_remove ( in list_name varchar ,
                          in order integer ,
                          in client_ip varchar ,
                          in flag integer ) ;
```

Description

This function can be used within application logic to remove ACLs rule.

Parameters

list_name
: a string designating which list to be used

order
: a string designating order

client_ip
: a string containing the IP number of client to remove rules

flag
: 0 - allow, 1 - deny

Return Types

The function returns the value of the HA_FLAG of the first matching rule. If no rule matches it returns -1.

See Also

`http` , `http_acl_get` , `http_acl_set` , `http_url` , `string_output` , `http_rewrite` , General ACLs .

http_body_read

http_body_read — Reads the HTTP body from the client HTTP connection and returns it as a string.

Synopsis

```
string http_body_read ( );
```

Description

This function reads the HTTP body from the client HTTP connection and returns it as a string output. This is suitable for processing POST requests with bodies encoded differently than `multipart/*` and `application/x-www-form-urlencoded` as in SOAP requests where the POST body is encoded as `text/xml`).

Example

Example 24.154. Reading a HTTP request entity body

Suppose we have the following HTTP request

```
POST /foo/bar.vsp HTTP/1.1
Content-Type: text/xml
Content-Length: ...

<document>abc</document>
```

The following VSP page will read the content and return an XML document back to the browser.

```
<?vsp
declare ses any;
ses := http_body_read ();
http_header ('Content-Type: text/xml\r\n');
http (string_output_string (ses));
?>
```

http_client

http_client — returns a varchar containing the body of the request uri

Synopsis

```
varchar http_client ( in url varchar ,
                      in uid varchar ,
                      in pwd varchar ,
                      in http_method varchar ,
                      in http_headers varchar ,
                      in body varchar ,
                      in cert_file varchar ,
                      in cert_pwd varchar ,
                      in timeout varchar ,
                      in proxy varchar ,
                      in ca_certs varchar ,
                      in insecure integer ,
                      in n_redirects integer ) ;
```

Description

This function is used to perform HTTP operations to retrieve generic content and/or to perform generic operations over HTTP/HTTPS protocols. It also supports HTTP authentication based on username/password credentials.

If the URL is https: an no x509 certificate given then it will operate as https client w/o client certificate.

Parameters

url
: target URL (http: or https: are supported)

uid
: user name

pwd
: user password

http_method
: 'GET', 'POST', 'HEAD' or 'PUT'

http_headers
: a string containing a HTTP headers supplied by application

body
: content to be sent

cert_file
: cpath to the certificate file where is stored x509 certificate, private key and CA certificates

cert_pwd
: password for opening the certificate file.

timeout
: use to set how many seconds to wait for reply from the client

proxy
: supports:

ca_certs
: Certificate CA. Default is null.

insecure
: Sets secure or not. Default is 0.

n_redirects
: By default int zero. If is given value greater than zero, so many redirects will be followed by client. Thus in pl no need to look at 30x response, just can add this number to follow the redirects.

http_client_ext

http_client_ext — returns a varchar containing the body of the request uri

Synopsis

```
varchar http_client_ext ( in url varchar ,
                          in uid varchar ,
                          in pwd varchar ,
                          in http_method varchar ,
                          in http_headers varchar ,
                          in body varchar ,
                          in cert_file varchar ,
                          in cert_pwd varchar ,
                          inout headers any ,
                          in timeout varchar ,
                          in proxy varchar ,
                          in ca_certs varchar ,
                          in insecure integer ,
                          in n_redirects integer ) ;
```

Description

This function is used to perform HTTP operations to retrieve generic content and/or to perform generic operations over HTTP/HTTPS protocols. It also supports HTTP authentication based on username/password credentials.

If the URL is https: an no x509 certificate given then it will operate as https client w/o client certificate.

Parameters

url
: target URL (http: or https: are supported)

uid
: user name

pwd
: user password

http_method
: 'GET', 'POST', 'HEAD' or 'PUT'

http_headers
: a string containing a HTTP headers supplied by application

body
: content to be sent

cert_file
: cpath to the certificate file where is stored x509 certificate, private key and CA certificates

cert_pwd
: password for opening the certificate file.

headers

return headers from the http reply.

timeout
: use to set how many seconds to wait for reply from the client

proxy
: supports:

ca_certs
: Certificate CA. Default is null.

insecure
: Sets secure or not. Default is 0.

n_redirects
: By default int zero. If is given value greater than zero, so many redirects will be followed by client. Thus in pl no need to look at 30x response, just can add this number to follow the redirects.

http_client_ip

http_client_ip — Returns the IP address of the calling client.

Synopsis

varchar **http_client_ip** (in *what* integer);

Description

This function is used to determine the IP address or DNS name of the calling client.

Please note that this function is slow when resolving a DNS names. It is advisable to use IP addresses to to make applications faster.

Parameters

what
: a flag designating what to return:

Return Types

By default, a string of the dotted IP address of the client user agent. If what=1 then the DNS name will be returned.

See Also

http , http_value , http_url , string_output , http_acl_get , http_rewrite .

Examples

Example 24.155. Obtaining the Client IP Address

```
<?vsp
  declare ip varchar;
  ip := http_client_ip ();
  http (sprintf ('<p>Your IP address is: %s</p>', ip));
?>
```

dns_txt_get

dns_txt_get — Use for DNS text record retrieval.

Synopsis

```
varchar dns_txt_get ( in dns_serevr_ip_or_null any ,
                      in dns_entry varchar ) ;
```

Description

This function can be used for DNS text record retrieval. It works on UNIX, Windows, Mac OS X w/o additional libraries.

Parameters

dns_serevr_ip_or_null
: DNS server IP or null. If null, then the system will try to find the system defined DNS servers. First argument null together with xenc_key_RSA_read() with 3d argument of 1 (int) can be used to write a PL procedure for DKIM signature check of mails.

dns_entry
: DNS entry.

Examples

Example 24.156. Obtaining DNS text record

```
SELECT dns_txt_get (null, 'x._domainkey.example.com');
dns_txt_get
VARCHAR
_______________________________________________________________________________

v=DKIM1; k=rsa; p=...
```

See Also

`http` , `http_client_ip` , `http_value` , `http_url` , `string_output` , `http_acl_get` , `http_rewrite` .

http_debug_log

http_debug_log — set WebDAV HTTP request logging

Synopsis

http_debug_log (in *file_path* varchar) ;

Description

When an valid path string is supplied and it is allowed in file ACL list, the WebDAV HTTP requests and responses will be logged in append mode in to that file. When an open logging session is encountered the second call will produce an error. Specifying a NULL instead of file_path string stops the logging.

The log file consists of lines with following fields:

- The request and response are marked by <<< and >>> signs
- Client IP address
- Date and time of request/response
- Timestamp (milliseconds)
- Request/response line

Errors

Table 24.39. Errors signalled by `http_debug_log`

SQLState	Error Code	Error Text	Description
42000	FA041	HTTP debug log is already being generated	
42000	FA040	Access to [file name] is denied due to access control in ini file	
39000	FA042	Can't open debug log file [file name], error : [OS error]	

Examples

Example 24.157. Logging DAV HTTP Requests

```
-- start the log session
SQL> http_debug_log ('dav.log');
... do some operations in WebDAV repository via WebFolders or other client ...
-- stop the session
SQL> http_debug_log (NULL);

Produces in the server working directory a file 'dav.log' with lines looking like this:
...
>>> [127.0.0.1] [02/Oct/2001 13:49:37 +0300] [40806] PROPFIND /DAV/css/one.css HTTP/1.1
<<< [127.0.0.1] [02/Oct/2001 13:49:37 +0300] [40896] HTTP/1.1 207 Multi-Status
...
```

http_enable_gz

http_enable_gz — Enable / Disable "Content-Encoding: gzip" for HTTP server

Synopsis

`integer` **`http_enable_gz`** `(` in *mode* integer `);`

Description

Enable (1)/ Disable (0) "Content-Encoding: gzip" for HTTP server.

Examples

Example 24.158. Using http_enable_gz()

```
SQL> select http_enable_gz (1);
callret
VARCHAR
_______________________________________________________________________________

1

1 Rows. -- 41 msec.
SQL>
```

http_file

http_file — Send a file to the HTTP client

Synopsis

```
varchar http_file ( in path varchar );
```

Description

This function causes the contents of the file specified by path to be sent as the response of the calling request. The file is not sent until the code calling this returns. Content types etc. are defaulted based on the file's extension. If this function is called, other output to the HTTP client by the caller is discarded.

Parameters

path
: Path to the file to send

Examples

Example 24.159. Sending A File To HTTP Client

```
<?vsp
http_file ('/index.html');
?>
```

http_flush

http_flush — Flush internal HTTP stream and disconnect client; Flush HTTP stream and try sending data in chunked mode.

Synopsis

http_flush (in *try_what* integer) ;

Description

This flushes the internal buffer where output of a VSP page is stored pending the execution of the page's code. This sends the content of the page output buffer along with headers and disconnects the client. The status is 200 OK by default, unless overridden by http_status. The purpose of this function is to allow a page to send output before terminating , thus the page can continue processing for an indefinite time without requiring the client to wait. This is useful for starting long running background tasks from HTTP clients.

VSP pages that use this function must be sure to supply appropriate content (or response headers) if needed before calling this function.

Virtuoso supports HTTP 1.1 Chunking Encoding which allows Virtuoso to send the user agent chunks of output as the page is still processing. Chunking is enabled by calling `http_flush(1)` within the VSP page. By default chunks are sent for every 4k worth of output generated, but in some cases the output needs to consist of smaller chunks, for example when run-time status needs to be shown in a status page. So to achieve this the http_flush (try_what=1) could be invoked in places where chunk must be flushed to the User agent.

Chunked mode requires the following conditions:

- no "Content-Length" header sent to the client using http_header()
- no "Content-Encoding" header sent to the client using http_header()
- use http_xslt() is not permitted
- The client supports HTTP 1.1

Failing these conditions, `http_flush(1)` will be a No-Operation.

If the function has actually switched to chunked mode it will return a non-zero integer. Otherwise and integer 0 will be returned.

Chunked mode is not supported for static content.

Parameters

try_what
: This optional parameter can be supplied the value one (1) to instruct Virtuoso to try sending the output of the VSP page in chunked mode.

Examples

Example 24.160. Using http_flush()

```
<?vsp
  http ('<p>Hit <a href="status.vsp">there</a> to go on status page</p>');
  http_flush ();
  long_task_procedure ();
?>
```

Example 24.161. Using http_flush() small chunks

The following example will render in browser at every loop iteration 'state=N'; so this will be visible at 'run-time' not when loop finished which may take a long.

```
<?vsp
  ....
  http_flush (1);

  while (i<1000)
    {
      process_some_item (); -- some procedure that takes a long time usually
      http ('state='||cast (i as varchar)||'<br>');
      http_flush (1);
      i := i + 1;
    }
?>
```

See Also

`http`, `http_value`, `http_url`, `string_output`, `http_rewrite`.

http_internal_redirect

http_internal_redirect — Performs internal redirect.

Synopsis

```
any http_internal_redirect ( in full_path varchar ,
                             in p_full_path varchar ,
                             in long_url varchar ,
                             in keep_lpath integer ) ;
```

Description

This function performs internal redirect. Can be used in handling situations where HTTP level redirection is inadequate. For example, 303 redirection offered when implementing hashless Linked Data URIs. Instead of sending a 303 Virtuoso will redirect to the URL in "Location:" and return 200 OK. Basically, this is like curl -iL instead of curl -i, but implemented inside Virtuoso.

The function can be used directly or via URI template syntax used to construct rewrite rules for Virtuoso virtual directories / web service endpoints.

Parameters

full_path
: Set new logical path to be redirected to.

p_full_path
: Set physical path to be redirected to.

long_url
: Reserved for internal usage.

keep_lpath
: Reserved for internal usage.

Examples

Example 24.162. Using http_internal_redirect()

```
create procedure my_redirect()
{
  declare full_path varchar;
      ...
      full_path := '/DAV/VAD/test/';
      http_internal_redirect (full_path);
      set_user_id ('demo');
      set http_charset='utf-8';
      http_header ('Content-Type: text/xml; charset=UTF-8\r\n');
      WS.WS.GET (path, pars, lines);
      return null;
    }
}
```

See Also

`http` , `http_value` , `http_url` , `string_output` , `http_rewrite` . `http_header` .

http_get

http_get — returns a varchar containing the body of the request uri

Synopsis

```
varchar http_get ( in target_uri varchar ,
                   out return_header any ,
                   in http_method varchar ,
                   in request_header varchar ,
                   in request_body varchar ,
                   in proxy varchar ) ;
```

Description

http_get returns a varchar containing the body of the requested target_uri or NULL if the body is not received.

Parameters

target_uri
: HTTP target in form http://<target_host>:<target_port>/<path> (if <target_port> is not given then 80 will be used by default)

return_header
: This output parameter is set to the array of HTTP response header lines from the target server, if the parameter is a constant it will be ignored.

http_method
: This parameter will be used to specify the HTTP request method. Possible values are: GET, POST, PUT, OPTIONS or see RFC2616[5.1.1] for details.

request_header
: This string will be sent to the target server together with other header fields. If more than one header field should be sent then header fields must be separated with CR/LF pair. (Warning: this string must not be terminated with CR/LF pair!).

request_body
: This string will be sent to the target server as the request body. The "Content-Length" header field is set to the length of this string.

proxy
: If this parameter is supplied the request will be passed through this HTTP proxy. The format is <proxy_host>:<proxy_port> .

Errors

Table 24.40. Errors signalled by

SQLState	Error Code	Error Text	Description
	HT001	Not valid host name or host IP address	
	HT002	Target host is unreachable	

Examples

Example 24.163. Using http_get()

```
declare header any;
page := http_get ('http://www.openlinksw.com/');
```

```
...
page := http_get ('http://www.openlinksw.com/',
                  header, 'GET', 'If-Modified-Since: Fri, 21 Jul 2000 11:19:45 GMT');
...
page := http_get ('http://example.com/some_link.html',
                  header, 'POST', '', 'a=1&b=2');
...
page := http_get ('http://www.openlinksw.com/',
                  NULL, 'GET', '', '', 'proxy.server.com:8080');
```

http_header

http_header — Specifies non-default HTTP response headers

Synopsis

http_header (in *head* varchar) ;

Description

This function is used to add additional HTTP header lines to the server response. The http_header parameter MUST finish with <CR><LF> characters. Warning: Each call of this function cancels the effect of the previous call. In order to add to previously set header lines, use the `http_header_get` function to retrieve the current headers.

A Content-Type or Media-Type header specified as a part of the headers given with this function will override the default. Otherwise the header lines set using this function add to but do not replace the default response headers. Note that this function cannot set the status line. Use http_request_status for that.

Examples

Example 24.164. Modifying the headers

```
<?vsp
http_header ('Content-type: text/plain\r\n');
-- the effect is browser will display content as text document
?>
```

http_header_get

http_header_get — returns header of current HTTP request

Synopsis

```
varchar http_header_get ( );
```

Description

Returns the response header associated with the current HTTP request. This will not return the default header lines, only those explicitly set with http_header.

This is useful for incrementally modifying response headers during processing of a URL.

Return Types

Varchar of the current headers

Examples

Example 24.165. Retrieving the current header

```
<?vsp
http_header (concat (http_header_get (), 'Location: default.html'));
?>
```

http_kill

http_kill — Kill VSP process whose details match parameter inputs

Synopsis

http_kill (in *client_IP_address* varchar ,
in *URL* varchar ,
in *process_request_id* integer) ;

Description

This function requires dba privileges.

This function is used to kill the process whose details match that of the input parameters. If Client's IP and URL are specified, then it will try to kill all matching pending HTTP requests for that peer requesting that URL. If all three parameters are given, then it will try to kill only that pending HTTP request.

Parameters

client_IP_address
: Client's IP as per the output of http_pending_req()

URL
: Process' URL as per the output of http_pending_req()

process_request_id
: The task ID of the request.

Errors

Table 24.41. Errors signalled by `http_kill`

SQLState	Error Code	Error Text	Description
42000	SR159	Function http_kill restricted to dba group	
22023	SR014	Function http_kill needs a string as argument 1, not an arg of type %s	
22023	SR014	Function http_kill needs a string as argument 2, not an arg of type %s	
22023	SR014	Function http_kill needs a string as argument 3, not an arg of type %s	

Examples

Example 24.166. Retrieving a list of VSP processes

```
declare ps any;

ps := http_pending_req ();

-- the ps value is (('127.0.0.1', '/long.vsp', 1234567), ('192.168.1.1', '/long.vsp', 345678))

http_kill ('192.168.1.1', '/long.vsp', 345678);
```

after this and calling http_pending_req() again we get (('127.0.0.1', '/long.vsp', 1234567)) only.

See Also

`http_pending_req`

`http`

http_listen_host

http_listen_host — Starts, stops and retrieves the state of a user-defined HTTP listener

Synopsis

```
integer http_listen_host ( in interface_address varchar ,
                           in action integer ,
                           in options vector ) ;
```

Description

This function requires dba privileges.

This function is used to start, stop or lookup the state of user-defined HTTP and HTTPS listeners. The return value is 0 or 1 and indicates state of the listener, 1 for started and 0 for stopped.

Parameters

interface_address
: IP address of interface to be started, stopped or queried for its current state.

action
: Can only take one of the following integer values:

options
: An array of name-value pairs for setting up a HTTPS listeners. This parameter only used for starting HTTPS listeners, and nothing more. The available options are:

Return Types

The return type is integer, and will be either 0 or 1 to indicate the state of the listener, 1 for started and 0 for stopped.

Examples

Example 24.167. Starting/stopping and state retrieval of a listener

```
SQL> http_listen_host ('127.0.0.1:7780', 0);
SQL> select http_listen_host ('127.0.0.1:7780', 2);
callret
VARCHAR
_______________________________________________________________________________

```

http_map_table

http_map_table — Update internal HTTP mapping table

Synopsis

```
http_map_table ( in logical_path varchar ,
                 in physical_path varchar ,
                 in vhost varchar ,
                 in listen_host varchar ,
                 in stored_in_dav integer ,
                 in is_browseable integer ,
                 in default_page varchar ,
                 in security_restriction varchar ,
                 in authentication varchar ,
                 in auth_function varchar ,
                 in postprocess_function varchar ,
                 in execute_vsp_as varchar ,
                 in execute_soap_as varchar ,
                 in have_persistent_session_variables integer ,
                 in soap_options any ,
                 in auth_options any ) ;
```

Description

This function requires dba privileges.

This function inserts an entry defining a virtual directory into the HTTP maps table.

Parameters

logical_path
: The absolute path string which the user agent will pass to the server in path part of URI

physical_path
: The absolute path of the real content. For directories or WebDAV collections physical_path MUST end with a slash '/' character, otherwise the point will be treated as a file (or resource).

vhost
: The host name that will be sent to the user-agent in HTTP request. This MUST be valid fully-qualified host name or alias and port separated with semi-column ':' character. This parameter accept special value '*ini*' which will be replaced with hostname and port from INI file.

listen_host
: The fully-qualified host name or IP address and port which will be listened on. Warning: This is only used to make an in-memory mapping, and will not start listening (for starting and stopping a listener see http_listen_host).

stored_in_dav
: Determine if the physical location is a WebDAV resource or collection. Can accept zero or one (1) integer values.

is_browseable
: Determine if directory browsing is allowed for this location. Accepts integer values 0 or 1, treated as false and true respectively. If true (1) enabled and a default page is not specified, a GET request of an URL pointing to this location will generate a directory listing as a response to the user-agent.

default_page
: File name of default page that will be sent to the user-agent if physical_path is a directory.

security_restriction
: A keyword that denotes security type controlling access to the location. Can be 'Digest', 'SSL' or NULL. This value can be used in the auth_function hook using http_map_get .

authentication
: A string value that will be passed as a parameter to the auth_function hook

auth_function
: Fully qualified name of a PL procedure that will perform HTTP authentication. The function must accept one input parameter of type VARCHAR and MUST return integer 0 or 1 as false or true, respectively. A zero return value from the authentication function will cause the HTTP request to be rejected.

postprocess_function
: Fully qualified name of a PL procedure that will be called every time after page processing. Usual purpose is to store session variables in a session table.

execute_vsp_as
: The name of DB user, as whom VSP pages will be executed. If the user is not specified (is null), execution is forbidden.

execute_soap_as
: The name of DB user, as whom SOAP calls will be executed. If null, execution of SOAP calls is forbidden.

have_persistent_session_variables
: Flag that determines if the location has persistent session variables. The value of this flag can be retrieved with http_map_get .

soap_options
: A vector with keyword/value pairs. Currently, valid keywords are 'Namespace' and 'ServiceName'. Namespace is a string defining the namespace for the SOAP service. ServiceName is a string containing name of the SOAP service. See example.

auth_options
: The value of this parameter can be used in the authentication hook. In practice an array of keyword/value pairs would be the input but a single string could be supplied. The user-specific authentication hook can retrieve the options by calling the http_map_get('auth_opts') function.

Examples

Example 24.168. Inserting A Map Entry

```
http_map_table ('/vdir', '/admin/', 'www.foo.com', 'host.foo.com');
```

Example 24.169. Create entry for a SOAP service

```
http_map_table ('/soapapp', '/soapapp/', 'www.foo.com', 'host.foo.com', NULL,
                NULL, NULL, 'SSL', 'SOAP_APP', 'mysoapapp_auth_hook', 'mysoapapp_post_processor',
                NULL, 'mysoapapp_user', 1, vector ('NameSpace', 'http://example.com/soap/v11/',
                                                   'ServiceName','soapApp'));
```

HTTP Authentication in main documentation

HTTP Session Management in main documentation .

http_map_get

http_map_get — get values from HTTP virtual host path mapping table

Synopsis

http_map_get (in *element_name* varchar) ;

Description

Retrieves information associated with the virtual host / HTTP path mapping in effect for the VSP page being processed. Values valid in current connection or URL context may be retrieved by *element_name* .

Calling http_map_get has no use outside of http context. In this case an error will be signalled.

Parameters

element_name
: The possible values for element_name are: 'vsp_uid', 'soap_uid', 'persist_ses_vars', 'default_page', 'browseable', 'security_level' , 'auth_opts', 'soap_opts', 'domain', 'mounted'.

Return Types

Value returned depends of *element_name* :

Table 24.42. Values returned by http_map_get

element_name	Datatype	Return value
vsp_uid	VARCHAR	Which SQL user active content will execute as
soap_uid	VARCHAR	Which SQL user SOAP calls will be executed as
persist_ses_vars	INTEGER	Is persisting of session variables enabled?
default_page	VARCHAR	Default page for current mapping
browseable	INTEGER	Is directory browsing enabled?
security_level	VARCHAR	Security level ('DIGEST', 'SSL', 'BASIC')
auth_opts	ANY	Application-specific authentication options
soap_opts	ANY	Application-specific SOAP options
domain	VARCHAR	Directory path that is the logical start point of current mapping.
mounted	VARCHAR	Physical path that is the physical start point of current mapping

Examples

Example 24.170. Retrieving Mapping Details

```
<?vsp
declare def_page varchar;
def_page := http_map_get ('default_page');
http (sprintf ('<p>The default page for this path is: %s </p>', def_page));
?>
```

Example 24.171. Warn users if non-SSL connection

```
<HTML>
  <HEAD>
    <TITLE>TEST</TITLE>
```

```
  </HEAD>
  <BODY>
    <P>We're executing as <?= http_map_get ('vsp_uid') ?></P>
<?vsp
    if (http_map_get ('security_level') <> 'SSL')
      {
?>
    Warning: This page is not protected by transport level encryption
    and may be viewable by anybody in the middle with a network
    sniffer.
<?vsp
      }
?>
  </BODY>
</HTML>
```

http_param

http_param — returns value of a HTML form parameter in VSP context

Synopsis

http_param (in *name* varchar) ;

Description

This function is used to return value of a HTML form parameter in VSP context. It's almost like call get_keyword ('name', params) used in VSP programming. When 'name' parameter is not supplied, the result of http_param() call will be all parameters, as they are contained in 'params' parameter of the VSP pages. This function is useful in HTTP authentication PL hook, as in this place there is no 'params' argument.

Parameters

name
: A string with name of the parameter to return

Return Types

Returns value of a HTML form parameter, or array of all parameters.

See Also

VSP pages `vhost_define()`

http_path

http_path — returns the absolute path to the logical path location of the current http request

Synopsis

```
http_path (   );
```

Description

This function returns the absolute path to the logical path location of current HTTP request.

Examples

Example 24.172. Retrieving Current Path of Request

```
<?vsp
  http (sprintf ('<p>The current location is : %s </p>', http_path ()));
?>
```

http_pending_req

http_pending_req — return array describing running VSP threads

Synopsis

```
http_pending_req (  );
```

Description

This function requires dba privileges.

`http_pending_req` returns an array of arrays of data on running VSP requests. Each array contains the Client IP Address, URL, and Process Request ID. These values can be used with the `http_kill()` function.

Return Types

An array of 3-part-arrays. Each 3-part-array consists of client_IP_address (string), URL (string), and process request ID (number).

The request ID's can be used to terminate requests with http_kill.

Errors

Table 24.43. Errors signalled by `http_pending_req`

SQLState	Error Code	Error Text	Description
42000	SR159	Function http_pending_req restricted to dba group	

Examples

Example 24.173. Retrieving a list of VSP processes

```
declare ps any;

ps := http_pending_req ();

-- the ps value is (('127.0.0.1', '/long.vsp', 1234567), ('192.168.1.1', '/long.vsp', 345678))
```

See Also

`http_kill`

`http`

http_physical_path

http_physical_path — returns the physical path location of the requested URL

Synopsis

http_physical_path ( );

Description

This function returns the absolute path to the physical path location of current HTTP request

Examples

Example 24.174. Retrieving Current Path of Request

```
<?vsp
  http (sprintf ('<p>The physical location is : %s </p>', http_physical_path ()));
?>
```

http_proxy

http_proxy — proxy request to another host and return content to calling client

Synopsis

http_proxy (in *host* varchar ,
in *header* any ,
in *content* varchar) ;

Description

This function is used to retrieve content from a foreign host and send the response to the HTTP client of the page calling this. This is useful for re-routing a request to another server in the middle of a VSP page.

Parameters

host
: The fully-qualified host name or alias. If a target port is specified the semi-column ':' character MUST be used as the separator. ('www.foo.com:8080')

header
: an array consisting of the HTTP request header lines. Warning: Each line MUST finish with <CR><LF> characters. This header lines will be sent to the target server without any conversion.

content
: In the case of posting of forms this parameter can contain the form data as specified in HTML standards.

Examples

Example 24.175. Retrieving Current Path of Request

```
<?vsp
  http_proxy ('www.foo.com', vector ('GET / HTTP/1.0'), null);
?>
```

http_request_header

http_request_header — returns array of HTTP request header lines

Synopsis

```
any http_request_header ( in array any ,
                          in field_name varchar ,
                          in attr-name varchar ,
                          in default_value varchar ) ;
```

Description

This function provides access to the HTTP request header lines.

Return Types

If no input parameters are supplied then this function returns a copy of the lines vector of VSP pages. If array, field_name and mime_attribute is supplied then this function will attempt to extract the associated value, if is cannot be found then the default_value input will be returned. If attr-name is supplied then the mime attribute from the field_name will be returned.

Note that when field value is requested then it will be treated as a MIME field and only value will be returned if found. For example consider presence of following header line: "Content-Type: text/plain; charset=utf-8", then if 'Content-Type' is requested, only "text/plain" will be returned. Use http_request_header_full to obtain the full field value.

Examples

Example 24.176. Accessing the HTTP request headers

```
<p>Your request follows</p>
  <?vsp
    declare header any;
    declare ix, len integer;
    declare host varchar;
    header := http_request_header ();
    len := length (header);
    ix := 0;
    while (ix < len)
    {
      http (aref (header, ix));
                 ix := ix + 1;
    }
    host := http_request_header(lines, 'Host', null, '*** NO HOST IN REQUEST ***')
  ?>
```

http_request_header_full

http_request_header_full — returns array of HTTP request header lines

Synopsis

```
any http_request_header_full ( in array any ,
                               in field_name varchar ,
                               in default_value varchar ) ;
```

Description

This function provides access to the HTTP request header lines.

Return Types

If no input parameters are supplied then this function returns a copy of the lines vector of VSP pages. If array and field_name is supplied then this function will attempt to extract the associated field value, if is cannot be found then the default_value input will be returned.

Examples

Example 24.177. Accessing the HTTP request headers

```
<p>Your request follows</p>
  <?vsp
    http (http_request_header_full(lines, 'Content-Type', '*none*'));
  ?>
```

http_request_status

http_request_status — set the status sent to the client in an HTTP response

Synopsis

http_request_status (in *status_line* varchar) ;

Description

This allows a VSP page to control the status sent to the client in the HTTP response. The argument will be presented as the first line of the reply instead of the default "HTTP/1.1 200 OK". The string should not contain a CR or LF at the end.

This allows a page to issue redirects, authentication challenges etc.

Use it with `http_headers` to control the content of the HTTP reply headers.

Parameters

status_line
: String conforming to HTTP/1.1 (see RFC2616). Examples of possible status lines are: 'HTTP/1.1 200 OK', 'HTTP/1.1 500 Internal Server Error', 'HTTP/1.1 401 Not found' or 'HTTP/1.1 400 Bad request' etc.

http_request_get

http_request_get — Access to the HTTP request line

Synopsis

http_request_get (in *variable_name* varchar) ;

Description

This function is used to access the HTTP request line within VSP or VSPX context. It returns 'CGI' style variables for protocol version, HTTP method and query string.

Parameters

variable_name
: A string designating what to return.

http_rewrite

http_rewrite — Clears output written to a string output or to an HTTP

Synopsis

http_rewrite (in *stream* any);

Description

This clears any previous output to the stream. If the stream is omitted or 0 the stream is the HTTP client stream of the calling procedure.

All output from VSP page procedures is buffered into a local string stream before being sent out. This is done so as to support the HTTP/1.1 required content length and to allow recovery from errors.

Parameters

stream
: Optional stream to clear. Null or zero (0) implies the default HTTP client stream.

Using http_rewrite()

Example 24.178. A VSP page excerpt.

```
<p>Nope. You won't see this.</p>

<?vsp
http ('<p>This line will contribute to your local entropy.</p>');
http_rewrite ();
http ('<p>Now THIS is what you wanted to see, isn't it?</p>');
?>
```

See Also

`http_value`, `http_url`, `string_output`.

http_root

http_root — Returns the absolute path of the server root directory.

Synopsis

```
varchar http_root ( );
```

Description

Returns the absolute path of the server root directory.

Return Types

String of the absolute path of the server root directory.

Examples

Example 24.179. Obtaining the Client IP Address

```
<?vsp
  http (file_to_string (sprintf ('%s/banner.html', http_root())));
?>
```

See Also

`http`, `http_value`, `http_url`, `string_output`, `http_rewrite`.

http_value

http_value — write to HTTP client or string output stream with HTML escapes

Synopsis

http_value (in *val_expr* any ,
in *tag* varchar ,
in *stream* any) ;

Description

The http_value is used to write to an HTTP client (when in a VSP context) or a specified string output stream. http_value uses HTML-escapes for characters that should be escaped according to the HTML spec.

Parameters

val_expr
: A value expression. May be any string expression. If val_expr is an XML entity, a serialization of the entity is written to the stream . This is not the string value of the XML fragment, but a serialization of the XML fragment as text including all the markup, i.e. elements, attributes, namespaces, text nodes, etc. To get the string value of an XML entity, convert it to a varchar using cast . Casting as varchar will only produce a concatenation of the text nodes in the XML fragment, leaving out elements, attributes, name spaces, etc.

tag
: Optional. If present and is a string, the output will be enclosed in tags named as the string content of tag . If the expression evaluates to 0 or null, it will be ignored.

stream
: Optional parameter. If omitted or is 0 and the function is executed within a VSP context, the val_expr will be written to the HTTP client. If present and non-zero, val_expr will be written to the specified stream. If non-zero, the value must be a valid stream obtained from function string_output

Return Values

None

Errors

Table 24.45. Errors signalled by http_value

SQLSTATE	Error Code	Error Text	Description
37000	HT006	http output function outside of http context and no stream specified: %s	occurs if called outside VSP and no string session is given
22023	SR066	Unsupported case in CONVERT (<data_type_of 1st arg> -> VARCHAR): %s	if the value passed as the 1st argument can't be converted to a VARCHAR value and it's not a XML/XQUERY tree

Using http_value()

Example 24.180. HTTP output

Output of various flavours of http . See string_output and string_output_string for examples how to use http to write to streams other than the HTTP output.

```
http (' % <b>')      ' <b>
```

```
http_value (' % <b>')    % &lt;b&gt;
http_url (' % <b>')  +%25+<b>
http_value (12, 'li')  <li>12</li>
```

See Also

`http`, `http_url`, `string_output`, `http_rewrite`.

json_parse

json_parse — Takes json string and returns parse tree.

Synopsis

```
integer json_parse ( in txt varchar );
```

Description

This function takes json string and returns parse tree.

Parameters

txt
: a json string

Return Types

The function returns tree.

Examples

Example 24.181. Simple example

```
SQL>create procedure json_tree_example ()
{
  declare qr, url, cnt, tree, xt, hdr any;
  cnt := '
{ "head": { "link": [], "vars": ["s", "p", "o"] },
  "results": { "distinct": false, "ordered": true, "bindings": [
    { "s": { "type": "uri", "value": "http://example.org/node" }        , "p": { "type": "uri", "value":
    { "s": { "type": "uri", "value": "http://example.org/node" }        , "p": { "type": "uri", "value":
  tree := json_parse (cnt);
  tree := get_keyword ('results', tree);
  tree := get_keyword ('bindings', tree);
  return tree[0][1];
}
;

Done.
SQL> SELECT json_tree_example();
json_tree_example
VARCHAR
 structure
No. of rows in result: 1
```

See Also

`http`, `http_value`, `http_url`, `string_output`, `http_rewrite`,

http_url

http_url — write to HTTP client or string output stream with URL escapes

Synopsis

http_url (in *val_expr* any ,
in *tag* varchar ,
in *stream* any) ;

Description

The `http_url` is used to write to an HTTP client (when in a VSP context) or a specified string output stream. `http_url` uses URL escapes for special characters.

Parameters

val_expr
: A value expression. May be any scalar expression. If val_expr is an XML entity, a serialization of the entity is written to the stream . This is not the XML as a text string, but a serialization of the internal representation of parsed XML data.

tag
: Optional. If present and is a string, the output will be enclosed in tags named by the string content of tag . If the expression evaluates to 0 or null, it will be ignored.

stream
: Optional parameter. If omitted or is 0 and the function is executed within VSP context, the val_expr will be written to the HTTP client. If present and non-zero, val_expr will be written to the specified stream. If non-zero, the value must be a valid stream obtained from function string_output

Return Values

None

Errors

Table 24.46. Errors signalled by `http_url`

SQLState	Error Code	Error Text	Description
37000	HT006	http output function outside of http context and no stream specified: %s	
22023	SR066	Unsupported case in CONVERT (%s -> VARCHAR)	

Examples

Example 24.182. HTTP output

Output of various flavours of `http` . See `string_output` and `string_output_string` for examples how to use http to write to streams other than the HTTP output.

```
http (' % <b>')      ' <b>
http_value (' % <b>')   % &lt;b&gt;
http_url (' % <b>')  +%25+<b>
http_value (12, 'li')  <li>12</li>
```

See Also

`http`, `http_value`, `string_output`, `http_rewrite`.

http_xslt

http_xslt — applies an XSLT stylesheet to the output of a VSP page

Synopsis

http_xslt (in *xslt_uri* varchar ,
in *params* any) ;

Description

This function can be called inside a VSP page to apply an XSLT stylesheet to the output of the page once the page is complete. This function will return immediately and the stylesheet will not be applied until the page is successfully formed. Any errors arising in the stylesheet processing will be reported to the web client.

The stylesheet does not have to be previously defined. The URI supplied will be used to locate the stylesheet. This can be a file, an HTTP URL or a virt:// URI for a stylesheet stored in a local table. Virtuoso will cache the stylesheet after first use. You can clear the cache entry with the `xslt_stale()` function.

For this to work the text generated by the VSP page should be well-formed XML.

This function is only valid in a VSP context. The *`xsl:output`* element will control the Content-Type sent to the user agent.

Parameters

xslt_uri
: Absolute URI of the XSL stylesheet

params
: Even length array of name/value pairs.

Examples

Example 24.183. Performing XSLT Transformation of VSP Output

```
<?vsp
  http ('<a><b>simple XML document</b></a>');
  http_xslt ('file://');
?>
```

URLREWRITE_CREATE_REGEX_RULE

URLREWRITE_CREATE_REGEX_RULE — Creates regex rules.

Synopsis

```
URLREWRITE_CREATE_REGEX_RULE ( in rule_iri varchar ,
                               in allow_update integer ,
                               in nice_match varchar ,
                               in nice_params any ,
                               in nice_min_params integer ,
                               in target_compose varchar ,
                               in target_params any ,
                               in target_expn varchar ,
                               in accept_pattern varchar ,
                               in do_not_continue integer ,
                               in http_redirect_code integer ,
                               in http_header_lines varchar ) ;
```

Description

Creates regex rules.

Parameters

rule_iri
: The rule's name / identifier

allow_update
: Indicates whether the rule can be updated. 1 indicates yes; 0 indicates no. The update is subject to the following rules:

nice_match
: A regex match expression to parse the URL into a vector of occurrences.

nice_params
: A vector of the names of the parsed parameters. The length of the vector should be equal to the number of '(...)' specifiers in the format string.

nice_min_params
: Used to specify the minimum number of sprintf format patterns to be matched in order to trigger the given rule. In existing versions of Virtuoso it only affects sprintf rules and has no effect for regex rules.

target_compose
: A regex compose expression for the URL of the destination page.

target_params
: A vector of names of parameters that should be passed to the compose expression (target_compose) as $1, $2 and so on.

target_expn
: Optional SQL text that should be executed instead of a regex compose call.

accept_pattern
: A regex expression to match the HTTP Accept header

do_not_continue

If the given rule satisfies the match conditions, 1 signifies do not try the next rule from same rule list, and 0 signifies try the next rule.

http_redirect_code
: NULL or the integer values 301, 302, 303, or 406, are currently allowed. If a 3xx redirect code is given, an HTTP redirect response will be sent back to client. If NULL is specified, the server will process the redirect internally.

http_header_lines
: Additional header lines to be added to the return value.

Return Types

The return value is not specified.

Examples

Example 24.184. Example 1

```
DB.DBA.URLREWRITE_CREATE_REGEX_RULE (
    'demo_nw_rule1',
    1,
    '(/[^#]*)',
    vector('path'),
    1,
    '/sparql?query=CONSTRUCT+{+%%3Chttp%%3A//^{URIQADefaultHost}^%U%%23this%%3E+%%3Fp+%%3Fo+}+FROM+%%3Cht
    vector('path', 'path', '*accept*'),
    null,
    '(text/rdf.n3)|(application/rdf.xml)',
    0,
    null
    );
```

Example 24.185. Example 2

```
DB.DBA.URLREWRITE_CREATE_REGEX_RULE (
    'demo_nw_rule2',
    1,
    '^/~(.*)',
    vector('uname'),
    1,
    '/home/%s',
    vector('uname'),
    null,
    null,
     2,
     null,
     'MS-Author-Via: DAV'
    );
```

identity_value

identity_value — returns the last assigned identity column value

Synopsis

```
integer identity_value ( );
```

Description

This function returns the value assigned to an identity column by the previous insert statement. Insert statements that do not assign identity columns do not affect this. Note that tables that have no primary key have n invisible identity column called _IDN. The scope is the connection. This function may be called from a client or from a stored procedure and will return the last given identity column value wherever it was given. The value stays set until overwritten by the next insert operation. This value is not set by rexecute or inserts to remote tables with autoincrement columns declared on the remote database since there is no standard way of getting this information from remote data sources.

The same value can be more efficiently accessed from clients using the SQLGetStmtOption ODBC call with the option SQL_GETLASTSERIAL. In this case the value is of type SQLINTEGER.

Return Types

The value assigned to an identity column by the previous insert or 0 if no identity column was assigned.

import_clr

import_clr — This function automatically creates the SQL Type wrappers based on the CLR Reflection API.

Synopsis

```
any import_clr ( in assemblies_vector any ,
                 in classes_vector any ,
                 in security_mode integer ) ;
```

Description

This function automatically creates the SQL Type wrappers based on the CLR Reflection API.

Parameters

assemblies_vector
: a vector of assembly names (as VARCHAR) to look into (or null).

classes_vector
: a vector of type names to create SQL type wrappers for (or null to mark all the types in the assemblies specified by assemblies_vector. In that case the assemblies_vector cannot be NULL).

security_mode
: This optional parameter defines the access mode as follows:

Examples

Example 24.186. Importing a Class

Here is a simple C# program that we can import and use with Virtuoso. This example requires that you are running Virtuoso with CLR support.

Using a text editor create a C# source file in the server root directory called sanity.cs, with the following contents:

```
using System;

public class sanity
{
    public static string test(string  name) {
       return "Hello "+ name + ", from Virtuoso";
    }
}
```

This sample needs to be compiled into bytecode assembly before it can be used. Use a command prompt that is suitably set up to find .NET utilities in its path, the .NET Framework SDK installation provides a shortcut in the Start menu to a command prompt that is preconfigured. From the command prompt change directory to the Virtuoso server root containing the C# source file. Execute:

```
C:\Program Files\OpenLink\Virtuoso 3.0\bin>csc /target:library sanity.cs
Microsoft (R) Visual C# .NET Compiler version 7.00.9466
for Microsoft (R) .NET Framework version 1.0.3705
Copyright (C) Microsoft Corporation 2001. All rights reserved.
```

Now this library must be introduce to the Virtuoso Server. Using ISQL use the following commands to test the CLR:

```
C:\Program Files\OpenLink\Virtuoso 3.0\bin>isql 1112
Connected to OpenLink Virtuoso
Driver: 03.00.2315 OpenLink Virtuoso ODBC Driver
OpenLink Interactive SQL (Virtuoso), version 0.9849b.
Type HELP; for help and EXIT; to exit.
```

```
SQL> DB..import_clr (vector ('sanity'), vector ('sanity'));

Done. -- 300 msec.
SQL> select sanity::test('Rob');
callret
VARCHAR
_______________________________________________

Hello Rob, from Virtuoso

1 Rows. -- 60 msec.
```

Congratulations, you have proven that your Virtuoso server can run .NET classes.

unimport_clr

import_jar

import_jar — Creates SQL wrapper types of selected Java classes

Synopsis

```
void import_jar ( in files any ,
                  in classes any ,
                  in security_mode integer ) ;
```

Description

This function calls the `jvm_ref_import()` function to produce the XML, then transforms it to a set of CREATE TYPE statements and executes them. The SQL names of the types are generated by retrieving the fully qualified name of the Java class and substituting the . with _ (e.g.: java.lang.System becomes java_lang_System). The names of the static members observer functions are composed by prepending the name of the static member with 'get' so the static Java member stat_m is mapped to a SQL static method getstat_m(). As a result it creates SQL type wrappers for the specified Java classes.

Parameters

files
: Null, string or vector of strings. This can contain one or many Java .class files, .zip or .jar files to pick classes from. Null means only the classes specified in the classes argument regardless of their physical location.

classes
: Wildcard string or a vector of strings specifying which classes to describe in the resulting XML.

security_mode
: This optional parameter defines the access mode as follows:

Examples

Example 24.187. Simple example

```
SQL> import_jar (null, vector ('java.lang.System'));
SQL> select java_lang_System::getProperty('java.vm.name');
callret
NVARCHAR
_______________________________________________________________________________

Java HotSpot(TM) Client VM
```

`unimport_jar()`

`jvm_ref_import()`

initcap

initcap — returns its argument with the first letter capitalized

Synopsis

initcap (*str* string);

Description

initcap returns a copy of string str with the first character, if it is a lowercase letter, converted to the corresponding uppercase letter. Otherwise, an identical copy of the string is returned. Notes about ucase apply also here.

```
initcap('simurg!')  -> 'Simurg!'
```

internal_to_sql_type

internal_to_sql_type — returns the integer standard SQL type of its argument

Synopsis

internal_to_sql_type (*internal_type* integer) ;

Description

internal_to_sql_type returns an integer value representing the standard SQL type converted from internal_type given as its argument.

```
internal_to_sql_type(182)       -> 12 (VARCHAR)
```

internal_type

internal_type — returns internal integer datatype of its argument

Synopsis

internal_type (*arg* anything);

Description

internal_type returns an integer value representing the internal type of its argument. These values are the same as what Virtuoso uses in the column COL_DTP of the system table SYS_COLS for keeping the track of the default types of each column of each table.

```
internal_type(space(5))          -> 182 (A long string)
```

internal_type_name

internal_type_name , dv_type_title — returns the internal type name of the argument

Synopsis

internal_type_name (*internal_type* integer) ;

dv_type_title (*internal_type* integer) ;

Description

internal_type_name returns a string which is a human-readable name for an internal_type integer given as its argument. The function `dv_type_title()` is an alias of `internal_type_name()` .

```
internal_type_name (internal_type ('kumikala'))
                -> 'SHORT_STRING'
select internal_type_name(COL_DTP) from SYS_COLS;
```

isarray

isarray — Check for a valid array

Synopsis

```
boolean isarray ( in x any );
```

Description

isarray is true if the argument is a valid argument to aref. This is the case for any string or vector.

Parameters

x
: The variable to be checked.

Return Values

1 - if arg is an array (vector()) or string (varchar, char) otherwise return 0.

Errors

No error, it always succeeds.

isblob

isblob — returns true if its argument is of type long varchar

Synopsis

isblob (*arg* anything);

Description

isblob returns one if its argument as a handle to an object of the type LONG VARCHAR, zero otherwise.

isbinary

isbinary — returns true if its argument is of type varbinary

Synopsis

```
boolean isbinary ( arg anything );
```

Description

isbinary returns one if its argument is of type VARBINARY, zero otherwise.

Parameters

arg
: Some variable to be assessed.

Examples

Example 24.188. Simple Use

```
SQL>select isbinary(0x1213);
-&gt; 1 (Yes it is a VARBINARY)
```

isdouble

isdouble — returns true is argument is a double

Synopsis

isdouble (*arg* anything) ;

Description

isdouble returns one if its argument is of type double precision float, zero otherwise.

```
isdouble(0.0)           -> 1 (Decimal literals are by
                             default converted to
                             double precision numbers)
```

isentity

isentity — returns true if its argument is an XML entity

Synopsis

```
boolean isentity ( in x any );
```

Description

`isentity` is true if the argument is an XML entity object, such as that returned from XPATH expressions etc.

isfloat

isfloat — returns true if its argument is a float

Synopsis

isfloat (*arg* anything);

Description

`isfloat` returns one if its argument is of type single float, zero otherwise.

```
isfloat(0.0)            -> 0 (No it is not, because decimal
                             literals are by default
                             converted to double precision
                             numbers)
isfloat(atof('0.0'))    -> 1 (Only with explicit atof we get
                             a single float)
```

isinteger

isinteger — returns true if its argument is of type integer

Synopsis

isinteger (*arg* anything) ;

Description

`isinteger` returns one if its argument is of type integer, zero otherwise.

```
isinteger(0)            -> 1 (Yes it is)
```

isnull

isnull — returns true if its argument is NULL

Synopsis

isnull (*arg* anything);

Description

isnull returns one if its argument is NULL, zero otherwise.

isnumeric

isnumeric — returns true if argument is of numeric type

Synopsis

isnumeric (*arg* anything) ;

Description

isnumeric returns one if its argument is of type integer, single float or double precision floating point number, zero otherwise.

isfinitenumeric

isfinitenumeric — returns 1 if its argument is of numeric type and its value is plain valid numeric value.

Synopsis

isfinitenumeric (*arg* anything) ;

Description

isfinitenumeric returns 1 if its argument is of numeric type and its value is plain valid numeric value, not a peculiarity like infinity or not-a-number.

Examples

Example 24.189. Simple Use

```
SQL>  SPARQL
INSERT INTO GRAPH <http://mygraph.com>
  {
    <http://mygraph2.com/pricing/#QVal1> <price1>  1 ;    <price2> "";    <price3> 5 .
    <http://mygraph2.com/pricing/#QVal2> <price1>  "" ;   <price2> 1 ;    <price3> 4 .
    <http://mygraph2.com/pricing/#QVal3> <price1>  6 ;    <price2> 2 ;    <price3> "".
  };

Insert into <http://mygraph.com>, 9 (or less) triples -- done
No. of rows in result: 1

SQL> SPARQL SELECT ?s (bif:isfinitenumeric(?pr1))
FROM <http://mygraph.com>
WHERE
  {
    ?s <price1> ?pr1 ;
       <price2> ?pr2 ;
       <price3> ?pr3
  };

Query result:
s                                    callret-1
VARCHAR                                    INTEGER
_______________________________________________
http://mygraph2.com/pricing/#QVal2       0
http://mygraph2.com/pricing/#QVal1       1
http://mygraph2.com/pricing/#QVal3       1

No. of rows in result: 3
```

isstring

isstring — returns true if its argument is of type varchar

Synopsis

```
boolean isstring ( arg anything );
```

Description

isstring returns one if its argument is of type VARCHAR, zero otherwise.

Parameters

arg
: Some variable to be assessed.

Examples

Example 24.190. Simple Use

```
SQL>select isstring('Cadena de los patos amarillos')
                -&gt; 1 (Yes it is a string)
```

iszero

iszero — returns true if argument is numeric zero

Synopsis

iszero (*arg* any);

Description

iszero returns one if its argument is an integer 0, a float 0.0 or a double 0.0 For any other arguments, of whatever type, it will return zero.

```
iszero(0)               -> 1 (Yes it is)
iszero(0.0)             -> 1 (Double precision zero also
                             is a zero)
iszero(atof('0.0'))     -> 1 (As well as single
                             precision floating point)
iszero(1)               -> 0 (No, it's not)
iszero('Cifra')         -> 0 (neither is this one)
iszero(NULL)            -> 0 (nor this one)
```

__min

__min — Returns minimum value among all its arguments.

Synopsis

```
any __min ( arg1 any ,
            arg2 any ,
            ... ,
            argN any ) ;
```

Description

The function returns the minimum value among all values in all its arguments.

Parameters

argI
: Values which can be with type float, integer etc.

Examples

Example 24.191.

Example 1

```
SQL> select __min(12, 2.34, 5, 20);
__min
VARCHAR
_______________________________________________________________________________

2.34

1 Rows. -- 32 msec.
```

Example 2

```
SQL> SPARQL
INSERT INTO GRAPH <http://mygraph2.com>
  {
    <http://mygraph2.com/pricing/#QVal1> <price1>  1 ; <price2> 9 ; <price3> 5 .
    <http://mygraph2.com/pricing/#QVal2> <price1>  3 ; <price2> 1 ; <price3> 4 .
    <http://mygraph2.com/pricing/#QVal3> <price1>  6 ; <price2> 2 ; <price3> 2 .
  };

Insert into <http://mygraph.com>, 9 (or less) triples -- done
No. of rows in result: 1

SQL> SPARQL SELECT ?s (bif:__min(?pr1, ?pr2, ?pr3))
FROM <http://mygraph2.com>
WHERE
  {
    ?s <price1> ?pr1 ;
       <price2> ?pr2 ;
       <price3> ?pr3
  };

Query result:
s                                       callret-1
VARCHAR                                       VARCHAR
_______________________________________________________
http://mygraph2.com/pricing/#QVal3              2
http://mygraph2.com/pricing/#QVal2              1
http://mygraph2.com/pricing/#QVal1              1
```

```
No. of rows in result: 3
```

__max()

__min_notnull()

__max_notnull()

__max

__max — Returns maximum value among all its arguments.

Synopsis

```
any __max ( arg1 any ,
            arg2 any ,
            ... ,
            argN any ) ;
```

Description

The function returns the maximum value among all values in all its arguments.

Parameters

argI
: Values which can be with type float, integer etc.

Examples

Example 24.192.

Example 1

```
SQL> select __max(12, 2.34, 5, 20.5);
__max
VARCHAR
_______________________________________________________________________________

20.5

1 Rows. -- 16 msec.
```

Example 2

```
SQL> SPARQL
INSERT INTO GRAPH <http://mygraph2.com>
  {
    <http://mygraph2.com/pricing/#QVal1> <price1>  1 ; <price2> 9 ; <price3> 5 .
    <http://mygraph2.com/pricing/#QVal2> <price1>  3 ; <price2> 1 ; <price3> 4 .
    <http://mygraph2.com/pricing/#QVal3> <price1>  6 ; <price2> 2 ; <price3> 2 .
  };

Insert into <http://mygraph2.com>, 9 (or less) triples -- done
No. of rows in result: 1

SQL> SPARQL SELECT ?s (bif:__max(?pr1, ?pr2, ?pr3))
FROM <http://mygraph2.com>
WHERE
  {
    ?s <price1> ?pr1 ;
       <price2> ?pr2 ;
       <price3> ?pr3
  };

Query result:
s                                     callret-1
VARCHAR                                     VARCHAR
_______________________________________________________
http://mygraph2.com/pricing/#QVal3          6
http://mygraph2.com/pricing/#QVal2          4

```

```
No. of rows in result: 3
```

See Also

__min()

__min_notnull()

__max_notnull()

__max_notnull

__max_notnull — Returns maximum value among all its arguments, ignoring NULLs entirely.

Synopsis

```
any __max_notnull ( arg1 any ,
                    arg2 any ,
                    ... ,
                    argN any ) ;
```

Description

The function returns the maximum value among all values in all its arguments by ignoring NULLs entirely.

Parameters

argI
: Values which can be with type float, integer etc.

Examples

Example 24.193.

Example 1

```
SQL> select __max_notnull (null, 1, 0);
__max_notnull
VARCHAR
_______________________________________________________________________________

1

1 Rows. -- 16 msec.

SQL> select __max (null, 1, 0);
__max
VARCHAR
_______________________________________________________________________________

NULL

1 Rows. -- 0 msec.
```

Example 2

```
SQL> SPARQL
INSERT INTO GRAPH <http://mygraph.com>
  {
    <http://mygraph2.com/pricing/#QVal1> <price1>  1 ;                    <price3> 5 .
    <http://mygraph2.com/pricing/#QVal2>                  <price2> 1 ;    <price3> 4 .
    <http://mygraph2.com/pricing/#QVal3> <price1>  6 ;    <price2> 2                 .
  };

Insert into <http://mygraph.com>, 6 (or less) triples -- done
No. of rows in result: 1

SQL> SPARQL SELECT ?s, (bif:__max_notnull (?pr1, ?pr2, ?pr3))
FROM <http://mygraph.com>
WHERE
  {
    {
      SELECT DISTINCT ?s
      WHERE
```

```
        {
          ?s ?p ?pr .
          FILTER (?p in (<price1>, <price2>, <price3>))
        }
    }
